# Contents

**1 Overview....1**
1.1 Database Logical Architecture....1
1.2 Query Request Handling Process....2
1.3 Managing Transactions....2
1.4 Concepts....4
**2 Working with Databases....6**
2.1 Connecting to a Database....6
2.1.1 APIs....6
2.2 Before You Start....7
2.3 Creating and Managing Databases....9
2.4 Planning a Storage Model....11
2.5 Creating and Managing Tablespaces....13
2.6 Creating and Managing Tables....16
2.6.1 Creating a Table....16
2.6.2 Inserting Data to a Table....17
2.6.3 Updating Data in a Table....20
2.6.4 Viewing Data....21
2.6.5 Deleting Data from a Table....21
2.7 Querying a System Catalog....22
2.8 Other Operations....24
2.8.1 Creating and Managing Schemas....24
2.8.2 Creating and Managing Partitioned Tables....27
2.8.3 Creating and Managing Indexes....31
2.8.4 Creating and Managing Views....35
2.8.5 Creating and Managing Sequences....36
2.8.6 Creating and Managing Scheduled Jobs....38
2.9 gsql Client Reference....41
2.9.1 Overview....41
2.9.2 How to Use gsql....49
2.9.3 Obtaining Help Information....52
2.9.4 Command Reference....53
2.9.5 Meta-Command Reference....59
2.9.6 Troubleshooting....78

**3 Development and Design Proposal..... 82**
3.1 Overview..... 82
3.2 Database Object Naming Conventions..... 82
3.3 Database Object Design..... 83
3.3.1 Database and Schema Design..... 83
3.3.2 Table Design..... 84
3.3.3 Column Design..... 88
3.3.4 Constraint Design..... 90
3.3.5 View and Joined Table Design..... 91
3.4 Tool Interconnection..... 91
3.4.1 JDBC Configuration..... 91
3.5 SQL Compilation..... 93
**4 Best Practices..... 97**
4.1 Best Practices of Table Design..... 97
4.1.1 Selecting a Storage Model..... 97
4.1.2 Selecting a Distribution Mode..... 97
4.1.3 Selecting Distribution Keys..... 99
4.1.4 Using PCKs..... 99
4.1.5 Using Partitioned Tables..... 99
4.1.6 Selecting a Data Type..... 100
4.1.7 Checking a Node Where a Table Resides..... 100
4.2 Best Practices of Data Import..... 101
4.3 Best Practices of SQL Queries..... 103
4.4 Best Practices for Data Skew Query..... 104
4.4.1 Detecting Storage Skew in Real Time During Data Import..... 105
4.4.2 Quickly Locating Tables That Cause Data Skew..... 105
**5 Tutorial: Using GDS to Import Data from a Remote Server..... 107**
5.1 Overview..... 107
5.2 Prerequisites..... 107
5.3 Step 1: Preparing Source Data..... 108
5.4 Step 2: Installing, Configuring, and Starting GDS on a Data Server..... 109
5.5 Step 3: Creating a Foreign Table in GaussDB..... 111
5.6 Step 4: Importing Data to GaussDB..... 114
5.7 Step 5: Analyzing and Handling Import Errors..... 115
5.8 Step 6: Improving Query Efficiency After Data Import..... 116
5.9 Step 7: Stopping GDS..... 116
5.10 Step 8: Cleaning Up Resources..... 117
**6 Application Development Guide..... 118**
6.1 Development Specifications..... 118
6.2 Obtaining the Driver Package..... 119
6.3 Development Based on JDBC..... 119

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

6.3.1 JDBC Package, Driver Class, and Environment Class 119
6.3.2 Development Process 122
6.3.3 Loading a Driver 122
6.3.4 Connecting to a Database 123
6.3.5 Connecting to the Database (Using SSL) 135
6.3.6 Connecting to a Database (Using UDS) 137
6.3.7 Running SQL Statements 138
6.3.8 Processing Data in a Result Set 142
6.3.9 Closing a Connection 145
6.3.10 Log Management 145
6.3.11 Example: Common Operations 149
6.3.12 Example: Retrying SQL Queries for Applications 153
6.3.13 Example: Importing and Exporting Data Through Local Files 156
6.3.14 Example: Migrating Data from MySQL 157
6.3.15 Example: Logic Replication Code 159
6.3.16 Example: Parameters for Connecting to the Database in Different Scenarios 164
6.3.17 JDBC Interface Reference 166
6.4 Development Based on ODBC 166
6.4.1 ODBC Packages, Dependent Libraries, and Header Files 167
6.4.2 Configuring a Data Source in the Linux OS 167
6.4.3 Configuring a Data Source in the Windows OS 177
6.4.4 Development Process 181
6.4.5 Example: Common Functions and Batch Binding 183
6.4.6 Typical Application Scenarios and Configurations 190
6.4.7 ODBC Interface Reference 198
6.5 Development Based on libpq 198
6.5.1 Dependent Header Files of libpq 198
6.5.2 Development Process 198
6.5.3 Example 199
6.5.4 libpq Interface Reference 204
6.5.5 Link Parameters 204
6.6 Psycopg-based Development 209
6.6.1 Psycopg Package 210
6.6.2 Development Process 211
6.6.3 Loading a Driver 211
6.6.4 Connecting a Database 212
6.6.5 Executing SQL Statements 212
6.6.6 Processing the Result Set 212
6.6.7 Closing the Connection 212
6.6.8 Connecting the Database (Using SSL) 212
6.6.9 Example: Common Operations 213
6.6.10 Psycopg API Reference 214

**7 Database Security Management ..... 215**
7.1 Checking the Number of Database Connections ..... 215
7.2 Managing Users and Their Permissions ..... 217
7.2.1 Default Permission Mechanism ..... 217
7.2.2 Administrator ..... 218
7.2.3 Separation of Duties ..... 219
7.2.4 Users ..... 222
7.2.5 Roles ..... 223
7.2.6 Schemas ..... 225
7.2.7 Setting User Permissions ..... 226
7.2.8 Row-Level Access Control ..... 227
7.2.9 Setting Security Policies ..... 229
7.2.9.1 Setting Account Security Policies ..... 229
7.2.9.2 Setting the Validity Period of an Account ..... 232
7.2.9.3 Setting Password Security Policies ..... 233
7.3 Configuring Database Audit ..... 238
7.3.1 Overview ..... 238
7.3.2 Querying Audit Results ..... 242
7.3.3 Maintaining Audit Logs ..... 244
**8 Importing Data ..... 247**
8.1 Importing Data in Parallel Using Foreign Tables ..... 247
8.1.1 Parallel Data Import ..... 248
8.1.2 Tutorial and Best Practice ..... 253
8.1.3 Preparing Source Data ..... 253
8.1.4 Installing, Configuring, and Starting GDS ..... 254
8.1.5 Creating a GDS Foreign Table ..... 259
8.1.6 Importing Data ..... 261
8.1.7 Handling Import Errors ..... 263
8.1.8 Stopping GDS ..... 266
8.1.9 Examples ..... 267
8.1.9.1 Example 1: Importing Data in Normal Mode ..... 267
8.1.9.2 Example 2: Importing Data in Shared Mode ..... 270
8.1.9.3 Example 3: Importing Data in Private Mode ..... 271
8.2 Running the INSERT Statement to Insert Data ..... 273
8.3 Running the COPY FROM STDIN Statement to Import Data ..... 273
8.3.1 Data Import Using COPY FROM STDIN ..... 273
8.3.2 Introduction to the CopyManager Class ..... 274
8.3.3 Example 1: Importing and Exporting Data Through Local Files ..... 275
8.3.4 Example 2: Migrating Data from a MySQL Database ..... 277
8.4 Using a gsql Meta-Command to Import Data ..... 278
8.5 Updating Data in a Table ..... 281
8.5.1 Updating a Table by Using DML Statements ..... 282

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

8.5.2 Updating and Inserting Data by Using the MERGE INTO Statement....283
8.6 Deep Copy....286
8.6.1 Performing a Deep Copy by Using the CREATE TABLE Statement....286
8.6.2 Performing a Deep Copy by Using the CREATE TABLE LIKE Statement....287
8.6.3 Performing a Deep Copy by Creating a Temporary Table and Truncating the Original Table....287
8.7 Checking for Data Skew....288
8.8 Analyzing Tables....291
8.9 Doing VACUUM to a Table....292
8.10 Managing Concurrent Write Operations....292
8.10.1 Transaction Isolation....292
8.10.2 Write and Read/Write Operations....293
8.10.3 Potential Deadlocks During Concurrent Write....293
8.10.4 Concurrent Write Examples....294
8.10.4.1 Concurrent INSERT and DELETE in the Same Table....294
8.10.4.2 Concurrent INSERT in the Same table....294
8.10.4.3 Concurrent UPDATE in the Same Table....295
8.10.4.4 Concurrent Data Import and Queries....295

**9 Exporting Data....297**

9.1 Exporting Data in Parallel Using a Foreign Table....297
9.1.1 Exporting Data In Parallel....297
9.1.2 Planning Data Export....300
9.1.3 Installing, Configuring, and Starting GDS....301
9.1.4 Creating a GDS Foreign Table....301
9.1.5 Exporting Data....303
9.1.6 Stopping GDS....304
9.1.7 Examples....304

**10 Performance Tuning....309**

10.1 Overview....309
10.2 Determining the Scope of Performance Tuning....311
10.2.1 Querying SQL Statements That Affect Performance Most....312
10.2.2 Checking Blocked Statements....314
10.3 SQL Optimization....315
10.3.1 Query Execution Process....315
10.3.2 Introduction to the SQL Execution Plan....318
10.3.2.1 Overview....318
10.3.2.2 Description....320
10.3.3 Optimization Process....328
10.3.4 Updating Statistics....329
10.3.5 Reviewing and Modifying a Table Definition....330
10.3.5.1 Overview....330
10.3.5.2 Selecting a Storage Model....331
10.3.5.3 Selecting a Distribution Mode....331

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

10.3.5.4 Selecting Distribution Keys 332
10.3.5.5 Using PCKs 333
10.3.5.6 Using Partitioned Tables 333
10.3.5.7 Selecting a Data Type 334
10.3.6 Typical SQL Optimization Methods 334
10.3.6.1 Optimizing SQL Self-Diagnosis 334
10.3.6.2 Optimizing Statement Pushdown 337
10.3.6.3 Optimizing Subqueries 345
10.3.6.4 Optimizing Statistics 354
10.3.6.5 Optimizing Operators 359
10.3.6.6 Optimizing Data Skew 360
10.3.7 Experience in Rewriting SQL Statements 366
10.3.8 Configuring Key Parameters for SQL Tuning 367
10.3.9 Hint-based Tuning 369
10.3.9.1 Plan Hint Optimization 369
10.3.9.2 Join Order Hints 372
10.3.9.3 Join Operation Hints 373
10.3.9.4 Rows Hints 374
10.3.9.5 Stream Operation Hints 375
10.3.9.6 Scan Operation Hints 377
10.3.9.7 Sublink Name Hints 378
10.3.9.8 Skew Hints 379
10.3.9.9 Parameterized Path Hint 384
10.3.9.10 Hint Errors, Conflicts, and Other Warnings 385
10.3.9.11 Plan Hint Cases 387
10.3.9.12 Optimizer GUC Parameter Hints 391
10.3.9.13 Hints for Selecting the Custom Plan or Generic Plan 392
10.3.9.14 Hints Specifying Not to Expand Subqueries 394
10.3.9.15 Hints Specifying Not to Use Global Plan Cache 394
10.3.9.16 Hint of Parameterized Paths at the Same Level 395
10.3.10 Checking the Implicit Conversion Performance 396
10.3.11 Using the Vectorized Executor for Tuning 397
10.4 Optimization Cases 399
10.4.1 Case: Selecting an Appropriate Distribution Key 399
10.4.2 Case: Creating an Appropriate Index 400
10.4.3 Case: Adding NOT NULL for JOIN Columns 401
10.4.4 Case: Pushing Down Sort Operations to DNs 403
10.4.5 Case: Setting cost_param and Optimizing Query Performance 404
10.4.6 Case: Adjusting Distribution Keys 407
10.4.7 Case: Adjusting Partial Clustering Keys 408
10.4.8 Case: Adjusting the Table Storage Model in a Medium Table 409
10.4.9 Case: Adjusting Partial Clustering Keys 410

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

10.4.10 Case: Modifying a Partitioned Table....411
10.4.11 Case: Adjusting the GUC Parameter best_agg_plan....412
10.4.12 Case: Rewriting SQL and Deleting Subqueries (1)....413
10.4.13 Case: Rewriting SQL and Deleting Subqueries (2)....414
10.4.14 Case: Rewriting SQL Statements to Eliminate Pruning Interference....415
10.4.15 Case: Rewriting SQL Statements and Deleting in-clause....416
10.4.16 Case: Setting Partial Cluster Keys....417
10.4.17 Case: Modifying the GUC Parameter rewrite_rule....420
10.4.18 Case: Using DN Gather to Reduce Stream Nodes in the Plan....426
10.4.19 Case: Adjusting I/O Parameters to Reduce the Log Bloat Rate....434

**11 Configuring Running Parameters....435**
11.1 Viewing Parameter Values....435
11.2 Resetting Parameters....436

**12 SQL Reference....439**
12.1 GaussDB SQL....439
12.2 Keywords....440
12.3 Data Type....475
12.3.1 Numeric Types....475
12.3.2 Monetary Types....481
12.3.3 Boolean Types....481
12.3.4 Character Types....482
12.3.5 Binary Types....486
12.3.6 Date/Time Types....488
12.3.7 Geometric Types....496
12.3.8 Network Address Types....499
12.3.9 Bit String Types....501
12.3.10 Text Search Types....502
12.3.11 UUID Type....504
12.3.12 JSON/JSONB Types....505
12.3.13 HLL....508
12.3.14 Range....512
12.3.15 Object Identifier Types....515
12.3.16 Pseudo-Types....517
12.3.17 Data Types Supported by Column-store Tables....519
12.3.18 Data Types Used by the Ledger Database....520
12.3.19 ACLItem....521
12.4 Constant and Macro....522
12.5 Functions and Operators....523
12.5.1 Logical Operators....523
12.5.2 Comparison Operators....523
12.5.3 Character Processing Functions and Operators....524
12.5.4 Binary String Functions and Operators....547

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

12.5.5 Bit String Functions and Operators....551
12.5.6 Pattern Matching Operators....553
12.5.7 Arithmetic Functions and Operators....557
12.5.8 Date and Time Processing Functions and Operators....572
12.5.9 Type Conversion Functions....593
12.5.10 Geometric Functions and Operators....611
12.5.11 Network Address Functions and Operators....621
12.5.12 Text Search Functions and Operators....627
12.5.13 JSON/JSONB Functions and Operators....633
12.5.14 HLL Functions and Operators....645
12.5.15 SEQUENCE Functions....658
12.5.16 Array Functions and Operators....660
12.5.17 Range Functions and Operators....668
12.5.18 Aggregate Functions....673
12.5.19 Window Functions....683
12.5.20 Security Functions....692
12.5.21 Ledger Database Functions....697
12.5.22 Encrypted Equality Functions....699
12.5.23 Set Returning Functions....702
12.5.24 Conditional Expression Functions....704
12.5.25 System Information Functions....707
12.5.26 System Administration Functions....747
12.5.26.1 Configuration Settings Functions....747
12.5.26.2 Universal File Access Functions....748
12.5.26.3 Server Signal Functions....750
12.5.26.4 Backup and Restoration Control Functions....751
12.5.26.5 Dual-Cluster DR Control Functions....757
12.5.26.6 Dual-Cluster DR Query Functions....759
12.5.26.7 Snapshot Synchronization Functions....763
12.5.26.8 Database Object Functions....764
12.5.26.9 Advisory Lock Functions....770
12.5.26.10 Logical Replication Functions....773
12.5.26.11 Segment-Page Storage Functions....784
12.5.26.12 Other Functions....787
12.5.27 Statistics Information Functions....815
12.5.28 Trigger Functions....873
12.5.29 Hash Function....874
12.5.30 Prompt Message Function....881
12.5.31 Fault Injection System Function....881
12.5.32 Redistribution Parameters....882
12.5.33 Distribution Column Recommendation Functions....884
12.5.34 Other System Functions....890

# 1 Overview

## 1.1 Database Logical Architecture

Each DN in a cluster stores data on disks. This section describes the objects on each DN from the logical view, the relationship between these objects, and how data is distributed on different nodes. **Figure 1-1** shows the database logical structure.

**Figure 1-1** Database logical architecture

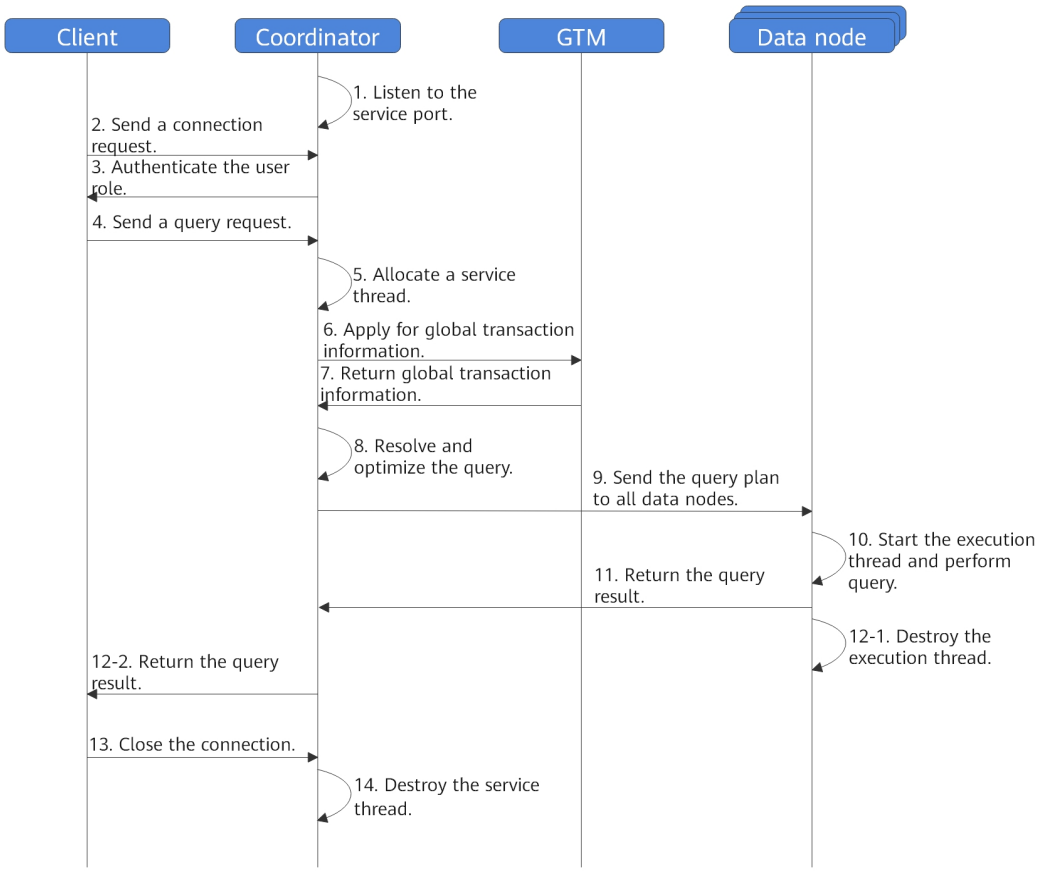
 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- A tablespace is a directory that stores physical files of databases. Multiple tablespaces can coexist. Each tablespace can contain files belonging to different databases.
- Each database manages various data objects and is isolated from each other. Objects managed by a database can be distributed to multiple tablespaces.
- A datafile segment stores data of only one table. A table containing more than 1 GB of data is stored in multiple datafile segments.
- One table belongs to only one database and one tablespace. The data file segments storing the data of the same table must be in the same tablespace.
- Block: Basic unit of database management. Its default size is 8 KB.
- Data can be distributed on DNs in replication, hash, range, or list mode. You can specify a mode when creating a table.

# 1.2 Query Request Handling Process

**Figure 1-2** GaussDB service response process



# 1.3 Managing Transactions

A transaction is a customized sequence of database operations, which form an integral unit of work. In GaussDB, you can start, set, commit, and roll back transactions. A GaussDB database supports the following transaction isolation levels: READ COMMITTED, READ UNCOMMITTED (not recommended),

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

REPEATABLE READ, and SERIALIZABLE. SERIALIZABLE is equivalent to REPEATABLE READ.

## Controlling Transactions

The following describes transaction operations supported by the database:

- Starting transactions

  You can use the START TRANSACTION or BEGIN syntax to start a transaction. For details, see **12.14.168 START TRANSACTION** and **12.14.41 BEGIN**.

- Setting transactions

  You can use the SET TRANSACTION or SET LOCAL TRANSACTION syntax to set transactions. For details, see **12.14.165 SET TRANSACTION**.

- Committing transactions

  You can use the COMMIT or END syntax to commit all operations of a transaction. For details, see **12.14.48 COMMIT | END**.

- Rolling back transactions

  Rollback indicates that the system cancels all changes that a transaction has made to a database if the transaction fails to be executed due to a fault. For details, see **12.14.155 ROLLBACK**.

## Transaction Isolation Levels

A transaction isolation level specifies how concurrent transactions process the same object.

NOTE

The isolation level cannot be changed after data is modified using SELECT, INSERT, DELETE, UPDATE, FETCH, or COPY in the transaction.

- **READ COMMITTED**: At this level, a transaction can access only committed data. This is the default level.

  The SELECT statement accesses the snapshot of the database taken when the query begins. It can also access the data updates in its transaction, regardless of whether they have been committed. Note that different database snapshots may be returned to two consecutive SELECT statements for the same transaction, because data may be committed for other transactions while the first SELECT statement is executed.

  At the READ COMMITTED level, the execution of each statement begins with a new snapshot, which contains all the transactions that have been committed by the execution time. Therefore, during a transaction, a statement can access the result of other committed transactions. Pay attention to whether a single statement always accesses completely consistent data in a database.

  Transaction isolation at this level meets the requirements of many applications, and is fast and easy to use. However, applications performing complicated queries and updates may require data that is more consistent than this level can provide.

- **READ UNCOMMITTED**: This level is not recommended, because it may result in data inconsistency. This level can be used for reading data in an emergency,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

such as when a coordinator node (CN) fails to be restored from a fault, to bypass the congestion caused by data inconsistency between the GTM and CN/DN. Do not use this level for data writing transactions, as this may lead to data inconsistency.

- **REPEATABLE READ**: At this level, a transaction can only read data committed before it starts. Uncommitted data or data committed in other concurrent transactions cannot be read. However, a query can read earlier data updates in its transaction, regardless of whether they have been committed. READ COMMITTED differs from this level in that a transaction reads the snapshot taken at the start of the transaction, not at the beginning of the current query within the transaction. Therefore, the SELECT statement within a transaction always reads the same data, and cannot read data committed by other concurrent transactions after the transaction starts. Applications at this level must be able to retry transactions, because serialization failures may occur.
- **SERIALIZABLE**: Currently, this isolation level is not supported in GaussDB. It is equivalent to REPEATABLE READ.

# 1.4 Concepts

## Database

Databases manage various data objects and are isolated from each other. While creating a database, you can specify a tablespace. If you do not specify it, the object will be saved to the **PG_DEFAULT** tablespace by default. Objects managed by a database can be distributed to multiple tablespaces.

## Tablespace

In GaussDB, a tablespace is a directory storing physical files of the databases the tablespace contains. Multiple tablespaces can coexist. Files are physically isolated using tablespaces and managed by a file system.

## Schema

GaussDB schemas logically separate databases. All database objects are created under certain schemas. In GaussDB, schemas and users are loosely bound. When you create a user, a schema with the same name as the user will be created automatically. You can also create a schema or specify another schema.

## User and Role

GaussDB uses users and roles to control the access to databases. A role can be a database user or a group of database users, depending on role settings. In GaussDB, the difference between roles and users is that a role does not have the **LOGIN** permission by default. In GaussDB, one user can have only one role, but you can put a user's role under a parent role to grant multiple permissions to the user.

## Transaction

In GaussDB, transactions are managed by multi-version concurrency control (MVCC) and two-phase locking (2PL). This enables smooth data reads and writes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

In GaussDB, MVCC saves historical version data together with the current tuple version. GaussDB uses the VACUUM thread instead of rollback segments to routinely delete historical version data. Generally, you do not need to pay special attention to the VACUUM thread unless you need to optimize the performance. In addition, GaussDB automatically commits transactions for single-statement queries (without using statements such as **BEGIN** to explicitly start a transaction block).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 2 Working with Databases

## 2.1 Connecting to a Database

Client tools for connecting to a database include DAS, gsql, and APIs (such as ODBC and JDBC).

- DAS enables you to manage databases on a web-based console and supports SQL execution, advanced database management, and intelligent O&M, simplifying database management and improving working efficiency and data security. The permissions required for connecting to a GaussDB instance through DAS are enabled by default. Using DAS to connect to your DB instance is recommended, which is more secure and convenient. For details about how to connect to GaussDB, see **Data Admin Service User Guide**.
- gsql is a client tool provided by GaussDB. You can use gsql to connect to the database and then enter, edit, and execute SQL statements in an interactive manner. For details about the connection modes, see **Connecting to a DB Instance**.
- You can use standard database APIs, such as ODBC and JDBC, to develop GaussDB-based applications.

**NOTICE**

- For distributed instances, you can use a client tool to connect to a database through any CN. Before connection, you must obtain the IP address and port number of the server where the CN is deployed. The client tool can access the database by connecting to any CN. Do not connect to a database through a DN when services are running properly.

### 2.1.1 APIs

You can use standard database APIs, such as **ODBC** and **JDBC**, to develop GaussDB-based applications.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

### Supported APIs

Each application is an independent GaussDB development project. APIs alleviate applications from directly operating in databases, and enhance the database portability, extensibility, and maintainability. **Table 2-1** lists the APIs supported by GaussDB and the download addresses.

**Table 2-1** Database APIs

| API | How to Obtain |
| --- | --- |
| ODBC | • Linux:<br>Driver: **GaussDB-Kernel-*VxxxRxxxCxx*-xxxxx-64bit-Odbc.tar.gz**<br>unixODBC source code package: **http://sourceforge.net/projects/unixodbc/files/unixODBC/2.3.0/unixODBC-2.3.0.tar.gz/download**<br>• Windows:<br>Driver: **GaussDB-Kernel-*VxxxRxxxCxx*-Windows-Odbc.tar.gz** |
| JDBC | • Driver: **GaussDB-Kernel-*VxxxRxxxCxx*-xxxxx-64bit-Jdbc.tar.gz**<br>• Driver: **org.postgresql.Driver** |

For details about more APIs, see **6 Application Development Guide**.

## 2.2 Before You Start

This section explains how to use databases, including creating databases and tables, inserting data to tables, and querying data in tables.

### Prerequisites

GaussDB runs properly.

### Procedure

**Step 1** Connect to a database. For details, see **2.1 Connecting to a Database**.

**Step 2** Create a database user.

Only administrators that are created during the cluster installation can access the initial database by default. You can also create other database users.

```
openGauss=# CREATE USER joe WITH PASSWORD "xxxxxxxxx";
```

If the following information is displayed, the user has been created:

```
CREATE ROLE
```

In this case, you have created a user named **joe**, and the user password is **xxxxxxxxxx**. Run the following command to set user **joe** as the system administrator:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# GRANT ALL PRIVILEGES TO joe;
```

Run the **GRANT** command to set related permissions. For details, see **12.14.140 GRANT**.

**Note**: For details about how to create users, see **7.2 Managing Users and Their Permissions**.

**Step 3** Create a database.

```
openGauss=# CREATE DATABASE db_tpcds;
```

If the following information is displayed, the database has been created:

```
CREATE DATABASE
```

After creating the **db_tpcds** database, you can run the following command to exit the **postgres** database and log in to the **db_tpcds** database as the user you created. You can also continue using the default **postgres** database for more operations.

```
openGauss=# \q
gsql -d db_tpcds -p 8000 -U joe
Password for user joe:
gsql((GaussDB Kernel VxxxRxxxCxx build f521c606) compiled at 2021-09-16 14:55:22 commit 2935 last mr 6385 release)
Non-SSL connection (SSL connection is recommended when requiring high-security)
Type "help" for help.

db_tpcds=>
```

**Note:**

New databases are created in the **pg_default** tablespace by default. To specify another tablespace, run the following statement:

```
openGauss=# CREATE DATABASE db_tpcds WITH TABLESPACE = hr_local;
CREATE DATABASE
```

*hr_local* indicates the tablespace name. For details about how to create a tablespace, see **2.5 Creating and Managing Tablespaces**.

**Step 4** Create a table.

- Create a table named **mytable** that has only one column. The column name is **firstcol** and the column type is **integer**.

  ```
  db_tpcds=>  CREATE TABLE mytable (firstcol int);
  ```

  If the **DISTRIBUTE BY** statement is not used to specify distribution columns, the system automatically specifies the first column as a hash distribution column and prompts you to confirm the operation. If **CREATE TABLE** is displayed at the end of the returned information, the table has been created.

  ```
  NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'firstcol' as the distribution column by default.
  HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
  CREATE TABLE
  ```

- Run the following command to insert data to the table:

  ```
  db_tpcds=> INSERT INTO mytable values (100);
  ```

  If the following information is displayed, the data has been inserted:

  ```
  INSERT 0 1
  ```

- Run the following command to view data in the table:

  ```
  db_tpcds=> SELECT * from mytable;
   firstcol
  ----------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
  100
(1 row)
```

**Note:**

- By default, new database objects, such as the **mytable** table, are created in the **$user** schema. For more details about schemas, see **2.8.1 Creating and Managing Schemas**.
- For more details about how to create a table, see **2.6 Creating and Managing Tables**.
- In addition to the created tables, a database contains many system catalogs. These system catalogs contain cluster installation, GaussDB queries and processes. You can collect information about the database by querying system catalogs. For details, see **2.7 Querying a System Catalog**.

  GaussDB supports hybrid row-column store, providing high query performance for interaction analysis in complex scenarios. For details about how to select a storage method, see **2.4 Planning a Storage Model**.

**----End**

# 2.3 Creating and Managing Databases

## Prerequisites

Only the database system administrator or users granted with database creation permissions can create a database. For details about how to grant database creation permissions to a user, see **7.2 Managing Users and Their Permissions**.

## Background

- GaussDB has two default template databases **template0** and **template1** and a default user database **postgres**.
- **CREATE DATABASE** creates a database by copying a template database. Only **template0** can be copied. Do not use a client or any other tools to connect to or to perform operations on the template databases.

  NOTE

  - The template database does not contain any user table. You can view the attributes of the template database in the **PG_DATABASE** system catalog.
  - The **template0** template database does not allow user connections. Only the initial user and the system administrator of the database can connect to **template1**.
- A database system consists of multiple databases. A client can connect to only one database at a time. Currently, cross-database query or cross-database transaction is not supported.
- If multiple databases exist in the database cluster, you can use the **-d** parameter of the client tool to specify the target database for login. Alternatively, you can run the **\c** command to switch the database after the client program logs in to the database.

## Precautions

Assume that the database encoding is SQL_ASCII. (You can run the **show server_encoding** command to query the encoding used for storing data in the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

current database.) If the database object name contains multi-byte characters (such as Chinese) or if the object name length exceeds the allowed maximum (63 bytes), the database truncates the last byte (not the last character) of the object name. In this case, half characters may appear.

To resolve this problem, you need to:

- Ensure that the name of the data object does not exceed the maximum length.
- Use a proper coded character set, such as UTF-8, as the default database storage code set (server_encoding).
- Exclude multi-byte characters from object names.
- If you fail to delete an object by specifying its name after truncation, specify its original name to delete it, or manually delete it from the system catalogs on each node.

## Procedure

**Step 1** Run the following command to create a database named **db_tpcds**:

```
openGauss=# CREATE DATABASE db_tpcds;
CREATE DATABASE
```

NOTE

- Database names must comply with the general naming convention rules of SQL identifiers. The current role automatically becomes the owner of this new database.
- If a database system is used to support independent users and projects, store them in different databases.
- If the projects or users are associated with each other and share resources, store them in one database. However, you can divide them into different schemas. A schema is a logical structure, and the access permission for a schema is controlled by the permission system module.
- A database name contains a maximum of 63 bytes and the excessive bytes at the end of the name will be truncated by the server. You are advised to specify a database name no longer than 63 bytes when you create a database.

**Step 2** View databases.

- Run the **\l** meta-command to view the database list of the database system.
  ```
  openGauss=# \l
  ```
- Run the following command to query the database list in the **pg_database** system catalog:
  ```
  openGauss=# SELECT datname FROM pg_database;
  ```

**Step 3** Modify the database.

You can modify database configuration such as the database owner, name, and default settings.

- Run the following command to rename the database:
  ```
  openGauss=# ALTER DATABASE db_tpcds RENAME TO human_tpcds;
  ALTER DATABASE
  ```

NOTE

After setting the parameters, you need to manually run the **CLEAN CONNECTION** command to clear the old connections. Otherwise, the parameter values between nodes may be inconsistent.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Step 4** Delete a database.

You can run the **DROP DATABASE** command to delete a database. This command deletes the system directory in the database, as well as the database directory on the disk that stores data. Only the database owner or system administrator can delete a database. A database accessed by users cannot be deleted. You need to connect to another database before deleting this database.

Run the following command to delete the database:

```
openGauss=# DROP DATABASE human_tpcds;
DROP DATABASE
```

**----End**

# 2.4 Planning a Storage Model

GaussDB supports hybrid row storage and column storage. Each storage model applies to specific scenarios. Select an appropriate model when creating a table.

Row-store stores tables to disk partitions by row, and column-store stores tables to disk partitions by column. By default, a row-store table is created. For details about differences between row storage and column storage, see **Figure 2-1**.

**Figure 2-1** Differences between row storage and column storage

In the preceding figure, the upper left part is a row-store table, and the upper right part shows how the row-store table is stored on a disk; the lower left part is a column-store table, and the lower right part shows how the column-store table is stored on a disk.

Both storage models have benefits and drawbacks.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Storage Model | Benefit | Drawback |
| --- | --- | --- |
| Row storage | Record data is stored together. Data can be easily inserted and updated. | All the columns of a record are read after the **SELECT** statement is executed even if only certain columns are required. |
| Column storage | • Only the columns involved in a query are read.<br>• Projections are efficient.<br>• Any column can serve as an index. | • The selected columns need to be reconstructed after the **SELECT** statement is executed.<br>• Data cannot be easily inserted or updated. |

Generally, if a table contains many columns (called a wide table) and its query involves only a few columns, column storage is recommended. Row storage is recommended if a table contains only a few columns and a query involves most of the fields.

| Storage Model | Application Scenario |
| --- | --- |
| Row storage | • Point queries (simple index-based queries that only return a few records)<br>• Scenarios requiring frequent addition, deletion, and modification |
| Column storage | • Statistical analysis queries (requiring a large number of association and grouping operations)<br>• Ad hoc queries (using uncertain query conditions and unable to utilize indexes to scan row-store tables) |

## Row-Store Tables

Row-store tables are created by default. In a row-store table, data is stored by row, that is, data in each row is stored continuously. Therefore, this storage model applies to scenarios where data needs to be updated frequently.

```
openGauss=# CREATE TABLE customer_t1
(
  state_ID   CHAR(2),
  state_NAME VARCHAR2(40),
  area_ID    NUMBER
);

--Delete the table.
openGauss=# DROP TABLE customer_t1;
```

## Column-Store Tables

In a column-store table, data is stored by column, that is, data in each column is stored continuously. The I/O of data query in a single column is small, and

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

column-store tables occupy less storage space than row-store tables. This storage model applies to scenarios where data is inserted in batches, less updated, and queried for statistical analysis. A column-store table cannot be used for point queries.

```
openGauss=# CREATE TABLE customer_t2
(
  state_ID   CHAR(2),
  state_NAME VARCHAR2(40),
  area_ID    NUMBER
)
WITH (ORIENTATION = COLUMN);

--Delete the table.
openGauss=# DROP TABLE customer_t2;
```

### Selecting a Storage Model

- Update frequency

  If data is frequently updated, use a row-store table.

- Data insertion frequency

  If a small amount of data is frequently inserted each time, use a row-store table. If a large amount of data is inserted at a time, use column storage.

- Number of columns

  If a table is to contain many columns, use a column-store table.

- Number of columns to be queried

  If only a small number of columns (less than 50% of the total) is queried each time, use a column-store table.

- Compression ratio

  The compression ratio of a column-store table is higher than that of a row-store table. High compression ratio consumes more CPU resources.

## 2.5 Creating and Managing Tablespaces

### Background

The administrator can use tablespaces to control the layout of disks where a database is installed. This has the following advantages:

- If the initial disk partition or volume allocated to the database is full and the space cannot be logically increased, you can create and use tablespaces in other partitions until the space is reconfigured.
- Tablespaces allow the administrator to distribute data based on the schema of database objects, improving system performance.
  - A frequently used index can be placed in a disk having stable performance and high computing speed, such as a solid device.
  - A table that stores archived data and is rarely used or has low performance requirements can be placed in a disk with a slow computing speed.
- The administrator can use tablespaces to set the maximum available disk space. In this way, when a partition is shared with other data, tablespaces will not occupy excessive space in the partition.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- You can use tablespaces to control the disk space occupied by data in a database. If the usage of a disk where a tablespace resides reaches 90%, the database switches to the read-only mode. It switches back to read/write mode when the disk usage becomes less than 90%.

  The automatic disk check of the cluster manager (CM) is enabled by default. To enable it, run the following command:

  ```
  gs_guc set -Z cmserver -N all -I all -c " enable_transaction_read_only = on "
  ```

  Restart the database to make the parameter settings take effect.

- Each tablespace corresponds to a file system directory. Run the following command to create a tablespace corresponding to **/pg_location/mount1/path1** and specify the maximum available space to 500 GB.

  ```
  -- Create a tablespace.
  openGauss=# CREATE TABLESPACE ds_location1 RELATIVE LOCATION '/pg_location/mount1/path1' MAXSIZE '500G';
  ```

  If **MAXSIZE** is used to manage tablespace quotas, the concurrent insertion performance may deteriorate by about 30%. **MAXSIZE** specifies the maximum quota for each each DN. The difference between the actual tablespace capacity of each DN and the specified quota should be within 500 MB. Determine whether to set a tablespace to its maximum size as required.

GaussDB provides two tablespaces: **pg_default** and **pg_global**.

- Default tablespace **pg_default**: stores non-shared system catalogs, user tables, user table indexes, temporary tables, temporary table indexes, and internal temporary tables. The corresponding storage directory is the base directory in the instance data directory.
- Shared tablespace **pg_global**: stores shared system tables. The corresponding storage directory is the base directory in the global data directory.

**Precautions**:

- You are not advised to use user-defined tablespaces.

  This is because user-defined tablespaces are usually used with storage media other than the main storage (storage device where the default tablespace is located, such as a disk) to isolate I/O resources that can be used by different services. Storage devices use standard configurations and do not have other available storage media in scenarios such as Huawei Cloud. If the user-defined tablespace is not properly used, the system cannot run stably for a long time and the overall performance is affected. Therefore, you are advised to use the default tablespace.

## Procedure

- Create a tablespace.

  a. Run the following command to create user **jack**:

  ```
  openGauss=# CREATE USER jack IDENTIFIED BY 'xxxxxxxxx';
  ```

  If the following information is displayed, the user has been created:

  ```
  CREATE ROLE
  ```

  b. Run the following command to create a tablespace:

  ```
  openGauss=# CREATE TABLESPACE fastspace RELATIVE LOCATION 'my_tablespace/tablespace1';
  ```

  If the following information is displayed, the tablespace has been created:

  ```
  CREATE TABLESPACE
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**fastspace** is the new tablespace, and *CN/DN data directory*/**pg_location/my_tablespace/tablespace1** is an empty directory on which users have read and write permissions.

c. A database system administrator can run the following command to grant the permission of accessing the **fastspace** tablespace to user **jack**:

```
openGauss=# GRANT CREATE ON TABLESPACE fastspace TO jack;
```

If the following information is displayed, the permission has been assigned:

```
GRANT
```

- Create an object in a tablespace.

  If you have the CREATE permission on the tablespace, you can create database objects in the tablespace, such as tables and indexes.

  Take creating a table as an example:

  – Method 1: Run the following command to create a table in a specified tablespace:

  ```
  openGauss=# CREATE TABLE foo(i int) TABLESPACE fastspace;
  ```

  If the following information is displayed, the table has been created:

  ```
  NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'i' as the distribution column by default.
  HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
  CREATE TABLE
  ```

  – Method 2: Use **set default_tablespace** to set the default tablespace and then create a table:

  ```
  openGauss=# SET default_tablespace = 'fastspace';
  SET
  openGauss=# CREATE TABLE foo2(i int);
  NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'i' as the distribution column by default.
  HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
  CREATE TABLE
  ```

  In this example, **fastspace** is the default tablespace, and **foo2** is the created table.

- Use one of the following methods to query a tablespace:

  – Method 1: Check the **pg_tablespace** system catalog. Run the following command to view all the tablespaces defined by the system and users:

  ```
  openGauss=# SELECT spcname FROM pg_tablespace;
  ```

  – Method 2: Run the following meta-command of the gsql program to query the tablespaces:

  ```
  openGauss=# \db
  ```

- Query the tablespace usage.

  a. Query the current usage of the tablespace.

  ```
  openGauss=# SELECT PG_TABLESPACE_SIZE('fastspace');
  ```

  Information similar to the following is displayed:

  ```
   pg_tablespace_size
  --------------------
             2146304
  (1 row)
  ```

  **2146304** is the size of the tablespace, and its unit is byte.

  b. Calculate the tablespace usage.

  Tablespace usage = Value of **PG_TABLESPACE_SIZE**/Size of the disk where the tablespace resides

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Modify a tablespace.

  Run the following command to rename tablespace **fastspace** to **fspace**:

  ```
  openGauss=# ALTER TABLESPACE fastspace RENAME TO fspace;
  ALTER TABLESPACE
  ```

- Delete a tablespace and related data.
  - Run the following command to delete user **jack**:

    ```
    openGauss=# DROP USER jack CASCADE;
    DROP ROLE
    ```

  - Run the following commands to delete tables **foo** and **foo2**:

    ```
    openGauss=# DROP TABLE foo;
    openGauss=# DROP TABLE foo2;
    ```

    If the following information is displayed, the tables have been deleted:

    ```
    DROP TABLE
    ```

  - Run the following command to delete tablespace **fspace**:

    ```
    openGauss=# DROP TABLESPACE fspace;
    DROP TABLESPACE
    ```

    NOTE

    Only the tablespace owner or system administrator can delete a tablespace.

# 2.6 Creating and Managing Tables

## 2.6.1 Creating a Table

### Background

A table is created in a database and can be saved in different databases. Tables under different schemas in a database can have the same name. Before creating a table, refer to **2.4 Planning a Storage Model**.

For details about how to design a table suitable for services, see **4.1 Best Practices of Table Design**.

### Creating a Table

Run the following command to create a table:

```
openGauss=# CREATE TABLE customer_t1
(
    c_customer_sk           integer,
    c_customer_id           char(5),
    c_first_name            char(6),
    c_last_name             char(8)
)
with (orientation = column,compression=middle)
distribute by hash (c_last_name);
```

If the following information is displayed, the table has been created:

```
CREATE TABLE
```

**c_customer_sk**, **c_customer_id**, **c_first_name**, and **c_last_name** are the column names of the table. **integer**, **char(5)**, **char(6)**, and **char(8)** are column name types.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 2.6.2 Inserting Data to a Table

A new table contains no data. You need to insert data to the table before using it. This section describes how to insert a row or multiple rows of data using the **INSERT** command and to insert data from a specified table. For details about how to insert a large amount of data to a table in batches, see **8 Importing Data**.

## Background

The length of a character on the server and client may vary by the character sets they use. A string entered on the client will be processed based on the server's character set, so the result may differ from expected.

**Table 2-2** Comparison of character set output between the client and server

| Operation Procedure | Server and Client Use Same Encoding | Server and Client Use Different Encoding |
| --- | --- | --- |
| No operations are performed to the string while it is saved and read. | Your expected result is returned. | If the encoding for input and output on the client is the same, your expected result is returned. |
| Operations (such as executing string functions) are performed to the string while it is saved and read. | Your expected result is returned. | The result may differ from expected, depending on the operations performed to the string. |
| A long string is truncated while it is saved. | Your expected result is returned. | If the character sets used on the client and server have different character length, the result may differ from expected. |

More than one of the preceding operations can be performed to a string. For example, if the character sets of the client and server are different, a string may be processed and then truncated. In this case, the result will also be unexpected. For details, see **Table 2-3**.

NOTE

Long strings are truncated only if **DBCOMPATIBILITY** is set to **TD** (compatible with Teradata) and **td_compatible_truncation** is set to **on**.

Run the following commands to create **table1** and **table2** to be used in the example:

```
openGauss=# CREATE TABLE table1(id int, a char(6), b varchar(6),c varchar(6));
openGauss=# CREATE TABLE table2(id int, a char(20), b varchar(20),c varchar(20));
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 2-3** Example

| No. | Server Character Set | Client Character Set | Automatic Truncation Enabled | Example | Result | Description |
| --- | --- | --- | --- | --- | --- | --- |
| 1 | SQL_ASCII | UTF8 | Yes | openGauss=# **INSERT INTO** *table1* **VALUES**(*1,reverse('123AA78'),reverse(''123AA78''),reverse('123AA78')*); | id \|a\|b\|c<br>----+------+------+------<br>1 \| 87\| 87\| 87 | A string is reversed on the server and then truncated. Because character sets used by the server and client are different, character A is displayed in multiple bytes on the server and the result is incorrect. |
| 2 | SQL_ASCII | UTF8 | Yes | openGauss=# **INSERT INTO** *table1* **VALUES**(*2,reverse('123A78'),reverse('123A78'),reverse('123A78')*); | id \|a\|b\|c<br>----+------+------+------<br>2 \| 873\| 873\| 873 | A string is reversed and then automatically truncated. Therefore, the result is unexpected. |
| 3 | SQL_ASCII | UTF8 | Yes | openGauss=# **INSERT INTO** *table1* **VALUES**(*3,'87A123','87A123','87A123'*); | id \| a \| b \| c<br>----+-------+-------+-------<br>3 \| 87A1 \| 87A1 \| 87A1 | The column length in the string type is an integer multiple of the length in client character encoding. Therefore, the result is correct after truncation. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| No. | Server Character Set | Client Character Set | Automatic Truncation Enabled | Example | Result | Description |
| --- | --- | --- | --- | --- | --- | --- |
| 4 | SQL_ASCII | UTF8 | No | openGauss=# **INSERT INTO** *table2* **VALUES**(*1,reverse('123AA78'),reverse('123AA78'),reverse('123AA78')*);<br>openGauss=# **INSERT INTO** *table2* **VALUES**(*2,reverse('123A78'),reverse('123A78'),reverse('123A78')*);<br> | id \|a\|b\|c<br>----<br>+----------<br>--+--------<br>+--------<br>1 \| 87 321\| 87 321 \| 87 321<br>2 \| 87321\| 87321\| 87321 | Similar to the first example, multi-byte characters no longer indicate the original characters after being reversed. |

## Procedure

You need to create a table before inserting data to it. For details about how to create a table, see **2.6 Creating and Managing Tables**.

- Insert a row to table **customer_t1**:

  Data values are arranged in the same order as the columns in the table and are separated by commas (,). Generally, column values are text values (constants). But column values can also be scalar expressions.

  ```
  openGauss=# INSERT INTO customer_t1(c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', 'Grace');
  ```

  If you know the sequence of the columns in the table, you can obtain the same result without listing these columns. For example, the following command generates the same result as the preceding command:

  ```
  openGauss=# INSERT INTO customer_t1 VALUES (3769, 'hello', 'Grace');
  ```

  If you do not know some of the column values, you can omit them. If no value is specified for a column, the column is set to the default value. For example:

  ```
  openGauss=# INSERT INTO customer_t1 (c_customer_sk, c_first_name) VALUES (3769, 'Grace');

  openGauss=# INSERT INTO customer_t1 VALUES (3769, 'hello');
  ```

  You can also specify the default value of a column or row:

  ```
  openGauss=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', DEFAULT);

  openGauss=# INSERT INTO customer_t1 DEFAULT VALUES;
  ```

- To insert multiple rows to a table, run the following command:

  ```
  openGauss=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES
      (6885, 'maps', 'Joes'),
      (4321, 'tpcds', 'Lily'),
      (9527, 'world', 'James');
  ```

  You can also insert multiple rows by running the command for inserting one row for multiple times. However, you are advised to run this command to improve efficiency.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Assume that you have created a backup table **customer_t2** for table **customer_t1**. To insert data from **customer_t1** to **customer_t2**, run the following commands:

```
openGauss=# CREATE TABLE customer_t2
(
    c_customer_sk             integer,
    c_customer_id             char(5),
    c_first_name              char(6),
    c_last_name               char(8)
);

openGauss=# INSERT INTO customer_t2 SELECT * FROM customer_t1;
```

  NOTE

  If implicit conversion is not implemented between the column data types of the specified table and those of the current table, the two tables must have the same column data types when data is inserted from the specified table to the current table.

- To delete a backup file, run the following command:

```
openGauss=# DROP TABLE customer_t2 CASCADE;
```

  NOTE

  If the table to be deleted is dependent on other tables, you need to delete its dependent tables first.

## 2.6.3 Updating Data in a Table

Existing data in a database can be updated. You can update one row, all rows, or specified rows of data, or update data in a single column without affecting the data in the other columns.

The following types of information are required when the **UPDATE** statement is used to update a row:

- Table name and column name of the data to be updated
- New column value
- Rows of the data to be updated

Generally, the SQL language does not provide a unique ID for a row of data. Therefore, it is impossible to directly specify the rows of the data to be updated. However, you can specify the rows by declaring the conditions that must be met by the updated row. If a table contains primary keys, you can specify a row using the primary keys.

For details about how to create a table and insert data to it, see **2.6.1 Creating a Table** and **2.6.2 Inserting Data to a Table**.

**c_customer_sk** in the table **customer_t1** must be changed from **9527** to **9876**:

```
openGauss=# UPDATE customer_t1 SET c_customer_sk = 9876 WHERE c_customer_sk = 9527;
```

You can use a schema to modify the table name. If no such modifier is specified, the table is located based on the default schema path. In the statement, **SET** is followed by the target column and the new column value. The new value can be a constant or an expression.

For example, run the following statement to increase all the values in the **c_customer_sk** column by 100:

```
openGauss=# UPDATE customer_t1 SET c_customer_sk = c_customer_sk + 100;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

This statement does not include the **WHERE** clause, so all rows are updated. If the statement includes the **WHERE** clause, only the rows matching the clause are updated.

In the **SET** clause, the equal sign (=) indicates value setting. In the **WHERE** clause, the equal sign indicates comparison. **WHERE** may not represent an equation and can be replaced by other operators.

You can run an **UPDATE** statement to update multiple columns by specifying multiple values in the **SET** clause. For example:

```
openGauss=# UPDATE customer_t1 SET  c_customer_id = 'Admin', c_first_name = 'Local' WHERE c_customer_sk = 4421;
```

After data has been updated or deleted in batches, a large number of deletion markers are generated in the data file. During query, data with these deletion markers needs to be scanned as well. In this case, a large amount of data with deletion marks can greatly affect the query performance after batch updates or deletions. If data needs to be updated or deleted in batches frequently, you are advised to periodically run the **VACUUM FULL** statement to maintain the query performance.

## 2.6.4 Viewing Data

- Run the following command to query information about all tables in a database in the system catalog **pg_tables**:
  ```
  openGauss=# SELECT * FROM pg_tables;
  ```
- Run the **\d+** command of the **gsql** tool to query table attributes:
  ```
  openGauss=# \d+ customer_t1;
  ```
- Run the following command to query the data volume of table **customer_t1**:
  ```
  openGauss=# SELECT count(*) FROM customer_t1;
  ```
- Run the following command to query all data in the table **customer_t1**:
  ```
  openGauss=# SELECT * FROM customer_t1;
  ```
- Run the following command to query only the data in the column **c_customer_sk**:
  ```
  openGauss=# SELECT c_customer_sk FROM customer_t1;
  ```
- Run the following command to filter repeated data in the column **c_customer_sk**:
  ```
  openGauss=# SELECT DISTINCT( c_customer_sk ) FROM customer_t1;
  ```
- Run the following command to query all data whose column **c_customer_sk** is **3869**:
  ```
  openGauss=# SELECT * FROM customer_t1 WHERE c_customer_sk = 3869;
  ```
- Run the following command to collate data based on the column **c_customer_sk**:
  ```
  openGauss=# SELECT * FROM customer_t1 ORDER BY c_customer_sk;
  ```

## 2.6.5 Deleting Data from a Table

Outdated data may need to be deleted when tables are used. Data can be deleted from tables only by row.

SQL statements can only access and delete an independent row by declaring conditions that match the row. If a table has a primary key, you can use it to specify a row. You can delete several rows that match the specified condition or delete all the rows from a table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

For example, to delete all the rows whose **c_customer_sk** column is **3869** from the table **customer_t1**, run the following command:

```
openGauss=# DELETE FROM customer_t1 WHERE c_customer_sk = 3869;
```

To delete all rows from the table, run either of the following commands:

```
openGauss=# DELETE FROM customer_t1;
or
openGauss=# TRUNCATE TABLE customer_t1;
```

NOTE

If you need to delete an entire table, you are advised to use the **TRUNCATE** statement rather than **DELETE**.

To delete a table, run the following command:

```
openGauss=# DROP TABLE customer_t1;
```

# 2.7 Querying a System Catalog

In addition to the created tables, a database contains many system catalogs. These system catalogs contain cluster installation, GaussDB queries and processes. You can collect information about the database by querying system catalogs.

In **16 Schemas**, the description about each table indicates whether the table is visible to all users or only the initial user. To query tables that are visible only to the initial user, log in as the user.

GaussDB provides the following types of system catalogs and views:

- System catalogs and views inherited from PG and PGXC

  These system catalogs and views have the prefix **PG** or **PGXC**.
- New system catalogs and views of GaussDB

  These system catalogs and views have the prefix **GS**.
- System catalogs and views that are compatible with Oracle

  These system catalogs and views have the prefix **ALL**, **DBA**, **USER**, or **PV**.

## Querying Database Tables

For example, you can run the following command to query the **PG_TABLES** system catalog for all tables in the **public** schema:

```
SELECT distinct(tablename) FROM pg_tables WHERE SCHEMANAME = 'public';
```

Information similar to the following is displayed:

```
    tablename
------------------
 err_hr_staffs
 test
 err_hr_staffs_ft3
 web_returns_p1
 mig_seq_table
 films4
(6 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Viewing Database Users

You can run the **PG_USER** command to view the list of all users in the database, and view the user ID (**USESYSID**) and permissions.

```
SELECT * FROM pg_user;
 usename | usesysid | usecreatedb | usesuper | usecatupd | userepl |  passwd  | valbegin | valuntil |
respool    | parent | spacelimit | useconfig | nodegroup | tempspacelimit | spillspacelimit
---------+----------+-------------+----------+-----------+---------+----------+----------+----------+--------------
+------
-------+------------+-----------+-----------+----------------+-----------------
 roach   |       10 | t          | t        | t         | t       | ******** |          |          | default_pool |
0      |          |          |          |              |
(1 row)
```

## Viewing and Stopping the Running Query Statements

You can view the running query statements in the **15.3.146 PG_STAT_ACTIVITY** view. You can use the following methods:

**Step 1** Set the parameter **track_activities** to **on**.

```
SET track_activities = on;
```

The database collects the running information about active queries only if the parameter is set to **on**.

**Step 2** View the running query statements. Run the following command to view the database names, users performing queries, query status, and the corresponding PID which are connected to the running query statements:

```
SELECT datname, usename, state,pid FROM pg_stat_activity;
 datname  | usename | state  |       pid
----------+---------+--------+-----------------
 postgres | Ruby    | active | 140298793514752
 postgres | Ruby    | active | 140298718004992
 postgres | Ruby    | idle   | 140298650908416
 postgres | Ruby    | idle   | 140298625742592
 postgres | omm | active | 140298575406848
(5 rows)
```

If the **state** column is **idle**, the connection is idle and requires a user to enter a command.

To identify only active query statements, run the following command:

```
SELECT datname, usename, state pid FROM pg_stat_activity WHERE state != 'idle';
```

**Step 3** To cancel queries that have been running for a long time, use the **PG_TERMINATE_BACKEND** function to end sessions based on the thread ID (corresponding to the PID in **Step 2**).

```
SELECT PG_TERMINATE_BACKEND(140298793514752);
```

If information similar to the following is displayed, the session is successfully terminated:

```
PG_TERMINATE_BACKEND
----------------------
 t
(1 row)
```

If information similar to the following is displayed, a user has terminated the current session:

```
FATAL:  terminating connection due to administrator command
FATAL:  terminating connection due to administrator command
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

If the **PG_TERMINATE_BACKEND** function is used to terminate the backend threads of the current session and the user is an initial user, the **gsql** client is reconnected automatically rather than be logged out. The message "The connection to the server was lost. Attempting reset: Succeeded." is returned. Otherwise, the client fails to be reconnected and the error message "The connection to the server was lost. Attempting reset: Failed." is returned because only the initial user can use password-free login.

2. If the **PG_TERMINATE_BACKEND** function is used to terminate inactive backend threads and the thread pool is opened, idle sessions do not have thread IDs and cannot be ended. In non-thread pool mode, ended sessions are not automatically reconnected.

**----End**

# 2.8 Other Operations

## 2.8.1 Creating and Managing Schemas

### Background

Schemas function as models. Schema management allows multiple users to use the same database without mutual impacts, to organize database objects as manageable logical groups, and to add third-party applications to the same schema without causing conflicts. Schema management involves creating a schema, using a schema, deleting a schema, setting a search path for a schema, and setting schema permissions.

### Precautions

- A database cluster can have one or more databases. Users and user groups are shared within entire cluster, but their data is exclusive. Any user who has connected to a server can access only the database specified in the connection request.
- A database can have one or more schemas, and a schema can contain tables and other data objects, such as data types, functions, and operators. One object name can be used in different schemas. For example, both **schema1** and **schema2** can have a table named **mytable**.
- Different from databases, schemas are not isolated. You can access the objects in a schema of the connected database if you have schema permissions. To manage schema permissions, you need to have knowledge about database permissions.
- A schema named with the **PG_** prefix cannot be created because this type of schema is reserved for the database system.
- Each time a new user is created, the system creates a schema with the same name for the new user in the current database. In other databases, such a schema needs to be manually created.
- To reference a table that is not modified with a schema name, the system uses **search_path** to find the schema that the table belongs to. **pg_temp** and **pg_catalog** are always the first two schemas to be searched no matter whether or how they are specified in **search_path**. **search_path** is a schema name list, and the first table detected in it is the target table. If no target

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

table is found, an error will be reported. (If a table exists but the schema it belongs to is not listed in **search_path**, the search fails as well.) The first schema in **search_path** is called "current schema". This schema is the first one to be searched. If no schema name is declared, newly created database objects are saved in this schema by default.

- Each database has a **pg_catalog** schema, which contains system catalogs and all embedded data types, functions, and operators. **pg_catalog** is a part of the search path and has the second highest search priority. It is searched after the schema of temporary tables and before other schemas specified in **search_path**. This search order ensures that database built-in objects can be found. To use a custom object that has the same name as a built-in object, you can specify the schema of the custom object.

## Procedure

- Create a schema.
  - Run the following command to create a schema:
    ```
    openGauss=# CREATE SCHEMA myschema;
    ```
    If the following information is displayed, the schema named **myschema** is successfully created:
    ```
    CREATE SCHEMA
    ```
    To create or access an object in the schema, the object name in the command should consist of the schema name and the object name, which are separated by a dot (.), for example, **myschema.table**.
  - Run the following command to create a schema and specify the owner:
    ```
    openGauss=# CREATE SCHEMA myschema AUTHORIZATION omm;
    ```
    If the following information is displayed, the **myschema** schema that belongs to **omm** is created successfully:
    ```
    CREATE SCHEMA
    ```
- Use a schema.

  If you want to create or access an object in a specified schema, the object name must contain the schema name. To be specific, the name consists of a schema name and an object name, which are separated by a dot (.).
  - Run the following command to create the **mytable** table in **myschema**:
    ```
    openGauss=# CREATE TABLE myschema.mytable(id int, name varchar(20));
    CREATE TABLE
    ```
    To specify the location of an object, the object name must contain the schema name.
  - Run the following command to query all data of the **mytable** table in **myschema**:
    ```
    openGauss=# SELECT * FROM myschema.mytable;
    id | name
    ----+------
    (0 rows)
    ```
- View **search_path** of a schema.

  You can set **search_path** to specify the sequence of schemas in which objects are searched. The first schema listed in **search_path** will become the default schema. If no schema is specified during object creation, the object will be created in the default schema.
  - Run the following command to view **search_path**:
    ```
    openGauss=# SHOW SEARCH_PATH;
     search_path
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
----------------
 "$user",public
(1 row)
```

  - Run the following command to set **search_path** to **myschema** and **public** (**myschema** will be searched first):

```
openGauss=# SET SEARCH_PATH TO myschema, public;
SET
```

- Set permissions for a schema.

  By default, a user can only access database objects in their own schema. Only after a user is granted with the usage permission for a schema by the schema owner, the user can access the objects in the schema.

  By granting the **CREATE** permission for a schema to a user, the user can create objects in this schema. By default, all roles have the **USAGE** permission in the **public** schema, but common users do not have the **CREATE** permission in the **public** schema. It is insecure for a common user to connect to a specified database and create objects in its **public** schema. If the common user has the **CREATE** permission on the **public** schema, it is advised to:

  - Run the following command to revoke **PUBLIC**'s permission to create objects in the **public** schema. **public** indicates the schema and **PUBLIC** indicates all roles.

```
openGauss=# REVOKE CREATE ON SCHEMA public FROM PUBLIC;
REVOKE
```

  - Run the following command to view the current schema:

```
openGauss=# SELECT current_schema();
 current_schema
----------------
 myschema
(1 row)
```

  - Run the following commands to create user **jack** and grant the **usage** permission for **myschema** to the user:

```
openGauss=# CREATE USER jack IDENTIFIED BY 'xxxxxxxxxx';
CREATE ROLE
openGauss=# GRANT USAGE ON schema myschema TO jack;
GRANT
```

  - Run the following command to revoke the usage permission for **myschema** from **jack**:

```
openGauss=# REVOKE USAGE ON schema myschema FROM jack;
REVOKE
```

- Delete a schema.

  - If a schema is empty, that is, it contains no database objects, you can execute the **DROP SCHEMA** command to delete it. For example, run the following command to delete an empty schema named **nullschema**:

```
openGauss=# DROP SCHEMA IF EXISTS nullschema;
DROP SCHEMA
```

  - To delete a schema that is not null, use the keyword **CASCADE** to delete it and all its objects. For example, run the following command to delete **myschema** and all its objects in it:

```
openGauss=# DROP SCHEMA myschema CASCADE;
DROP SCHEMA
```

  - Run the following command to delete user **jack**:

```
openGauss=# DROP USER jack;
DROP ROLE
```

# 2.8.2 Creating and Managing Partitioned Tables

## Background

GaussDB supports range partitioned tables.

In a range partitioned table, data within a certain range is mapped to each partition. The range is determined by the partition key specified when the partitioned table is created. This partitioning mode is most commonly used. The partition key is usually a date. For example, sales data is partitioned by month.

A partitioned table has the following advantages over an ordinary table:

- High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
- High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
- Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.

To convert an ordinary table to a partitioned table, you need to create a partitioned table and import data to it from the ordinary table. When you design tables, plan whether to use partitioned tables based on service requirements.

## Procedure

Example 1: using the default tablespace

- Creating a partitioned table (assuming that the **tpcds** schema has been created)

```
openGauss=# CREATE TABLE tpcds.customer_address
(
    ca_address_sk       integer                 NOT NULL   ,
    ca_address_id       character(16)           NOT NULL   ,
    ca_street_number    character(10)                      ,
    ca_street_name      character varying(60)              ,
    ca_street_type      character(15)                      ,
    ca_suite_number     character(10)                      ,
    ca_city             character varying(60)              ,
    ca_county           character varying(30)              ,
    ca_state            character(2)                       ,
    ca_zip              character(10)                      ,
    ca_country          character varying(20)              ,
    ca_gmt_offset       numeric(5,2)                       ,
    ca_location_type    character(20)
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
        PARTITION P1 VALUES LESS THAN(5000),
        PARTITION P2 VALUES LESS THAN(10000),
        PARTITION P3 VALUES LESS THAN(15000),
        PARTITION P4 VALUES LESS THAN(20000),
        PARTITION P5 VALUES LESS THAN(25000),
        PARTITION P6 VALUES LESS THAN(30000),
        PARTITION P7 VALUES LESS THAN(40000),
        PARTITION P8 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;
```

  If the following information is displayed, the partitioned table has been created:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
CREATE TABLE
```

**NOTE**

You are advised to create a maximum of 1000 column-store partitioned tables.

- Inserting data

  Insert data from the **tpcds.customer_address** table to the **tpcds.web_returns_p2** table.

  Suppose a backup table **tpcds.web_returns_p2** of the **tpcds.customer_address** table has been created in the database. You can run the following command to insert the data of the **tpcds.customer_address** table into the backup table **tpcds.web_returns_p2**:

```
openGauss=# CREATE TABLE tpcds.web_returns_p2
(
    ca_address_sk       integer                 NOT NULL   ,
    ca_address_id       character(16)           NOT NULL   ,
    ca_street_number    character(10)                      ,
    ca_street_name      character varying(60)              ,
    ca_street_type      character(15)                      ,
    ca_suite_number     character(10)                      ,
    ca_city             character varying(60)              ,
    ca_county           character varying(30)              ,
    ca_state            character(2)                       ,
    ca_zip              character(10)                      ,
    ca_country          character varying(20)              ,
    ca_gmt_offset       numeric(5,2)                       ,
    ca_location_type    character(20)
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
        PARTITION P1 VALUES LESS THAN(5000),
        PARTITION P2 VALUES LESS THAN(10000),
        PARTITION P3 VALUES LESS THAN(15000),
        PARTITION P4 VALUES LESS THAN(20000),
        PARTITION P5 VALUES LESS THAN(25000),
        PARTITION P6 VALUES LESS THAN(30000),
        PARTITION P7 VALUES LESS THAN(40000),
        PARTITION P8 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;
CREATE TABLE
openGauss=# INSERT INTO tpcds.web_returns_p2 SELECT * FROM tpcds.customer_address;
INSERT 0 0
```

- Modifying the row movement attributes of the partitioned table

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 DISABLE ROW MOVEMENT;
ALTER TABLE
```

- Deleting a partition

  Run the following command to delete partition **P8**:

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 DROP PARTITION P8;
ALTER TABLE
```

- Adding a partition

  Run the following command to add partition **P8** and set its range to [40000,MAXVALUE]:

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN
(MAXVALUE);
ALTER TABLE
```

- Renaming a partition
  - Run the following command to rename partition **P8** to **P_9**:

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION P8 TO P_9;
ALTER TABLE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

  - Run the following command to rename partition **P_9** to **P8**:
    ```
    openGauss=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;
    ALTER TABLE
    ```

- Querying a partition

  Run the following command to query partition **P6**:
  ```
  openGauss=# SELECT * FROM tpcds.web_returns_p2 PARTITION (P6);
  openGauss=# SELECT * FROM tpcds.web_returns_p2 PARTITION FOR (35888);
  ```

- Deleting a partitioned table and its tablespaces
  ```
  openGauss=# DROP TABLE tpcds.customer_address;
  DROP TABLE
  openGauss=# DROP TABLE tpcds.web_returns_p2;
  DROP TABLE
  ```

Example 2: using a user-defined tablespace

Perform the following operations on the range partitioned table (the **tpcds** namespace in the example must be created in advance):

- Creating tablespaces
  ```
  openGauss=# CREATE TABLESPACE example1 RELATIVE LOCATION 'tablespace1/tablespace_1';
  openGauss=# CREATE TABLESPACE example2 RELATIVE LOCATION 'tablespace2/tablespace_2';
  openGauss=# CREATE TABLESPACE example3 RELATIVE LOCATION 'tablespace3/tablespace_3';
  openGauss=# CREATE TABLESPACE example4 RELATIVE LOCATION 'tablespace4/tablespace_4';
  ```

  If the following information is displayed, the tablespaces have been created:
  ```
  CREATE TABLESPACE
  ```

- Creating a partitioned table
  ```
  openGauss=# CREATE TABLE tpcds.customer_address
  (
      ca_address_sk       integer                 NOT NULL   ,
      ca_address_id       character(16)           NOT NULL   ,
      ca_street_number    character(10)                      ,
      ca_street_name      character varying(60)              ,
      ca_street_type      character(15)                      ,
      ca_suite_number     character(10)                      ,
      ca_city             character varying(60)              ,
      ca_county           character varying(30)              ,
      ca_state            character(2)                       ,
      ca_zip              character(10)                      ,
      ca_country          character varying(20)              ,
      ca_gmt_offset       numeric(5,2)                       ,
      ca_location_type    character(20)
  )
  TABLESPACE example1
  DISTRIBUTE BY HASH (ca_address_sk)
  PARTITION BY RANGE (ca_address_sk)
  (
      PARTITION P1 VALUES LESS THAN(5000),
      PARTITION P2 VALUES LESS THAN(10000),
      PARTITION P3 VALUES LESS THAN(15000),
      PARTITION P4 VALUES LESS THAN(20000),
      PARTITION P5 VALUES LESS THAN(25000),
      PARTITION P6 VALUES LESS THAN(30000),
      PARTITION P7 VALUES LESS THAN(40000),
      PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
  )
  ENABLE ROW MOVEMENT;
  ```

  If the following information is displayed, the partitioned table has been created:
  ```
  CREATE TABLE
  ```

  **NOTE**

  You are advised to create a maximum of 1000 column-store partitioned tables.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Inserting data

  Insert data from the **tpcds.customer_address** table to the **tpcds.web_returns_p2** table.

  Suppose a backup table **tpcds.web_returns_p2** of the **tpcds.customer_address** table has been created in the database. You can run the following command to insert the data of the **tpcds.customer_address** table into the backup table **tpcds.web_returns_p2**:

```
openGauss=# CREATE TABLE tpcds.web_returns_p2
(
    ca_address_sk       integer                 NOT NULL   ,
    ca_address_id       character(16)           NOT NULL   ,
    ca_street_number    character(10)                      ,
    ca_street_name      character varying(60)              ,
    ca_street_type      character(15)                      ,
    ca_suite_number     character(10)                      ,
    ca_city             character varying(60)              ,
    ca_county           character varying(30)              ,
    ca_state            character(2)                       ,
    ca_zip              character(10)                      ,
    ca_country          character varying(20)              ,
    ca_gmt_offset       numeric(5,2)                       ,
    ca_location_type    character(20)
)
TABLESPACE example1
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
        PARTITION P1 VALUES LESS THAN(5000),
        PARTITION P2 VALUES LESS THAN(10000),
        PARTITION P3 VALUES LESS THAN(15000),
        PARTITION P4 VALUES LESS THAN(20000),
        PARTITION P5 VALUES LESS THAN(25000),
        PARTITION P6 VALUES LESS THAN(30000),
        PARTITION P7 VALUES LESS THAN(40000),
        PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
)
ENABLE ROW MOVEMENT;
CREATE TABLE
openGauss=# INSERT INTO tpcds.web_returns_p2 SELECT * FROM tpcds.customer_address;
INSERT 0 0
```

- Modifying the row movement attributes of the partitioned table

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 DISABLE ROW MOVEMENT;
ALTER TABLE
```

- Deleting a partition

  Run the following command to delete partition **P8**:

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 DROP PARTITION P8;
ALTER TABLE
```

- Adding a partition

  Run the following command to add partition **P8** and set its range to [40000,MAXVALUE]:

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN
(MAXVALUE);
ALTER TABLE
```

- Renaming a partition
  - Run the following command to rename partition **P8** to **P_9**:

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION P8 TO P_9;
ALTER TABLE
```

  - Run the following command to rename partition **P_9** to **P8**:

```
openGauss=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;
ALTER TABLE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Modifying the tablespace of a partition
  - Run the following command to change the tablespace of partition **P6** to **example3**:
    ```
    openGauss=# ALTER TABLE tpcds.web_returns_p2 MOVE PARTITION P6 TABLESPACE example3;
    ALTER TABLE
    ```
  - Run the following command to change the tablespace of partition **P4** to **example4**:
    ```
    openGauss=# ALTER TABLE tpcds.web_returns_p2 MOVE PARTITION P4 TABLESPACE example4;
    ALTER TABLE
    ```
- Querying a partition

  Run the following command to query partition **P6**:
  ```
  openGauss=# SELECT * FROM tpcds.web_returns_p2 PARTITION (P6);
  openGauss=# SELECT * FROM tpcds.web_returns_p2 PARTITION FOR (35888);
  ```
- Deleting a partitioned table and its tablespaces
  ```
  openGauss=# DROP TABLE tpcds.customer_address;
  DROP TABLE
  openGauss=# DROP TABLE tpcds.web_returns_p2;
  DROP TABLE
  openGauss=# DROP TABLESPACE example1;
  openGauss=# DROP TABLESPACE example2;
  openGauss=# DROP TABLESPACE example3;
  openGauss=# DROP TABLESPACE example4;
  DROP TABLESPACE
  ```

# 2.8.3 Creating and Managing Indexes

## Background

Indexes accelerate data access but increase the processing time of insertion, update, and deletion operations. Therefore, before creating an index, consider whether it is necessary and select the columns where indexes are to be created. You can determine whether to add an index for a table by analyzing the service processing and data use of applications, as well as columns that are frequently used as search criteria or need to be collated.

Indexes are created based on columns in database tables. Therefore, you must correctly identify which columns require indexes. You are advised to create indexes for any of the following columns:

- Columns that are often searched and queried. This speeds up searches.
- Columns that function as primary keys. This enforces the uniqueness of the columns and the data collation structures in organized tables.
- Columns that are often joined and function as foreign keys. This increases the join efficiency.
- Columns that are often searched by range. The index helps collate data, and therefore the specified ranges are contiguous.
- Columns that often need to be collated. The index helps collate data, reducing the time for a collation query.
- Columns where the WHERE clause is executed frequently. This speeds up condition judgment.
- Columns that often appear after the keywords ORDER BY, GROUP BY, and DISTINCT.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- After an index is created, the system automatically determines when to reference it. If the system determines that indexing is faster than sequenced scanning, the index will be used.
- After an index is successfully created, it must be synchronized with the associated table to ensure new data can be accurately located, which increases the data operation load. Therefore, delete unnecessary indexes periodically.

- When logical replication is enabled, if you need to create a primary key index that contains system columns, you must set the **REPLICA IDENTITY** attribute of the table to **FULL** or use USING INDEX to specify a unique, non-local, non-deferrable index that does not contain system columns and contains only columns marked **NOT NULL**.

## Procedure

For details about how to create a partitioned table, see **2.8.2 Creating and Managing Partitioned Tables**.

- Creating an index
  - Create the partitioned table index **tpcds_web_returns_p2_index1** without specifying the partition name.

    ```
    openGauss=# CREATE INDEX tpcds_web_returns_p2_index1 ON tpcds.web_returns_p2 (ca_address_id) LOCAL;
    ```

    If the following information is displayed, the index has been created:

    ```
    CREATE INDEX
    ```

  - Create the partitioned table index **tpcds_web_returns_p2_index2** with the partition name specified.

    ```
    openGauss=# CREATE INDEX tpcds_web_returns_p2_index2 ON tpcds.web_returns_p2 (ca_address_sk) LOCAL
    (
        PARTITION web_returns_p2_P1_index,
        PARTITION web_returns_p2_P2_index TABLESPACE example3,
        PARTITION web_returns_p2_P3_index TABLESPACE example4,
        PARTITION web_returns_p2_P4_index,
        PARTITION web_returns_p2_P5_index,
        PARTITION web_returns_p2_P6_index,
        PARTITION web_returns_p2_P7_index,
        PARTITION web_returns_p2_P8_index
    ) TABLESPACE example2;
    ```

    If the following information is displayed, the index has been created:

    ```
    CREATE INDEX
    ```

- Modifying the tablespace of an index partition
  - Change the tablespace of index partition **web_returns_p2_P2_index** to **example1**.

    ```
    openGauss=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 MOVE PARTITION web_returns_p2_P2_index TABLESPACE example1;
    ```

    If the following information is displayed, the tablespace of the index partition has been modified:

    ```
    ALTER INDEX
    ```

  - Change the tablespace of index partition **web_returns_p2_P3_index** to **example2**.

    ```
    openGauss=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 MOVE PARTITION web_returns_p2_P3_index TABLESPACE example2;
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

If the following information is displayed, the tablespace of the index partition has been modified:

```
ALTER INDEX
```

- Renaming an index partition

  Rename the name of index partition **web_returns_p2_P8_index** to **web_returns_p2_P8_index_new**.

  ```
  openGauss=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 RENAME PARTITION web_returns_p2_P8_index TO web_returns_p2_P8_index_new;
  ```

  If the following information is displayed, the index partition has been renamed:

  ```
  ALTER INDEX
  ```

- Querying indexes
  - Run the following command to query all indexes defined by the system and users:

    ```
    openGauss=# SELECT RELNAME FROM PG_CLASS WHERE RELKIND='i';
    ```

  - Run the following command to query information about a specified index:

    ```
    openGauss=# \di+ tpcds.tpcds_web_returns_p2_index2
    ```

- Deleting indexes

  ```
  openGauss=# DROP INDEX tpcds.tpcds_web_returns_p2_index1;
  openGauss=# DROP INDEX tpcds.tpcds_web_returns_p2_index2;
  ```

  If the following information is displayed, the indexes have been deleted:

  ```
  DROP INDEX
  ```

GaussDB supports four methods for creating indexes. For details, see **Table 2-4**.

NOTE

- After an index is created, the system automatically determines when to reference it. If the system determines that indexing is faster than sequenced scanning, the index will be used.
- After an index is successfully created, it must be synchronized with the associated table to ensure new data can be accurately located, which increases the data operation load. Therefore, delete unnecessary indexes periodically.

**Table 2-4** Indexing method

| Indexing Method | Description |
| --- | --- |
| Unique index | An index that requires the uniqueness of an index attribute or an attribute group. If a table declares unique constraints or primary keys, GaussDB automatically creates unique indexes (or composite indexes) for columns that form the primary keys or unique constraints. Currently, unique indexes can be created only for the B-tree and UB-tree in GaussDB. |
| Composite index | An index that can be defined for multiple attributes of a table. Currently, composite indexes can be created only for B-tree in GaussDB and up to 32 columns can share a composite index. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Indexing Method | Description |
| --- | --- |
| Partial index | An index that can be created for subsets of a table. This indexing method contains only tuples that meet condition expressions. |
| Expression index | An index that is built on a function or expression calculated based on one or more attributes of a table. An expression index works only when the queried expression is the same as the created expression. |

- Create an ordinary table.
  ```
  openGauss=# CREATE TABLE tpcds.customer_address_bak AS TABLE tpcds.customer_address;
  INSERT 0 0
  ```
- Create an ordinary index.

  For the **tpcds.customer_address_bak** table, you need to perform the following operations frequently:
  ```
  openGauss=# SELECT ca_address_sk FROM tpcds.customer_address_bak WHERE ca_address_sk=14888;
  ```

  Generally, the database system needs to scan the **tpcds.customer_address_bak** table row by row to find all matched tuples. If the size of the **tpcds.customer_address_bak** table is large but only a few (possibly zero or one) of the WHERE conditions are met, the performance of this sequential scan is low. If the database system uses an index to maintain the **ca_address_sk** attribute, the database system only needs to search a few tree layers for the matched tuples. This greatly improves data query performance. Furthermore, indexes can improve the update and deletion operation performance in the database.

  Run the following command to create an index:

  ```
  openGauss=# CREATE INDEX index_wr_returned_date_sk ON tpcds.customer_address_bak (ca_address_sk);
  CREATE INDEX
  ```
- Create a unique index.

  Create a unique index on the **SM_SHIP_MODE_SK** column in the **tpcds.ship_mode_t1** table.

  ```
  openGauss=# CREATE UNIQUE INDEX ds_ship_mode_t1_index1 ON tpcds.ship_mode_t1(SM_SHIP_MODE_SK);
  ```
- Create a multi-column index.

  Assume you need to frequently query records with **ca_address_sk** being **5050** and **ca_street_number** smaller than **1000** in the **tpcds.customer_address_bak** table. Run the following commands:
  ```
  openGauss=# SELECT ca_address_sk,ca_address_id FROM tpcds.customer_address_bak WHERE ca_address_sk = 5050 AND ca_street_number < 1000;
  ```

  Run the following command to define a composite index on **ca_address_sk** and **ca_street_number** columns:
  ```
  openGauss=# CREATE INDEX more_column_index ON tpcds.customer_address_bak(ca_address_sk ,ca_street_number );
  CREATE INDEX
  ```
- Create a partial index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

If you only want to find records whose **ca_address_sk** is **5050**, you can create a partial index to facilitate your query.

```
openGauss=# CREATE INDEX part_index ON tpcds.customer_address_bak(ca_address_sk) WHERE ca_address_sk = 5050;
CREATE INDEX
```

- Create an expression index.

  Assume that you need to frequently query records with **ca_street_number** smaller than **1000**, run the following command:

  ```
  openGauss=# SELECT * FROM tpcds.customer_address_bak WHERE trunc(ca_street_number) < 1000;
  ```

  The following expression index can be created for this query task:

  ```
  openGauss=# CREATE INDEX para_index ON tpcds.customer_address_bak (trunc(ca_street_number));
  CREATE INDEX
  ```

- Delete the **tpcds.customer_address_bak** table.

  ```
  openGauss=# DROP TABLE tpcds.customer_address_bak;
  DROP TABLE
  ```

# 2.8.4 Creating and Managing Views

## Background

If some columns in one or more tables in a database are frequently searched for, an administrator can define a view for these columns, and then users can directly access these columns in the view without entering search criteria.

A view is different from a base table. It is only a virtual object rather than a physical one. Only view definition is stored in the database and view data is not. The data is stored in a base table. If data in the base table changes, the data in the view changes accordingly. In this sense, a view is like a window through which users can know their interested data and data changes in the database. A view is triggered every time it is referenced.

## Managing Views

- Creating a view

  Run the following command to create the **MyView** view. In the command, **tpcds.***web_returns* indicates the created user table that contains the *wr_refunded_cash* integer field.

  ```
  openGauss=# CREATE OR REPLACE VIEW MyView AS SELECT * FROM tpcds.web_returns WHERE trunc(wr_refunded_cash) > 10000;
  CREATE VIEW
  ```

  NOTE

  The **OR REPLACE** parameter in this command is optional. It indicates that if the view exists, the new view will replace the existing view.

- Querying a view

  Run the following command to query **MyView**:

  ```
  openGauss=# SELECT * FROM MyView;
  ```

- Querying views of the current user

  ```
  openGauss=# SELECT * FROM my_views;
  ```

- Querying all views

  ```
  openGauss=# SELECT * FROM adm_views;
  ```

- Viewing details about a specified view

  Run the following command to view details about **MyView**:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# \d+ MyView
                    View "PG_CATALOG.MyView"
 Column  |          Type          | Modifiers | Storage  | Description
----------+------------------------+-----------+----------+-------------
 USERNAME | CHARACTER VARYING(64) |           | extended |
View definition:
 SELECT PG_AUTHID.ROLNAME::CHARACTER VARYING(64) AS USERNAME
   FROM PG_AUTHID;
```

- Deleting a view

  Run the following command to delete **MyView**:

  ```
  openGauss=# DROP VIEW MyView;
  DROP VIEW
  ```

# 2.8.5 Creating and Managing Sequences

## Background

A sequence is a database object that generates unique integers. Sequence numbers are generated according to a certain rule. Sequences are unique because they increase automatically. This is why they are often used as primary keys.

You can create a sequence for a column in either of the following methods:

- Set the data type of a column to **sequence integer**. A sequence will be automatically created by the database for this column.
- Run the **CREATE SEQUENCE** statement to create a sequence. Set the initial value of the **nextval**('*sequence_name*') function to the default value of a column.

## Procedure

Method 1: Set the data type of a column to a sequence integer. For example:

```
openGauss=# CREATE TABLE T1
(
    id    serial,
    name  text
);
```

If the following information is displayed, the table has been created:

```
CREATE TABLE
```

Method 2: Create a sequence and set the initial value of the **nextval**('*sequence_name*') function to the default value of a column. You can cache a specific number of sequence values to reduce the requests to the GTM, improving the performance.

1. Create a sequence.

   ```
   openGauss=# CREATE SEQUENCE seq1 cache 100;
   ```

   If the following information is displayed, the sequence has been created:

   ```
   CREATE SEQUENCE
   ```

2. Set the initial value of the **nextval**('*sequence_name*') function to the default value of a column.

   ```
   openGauss=# CREATE TABLE T2
   (
      id   int not null default nextval('seq1'),
      name text
   );
   ```

   If the following information is displayed, the default value has been specified:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
CREATE TABLE
```

3. Associate the sequence with a column.

   Associate a sequence with a specified column included in a table. In this way, the sequence will be deleted when you delete its associated field or the table where the field belongs.

   ```
   openGauss=# ALTER SEQUENCE seq1 OWNED BY T2.id;
   ```

   If the following information is displayed, the column has been specified:

   ```
   ALTER SEQUENCE
   ```

**NOTE**

The preceding methods are similar, except that the second method specifies cache for the sequence. A sequence having cache defined has inconsecutive values (such as 1, 4, and 5) and cannot maintain the order of its values. After the dependent column of a sequence has been specified, once the sequence is deleted, the sequence of the dependent will be deleted. A sequence shared by multiple columns is not forbidden in a database, but you are not advised to do that.

In the current version, you can specify the auto-increment column or set the default value of a column to **nextval('seqname')** when defining a table. You cannot add an auto-increment column or a column whose default value is **nextval('seqname')** to an existing table.

## Precautions

Sequence values are generated by the GTM. By default, each request for a sequence value is sent to the GTM. The GTM calculates the result of the current value plus the step and then returns the result. The GTM is a globally unique node and is the performance bottleneck. Therefore, you are not advised to generate sequence values frequently and numerously, such as to use BulkLoad to import data. For example, the **INSERT FROM SELECT** statement has poor performance in the following scenario:

```
openGauss=# CREATE SEQUENCE newSeq1;
openGauss=# CREATE TABLE newT1
        (
          id   int not null default nextval('newSeq1'),
          name text
        );
openGauss=# INSERT INTO newT1(name) SELECT name from T1;
```

Assume that data imported from table **T1** to table **newT1** has 10,000 rows. The following statements achieve better performance:

```
openGauss=# INSERT INTO newT1(id, name) SELECT id,name from T1;
openGauss=# SELECT SETVAL('newSeq1',10000);
```

**NOTE**

Rollback is not supported by sequence functions, including **nextval()** and **setval()**. The value of the **setval** function immediately takes effect on **nextval** in the current session in any cases and take effect in other sessions only when no cache is specified for them. If cache is specified for a session, it takes effect only after all the cached values have been used. To avoid duplicate values, use **setval** only when necessary. Do not set it to an existing sequence value or a cached sequence value.

To generate the default sequence value using BulkLoad, set sufficient cache for **newSeq1** and do not set **Maxvalue** or **Minvalue**. The database will push down the calling of **nextval('sequence_name')** to DNs to improve performance. Currently, the concurrent connection requests that can be processed by the GTM

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

are limited. If there are too many DNs, a large number of concurrent connection requests will be sent to the GTM. In this case, you need to limit the bulk loading concurrency, so that DNs do not fully occupy GTM connections. If the target table is a duplicate table (DISTRIBUTE BY REPLICATION), pushdown cannot be performed. A large amount of data would be a disaster to the database. Also, the occupied space may dramatically expand. After the import is completed, you need to run **VACUUM FULL** to free space. The best way is not to use BulkLoad to generate the default sequence value.

After a sequence is created, one single-row table is maintained on each node to store the sequence definition and value, which is obtained from the last interaction with the GTM rather than updated in real time. The single-row table on a node does not update when other nodes request a new value from the GTM or when the sequence is modified using **setval**.

## 2.8.6 Creating and Managing Scheduled Jobs

### Background

Time-consuming jobs, such as summarizing statistics or synchronizing data from another database, affect service performance if they are performed during the daytime and incur overtime hours if performed at night. To solve this problem, the database is compatible with the scheduled job function in Oracle. You can create scheduled jobs that are automatically triggered to reduce O&M workload.

This function calls interfaces provided by the **DBE_TASK** package to create scheduled jobs, execute jobs automatically, delete jobs, and modify job attributes (including job ID, the enabled/disabled status of a job, job triggering time, triggering interval, and job contents).

### Managing Scheduled Jobs

**Step 1** Create a test table.

```
openGauss=# CREATE TABLE test(id int, time date);
```

If the following information is displayed, the test table has been created:

```
CREATE TABLE
```

**Step 2** Create a customized storage procedure.

```
openGauss=# CREATE OR REPLACE PROCEDURE PRC_JOB_1()
AS
N_NUM integer :=1;
BEGIN
FOR I IN 1..1000 LOOP
INSERT INTO test VALUES(I,SYSDATE);
END LOOP;
END;
/
```

If the following information is displayed, the procedure has been created:

```
CREATE PROCEDURE
```

**Step 3** Create a job.

- Create a job with unspecified **job_id** and execute the **PRC_JOB_1** stored procedure every minute.

  ```
  openGauss=# call dbe_task.submit('call public.prc_job_1(); ', sysdate, 'interval ''1 minute''', :a);
  job
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
-----
1
(1 row)
```

- Specify **job_id** to create a job. The value of **job_id** ranges from 1 to 32767.

```
openGauss=# call dbe_task.id_submit(2,'call public.prc_job_1(); ', sysdate, 'interval ''1 minute''');
isubmit
---------

(1 row)
```

**Step 4** View details of jobs created by the current user.

```
openGauss=# select job,dbname,start_date,last_date,this_date,next_date,broken,status,interval,failures,what
from my_jobs;
job | dbname |     start_date      |         last_date          |         this_date          |      next_date      | broken |
status |      interval       | failures |           what
-----+--------+---------------------+----------------------------+----------------------------+---------------------
+--------+--------+---------------------+----------+----------------------------
1 | postgres   | 2017-07-18 11:38:03 | 2017-07-18 13:53:03.607838 | 2017-07-18 13:53:03.607838 |
2017-07-18 13:54:03 | n      | s      | interval '1 minute' |        0 | call public.prc_job_1();
(1 row)
```

**Step 5** Stop a job.

```
openGauss=# call dbe_task.finish(1,true);
broken
--------

(1 row)
```

**Step 6** Start a job.

```
openGauss=# call dbe_task.finish(1,false);
broken
--------

(1 row)
```

**Step 7** Modify job attributes.

- Modify the **Next_date** parameter information about a job.

  -- Set **Next_date** of **Job1** to 1 hour so that **Job1** will be executed in one hour.

```
openGauss=# call dbe_task.next_time(1, sysdate+1.0/24);
next_date
-----------

(1 row)
```

- Modify the **Interval** parameter about a job.

  -- Set **Interval** of **Job1** to **1**.

```
openGauss=# call dbe_task.interval(1,'sysdate + 1.0/24');
interval
----------

(1 row)
```

- Modify the **What** parameter about a job.

  -- Set **What** to the SQL statement **insert into public.test values(333, sysdate+5);** for **Job1**.

```
openGauss=# call dbe_task.content(1,'insert into public.test values(333, sysdate+5);');
what
------

(1 row)
```

- Modify **Next_date**, **Interval**, and **What** parameters about a job.

```
openGauss=# call dbe_task.update(1, 'call public.prc_job_1();', sysdate, 'interval ''1 minute''');
change
--------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
(1 row)
```

**Step 8** Delete a job.

```
openGauss=# call dbe_task.cancel(1);
remove
--------

(1 row)
```

**Step 9** View the job execution status.

If a job fails to execute automatically, (the status of **job_status** is **f**), you can query the failure information by visiting the **pg_log** subdirectory of the CN data directory where the job belongs to.

From **detail error msg**, you can see the failure causes.

```
LOG:  Execute Job Detail:
        job_id: 1
        what: call public.test();
        start_date: 2017-07-19 23:30:47.401818
        job_status: failed
        detail error msg: relation "test" does not exist
        end_date: 2017-07-19 23:30:47.401818
        next_run_date: 2017-07-19 23:30:56.855827
```

**Step 10** Set job permissions.

- During the creation of a job, the job is bound to the user and database that created the job. Accordingly, the user and database are added to **dbname** and **log_user** columns in the **pg_job** system catalog, respectively.
- If the current user is a database administrator, system administrator, or the user who created the job, (**log_user** of **pg_job**), the user has permissions to delete or modify job parameters using the **Remove**, **Change**, **Next_date**, **What**, or **Interval** parameter. Otherwise, the system displays a message indicating that the user has no permissions to perform operations on this job.
- If the current database is the one that created a job, (that is, **dbname** in **pg_job**), you can delete or modify parameter settings of the job using the **cancel**, **update**, **next_data**, **content**, or **interval** parameter.
- When deleting the database that created a job, (that is, **dbname** in **pg_job**), the system automatically deletes the job records of the database.
- When deleting the user who created a job, (that is, **log_user** in **pg_job**), the system automatically deletes the job records of the user.

**Step 11** Manage job concurrency. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)

You can configure parameter **job_queue_processes** to adjust the number of jobs running at the same time.

- Setting **job_queue_processes** to **0** indicates that the scheduled job function is disabled and all jobs will not be executed.
- Setting **job_queue_processes** to a value that is greater than **0** indicates that the scheduled job function is enabled and this value is the maximum number of jobs that can be concurrently processed.

Too many concurrent jobs consume many system resources, so you need to set the number of concurrent jobs to be processed. If the current number of concurrent jobs reaches the value of **job_queue_processes** and some of them expire, these

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

jobs will be postponed to the next polling period. Therefore, you are advised to set the polling interval (the **Interval** parameter of the **submit** interface) based on the execution duration of each job to avoid the problem that jobs in the next polling period cannot be properly processed because of overlong job execution time.

Note: For clusters that do not use jobs, set **job_queue_processes** to **0** to disable job functions to reduce the resource consumption.

**----End**

# 2.9 gsql Client Reference

**gsql** is a database connection tool provided by GaussDB and runs in the command-line interface. You can use **gsql** to connect to the server and perform operations and maintenance. In addition to basic functions for performing operations on a database, **gsql** provides multiple advanced features. For details, see **Advanced Features**.

## 2.9.1 Overview

### Basic Features

- **Connect to a database**: By default, only remote connection to the database is supported.

  NOTE

  If **gsql** is used to connect to a database, the connection timeout period will be 5 minutes. If the database has not correctly set up a connection and authenticated the identity of the client within this period, **gsql** will time out and exit.

  To resolve this problem, see **2.9.6 Troubleshooting**.
- **Run SQL statements**: Interactively entered SQL statements and specified SQL statements in a file can be run.
- **Run meta-commands**: Meta-commands help the administrator view database object information, query cache information, format SQL output, and connect to a new database. For details about meta-commands, see **2.9.5 Meta-Command Reference**.

### Advanced Features

**Table 2-5** lists the advanced features of **gsql**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 2-5** Advanced features of **gsql**

| Feature Name | Description |
| --- | --- |
| Variable | **gsql** provides a variable feature that is similar to the **shell** command of Linux. The following **\set** meta-command of **gsql** can be used to set a variable:<br>**\set** *varname value*<br>To delete the variables set by the **\set** command, run the following command:<br>**\unset** *varname*<br>**NOTE**<br>• A variable is a simple name-value pair. The value can be any characters in any length.<br>• Variable names must consist of case-sensitive letters (including non-Latin letters), digits, and underscores (_).<br>• If the **\set** *varname* meta-command (without the second parameter) is used, the variable is set without a value specified.<br>• If the **\set** meta-command without parameters is used, values of all variables are displayed.<br>For details about variable examples and descriptions, see **Variables**. |
| SQL substitution | Common SQL statements can be set to variables using the variable feature of **gsql** to simplify operations.<br>For details about SQL substitution examples and descriptions, see **SQL substitution**. |
| Customized prompt | Prompts of **gsql** can be customized. Prompts can be modified by changing the reserved three variables of **gsql**: *PROMPT1*, *PROMPT2*, and *PROMPT3*.<br>These variables can be set to customized values or the values predefined by **gsql**. For details, see **Prompt**. |
| Historical client operation records | **gsql** can record historical client operations. This function is enabled by specifying the **-r** parameter when a client is connected. The number of historical records can be set using the **\set** command. For example, **\set HISTSIZE 50** indicates that the number of historical records is set to **50**. **\set HISTSIZE 0** indicates that the operation history is not recorded.<br>**NOTE**<br>• The default number of historical records is **32**. The maximum number of historical records is **500**. If interactively entered SQL commands contain Chinese characters, only the UTF-8 encoding environment is supported.<br>• For security purposes, the records containing character strings such as PASSWORD, IDENTIFIED, GS_ENCRYPT_AES128, GS_DECRYPT_AES128, GS_ENCRYPT, GS_DECRYPT, PG_CREATE_PHYSICAL_REPLICATION_SLOT_EXTERN, SECRET_ACCESS_KEY, SECRETKEY and CREATE_CREDENTIAL (case-insensitive) are considered as sensitive information and will not be recorded in historical information. This indicates that you cannot view these records in command output histories. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Variables

  To set a variable, run the **\set** meta-command of **gsql**. For example, to set variable *foo* to **bar**, run the following command:

  ```
  openGauss=# \set foo bar
  ```

  To reference the value of a variable, add a colon (:) before the variable. For example, to view the value of variable *foo*, run the following command:

  ```
  openGauss=# \echo :foo
  bar
  ```

  The variable reference method is suitable for regular SQL statements and meta-commands.

  **gsql** pre-defines some special variables and plans the values of these variables. To ensure compatibility with later versions, do not use these variables for other purposes. For details about special variables, see **Table 2-6**.

  NOTE

  - All the special variables consist of upper-case letters, digits, and underscores (_).
  - To view the default value of a special variable, run the **\echo :***varname* meta-command, for example, **\echo :***DBNAME*.

  **Table 2-6** Settings of special variables

| Variable | Setting Method | Description |
| --- | --- | --- |
| DBNAME | \set DBNAME *dbname* | Name of the connected database. This variable is set again when a database is connected. |
| ECHO | \set ECHO all \| queries | • If this variable is set to **all**, only the query information is displayed. This has the same effect as specifying the **-a** parameter when **gsql** is used to connect to a database.<br>• If this variable is set to **queries**, the command line and query information are displayed. This has the same effect as specifying the **-e** parameter when **gsql** is used to connect to a database. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Variable | Setting Method | Description |
| --- | --- | --- |
| ECHO_HIDDEN | \set ECHO_HIDDEN on \| off \| noexec | When a meta-command (such as **\dg**) is used to query database information, the value of this variable determines the query behavior.<br>● If this variable is set to **on**, the query statements that are called by the meta-command are displayed, and then the query result is displayed. This has the same effect as specifying the **-E** parameter when **gsql** is used to connect to a database.<br>● If this variable is set to **off**, only the query result is displayed.<br>● If this variable is set to **noexec**, only the query information is displayed, and the query is not run. |
| ENCODING | \set ENCODING *encoding* | Character set encoding of the current client. |
| FETCH_COUNT | \set FETCH_COUNT *variable* | ● If the value is an integer greater than **0**, for example, *n*, *n* lines will be selected from the result set to the cache and displayed on the screen when the **SELECT** statement is run.<br>● If this variable is not set or set to a value less than or equal to **0**, all results are selected at a time to the cache when the **SELECT** statement is run.<br>**NOTE**<br>A proper variable value helps reduce the memory usage. The recommended value range is from 100 to 1000. |
| HISTCONTROL | \set HISTCONTROL ignorespace \| ignoredups \| ignoreboth \| none | ● **ignorespace**: A line started with a space is not written to the historical record.<br>● **ignoredups**: A line that exists in the historical record is not written to the historical record.<br>● **ignoreboth**, **none**, or other values: All the lines read in interaction mode are saved in the historical record.<br>**NOTE**<br>**none** indicates that **HISTCONTROL** is not set. |
| HISTFILE | \set HISTFILE *filename* | Specifies the file for storing historical records. The default value is **~/.bash_history**. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Variable | Setting Method | Description |
| --- | --- | --- |
| HISTSIZE | \set HISTSIZE *size* | Specifies the number of commands to store in the command history. The default value is **500**. |
| HOST | \set HOST *hostname* | Specifies the name of a connected host. |
| IGNOREEOF | \set IGNOREEOF *variable* | • If this variable is set to a number, for example, **10**, the first nine EOF characters (generally **Ctrl**+**C**) entered in **gsql** are neglected and the **gsql** program exits when the tenth **Ctrl**+**C** is entered.<br>• If this variable is set to a non-numeric value, the default value is **10**.<br>• If this variable is deleted, **gsql** exits when an EOF is entered. |
| LASTOID | \set LASTOID *oid* | Specifies the last OID, which is the value returned by an **INSERT** or **lo_import** command. This variable is valid only before the output of the next SQL statement is displayed. |
| ON_ERROR_ROLLBACK | \set ON_ERROR_ROLLBACK on \| interactive \| off | • If the value is **on**, an error that may occur in a statement in a transaction block is ignored and the transaction continues.<br>• If the value is **interactive**, the error is ignored only in an interactive session.<br>• If the value is **off** (default value), the error triggers the rollback of the transaction block. In **on_error_rollback-on** mode, a **SAVEPOINT** is set before each statement of a transaction block, and an error triggers the rollback of the transaction block. |
| ON_ERROR_STOP | \set ON_ERROR_STOP on \| off | • **on**: specifies that the execution stops if an error occurs. In interactive mode, **gsql** returns the output of executed commands immediately.<br>• **off** (default value): specifies that an error, if occurring during the execution, is ignored, and the execution continues. |
| PORT | \set PORT *port* | Specifies the port number of a connected database. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Variable | Setting Method | Description |
| --- | --- | --- |
| USER | \set USER *username* | Specifies the database user you are currently connected as. |
| VERBOSITY | \set VERBOSITY terse \| default \| verbose | This variable can be set to **terse**, **default**, or **verbose** to control redundant lines of error reports.<br>• **terse**: Only critical and major error texts and text locations are returned (which is generally suitable for single-line error information).<br>• **default**: Critical and major error texts and text locations, error details, and error messages (possibly involving multiple lines) are all returned.<br>• **verbose**: All error information is returned. |

- SQL substitution

  **gsql**, like a parameter of a meta-command, provides a key feature that enables you to substitute a standard SQL statement for a **gsql** variable. **gsql** also provides a new alias or identifier for the variable. To replace the value of a variable using the SQL substitution method, add a colon (:) before the variable. For example:

```
openGauss=# \set foo 'HR.areaS'
openGauss=# select * from :foo;
 area_id |       area_name
---------+------------------------
       4 | Middle East and Africa
       3 | Asia
       1 | Europe
       2 | Americas
(4 rows)
```

  The above command queries the HR.areaS table.

  **NOTICE**

  The value of the variable is copied literally, so it can even contain unbalanced quotation marks or backslash commands. Therefore, the input content must be meaningful.

- Prompt

  The **gsql** prompt can be set using the three variables in **Table 2-7**. These variables consist of characters and special escape characters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 2-7** Prompt variables

| Variable | Description | Example |
| --- | --- | --- |
| PROMPT1 | Specifies the normal prompt used when **gsql** requests a new command.<br>The default value of *PROMPT1* is:<br>`%/%R%#` | *PROMPT1* can be used to change the prompt.<br>• Change the prompt to **[local]**:<br>`openGauss=> \set PROMPT1 %M`<br>`[local:/tmp/gaussdba_mppdb]`<br>• Change the prompt to **name**:<br>`openGauss=> \set PROMPT1 name`<br>`name`<br>• Change the prompt to **=**:<br>`openGauss=> \set PROMPT1 %R`<br>`=` |
| PROMPT2 | Specifies the prompt displayed when more input is expected because the command that is not terminated with a semicolon (;) or a quote (') is not closed. | *PROMPT2* can be used to display the prompt.<br>`openGauss=# \set PROMPT2 TEST`<br>`openGauss=# select * from HR.areaS TEST;`<br>` area_id \|  area_name`<br>`---------+--------------------`<br>`  1 \| Europe`<br>`  2 \| Americas`<br>`  4 \| Middle East and Africa`<br>`  3 \| Asia`<br>`(4 rows))` |
| PROMPT3 | Specifies the prompt displayed when the **COPY** statement (such as **COPY FROM STDIN**) is run and data input is expected. | *PROMPT3* can be used to display the **COPY** prompt.<br>`openGauss=# \set PROMPT3 '>>>>'`<br>`openGauss=# copy HR.areaS from STDIN;`<br>`Enter data to be copied followed by a newline.`<br>`End with a backslash and a period on a line by itself.`<br>`>>>>1 aa`<br>`>>>>2 bb`<br>`>>>>\.` |

The value of the selected prompt variable is printed literally. However, a value containing a percent sign (%) is replaced by the predefined contents depending on the character following the percent sign (%). For details about the defined substitutions, see **Table 2-8**.

**Table 2-8** Defined substitutions

| Symbol | Description |
| --- | --- |
| %M | Replaced with the full host name (with domain name). The full name is **[local]** if the connection is over a Unix domain socket, or **[local:/dir/name]** if the Unix domain socket is not at the compiled default location. |
| %m | Replaced with the host name truncated at the first dot. It is **[local]** if the connection is over a Unix domain socket. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Symbol | Description |
| --- | --- |
| %> | Replaced with the number of the port that the host is listening on. |
| %n | Replaced with the database session username. |
| %/ | Replaced with the name of the current database. |
| %~ | Similar to **%/**. However, the output is tilde (~) if the database is your default database. |
| %# | Uses **#** if the session user is the database administrator. Otherwise, uses **>**. |
| %R | • In *PROMPT1* normally **=**, but **^** if in single-line mode, or **!** if the session is disconnected from the database (which can happen if **\connect** fails).<br>• In *PROMPT2* %R is replaced with a hyphen (-), an asterisk (*), a single or double quotation mark, or a dollar sign ($), depending on whether **gsql** expects more input because the query is inside a /*...*/ comment or inside a quoted or dollar-escaped string. |
| %x | Replaced with the transaction status.<br>• An empty string when it is not in a transaction block<br>• An asterisk (*) when it is in a transaction block<br>• An exclamation mark (!) when it is in a failed transaction block<br>• A question mark (?) when the transaction status is indefinite (for example, because there is no connection). |
| %digits | Replaced with the character with the specified byte. |
| %:name | Replaced with the value of the *name* variable of **gsql**. |
| %command | Replaced with the command output, similar to substitution with the "^" symbol. |
| %[ . . . %] | Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. For example:<br>potgres=> \set PROMPT1 '%[%033[1;33;40m%]%n@%/%R%[%033[0m%]%#'<br>The output is a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Environment Variables

**Table 2-9** Environment variables related to **gsql**

| Name | Description |
| --- | --- |
| COLUMNS | If **\set columns** is set to **0**, this parameter controls the width of the wrapped format. This width determines whether to change the wide output mode into the vertical output mode if automatic expansion is enabled. |
| PAGER | If the query results do not fit on the screen, they are redirected through this command. You can use the **\pset** command to disable the pager. Typically, the **more** or **less** command is used for viewing the query result page by page. The default is platform-dependent.<br>**NOTE**<br>Display of the **less** command is affected by the *LC_CTYPE* environment variable. |
| PSQL_EDITOR | The **\e** and **\ef** commands use the editor specified by the environment variables. The variables are examined in the order listed. The default editor on Unix is vi. |
| EDITOR | |
| VISUAL | |
| PSQL_EDITOR_LINENUMBER_ARG | When the **\e** or **\ef** command is used with a line number parameter, this variable specifies the command-line parameter used to pass the starting line number to the editor. For editors, such as Emacs or vi, this is a plus sign. Include a space in the value of the variable if space is needed between the option name and the line number. For example:<br>`PSQL_EDITOR_LINENUMBER_ARG = '+'`<br>`PSQL_EDITOR_LINENUMBER_ARG='--line '`<br>A plus sign (+) is used by default on Unix. |
| PSQLRC | Specifies the location of the user's .gsqlrc file. |
| SHELL | Has the same effect as the **\!** command. |
| TMPDIR | Specifies the directory for storing temporary files. The default value is **/tmp**. |

# 2.9.2 How to Use gsql

## Prerequisites

The user using **gsql** must have the permission to access the database.

## Procedure

**Step 1** Use **gsql** to connect to a GaussDB instance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The **gsql** tool uses the **-d** parameter to specify the target database name, the **-U** parameter to specify the database username, the **-h** parameter to specify the host name, and the **-p** parameter to specify the port number.

NOTE

If the database name is not specified, the default database name generated during initialization will be used. If the database username is not specified, the current OS username will be used by default. If a variable does not belong to any parameter (such as **-d** and **-U**), and **-d** is not specified, the variable will be used as the database name. If **-d** is specified but **-U** is not specified, the variable will be used as the database username.

Example 2: Connect to the 8000 port of the remote postgres database as user **jack**.

```
gsql -h 10.180.123.163 -d postgres -U jack -p 8000
```

For details about the **gsql** parameters, see **2.9.4 Command Reference**.

**Step 2** Run a SQL statement.

The following takes creating database **human_staff** as an example:

```
CREATE DATABASE human_staff;
CREATE DATABASE
```

Ordinarily, input lines end when a command-terminating semicolon is reached. If the command is sent and executed without any error, the command output is displayed on the screen.

**Step 3** Execute gsql meta-commands.

The following takes all GaussDB databases and description information as an example:

```
openGauss=# \l
                             List of databases
     Name      |  Owner   | Encoding  | Collate | Ctype |   Access privileges
---------------+----------+-----------+---------+-------+-----------------------
 human_resource | root | SQL_ASCII | C       | C     |
 postgres       | root | SQL_ASCII | C       | C     |
 template0      | root | SQL_ASCII | C       | C     | =c/root          +
                |      |           |         |       | root=CTc/root
 template1      | root | SQL_ASCII | C       | C     | =c/root          +
                |      |           |         |       | root=CTc/root
 human_staff    | root | SQL_ASCII | C       | C     |
(5 rows)
```

For details about **gsql** meta-commands, see **2.9.5 Meta-Command Reference**.

**----End**

## Example

The example shows how to spread a command over several lines of input. Note the prompt change:

```
openGauss=# CREATE TABLE HR.areaS(
postgres(# area_ID   NUMBER,
openGauss(# area_NAME VARCHAR2(25)
openGauss-# )tablespace EXAMPLE;
CREATE TABLE
```

Query the table definition:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# \d HR.areaS
              Table "hr.areas"
  Column   |         Type          | Modifiers
-----------+-----------------------+-----------
 area_id   | numeric               | not null
 area_name | character varying(25) |
```

Insert four lines of data into **HR.areaS**.

```
openGauss=# INSERT INTO HR.areaS (area_ID, area_NAME) VALUES (1, 'Europe');
INSERT 0 1
openGauss=# INSERT INTO HR.areaS (area_ID, area_NAME) VALUES (2, 'Americas');
INSERT 0 1
openGauss=# INSERT INTO HR.areaS (area_ID, area_NAME) VALUES (3, 'Asia');
INSERT 0 1
openGauss=# INSERT INTO HR.areaS (area_ID, area_NAME) VALUES (4, 'Middle East and Africa');
INSERT 0 1
```

Change the prompt.

```
openGauss=# \set PROMPT1 '%n@%m %~%R%#'
```

Query the table:

```
openGauss=#SELECT * FROM HR.areaS;
 area_id |       area_name
---------+------------------------
       1 | Europe
       4 | Middle East and Africa
       2 | Americas
       3 | Asia
(4 rows)
```

Use the **\pset** command to display the table in different ways:

```
openGauss=#\pset border 2
Border style is 2.
openGauss=#SELECT * FROM HR.areaS;
+---------+------------------------+
| area_id |       area_name        |
+---------+------------------------+
|       1 | Europe                 |
|       2 | Americas               |
|       3 | Asia                   |
|       4 | Middle East and Africa |
+---------+------------------------+
(4 rows)
openGauss=#\pset border 0
Border style is 0.
openGauss=#SELECT * FROM HR.areaS;
area_id       area_name
------- ----------------------
      1 Europe
      2 Americas
      3 Asia
      4 Middle East and Africa
(4 rows)
```

Use the meta-command:

```
openGauss=#\a \t \x
Output format is unaligned.
Showing only tuples.
Expanded display is on.
openGauss=#SELECT * FROM HR.areaS;
area_id|2
area_name|Americas

area_id|1
area_name|Europe
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
area_id|4
area_name|Middle East and Africa

area_id|3
area_name|Asia
```

# 2.9.3 Obtaining Help Information

## Procedure

- When connecting to the database, run the following command to obtain the help information:
  ```
  gsql --help
  ```
  The following help information is displayed:
  ```
  ......
  Usage:
    gsql [OPTION]... [DBNAME [USERNAME]]

  General options:
    -c, --command=COMMAND    run only single command (SQL or internal) and exit
    -d, --dbname=DBNAME      database name to connect to (default: "omm")
    -f, --file=FILENAME      execute commands from file, then exit
  ......
  ```
- When connecting to the database, run the following command to obtain the help information:
  ```
  help
  ```
  The following help information is displayed:
  ```
  You are using gsql, the command-line interface to gaussdb.
  Type:  \copyright for distribution terms
         \h for help with SQL commands
         \? for help with gsql commands
         \g or terminate with semicolon to execute query
         \q to quit
  ```

## Examples

**Step 1** View the **gsql** help information. For details, see **Table 2-10**.

**Table 2-10 gsql** online help

| Description | Example |
| --- | --- |
| Query the copyright. | \copyright |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Description | Example |
| --- | --- |
| View help information about SQL statements supported by GaussDB. | View help information about SQL statements supported by GaussDB.<br>For example, view all SQL statements supported by GaussDB.<br>openGauss=# \h<br>Available help:<br>ABORT<br>ALTER AGGREGATE<br>ALTER APP WORKLOAD GROUP<br>... ...<br>For example, view parameters of the **CREATE DATABASE** command:<br>openGauss=# \help CREATE DATABASE<br>Command: CREATE DATABASE<br>Description: create a new database<br>Syntax:<br>CREATE DATABASE database_name<br>[ [ WITH ] {[ OWNER [=] user_name ]\|<br>[ TEMPLATE [=] template ]\|<br>[ ENCODING [=] encoding ]\|<br>[ LC_COLLATE [=] lc_collate ]\|<br>[ LC_CTYPE [=] lc_ctype ]\|<br>[ DBCOMPATIBILITY [=] compatibility_type ]\|<br>[ TABLESPACE [=] tablespace_name ]\|<br>[ CONNECTION LIMIT [=] connlimit ]}[...] ]; |
| View the help information about **gsql** commands. | For example, view commands supported by **gsql**.<br>openGauss=# \?<br>General<br>\copyright show openGauss usage and distribution terms<br>\g [FILE] or ; execute query (and send results to file or \|pipe)<br>\h(\help) [NAME] help on syntax of SQL commands, * for all commands<br>\q quit gsql<br>... ... |

**----End**

## 2.9.4 Command Reference

Table 2-11, Table 2-12, Table 2-13 and Table 2-14 list the **gsql** parameters.

**Table 2-11** Common parameters

| Parameter | Description | Value Range |
| --- | --- | --- |
| -c, --command=COMMAND | Specifies that **gsql** is to run a string command and then exit. | - |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Value Range |
| --- | --- | --- |
| -d, --dbname=DBNAME | Specifies the name of the database to connect to.<br>In addition, gsql allows you to use extended database names, that is, connection strings in the format of **'postgres[ql]://[user[:password]@][netloc][:port][, ...][/dbname][?param1=value1&...]'** or **'[key=value][...]'** as database names. gsql parses connection information from the connection strings and preferentially uses the information. | String |
| -f, --file=FILENAME | Specifies that files are used as the command source instead of interactively-entered commands. After the files are processed, **gsql** exits. If *FILENAME* is - (hyphen), then standard input is read. | An absolute path or relative path that meets the OS path naming convention |
| -l, --list | Lists all available databases and then exits. | - |
| -v, --set, --variable=NAME=VALUE | Sets **gsql** variable *NAME* to *VALUE*.<br>For details about variable examples and descriptions, see **Variables**. | - |
| -X, --no-gsqlrc | Does not read the startup file (neither the system-wide **gsqlrc** file nor the user's **~/.gsqlrc** file).<br>**NOTE**<br>The startup file is **~/.gsqlrc** by default or it can be specified by the environment variable *PSQLRC*. | - |
| -1 ("one"), --single-transaction | When **gsql** uses the **-f** parameter to execute a script, **START TRANSACTION**/**COMMIT** are added to the start and end of the script, respectively, so that the script is executed as one transaction. This ensures that the script is executed successfully. If the script cannot be executed, the script is invalid.<br>**NOTE**<br>If the script has used **START TRANSACTION**, **COMMIT**, or **ROLLBACK**, this parameter is invalid. | - |
| -?, --help | Displays help information about **gsql** command parameters, and exits. | - |
| -V, --version | Prints the **gsql** version information and exits. | - |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 2-12** Input and output parameters

| Parameter | Description | Value Range |
| --- | --- | --- |
| -a, --echo-all | Prints all input lines to standard output as they are read.<br>**CAUTION**<br>When this parameter is used in some SQL statements, the sensitive information, such as user password, may be disclosed. Use this parameter with caution. | - |
| -e, --echo-queries | Displays all SQL commands sent to the server to the standard output as well.<br>**CAUTION**<br>When this parameter is used in some SQL statements, the sensitive information, such as user password, may be disclosed. Use this parameter with caution. | - |
| -E, --echo-hidden | Echoes the actual queries generated by **\d** and other backslash commands. | - |
| -k, --with-key=KEY | Uses **gsql** to decrypt imported encrypted files.<br>**NOTICE**<br>• For key characters, such as the single quotation mark (') or double quotation mark (") in shell commands, Linux shell checks whether the input single quotation mark (') or double quotation mark (") matches. If no match is found, Linux shell does not enter the **gsql** program until input is complete.<br>• Stored procedures and functions cannot be decrypted and imported. | - |
| -L, --log-file=FILENAME | Writes normal output source and all query output into the **FILENAME** file.<br>**CAUTION**<br>• When this parameter is used in some SQL statements, the sensitive information, such as user password, may be disclosed. Use this parameter with caution.<br>• This parameter retains only the query result in the corresponding file, so that the result can be easily found and parsed by other invokers (for example, automatic O&M scripts). Logs about **gsql** operations are not retained. | An absolute path or relative path that meets the OS path naming convention |
| -m, --maintenance | Allows a cluster to be connected when a two-phase transaction is being restored.<br>**NOTE**<br>The parameter is for engineers only. When this parameter is used, **gsql** can be connected to the standby server to check data consistency between the primary and standby server. | - |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Value Range |
| --- | --- | --- |
| -n, --no-libedit | Closes command line editing. | - |
| -o, --output=FILENAME | Puts all query output into the **FILENAME** file. | An absolute path or relative path that meets the OS path naming convention |
| -q, --quiet | Indicates the quiet mode and no additional information will be printed. | By default, **gsql** displays various information. |
| -s, --single-step | Runs in single-step mode. It indicates that the user is prompted before each command is sent to the server. This option can be also used for canceling execution. Use this option to debug scripts.<br>**CAUTION**<br>When this parameter is used in some SQL statements, the sensitive information, such as user password, may be disclosed. Use this parameter with caution. | - |
| -S, --single-line | Runs in single-line mode where a line break terminates an SQL command, as a semicolon does. | - |
| -C, --enable-client-encryption | When **-C** is used to connect to a local or remote database, you can use this option to enable the encrypted database function. | - |

**Table 2-13** Output format parameters

| Parameter | Description | Value Range |
| --- | --- | --- |
| -A, --no-align | Switches to unaligned output mode. | The default output mode is aligned. |
| -F, --field-separator=STRING | Specifies the field separator. The default is the vertical bar (\|). | - |
| -H, --html | Turns on the HTML tabular output. | - |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Value Range |
| --- | --- | --- |
| -P, --pset=VAR[=ARG] | Specifies the print option in the **\pset** format in the command line.<br>**NOTE**<br>The equal sign (=), instead of the space, is used here to separate the name and value. For example, enter **-P format=latex** to set the output format to **LaTeX**. | - |
| -R, --record-separator=STRING | Sets the record separator. | - |
| -r | Enables the editing mode on the client. | This function is disabled by default. |
| -t, --tuples-only | Prints only tuples. | - |
| -T, --table-attr=TEXT | Specifies options to be placed within the HTML table tag.<br>Use this parameter with the **-H,--html** parameter to specify the output to the HTML format. | - |
| -x, --expanded | Turns on the expanded table formatting mode. | - |
| -z, --field-separator-zero | Sets the field separator in the unaligned output mode to be blank.<br>Use this parameter with the **-A, --no-align** parameter to switch to unaligned output mode. | - |
| -0, --record-separator-zero | Sets the record separator in the unaligned output mode to be blank.<br>Use this parameter with the **-A, --no-align** parameter to switch to unaligned output mode. | - |
| -2, --pipeline | Uses a pipe to transmit the password. This parameter cannot be used on devices and must be used together with the **-c** or **-f** parameter. | - |
| -g, | Prints all SQL statements from a file. | - |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 2-14** Connection parameters

| Parameter | Description | Value Range |
| --- | --- | --- |
| -h, --host=HOSTNAME | Specifies the host name of the machine on which the server is running or the directory for the Unix-domain socket. | If the host name is omitted, **gsql** connects to the server of the local host over the Unix domain socket or over TCP/IP to connect to local host without the Unix domain socket. |
| -p, --port=PORT | Specifies the port number of the database server.<br>You can modify the default port number using the **-p, --port=PORT** parameter. | The default value is **8000**. |
| -U, --username=USERNAME | Specifies the user that connects to the database.<br>**NOTE**<br>• If this parameter is specified, you also need to enter your password for identity authentication when connecting to the database. You can enter the password interactively or use the **-W** parameter to specify a password.<br>• To connect to a database, add an escape character before any dollar sign ($) in the username. | String. The default user is the current user that operates the system. |
| -W, --password=PASSWORD | Specifies a password when the **-U** parameter is used to connect to the local database or a remote database.<br>**NOTE**<br>• When you attempt to connect to the CN after you have logged in to the server where the CN resides, the trust connection is used by default, and this parameter does not need to be set.<br>• To connect to a database, add an escape character before any backslash (\) or back quote (`) in the password.<br>• If this parameter is not specified but database connection requires your password, you will be prompted to enter your password in interactive mode. The maximum length of the password is 999 bytes, which is restricted by the maximum value of the GUC parameter **password_max_length**. | String |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 2.9.5 Meta-Command Reference

This section describes meta-commands provided by **gsql** after the GaussDB database CLI tool is used to connect to a database. A **gsql** meta-command can be anything that you enter in **gsql** and begins with an unquoted backslash.

## Precautions

- The format of the **gsql** meta-command is a backslash (\) followed by a command verb, and then a parameter. The parameters are separated from the command verb and from each other by any number of whitespace characters.
- To include whitespace characters into an argument, you must quote them with a single straight quotation mark. To include a single straight quotation mark into such an argument, precede it by a backslash. Anything contained in single quotation marks is furthermore subject to C-like substitutions for \n (new line), \t (tab), \b (backspace), \r (carriage return), \f (form feed), \digits (octal), and \xdigits (hexadecimal).
- Within a parameter, text enclosed in double quotation marks ("") is taken as a command line input to the shell. The output of the command (with any trailing newline removed) is taken as the argument value.
- If an unquoted argument begins with a colon (:), the argument is taken as a **gsql** variable and the value of the variable is used as the argument value instead.
- Some commands take an SQL identifier (such as a table name) as a parameter. These parameters follow the SQL syntax rules: Unquoted letters are forced to lowercase, while double quotation marks ("") protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotation marks, paired double quotation marks reduce to a single double quotation mark in the result name. For example, **FOO"BAR"BAZ** is interpreted as **fooBARbaz**, and **"Aweird""name"** becomes **A weird"name**.
- Parsing for arguments stops when another unquoted backslash is found. This is taken as the beginning of a new meta-command. The special sequence \\ (two backslashes) marks the end of parameters and continues parsing SQL statements if any. In this way, SQL and **gsql** commands can be freely mixed in a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

## Meta-command

For details about meta-commands, see **Table 2-15**, **Table 2-16**, **Table 2-17**, **Table 2-18**, **Table 2-20**, **Table 2-22**, **Table 2-23**, **Table 2-24** and **Table 2-26**.

**NOTICE**

*FILE* mentioned in the following commands indicates a file path. This path can be an absolute path such as **/home/gauss/file.txt** or a relative path, such as **file.txt**. By default, a **file.txt** is created in the path where the user runs **gsql** commands.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 2-15** Common meta-commands

| Parameter | Description | Value Range |
| --- | --- | --- |
| \copyright | Displays version and copyright information about GaussDB. | - |
| \g [FILE] or ; | Performs a query operation and sends the result to a file or pipe. | - |
| \h(\help) [NAME] | Provides syntax help on the specified SQL statement. | If the name is not specified, then **gsql** will list all the commands for which syntax help is available. If the name is an asterisk (*), syntax help on all SQL statements is displayed. |
| \parallel [on [num]\|off] | Controls the parallel execution function.<br>• **on**: The switch is enabled and the maximum number of concurrently executed tasks is **num**.<br>• **off**: This switch is disabled.<br>**NOTE**<br>• Parallel execution is not allowed in a running transaction and a transaction is not allowed to be started during parallel execution.<br>• Parallel execution of **\d** meta-commands is not allowed.<br>• If **SELECT** statements are run concurrently, customers can accept the problem that the return results are displayed randomly but they cannot accept it if a core dump or process response failure occurs.<br>• **SET** statements are not allowed in concurrent tasks because they may cause unexpected results.<br>• Temporary tables cannot be created in parallel. If temporary tables are required, create them before parallel execution is enabled, and use them only in the parallel execution. Temporary tables cannot be created in parallel execution.<br>• When **\parallel** is executed, *num* independent gsql processes can be connected to the database server.<br>• The total duration of all **\parallel** tasks cannot exceed **session_timeout**. Otherwise, the connection may fail during concurrent execution. | The default value of *num* is **1024**.<br>**NOTICE**<br>• The maximum number of connections allowed by the server is determined based on **max_connection** and the number of current connections.<br>• Set the value of *num* based on the allowed number of connections. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Value Range |
| --- | --- | --- |
| \q | Exits the gsql program. This command is executed only when a script terminates in a script file. | - |

**Table 2-16** Query buffer meta-commands

| Parameter | Description |
| --- | --- |
| \e [FILE] [LINE] | Uses an external editor to edit the query buffer or file. |
| \ef [FUNCNAME [LINE]] | Edits the function definition using an external editor. If **LINE** is specified, the cursor will point to the specified line of the function body. |
| \p | Prints the current query buffer to the standard output. |
| \r | Resets or clears the query buffer. |
| \w FILE | Outputs the current query buffer to a file. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 2-17** Input/Output commands

| Parameter | Description |
| --- | --- |
| \copy { table [ ( column_list ) ] \| ( query ) } { from \| to } { filename \| stdin \| stdout \| pstdin \| pstdout } [ with ] [ binary ] [ oids ] [ delimiter [ as ] 'character' ] [ null [ as ] 'string' ] [ csv [ header ] [ quote [ as ] 'character' ] [ escape [ as ] 'character' ] [ force quote column_list \| * ] [ force not null column_list ] ] [parallel integer] | After logging in to the database on any **gsql** client, you can import and export data. This is an operation of running the **SQL COPY** command, but not the server that reads or writes data to a specified file. Instead, data is transferred between the server and the local file system. In this way, local user permissions instead of server permissions are required for file access, and the user permissions do not need to be initialized.<br>**NOTE**<br>• **\COPY** is applicable only to small-batch data import in a good format. It does not preprocess invalid characters and does not have the error tolerance capability. GDS or **COPY** is preferred for data import.<br>• \COPY specifies the number of clients to import data to implement parallel import of data files. Currently, the value ranges from 1 to 8.<br>• The parallel import using \COPY has the following constraints:<br>Parallel import of temporary tables is not supported. Parallel import within transactions is not supported. Parallel import of binary files is not supported. Parallel import of data encrypted using AES-128 is not supported. The COPY option contains EOL. In these cases, even if the parallel parameter is specified, a non-parallel process is performed. |
| \echo [STRING] | Writes character strings to the standard output. |
| \i FILE | Reads content from *FILE* and uses them as the input for a query. |
| \i+ FILE KEY | Runs commands in an encrypted file. |
| \ir FILE | Similar to **\i**, but resolves relative path names differently. |
| \ir+ FILE KEY | Similar to **\i+**, but resolves relative path names differently. |
| \o [FILE] | Saves all query results to a file. |
| \qecho [STRING] | Writes character strings to the query output flow. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

In Table 2-18, **S** indicates that the system object is displayed, and **+** indicates that additional object descriptions are displayed. **PATTERN** specifies the name of an object to be displayed.

**Table 2-18** Information display meta-commands

| Parameter | Description | Value Range | Example |
| --- | --- | --- | --- |
| \d[S+] | Lists all tables, views, and sequences of all schemas in the search_path. When objects with the same name exist in different schemas in **search_path**, only the object in the schema that ranks first in **search_path** is displayed. | - | Lists all tables, views, and sequences of all schemas in the search_path.<br>`openGauss=# \d` |
| \d[S+] NAME | Lists the structure of specified tables, views, and indexes. | - | Lists the structure of table **a**.<br>`openGauss=# \dtable+ a` |
| \d+ [PATTERN] | Lists all tables, views, and indexes. | If **PATTERN** is specified, only tables, views, and indexes whose names match **PATTERN** are displayed. | Lists all tables, views, and indexes whose names start with **f**.<br>`openGauss=# \d+ f*` |
| \da[S] [PATTERN] | Lists all available aggregate functions, together with the data type they perform operations on and the return value types. | If **PATTERN** is specified, only aggregate functions whose names match **PATTERN** are displayed. | Lists all available aggregate functions whose names start with **f**, together with their return value types and the data types.<br>`openGauss=# \da f*` |
| \db[+] [PATTERN] | Lists all available tablespaces. | If **PATTERN** is specified, only tablespaces whose names match **PATTERN** are displayed. | Lists all available tablespaces whose names start with **p**.<br>`openGauss=# \db p*` |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Value Range | Example |
| --- | --- | --- | --- |
| \dc[S+] [PATTERN] | Lists all available conversions between character-set encodings. | If **PATTERN** is specified, only conversions whose names match **PATTERN** are displayed. | Lists all available conversions between character-set encodings.<br>openGauss=# \dc * |
| \dC[+] [PATTERN] | Lists all available type conversions.<br>PATTERN must be the actual type name and cannot be an alias. | If **PATTERN** is specified, only conversions whose names match **PATTERN** are displayed. | Lists all type conversions whose pattern names start with **c**.<br>openGauss=# \dC c* |
| \dd[S] [PATTERN] | Lists descriptions about objects matching **PATTERN**. | If **PATTERN** is not specified, all visible objects are displayed. The objects include aggregations, functions, operators, types, relations (tables, views, indexes, sequences, and large objects), and rules. | Lists all visible objects.<br>openGauss=# \dd |
| \ddp [PATTERN] | Lists all default permissions. | If **PATTERN** is specified, only permissions whose names match **PATTERN** are displayed. | Lists all default permissions.<br>openGauss=# \ddp |
| \dD[S+] [PATTERN] | Lists all available domains. | If **PATTERN** is specified, only domains whose names match **PATTERN** are displayed. | Lists all available domains.<br>openGauss=# \dD |
| \ded[+] [PATTERN] | Lists all Data Source objects. | If **PATTERN** is specified, only objects whose names match **PATTERN** are displayed. | Lists all Data Source objects.<br>openGauss=# \ded |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Value Range | Example |
| --- | --- | --- | --- |
| \det[+] [PATTERN] | Lists all external tables. | If **PATTERN** is specified, only tables whose names match **PATTERN** are displayed. | Lists all external tables.<br>openGauss=# \det |
| \des[+] [PATTERN] | Lists all external servers. | If **PATTERN** is specified, only servers whose names match **PATTERN** are displayed. | Lists all external servers.<br>openGauss=# \des |
| \deu[+] [PATTERN] | Lists all user mappings. | If **PATTERN** is specified, only information whose name matches **PATTERN** is displayed. | Lists all user mappings.<br>openGauss=# \deu |
| \dew[+] [PATTERN] | Lists all encapsulated external data. | If **PATTERN** is specified, only data whose name matches **PATTERN** is displayed. | Lists all encapsulated external data.<br>openGauss=# \dew |
| \df[antw][S+] [PATTERN] | Lists all available functions, together with their parameters and return types. **a** indicates an aggregate function, **n** indicates a common function, **t** indicates a trigger, and **w** indicates a window function. | If **PATTERN** is specified, only functions whose names match **PATTERN** are displayed. | Lists all available functions, together with their parameters and return types.<br>openGauss=# \df |
| \dF[+] [PATTERN] | Lists all text search configuration information. | If **PATTERN** is specified, only configurations whose names match **PATTERN** are displayed. | Lists all text search configuration information.<br>openGauss=# \dF+ |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Value Range | Example |
| --- | --- | --- | --- |
| \dFd[+] [PATTERN] | Lists all text search dictionaries. | If **PATTERN** is specified, only dictionaries whose names match **PATTERN** are displayed. | Lists all text search dictionaries.<br>openGauss=# \dFd |
| \dFp[+] [PATTERN] | Lists all text search analyzers. | If **PATTERN** is specified, only analyzers whose names match **PATTERN** are displayed. | Lists all text search analyzers.<br>openGauss=# \dFp |
| \dFt[+] [PATTERN] | Lists all text search templates. | If **PATTERN** is specified, only templates whose names match **PATTERN** are displayed. | Lists all text search templates.<br>openGauss=# \dFt |
| \dg[+] [PATTERN] | Lists all database roles.<br>**NOTE**<br>Since the concepts of "users" and "groups" have been unified into "roles", this command is now equivalent to **\du**. Both commands are retained to ensure compatibility with earlier versions. | If **PATTERN** is specified, only roles whose names match **PATTERN** are displayed. | Lists all database roles whose names start with **j** and end with **e**.<br>openGauss=# \dg j?e |
| \dl | This is an alias for **\lo_list**, which shows a list of large objects. | - | Lists all large objects.<br>openGauss=# \dl |
| \dL[S+] [PATTERN] | Lists all available program languages. | If **PATTERN** is specified, only languages whose names match **PATTERN** are displayed. | Lists all available program languages.<br>openGauss=# \dL |
| \dm[S+] [PATTERN] | Lists materialized views. | If **PATTERN** is specified, only materialized views whose names match **PATTERN** are displayed. | Lists materialized views.<br>openGauss=# \dm |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Value Range | Example |
| --- | --- | --- | --- |
| \dn[S+] [PATTERN] | Lists all schemas (namespace). If **+** is added to the command, the permission and description of each schema are listed. | If **PATTERN** is specified, only schemas whose names match the pattern are shown. By default, only schemas you created are displayed. | Lists information about all schemas whose names start with **d**.<br>openGauss=# \dn+ d* |
| \do[S] [PATTERN] | Lists available operators with their operand and return types. | If **PATTERN** is specified, only operators whose names match **PATTERN** are displayed. By default, only the operators created by the user are listed. | Lists available operators with their operand and return types.<br>openGauss=# \do |
| \dO[S+] [PATTERN] | Lists collation rules. | If **PATTERN** is specified, only rules whose names match **PATTERN** are displayed. By default, only user-created rules are shown. | Lists collation rules.<br>openGauss=# \dO |
| \dp [PATTERN] | Lists tables, views, and related permissions.<br>The following result about **\dp** is displayed:<br>rolename=xxxx/yyyy --Assigns permissions to a role.<br>=xxxx/yyyy --Assigns permissions to public.<br>*xxxx* indicates the assigned permissions, and *yyyy* indicates the roles with the assigned permissions. For details about permission descriptions, see **Table 2-19**. | If **PATTERN** is specified, only tables and views whose names match the pattern are shown. | Lists tables, views, and related permissions.<br>openGauss=# \dp |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Value Range | Example |
| --- | --- | --- | --- |
| \drds [PATTERN1 [PATTERN2]] | Lists all parameters that have been modified. These settings can be for roles, for databases, or for both. **PATTERN1** and **PATTERN2** indicate a role pattern and a database pattern, respectively. | If **PATTERN** is specified, only collations rules whose names match **PATTERN** are displayed. If the default value is used or ***** is specified, all settings are listed. | Lists all modified configuration parameters of the **postgres** database.<br>`openGauss=# \drds * postgres` |
| \dT[S+] [PATTERN] | Lists all data types. | If **PATTERN** is specified, only types whose names match **PATTERN** are displayed. | Lists all data types.<br>`openGauss=# \dT` |
| \du[+] [PATTERN] | Lists all database roles.<br>**NOTE**<br>Since the concepts of "users" and "groups" have been unified into "roles", this command is now equivalent to **\dg**. Both commands are retained to ensure compatibility with earlier versions. | If **PATTERN** is specified, only roles whose names match **PATTERN** are displayed. | Lists all database roles.<br>`openGauss=# \du` |
| \dE[S+] [PATTERN]<br>\di[S+] [PATTERN]<br>\ds[S+] [PATTERN]<br>\dt[S+] [PATTERN]<br>\dv[S+] [PATTERN] | In this group of commands, the letters E, i, s, t, and v stand for foreign table, index, sequence, table, and view, respectively. You can specify any or a combination of these letters sequenced in any order to obtain an object list. For example, **\dit** lists all indexes and tables. If + is added to the end of a command name, the physical size and related description of each object are also listed. | If **PATTERN** is specified, only objects whose names match **PATTERN** are displayed. By default, only objects you created are displayed. You can specify **PATTERN** or **S** to view other system objects. | Lists all indexes and views.<br>`openGauss=# \div` |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Value Range | Example |
| --- | --- | --- | --- |
| \dx[+] [PATTERN] | Lists installed extensions. | If **PATTERN** is specified, only extensions whose names match **PATTERN** are displayed. | Lists installed extensions.<br>openGauss=# \dx |
| \l[+] | Lists the names, owners, character set encodings, and permissions of all the databases in the server. | - | List the names, owners, character set encodings, and permissions of all the databases in the server.<br>openGauss=# \l |
| \sf[+] FUNCNAME | Displays the definition of a function.<br>**NOTE**<br>If the function name contains parentheses, enclose the function name with double quotation marks and add the parameter type list following the double quotation marks. Also enclose the list with parentheses. | - | Assume a function **function_a** and a function **func()name**. This parameter will be as follows:<br>openGauss=# \sf function_a<br>openGauss=# \sf "func()name"(argtype1, argtype2) |
| \z [PATTERN] | Lists all tables, views, and sequences in the database and their access permissions. | If a pattern is given, it is a regular expression, and only matched tables, views, and sequences are shown. | Lists all tables, views, and sequences in the database and their access permissions.<br>openGauss=# \z |

**Table 2-19** Description of permissions

| Parameter | Description |
| --- | --- |
| r | **SELECT**: allows users to read data from specified tables and views. |
| w | **UPDATE**: allows users to update columns for specified tables. |
| a | **INSERT**: allows users to insert data to specified tables. |
| d | **DELETE**: allows users to delete data from specified tables. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| D | **TRUNCATE**: allows users to delete all data from specified tables. |
| x | **REFERENCES**: allows users to create foreign key constraints. |
| t | **TRIGGER**: allows users to create a trigger on specified tables. |
| X | **EXECUTE**: allows users to use specified functions and the operators that are realized by the functions. |
| U | **USAGE**:<br>● For procedural languages, allows users to specify a procedural language when creating a function.<br>● For schemas, allows users to access objects included in specified schemas.<br>● For sequences, allows users to use the nextval function. |
| C | **CREATE**:<br>● For databases, allows new schemas to be created within the database.<br>● For schemas, allows users to create objects in a schema.<br>● For tablespaces, allows users to create tables in a tablespace and set the tablespace to default one when creating databases and schemas. |
| c | **CONNECT**: allows users to connect to specified databases. |
| T | **TEMPORARY**: allows users to create temporary tables. |
| A | **ALTER**: allows users to modify the attributes of a specified object. |
| P | **DROP**: allows users to delete specified objects. |
| m | **COMMENT**: allows users to define or modify comments of a specified object. |
| i | **INDEX**: allows users to create indexes on specified tables. |
| v | **VACUUM**: allows users to perform ANALYZE and VACUUM operations on specified tables. |
| * | Authorization options for preceding permissions. |

**Table 2-20** Formatting meta-commands

| Parameter | Description |
| --- | --- |
| \a | Switches between aligned and unaligned table output formats. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| \C [STRING] | Sets the title of any table being printed as the result of a query or unsets any such title. |
| \f [STRING] | Sets the field separator for unaligned query outputs. |
| \H | • If the text format schema is used, switches to the HTML format.<br>• If the HTML format schema is used, switches to the text format. |
| \pset NAME [VALUE] | Sets options affecting the output of query result tables. For details about the value of **NAME**, see **Table 2-21**. |
| \t [on\|off] | Switches the display of output name information and row count footer. |
| \T [STRING] | Specifies attributes to be placed within the table tag in HTML output format. If this parameter is empty, no attribute is specified. |
| \x [on\|off\|auto] | Switches expanded table formatting mode. |

**Table 2-21** Adjustable printing options

| Option | Description | Value Range |
| --- | --- | --- |
| border | The value must be a number. In general, the larger the number, the more borders and lines the tables will have, but this depends on the particular format. | • The value is an integer greater than 0 in HTML format.<br>• The value range in other formats is as follows:<br>– 0: no border<br>– 1: internal dividing line<br>– 2: table frame |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Option | Description | Value Range |
| --- | --- | --- |
| expanded (or x) | Switches between regular and expanded formats. | • When the expanded format is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data does not fit on the screen in the normal "horizontal" mode.<br>• Use the expanded format when the query output format is wider than the screen in regular format. The regular format is effective only in the aligned and wrapped formats. |
| fieldsep | Specifies the field separator to be used in unaligned output mode. In this way, you can create tab- or comma-separated output required by other programs. To set a tab as field separator, type **\pset fieldsep '\t'**. The default field separator is a vertical bar ('\|'). | - |
| fieldsep_zero | Sets the field separator to use in unaligned output format to a zero byte. | - |
| footer | Switches the display of the default footer. | - |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Option | Description | Value Range |
| --- | --- | --- |
| format | Selects the output format. Unique abbreviations are allowed (this indicates that one letter is enough). | Value range:<br>• **unaligned**: Write all columns of a row on one line, separated by the currently active column separator.<br>• **aligned**: This format is standard and human-readable.<br>• **wrapped**: This format is similar to **aligned**, but includes the packaging cross-line width data value to suit the width of the target field output.<br>• **html**: This format outputs tables to the markup language for a document. The output is not a complete document.<br>• **latex**: This format outputs tables to the markup language for a document. The output is not a complete document.<br>• **troff-ms:** This format outputs tables to the markup language for a document. The output is not a complete document. |
| null | Sets a character string to be printed in place of a null value. | The default is to print nothing, which can be easily mistaken for an empty string. |
| numericlocale | Switches the display of a locale-aware character to separate groups of digits to the left of the decimal marker. | • **on**: The specified separator is displayed.<br>• **off**: The specified separator is not displayed<br>If this parameter is ignored, the default separator is displayed. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Option | Description | Value Range |
| --- | --- | --- |
| pager | Controls the use of a pager for query and **gsql** help outputs. If the **PAGER** environment variable is set, the output is redirected to the specified program. Otherwise, the platform-dependent default value is used. | • **on**: The pager is used for terminal output that does not fit the screen.<br>• **off**: The pager is not used.<br>• **always**: The pager is used for all terminal output regardless of whether it fits the screen. |
| recordsep | Specifies the record separator to use in unaligned output mode. | - |
| recordsep_zero | Sets the record separator to use in unaligned output format to a zero byte. | - |
| tableattr (or T) | Specifies attributes to be placed inside the HTML table tag in HTML output format (such as cellpadding or bgcolor). Note that you do not need to specify **border** here because it has been used by **\pset border**. If no value is given, the table attributes do not need to be set. | - |
| title | Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no value is given, the title does not need to be set. | - |
| tuples_only (or t) | Enables or disables the tuples-only mode. Full display may show extra information, such as column headers, titles, and various footers. In tuples_only mode, only the table data is displayed. | - |
| feedback | Specifies whether to output the number of result lines. | - |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 2-22** Connection meta-commands

| Parameter | Description | Value Range |
| --- | --- | --- |
| \c[onnect] [DBNAME\|- USER\|- HOST\|- PORT\|-] | Connects to a new database. (The current database is postgres.) If a database name contains more than 63 bytes, only the first 63 bytes are valid and are used for connection. However, the database name displayed in the command line of **gsql** is still the name before the truncation.<br>**NOTE**<br>If the database login user is changed during reconnection, you need to enter the password of the new user. The maximum length of the password is 999 bytes, which is restricted by the maximum value of the GUC parameter **password_max_length**. | - |
| \encoding [ENCODING] | Sets the client character set encoding. | Without an argument, this command shows the current encoding. |
| \conninfo | Prints information about the current connected database. | - |

**Table 2-23** OS meta-commands

| Parameter | Description | Value Range |
| --- | --- | --- |
| \cd [DIR] | Changes the current working directory. | An absolute path or relative path that meets the OS path naming convention |
| \setenv NAME [VALUE] | Sets the **NAME** environment variable to **VALUE**. If **VALUE** is not provided, do not set the environment variable. | - |
| \timing [on\|off] | Displays how long each SQL statement takes, in milliseconds. | • **on**: specifies that the display is enabled.<br>• **off**: indicates that the display is disabled. |
| \! [COMMAND] | Escapes to a separate Unix shell or runs a Unix command. | - |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 2-24** Variable meta-commands

| Parameter | Description |
| --- | --- |
| \prompt [TEXT] NAME | Prompts the user to use texts to specify a variable name. |
| \set [NAME [VALUE]] | Sets the *NAME* internal variable to **VALUE**. If more than one value is provided, *NAME* is set to the concatenation of all of them. If no second argument is given, the variable is just set with no value.<br>Some common variables are processed differently in **gsql** and they are combinations of uppercase letters, numbers and underscores. **Table 2-25** describes a list of variables that are processed in a way different from other variables. |
| \unset NAME | Deletes the variable name of **gsql**. |

**Table 2-25** Common **\set** commands

| Command | Command Description | Value Range |
| --- | --- | --- |
| \set VERBOSITY value | This variable can be set to **default**, **verbose**, or **terse** to control redundant lines of error reports. | Value range: **default**, **verbose**, **terse** |
| \set ON_ERROR_STOP value | If this variable is set, the script execution stops immediately. If this script is invoked from another script, that script will be stopped immediately as well. If the primary script is invoked using the **-f** option rather than from one **gsql** session, **gsql** will return error code **3**, indicating the difference between the current error and critical errors. (The error code for critical errors is **1**.) | Value range: **on/off**, **true/false**, **yes/no**, and **1/0** |

**Table 2-26** Large object meta-commands

| Parameter | Description |
| --- | --- |
| \lo_list | Shows a list of all GaussDB large objects stored in the database, along with the comments provided for them. |

## PATTERN

The various **\d** commands accept a **PATTERN** parameter to specify the object name to be displayed. In the simplest case, PATTERN is the exact name of the object. Characters in **PATTERN** are usually converted to lowercase (as in SQL

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

names), for example, **\dt FOO** will display a table named **foo**. As in SQL names, placing double quotation marks (") around a pattern prevents them being folded to lower case. If you need to include a double quotation mark (") in a pattern, write it as a pair of double quotation marks ("") within a double-quote sequence, which is in accordance with the rules for SQL quoted identifiers. For example, **\dt "FOO""BAR"** will be displayed as a table named **FOO"BAR** instead of **foo"bar**. You cannot put double quotation marks around just part of a pattern, which is different from the normal rules for SQL names. For example, **\dt FOO"FOO"BAR** will be displayed as a table named **fooFOObar** if just part of a pattern is quoted.

Whenever the **PATTERN** parameter is omitted completely, the **\d** commands display all objects that are visible in the current schema search path, which is equivalent to using an asterisk (*) as the pattern. An object is regarded to be visible if it can be referenced by name without explicit schema qualification. To see all objects in the database regardless of their visibility, use a dot within double quotation marks (*.*) as the pattern.

Within a pattern, the asterisk (*) matches any sequence of characters (including no characters) and a question mark (?) matches any single character. This notation is comparable to Unix shell file name patterns. For example, **\dt int*** displays tables whose names start with **int**. But within double quotation marks, the asterisk (*) and the question mark (?) lose these special meanings and are just matched literally.

A pattern that contains a dot (.) is interpreted as a schema name pattern followed by an object name pattern. For example, **\dt foo*.*bar*** displays all tables (whose names include **bar**) in schemas starting with **foo**. If no dot appears, then the pattern matches only visible objects in the current schema search path. Likewise, the dot within double quotation marks loses its special meaning and becomes an ordinary character.

Senior users can use regular-expression notations, such as character classes. For example [0-9] can be used to match any digit. All regular-expression special characters work as specified in POSIX. The following characters are excluded:

- A dot (.) is used as a separator.
- An asterisk (*) is translated into an asterisk prefixed with a dot (.*), which is a regular-expression marking.
- A question mark (?) is translated into a dot (.).
- A dollar sign ($) is matched literally.

You can write ?, (*R*+|), (*R*|), and *R* to the following pattern characters: ., *R**, and *R*?. The dollar sign ($) does not need to be used as a regular expression character because **PATTERN** must match the entire name instead of being interpreted as a regular expression (in other words, $ is automatically appended to **PATTERN**). If you do not expect a pattern to be anchored, write an asterisk (*) at its beginning or end. All regular-expression special characters within double quotation marks lose their special meanings and are matched literally. Regular-expression special characters in operator name patterns (such as the **\do** parameter) are also matched literally.

# 2.9.6 Troubleshooting

## Low Connection Performance

- **log_hostname** is enabled, but DNS is incorrect.

  Connect to the database, and run **show log_hostname** to check whether **log_hostname** is enabled in the database.

  If it is enabled, the database kernel will use DNS to check the name of the host where the client is deployed. If the database of the host where the CN resides is configured with an incorrect or unreachable DNS server, the database connection will take a long time to set up.

- The database kernel slowly runs the initialization statement.

  Problems are difficult to locate in this scenario. Try using the **strace** Linux trace command.

  ```
  strace gsql -U MyUserName -d postgres -h 127.0.0.1 -p 23508 -r -c '\q'
  Password for MyUserName:
  ```

  The database connection process will be printed on the screen. If the following statement takes a long time to run:

  ```
  sendto(3, "Q\0\0\0\25SELECT VERSION()\0", 22, MSG_NOSIGNAL, NULL, 0) = 22
  poll([{fd=3, events=POLLIN|POLLERR}], 1, -1) = 1 ([{fd=3, revents=POLLIN}])
  ```

  It indicates that the **SELECT VERSION()** statement was run slowly.

  After the database is connected, you can run the **explain performance select version()** statement to find the reason why the initialization statement was run slowly.

  An uncommon scenario is that the disk of the machine where the database CN resides is full or faulty, affecting queries and leading to user authentication failures. As a result, the connection process is suspended. To solve this problem, contact customer service to clear the data disk of the database CN.

- TCP connection is set up slowly.

  Adapt the steps of troubleshooting slow initialization statement execution. Use **strace**. If the following statement is run slowly:

  ```
  connect(3, {sa_family=AF_FILE, path="/home/test/tmp/gaussdb_llt1/.s.PGSQL.61052"}, 110) = 0
  ```

  Or,

  ```
  connect(3, {sa_family=AF_INET, sin_port=htons(61052), sin_addr=inet_addr("127.0.0.1")}, 16) = -1
  EINPROGRESS (Operation now in progress)
  ```

  It indicates that the physical connection between the client and the database is set up slowly. In this case, check whether the network is unstable or has high throughput.

## Problems in Setting Up Connections

- gsql: could not connect to server: No route to host

  This problem occurs generally because an unreachable IP address or port number was specified. Check whether the values of **-h** and **-p** parameters are correct.

- gsql: FATAL: Invalid username/password,login denied.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

This problem occurs generally because an incorrect username or password was entered. Contact the database administrator to check whether the username and password are correct.

- The "libpq.so" loaded mismatch the version of gsql, please check it.

  This problem occurs because the version of **libpq.so** used in the environment does not match that of **gsql**. Run the **ldd gsql** command to check the version of the loaded **libpq.so**, and then load correct **libpq.so** by modifying the environment variable **LD_LIBRARY_PATH**.

- gsql: symbol lookup error: xxx/gsql: undefined symbol: libpqVersionString

  This problem occurs because the version of **libpq.so** used in the environment does not match that of **gsql** (or the PostgreSQL **libpq.so** exists in the environment). Run the **ldd gsql** command to check the version of the loaded **libpq.so**, and then load correct **libpq.so** by modifying the environment variable **LD_LIBRARY_PATH**.

- gsql: connect to server failed: Connection timed out

  Is the server running on host "xx.xxx.xxx.xxx" and accepting TCP/IP connections on port xxxx?

  This problem is caused by network connection faults. Check the network connection between the client and the database server. If you cannot ping from the client to the database server, the network connection is abnormal. Contact network management personnel for troubleshooting.

  ```
  ping -c 4 10.10.10.1
  PING 10.10.10.1 (10.10.10.1) 56(84) bytes of data.
  From 10.10.10.1: icmp_seq=2 Destination Host Unreachable
  From 10.10.10.1 icmp_seq=2 Destination Host Unreachable
  From 10.10.10.1 icmp_seq=3 Destination Host Unreachable
  From 10.10.10.1 icmp_seq=4 Destination Host Unreachable
  --- 10.10.10.1 ping statistics ---
  4 packets transmitted, 0 received, +4 errors, 100% packet loss, time 2999ms
  ```

- gsql: FATAL: permission denied for database "postgres"

  DETAIL: User does not have CONNECT privilege.

  This problem occurs because the user does not have the permission to access the database. To solve this problem, perform the following steps:

  a. Connect to the database as the database administrator.
  b. Grant the user with the permission to access the database.

     GRANT CONNECT ON DATABASE postgres TO user1;

     **NOTE**

     Actually, some common misoperations may also cause a database connection failure, for example, entering an incorrect database name, username, or password. In this case, the client tool will display the corresponding error messages.

- gsql: FATAL: sorry, too many clients already, active/non-active: 197/3.

  This problem occurs because the number of system connections exceeds the allowed maximum. Contact the DBA database administrator to release unnecessary sessions.

  You can check the number of connections as described in **Table 2-27**.

  You can view the session status in the **PG_STAT_ACTIVITY** view. To release unnecessary sessions, use the **pg_terminate_backend** function.

  ```
  select datid,pid,state from pg_stat_activity;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 datid |       pid       | state
-------+-----------------+--------
 13205 | 139834762094352 | active
 13205 | 139834759993104 | idle
(2 rows)
```

The value of **pid** is the thread ID of the session. Terminate the session using its thread ID.

```
SELECT PG_TERMINATE_BACKEND(139834759993104);
```

If a command output similar to the following is displayed, the session is successfully terminated.

```
PG_TERMINATE_BACKEND
----------------------
 t
(1 row)
```

**Table 2-27** Viewing the number of session connections

| Description | Command |
| --- | --- |
| View the maximum number of sessions connected to a specific user. | Run the following command to view the upper limit of the number of **USER1**'s session connections. **-1** indicates that no upper limit is set for the number of **USER1**'s session connections.<br>`SELECT ROLNAME,ROLCONNLIMIT FROM PG_ROLES WHERE ROLNAME='user1';`<br>`rolname \| rolconnlimit`<br>`---------+--------------`<br>`user1 \| -1`<br>`(1 row)` |
| View the number of session connections that have been used by a specified user. | Run the following command to view the number of session connections that have been used by **USER1**. **1** indicates the number of session connections that have been used by **USER1**.<br>`SELECT COUNT(*) FROM dv_sessions WHERE USERNAME='user1';`<br>`count`<br>`-------`<br>`1`<br>`(1 row)` |
| View the maximum number of sessions connected to a specific database. | Run the following command to view the upper limit of the number of **postgres**'s session connections. **-1** indicates that no upper limit is set for the number of **postgres**'s session connections.<br>`SELECT DATNAME,DATCONNLIMIT FROM PG_DATABASE WHERE DATNAME='postgres';`<br>`datname \| datconnlimit`<br>`----------+--------------`<br>`postgres \| -1`<br>`(1 row)` |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Description | Command |
| --- | --- |
| View the number of session connections that have been used by a specific database. | Run the following command to view the number of session connections that have been used by **postgres**. **1** indicates the number of session connections that have been used by **postgres**.<br>SELECT COUNT(*) FROM PG_STAT_ACTIVITY WHERE DATNAME='postgres';<br> count<br>-------<br> 1<br>(1 row) |
| View the number of session connections that have been used by all users. | Run the following command to view the number of session connections that have been used by all users:<br>SELECT COUNT(*) FROM dv_sessions;<br><br> count<br>-------<br> 10<br>(1 row) |

- gsql: wait xxx.xxx.xxx.xxx:xxxx timeout expired

  When **gsql** initiates a connection request to the database, a 5-minute timeout period is used. If the database cannot correctly authenticate the client request and client identity within this period, **gsql** will exit the connection process for the current session, and will report the above error.

  Generally, this problem is caused by the incorrect host and port (that is, the *xxx* part in the error information) specified by the **-h** and **-p** parameters. As a result, the communication fails. Occasionally, this problem is caused by network faults. To resolve this problem, check whether the host name and port number of the database are correct.

## Other Faults

- There is a core dump or abnormal exit due to the bus error.

  Generally, this problem is caused by changes in loading the shared dynamic library (.so file in Linux) during process running. Alternatively, if the process binary file changes, the execution code for the OS to load machines or the entry for loading a dependent library will change accordingly. In this case, the OS kills the process for protection purposes, generating a core dump file.

  To resolve this problem, try again. In addition, do not run service programs in a cluster during O&M operations, such as an upgrade, preventing such a problem caused by file replacement during the upgrade.

  **NOTE**

  A possible stack of the core dump file contains dl_main and its function calling. The file is used by the OS to initialize a process and load the shared dynamic library. If the process has been initialized but the shared dynamic library has not been loaded, the process cannot be considered completely started.

# 3 Development and Design Proposal

## 3.1 Overview

This chapter describes the design specifications for database modeling and application development. Modeling compliant with these specifications fits the distributed processing architecture of GaussDB and provides efficient SQL code.

The meaning of "Proposal" and "Notice" in this chapter is as follows:

- **Proposal**: Design rules. Services compliant with the rules can run efficiently, and those violating the rules may have low performance or logic errors.
- **Notice**: Details requiring attention during service development. This term identifies SQL behavior that complies with SQL standards but users may have misconceptions about, and default behavior that users may be unaware of in a program.

## 3.2 Database Object Naming Conventions

The name of a database object must meet the following requirements: The name of a non-time series table ranges from 1 to 63 bytes and that of a time series table ranges from 1 to 53 characters. The name must start with a letter or underscore (_), and can contain letters, digits, underscores (_), dollar signs ($), and number signs (#).

- [Proposal] Do not use reserved or non-reserved keywords to name database objects.

  NOTE

  To query the keywords of GaussDB, run **select * from pg_get_keywords()** or refer to **12.2 Keywords**.

- [Proposal] Do not use a string enclosed in double quotation marks ("") to define the database object name, unless you need to specify its capitalization. Case sensitivity of database object names makes problem location difficult.
- [Proposal] Use the same naming format for database objects.
  - In a system undergoing incremental development or service migration, you are advised to comply with its historical naming conventions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

  - You are advised to use multiple words separated with underscores (_).
  - You are advised to use intelligible names and common acronyms or abbreviations for database objects. Acronyms or abbreviations that are generally understood are recommended. For example, you can use English words or Chinese pinyin indicating actual business terms. The naming format should be consistent within a cluster.
  - A variable name must be descriptive and meaningful. It must have a prefix indicating its type.
- [Proposal] The name of a table object should indicate its main characteristics, for example, whether it is an ordinary, temporary, or unlogged table.
  - An ordinary table name should indicate the business relevant to a dataset.
  - Temporary tables are named in the format of **tmp**_*Suffix*.
  - Unlogged tables are named in the format of **ul**_*Suffix*.
  - Foreign tables are named in the format of **f**_*Suffix*.
  - Do not create database objects whose names start with **redis**_.
  - Do not create database objects whose names start with **mlog**_ or **matviewmap**_.
- [Proposal] The name of a non-time series table object shall not exceed 63 bytes. If the length of a table name exceeds this value, the kernel truncates the table name. As a result, the actual name is inconsistent with the configured value. In addition, characters may be truncated in different character sets and unexpected characters may appear.

# 3.3 Database Object Design

## 3.3.1 Database and Schema Design

In GaussDB, services can be isolated by databases and schemas. Databases share little resources and cannot directly access each other. Connections to and permissions on them are also isolated. Schemas share more resources than databases do. User permissions on schemas and subordinate objects can be controlled using the **GRANT** and **REVOKE** syntax.

- You are advised to use schemas to isolate services for convenience and resource sharing.
- It is recommended that system administrators create schemas and databases and then assign required permissions to users.

### Database Design

- [Rule] Create databases as required by your business. Do not use the default **postgres** database of a cluster.
- [Proposal] Create up to three customized databases in a cluster.
- [Proposal] To make your database compatible with most characters, you are advised to use the UTF-8 encoding when creating a database.
- [Notice] When you create a database, exercise caution when you set **ENCODING** and **DBCOMPATIBILITY** configuration items. GaussDB supports

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

the Teradata, Oracle, MySQL, and PostgreSQL compatibility modes which are partially compatible with the Teradata syntax, Oracle syntax, MySQL syntax, and PostgreSQL syntax, respectively. The syntax behavior varies according to the compatibility mode. By default, the MySQL compatibility mode is used.

- [Notice] By default, a database owner has all permissions for all objects in the database, including the deletion permission. Exercise caution when using the deletion permission.

### Schema Design

- [Notice] To let a user access an object in a schema, assign the usage permission and the permissions for the object to the user, unless the user has the **sysadmin** permission or is the schema owner.
- [Notice] To let a user create an object in the schema, grant the create permission for the schema to the user.
- [Notice] By default, a schema owner has all permissions for all objects in the schema, including the deletion permission. Exercise caution when using the deletion permission.

## 3.3.2 Table Design

GaussDB uses a distributed architecture. Data is distributed on DNs. Generally, well-designed table must comply with the following rules:

- [Notice] Evenly distribute data on each DN to prevent data skew. If most data is stored on several DNs, the effective capacity of a cluster decreases. Select a proper distribution key to avoid data skew.
- [Notice] Evenly scan each DN when querying tables. Otherwise, DNs most frequently scanned will become the performance bottleneck. For example, when you use equivalent filter conditions on a fact table, the nodes are not evenly scanned.
- [Notice] Reduce the amount of data to be scanned. You can use the pruning mechanism of a partitioned table.
- [Notice] Minimize random I/O. By clustering or local clustering, you can sequentially store hot data, converting random I/O to sequential I/O to reduce the cost of I/O scanning.
- [Notice] Try to avoid data shuffling. To shuffle data is to physically transfer it from one node to another. This unnecessarily occupies many network resources. To reduce network pressure, locally process data, and to improve cluster performance and concurrency, you can minimize data shuffling by using proper association and grouping conditions.

### Selecting a Storage Model

[Proposal] Selecting a storage model is the first step in defining a table. The storage model mainly depends on the customer's service type. For details, see **Table 3-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 3-1** Table storage models and scenarios

| Storage Model | Application Scenario |
| --- | --- |
| Row storage | • Point queries (simple index-based queries that only return a few records)<br>• Scenarios requiring frequent addition, deletion, and modification |
| Column storage | • Statistical analysis queries (requiring a large number of association and grouping operations)<br>• Ad hoc queries (using uncertain query conditions and unable to utilize indexes to scan row-store tables) |

## Selecting a Distribution Mode

[Proposal] Comply with the following rules to distribute table data.

**Table 3-2** Table distribution modes and scenarios

| Distribution Mode | Description | Application Scenario |
| --- | --- | --- |
| Hash | Table data is distributed on all DNs in a cluster by hash. | Fact tables containing a large amount of data |
| Replication | Full data in a table is stored on every DN in the cluster. | Dimension tables and fact tables containing a small amount of data |
| Range | Table data is mapped to specified columns based on the range and distributed to the corresponding DNs. | Users need to customize distribution rules. |
| List | Table data is mapped to specified columns based on specific values and distributed to corresponding DNs. | Users need to customize distribution rules. |

NOTE

- When hash, range, or list distribution is specified, the primary key and unique index to be created must contain distribution columns.
- When hash, range, or list distribution is specified for a referenced table, the foreign key of the referencing table must contain distribution columns.

The example of defining a distribution table is as follows:

```
-- Define a table with each row stored in all DNs.
CREATE TABLE warehouse_d1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
(
    W_WAREHOUSE_SK            INTEGER               NOT NULL,
    W_WAREHOUSE_ID            CHAR(16)              NOT NULL,
    W_WAREHOUSE_NAME          VARCHAR(20)                   ,
    W_WAREHOUSE_SQ_FT         INTEGER                       ,
    W_STREET_NUMBER           CHAR(10)                      ,
    W_STREET_NAME             VARCHAR(60)                   ,
    W_STREET_TYPE             CHAR(15)                      ,
    W_SUITE_NUMBER            CHAR(10)                      ,
    W_CITY                    VARCHAR(60)                   ,
    W_COUNTY                  VARCHAR(30)                   ,
    W_STATE                   CHAR(2)                       ,
    W_ZIP                     CHAR(10)                      ,
    W_COUNTRY                 VARCHAR(20)                   ,
    W_GMT_OFFSET              DECIMAL(5,2)
)DISTRIBUTE BY REPLICATION;

-- Define a hash table.
CREATE TABLE warehouse_d2
(
    W_WAREHOUSE_SK            INTEGER               NOT NULL,
    W_WAREHOUSE_ID            CHAR(16)              NOT NULL,
    W_WAREHOUSE_NAME          VARCHAR(20)                   ,
    W_WAREHOUSE_SQ_FT         INTEGER                       ,
    W_STREET_NUMBER           CHAR(10)                      ,
    W_STREET_NAME             VARCHAR(60)                   ,
    W_STREET_TYPE             CHAR(15)                      ,
    W_SUITE_NUMBER            CHAR(10)                      ,
    W_CITY                    VARCHAR(60)                   ,
    W_COUNTY                  VARCHAR(30)                   ,
    W_STATE                   CHAR(2)                       ,
    W_ZIP                     CHAR(10)                      ,
    W_COUNTRY                 VARCHAR(20)                   ,
    W_GMT_OFFSET              DECIMAL(5,2),
    CONSTRAINT W_CONSTR_KEY3 UNIQUE(W_WAREHOUSE_SK)
)DISTRIBUTE BY HASH(W_WAREHOUSE_SK);

-- Define a table using RANGE distribution.
CREATE TABLE warehouse_d3
(
W_WAREHOUSE_SK            INTEGER               NOT NULL,
W_WAREHOUSE_ID            CHAR(16)              NOT NULL,
W_WAREHOUSE_NAME          VARCHAR(20)                   ,
W_WAREHOUSE_SQ_FT         INTEGER                       ,
W_STREET_NUMBER           CHAR(10)                      ,
W_STREET_NAME             VARCHAR(60)                   ,
W_STREET_TYPE             CHAR(15)                      ,
W_SUITE_NUMBER            CHAR(10)                      ,
W_CITY                    VARCHAR(60)                   ,
W_COUNTY                  VARCHAR(30)                   ,
W_STATE                   CHAR(2)                       ,
W_ZIP                     CHAR(10)                      ,
W_COUNTRY                 VARCHAR(20)                   ,
W_GMT_OFFSET              DECIMAL(5,2)
)DISTRIBUTE BY RANGE(W_WAREHOUSE_ID)
(
  SLICE s1 VALUES LESS THAN (10) DATANODE dn1,
  SLICE s2 VALUES LESS THAN (20) DATANODE dn2,
  SLICE s3 VALUES LESS THAN (30) DATANODE dn3,
  SLICE s4 VALUES LESS THAN (MAXVALUE) DATANODE dn4
);

-- Define a table using LIST distribution.
CREATE TABLE warehouse_d4
(
W_WAREHOUSE_SK            INTEGER               NOT NULL,
W_WAREHOUSE_ID            CHAR(16)              NOT NULL,
W_WAREHOUSE_NAME          VARCHAR(20)                   ,

W_STATE                  CHAR(2)                   ,
W_ZIP                    CHAR(10)                  ,
W_COUNTRY                VARCHAR(20)               ,
W_GMT_OFFSET             DECIMAL(5,2)
)DISTRIBUTE BY LIST(W_COUNTRY)
(
   SLICE s1 VALUES ('USA') DATANODE dn1,
   SLICE s2 VALUES ('CANADA') DATANODE dn2,
   SLICE s3 VALUES ('UK') DATANODE dn3,
   SLICE s4 VALUES (DEFAULT) DATANODE dn4
);
```

For details about the table distribution syntax, see **12.14.80 CREATE TABLE**.

## Selecting a Distribution Key

A distribution key is important for a distribution table. An improper distribution key may cause data skew. As a result, the I/O load is heavy on several DNs, affecting the overall query performance. Therefore, after determining the distribution policy of a distribution table, you need to check the table data skew to ensure that data is evenly distributed. Comply with the following rules to select a distribution key:

- [Proposal] Select a column containing discrete data as the distribution key, so that data can be evenly distributed on each DN. If the data in a single column is not discrete enough, consider using multiple columns as distribution keys. You can select the primary key of a table as the distribution key. For example, in an employee information table, select the certificate number column as the distribution key.
- [Proposal] If the first rule is met, do not select a column having constant filter conditions as the distribution key. For example, in a query on the **dwcjk** table, if the **zqdh** column contains the constant filter condition **zqdh='000001'**, avoid selecting the **zqdh** column as the distribution key.
- [Proposal] If the first and second rules are met, select the join conditions in a query as distribution keys. If a join condition is used as a distribution key, the data involved in a join task is locally distributed on DNs, which greatly reduces the data flow cost among DNs.

## Selecting a Partitioning Mode

Comply with the following rules to partition a table containing a large amount of data:

- [Proposal] Create partitions on columns that indicate certain ranges, such as dates and regions.
- [Proposal] A partition name should show the data characteristics of a partition. For example, its format can be *Keyword+Range* characteristics.
- [Proposal] Set the upper limit of a partition to **MAXVALUE** to prevent data overflow.

The example of a partitioned table definition is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
CREATE TABLE staffS_p1
(
  staff_ID       NUMBER(6) not null,

   PARTITION HIRE_maxvalue VALUES LESS THAN (MAXVALUE)
);
```

## 3.3.3 Column Design

### Selecting a Data Type

Comply with the following rules to improve query efficiency when you design columns:

- [Proposal] Use the most efficient data types allowed.

  If all of the following number types provide the required service precision, they are recommended in descending order of priority: integer, floating point, and numeric.
- [Proposal] In tables that are logically related, columns having the same meaning should use the same data type.
- [Proposal] For string data, you are advised to use variable-length strings and specify the maximum length. To avoid truncation, ensure that the specified maximum length is greater than the maximum number of characters to be stored. You are not advised to use CHAR(n), BPCHAR(n), NCHAR(n), or CHARACTER(n), unless you know that the string length is fixed.

  For details about string types, see **Common String Types**.

### Common String Types

Every column requires a data type suitable for its data characteristics. The following table lists common string types in GaussDB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 3-3** Common string types

| String Type | Description | Max. Storage Capacity |
| --- | --- | --- |
| CHAR(n) | Fixed-length string, where *n* indicates the stored bytes. If the length of an input string is smaller than *n*, the string is automatically padded to *n* bytes using NULL characters. | 10 MB |
| CHARACTER(n) | Fixed-length string, where *n* indicates the stored bytes. If the length of an input string is smaller than *n*, the string is automatically padded to *n* bytes using NULL characters. | 10 MB |
| NCHAR(n) | Fixed-length string, where *n* indicates the stored bytes. If the length of an input string is smaller than *n*, the string is automatically padded to *n* bytes using NULL characters. | 10 MB |
| BPCHAR(n) | Fixed-length string, where *n* indicates the stored bytes. If the length of an input string is smaller than *n*, the string is automatically padded to *n* bytes using NULL characters. | 10 MB |
| VARCHAR(n) | Variable-length string, where *n* indicates the maximum number of bytes that can be stored. | 10 MB |
| CHARACTER VARYING(n) | Variable-length string, where *n* indicates the maximum number of bytes that can be stored. This data type and VARCHAR(n) are different representations of the same data type. | 10 MB |
| VARCHAR2(n) | Variable-length string, where *n* indicates the maximum number of bytes that can be stored. This data type is added to be compatible with the Oracle database, and its behavior is the same as that of VARCHAR(n). | 10 MB |
| NVARCHAR2(n) | Variable-length string, where *n* indicates the maximum number of bytes that can be stored. | 10 MB |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| String Type | Description | Max. Storage Capacity |
| --- | --- | --- |
| TEXT | Variable-length string. Its maximum length is 1 GB minus 8203 bytes. | 1 GB minus 8203 bytes |

## 3.3.4 Constraint Design

### DEFAULT and NULL Constraints

- [Proposal] If all the column values can be obtained from services, you are not advised to use the **DEFAULT** constraint. Otherwise, unexpected results will be generated during data loading.
- [Proposal] Add **NOT NULL** constraints to columns that never have NULL values. The optimizer automatically optimizes the columns in certain scenarios.
- [Proposal] Explicitly name all constraints excluding **NOT NULL** and **DEFAULT**.

### Partial Cluster Keys

A partial cluster key (PCK) is a local clustering technology used for column-store tables. After creating a PCK, you can quickly filter and scan fact tables using min or max sparse indexes in GaussDB. Comply with the following rules to create a PCK:

- [Notice] Only one PCK can be created in a table. A PCK can contain multiple columns, preferably no more than two columns.
- [Proposal] Create a PCK on simple expression filter conditions in a query. Such filter conditions are usually in the form of *col op const*, where *col* specifies a column name, *op* specifies an operator (such as =, >, >=, <=, and <), and *const* specifies a constant.
- [Proposal] If the preceding conditions are met, create a PCK on the column having the most distinct values.

### Unique Constraints

- [Notice] Unique constraints can be used in row-store tables but not in column-store tables.
- [Proposal] The constraint name should indicate that it is a unique constraint, for example, **UNI***Included columns*.

### Primary Key Constraints

- [Notice] Primary key constraints can be used in row-store tables but not in column-store tables.
- [Proposal] The constraint name should indicate that it is a primary key constraint, for example, **PK***Included columns*.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

### Check Constraints

- [Notice] Check constraints can be used in row-store tables but not in column-store tables.
- [Proposal] The constraint name should indicate that it is a check constraint, for example, **CK***Included columns*.

## 3.3.5 View and Joined Table Design

### View Design

- [Proposal] Do not nest views unless they have strong dependency on each other.
- [Proposal] Try to avoid collation operations in a view definition.

### Joined Table Design

- [Proposal] Minimize joined columns across tables.
- [Proposal] Use the same data type for joined columns.
- [Proposal] The names of joined columns should indicate their relationship. For example, they can use the same name.

# 3.4 Tool Interconnection

## 3.4.1 JDBC Configuration

Currently, third-party tools are connected to GaussDB through JDBC. This section describes the precautions for configuring the tool.

### Connection Parameters

- [Notice] When a third-party tool connects to GaussDB through JDBC, JDBC sends a connection request to GaussDB. By default, the following parameters are added. For details, see the implementation of the ConnectionFactoryImpl JDBC code.

```
params = {
{ "user", user },
{ "database", database },
{ "client_encoding", "UTF8" },
{ "DateStyle", "ISO" },
{ "extra_float_digits", "3" },
{ "TimeZone",  createPostgresTimeZone() },
};
```

  These parameters may cause the JDBC and **gsql** clients to display inconsistent data, for example, date data display mode, floating point precision representation, and timezone.

  If the result is not as expected, you are advised to explicitly set these parameters in the Java connection setting.

  [Proposal] When the database is connected through JDBC, **extra_float_digits** is set to **3**. When the database is connected using gsql, **extra_float_digits** is set to **0**. As a result, the precision of the same data displayed in JDBC clients may be different from that displayed in gsql clients.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

[Proposal] In precision-sensitive scenarios, the numeric type is recommended.

- [Suggestion] When connecting to the database through JDBC, ensure that the following three time zones are the same:
  - Time zone of the host where the JDBC client is located
  - Time zone of the host where the GaussDB instance is located
  - Time zone during GaussDB instance configuration

    NOTE

    For details about how to set the time zone, contact the administrator.

## fetchsize

[Notice] To use **fetchsize** in applications, disable the **autocommit** switch. Enabling the **autocommit** switch makes the **fetchsize** configuration invalid.

## autocommit

[Suggestion] It is recommended that you enable the **autocommit** switch in the code for connecting to GaussDB by the JDBC. If **autocommit** needs to be disabled to improve performance or for other purposes, applications need to ensure their transactions are committed. For example, explicitly commit translations after specifying service SQL statements. Particularly, ensure that all transactions are committed before the client exits.

## Connection Releasing

[Suggestion] You are advised to use connection pools to limit the number of connections from applications. Do not connect to a database every time you run an SQL statement.

[Suggestion] After an application completes its jobs, disconnect it from GaussDB to release occupied resources. You are advised to set the session timeout interval in the jobs.

[Suggestion] Reset the session environment before releasing connections to the JDBC connection tool. Otherwise, historical session information may cause object conflicts.

- If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
- If a temporary table is used, delete the temporary table before you return the connection to the connection pool.

## CopyManager

[Suggestion] In the scenario where the ETL tool is not used and real-time data import is required, it is recommended that you use **CopyManager** driven by the GaussDB JDBC to import data in batches during application development.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 3.5 SQL Compilation

## DDL

- [Proposal] In GaussDB, you are advised to execute DDL operations, such as creating table or making comments, separately from batch processing jobs to avoid performance deterioration caused by many concurrent transactions.
- [Proposal] Execute data truncation after unlogged tables are used because GaussDB cannot ensure the security of unlogged tables in abnormal scenarios.
- [Proposal] Suggestions on the storage model of temporary and unlogged tables are the same as those on base tables. Create temporary tables in the same storage model as the base tables to avoid high computing costs caused by hybrid row and column correlation.
- [Proposal] The total length of an index column cannot exceed 50 bytes. Otherwise, the index size will increase greatly, resulting in large storage cost and low index performance.
- [Proposal] Do not delete objects using **DROP...CASCADE**, unless the dependency between objects is specified. Otherwise, the objects may be deleted by mistake.

## Data Loading and Uninstalling

- [Proposal] Provide the inserted column list in the insert statement. For example:
  ```
  INSERT INTO task(name,id,comment) VALUES ('task1','100','100th task');
  ```
- [Proposal] After data is imported to the database in batches or the data increment reaches the threshold, you are advised to analyze tables to prevent the execution plan from being degraded due to inaccurate statistics.
- [Proposal] To clear all data in a table, you are advised to use **TRUNCATE TABLE** instead of **DELETE TABLE**. **DELETE TABLE** is not efficient and cannot release disk space occupied by the deleted data.

## Type Conversion

- [Proposal] Convert data types explicitly. If you perform implicit conversion, the result may differ from expected.
- [Proposal] During data query, explicitly specify the data type for constants, and do not attempt to perform any implicit data type conversion.
- [Notice] If **sql_compatibility** is set to **ORA**, null strings will be automatically converted to NULL during data import. If null strings need to be reserved, set **sql_compatibility** to **TD**.

## Query Operation

- [Proposal] Do not return a large number of result sets to a client except the ETL program. If a large result set is returned, consider modifying your service design.
- [Proposal] Perform DDL and DML operations encapsulated in transactions. Operations like table truncation, update, deletion, and dropping, cannot be

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

rolled back once committed. You are advised to encapsulate such operations in transactions so that you can roll back the operations if necessary.

- [Proposal] During query compilation, you are advised to list all columns to be queried and avoid using **SELECT ***. Doing so reduces output lines, improves query performance, and avoids the impact of adding or deleting columns on front-end service compatibility.
- [Proposal] During table object access, add the schema prefix to the table object to avoid accessing an unexpected table due to schema switchover.
- [Proposal] The cost of joining more than three tables or views, especially full joins, is difficult to be estimated. You are advised to use the **WITH TABLE AS** statement to create interim tables to improve the readability of SQL statements.
- [Proposal] Avoid using Cartesian products or full joins. Cartesian products and full joins will result in a sharp expansion of result sets and poor performance.
- [Notice] Only **IS NULL** and **IS NOT NULL** can be used to determine NULL value comparison results. If any other method is used, NULL is returned. For example, NULL instead of expected Boolean values is returned for **NULL<>NULL**, **NULL=NULL**, and **NULL<>1**.
- [Notice] Do not use **count(col)** instead of **count(*)** to count the total number of records in a table. **count(*)** counts the NULL value (actual rows) while **count(col)** does not.
- [Notice] While executing **count(col)**, the number of NULL record rows is counted as 0. While executing **sum(col)**, NULL is returned if all records are NULL. If not all the records are NULL, the number of NULL record rows is counted as 0.
- [Notice] To count multiple columns using **count()**, column names must be enclosed in parentheses. For example, count ((col1, col2, col3)). Note: When multiple columns are used to count the number of NULL record rows, a row is counted even if all the selected columns are NULL. The result is the same as that when **count(*)** is executed.
- [Notice] Null records are not counted when **count(distinct col)** is used to calculate the number of non-NULL columns that are not repeated.
- [Notice] If all statistical columns are NULL when **count(distinct (col1,col2,...))** is used to count the number of unique values in multiple columns, Null records are also counted, and the records are considered the same.
- [Proposal] Use the connection operator (||) to replace the **concat** function for string connection, because the output of the **concat** function depends on the data type of the strings to be connected. When the execution plan is generated, the value cannot be calculated in advance. As a result, the query performance deteriorates severely.
- [Proposal] Use the following time-related macros to replace the **now** function and obtain the current time, because the execution plan generated by the **now** function cannot be pushed down to disks. As a result, the query performance deteriorates severely.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 3-4** Time-related macros

| Macro Name | Description | Example |
| --- | --- | --- |
| CURRENT_DATE | Obtains the current date, excluding the hour, minute, and second details. | openGauss=# select CURRENT_DATE;<br>date<br>------------<br>2018-02-02<br>(1 row) |
| CURRENT_TIME | Obtains the current time, excluding the year, month, and day. | openGauss=# select CURRENT_TIME;<br>timetz<br>--------------------<br>00:39:34.633938+08<br>(1 row) |
| CURRENT_TIMESTAMP(n) | Obtains the current date and time, including year, month, day, hour, minute, and second.<br>**NOTE**<br>*n* indicates the number of digits after the decimal point in the time string. | openGauss=# select CURRENT_TIMESTAMP(6);<br>timestamptz<br>-------------------------------<br>2018-02-02 00:39:55.231689+08<br>(1 row) |

- [Proposal] Do not use scalar subquery statements. A scalar subquery appears in the output list of a **SELECT** statement. In the following example, the underlined part is a scalar subquery statement:

  ```
  SELECT id, (SELECT COUNT(*) FROM films f WHERE f.did = s.id) FROM staffs_p1 s;
  ```

  Scalar subqueries often result in query performance deterioration. During application development, scalar subqueries need to be converted into equivalent table associations based on the service logic.

- [Proposal] In **WHERE** clauses, the filtering conditions should be collated. The condition that few records are selected for reading (the number of filtered records is small) is listed at the beginning.

- [Proposal] Filtering conditions in **WHERE** clauses should comply with unilateral rules, that is, to place the column name on one side of a comparison operator. In this way, the optimizer automatically performs pruning optimization in some scenarios. Filtering conditions in a **WHERE** clause will be displayed in *col op expression* format, where *col* indicates a table column, *op* indicates a comparison operator, such as = and >, and *expression* indicates an expression that does not contain a column name. For example:

  ```
  SELECT id, from_image_id, from_person_id, from_video_id FROM face_data WHERE
  current_timestamp(6) - time < '1 days'::interval;
  ```

  The modification is as follows:

  ```
  SELECT id, from_image_id, from_person_id, from_video_id FROM face_data where time >
  current_timestamp(6) - '1 days'::interval;
  ```

- [Proposal] Do not perform unnecessary collation operations. Collation requires a large amount of memory and CPU. If service logic permits, **ORDER BY** and **LIMIT** can be combined to reduce resource overhead. By default, data in GaussDB is collated by ASC & NULL LAST.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- [Proposal] When the **ORDER BY** clause is used for collation, specify collation modes (ASC or DESC), and use NULL FIRST or NULL LAST for NULL record sorting.
- [Proposal] Do not rely on only the **LIMIT** clause to return the result set displayed in a specific sequence. Combine **ORDER BY** and **LIMIT** clauses for some specific result sets and use **OFFSET** to skip specific results if necessary.
- [Proposal] If the service logic is accurate, you are advised to use **UNION ALL** instead of **UNION**.
- [Proposal] If a filtering condition contains only an **OR** expression, convert the **OR** expression to **UNION ALL** to improve performance. SQL statements that use **OR** expressions cannot be optimized, resulting in slow execution. For example:

  ```
  SELECT * FROM scdc.pub_menu
  WHERE (cdp= 300 AND inline=301) OR (cdp= 301 AND inline=302) OR (cdp= 302 ANDinline=301);
  ```

  Convert the statement to the following:

  ```
  SELECT * FROM scdc.pub_menu
  WHERE (cdp= 300 AND inline=301)
  union all
  SELECT * FROM scdc.pub_menu
  WHERE (cdp= 301 AND inline=302)
  union all
  SELECT * FROM tablename
  WHERE (cdp= 302 AND inline=301)
  ```

- [Proposal] If an **in(val1, val2, val3...)** expression contains a large number of columns, you are advised to replace it with the **in (values (va11), (val2), (val3)...)** statement. The optimizer will automatically convert the **IN** constraint into a non-correlated subquery to improve the query performance.
- [Proposal] Replace **(not) in** with **(not) exist** when associated columns do not contain null values. For example, in the following query statement, if the **T1.C1** column does not contain any NULL value, add the **NOT NULL** constraint to the **T1.C1** column, and then rewrite the statements.

  ```
  SELECT * FROM T1 WHERE T1.C1 NOT IN (SELECT T2.C2 FROM T2);
  ```

  Rewrite the statement as follows:

  ```
  SELECT * FROM T1 WHERE NOT EXISTS (SELECT  * FROM T2 WHERE T1.C1=T2.C2);
  ```

  **NOTE**

  - If the value of the **T1.C1** column will possibly be NULL, the preceding rewriting cannot be performed.
  - If the **T1.C1** column is the output of a subquery, check whether the output is NOT NULL based on the service logic.
- [Proposal] Use cursors instead of the **LIMIT OFFSET** syntax to perform pagination queries to avoid resource overheads caused by multiple executions. A cursor must be used in a transaction, and you must disable the cursor and commit the transaction once the query is finished.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 4 Best Practices

## 4.1 Best Practices of Table Design

### 4.1.1 Selecting a Storage Model

During database design, some key factors about table design will greatly affect the subsequent query performance of the database. Table design affects data storage as well. Scientific table design reduces I/O operations and minimizes memory usage, improving the query performance.

Selecting a model for table storage is the first step of table definition. Select a proper storage model for your service based on the following table.

| Storage Model | Application Scenario |
| --- | --- |
| Row storage | Point queries (simple index-based queries that only return a few records)<br>Scenarios requiring frequent addition, deletion, and modification operations |
| Column storage | Statistics analysis query, in which operations, such as group and join, are performed many times |

### 4.1.2 Selecting a Distribution Mode

In replication mode, full data in a table is copied to each DN in the cluster. This mode is used for tables containing a small volume of data. Full data in a table stored on each DN avoids data redistribution during the join operation. This reduces network costs and plan segment (each having a thread), but generates much redundant data. Generally, this mode is only used for small dimension tables.

In hash mode, hash values are generated for one or more columns. You can obtain the storage location of a tuple based on the mapping between DNs and the hash

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

values. In a hash table, I/O resources on each node can be used during data read/write, which improves the read/write speed of a table. Generally, a table containing a large amount data is defined as a hash table.

Range distribution and list distribution are user-defined distribution policies. Values in a distribution column are within a certain range or fall into a specific value range of the corresponding target DN. The two distribution modes facilitate flexible data management, which, however, requires users equipped with certain data abstraction capability.

| Policy | Description | Application Scenario |
| --- | --- | --- |
| Hash | Table data is distributed on all DNs in the cluster. | Fact tables containing a large amount of data |
| Replication | Full data in a table is stored on every DN in the cluster. | Small tables and dimension tables |
| Range | Table data is mapped to specified columns based on the range and distributed to the corresponding DNs. | Users need to customize distribution rules. |
| List | Table data is mapped to specified columns based on specific values and distributed to corresponding DNs. | Users need to customize distribution rules. |

As shown in **Figure 4-1**, T1 is a replication table and T2 is a hash table.

**Figure 4-1** Replication tables and hash tables

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## 4.1.3 Selecting Distribution Keys

Selecting a distribution key for a hash table is essential. Details are as follows:

1. **Ensure that the column values are discrete so that data can be evenly distributed to each DN.** You can select the primary key of the table as the distribution key. For example, for a person information table, choose the ID card number column as the distribution key.
2. **With the above principles met, you can select join conditions as distribution keys** so that join tasks can be pushed down to DNs, reducing the amount of data transferred between the DNs.

For a hash table, an improper distribution key may cause data skew or poor I/O performance on certain DNs. Therefore, you need to check the table to ensure that data is evenly distributed on each DN. You can run the following SQL statement to check for data skew:

```
select
xc_node_id, count(1)
from tablename
group by xc_node_id
order by xc_node_id desc;
```

**xc_node_id** corresponds to a DN. Generally, **over 5% difference between the amount of data on different DNs is regarded as data skew. If the difference is over 10%, choose another distribution key.**

Multiple distribution keys can be selected in GaussDB to evenly distribute data.

You can select the distribution key of the range or list distribution table as required. In addition to selecting a proper distribution key, pay attention to the impact of distribution rules on data distribution.

## 4.1.4 Using PCKs

The PCK is the column-store-based technology. It can minimize or maximize sparse indexes to quickly filter base tables. You are advised to select a maximum of two columns as PCKs. Use the following principles to specify PCKs:

1. The selected PCKs must be restricted by simple expressions in base tables. Such constraints are usually represented by *col op const*, in which *col* indicates the column name, *op* indicates operators, (including =, >, >=, <=, and <), and *const* indicates constants.
2. Select columns that are frequently selected (to filter much more undesired data) in simple expressions.
3. List the most frequently selected columns at the top.
4. List the columns of the enumerated type at the top.

## 4.1.5 Using Partitioned Tables

Partitioning refers to splitting what is logically one large table into smaller physical pieces based on specific schemes. The table based on the logic is called a partitioned table, and a physical piece is called a partition. Data is stored on these physical partitions, instead of the logical partitioned table. A partitioned table has the following advantages over an ordinary table:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

1. High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
2. High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
3. Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.

GaussDB supports range partitioned tables.

Range partitioned table: Data in different ranges is mapped to different partitions. The range is determined by the partition key specified during the partitioned table creation. The partition key is usually a date. For example, sales data is partitioned by month.

## 4.1.6 Selecting a Data Type

Use the following principles to select efficient data types:

1. **Select data types that facilitate data calculation.**

   Generally, the calculation of integers (including common comparison calculations, such as =, >, <, ≥, ≤, and ≠ and group by) is more efficient than that of strings and floating point numbers. For example, if you need to perform a point query on a column-store table whose numeric column is used as a filter condition, the query will take over 10s. If you change the data type from **NUMERIC** to **INT**, the query duration will be reduced to 1.8s.

2. **Select data types with a short length.**

   Data types with short length reduce both the data file size and the memory used for computing, improving the I/O and computing performance. For example, use **SMALLINT** instead of **INT**, and **INT** instead of **BIGINT**.

3. **Use the same data type for a join.**

   You are advised to use the same data type for a join. To join columns with different data types, the database needs to convert them to the same type, which leads to additional performance overheads.

## 4.1.7 Checking a Node Where a Table Resides

When creating a table, you can specify how the table is distributed or replicated among nodes. For details, see **•DISTRIBUTEBY**. For details about distribution modes, see **4.1.2 Selecting a Distribution Mode**.

When creating a table, you can also set **Node Group** to specify a group to which the table belongs. For details, see **•TO{GROUPgroupname|...**.

You can also run the following command to view the instance where the table is located.

1. Query the schema to which the table belongs.

   ```
   select t1.nspname,t2.relname from pg_namespace t1,pg_class t2 where t1.oid = t2.relnamespace and t2.relname = 'table1';
   ```

   In the preceding command, **nspname** indicates the name of a schema, **relname** indicates the name of a table, an index, or a view, **oid** indicates the row identifier, **relnamespace** is the OID of the namespace that contains the relationship, and **table1** indicates a table name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

2. Check **relname** and **nodeoids** of the table.
   ```
   select t1.relname,t2.nodeoids from pg_class t1, pgxc_class t2, pg_namespace t3  where t1.relfilenode =  t2.pcrelid and t1.relnamespace=t3.oid and t1.relname = 'table1' and t3.nspname ='schema1';
   ```
   In the preceding command, **nodeoids** indicates the OID list of the nodes where the table is distributed, **relfilenode** indicates the name of the file related to the table on the disk, **pcrelid** indicates the OID of the table, and **schema1** indicates the schema of the table queried in step 1.
3. Query the instance where the table is located based on the queried node where the table is distributed.
   ```
   select * from pgxc_node where oid in (nodeoids1, nodeoids2, nodeoids3);
   ```
   In the preceding command, **nodeoids1, nodeoids2, nodeoids3** indicates the three nodeoids queried in step 2. Use the actual nodeoids and separate them with commas (,).

# 4.2 Best Practices of Data Import

## Using GDS to Import Data

- Data skew deteriorates the query performance. Before importing all the data from a table containing over 10 million records, you are advised to import some of the data and check whether there is data skew and whether the distribution keys need to be changed. Troubleshoot the data skew if any. It is costly to address data skew and change the distribution keys after a large amount of data has been imported. For details, see **8.7 Checking for Data Skew**.
- To speed up the import, you are advised to split files and use multiple Gauss Data Services (GDSs) to import data in parallel. An import task can be split into multiple concurrent import tasks. If multiple import tasks use the same GDS, you can specify the **-t** parameter to enable GDS multi-thread concurrent import. To prevent physical I/O and network bottleneck, you are advised to mount GDSs to different physical disks and NICs.
- To ensure normal job execution, configure robust system resources in the physical environment where GDSs are located based on the load and concurrency of GDSs. The system resources include but are not limited to the memory size, number of handles, and available space of the disk corresponding to the GDS data directory. If GDSs are deployed outside the GaussDB cluster, ensure that their physical environment configuration is consistent with that in the cluster.
- If the GDS I/O and NICs do not reach their physical bottleneck, you can enable SMP on GaussDB for acceleration. SMP will multiply pressure on GDSs. Note that SMP adaptation is implemented based on the GaussDB CPU pressure rather than the GDS pressure.
- The communication between GDS and GaussDB must be smooth. 10GE network is recommended. Gigabit networks cannot bear the high-speed data transmission. That is, Gigabit networks cannot guarantee the network communications of GaussDB. To maximize the import speed of a single file, ensure that a 10GE network is used, and the data disk group I/O rate is greater than the upper limit of the GDS single-core processing capability (about 400 Mbit/s).
- Similar to the single-table import, ensure that the I/O rate is greater than the maximum network throughput in the concurrent import.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- You are advised to deploy one or two GDSs on a RAID of a data server.
- It is recommended that the ratio of GDS quantity to DN quantity be in the range of 1:3 to 1:6.
- To improve the efficiency of importing data in batches to column-store partitioned tables, the data is buffered before being written into a disk. You can specify the number of buffers and the buffer size by setting **partition_mem_batch** and **partition_max_cache_size**, respectively. The smaller the values, the slower the batch import to column-store partitioned tables. The larger the values, the higher the memory consumption.

## Using INSERT to Insert Multiple Rows

If the **COPY** statement cannot be used and you require SQL insert, use multi-row insert whenever possible. If you use a column-store table and insert one or more rows at a time, the data compression efficiency is low.

Multi-row insert improves performance by batching up a series of inserts. The following example inserts three rows into a three-column table using a single **INSERT** statement. This is still a small insert, shown simply to illustrate the syntax of a multi-row insert. For details about how to create a table, see **2.6 Creating and Managing Tables**.

To insert multiple rows of data to the table **customer_t1**, run the following command:

```
openGauss=# INSERT INTO customer_t1 VALUES
(68, 'a1', 'zhou','wang'),
(43, 'b1', 'wu', 'zhao'),
(95, 'c1', 'zheng', 'qian');
```

For more details and examples, see **12.14.141 INSERT**.

## Using COPY to Import Data

The **COPY** statement imports data from local and remote databases in parallel. It imports large amounts of data more efficiently than using **INSERT** statements.

For details about how to use the **COPY** statement, see **8.3 Running the COPY FROM STDIN Statement to Import Data**.

## Using a gsql Meta-Command to Import Data

The **\copy** command can be used to import data after you log in to a database through any **psql** client. Unlike the **COPY** statement, the **\copy** command reads from or writes to a file.

Data read or written using the **\copy** command is transferred through the connection between the server and the client and may not be efficient. The **COPY** statement is recommended when the amount of data is large.

For details about how to use the **\copy** command, see **8.4 Using a gsql Meta-Command to Import Data**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

**\copy** applies only to small-scale data import in good format. It does not preprocess invalid characters nor provide error tolerance. Therefore, **\copy** cannot be used in scenarios where abnormal data exists. GDS or **COPY** is preferred for data import.

### Using INSERT for Bulk Insert

Use a bulk insert operation with a **SELECT** clause for high-performance data insertion.

Use the **12.14.141 INSERT** and **12.14.82 CREATE TABLE AS** statements when you need to move data or a subset of data from one table into another.

Assume that you have created a backup table **customer_t2** for table **customer_t1**. To insert data from **customer_t1** to **customer_t2**, run the following statements:

```
openGauss=# CREATE TABLE customer_t2
(
    c_customer_sk             integer,
    c_customer_id             char(5),
    c_first_name              char(6),
    c_last_name               char(8)
);
openGauss=# INSERT INTO customer_t2 SELECT * FROM customer_t1;
```

The preceding example is equivalent to:

```
openGauss=# CREATE TABLE customer_t2 AS SELECT * FROM customer_t1;
```

## 4.3 Best Practices of SQL Queries

Based on the SQL execution mechanism and a large number of practices, SQL statements can be optimized by following certain rules to enable the database to execute SQL statements more quickly and obtain correct results.

- Replace **UNION** with **UNION ALL**.

  **UNION** eliminates duplicate rows while merging two result sets but **UNION ALL** merges the two result sets without deduplication. Therefore, replace **UNION** with **UNION ALL** if you are sure that the two result sets do not contain duplicate rows based on the service logic.

- Add **NOT NULL** to the join columns.

  If there are many NULL values in the **JOIN** columns, you can add the filter criterion **IS NOT NULL** to filter data in advance to improve the **JOIN** efficiency.

- Convert **NOT IN** to **NOT EXISTS**.

  **nestloop anti join** must be used to implement **NOT IN**, and **hash anti join** is required for **NOT EXISTS**. If no NULL value exists in the **JOIN** columns, **NOT IN** is equivalent to **NOT EXISTS**. Therefore, if you are sure that no NULL value exists, you can convert **NOT IN** to **NOT EXISTS** to generate **hash join** and to improve the query performance.

  As shown in the following figure, the **t2.d2** column does not contain null values (it is set to **NOT NULL**) and **NOT EXISTS** is used for the query.

  ```
  SELECT * FROM t1 WHERE  NOT EXISTS (SELECT * FROM t2 WHERE t1.c1=t2.d2);
  ```

  The generated execution plan is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Figure 4-2** NOT EXISTS execution plan

```
 id |                 operation
----+-------------------------------------------
  1 | -> Streaming (type: GATHER)
  2 |    ->  Hash Anti Join (3, 4)
  3 |       ->  Seq Scan on t1
  4 |       ->  Hash
  5 |          ->  Streaming (type: REDISTRIBUTE)
  6 |             ->  Seq Scan on t2
(6 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
  2 --Hash Anti Join (3, 4)
        Hasn Cond: (t1.c1 = t2.d2)
(2 rows)
```

- Use **hashagg**.

  If a plan involving groupAgg and SORT operations generated by the **GROUP BY** statement is poor in performance, you can set **work_mem** to a larger value to generate a **hashagg** plan, which does not require sorting and improves the performance.

- Replace functions with **CASE** statements.

  The GaussDB performance greatly deteriorates if a large number of functions are called. In this case, you can modify the pushdown functions to **CASE** statements.

- Do not use functions or expressions for indexes.

  Using functions or expressions for indexes stops indexing. Instead, it enables scanning on the full table.

- Do not use **!=** or **<>** operators, **NULL**, **OR**, or implicit parameter conversion in **WHERE** clauses.

- Split complex SQL statements.

  You can split an SQL statement into several ones and save the execution result to a temporary table if the SQL statement is too complex to be tuned using the solutions above, including but not limited to the following scenarios:

  - The same subquery is involved in multiple SQL statements of a job and the subquery contains large amounts of data.
  - Incorrect plan cost causes a small hash bucket of subquery. For example, the actual number of rows is 10 million, but only 1000 rows are in hash bucket.
  - Functions such as **substr** and **to_number** cause incorrect measures for subqueries containing large amounts of data.
  - **BROADCAST** subqueries are performed on large tables in multi-DN environment.

For details about optimization, see **10.3.6 Typical SQL Optimization Methods**.

# 4.4 Best Practices for Data Skew Query

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## 4.4.1 Detecting Storage Skew in Real Time During Data Import

During the import, the system collects statistics on the number of rows imported on each DN. After the import is complete, the system calculates the skew ratio. If the skew ratio exceeds the specified threshold, an alarm is generated immediately. The skew ratio is calculated as follows: Skew ratio = (Maximum number of rows imported on a DN – Minimum number of rows imported on a DN)/Number of imported rows. Currently, data can be imported only by running **INSERT** or **COPY**.

NOTE

**enable_stream_operator** must be set to **on** so that DNs can return the number of imported rows at a time when a plan is delivered to them. Then, the skew ratio is calculated on CNs based on the returned values.

### Procedure

1. Set parameters **table_skewness_warning_threshold** (threshold for triggering a table skew alarm) and **table_skewness_warning_rows** (minimum number of rows for triggering a table skew alarm).
   - The value of **table_skewness_warning_threshold** ranges from 0 to 1. The default value is **1**, indicating that the alarm is disabled. Other values indicate that the alarm is enabled.
   - The value of **table_skewness_warning_rows** ranges from 0 to 2147483647. The default value is **100,000**. The alarm is triggered only when the following condition is met: Total number of imported rows > Value of **table_skewness_warning_rows** x Number of DNs involving in the import.

   ```
   show table_skewness_warning_threshold;
   set table_skewness_warning_threshold = xxx;
   show table_skewness_warning_rows;
   set table_skewness_warning_rows = xxx;
   ```

2. Import data by running the **INSERT** or **COPY** statement.
3. Detect and handle alarms. The alarm information includes the table name, minimum number of rows, maximum number of rows, total number of rows, average number of rows, skew rate, and prompt information about data distribution or parameter modification.

   ```
   WARNING: Skewness occurs, table name: xxx, min value: xxx, max value: xxx, sum value: xxx, avg value: xxx, skew ratio: xxx
   HINT: Please check data distribution or modify warning threshold
   ```

## 4.4.2 Quickly Locating Tables That Cause Data Skew

Currently, the **table_distribution(schemaname text, tablename text)** and **table_distribution()** functions as well as the **15.3.192 PGXC_GET_TABLE_SKEWNESS** view are provided to query for data skew. You can choose any of them as needed.

### Scenario 1: Data Skew Caused by a Full Disk

First, use the **pg_stat_get_last_data_changed_time(oid)** function to query for the tables whose data is changed recently. The last change time of a table is recorded only on the CN where **INSERT**, **UPDATE**, and **DELETE** operations are performed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Therefore, you need to query for tables that are changed within the last day (the period can be changed in the function).

```
CREATE OR REPLACE FUNCTION get_last_changed_table(OUT schemaname text, OUT relname text)
RETURNS setof record
AS $$
DECLARE
   row_data record;
   row_name record;
   query_str text;
   query_str_nodes text;
   BEGIN
      query_str_nodes := 'SELECT node_name FROM pgxc_node where node_type = ''C''';
      FOR row_name IN EXECUTE(query_str_nodes) LOOP
         query_str := 'EXECUTE DIRECT ON (' || row_name.node_name || ') ''SELECT b.nspname,a.relname
FROM pg_class a INNER JOIN pg_namespace b on a.relnamespace = b.oid where
pg_stat_get_last_data_changed_time(a.oid) BETWEEN current_timestamp - 1 AND current_timestamp;''';
         FOR row_data IN EXECUTE(query_str) LOOP
            schemaname = row_data.nspname;
            relname = row_data.relname;
            return next;
         END LOOP;
      END LOOP;
      return;
   END; $$
LANGUAGE 'plpgsql';
```

Then, execute the **table_distribution(schemaname text, tablename text)** function to query for the storage space occupied the tables on each DN.

```
SELECT table_distribution(schemaname,relname) FROM get_last_changed_table();
```

## Scenario 2: Routine Data Skew Inspection

- If the number of tables in the database is less than 10,000, use the skew view to query data skew of all tables in the database.
  ```
  SELECT * FROM pgxc_get_table_skewness ORDER BY totalsize DESC;
  ```
- If the number of tables in the database is no less than 10,000, you are advised to use the **table_distribution()** function instead of the **15.3.192 PGXC_GET_TABLE_SKEWNESS** view because the view takes a longer time (hours) due to the query of the entire database for skew columns. When you use the **table_distribution()** function, you can define the output based on **15.3.192 PGXC_GET_TABLE_SKEWNESS**, optimizing the calculation and reducing the output columns. For example:
  ```
  SELECT schemaname,tablename,max(dnsize) AS maxsize, min(dnsize) AS minsize
  FROM pg_catalog.pg_class c
  INNER JOIN pg_catalog.pg_namespace n ON n.oid = c.relnamespace
  INNER JOIN pg_catalog.table_distribution() s ON s.schemaname = n.nspname AND s.tablename =
  c.relname
  INNER JOIN pg_catalog.pgxc_class x ON c.oid = x.pcrelid AND x.pclocatortype = 'H'
  GROUP BY schemaname,tablename;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 5 Tutorial: Using GDS to Import Data from a Remote Server

## 5.1 Overview

This tutorial demonstrates how to use GDS to import data from remote servers to GaussDB.

In this tutorial, you will:

- Generate the source data files in CSV format to be used in this tutorial.
- Upload the source data files to a data server.
- Create foreign tables used for importing data from a data server to GaussDB through GDS.
- Start GaussDB, create a table, and import data to the table.
- Analyze import errors based on the information in the error table and correct the faults.

## 5.2 Prerequisites

A server for storing source data has been prepared, and it can communicate with GaussDB. The server has robust system resources such as memory, disk spaces, and file handles.

### Obtaining the Driver Package

Download particular packages listed in **Table 5-1** based on the version of your instance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 5-1** Driver package download list

| Version | Download Address |
| --- | --- |
| 3.*x* | **Driver package**<br>**Verification package for the driver package** |
| 2.*x* | **Driver package**<br>**Verification package for the driver package** |

To prevent a software package from being tampered with during transmission or storage, download the corresponding verification package and perform the following steps to verify the software package:

1. Upload the software package and verification package to the same directory on a Linux VM.
2. Run the following command to verify the integrity of the software package:

   **cat** *GaussDB_driver.zip.sha256* **| sha256sum --check**

   If **OK** is displayed in the command output, the verification is successful.

   ```
   GaussDB_driver.zip: OK
   ```

# 5.3 Step 1: Preparing Source Data

You can import data in TEXT, CSV, or FIXED format from a remote server to GaussDB. This tutorial uses data in CSV format as an example. The method is the same for data in TEXT and FIXED format except that the parameter settings of foreign tables are different. For details, see **8.1 Importing Data in Parallel Using Foreign Tables**.

## Preparing Source Data Files

To demonstrate how to import multiple files, this tutorial uses the following three CSV data files as an example. Generally, source data files are exported from a database. In this tutorial, the CSV source data files are manually created.

- Data file **product_info0.csv**

  The file contains the following data:

  ```
  100,XHDK-A,2017-09-01,A,2017 Shirt Women,red,M,328,2017-09-04,715,good!
  205,KDKE-B,2017-09-01,A,2017 T-shirt Women,pink,L,584,2017-09-05,40,very good!
  300,JODL-X,2017-09-01,A,2017 T-shirt men,red,XL,15,2017-09-03,502,Bad.
  310,QQPX-R,2017-09-02,B,2017 jacket women,red,L,411,2017-09-05,436,It's nice.
  150,ABEF-C,2017-09-03,B,2017 Jeans Women,blue,M,123,2017-09-06,120,good.
  ```

- Data file **product_info1.csv**

  The file contains the following data:

  ```
  200,BCQP-E,2017-09-04,B,2017 casual pants men,black,L,997,2017-09-10,301,good quality.
  250,EABE-D,2017-09-10,A,2017 dress women,black,S,841,2017-09-15,299,This dress fits well.
  108,CDXK-F,2017-09-11,A,2017 dress women,red,M,85,2017-09-14,22,It's really amazing to buy.
  450,MMCE-H,2017-09-11,A,2017 jacket women,white,M,114,2017-09-14,22,very good.
  260,OCDA-G,2017-09-12,B,2017 woolen coat women,red,L,2004,2017-09-15,826,Very comfortable.
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Data file **product_info2.csv**

  The file contains the following data:

```
980,"ZKDS-J",2017-09-13,"B","2017 Women's Cotton Clothing","red","M",112,,,
98,"FKQB-I",2017-09-15,"B","2017 new shoes men","red","M",4345,2017-09-18,5473
50,"DMQY-K",2017-09-21,"A","2017 pants men","red","37",28,2017-09-25,58,"good","good","good"
80,"GKLW-l",2017-09-22,"A","2017 Jeans Men","red","39",58,2017-09-25,72,"Very comfortable."
30,"HWEC-L",2017-09-23,"A","2017 shoes women","red","M",403,2017-09-26,607,"good!"
40,"IQPD-M",2017-09-24,"B","2017 new pants Women","red","M",35,2017-09-27,52,"very good."
50,"LPEC-N",2017-09-25,"B","2017 dress Women","red","M",29,2017-09-28,47,"not good at all."
60,"NQAB-O",2017-09-26,"B","2017 jacket women","red","S",69,2017-09-29,70,"It's beautiful."
70,"HWNB-P",2017-09-27,"B","2017 jacket women","red","L",30,2017-09-30,55,"I like it so much"
80,"JKHU-Q",2017-09-29,"C","2017 T-shirt","red","M",90,2017-10-02,82,"very good."
```

  CSV is short for Comma Separated Values. A CSV file is similar to a TXT or DOC file, which is a type of text files. A CSV file is composed of records that are separated as columns by tabs. Each record shares the same column sequence. In Windows, CSV files can be opened in different applications, such as Notepad and Notepad++.

  The following describes how to generate a CSV file in Windows:

**Step 1** Create a text file and open it in Notepad++. Copy the sample data into it. Then, check the total number of rows and check whether the data of rows is correctly separated.

**Step 2** Choose **Encoding** > **Encode in UTF-8 without BOM**.

**Step 3** Choose **File** > **Save as**.

**Step 4** In the displayed dialog box, enter the file name and click **Save**.

To identify the file type, use the file name extension .csv when entering the file name.

**----End**

## Uploading Source Data Files to a Data Server

**Step 1** Log in to the server 192.168.0.90 storing source data files (also known as the data server or GDS server).

**Step 2** Run the following command to create a directory named **/input_data**:

```
mkdir -p /input_data
```

**Step 3** Use MobaXterm to upload source data files to the created directory.

**----End**

# 5.4 Step 2: Installing, Configuring, and Starting GDS on a Data Server

## Obtaining the Driver Package

Download particular packages listed in **Table 5-2** based on the version of your instance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 5-2** Driver package download list

| Version | Download Address |
| --- | --- |
| 3.*x* | **Driver package**<br>**Verification package for the driver package** |
| 2.*x* | **Driver package**<br>**Verification package for the driver package** |

To prevent a software package from being tampered with during transmission or storage, download the corresponding verification package and perform the following steps to verify the software package:

1. Upload the software package and verification package to the same directory on a Linux VM.
2. Run the following command to verify the integrity of the software package:

   **cat** *GaussDB_driver.zip.sha256* **| sha256sum --check**

   If **OK** is displayed in the command output, the verification is successful.

   ```
   GaussDB_driver.zip: OK
   ```

Before data import, install, configure, and start GDS on the servers where source data files are stored. Then you can connect GDS to GaussDB to import data.

**Step 1** Log in to the data server 192.168.0.90 where GDS is to be installed, and create user **gds_user** and its user group **gdsgrp**. This user is used to start GDS and must have the permission to read the source data file directory.

```
groupadd gdsgrp
useradd -g gdsgrp gds_user
```

**Step 2** Switch to user **gds_user**.

```
su - gds_user
```

**Step 3** Create the **/opt/bin** directory for storing the GDS package.

```
mkdir -p /opt/bin
```

**Step 4** Change the owner of the GDS package and source data file directory to **gds_user** and the user group to **gdsgrp**.

```
chown -R gds_user:gdsgrp /opt/bin
chown -R gds_user:gdsgrp /input_data
```

**Step 5** Upload the GDS package to the created directory.

Use the Euler Linux tool package as an example. Upload the GDS tool package **GaussDB-Kernel-VxxxRxxxCxx-xxxxx-64bit-Gds.tar.gz** in the software installation package to the created directory.

Download link of **GaussDB-Kernel-VxxxRxxxCxx-xxxxx-64bit-Gds.tar.gz**: **Driver package**

**Step 6** Run the following commands to go to the directory and decompress the package:

```
cd /opt/bin
tar -zxvf GaussDB-Kernel-VxxxRxxxCxx-xxxxx-64bit-Gds.tar.gz
export LD_LIBRARY_PATH="/opt/bin/lib:$LD_LIBRARY_PATH"  // GDS depends on the Cjson dynamic library. Therefore, you need to configure the path of the dynamic library.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Step 7** (Optional) If SSL is used, upload the SSL certificate to the directory created in **Step 1**.

The SSL certificate is stored in the ***$GAUSSHOME*/share/sslcert/gds** directory of GaussDB.

In this example, *$GAUSSHOME* of the GaussDB server (192.168.10.60) is **/opt/huawei/Bigdata/gaussdb/core**. You can download the SSL certificate to the **/opt/bin** directory for GDS by using the following command:

```
scp -r root@192.168.10.60:/opt/huawei/Bigdata/gaussdb/core/share/sslcert/gds ./
```

**Step 8** Start the GDS.

- If SSL is not enabled, run the following command to start GDS:
  ```
  /opt/bin/gds/gds -d /input_data/ -p 192.168.0.90:5000 -H 10.10.0.1/24 -l /opt/bin/gds/gds_log.txt -D
  --enable-ssl off
  ```
- If SSL encryption is used, run the following command to start GDS after performing **Step 7**:
  ```
  /opt/bin/gds/gds -d /input_data/ -p 192.168.0.90:5000 -H 10.10.0.1/24 -l /opt/bin/gds/gds_log.txt -D
  --enable-ssl on --ssl-dir /opt/bin/gds
  ```

Replace the italic parts as required.

- **-d** *dir*: directory storing data files that contain data to be imported. It is **/input_data/** in this tutorial.
- **-p** *ip:port*: listening IP address and port for GDS. The default value is **127.0.0.1**. Replace it with the IP address of a 10GE network that can communicate with GaussDB. The listening port can be any one ranging from 1024 to 65535. The default port is **8098**. This parameter is set to **192.168.0.90:5000** in this tutorial.
- **-H** *address_string*: network segment for hosts that can connect to and use GDS. The value must be in CIDR format. Set this parameter to enable the GaussDB instance to access GDS for data import. Ensure that the network segment covers all hosts in the GaussDB instance.
- **-l** *log_file*: GDS log directory and log file name. This parameter is set to **/opt/bin/gds/gds_log.txt** in this tutorial.
- **-D**: GDS in daemon mode. This parameter is used only in Linux.
- **--enable-ssl**: Data transmission in SSL encryption mode. By default, the SSL encryption mode is enabled. If this parameter is not used, you need to add **--ssl-dir** to specify the SSL certificate directory.
- **--ssl-dir**: SSL certificate directory. Set it to the certificate directory mentioned in **Step 7**.

**----End**

# 5.5 Step 3: Creating a Foreign Table in GaussDB

**Step 1** Use the SQL client tool to connect to the GaussDB database.

**Step 2** Create a foreign table based on **Table 5-3**.

```
openGauss=# DROP FOREIGN TABLE IF EXISTS product_info_ext;
openGauss=# CREATE FOREIGN TABLE product_info_ext
(
    product_price               integer       not null,
    product_id                  char(30)      not null,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
    product_time                date          ,
    product_level               char(10)      ,
    product_name                varchar(200)  ,
    product_type1               varchar(20)   ,
    product_type2               char(10)      ,
    product_monthly_sales_cnt   integer       ,
    product_comment_time        date          ,
    product_comment_num         integer       ,
    product_comment_content     varchar(200)
)
SERVER gsmpp_server
OPTIONS(
LOCATION 'gsfs://192.168.0.90:5000/*',
FORMAT 'CSV' ,
DELIMITER ',',
ENCODING 'utf8',
HEADER 'false',
FILL_MISSING_FIELDS 'true',
IGNORE_EXTRA_DATA 'true'
)
READ ONLY
LOG INTO product_info_err
PER NODE REJECT LIMIT 'unlimited';
```

If the following information is displayed, the foreign table has been created:

```
CREATE FOREIGN TABLE
```

**Table 5-3** Configurations in the foreign table

| Configuration Item | Value | Description |
| --- | --- | --- |
| SERVER | gsmpp_server | Use the default value **gsmpp_server**. |
| LOCATION | gsfs://192.168.0.90:5000/* | Location of source data files.<br>If SSL is used for encrypted transmission, use the gsfss protocol. In this case, the location is **gsfss://192.168.0.90:5000/***. |
| FORMAT | CSV | Format of source data files. |
| ENCODING | UTF-8 | Data encoding format. |
| DELIMITER | It is set to a comma (,). | Field separator. |
| HEADER | **false** (default value) | Specifies whether a data file contains a header. This parameter is valid only for data files in CSV or FIXED format. The first line of data files in **Preparing Source Data Files** is not a header. Therefore, it is set to **false**. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Configuration Item | Value | Description |
| --- | --- | --- |
| FILL_MISSING_FIELDS | true | Specifies how to handle the problem that the last column of a row in a source data file is lost during data import. The default value is **false/off**. **true** is used in this tutorial.<br>• **true/on**: The last column is set to **NULL**. No error is reported.<br>• **false/off**: Error "missing data for column "tt"" is reported.<br>For example, the last column **product_comment_content** of the second row in the **product_info2.csv** source data file is lost. If **FILL_MISSING_FIELDS** is set to **false/off**, information similar to the following will be displayed in the error table during data import:<br>**missing data for column** "product_comment_content" |
| IGNORE_EXTRA_DATA | true | Specifies whether to ignore excessive columns when the number of columns in a source data file exceeds that defined in the foreign table. The default value is **false/off**. **true** is used in this tutorial.<br>• **true/on**: The excessive columns of a row are ignored. No error is reported.<br>• **false/off**: Error "extra data after last expected column" is reported.<br>For example, the number of columns in the third record in the **product_info2.csv** source data file is greater than that defined in the foreign table. If **IGNORE_EXTRA_DATA** is set to **false/off**, information similar to the following will be displayed in the error table during data import:<br>**extra data after last expected column** |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Configuration Item | Value | Description |
| --- | --- | --- |
| PER NODE REJECT LIMIT 'value' | unlimited | Maximum number of data format errors allowed on each DN during data import. If the number of errors exceeds the specified value on any DN, data import fails, an error is reported, and the system exits data import.<br>It is set to **unlimited** in this tutorial, indicating that all data format errors during import are allowed. |
| READ ONLY | - | Syntax defined in a foreign table can be used for both importing data to and exporting data from GaussDB. To import data to the cluster, use **READ ONLY** in the foreign table. To export data, use **WRITE ONLY**. |
| WITH error_table_name | Error table name: **product_info_err** | Data format errors during import are recorded in the table specified by **product_info_err**. You can query this table after the import to obtain error details. |

For more configuration items, see **12.14.60 CREATE FOREIGN TABLE (for Import and Export)**.

**----End**

# 5.6 Step 4: Importing Data to GaussDB

**Step 1** Run the following statements to create the target table **product_info** in GaussDB to store imported data:

```
openGauss=# DROP TABLE IF EXISTS product_info;
openGauss=# CREATE TABLE product_info
(
    product_price               integer        not null,
    product_id                  char(30)       not null,
    product_time                date           ,
    product_level               char(10)       ,
    product_name                varchar(200)   ,
    product_type1               varchar(20)    ,
    product_type2               char(10)       ,
    product_monthly_sales_cnt   integer        ,
    product_comment_time        date           ,
    product_comment_num         integer        ,
    product_comment_content     varchar(200)
)
WITH (
orientation = column,
compression=middle
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
)
DISTRIBUTE BY hash (product_id);
```

**Step 2** (Optional) This step is not required in this example because no index is created in **Step 1**. If the target table has indexes, the index information will be incrementally updated during import, affecting data import performance. You are advised to delete the indexes from the target table before the import. You can create the indexes again after the import is complete.

1. Assume that there is an ordinary index **product_idx** in the **product_id** column of the target table **product_info**. Delete the index in the table.
   ```
   openGauss=# DROP INDEX product_idx;
   ```
2. After importing the data, create the index again.
   ```
   openGauss=# CREATE INDEX product_idx ON product_info(product_id);
   ```
3. Set **enable_stream_operator** to **on**.
   ```
   openGauss=# set enable_stream_operator=on;;
   ```

NOTE

- You can temporarily add the GUC parameter **maintenance_work_mem** or **psort_work_mem** to accelerate index recreation.
- To import foreign tables in parallel, you must enable the stream operator.
- If **enable_stream_operator** is set to **on**, the performance is affected. If there are other SQL statements to be executed in the session, you are advised to set **enable_stream_operator** to **off**. If there is no SQL statement to be executed in the session, disconnect the session.

**Step 3** Import data from source data files to the **product_info** table through the foreign table **product_info_ext**.

```
openGauss=# INSERT INTO product_info SELECT * FROM product_info_ext ;
```

If information similar to the following is displayed, the data has been imported:

```
INSERT 0 20
```

**Step 4** Run **SELECT** to view the data imported to the target table **product_info** in GaussDB.

```
openGauss=# SELECT count(*) FROM product_info;
```

If the following information is displayed, the import is successful:

```
count
-------
    20
(1 row)
```

**----End**

# 5.7 Step 5: Analyzing and Handling Import Errors

This section describes how to handle data format errors that occurred during import. If no error information is reported, skip this section.

**Step 1** Query error information in the error table.

```
openGauss=# SELECT * FROM product_info_err ;
```

**Step 2** Handle errors if any.

In this tutorial, there should be no error information in the error table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Alternatively, you can change **FILL_MISSING_FIELDS** and **IGNORE_EXTRA_DATA** in the foreign table created in **5.4 Step 2: Installing, Configuring, and Starting GDS on a Data Server** to **false**, and import the data again. Then, query the error table. In this case, you will find the following data format error information:

- The last column **product_comment_content** of the second row in the **product_info2.csv** source data file is lost.
- The number of columns in the third row in the **product_info2.csv** source data file is greater than that defined in the foreign table.

```
openGauss=# select * from product_info_err;
 nodeid |          begintime          |          filename          | rownum |                                rawrecord                                 |                  detail
--------+-----------------------------+----------------------------+--------+--------------------------------------------------------------------------+-------------------------------------------
      0 | 2018-08-31 15:57:32.221265+08 | /input_data/product_info2.csv |      2 | 98,"FKQB-I",2017-09-15,"B","2017 new shoes men","red","M",4345,2017-09-18,5473              | missing data for column "product_comment_content"
      0 | 2018-08-31 15:57:32.221265+08 | /input_data/product_info2.csv |      3 | 50,"DMQY-K",2017-09-21,"A","2017 pants men","red","37",28,2017-09-25,58,"good","good","good" | extra data after last expected column
(2 rows)
```

For details about error tables and troubleshooting, see **8.1.7 Handling Import Errors**.

**----End**

# 5.8 Step 6: Improving Query Efficiency After Data Import

After data is imported, run the **ANALYZE** statement to generate table statistics. The statistics data is useful when you run the planner, which provides you with an efficient query execution plan.

If a large number of rows were updated or deleted during import, run **VACUUM FULL** before **ANALYZE**. A large number of updates and delete operations generate huge disk page fragments, which reduces the query efficiency. **VACUUM FULL** can restore disk page fragments and return them to the OS.

**Step 1** Run **VACUUM FULL** on the **product_info** table.

```
openGauss=# VACUUM FULL product_info;
VACUUM
```

**Step 2** Update statistics in the **product_info** table.

```
openGauss=# ANALYZE product_info;
ANALYZE
```

**----End**

# 5.9 Step 7: Stopping GDS

Stop GDS after data is imported successfully.

## Procedure

**Step 1** Log in as user **gds_user** to the data server where GDS is installed.

**Step 2** Perform the following operations to stop GDS:

1. Query the GDS process ID. The GDS process ID is 128954.

```
ps -ef|grep gds
gds_user 128954     1  0 15:03 ?        00:00:00 gds -d /input_data/ -p 192.168.0.90:5000 -
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
l /opt/bin/gds/gds_log.txt  -D
gds_user 129003 118723  0 15:04 pts/0    00:00:00 grep gds
```

2. Run the **kill** command to stop GDS. **128954** in the command is the GDS process ID.

```
kill -9 128954
```

**----End**

# 5.10 Step 8: Cleaning Up Resources

After completing operations in this tutorial, if you no longer need to use the resources created during the operations, you can delete them to avoid resource waste or quota occupation.

## Deleting the Foreign Table and Target Table

**Step 1** Run the following command to delete the target table **product_info**:

```
openGauss=# DROP TABLE product_info;
```

If the following information is displayed, the target table has been deleted:

```
DROP TABLE
```

**Step 2** Run the following command to delete the foreign table **product_info_ext**:

```
openGauss=# DROP FOREIGN TABLE product_info_ext;
```

If the following information is displayed, the foreign table has been deleted:

```
DROP FOREIGN TABLE
```

**----End**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 6 Application Development Guide

## 6.1 Development Specifications

If the connection pool mechanism is used during application development, comply with the following specifications:

- If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
- If a temporary table is used, delete the temporary table before you return the connection to the connection pool.

If you do not do so, the connection state in the connection pool will remain, which affects subsequent operations using the connection pool.

Compatibility:

The new driver is forward compatible with the database. However, to use the new features added to the driver and database, you must upgrade the database.

If the driver is used in a multi-thread environment:

The JDBC driver is not thread-safe and does not guarantee that the connection methods are synchronized. The caller synchronizes the calls to the driver.

Table 6-1 describes the compatibility of application development drivers.

**Table 6-1** Description of compatibility

| Driver | Compatibility |
| --- | --- |
| JDBC | The driver is forward compatible with earlier database versions. However, to use the new features added to the driver and database, you must upgrade the database. |
| ODBC, libpq, and Psycopg | The driver version must match the database version. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 6.2 Obtaining the Driver Package

## Obtaining the Driver Package

Download the required packages listed in **Table 6-2**.

**Table 6-2** Driver package download list

| Version | Download Address |
| --- | --- |
| 2.*x* | **Driver package**<br>**Verification package for the driver package** |

To prevent a software package from being tampered with during transmission or storage, download the corresponding verification package and perform the following steps to verify the software package:

1. Upload the software package and verification package to the same directory on a Linux VM.
2. Run the following command to verify the integrity of the software package:

   **cat** *GaussDB_driver.zip.sha256* **| sha256sum --check**

   If **OK** is displayed in the command output, the verification is successful.

   ```
   GaussDB_driver.zip: OK
   ```

# 6.3 Development Based on JDBC

Java Database Connectivity (JDBC) is a Java API for running SQL statements. It provides unified access interfaces for different relational databases, based on which applications process data. The GaussDB library supports JDBC 4.0 and requires JDK 1.8 for code compiling. It does not support JDBC-ODBC bridge.

## 6.3.1 JDBC Package, Driver Class, and Environment Class

### JDBC Package

Obtain the driver package named **GaussDB-Kernel-*VxxxRxxxCxx-OS version number*-64bit-Jdbc.tar.gz**.

After the decompression, you will obtain the following JDBC packages in .jar format:

- **gsjdbc4.jar**: The driver class name and loading path are the same as those of PostgreSQL driver, which facilitates the migration of services running on PostgreSQL. However, some interfaces supported by **gsjdbc4.jar** are different from those supported by PostgreSQL and need to be adjusted on the service side.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- **gsjdbc200.jar**: The driver class name and loading path are the same as those of GaussDB 200, which facilitates the migration of services running on GaussDB 200. However, some interfaces supported by **gsjdbc200.jar** are different from those supported by GaussDB 200 and need to be adjusted on the service side.
- **opengaussjdbc.jar**: The main class name is **com.huawei.opengauss.jdbc.Driver**. The URL prefix of the database connection is **jdbc:opengauss**. This driver package is recommended. This driver package is used when both PostgreSQL and GaussDB are accessed in a JVM process.

**NOTICE**

- The loading paths of driver classes in different driver packages are different, but the interface functions are the same.
- The **gsjdbc4** driver package cannot be used to operate the PostgreSQL database. Although the connection can be successfully established in some versions, some interface behaviors are different from those of PostgreSQL JDBC, which may cause unknown errors.
- The PostgreSQL driver package cannot be used to operate the GaussDB database. Although the connection can be successfully established in some versions, some interface behaviors are different from those of GaussDB JDBC, which may cause unknown errors.

## Driver Class

Before creating a database connection, load the database driver class **org.postgresql.Driver** (decompressed from **gsjdbc4.jar**).

**NOTE**

1. GaussDB is compatible with PostgreSQL in the use of JDBC. Therefore, when two JDBC drivers are used in the same process, class names may conflict.
2. JDBC of this version does not support identity & access management suite (IAM) for authentication.
3. Compared with the PostgreSQL driver, the GaussDB JDBC driver has the following enhanced features:
    1. The SHA256 encryption mode is supported for login.
    2. The third-party log framework that implements the sf4j API can be connected.
    3. Distributed load balancing at the connection level is supported.
    4. DR failover is supported.

## Environment Class

The JDK1.8 must be configured on the client. JDK supports multiple platforms such as Windows and Linux. The following uses Windows as an example to describe how to configure JDK.

**Step 1** In the MS-DOS window, run **java -version** to check the JDK version. Ensure that the version is JDK 1.8. If the JDK is not installed, download the installation package and install it.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Step 2** On the Windows desktop, right-click **This PC** and choose **Properties** from the shortcut menu.

**Step 3** In the displayed **System** window, click **Advanced system settings** in the navigation tree on the left.

**Step 4** In the **System Properties** dialog box, click **Environment Variables** in the lower right corner.

**Step 5** In the **System variables** area of the **Environment Variables** dialog box that is displayed, set the following variables.

| Variable | Operation | Variable Value |
| --- | --- | --- |
| JAVA_HOME | • If the variable exists, click **Edit**.<br>• If the variable does not exist, click **New**. | Specifies the Java installation directory.<br>Example: C:\Program Files\Java\jdk1.8.0_131 |
| Path | Edit | • If JAVA_HOME is configured, add **%JAVA_HOME%\bin** before the variable value.<br>• If JAVA_HOME is not configured, add the full Java installation path before the variable value:<br>C:\Program Files\Java\jdk1.8.0_131\bin; |
| CLASSPATH | New | .;%JAVA_HOME%\lib;%JAVA_HOME%\lib\tools.jar; |

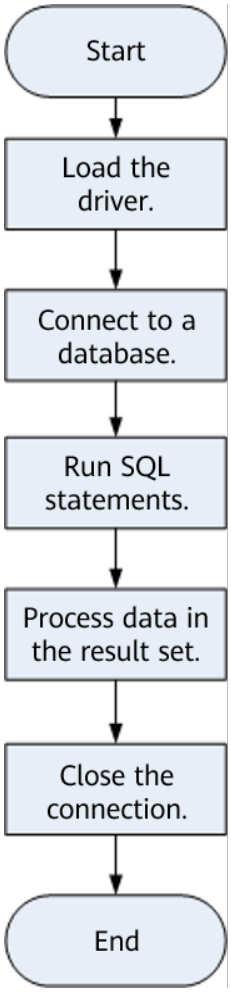
**Step 6** Click **OK** and close the windows one by one.

**----End**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## 6.3.2 Development Process

**Figure 6-1** Application development process based on JDBC



## 6.3.3 Loading a Driver

Load the database driver before creating a database connection.

You can load the driver in the following ways:

- Before creating a connection, implicitly load the driver in the code using the Class.forName("org.postgresql.Driver") method.
- During the JVM startup, transfer the driver as a parameter to JVM using the **java -Djdbc.drivers=org.postgresql.Driver jdbctest** argument.

  NOTE

  - **jdbctest** is the name of a test application.
  - If **opengaussjdbc.jar** is used, change the driver class name to **com.huawei.opengauss.jdbc.Driver**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 6.3.4 Connecting to a Database

After a database is connected, you can use JDBC to run SQL statements to operate data.

## Function Prototype

JDBC provides the following three database connection methods:

- DriverManager.getConnection(String url);
- DriverManager.getConnection(String url, Properties info);
- DriverManager.getConnection(String url, String user, String password);

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Parameters

**Table 6-3** Database connection parameters

| Parameter | Description |
| --- | --- |
| url | **gsjdbc4.jar** database connection descriptor. The format is as follows:<br>• jdbc:postgresql: (The default database name is the same as the username.)<br>• jdbc:postgresql:database<br>• jdbc:postgresql://host/database (If the port number is not specified, the default port number is used.)<br>• jdbc:postgresql://*host*:*port*/*database*<br>• jdbc:postgresql://*host*:*port*/*database*?*param1*=*value1*&*param2*=*value2*<br>• jdbc:postgresql://*host1*:*port1*,*host2*:*port2*/*database*?*param1*=*value1*&*param2*=*value2*<br>**NOTE**<br>If **gsjdbc200.jar** is used, replace **jdbc:postgresql** with **jdbc:gaussdb**.<br>• **database** indicates the name of the database to connect.<br>• **host** indicates the name or IP address of the database server.<br>For security purposes, the database CN forbids access from other nodes in the cluster without authentication. To access the CN from inside the cluster, deploy the JDBC program on the host where the CN is located and set **host** to **127.0.0.1**. Otherwise, the error message "FATAL: Forbid remote connection with trust method!" may be displayed.<br>It is recommended that the service system be deployed outside the cluster. If it is deployed inside, database performance may be affected.<br>By default, the local host is used to connect to the server.<br>• **port** indicates the port number of the database server.<br>By default, the database on port 5431 of the local host is connected.<br>• **param** indicates a database connection attribute.<br>The parameter can be configured in the URL. The URL starts with a question mark (?), uses an equal sign (=) to assign a value to the parameter, and uses an ampersand (&) to separate parameters. You can also use the attributes of the **info** object for configuration. For details, see the example below.<br>• **value** indicates the database connection attribute values.<br>• In a distributed environment, you are advised to configure the **autoBalance** parameter for the connection strings for load balancing and configure at least two CNs to prevent connection setup failures due to node faults. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| info | Database connection attributes (all attributes are case sensitive). Common attributes are described as follows:<br>• **PGDBNAME**: string type. This parameter specifies the database name. You do not need to set this parameter in the URL because the database name is automatically parsed from the URL.<br>• **PGHOST**: string type. This parameter specifies the host IP address. Use colons (:) to separate IP addresses and port numbers, and use commas (,) to separate multiple CNs. (This parameter does not need to be set in the URL. The system automatically parses the URL to obtain its value.) For details, see the example below.<br>• **PGPORT**: integer type. This parameter specifies the host port number. Use colons (:) to separate IP addresses and port numbers, and use commas (,) to separate multiple CNs. (This parameter does not need to be set in the URL. The system automatically parses the URL to obtain its value.) For details, see the example below.<br>• **user**: string type. This parameter specifies the database user who creates the connection.<br>• **password**: string type. This parameter specifies the password of the database user.<br>• **enable_ce**: string type. If **enable_ce** is set to **1**, JDBC supports encrypted equality queries.<br>• **refreshClientEncryption**: string type. If **refreshClientEncryption** is set to **1** (default value), the encrypted database supports cache update on the client.<br>• **loggerLevel**: string type. The following log levels are supported: **OFF**, **INFO**, **DEBUG**, and **TRACE**. Set this parameter to **OFF** to disable the log function. **INFO**, **DEBUG** and **TRACE** logs record information of different levels.<br>• **loggerFile**: string type. This parameter specifies the log output path (directory and file name). If only the file name is specified and the directory is not specified, logs are generated in the client running program directory. If no path is configured or the configured path does not exist, logs are output through flows by default. This parameter has been discarded and does not take effect. To use this parameter, you can configure it in the **java.util.logging** attribute file or system attributes.<br>• **logger**: string type. It indicates the log output framework used by the JDBC driver. The JDBC driver supports the log output framework used for interconnecting with applications. Currently, only the third-party Slf4j-API-based log framework is supported. For details, see **6.2.9 Log Management**.<br>1. If this parameter is not set or is set to **JDK LOGGER**, JDK LOGGER is used.<br>2. Otherwise, the slf4j-API-based third-party log framework must be used. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| | • **allowEncodingChanges**: Boolean type. If this parameter is set to **true**, the character set type can be changed. This parameter is used together with **characterEncoding=CHARSET** to set the character set. The two parameters are separated by ampersands (&). The value of **characterEncoding** can be **UTF8**, **GBK**, or **LATIN1**.<br>• **currentSchema**: string type. This parameter specifies the schema to be set in **search-path**.<br>• **loadBalanceHosts**: Boolean type. In the default mode (disabled), multiple hosts specified in the URL are connected in sequence. If load balancing is enabled, the shuffle algorithm is used to randomly select a host from the candidate hosts to establish a connection.<br>• **autoBalance**: string type.<br>1. If this parameter is set to **true**, **balance**, or **roundrobin**, the JDBC load balancing function is enabled to balance multiple connections of an application to each CN available in the database cluster. Example: jdbc:postgresql://host1:port1,host2:port2/database?autoBalance=true<br>JDBC periodically obtains the list of available CNs in the entire cluster. For example, the obtained list is **host1:port1,host2:port2,host3:port3,host4:port4**. The **refreshCNIpListTime** parameter specifies the interval for obtaining the list, and the default value is **10s**. Hosts obtained from the CN list are data IP addresses. Generally, floating IP addresses are used in the cloud environment. Before using the load balancing capability, ensure that the access permissions of the data IP addresses have been added.<br>When **autoBalance** is enabled on **host1** and **host2**, HA is implemented only for the first connection. The JDBC driver will select available CNs from **host1**, **host2**, **host3**, and **host4** in sequence to update the available CN listm and new connections will be established on **host1**, **host2**, **host3**, and **host4** using the RoundRobin algorithm.<br>2. **priority***n* indicates that the JDBC-based load balancing function is enabled. Multiple connections of an application are balanced to the first *n* available CNs configured in the URL. When the first *n* CNs are unavailable, connections are randomly allocated to other available CNs in the database cluster. *n* is a number not less than 0 and less than the number of CNs configured in the URL. Example: jdbc:postgresql://host1:port1,host2:port2,host3:port3,host4:port4/database?autoBalance=priority2<br>JDBC periodically obtains the list of available CNs in the entire cluster (defined by **refreshCNIpListTime**). For example, the obtained list is |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| | **host1:port1,host2:port2,host3:port3,host4:port4,host5:port5,host6:port6**, where **host1** and **host2** are in **AZ1**, and **host3** and **host4** are in **AZ2**.<br>The JDBC driver preferentially selects **host1** and **host2** for load balancing. If both **host1** and **host2** are unavailable, the JDBC driver randomly selects a CN from **host3**, **host4**, **host5**, and **host6** for connection.<br>3. If this parameter is set to **shuffle**, JDBC random load balancing is enabled to randomly and evenly distribute multiple connections of the application to available CNs in the database cluster. Example: jdbc:postgresql://host1:port1,host2:port2,host3:port3/database?autoBalance=shuffle<br>JDBC periodically obtains the list of available CNs in the entire cluster. For example, the obtained list is **host1:port1,host2:port2,host3:port3,host4:port4**. The **refreshCNIpListTime** parameter specifies the interval for obtaining the list, and the default value is **10s**.<br>For the first connection, **host1:port1,host2:port2,host3:port3** is used for HA. For subsequent connections, the shuffle algorithm is used to randomly select a CN from the refreshed CN list.<br>4. If this parameter is set to **false**, the JDBC load balancing and priority-based load balancing functions are disabled. The default value is **false**.<br>**CAUTION**<br>1. Load balancing is based on the connection level rather than the transaction level. If the connection is persistent and the load on the connection is unbalanced, the load on the CN may be unbalanced.<br>2. Load balancing can be used only in distributed scenarios and cannot be used in centralized scenarios.<br>• **refreshCNIpListTime**: integer type. This parameter specifies the interval at which JDBC periodically checks the status of CNs in the database cluster and obtains the IP address list of available CNs. The default value is 10 seconds.<br>• **hostRecheckSeconds**: integer type. After JDBC attempts to connect to a host, the host status is saved: connection success or connection failure. This status is trusted within the duration specified by **hostRecheckSeconds**. After the duration expires, the status becomes invalid. The default value is 10 seconds.<br>• **ssl**: Boolean type. This parameter specifies a connection in SSL mode. When **ssl** is set to **true**, the NonValidatingFactory channel and certificate mode are supported.<br>1. For the NonValidatingFactory channel, configure the username and password and set **SSL** to **true**.<br>2. In certification mode, configure the client certificate, key, and root certificate, and set **SSL** to **true**. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| | • **sslmode**: string type. This parameter specifies the SSL authentication mode. The value can be **require**, **verify-ca**, or **verify-full**.<br>– **require**: The system only attempts to set up an SSL connection. It neither checks whether the server certificate is issued by a trusted CA, nor checks whether the host name of the server is the same as that in the certificate.<br>– **verify-ca**: attempts to set up an SSL connection and checks whether the server certificate is issued by a trusted CA.<br>– **verify-full**: The system attempts to set up an SSL connection, checks whether the server certificate is issued by a trusted CA, and checks whether the host name of the server is the same as that in the certificate.<br>• **sslcert**: string type. This parameter specifies the complete path of the certificate file. The type of the client and server certificates is **End Entity**.<br>• **sslkey**: string type. This parameter specifies the complete path of the key file. You need to convert the client certificate to the DER format. For details, see **6.3.5 Connecting to the Database (Using SSL)**.<br>• **sslrootcert**: string type. This parameter specifies the name of the SSL root certificate. The root certificate type is CA.<br>• **sslpassword**: string type. This parameter is provided for ConsoleCallbackHandler.<br>• **sslpasswordcallback**: string type. This parameter specifies the class name of the SSL password provider. The default value is **org.postgresql.ssl.jdbc4.LibPQFactory.ConsoleCallbackHandler**.<br>• **sslfactory**: string type. This parameter specifies the class name used by SSLSocketFactory to establish an SSL connection.<br>• **sslprivatekeyfactory**: string type. This parameter specifies the fully qualified name of the implementation class of the **org.postgresql.ssl.PrivateKeyFactory** interface that implements the private key decryption method. If this parameter is not specified, try the default JDK private key decryption algorithm. If the decryption fails, use **org.postgresql.ssl.BouncyCastlePrivateKeyFactory**. You need to provide the **bcpkix-jdk15on.jar** package. The recommended version is 1.65 or later.<br>• **sslfactoryarg**: string type. The value is an optional parameter of the constructor function of the **sslfactory** (This parameter is not recommended).<br>• **sslhostnameverifier**: string type. This parameter specifies the class name of the host name verifier. The interface must implement javax.net.ssl.HostnameVerifier. The default value is **org.postgresql.ssl.PGjdbcHostnameVerifier**.<br>• **loginTimeout**: integer type. This parameter specifies the waiting time for establishing the database connection, in seconds. When multiple IP |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| | addresses are configured in the URL, if the time for obtaining the connection exceeds the value of this parameter, the connection fails and the subsequent IP addresses are not tried.<br>• **connectTimeout**: integer type. This parameter specifies the timeout duration for connecting to a server, in seconds. If the time taken to connect to a server exceeds the value specified, the connection is interrupted. If the value is **0**, the timeout mechanism is disabled. When multiple IP addresses are configured in the URL, this parameter indicates the timeout interval for connecting to a single IP address.<br>• **socketTimeout**: integer type. This parameter specifies the timeout duration for a socket read operation, in seconds. If the time taken to read data from a server exceeds the value specified, the connection is closed. If the value is **0**, the timeout mechanism is disabled.<br>• **cancelSignalTimeout**: integer type. Cancel messages may cause a block. This parameter controls **connectTimeout** and **socketTimeout** in a cancel message, in seconds. The default value is 10 seconds.<br>• **tcpKeepAlive**: Boolean type. This parameter is used to enable or disable TCP keepalive detection. The default value is **false**.<br>• **logUnclosedConnections**: Boolean type. The client may leak a connection object because it does not call the connection object's close() method. These objects will be collected as garbage and finalized using the finalize() method. If the caller ignores this operation, this method closes the connection.<br>• **assumeMinServerVersion** (discarded): string type. This parameter indicates the version of the server to connect.<br>• **ApplicationName**: string type. This parameter specifies the name of the application that is being connected. You can query the **pgxc_stat_activity** table on the CN to view information about the client that is being connected. The name is displayed in the **application_name** column. The default value is **PostgreSQL JDBC Driver**.<br>• **connectionExtraInfo**: Boolean type. This parameter specifies whether the JDBC driver reports the driver deployment path and process owner to the database.<br>The value can be **true** or **false**. The default value is **false**. If **connectionExtraInfo** is set to **true**, the JDBC driver reports the driver deployment path, process owner, and URL connection configuration information to the database and displays the information in the **connection_info** parameter. In this case, you can query the information from **PG_STAT_ACTIVITY** or **PGXC_STAT_ACTIVITY**.<br>• **autosave**: string type. The value can be **always**, **never**, or **conservative**. The default value is **never**. This parameter specifies the action that the driver should perform upon a query failure. If **autosave** is set to **always**, the JDBC driver sets a savepoint before each query and |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| | rolls back to the savepoint if the query fails. If **autosave** is set to **never**, there is no savepoint. If **autosave** is set to **conservative**, a savepoint is set for each query. However, the system rolls back and retries only when there is an invalid statement.<br>• **protocolVersion**: integer type. This parameter specifies the connection protocol version. Only versions 1 and 3 are supported. Note: If this parameter is set to **1**, only the V1 server is connected. MD5 encryption is used when this parameter is set to **3**. You need to set **password_encryption_type** to **1** to change the database encryption mode. After the cluster is restarted, create a user that uses MD5 encryption to encrypt passwords. You must also change the client connection mode to **md5** in the **pg_hba.conf** file. Log in to the system as the new user. (You are not advised to set this parameter because the MD5 encryption algorithm has lower security and poses security risks.)<br>**NOTE**<br>The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.<br>• **prepareThreshold**: integer type. This parameter specifies the number of times that the PreparedStatement object is executed before the prepared statement on the server is used. The default value is **5**, indicating that when the same PreparedStatement object is executed for five or more times, the parse message is not sent to the server to parse the statement. Instead, the statement that has been parsed on the server is used.<br>• **preparedStatementCacheQueries**: integer type. This parameter specifies the maximum number of queries generated by the cache statement object of each connection. The default value is **256**. If the number of queries generated by the statement object is greater than 256, the least recently used queries will be discarded from the cache. The value **0** indicates that the cache function is disabled.<br>• **preparedStatementCacheSizeMiB**: integer type. This parameter specifies the maximum number of queries generated by the cache statement object of each connection. The unit is MB. The default value is **5**. If the size of the cached queries exceeds 5 MB, the least recently used query cache will be discarded. The value **0** indicates that the cache function is disabled.<br>• **databaseMetadataCacheFields**: integer type. The default value is **65536**. This parameter specifies the maximum number of columns that can be cached in each connection. The value **0** indicates that the cache function is disabled.<br>• **databaseMetadataCacheFieldsMiB**: integer type. The default value is **5**. This parameter indicates the maximum size of columns that can be cached in each connection, in MB. The value **0** indicates that the cache function is disabled. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| | • **stringtype**: string type. The value can be **unspecified** or **varchar**. This parameter specifies the type of the **PreparedStatement** parameter used by the setString() method. If **stringtype** is set to **varchar**, these parameters are sent to the server as varchar parameters. If **stringtype** is set to **unspecified**, these parameters are sent to the server as an untyped value, and the server attempts to infer their appropriate type.<br>• **batchMode**: string type. This parameter specifies whether to connect the database in batch mode. The default value is **on**, indicating that the batch mode is enabled.<br>• **fetchsize**: integer type. This parameter specifies the default fetchsize for statements in the created connection. The default value is **0**, indicating that all results are obtained at a time. It is equivalent to **defaultRowFetchSize**.<br>• **reWriteBatchedInserts**: Boolean type. During batch import, set this parameter to **true** to combine *N* insertion statements into one: **insert into TABLE_NAME values(values1, ..., valuesN), ..., (values1, ..., valuesN)**. To use this parameter, set **batchMode** to **off**.<br>• **unknownLength**: integer type. The default value is **Integer.MAX_VALUE**. This parameter specifies the length of the unknown length type when the data of some postgresql types (such as TEXT) is returned by functions such as ResultSetMetaData.getColumnDisplaySize and ResultSetMetaData.getPrecision.<br>• **defaultRowFetchSize**: integer type. This parameter specifies the number of rows read by fetch in ResultSet at a time. Limiting the number of rows read each time in a database access request can avoid unnecessary memory consumption, thereby avoiding out of memory exception. The default value is **0**, indicating that all rows are obtained at a time in ResultSet. This parameter cannot be set to a negative value.<br>• **binaryTransfer**: Boolean type. This parameter specifies whether data is sent and received in binary format. The default value is **false**.<br>• **binaryTransferEnable**: string type. This parameter specifies the type for which binary transmission is enabled. Every two types are separated by commas (,). You can select either the OID or name, for example, **binaryTransferEnable=INT4_ARRAY,INT8_ARRAY**.<br>For example, if the OID name is **BLOB** and the OID number is **88**, you can configure the OID as follows:<br>**binaryTransferEnable=BLOB** or **binaryTransferEnable=88**<br>• **binaryTransferDisEnable**: string type. This parameter specifies the type for which binary transmission is disabled. Every two types are separated by commas (,). You can select either the OID or name. The value of this parameter overwrites the value of **binaryTransferEnable**.<br>• **blobMode**: string type. This parameter is used to set the data type of parameters bound to the setBinaryStream method. If the value is **on**, |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| | the data type is blob. If the value is **off**, the data type is bytea. The default value is **on**. You are advised to set this parameter to **on** for systems migrated from Oracle and MySQL and to **off** for systems migrated from PostgreSQL.<br>• **socketFactory**: string type. This parameter specifies the name of the class used to create a socket connection with the server. This class must implement the **javax.net.SocketFactory** interface and define a constructor with no parameter or a single string parameter.<br>• **socketFactoryArg**: string type. The value is an optional parameter of the constructor function of the socketFactory class and is not recommended.<br>• **receiveBufferSize**: integer type. This parameter is used to set **SO_RCVBUF** on the connection stream.<br>• **sendBufferSize**: integer type. This parameter is used to set **SO_SNDBUF** on the connection stream.<br>• **preferQueryMode**: string type. The value can be **extended**, **extendedForPrepared**, **extendedCacheEverything**, or **simple**. This parameter specifies the query mode. The default value is **extended**. In **simple** mode, only the Q message in text mode can be sent. The parse and bind messages are not supported. In **extended** mode, parse, bind, and execute messages are used. In **extendedForPrepared** mode, only the prepared statement object uses extended query, and the statement object uses only simple query. The **extendedCacheEverything** mode caches the query generated by each statement object.<br>• **ApplicationType**: string type. The value can be **not_perfect_sharding_type** or **perfect_sharding_type**. It indicates whether to enable distributed write and query. The default value is **not_perfect_sharding_type**. Distributed write and query are enabled if this parameter is set to **not_perfect_sharding_type**. If it is set to **perfect_sharding_type**, distributed write and query are disabled by default. Distributed write and query can be performed only when **/* multinode */** is added to the SQL statement. This parameter is valid only when the database is in the GTM-free scenario.<br>• **priorityServers**: integer type. This value is used to specify the first *n* nodes configured in the URL as the primary cluster to be connected preferentially. The default value is **null**. The value is a number greater than 0 and less than the number of CNs configured in the URL. It is used in streaming DR scenarios.<br>Example: jdbc:postgresql://host1:port1,host2:port2,host3:port3,host4:port4,/database?priorityServers=2. That is, **host1** and **host2** are primary cluster nodes, and **host3** and **host4** are DR cluster nodes.<br>• **usingEip**: Boolean type. The value specifies whether to use the elastic IP address for load balancing. The default value is **true**, indicating that |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| | an elastic IP address is used for load balancing. The value **false** indicates that a data IP address is used for load balancing.<br>• **iamUser**: string type. The fully-encrypted database encrypts data on the client. During encryption, you can access the Key Management Service (KMS) provided by Huawei Cloud to obtain keys. When accessing the KMS, you need to provide the IAM identity authentication information and KMS project information. **iamUser** and **iamPassword** are used to set identity authentication information. **kmsDomain**, **kmsProjectId**, and **kmsProjectName** are used to set KMS project information. To obtain the preceding five parameters, log in to the Huawei Cloud official website and choose **Console** > **My Credential**.<br>• **iamPassword**: string type, used to set the password of the IAM user.<br>• **kmsDoamin**: string type, used to set the Huawei Cloud account to which the KMS belongs.<br>• **kmsProjectName**: string type, used to set the deployment zone of a KMS project. KMS projects deployed in different zones are isolated from each other.<br>• **kmsProjectId**: string type, used to set the ID of a KMS project.<br>• **traceInterfaceClass**: string type. The default value is **null**, which is used to obtain the implementation class of **traceId**. The value is the fully qualified name of the implementation class of the **org.postgresql.log.Tracer** API that implements the method for obtaining **traceId**.<br>• **use_boolean**: Boolean type. This parameter is used to set the OID type bound to the setBoolean method in extended mode. The default value is **false**, indicating that the int2 type is bound. The value **true** indicates that the Boolean type is bound.<br>• **allowReadOnly**: Boolean type. This parameter specifies whether the read-only mode is allowed. The default value is **true**, indicating that the read-only mode is allowed. If this parameter is set to **false**, the read-only mode is disabled.<br>• **TLSCiphersSupperted**: string type. This parameter is used to set the supported TLS encryption suite. The default value is **TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,TLS_DHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384**.<br>• **stripTrailingZeros**: Boolean type. The default value is **false**. If this parameter is set to **true**, trailing 0s of the numeric type are removed. This parameter is valid only for **ResultSet.getObject(int columnIndex)**.<br>• **enableTimeZone**: Boolean type. The default value is **true**. This parameter specifies whether to enable the time zone setting on the |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| | server. The value **true** indicates that the JVM time zone is obtained to specify the database time zone. The value **false** indicates that the database time zone is used.<br>• **socketTimeoutInConnecting**: integer type. The default value is **5s**. It specifies the timeout value for a socket read operation during connection establishment. If the time taken to read data from a server exceeds the value specified during connection establishment, the connection is closed. If the value is **0**, the timeout mechanism is disabled. |
| user | Database user. |
| password | Password of the database user. |

NOTE

After the **uppercaseAttributeName** parameter is enabled, if the database contains metadata with a mixture of uppercase and lowercase letters, only the metadata in lowercase letters can be queried and output in uppercase letters. Before using the metadata, ensure that the metadata is stored in lowercase letters to prevent data errors.

## Examples

```
// The following uses gsjdbc4.jar as an example.
// The following code encapsulates database connection operations into an interface. The database can then be connected using an authorized username and a password.
public static Connection getConnect(String username, String passwd)
   {
      // Driver class.
      String driver = "org.postgresql.Driver";
      // Database connection descriptor.
      String sourceURL = "jdbc:postgresql://10.10.0.13:8000/postgres";
      Connection conn = null;

      try
      {
         // Load the driver.
         Class.forName(driver);
      }
      catch( Exception e )
      {
         e.printStackTrace();
         return null;
      }

      try
      {
          // Create a connection.
         conn = DriverManager.getConnection(sourceURL, username, passwd);
         System.out.println("Connection succeed!");
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
        }
        catch(Exception e)
        {
            e.printStackTrace();
            return null;
        }

        return conn;
    }
// The following code uses the Properties object as a parameter to establish a connection.
public static Connection getConnectUseProp(String username, String passwd)
    {
        // Driver class.
        String driver = "org.postgresql.Driver";
        // Database connection descriptor.
        String sourceURL = "jdbc:postgresql://10.10.0.13:8000/postgres?autoBalance=true";
        Connection conn = null;
        Properties info = new Properties();

        try
        {
            // Load the driver.
            Class.forName(driver);
        }
        catch( Exception e )
        {
            e.printStackTrace();
            return null;
        }

        try
        {
             info.setProperty("user", username);
             info.setProperty("password", passwd);
             // Create a connection.
             conn = DriverManager.getConnection(sourceURL, info);
             System.out.println("Connection succeed!");
        }
        catch(Exception e)
        {
            e.printStackTrace();
            return null;
        }

        return conn;
    }
```

# 6.3.5 Connecting to the Database (Using SSL)

When establishing connections to the GaussDB server using JDBC, you can enable SSL connections to encrypt client and server communications for security of sensitive data transmission on the Internet. This section describes how applications establish an SSL connection to GaussDB using JDBC. To start the SSL mode, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

## Configuring the Client

Unlike GSQL program, the JDBC driver supports server certificate validation by default. If a CA certificate is in use, no configuration is required because Java has copies of the most common CAs' certificates. If a self-signed license is in use, a client program must be configured based on the openssl or Java keytool for license authentication. The procedure is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

> **NOTE**
>
> If the built-in certificate is used, the following steps are valid.

**Step 1** Upload the certificate file on the client.

1. Log in to the host where the client resides as a common user.
2. Create the **/tmp/cacert** directory.
   ```
   mkdir /tmp/cacert
   ```
3. Save the root certificate file, client certificate file, and private key file to the created directory.

**Step 2** Import the root certificate to TrustStore.

```
openssl x509 -in cacert.pem -out cacert.crt.der -outform der
```

Generate the intermediate file **cacert.crt.der**.

```
keytool -keystore mytruststore -alias cacert -import -file cacert.crt.der
```

Enter the trustStorePassword (for example, **xxxxxxxxx**) as prompted to generate **mytruststore**.

- **cacert.pem** indicates the root certificate.
- **cacert.crt.der** indicates the intermediate file.
- **mytruststore** indicates the generated KeyStore name. You can change the name and its alias as needed.

**Step 3** Import the client certificate and key to KeyStore.

```
openssl pkcs12 -export -out client.pkcs12 -in client.crt -inkey client.key
```

Enter the clientkey (for example, **xxxxxxxxx**) as prompted to generate **client.pkcs12**.

```
keytool -importkeystore -deststorepass xxxxxxxxxx -destkeystore client.jks -srckeystore client.pkcs12 -srcstorepass xxxxxxxxx -srcstoretype PKCS12 -alias 1 -destkeypass xxxxxxxxx
```

**deststorepass** must be consistent with **destkeypass**, and **srcstorepass** must be the same as the export password in the preceding command. Generate **client.jks**.

**----End**

## Examples

Note: Select either example 1 or example 2.

```
public class SSL{
    public static void main(String[] args) {
        Properties urlProps = new Properties();
        String urls = "jdbc:postgresql://10.29.37.136:8000/postgres";

        /**
         * ================== Example 1: Use the NonValidatingFactory channel.
         */
        urlProps.setProperty("sslfactory","org.postgresql.ssl.NonValidatingFactory");
        urlProps.setProperty("user", "world");
        urlProps.setProperty("password", "test@123");
        urlProps.setProperty("ssl", "true");
        /**
         * ==================  Examples 2: Use a certificate.
         */
        urlProps.setProperty("sslcert", "client.crt");
        urlProps.setProperty("sslkey", "client.key.pk8");
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
        urlProps.setProperty("sslrootcert", "cacert.pem");
        urlProps.setProperty("user", "world");
        urlProps.setProperty("ssl", "true");
        /* sslmode can be set to require, verify-ca, or verify-full. Select one from the following three
examples.*/
       /* ================== Example 2.1: Set sslmode to require to use the certificate for authentication.
*/
        urlProps.setProperty("sslmode", "require");
       /* ================== Example 2.2: Set sslmode to verify-ca to use the certificate for
authentication. */
        urlProps.setProperty("sslmode", "verify-ca");
       /* ================== Example 2.3: Set sslmode to verify-full to use the certificate (in the Linux
OS) for authentication. */
        urls = "jdbc:postgresql://world:8000/postgres";
        urlProps.setProperty("sslmode", "verify-full");

        try {
            Class.forName("org.postgresql.Driver").newInstance();
        } catch (Exception e) {
            e.printStackTrace();
        }
        try {
            Connection conn;
            conn = DriverManager.getConnection(urls,urlProps);
            conn.close();
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
/**
 * Note: Convert the client key to the DER format.
 * openssl pkcs8 -topk8 -outform DER -in client.key -out client.key.pk8 -nocrypt
 * openssl pkcs8 -topk8 -inform PEM -in client.key -outform DER -out client.key.der -v1 PBE-MD5-DES
 * openssl pkcs8 -topk8 -inform PEM -in client.key -outform DER -out client.key.der -v1 PBE-SHA1-3DES
 * The preceding algorithms are not recommended due to their low security.
 * If the customer needs to use a higher-level private key encryption algorithm, the following private key
encryption algorithms can be used after the BouncyCastle or a third-party private key is used to decrypt the
password package:
 * openssl pkcs8 -in client.key -topk8  -outform DER -out client.key.der -v2 AES128
 * openssl pkcs8 -in client.key -topk8  -outform DER -out client.key.der -v2 aes-256-cbc -iter 1000000
 * openssl pkcs8 -in client.key -topk8 -out client.key.der  -outform Der -v2 aes-256-cbc -v2prf
hmacWithSHA512
 * Enable BouncyCastle: Introduce the bcpkix-jdk15on.jar package for projects that use JDBC. The
recommended version is 1.65 or later.
 */
```

## 6.3.6 Connecting to a Database (Using UDS)

The Unix domain socket is used for data exchange between different processes on the same host. You can add **junixsocket** to obtain the socket factory.

The **junixsocket-core-*XXX*.jar**, **junixsocket-common-*XXX*.jar**, and **junixsocket-native-common-*XXX*.jar** JAR packages need to be referenced. In addition, you need to add **socketFactory=org.newsclub.net.unix.AFUNIXSocketFactory$FactoryArg&socketFactoryArg=** *[path-to-the-unix-socket]* to the URL connection string.

Example:

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.util.Properties;

public class Test {
    public static void main(String[] args) {
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
        String driver = "org.postgresql.Driver";
        Connection conn;
        try {
            Class.forName(driver).newInstance();
            Properties properties = new Properties();
            properties.setProperty("user", "username");
            properties.setProperty("password", "password");
            conn = DriverManager.getConnection("jdbc:postgresql://localhost:8000/postgres?
socketFactory=org.newsclub" +
                            ".net.unix" +
                            ".AFUNIXSocketFactory$FactoryArg&socketFactoryArg=/data/tmp/.s.PGSQL.8000",
                    properties);
            System.out.println("Connection Successful!");
            Statement statement = conn.createStatement();
            statement.executeQuery("select 1");
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

**NOTICE**

- Set the **socketFactoryArg** parameter based on the actual path. The value must be the same as that of the GUC parameter **unix_socket_directory**.
- The connection host name must be set to **localhost**.

# 6.3.7 Running SQL Statements

## Running a Common SQL Statement

To enable an application to operate data in the database by running SQL statements (statements that do not need to transfer parameters), perform the following operations:

**Step 1** Create a statement object by calling the **createStatement** method in **Connection**.

```
Connection conn = DriverManager.getConnection("url","user","password");
Statement stmt = conn.createStatement();
```

**Step 2** Run the SQL statement by calling the **executeUpdate** method in **Statement**.

```
int rc = stmt.executeUpdate("CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name
VARCHAR(32));");
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. The VACUUM operation is not supported in a transaction block. If one of the statements fails, the entire request will be rolled back.
- Use semicolons (;) to separate statements. Stored procedures, functions, and anonymous blocks do not support multi-statement execution. When **preferQueryMode** is set to **simple**, the statement does not execute the parsing logic, and the semicolons (;) cannot be used to separate statements in this scenario.
- The slash (/) can be used as the terminator for creating a single stored procedure, function, anonymous block, or package body. When **preferQueryMode** is set to **simple**, the statement does not execute the parsing logic, and the slash (/) cannot be used as the terminator in this scenario.
- When **prepareThreshold** is set to **1**, each SQL statement executed by the statement is cached because cached statements are not evicted by default (default value of **preferQueryMode**). As a result, memory bloat may occur. In this case, set **preferQueryMode** to **extendedCacheEverything** to evict cached statements.

**Step 3** Close the statement object.

```
stmt.close();
```

**----End**

## Running a Prepared SQL Statement

Prepared statements are complied and optimized once but can be used in different scenarios by assigning multiple values. Using prepared statements improves execution efficiency. If you want to run a statement for several times, use a precompiled statement. Perform the following operations:

**Step 1** Create a prepared statement object by calling the **prepareStatement** method in **Connection.**

```
PreparedStatement pstmt = con.prepareStatement("UPDATE customer_t1 SET c_customer_name = ? WHERE c_customer_sk = 1");
```

**Step 2** Set parameters by calling the **setShort** method in **PreparedStatement**.

```
pstmt.setShort(1, (short)2);
```

**Step 3** Run the prepared statement by calling the **executeUpdate** method in **PreparedStatement**.

```
int rowcount = pstmt.executeUpdate();
```

**Step 4** Close the prepared statement object by calling the **close** method in **PreparedStatement**.

```
pstmt.close();
```

**----End**

## Calling a Stored Procedure

To call an existing stored procedure by using JDBC in GaussDB, perform the following operations:

**Step 1** Create a call statement object by calling the **prepareCall** method in **Connection**.

```
Connection myConn = DriverManager.getConnection("url","user","password");
CallableStatement cstmt = myConn.prepareCall("{? = CALL TESTPROC(?,?,?)}");
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Step 2** Set parameters by calling the **setInt** method in **CallableStatement**.

```
cstmt.setInt(2, 50);
cstmt.setInt(1, 20);
cstmt.setInt(3, 90);
```

**Step 3** Register an output parameter by calling the **registerOutParameter** method in **CallableStatement**.

```
cstmt.registerOutParameter(4, Types.INTEGER);  // Register an OUT parameter of the integer type.
```

**Step 4** Call the stored procedure by calling the **execute** method in **CallableStatement**.

```
cstmt.execute();
```

**Step 5** Obtain the output parameter by calling the **getInt** method in **CallableStatement**.

```
int out = cstmt.getInt(4);  // Obtain the OUT parameter.
```

Example:

```
// The following stored procedure (containing the OUT parameter) has been created:
create or replace procedure testproc
(
    psv_in1 in integer,
    psv_in2 in integer,
    psv_inout in out integer
)
as
begin
    psv_inout := psv_in1 + psv_in2 + psv_inout;
end;
/
```

**Step 6** Close the call statement by calling the **close** method in **CallableStatement**.

```
cstmt.close();
```

NOTE

- Many database classes such as Connection, Statement, and ResultSet have a close() method. Close these classes after using their objects. Closing Connection will close all the related Statements, and closing a Statement will close its ResultSet.
- Some JDBC drivers support named parameters, which can be used to set parameters by name rather than sequence. If a parameter has the default value, you do not need to specify any parameter value but can use the default value directly. Even though the parameter sequence changes during a stored procedure, the application does not need to be modified. Currently, the GaussDB JDBC driver does not support this method.
- GaussDB does not support functions containing OUT parameters, or stored procedures and function parameters containing default values.
- When you bind parameters in **myConn.prepareCall("{? = CALL TESTPROC(?,?,?)}")** during a stored procedure calling, you can bind parameters according to the placeholders sequence and register the first or the fourth parameter as the output parameter. The preceding example registers the fourth parameter.

NOTICE

- If JDBC is used to call a stored procedure whose returned value is a cursor, the returned cursor cannot be used.
- A stored procedure and an SQL statement must be run separately.
- Output parameters must be registered for parameters of the inout type in the stored procedure.

**----End**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Batch Processing

When a prepared statement processes multiple pieces of similar data, the database creates only one execution plan. This improves compilation and optimization efficiency. Perform the following operations:

**Step 1** Create a prepared statement object by calling the **prepareStatement** method in **Connection.**

```
Connection conn = DriverManager.getConnection("url","user","password");
PreparedStatement pstmt = conn.prepareStatement("INSERT INTO customer_t1 VALUES (?)");
```

**Step 2** Call the setShort parameter for each piece of data, and call addBatch to confirm that the setting is complete.

```
pstmt.setShort(1, (short)2);
pstmt.addBatch();
```

**Step 3** Perform batch processing by calling the **executeBatch** method in **PreparedStatement**.

```
int[] rowcount = pstmt.executeBatch();
```

**Step 4** Close the prepared statement object by calling the **close** method in **PreparedStatement**.

```
pstmt.close();
```

NOTE

Do not terminate a batch processing action when it is ongoing; otherwise, database performance will deteriorate. Therefore, disable automatic commit during batch processing. Manually commit several rows at a time. The statement for disabling automatic commit is **conn.setAutoCommit(false);**.

**----End**

## Adding Single-Shard Execution Syntaxes to Statements

**Step 1** Set the **nodeName** parameter by calling **setClientInfo("nodeName","dnx")** in **Connection**.

```
Connection conn = getConnection();
conn.setClientInfo("nodeName","datanode1");
```

**Step 2** Execute the SQL statements by using the **executeQuery(String sql)** and **execute(String sql)** methods in **Statement** and the **executeQuery()** and **execute()** methods in **PreparedStatement**.

```
PreparedStatement pstm = conn.prepareStatement("select * from test");
pstm.execute();
pstm.executeQuery();
Statement stmt=conn.createStatement();
stmt.execute("select * from test");
stmt.executeQuery("select * from test");
```

**Step 3** Set the parameter to an empty string to disable it.

```
conn.setClientInfo("nodeName","");
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**NOTICE**

1. This function is adapted based on the single-shard execution function of the kernel. Therefore, before using this function, check whether the database kernel supports single-shard execution.
2. After the parameter is enabled, you must manually disable it. Otherwise, the execution of other query statements will be affected.
3. Once this parameter is enabled, all statements of the current connection will be executed on a specified DN.
4. After the parameter is enabled, the cache mechanism of **PreparedStatement** will be affected, cached statements will be cleared, and subsequent statements executed for single-shard queries will not be cached until the parameter is disabled.
5. The parameter is a connection parameter. Therefore, the parameter value takes effect once. The API cannot be used to execute the statements on different shards at the same time.

**----End**

# 6.3.8 Processing Data in a Result Set

## Setting a Result Set Type

Different types of result sets apply to different application scenarios. Applications select proper types of result sets based on requirements. Before running an SQL statement, you must create a statement object. Some methods of creating statement objects can set the type of a result set. **Table 6-4** lists result set parameters. The related Connection methods are as follows:

```
// Create a Statement object. This object will generate a ResultSet object with a specified type and concurrency.
createStatement(int resultSetType, int resultSetConcurrency);

// Create a PreparedStatement object. This object will generate a ResultSet object with a specified type and concurrency.
prepareStatement(String sql, int resultSetType, int resultSetConcurrency);

// Create a CallableStatement object. This object will generate a ResultSet object with a specified type and concurrency.
prepareCall(String sql, int resultSetType, int resultSetConcurrency);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 6-4** Result set types

| Parameter | Description |
| --- | --- |
| resultSetType | Type of a result set. There are three types of result sets:<br>• **ResultSet.TYPE_FORWARD_ONLY**: The ResultSet object can only be navigated forward. It is the default value.<br>• **ResultSet.TYPE_SCROLL_SENSITIVE**: You can view the modified result by scrolling to the modified row.<br>• **ResultSet.TYPE_SCROLL_INSENSITIVE**: The ResultSet object is insensitive to changes in the underlying data source.<br>**NOTE**<br>After a result set has obtained data from the database, the result set is insensitive to data changes made by other transactions, even if the result set type is **ResultSet.TYPE_SCROLL_SENSITIVE**. To obtain up-to-date data of the record pointed by the cursor from the database, call the refreshRow() method in a ResultSet object. |
| resultSetConcurrency | Concurrency type of a result set. There are two types of concurrency.<br>• **ResultSet.CONCUR_READ_ONLY**: Data in a result set cannot be updated except that an updated statement has been created in the result set data.<br>• **ResultSet.CONCUR_UPDATEABLE**: changeable result set. The concurrency type for a result set object can be updated if the result set is scrollable. |

## Positioning a Cursor in a Result Set

ResultSet objects include a cursor pointing to the current data row. The cursor is initially positioned before the first row. The next method moves the cursor to the next row from its current position. When a ResultSet object does not have a next row, a call to the next method returns **false**. Therefore, this method is used in the while loop for result set iteration. However, the JDBC driver provides more cursor positioning methods for scrollable result sets, which allows positioning cursor in the specified row. **Table 6-5** describes these methods.

**Table 6-5** Methods for positioning a cursor in a result set

| Method | Description |
| --- | --- |
| next() | Moves cursor to the next row from its current position. |
| previous() | Moves cursor to the previous row from its current position. |
| beforeFirst() | Places cursor before the first row. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Method | Description |
| --- | --- |
| afterLast() | Places cursor after the last row. |
| first() | Places cursor to the first row. |
| last() | Places cursor to the last row. |
| absolute(int) | Places cursor to a specified row. |
| relative(int) | Moves the row specified by the parameter forward (that is, the value is 1, which is equivalent to next()) or backward (that is, the value is -1, which is equivalent to previous()). |

## Obtaining the Cursor Position from a Result Set

This cursor positioning method will be used to change the cursor position for a scrollable result set. The JDBC driver provides a method to obtain the cursor position in a result set. **Table 6-6** describes these methods.

**Table 6-6** Methods for obtaining a cursor position in a result set

| Method | Description |
| --- | --- |
| isFirst() | Checks whether the cursor is in the first row. |
| isLast() | Checks whether the cursor is in the last row. |
| isBeforeFirst() | Checks whether the cursor is before the first row. |
| isAfterLast() | Checks whether the cursor is after the last row. |
| getRow() | Gets the current row number of the cursor. |

## Obtaining Data from a Result Set

ResultSet objects provide a variety of methods to obtain data from a result set. **Table 6-7** describes the common methods for obtaining data. If you want to know more about other methods, see JDK official documents.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 6-7** Common methods for obtaining data from a result set

| Method | Description |
| --- | --- |
| int getInt(int columnIndex) | Retrieves the value of the column designated by a column index in the current row as an integer. |
| int getInt(String columnLabel) | Retrieves the value of the column designated by a column label in the current row as an integer. |
| String getString(int columnIndex) | Retrieves the value of the column designated by a column index in the current row as a string. |
| String getString(String columnLabel) | Retrieves the value of the column designated by a column label in the current row as a string. |
| Date getDate(int columnIndex) | Retrieves the value of the column designated by a column index in the current row as a date. |
| Date getDate(String columnLabel) | Retrieves the value of the column designated by a column name in the current row as a date. |

## 6.3.9 Closing a Connection

After you complete required data operations in the database, close the database connection.

Call the close method to close the connection, for example, **Connection conn = DriverManager.getConnection("url","user","password"); conn.close();**

## 6.3.10 Log Management

The GaussDB JDBC driver uses log records to help solve problems when the GaussDB JDBC driver is used in applications. GaussDB JDBC supports the following log management methods:

1. Use the SLF4J log framework for interconnecting with applications.
2. Use the JdkLogger log framework for interconnecting with applications.

SLF4J and JdkLogger are mainstream frameworks for Java application log management in the industry. For details about how to use these frameworks, see the official documents (SLF4J: **http://www.slf4j.org/manual.html**; JdkLogger: **https://docs.oracle.com/javase/8/docs/technotes/guides/logging/overview.html**).

Method 1: Use the SLF4J log framework for interconnecting with applications.

When a connection is set up, **logger=Slf4JLogger** is configured in the URL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The SLF4J may be implemented by using Log4j or Log4j2. When the Log4j is used to implement the SLF4J, the following JAR packages need to be added: **log4j-*.jar**, **slf4j-api-*.jar**, and **slf4j-log4*-*.jar** (* varies according to versions), and configuration file **log4j.properties**. If the Log4j2 is used to implement the SLF4J, you need to add the following JAR packages: **log4j-api-*.jar**, **log4j-core-*.jar**, **log4j-slf4j18-impl-*.jar**, and **slf4j-api-*-alpha1.jar** (* varies according to versions), and configuration file **log4j2.xml**.

This method supports log management and control. The SLF4J can implement powerful log management and control functions through related configurations in files. This method is recommended.

Example:

```
public static Connection GetConnection(String username, String passwd){

    String sourceURL = "jdbc:postgresql://10.10.0.13:8000/postgres?logger=Slf4JLogger";
    Connection conn = null;

    try{
// Create a connection.
        conn = DriverManager.getConnection(sourceURL,username,passwd);
        System.out.println("Connection succeed!");
    }catch (Exception e){
        e.printStackTrace();
        return null;
    }
    return conn;
}
```

The following is an example of the **log4j.properties** file:

```
log4j.logger.org.postgresql=ALL, log_gsjdbc

# Default file output configuration
log4j.appender.log_gsjdbc=org.apache.log4j.RollingFileAppender
log4j.appender.log_gsjdbc.Append=true
log4j.appender.log_gsjdbc.File=gsjdbc.log
log4j.appender.log_gsjdbc.Threshold=TRACE
log4j.appender.log_gsjdbc.MaxFileSize=10MB
log4j.appender.log_gsjdbc.MaxBackupIndex=5
log4j.appender.log_gsjdbc.layout=org.apache.log4j.PatternLayout
log4j.appender.log_gsjdbc.layout.ConversionPattern=%d %p %t %c - %m%n
log4j.appender.log_gsjdbc.File.Encoding = UTF-8
```

The following is an example of the **log4j2.xml** file:

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration status="OFF">
    <appenders>
        <Console name="Console" target="SYSTEM_OUT">
            <PatternLayout pattern="%d %p %t %c - %m%n"/>
        </Console>
        <File name="FileTest" fileName="test.log">
            <PatternLayout pattern="%d %p %t %c - %m%n"/>
        </File>
        <!-- JDBC driver log file output configuration. Log rewinding is supported. When the log size exceeds
10 MB, a new file is created. The new file is named in the format of yyyy-mm-dd-file ID. -->
        <RollingFile name="RollingFileJdbc" fileName="gsjdbc.log" filePattern="%d{yyyy-MM-dd}-%i.log">
            <PatternLayout pattern="%d %p %t %c - %m%n"/>
            <Policies>
                <SizeBasedTriggeringPolicy size="10 MB"/>
            </Policies>
        </RollingFile>
    </appenders>
    <loggers>
        <root level="all">
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
        <appender-ref ref="Console"/>
        <appender-ref ref="FileTest"/>
    </root>
    <!-- JDBC driver logs. The log level is all. All logs can be viewed and exported to the gsjdbc.log file. -->
    <!-- If opengaussjdbc.jar is used, replace org.postgresql with com.huawei.opengauss.jdbc.Driver.-->
    <logger name="org.postgresql" level="all" additivity="false">
        <appender-ref ref="RollingFileJdbc"/>
    </logger>
  </loggers>
</configuration>
```

Method 2: Use the JdkLogger log framework for interconnecting with applications.

The default Java logging framework stores its configurations in a file named **logging.properties**. Java installs the global configuration file in the folder in the Java installation directory. The **logging.properties** file can also be created and stored with a single project.

Configuration example of **logging.properties**:

```
# Specify the processing program as a file.
handlers= java.util.logging.FileHandler

# Specify the default global log level.
.level= ALL

# Specify the log output control standard.
java.util.logging.FileHandler.level=ALL
java.util.logging.FileHandler.pattern = gsjdbc.log
java.util.logging.FileHandler.limit = 500000
java.util.logging.FileHandler.count = 30
java.util.logging.FileHandler.formatter = java.util.logging.SimpleFormatter
java.util.logging.FileHandler.append=false
```

The following is a code example:

```
System.setProperty("java.util.logging.FileHandler.pattern","jdbc.log");
FileHandler fileHandler = new FileHandler(System.getProperty("java.util.logging.FileHandler.pattern"));
Formatter formatter = new SimpleFormatter();
fileHandler.setFormatter(formatter);
Logger logger = Logger.getLogger("org.postgresql");
logger.addHandler(fileHandler);
logger.setLevel(Level.ALL);
logger.setUseParentHandlers(false);
```

**Link trace function**

The GaussDB JDBC driver provides the application-to-database link trace function to associate discrete SQL statements on the database side with application requests. This function requires application developers to implement the **org.postgresql.log.Tracer** API class and specify the full name of the API implementation class in the URL.

URL example:

```
String URL = "jdbc:postgresql://127.0.0.1:8000/postgres?
traceInterfaceClass=xxx.xxx.xxx.OpenGaussTraceImpl";
```

The **org.postgresql.log.Tracer** API class is defined as follows:

```
public interface Tracer {
// Retrieves the value of traceId.
String getTraceId();
}
```

The following is an example of the **org.postgresql.log.Tracer** API implementation class:

```
import org.postgresql.log.Tracer;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
public class OpenGaussTraceImpl implements Tracer {
    private static MDC mdc = new MDC();

    private final String TRACE_ID_KEY = "traceId";

    public void set(String traceId) {
        mdc.put(TRACE_ID_KEY, traceId);
    }

    public void reset() {
        mdc.clear();
    }

    @Override
    public String getTraceId() {
        return mdc.get(TRACE_ID_KEY);
    }
}
```

The following is an example of context mapping which is used to store **traceId** generated for different requests.

```
import java.util.HashMap;

public class MDC {
    static final private ThreadLocal<HashMap<String, String>> threadLocal = new ThreadLocal<>();

    public void put(String key, String val) {
        if (key == null || val == null) {
            throw new IllegalArgumentException("key or val cannot be null");
        } else {
            if (threadLocal.get() == null) {
                threadLocal.set(new HashMap<>());
            }
            threadLocal.get().put(key, val);
        }
    }

    public String get(String key) {
        if (key == null) {
            throw new IllegalArgumentException("key cannot be null");
        } else if (threadLocal.get() == null) {
            return null;
        } else {
            return threadLocal.get().get(key);
        }
    }

    public void clear() {
        if (threadLocal.get() == null) {
            return;
        } else {
            threadLocal.get().clear();
        }
    }
}
```

The following is an example of using **traceId**:

```
String traceId = UUID.randomUUID().toString().replaceAll("-", "");
openGaussTrace.set(traceId);
pstm = con.prepareStatement("select * from test_trace_id where id = ?");
pstm.setInt(1, 1);
pstm.execute();
pstm = con.prepareStatement("insert into test_trace_id values(?,?)");
pstm.setInt(1, 2);
pstm.setString(2, "test");
pstm.execute();
openGaussTrace.reset();
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- When the link trace function is used, the link function at the application layer is guaranteed by services.
- The application must expose the API for obtaining **traceId** to the JDBC and configure the API implementation class to the JDBC connection string.
- SQL statements of the same request must use the same **traceId**.
- The value of **traceId** transferred by the application cannot exceed 32 bytes. Otherwise, the extra bytes will be truncated.

# 6.3.11 Example: Common Operations

## Example 1:

This example illustrates how to develop applications based on the JDBC API provided by GaussDB. Before executing the code in this example, load the driver first. For details about how to obtain and load the driver, see **6.3.1 JDBC Package, Driver Class, and Environment Class**.

```
//DBtest.java
/*The following uses gsjdbc4.jar as an example.*/
// This example illustrates the main processes of JDBC-based development, covering database connection creation, table creation, and data insertion.

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.CallableStatement;
import java.sql.Types;

public class DBTest {

 // Create a database connection.
 public static Connection GetConnection(String username, String passwd) {
   String driver = "org.postgresql.Driver";
   String sourceURL = "jdbc:postgresql://localhost:8000/postgres";
   Connection conn = null;
   try {
     // Load the database driver.
     Class.forName(driver).newInstance();
   } catch (Exception e) {
     e.printStackTrace();
     return null;
   }

   try {
     // Create a database connection.
     conn = DriverManager.getConnection(sourceURL, username, passwd);
     System.out.println("Connection succeed!");
   } catch (Exception e) {
     e.printStackTrace();
     return null;
   }

   return conn;
 };

 // Run a common SQL statement to create table customer_t1.
 public static void CreateTable(Connection conn) {
   Statement stmt = null;
   try {
     stmt = conn.createStatement();
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
    // Run a common SQL statement.
    int rc = stmt
        .executeUpdate("CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name
VARCHAR(32));");

    stmt.close();
  } catch (SQLException e) {
    if (stmt != null) {
      try {
        stmt.close();
      } catch (SQLException e1) {
        e1.printStackTrace();
      }
    }
    e.printStackTrace();
  }
}

// Run a prepared statement to insert data in batches.
public static void BatchInsertData(Connection conn) {
  PreparedStatement pst = null;

  try {
    // Generate a prepared statement.
    pst = conn.prepareStatement("INSERT INTO customer_t1 VALUES (?,?)");
    for (int i = 0; i < 3; i++) {
      // Add parameters.
      pst.setInt(1, i);
      pst.setString(2, "data " + i);
      pst.addBatch();
    }
    // Perform batch processing.
    pst.executeBatch();
    pst.close();
  } catch (SQLException e) {
    if (pst != null) {
      try {
        pst.close();
      } catch (SQLException e1) {
      e1.printStackTrace();
      }
    }
    e.printStackTrace();
  }
}

// Run a prepared statement to update data.
public static void ExecPreparedSQL(Connection conn) {
  PreparedStatement pstmt = null;
  try {
    pstmt = conn
        .prepareStatement("UPDATE customer_t1 SET c_customer_name = ? WHERE c_customer_sk = 1");
    pstmt.setString(1, "new Data");
    int rowcount = pstmt.executeUpdate();
    pstmt.close();
  } catch (SQLException e) {
    if (pstmt != null) {
      try {
        pstmt.close();
      } catch (SQLException e1) {
        e1.printStackTrace();
      }
    }
    e.printStackTrace();
  }
}
```

```
// Run a stored procedure.
 public static void ExecCallableSQL(Connection conn) {
   CallableStatement cstmt = null;
   try {
     // The stored procedure TESTPROC must be created in advance.
     cstmt=conn.prepareCall("{? = CALL TESTPROC(?,?,?)}");
     cstmt.setInt(2, 50);
     cstmt.setInt(1, 20);
     cstmt.setInt(3, 90);
     cstmt.registerOutParameter(4, Types.INTEGER);  // Register an OUT parameter of the integer type.
     cstmt.execute();
     int out = cstmt.getInt(4);  // Obtain the OUT parameter.
     System.out.println("The CallableStatment TESTPROC returns:"+out);
     cstmt.close();
   } catch (SQLException e) {
     if (cstmt != null) {
       try {
         cstmt.close();
       } catch (SQLException e1) {
         e1.printStackTrace();
       }
     }
     e.printStackTrace();
   }
 }

 /**
  *Main process. Call static methods one by one.
  * @param args
 */
 public static void main(String[] args) {
   // Create a database connection.
   Connection conn = GetConnection("tester", "Password1234");

   // Create a table.
   CreateTable(conn);

   // Insert data in batches.
   BatchInsertData(conn);

 // Run a prepared statement to update data.
   ExecPreparedSQL(conn);

   // Run a stored procedure.
   ExecCallableSQL(conn);

   // Close the connection to the database.
   try {
     conn.close();
   } catch (SQLException e) {
     e.printStackTrace();
   }

 }

}
```

## Example 2: High Client Memory Usage

In this example, **setFetchSize** adjusts the memory usage of the client by using the database cursor to obtain server data in batches. It may increase network interaction and damage some performance.

The cursor is valid within a transaction. Therefore, disable automatic commit and then manually commit the code.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
// Disable automatic commit.
conn.setAutoCommit(false);
Statement st = conn.createStatement();

// Open the cursor and obtain 50 lines of data each time.
st.setFetchSize(50);
ResultSet rs = st.executeQuery("SELECT * FROM mytable");
while (rs.next())
{
    System.out.print("a row was returned.");
}
conn.commit();
rs.close();

// Disable the server cursor.
st.setFetchSize(0);
rs = st.executeQuery("SELECT * FROM mytable");
while (rs.next())
{
    System.out.print("many rows were returned.");
}
conn.commit();
rs.close();

// Close the statement.
st.close();
conn.close();
```

Run the following command to enable automatic commit:

```
conn.setAutoCommit(true);
```

## Example 3: Example of Common Data Types

```
// Example of the bit type. Note that the value range of the bit type is [0,1].
Statement st = conn.createStatement();
String sqlstr = "create or replace function fun_1()\n" +
        "returns bit AS $$\n" +
        "select col_bit from t_bit limit 1;\n" +
        "$$\n" +
        "LANGUAGE SQL;";
st.execute(sqlstr);
CallableStatement c = conn.prepareCall("{ ? = call fun_1() }");
// Register the output type, which is a bit string.
c.registerOutParameter(1, Types.BIT);
c.execute();
// Use the Boolean type to obtain the result.
System.out.println(c.getBoolean(1));

// Example of using the money type
// Example of using a column of the money type in the table structure.
st.execute("create table t_money(id int,col1 money)");
PreparedStatement pstm = conn.prepareStatement("insert into t_money values(1,?)");
// Use PGobject to assign a value. The value range is [–92233720368547758.08,92233720368547758.07].
PGobject minMoney = new PGobject();
minMoney.setType("money");
minMoney.setValue("-92233720368547758.08");
pstm.setObject(1, minMoney);
pstm.execute();
// Use PGMoney to assign a value. The value range is [–9999999.99,9999999.99].
pstm.setObject(1,new PGmoney(9999999.99));
pstm.execute();

// Example of using the function whose return value is of the money type.
st.execute("create or replace function func_money() " +
            "return money " +
            "as declare " +
            "var1 money; " +
            "begin " +
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
            " select col1 into var1 from t_money limit 1; " +
            " return var1; " +
            "end;");
CallableStatement cs = conn.prepareCall("{? = call func_money()}");
cs.registerOutParameter(1,Types.DOUBLE);
cs.execute();
cs.getObject(1);
```

### Example 4: Obtaining the Driver Version

```
Driver.getGSVersion();
```

## 6.3.12 Example: Retrying SQL Queries for Applications

If the primary DN is faulty and cannot be restored within 10s, GaussDB automatically promotes the standby DN to primary to ensure that the cluster runs properly. Jobs running during the failover will fail and those started after the failover will not be affected. To prevent upper-layer services from being affected by the DN failover, refer to the following example to construct an SQL retry mechanism at the service layer. Before executing the code in this example, load the driver first. For details about how to obtain and load the driver, see **6.3.1 JDBC Package, Driver Class, and Environment Class**.

```
// The following uses gsjdbc4.jar as an example.
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;

class ExitHandler extends Thread {
    private Statement cancel_stmt = null;

    public ExitHandler(Statement stmt) {
        super("Exit Handler");
        this.cancel_stmt = stmt;
    }
    public void run() {
        System.out.println("exit handle");
        try {
            this.cancel_stmt.cancel();
        } catch (SQLException e) {
            System.out.println("cancel query failed.");
            e.printStackTrace();
        }
    }
}

public class SQLRetry {
  // Create a database connection.
  public static Connection GetConnection(String username, String passwd) {
    String driver = "org.postgresql.Driver";
    String sourceURL = "jdbc:postgresql://10.131.72.136:8000/postgres";
    Connection conn = null;
    try {
     // Load the database driver.
      Class.forName(driver).newInstance();
    } catch (Exception e) {
      e.printStackTrace();
      return null;
    }

    try {
     // Create a database connection.
      conn = DriverManager.getConnection(sourceURL, username, passwd);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
      System.out.println("Connection succeed!");
    } catch (Exception e) {
      e.printStackTrace();
      return null;
    }

    return conn;
}

  // Execute an ordinary SQL statement. Create a jdbc_test1 table.
  public static void CreateTable(Connection conn) {
    Statement stmt = null;
    try {
      stmt = conn.createStatement();

      Runtime.getRuntime().addShutdownHook(new ExitHandler(stmt));

     // Run a common SQL statement.
      int rc2 = stmt
         .executeUpdate("DROP TABLE if exists jdbc_test1;");

      int rc1 = stmt
         .executeUpdate("CREATE TABLE jdbc_test1(col1 INTEGER, col2 VARCHAR(10));");

      stmt.close();
    } catch (SQLException e) {
      if (stmt != null) {
        try {
          stmt.close();
        } catch (SQLException e1) {
          e1.printStackTrace();
        }
      }
      e.printStackTrace();
    }
  }

 // Run a prepared statement to insert data in batches.
  public static void BatchInsertData(Connection conn) {
    PreparedStatement pst = null;

    try {

    }

  }

}
```

## 6.3.13 Example: Importing and Exporting Data Through Local Files

When Java is used for secondary development based on GaussDB, you can use the CopyManager interface to export data from the database to a local file or import a local file to the database by streaming. The file can be in CSV or TEXT format.

The sample program is as follows. Load the driver before executing the sample code. For details about how to obtain and load the driver, see **6.3.1 JDBC Package, Driver Class, and Environment Class**.

```
// The following uses gsjdbc4.jar as an example.
import java.sql.Connection;
import java.sql.DriverManager;
import java.io.IOException;
import java.io.FileInputStream;
import java.io.FileOutputStream;
import java.sql.SQLException;
import org.postgresql.copy.CopyManager;
import org.postgresql.core.BaseConnection;

public class Copy{

    public static void main(String[] args)
    {
     String urls = new String("jdbc:postgresql://10.180.155.74:8000/postgres"); // Database URL
     String username = new String("jack");            // Username
     String password = new String("xxxxxxxxx");             // Password
     String tablename = new String("migration_table"); // Table information
     String tablename1 = new String("migration_table_1"); // Table information
     String driver = "org.postgresql.Driver";
     Connection conn = null;

     try {
           Class.forName(driver);
           conn = DriverManager.getConnection(urls, username, password);
         } catch (ClassNotFoundException e) {
             e.printStackTrace(System.out);
         } catch (SQLException e) {
             e.printStackTrace(System.out);
         }

     // Export the query result of SELECT * FROM migration_table to the local file d:/data.txt.
     try {
    copyToFile(conn, "d:/data.txt", "(SELECT * FROM migration_table)");
  } catch (SQLException e) {

 e.printStackTrace();
  } catch (IOException e) {

 e.printStackTrace();
  }
     // Import data from the d:/data.txt file to the migration_table_1 table.
     try {
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
    copyFromFile(conn, "d:/data.txt", tablename1);
  } catch (SQLException e) {
       e.printStackTrace();
} catch (IOException e) {

 e.printStackTrace();
}

    // Export the data from the migration_table_1 table to the d:/data1.txt file.
    try {
    copyToFile(conn, "d:/data1.txt", tablename1);
  } catch (SQLException e) {

 e.printStackTrace();
  } catch (IOException e) {

 e.printStackTrace();
}
   }
 // Use copyIn to import data from a file to the database.
 public static void copyFromFile(Connection connection, String filePath, String tableName)
       throws SQLException, IOException {

   FileInputStream fileInputStream = null;

   try {
      CopyManager copyManager = new CopyManager((BaseConnection)connection);
      fileInputStream = new FileInputStream(filePath);
      copyManager.copyIn("COPY " + tableName + " FROM STDIN", fileInputStream);
   } finally {
      if (fileInputStream != null) {
         try {
            fileInputStream.close();
         } catch (IOException e) {
            e.printStackTrace();
         }
      }
   }
}

 // Use copyOut to export data from the database to a file.
 public static void copyToFile(Connection connection, String filePath, String tableOrQuery)
       throws SQLException, IOException {

    FileOutputStream fileOutputStream = null;

    try {
       CopyManager copyManager = new CopyManager((BaseConnection)connection);
       fileOutputStream = new FileOutputStream(filePath);
       copyManager.copyOut("COPY " + tableOrQuery + " TO STDOUT", fileOutputStream);
    } finally {
       if (fileOutputStream != null) {
          try {
             fileOutputStream.close();
          } catch (IOException e) {
             e.printStackTrace();
          }
       }
    }
 }
}
```

## 6.3.14 Example: Migrating Data from MySQL

The following example shows how to use CopyManager to migrate data from MySQL. Before executing the code in this example, load the driver first. For details

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

about how to obtain and load the driver, see **6.3.1 JDBC Package, Driver Class, and Environment Class**.

```
// The following uses gsjdbc4.jar as an example.
import java.io.StringReader;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;

import org.postgresql.copy.CopyManager;
import org.postgresql.core.BaseConnection;

public class Migration{

    public static void main(String[] args) {
        String url = new String("jdbc:postgresql://10.180.155.74:8000/postgres"); // Database URL
        String user = new String("jack");            // database username
String pass = new String(" xxxxxxxxx "); //database password
        String tablename = new String("migration_table"); // Table information
        String delimiter = new String("|");              // Delimiter
        String encoding = new String("UTF8");           // Character set
        String driver = "org.postgresql.Driver";
        StringBuffer buffer = new StringBuffer();       // Buffer to store formatted data

        try {
            // Obtain the query result set of the source database.
            ResultSet rs = getDataSet();

            // Traverse the result set and obtain records row by row.
            // The values of columns in each record are separated by the specified delimiter and end with a
linefeed, forming strings.
            // Add the strings to the buffer.
            while (rs.next()) {
                buffer.append(rs.getString(1) + delimiter
                        + rs.getString(2) + delimiter
                        + rs.getString(3) + delimiter
                        + rs.getString(4)
                        + "\n");
            }
            rs.close();

            try {
                // Connect to the target database.
                Class.forName(driver);
                Connection conn = DriverManager.getConnection(url, user, pass);
                BaseConnection baseConn = (BaseConnection) conn;
                baseConn.setAutoCommit(false);

                // Initialize the table.
                String sql = "Copy " + tablename + " from STDIN DELIMITER " + "'" + delimiter + "'" + "
ENCODING " + "'" + encoding + "'";

                // Commit data in the buffer.
                CopyManager cp = new CopyManager(baseConn);
                StringReader reader = new StringReader(buffer.toString());
                cp.copyIn(sql, reader);
                baseConn.commit();
                reader.close();
                baseConn.close();
            } catch (ClassNotFoundException e) {
                e.printStackTrace(System.out);
            } catch (SQLException e) {
                e.printStackTrace(System.out);
            }

        } catch (Exception e) {
            e.printStackTrace();
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
        }
    }

    //**********************************
    // Return the query result set from the source database.
    //**********************************
    private static ResultSet getDataSet() {
        ResultSet rs = null;
        try {
            Class.forName("com.mysql.jdbc.Driver").newInstance();
            Connection conn = DriverManager.getConnection("jdbc:mysql://10.119.179.227:3306/jack?
useSSL=false&allowPublicKeyRetrieval=true", "jack", "xxxxxxxxx");
            Statement stmt = conn.createStatement();
            rs = stmt.executeQuery("select * from migration_table");
        } catch (SQLException e) {
            e.printStackTrace();
        } catch (Exception e) {
            e.printStackTrace();
        }
        return rs;
    }
}
```

## 6.3.15 Example: Logic Replication Code

The following example demonstrates how to use the logical replication function through the JDBC API.

For logical replication, in addition to the configuration items described in section "Logical Decoding", the following configuration items are added for streaming decoders such as JDBC:

1. Decoding thread concurrency

   Set **parallel-decode-num** to specify the number of decoder threads for parallel decoding. The value is an integer ranging from 1 to 20. The value **1** indicates that decoding is performed based on the original serial logic. Other values indicate that parallel decoding is enabled. The default value is **1**. When this parameter is set to **1**, do not configure the following options: **decode-style**, **sending-batch**, and **parallel-queue-size**.

2. Decoding format

   Configure **decode-style** to specify the decoding format. The value can be **'j'**, **'t'**, or **'b'** of the char type, indicating the JSON, text, or binary format, respectively. The default value is **'b'**, indicating binary decoding. This item is set only when parallel decoding is allowed and the binary decoding is supported only in the parallel decoding scenario. For the JSON and text formats corresponding to the binary format, in the decoding result sent in batches, the uint32 consisting of the first four bytes of each decoding statement indicates the total number of bytes of the statement (the four bytes occupied by the uint32 are excluded, and **0** indicates that the decoding of this batch ends). The 8-byte uint64 indicates the corresponding LSN (**begin** corresponds to **first_lsn**, **commit** corresponds to **end_lsn**, and other values correspond to the LSN of the statement).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**NOTE**

The binary encoding rules are as follows:

1. The first four bytes represent the total number of bytes of the decoding result of statements following the statement-level delimiter letter P (excluded) or the batch end character F (excluded). If the value is **0**, the decoding of this batch ends.
2. The next eight bytes (uint64) indicate the corresponding LSN (**begin** corresponds to **first_lsn**, **commit** corresponds to **end_lsn**, and other values correspond to the LSN of the statement).
3. The next one-byte letter can be **B**, **C**, **I**, **U**, or **D**, representing BEGIN, COMMIT, INSERT, UPDATE, or DELETE.
4. If **B** is used in the step 3:
    1. The next eight bytes (uint64) indicate the CSN.
    2. The next eight bytes (uint64) indicate **first_lsn**.
    3. (Optional) If the next one-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length for committing the transaction. The following characters with the same length are the timestamp character string.
    4. (Optional) If the next one-byte letter is **N**, the following four bytes (uint32) indicate the length of the transaction user name. The following characters with the same length are the transaction user name.
    5. Because there may still be a decoding statement subsequently, a 1-byte letter **P** or **F** is used as a separator between statements. **P** indicates that there are still decoded statements in this batch, and **F** indicates that this batch is completed.
5. If **C** is used in the step 3:
    1. (Optional) If the next one-byte letter is **X**, the following eight bytes (uint64) indicate the XID.
    2. (Optional) If the next one-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length. The following characters with the same length are the timestamp character string.
    3. When logs are sent in batches, decoding results of other transactions may still exist after a COMMIT log is decoded. If the next one-byte letter is **P**, the batch still needs to be decoded. If the letter is **F**, the decoding of the batch ends.
6. If **I**, **U**, or **D** is used in the step 3:
    1. The next two bytes (uint16) indicate the length of the schema name.
    2. The schema name is read based on the preceding length.
    3. The next two bytes (uint16) indicate the length of the table name.
    4. The table name is read based on the preceding length.
    5. (Optional) If the next one-byte letter is **N**, it indicates a new tuple. If the letter is **O**, it indicates an old tuple. In this case, the new tuple is sent first.
        1. The next two bytes (uint16) indicate the number of columns to be decoded for the tuple, which is recorded as **attrnum**.
        2. The following procedure is repeated for *attrnum* times.
            1. The next two bytes (uint16) indicate the length of the column name.
            2. The column name is read based on the preceding length.
            3. The next four bytes (uint32) indicate the OID of the current column type.
            4. The next four bytes (uint32) indicate the length of the value (stored in the character string format) in the current column. If the value is **0xFFFFFFFF**, it indicates a null value. If the value is **0**, it indicates a character string whose length is 0.
            5. The column value is read based on the preceding length.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

6. Because there may still be a decoding statement subsequently, if the next one-byte letter is **P**, it indicates that the batch still needs to be decoded, and if the next one-byte letter is **F**, it indicates that decoding of the batch ends.

3. Decoding only on the standby node

   Configure **standby-connection** to specify whether to perform decoding only on the standby node. The value is of the Boolean type (**0** or **1**). The value **true** (or **1**) indicates that only the standby node can be connected for decoding. When the primary node is connected for decoding, an error is reported and the system exits. The value **false** (or **0**) indicates that there is no restriction. The default value is **false** (**0**).

4. Batch sending

   Configure **sending-batch** to specify whether to send results in batches. The value is an integer ranging from 0 to 1. The value **0** indicates that decoding results are sent one by one. The value **1** indicates that decoding results are sent in batches when the accumulated size of decoding results reaches 1 MB. The default value is **0**. This parameter can be set only during parallel decoding. In the scenario where batch sending is enabled, if the decoding format is 'j' or 't', before each original decoding statement, a uint32 number is added indicating the length of the decoding result (excluding the current uint32 number), and a uint64 number is added indicating the LSN corresponding to the current decoding result.

5. Length of the parallel decoding queue

   Configure **parallel-queue-size** to specify the length of the queue for interaction among parallel logical decoding threads. The value ranges from 2 to 1024 and must be a power of 2. The default value is **128**. The queue length is positively correlated with the memory usage during decoding.

6. Memory threshold for logical decoding

   Configure **max-txn-in-memory** to specify the memory threshold for caching the intermediate decoding result of a single transaction. The value ranges from 0 to 100, in MB. The default value is **0**, indicating that the memory usage is not controlled. Configure **max-reorderbuffer-in-memory** to specify the memory threshold for caching the intermediate decoding result of all transactions. The value ranges from 0 to 100, in GB. The default value is **0**, indicating that the memory usage is not controlled. When the memory usage exceeds the threshold, the intermediate decoding result is written into a temporary file during decoding, which affects the logical decoding performance.

7. Logical decoding sending timeout threshold

   The **sender-timeout** configuration item specifies the heartbeat timeout threshold between the kernel and client. If no message is received from the client within the period, the logic decoding stops and disconnects from the client. The unit is ms, and the value range is [0,2147483647]. The default value depends on the value of **logical_sender_timeout**.

8. User blacklist options for logical decoding

   Use the user blacklist for logical decoding. The transaction operations of blacklisted users are filtered from the logic decoding result. The options are as follows:

   a. **exclude-userids**: specifies the OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not check whether the user

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

OIDs exist. Note: The OIDs of the same service user on different DNs may be different. Therefore, the OID of the service user on each DN needs to be transferred for logic decoding of directly connected DNs in distributed mode. Otherwise, the logic decoding results of some DNs may be filtered while those of some DNs are not filtered.

b. **exclude-users**: specifies blacklisted user names. Multiple user names are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify user names. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the user name from the blacklist to start decoding and continue to obtain logical logs.

c. **dynamic-resolution**: indicates whether to dynamically parse blacklisted user names. The default value is **true**. If the parameter is set to **false**, an error is reported and the logic decoding exits when the decoding detects that the user does not exist in blacklist **exclude-users**. If the parameter is set to **true**, decoding continues when it detects that the user does not exist in blacklist **exclude-users**.

9. Output options for transaction logic logs

   a. **include-xids**: indicates whether the BEGIN logical log of a transaction outputs the transaction ID. The default value is **true**.

   b. **include-timestamp**: indicates whether the BEGIN logical log of a transaction outputs the time when the transaction is committed. The default value is **false**.

   c. **include-user**: indicates whether the BEGIN logical log of a transaction outputs the user name of the transaction. The default value is **false**. The user name of a transaction refers to the authorized user, that is, the login user who executes the session corresponding to the transaction. The user name does not change during the execution of the transaction.

10. By default, **socketTimeout** of the logical decoding connection is set to **10s**. When the primary node is overloaded during decoding on the standby node, the connection may be closed due to timeout. You can set **withStatusInterval(10000,TimeUnit.MILLISECONDS)** to adjust the timeout interval.

The decoding performance (Xlog consumption) is greater than or equal to 100 MBps in the following standard parallel decoding scenario: 16-core CPU, 128 GB memory, network bandwidth > 200 MBps, 10 to 100 columns in a table, 0.1 KB to 1 KB data volume in a single row, DML operations are mainly INSERT operations, the number of statements in a single transaction is less than 4096, **parallel-decode-num** is set to **8**, the decoding format is **'b'**, and the batch sending function is enabled. To ensure that the decoding performance meets the requirements and minimize the impact on services, you are advised to set up only one parallel decoding connection on a standby node to ensure that the CPU, memory, and bandwidth resources are sufficient.

Note: The logical replication class PGReplicationStream is a non-thread-safe class. Concurrent calls may cause data exceptions. Before executing the code in this example, load the driver first. For details about how to obtain and load the driver, see **6.3.1 JDBC Package, Driver Class, and Environment Class**.

```
// The following uses gsjdbc4.jar as an example.
// Logical replication function example: file name, LogicalReplicationDemo.java

                    .dropReplicationSlot("replication_slot");
        }
    } catch (Exception e) {
        e.printStackTrace();
        return;
    }
  }
}
```

# 6.3.16 Example: Parameters for Connecting to the Database in Different Scenarios

NOTE

In the following example, **host:port** represents a node, where **host** indicates the name or IP address of the server where the database resides, and **port** indicates the port number of the server where the database resides.

## Load Balancing

A customer has a database cluster that contains the following nodes: {node1,node2,node3,node4,node5,node6,node7,node8,node9,node10,node11,node12}.

1. The customer establishes 120 persistent connections in application A and expects that the connections on application A can be evenly distributed on each node in the current cluster. The URL can be configured as follows.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
jdbc:postgresql://node1,node2,node3/database?autoBalance=true
```

2. The customer develops two applications B and C and wants the three applications to be evenly distributed on specified nodes. For example, the connections of application A are distributed on {node1,node2,node3,node4}. The connections of application B are distributed on {node5,node6,node7,node8}. The connections of application C are distributed on {node9,node10,node11,node12}. The URLs can be configured as follows.

   Application A: **jdbc:postgresql://node1,node2,node3,node4,node5/database?autoBalance=priority4**

   Application B: **jdbc:postgresql://node5,node6,node7,node8,node9/database?autoBalance=priority4**

   Application C: **jdbc:postgresql://node9,node10,node11,node12,node1/database?autoBalance=priority4**

3. The customer develops more applications, uses the same connection configuration string, and expects that the application connections can be evenly distributed on each node in the cluster. The URL can be configured as follows.

   ```
   jdbc:postgresql://node1,node2,node3,node4/database?autoBalance=shuffle
   ```

4. If the customer does not want to use the load balancing function, configure the URL as follows.

   ```
   jdbc:postgresql://node1/database
   ```

   Or

   ```
   jdbc:postgresql://node1/database?autoBalance=false
   ```

   **NOTE**

   When the **autoBalance** parameter is enabled, the interval for the JDBC to refresh the available CN list is 10s by default. You can use **refreshCNIpListTime** to set the interval:

   ```
   jdbc:postgresql://node1,node2,node3,node4/database?autoBalance=true&refreshCNIpListTime=3
   ```

## Log Diagnosis

To locate faults, a customer can enable the trace log function for diagnosis. The URL can be configured as follows.

```
jdbc:postgresql://node1/database?loggerLevel=trace&loggerFile=jdbc.log
```

## High Performance

A customer may execute the same SQL statement for multiple times with different input parameters. To improve the execution efficiency, the **prepareThreshold** parameter can be enabled to avoid repeatedly generating execution plans. The URL can be configured as follows.

```
jdbc:postgresql://node1/database?prepareThreshold=5
```

A customer queries 10 million data records at a time. To prevent memory overflow caused by simultaneous return of the data records, the **defaultRowFetchSize** parameter can be used. The URL can be configured as follows.

```
jdbc:postgresql://node1/database?defaultRowFetchSize=50000
```

A customer needs to insert 10 million data records in batches. To improve efficiency, the **batchMode** parameter can be used. The URL can be configured as follows.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
jdbc:postgresql://node1/database?batchMode=true
```

## 6.3.17 JDBC Interface Reference

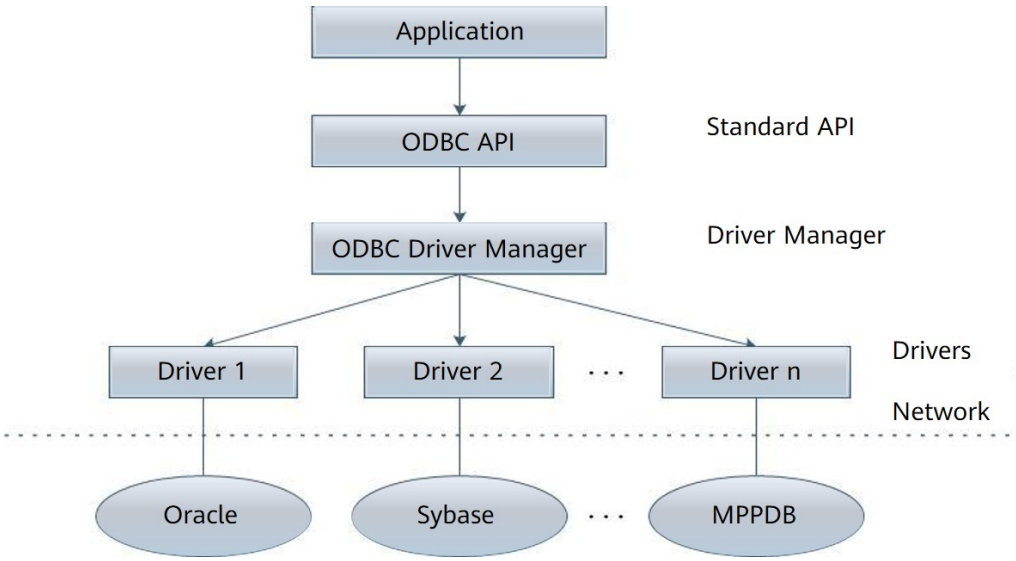
For details, see **21.1 JDBC Interface Reference**.

# 6.4 Development Based on ODBC

ODBC is a Microsoft API for accessing databases based on the X/OPEN CLI. ODBC APIs alleviate applications from directly operating in databases, and enhance the database portability, extensibility, and maintainability.

**Figure 6-2** shows the system structure of ODBC.

**Figure 6-2** ODBC system structure



GaussDB supports ODBC 3.5 in the following environments.

**Table 6-8** OSs Supported by ODBC

| OS | Platform |
| --- | --- |
| EulerOS 2.5 | x86_64 |
| EulerOS 2.8 | ARM64 |
| Windows 7 | x86_32 |
| Windows 7 | x86_64 |
| Windows Server 2008 | x86_32 |
| Windows Server 2008 | x86_64 |
| Kylin V10 | x86_64 |
| Kylin V10 | ARM64 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The ODBC Driver Manager running on UNIX or Linux can be unixODBC or iODBC. unixODBC-2.3.0 is used as the component for connecting to the database.

Windows has a native ODBC Driver Manager. You can locate **Data Sources (ODBC)** by choosing **Control Panel > Administrative Tools**.

NOTE

The current database ODBC driver is based on an open-source version and may be incompatible with Huawei-developed data types such as tinyint, smalldatetime, and nvarchar2.

## 6.4.1 ODBC Packages, Dependent Libraries, and Header Files

### ODBC Packages for the Linux OS

Obtain the ODBC package **GaussDB-Kernel-*VxxxRxxxCxx*-xxxxx-64bit-Odbc.tar.gz** from the release package. In the Linux OS, header files (including **sql.h** and **sqlext.h**) and the library (**libodbc.so**) are required in application development. These header files and library can be obtained from the unixODBC-2.3.0 installation package.

### ODBC Packages for the Windows OS

Obtain the ODBC package **GaussDB-Kernel-*VxxxRxxxCxx*-Windows-Odbc-X86.tar.gz** from the release package. In the Windows OS, the required header files and library files are system-resident.

## 6.4.2 Configuring a Data Source in the Linux OS

The ODBC DRIVER (**psqlodbcw.so**) provided by GaussDB can be used after it has been configured in a data source. To configure a data source, you must configure the **odbc.ini** and **odbcinst.ini** files on the server. The two files are generated during the unixODBC compilation and installation, and are saved in the **/usr/local/etc** directory by default.

### Procedure

**Step 1** Obtain the source code package of unixODBC by the following link:

**https://sourceforge.net/projects/unixodbc/files/unixODBC**

After the download, verify the integrity based on the integrity verification algorithm provided by the community.

**Step 2** Install unixODBC. It does not matter if unixODBC of another version has been installed.

Currently, unixODBC-2.2.1 is not supported. For example, to install unixODBC-2.3.0, run the commands below. It is installed in the **/usr/local** directory by default. The data source file is generated in the **/usr/local/etc** directory, and the library file is generated in the **/usr/local/lib** directory.

```
tar zxvf unixODBC-2.3.0.tar.gz
cd unixODBC-2.3.0
# Modify the configure file and find LIB_VERSION.
# Change the value of LIB_VERSION to 1:0:0 to compile a *.so.1 dynamic library with the same dependency
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
on psqlodbcw.so.
vim configure

./configure --enable-gui=no # To perform compilation on an Arm server, add the configure parameter: --build=aarch64-unknown-linux-gnu.
make
# The installation may require root permissions.
make install
```

**Step 3** Replace the GaussDB client driver.

Decompress the **GaussDB-Kernel-*VxxxRxxxCxx*-xxxxx-64bit-Odbc.tar.gz** package. After the decompression, the **lib** and **odbc** folders are generated. The **odbc** folder contains another **lib** folder. Copy all dynamic libraries in the **/lib** and **/odbc/lib** folders to the **/usr/local/lib** directory.

**Step 4** Configure a data source.

1. Configure the ODBC driver file.

   Add the following content to the **/usr/local/etc/odbcinst.ini** file:

   ```
   [GaussMPP]
   Driver64=/usr/local/lib/psqlodbcw.so
   setup=/usr/local/lib/psqlodbcw.so
   ```

   For descriptions of the parameters in the **odbcinst.ini** file, see **Table 6-9**.

   **Table 6-9** odbcinst.ini configuration parameters

   | Parameter | Description | Example Value |
   | --- | --- | --- |
   | [DriverName] | Driver name, corresponding to Driver in DSN. | [DRIVER_N] |
   | Driver64 | Path of the dynamic driver library. | Driver64=/usr/local/lib/psqlodbcw.so |
   | setup | Driver installation path, which is the same as the dynamic library path in Driver64. | setup=/usr/local/lib/psqlodbcw.so |

2. Configure the data source file.

   Add the following content to the end of the **/usr/local/etc/odbc.ini** file:

   ```
   [gaussdb]
   Driver=GaussMPP
   Servername=10.145.130.26 (IP address of the server where the database resides)
   Database=postgres  (database name)
   Username=omm  (database username)
   Password=    (database user password)
   Port=8000 (database listening port)
   Sslmode=allow
   ```

   For descriptions of the parameters in the **odbc.ini** file, see **Table 6-10**.

   **Table 6-10** odbc.ini configuration parameters

   | Parameter | Description | Example Value |
   | --- | --- | --- |
   | [DSN] | Data source name. | [gaussdb] |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Example Value |
| --- | --- | --- |
| Driver | Driver name, corresponding to DriverName in **odbcinst.ini**. | Driver=DRIVER_N |
| Servername | Server IP address. Multiple IP addresses can be configured. | Servername=10.145.130.26 |
| Database | Name of the database to connect. | Database=postgres |
| Username | Database username. | Username=omm |
| Password | Database user password. | Password=<br>**NOTE**<br>After a user established a connection, the ODBC driver automatically clears their password stored in memory.<br>However, if this parameter is configured, UnixODBC will cache data source files, which may cause the password to be stored in the memory for a long time.<br>When you connect to an application, you are advised to send your password through an API instead of writing it in a data source configuration file. After the connection has been established, immediately clear the memory segment where your password is stored.<br>**CAUTION**<br>The password in the configuration file must comply with the following HTTP rules:<br>1. Characters must comply with the URL encoding specifications. For example, the exclamation mark (!) must be written as %21, and the percent sign (%) must be written as %25. Therefore, pay attention to the handling of the percent sign (%).<br>2. A plus sign (+) will be replaced with a space. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Example Value |
| --- | --- | --- |
| Port | Port number of the server. When load balancing is enabled, multiple port numbers can be configured and must correspond to multiple IP addresses. If multiple IP addresses are configured and only one port number is configured when load balancing is enabled, all IP addresses share the same port number by default, that is, the configured port number. | Port=8000 |
| Sslmode | Whether to enable SSL. | Sslmode=allow |
| Debug | If this parameter is set to **1**, the **mylog** file of the PostgreSQL ODBC driver will be printed. The directory generated for storing logs is **/tmp/**. If this parameter is set to **0**, no directory is generated. | Debug=1 |
| UseServerSidePrepare | Whether to enable the extended query protocol for the database.<br>The value can be **0** or **1**. The default value is **1**, indicating that the extended query protocol is enabled. | UseServerSidePrepare=1 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Example Value |
| --- | --- | --- |
| UseBatchProtocol | Whether to enable the batch query protocol. If it is enabled, DML performance can be improved. The value can be **0** or **1**. The default value is **1**.<br>If this parameter is set to **0**, the batch query protocol is disabled (mainly for communication with earlier database versions).<br>If this parameter is set to **1** and **support_batch_bind** is set to **on**, the batch query protocol is enabled. | UseBatchProtocol=1 |
| ForExtensionConnec-tor | This parameter specifies whether the savepoint is sent. | ForExtensionConnector=1 |
| ConnectionExtraInfo | Whether to display the driver deployment path and process owner in the **connection_info** parameter mentioned in **connection_info**. | ConnectionExtraInfo=1<br>**NOTE**<br>The default value is **0**. If this parameter is set to **1**, the ODBC driver reports the driver deployment path and process owner to the database and displays the information in the **connection_info** parameter (see **connection_info**). In this case, you can query the information from **15.3.146 PG_STAT_ACTIVITY** or **15.3.197 PGXC_STAT_ACTIVITY**. |
| BoolAsChar | If this parameter is set to **Yes**, the Boolean value is mapped to the SQL_CHAR type. If this parameter is not set, the value is mapped to the SQL_BIT type. | BoolsAsChar = Yes |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Example Value |
| --- | --- | --- |
| RowVersioning | When an attempt is made to update a row of data, setting this parameter to **Yes** allows the application to detect whether the data has been modified by other users. | RowVersioning=Yes |
| ShowSystemTables | By default, the driver regards the system table as a common SQL table. | ShowSystemTables=Yes |
| AutoBalance | Specifies whether ODBC enables load balancing. The default value is **0**, indicating that load balancing is disabled. The value **1** indicates that load balancing is enabled. All values except **1** indicate that load balancing is disabled. | AutoBalance=1 |
| RefreshCNListTime | Specifies the interval for refreshing the CN list. The value is an integer and the default value is **10**. This parameter can be configured when load balancing is enabled. | RefreshCNListTime=5 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Example Value |
| --- | --- | --- |
| Priority | This parameter can be configured for load balancing. The default value is **0**, indicating that load balancing is disabled. The value **1** indicates that load balancing is enabled. All values except **1** indicate that load balancing is disabled. When **Priority** is enabled, all connections initiated by applications are preferentially sent to the CNs configured in the configuration file. If all the configured CNs are unavailable, the connections are sent to the remaining CNs. | Priority=1 |
| UsingEip | This parameter can be configured for load balancing. The default value is **0**, indicating that load balancing is disabled. The value **1** indicates that load balancing is enabled. All values except **1** indicate that load balancing is disabled. The value specifies whether to use the elastic IP address for load balancing. If **UsingEip** is enabled, the elastic IP address is used for load balancing. If **UsingEip** is disabled, the data IP address is used for load balancing. | UsingEip=1 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Example Value |
| --- | --- | --- |
| TcpUserTimeout | Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an operating system that supports the **TCP_USER_TIMEOUT** socket option. The unit is millisecond. The value **0** indicates that the default value is used. Ignore this parameter for Unix-domain connections. | TcpUserTimeout=5000 |

The valid values of **Sslmode** are as follows:

**Table 6-11** sslmode options and description

| sslmode | Whether SSL Encryption Is Enabled | Description |
| --- | --- | --- |
| disable | No | SSL connection is not enabled. |
| allow | Possible | If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified. |
| prefer | Possible | If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified. |
| require | Yes | SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified. |
| verify-ca | Yes | SSL connection is required and whether the database has a trusted certificate will be verified. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| sslmode | Whether SSL Encryption Is Enabled | Description |
| --- | --- | --- |
| verify-full | Yes | SSL connection is required. In addition to the check scope specified by **verify-ca**, the system checks whether the name of the host where the database resides is the same as that on the certificate. If they are different, modify the **/etc/hosts** file as user **root** and add the IP address and host name of the connected database node to the file. |

**----End**

## Verifying the Data Source Configuration

After the installation, the generated binary file is stored in the **/usr/bin** directory. You can run the **isql -v** *gaussdb* command (*gaussdb* is the data source name).

- If the following information is displayed, the configuration is correct and the connection succeeds.

```
+---------------------------------------+
| Connected!                            |
|                                       |
| sql-statement                         |
| help [tablename]                      |
| quit                                  |

+---------------------------------------+
SQL>
```

- If error information is displayed, the configuration is incorrect. Check the configuration.
- In a cluster environment, you need to copy and configure the unixODBC file on all nodes.

## FAQs

- [UnixODBC][Driver Manager]Can't open lib 'xxx/xxx/psqlodbcw.so' : file not found.

  Possible causes:

  – The path configured in the **odbcinst.ini** file is incorrect.

  Run **ls** to check the path in the error information, and ensure that the **psqlodbcw.so** file exists and you have execute permissions on it.

  – The dependent library of **psqlodbcw.so** does not exist or is not in system environment variables.

  Run the **ldd** command to check the path in the error information. If the UnixODBC library such as **libodbc.so.1** is missing, reconfigure UnixODBC according to the operation procedure, ensure that the **lib** directory in the installation path is added to **LD_LIBRARY_PATH**. If the problem persists after reinstallation, manually copy the contents in the **unixodbc/lib**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

directory of the database installation package to the **lib** directory in the installation path of the UnixODBC. If other libraries are missing, add the **lib** directory in the ODBC driver package to **LD_LIBRARY_PATH**.

- [UnixODBC]connect to server failed: no such file or directory

  Possible causes:

  – An incorrect or unreachable database IP address or port was configured.

    Check the **Servername** and **Port** configuration items in data sources.

  – Server monitoring is improper.

    If **Servername** and **Port** are correctly configured, ensure the proper network adapter and port are monitored by following the database server configurations in the procedure in this section.

  – Firewall and network gatekeeper settings are improper.

    Check firewall settings, and ensure that the database communication port is trusted.

    Check to ensure network gatekeeper settings are proper (if any).

- [unixODBC]The password-stored method is not supported.

  Possible causes:

  The **sslmode** configuration item is not configured in the data sources.

  Solution:

  Set the configuration item to **allow** or a higher level. For details, see **Table 6-11**.

- Server common name "xxxx" does not match host name "xxxxx"

  Possible causes:

  When **verify-full** is used for SSL encryption, the driver checks whether the host name in certificates is the same as the actual one.

  Solution:

  To solve this problem, use **verify-ca** to stop checking host names, or generate a set of server certificates containing the actual host names.

- Driver's SQLAllocHandle on SQL_HANDLE_DBC failed

  Possible causes:

  The executable file (such as the **isql** tool of unixODBC) and the database driver (**psqlodbcw.so**) depend on different library versions of ODBC, such as **libodbc.so.1** and **libodbc.so.2**. You can verify this problem by using the following method:

  ```
  ldd `which isql` | grep odbc
  ldd psqlodbcw.so | grep odbc
  ```

  If the suffix digits of the outputs **libodbc.so** are different or indicate different physical disk files, this problem exists. Both **isql** and **psqlodbcw.so** load **libodbc.so**. If different physical files are loaded, different ODBC libraries with the same function list conflict with each other in a visible domain. As a result, the database driver cannot be loaded.

  Solution:

  Uninstall the unnecessary unixODBC, such as libodbc.so.2, and create a soft link with the same name and the .so.2 suffix for the remaining libodbc.so.1 library.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- FATAL: Forbid remote connection with trust method!

  For security purposes, the database CN forbids access from other nodes in the cluster without authentication.

  To access the CN from inside the cluster, deploy the ODBC program on the host where the CN is located and use 127.0.0.1 as the server address. It is recommended that the service system be deployed outside the cluster. If it is deployed inside, database performance may be affected.

- [unixODBC][Driver Manager]Invalid attribute value

  This problem occurs when you use SQL on other GaussDB. The possible cause is that the unixODBC version is not the recommended one. You are advised to run the **odbcinst --version** command to check the unixODBC version.

- authentication method 10 not supported.

  If this error occurs on an open-source client, the cause may be:

  The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

  NOTE

  - The database stores the hashes of user passwords instead of actual passwords.
  - If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
  - An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the old version will only have SHA-256 hashes and not support MD5 authentication.
  - The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

  To solve this problem, you can update the user password (see **12.14.37 ALTER USER**) or create a user (see **12.14.88 CREATE USER**) having the same permissions as the faulty user.

- unsupported frontend protocol 3.51: server supports 1.0 to 3.0

  The database version is too early or the database is an open-source database. Use the driver of the required version to connect to the database.

- isql: error while loading shared libraries: xxx

  The dynamic library does not exist in the environment. You need to install the corresponding library.

## 6.4.3 Configuring a Data Source in the Windows OS

Configure an ODBC data source using the ODBC data source manager preinstalled in the Windows OS.

### Procedure

**Step 1** Replace the GaussDB client driver.

Decompress **GaussDB-Kernel-*VxxxRxxxCxx*-Windows-Odbc.tar.gz** and install **psqlodbc.exe** (for the 32-bit OS) as required.

**Step 2** Open Driver Manager.

Use the ODBC Driver Manager for the 32-bit OS to configure the data source. (Currently, only the ODBC Driver Manager for the 32-bit OS is supported. The

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

following description assumes that the OS is installed on drive C. If the OS is installed on another drive, change the path accordingly.)

- For a 64-bit OS, open **C:\Windows\SysWOW64\odbcad32.exe**. Do not choose **Control Panel** > **Administrative Tools** > **Data Sources (ODBC)**.

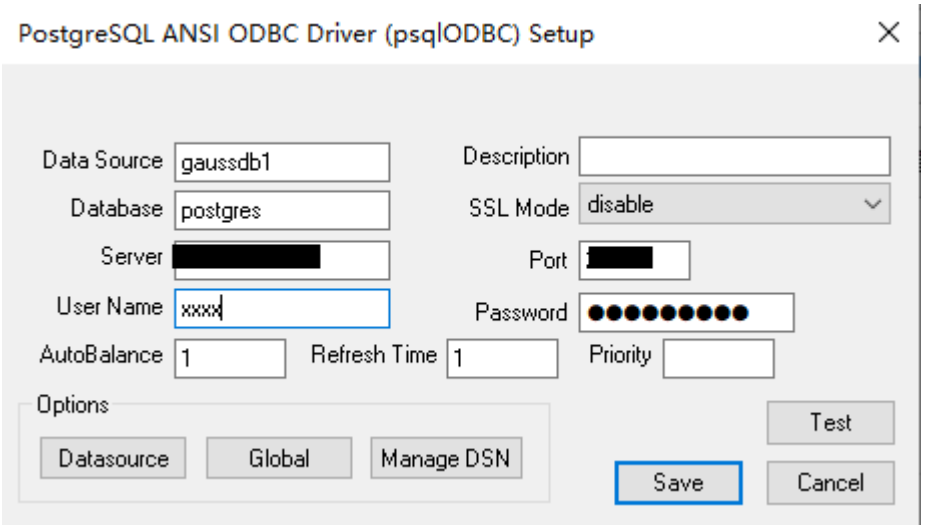
  NOTE

  WoW64 is short for Windows 32-bit on Windows 64-bit. **C:\Windows\SysWOW64** stores the 32-bit environment on a 64-bit system. **C:\Windows\System32** stores the environment consistent with the current OS. For technical details, see Windows technical documents.

- For a 32-bit OS, open **C:\Windows\System32\odbcad32.exe** or choose **Computer** > **Control Panel** > **Administrative Tools** > **Data Sources (ODBC)** to open Driver Manager.

**Step 3** Configure a data source.

On the **User DSN** tab, click **Add** and choose **PostgreSQL Unicode** for setup.



NOTICE

The entered username and password will be recorded in the Windows registry and you do not need to enter them again when connecting to the database next time. For security purposes, you are advised to delete sensitive information before clicking **Save** and enter the required username and password again when using ODBC APIs to connect to the database.

**Step 4** Enable the SSL mode.

Copy the **client.crt**, **client.key**, **client.key.cipher**, and **client.key.rand** files in the certificate file folder to the manually created directory **%APPDATA%\postgresql**. Change **client** in the file names to **postgres**, for example, change **client.key** to **postgres.key**. Copy the **cacert.pem** file to the **%APPDATA%\postgresql** directory and change its name to **root.crt**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

**%APPDATA%** is located in **C:\Users\[username]\AppData** by default, and its values is specified by customers during installation.

Change the value of **SSL Mode** in Step 2 to **require**.

**Table 6-12** sslmode options and description

| sslmode | Whether SSL Encryption Is Enabled | Description |
| --- | --- | --- |
| disable | No | SSL connection is not enabled. |
| allow | Possible | If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified. |
| prefer | Possible | If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified. |
| require | Yes | SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified. |
| verify-ca | Yes | SSL connection is required and whether the database has a trusted certificate will be verified. Currently, Windows ODBC does not support the cert authentication. |
| verify-full | Yes | SSL connection is required. In addition to the check scope specified by **verify-ca**, the system checks whether the name of the host where the database resides is the same as that in the certificate. Currently, Windows ODBC does not support the cert authentication. |

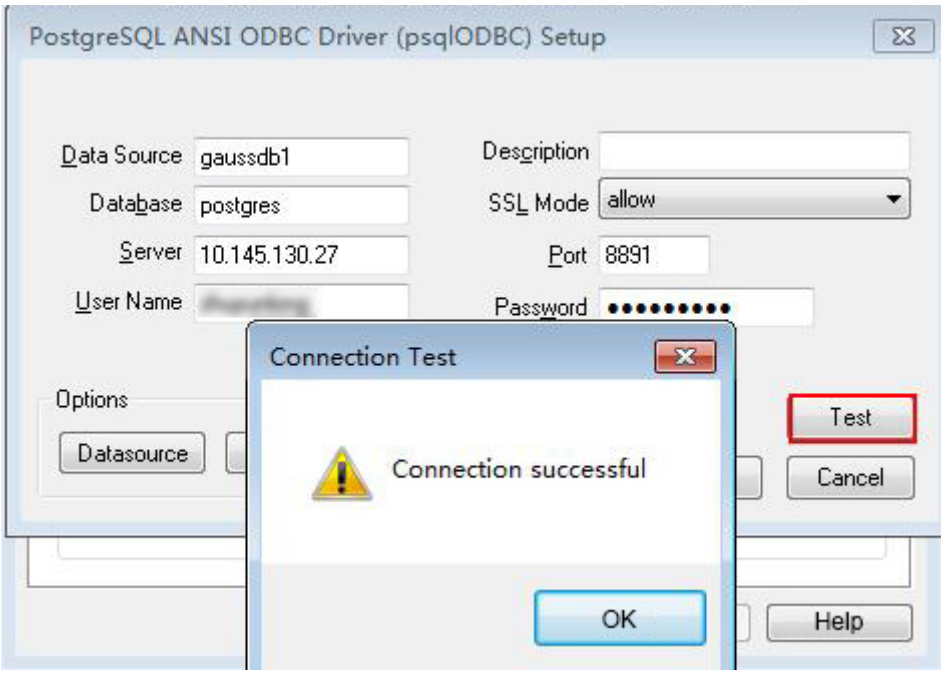
**----End**

## Verifying the Data Source Configuration

Click **Test**.

- If the following information is displayed, the configuration is correct and the connection succeeds.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 



- If error information is displayed, the configuration is incorrect. Check the configuration.

## FAQs

- connect to server failed: no such file or directory

  Possible causes:

  – An incorrect or unreachable database IP address or port was configured.

  Check the **Servername** and **Port** configuration items in data sources.

  – Server monitoring is improper.

  If **Servername** and **Port** are correctly configured, ensure the proper network adapter and port are monitored by following the database server configurations in the procedure in this section.

  – Firewall and network gatekeeper settings are improper.

  Check firewall settings, and ensure that the database communication port is trusted.

  Check to ensure network gatekeeper settings are proper (if any).

- The password-stored method is not supported.

  Possible causes:

  **sslmode** is not configured for the data source. Set this configuration item to **allow** or a higher level to enable SSL connections. For details on **sslmode**, see **Table 6-12**.

- authentication method 10 not supported.

  If this error occurs on an open-source client, the cause may be:

  The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- The database stores the hashes of user passwords instead of actual passwords.
- If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
- An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the old version will only have SHA-256 hashes and not support MD5 authentication.
- The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

To solve this problem, you can update the user password (see **12.14.37 ALTER USER**) or create a user (see **12.14.88 CREATE USER**) having the same permissions as the faulty user.

- unsupported frontend protocol 3.51: server supports 1.0 to 3.0

  The database version is too early or the database is an open-source database. Use the driver of the required version to connect to the database.

## 6.4.4 Development Process

**Figure 6-3** ODBC-based application development process

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## APIs Involved in the Development Process

**Table 6-13** API description

| Function | API |
| --- | --- |
| Allocate a handle | **21.2.3 SQLAllocHandle** is a generic function for allocating a handle. It can replace the following functions:<br>• **21.2.1 SQLAllocEnv**: allocate an environment handle<br>• **21.2.2 SQLAllocConnect**: allocate a connection handle<br>• **21.2.4 SQLAllocStmt**: allocate a statement handle |
| Set environment attributes | **21.2.21 SQLSetEnvAttr** |
| Set connection attributes | **21.2.20 SQLSetConnectAttr** |
| Set statement attributes | **21.2.22 SQLSetStmtAttr** |
| Connect to a data source | **21.2.8 SQLConnect** |
| Bind a buffer to a column in the result set | **21.2.5 SQLBindCol** |
| Bind the parameter marker of an SQL statement to a buffer | **21.2.6 SQLBindParameter** |
| Return the error message of the last operation | **21.2.19 SQLGetDiagRec** |
| Prepare an SQL statement for execution | **21.2.17 SQLPrepare** |
| Run a prepared SQL statement | **21.2.11 SQLExecute** |
| Run an SQL statement directly | **21.2.10 SQLExecDirect** |
| Fetch the next row (or rows) from the result set | **21.2.12 SQLFetch** |
| Return data in a column of the result set | **21.2.18 SQLGetData** |
| Get the column information from a result set | **21.2.7 SQLColAttribute** |
| Disconnect from a data source | **21.2.9 SQLDisconnect** |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Function | API |
| --- | --- |
| Release a handle | 21.2.15 SQLFreeHandle is a generic function for releasing a handle. It can replace the following functions:<br>• 21.2.16 SQLFreeEnv: release an environment handle<br>• 21.2.14 SQLFreeConnect: release a connection handle<br>• 21.2.13 SQLFreeStmt: release a statement handle |

NOTE

If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. If one of the statements fails, the entire request will be rolled back.

WARNING

ODBC connects applications to the database and delivers the SQL statements sent by an application to the database. It does not parse the SQL syntax. Therefore, when confidential information (such as a plaintext password) is written into the SQL statement sent by an application, the confidential information is exposed in the driver log.

## 6.4.5 Example: Common Functions and Batch Binding

### Code for Common Functions

```
//The following example shows how to obtain data from GaussDB through the ODBC interface.
// DBtest.c (compile with: libodbc.so)
#include <stdlib.h>
#include <stdio.h>
#include <sqlext.h>
#ifdef WIN32
#include <windows.h>
#endif
SQLHENV       V_OD_Env;        // Handle ODBC environment
SQLHSTMT      V_OD_hstmt;      // Handle statement
SQLHDBC       V_OD_hdbc;       // Handle connection
char          typename[100];
SQLINTEGER    value = 100;
SQLINTEGER    V_OD_erg,V_OD_buffer,V_OD_err,V_OD_id;
int main(int argc,char *argv[])
{
    // 1. Allocate an environment handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_ENV,SQL_NULL_HANDLE,&V_OD_Env);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        printf("Error AllocHandle\n");
        exit(0);
    }
    // 2. Set environment attributes (version information).
    SQLSetEnvAttr(V_OD_Env, SQL_ATTR_ODBC_VERSION, (void*)SQL_OV_ODBC3, 0);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
    // 3. Allocate a connection handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_DBC, V_OD_Env, &V_OD_hdbc);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
        exit(0);
    }
    // 4. Set connection attributes.
    SQLSetConnectAttr(V_OD_hdbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_ON, 0);
   // 5. Connect to the data source. userName and password indicate the username and password for connecting to the database. Set them as needed.
    // If the username and password have been set in the odbc.ini file, you do not need to set userName or password here, retaining "" for them. However, you are not advised to do so because the username and password will be disclosed if the permission for odbc.ini is abused.
    V_OD_erg = SQLConnect(V_OD_hdbc, (SQLCHAR*) "gaussdb", SQL_NTS,
                          (SQLCHAR*) "userName", SQL_NTS,  (SQLCHAR*) "password", SQL_NTS);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        printf("Error SQLConnect %d\n",V_OD_erg);
        SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
        exit(0);
    }
    printf("Connected !\n");
    // 6. Set statement attributes.
    SQLSetStmtAttr(V_OD_hstmt,SQL_ATTR_QUERY_TIMEOUT,(SQLPOINTER *)3,0);
     // 7. Allocate a statement handle.
    SQLAllocHandle(SQL_HANDLE_STMT, V_OD_hdbc, &V_OD_hstmt);
    // 8. Run SQL statements.
    SQLExecDirect(V_OD_hstmt,"drop table IF EXISTS customer_t1",SQL_NTS);
    SQLExecDirect(V_OD_hstmt,"CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name VARCHAR(32));",SQL_NTS);
    SQLExecDirect(V_OD_hstmt,"insert into customer_t1 values(25,'li')",SQL_NTS);
    // 9. Prepare for execution.
    SQLPrepare(V_OD_hstmt,"insert into customer_t1 values(?)",SQL_NTS);
    // 10. Bind parameters.
    SQLBindParameter(V_OD_hstmt,1,SQL_PARAM_INPUT,SQL_C_SLONG,SQL_INTEGER,0,0,
                     &value,0,NULL);
    // 11. Run prepared statements.
    SQLExecute(V_OD_hstmt);
    SQLExecDirect(V_OD_hstmt,"select c_customer_sk from customer_t1",SQL_NTS);
    // 12. Obtain attributes of a specific column in the result set.
    SQLColAttribute(V_OD_hstmt,1,SQL_DESC_TYPE,typename,100,NULL,NULL);
    printf("SQLColAtrribute %s\n",typename);
    // 13. Bind the result set.
    SQLBindCol(V_OD_hstmt,1,SQL_C_SLONG, (SQLPOINTER)&V_OD_buffer,150,
            (SQLLEN *)&V_OD_err);
    // 14. Obtain data in the result set by executing SQLFetch.
    V_OD_erg=SQLFetch(V_OD_hstmt);
    // 15. Obtain and return data by executing SQLGetData.
    while(V_OD_erg != SQL_NO_DATA)
    {
        SQLGetData(V_OD_hstmt,1,SQL_C_SLONG,(SQLPOINTER)&V_OD_id,0,NULL);
        printf("SQLGetData ----ID = %d\n",V_OD_id);
        V_OD_erg=SQLFetch(V_OD_hstmt);
    };
    printf("Done !\n");
    // 16. Disconnect data source connections and release handles.
    SQLFreeHandle(SQL_HANDLE_STMT,V_OD_hstmt);
    SQLDisconnect(V_OD_hdbc);
    SQLFreeHandle(SQL_HANDLE_DBC,V_OD_hdbc);
    SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
    return(0);
}
```

## Code for Batch Processing

```
/*****************************************************************
*Enable UseBatchProtocol in the data source and set the database parameter support_batch_bind
*to on.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
*The CHECK_ERROR command is used to check and print error information.
*This example is used to interactively obtain the DSN, data volume to be processed, and volume of ignored data from users, and insert required data into the test_odbc_batch_insert table.
**************************************************************************/
#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
#include <string.h>

# 6.4.6 Typical Application Scenarios and Configurations

## Log Diagnosis

ODBC logs are classified into unixODBC driver manager logs and psqlODBC driver logs. The former is used to trace whether the application API is successfully executed, and the latter is used to locate problems based on DFX logs generated during underlying implementation.

The unixODBC log needs to be configured in the **odbcinst.ini** file:

```
[ODBC]
Trace=Yes
TraceFile=/path/to/odbctrace.log

[GaussMPP]
Driver64=/usr/local/lib/psqlodbcw.so
setup=/usr/local/lib/psqlodbcw.so
```

You only need to add the following information to the **odbc.ini** file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 (database server IP address)
...
Debug=1 (Enable the debug log function of the driver.)
```

NOTE

The unixODBC logs are generated in the path configured by **TraceFile**. The psqlODBC generates the **mylog**_*xxx*.**log** file in the **/tmp/** directory.

## High Performance

If a large amount of data needs to be inserted, you are advised to perform the following operations:

- Set **UseBatchProtocol** to **1** in **odbc.ini** and set **support_batch_bind** in the database.
- Set the ODBC program binding type to be the same as that in the database.
- Set the character set of the client to be the same as that in the database.
- Commit the transaction manually.

**odbc.ini** configuration file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 (database server IP address)
...
UseBatchProtocol=1 (enabled by default)
ConnSettings=set client_encoding=UTF8 (Set the character code on the client to be the same as that on the server.)
```

Binding type case:

```
#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
#include <string.h>
#include <sys/time.h>

#define MESSAGE_BUFFER_LEN  128
SQLHANDLE   h_env = NULL;
SQLHANDLE   h_conn = NULL;
```

    /* Final step. Delete the table and restore the environment. */
    RETURN_IF_NOT_SUCCESS(execute_cmd(sql_drop));

    end_unit_test();
}
```

**NOTE**

In the example, the number column is defined. When the SQLBindParameter API is called, the performance of binding SQL_NUMERIC is higher than that of SQL_LONG. If char is used, the data type needs to be converted when data is inserted to the database server, causing a performance bottleneck.

## Load Balancing

Load balancing can be enabled when there are a large number of concurrent applications.

- Randomly distribute concurrent connections to all CNs to enable load balancing, preventing a single CN from being overloaded and achieving high performance.
- Set **AutoBalance** to **1** to enable load balancing.
- Set **RefreshCNListTime** to **5** as required. The default refresh interval is 10 seconds.
- Set **Priority** to **1** as required. In this case, concurrent connections are preferentially sent to the CNs configured in the configuration file. If all the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

configured CNs are unavailable, the connections are distributed to the remaining CNs.

Example:

Six CNs, namely, CN1, CN2, CN3, CN4, CN5, and CN6, are configured in the cluster, and four CNs, namely, CN1, CN2, CN3, and CN4, are configured in the configuration file.

Example content of the configuration file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.145.130.26,10.145.130.27,10.145.130.28,10.145.130.29 (IP address of the database server)
Database=postgres  (database name)
Username=omm  (database username)
Password=    (user password of the database)
Port=8000 (database listening port)
Sslmode=allow
AutoBalance=1
RefreshCNListTime=3
Priority=1
```

If the configuration file and cluster environment are the same as those in the example, concurrent connections are randomly and evenly distributed to CN1, CN2, CN3, and CN4. When CN1, CN2, CN3, and CN4 are all unavailable, concurrent connections are randomly and evenly sent to CN5 and CN6. If any CN among CN1, CN2, CN3, and CN4 becomes available, the connections are not sent to CN5 and CN6 but to the available CN.

## 6.4.7 ODBC Interface Reference

For details, see **21.2 ODBC Interface Reference**.

# 6.5 Development Based on libpq

**libpq** is a C application programming interface to GaussDB. libpq contains a set of library functions that allow client programs to send query requests to GaussDB servers and obtain query results. It is also the underlying engine of other GaussDB application interfaces, such as ODBC. This chapter provides two examples to show how to write code using **libpq**.

## 6.5.1 Dependent Header Files of libpq

Client programs that use libpq must include the header file **libpq-fe.h** and must link with the libpq library.

## 6.5.2 Development Process

To compile and connect to a libpq source program, perform the following operations:

- Decompress the **GaussDB-Kernel-VxxxRxxxCxx-xxxxx-64bit-Libpq.tar.gz** file. The required header file is stored in the **include** folder, and the **lib** folder contains the required libpq library file.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

> **NOTE**
>
> In addition to **libpq-fe.h**, the **include** folder contains the header files **postgres_ext.h**, **gs_thread.h**, and **gs_threadlocal.h** by default. These three header files are the dependency files of **libpq-fe.h**.

- Include the **libpq-fe.h** header file.
  ```
  #include <libpq-fe.h>
  ```
- Provide the **-I** *directory* option to provide the installation location of the header file. (Sometimes the compiler looks for the default directory, so this option can be ignored.) Example:
  ```
  gcc -I (Directory where the header file is located) -L (Directory where the libpq library is located)
  testprog.c -lpq
  ```
- If the makefile is used, add the following option to variables *CPPFLAGS*, *LDFLAGS*, and *LIBS*:
  ```
  CPPFLAGS += -I (Directory of the header file)
  LDFLAGS += -L (Directory of the libpq library)
  LIBS += -lpq
  ```

# 6.5.3 Example

## Code for Common Functions

Example 1:

```
/*
 * testlibpq.c
 */
#include <stdio.h>
#include <stdlib.h>
#include <libpq-fe.h>

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

int
main(int argc, char **argv)
{
    const char *conninfo;
    PGconn     *conn;
    PGresult   *res;
    int         nFields;
    int         i,j;

    /*
     * This value is used when the user provides the value of the conninfo character string in the command
line.
     * Otherwise, the environment variables or the default values
     * are used for all other connection parameters.
     */
    if (argc > 1)
        conninfo = argv[1];
    else
        conninfo = "dbname=postgres port=42121 host='10.44.133.171' application_name=test
connect_timeout=5 sslmode=allow user='test' password='test_1234'";

    /* Connect to the database. */
    conn = PQconnectdb(conninfo);

    /* Check whether the backend connection was successfully established. */
    if (PQstatus(conn) != CONNECTION_OK)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
{
    fprintf(stderr, "Connection to database failed: %s",
            PQerrorMessage(conn));
    exit_nicely(conn);
}

/*
 * Since a cursor is used in the test case, a transaction block is required.
 * Put all data in one "select * from pg_database"
 * PQexec() is too simple and is not recommended.
 */

/* Start a transaction block. */
res = PQexec(conn, "BEGIN");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "BEGIN command failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/*
 * PQclear PGresult should be executed when it is no longer needed, to avoid memory leakage.
 */
PQclear(res);

/*
 * Fetch data from the pg_database system catalog.
 */
res = PQexec(conn, "DECLARE myportal CURSOR FOR select * from pg_database");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "DECLARE CURSOR failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}
PQclear(res);

res = PQexec(conn, "FETCH ALL in myportal");
if (PQresultStatus(res) != PGRES_TUPLES_OK)
{
    fprintf(stderr, "FETCH ALL failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/* First, print out the attribute name. */
nFields = PQnfields(res);
for (i = 0; i < nFields; i++)
    printf("%-15s", PQfname(res, i));
printf("\n\n");

/*Print lines.*/
for (i = 0; i < PQntuples(res); i++)
{
    for (j = 0; j < nFields; j++)
        printf("%-15s", PQgetvalue(res, i, j));
    printf("\n");
}

PQclear(res);

/* Close the portal. We do not need to check for errors. */
res = PQexec(conn, "CLOSE myportal");
PQclear(res);

/* End the transaction. */
res = PQexec(conn, "END");
PQclear(res);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
    /* Close the database connection and clean up the database. */
    PQfinish(conn);

    return 0;
}
```

Example 2:

```
/*
 * testlibpq2.c
 *      Test out-of-line parameters and binary I/Os.
 *
 * Before running this example, run the following command to populate a database:
 *
 *
 * CREATE TABLE test1 (i int4, t text);
 *
  * INSERT INTO test1 values (2, 'ho there');
 *
 * Expected output:
 *
 *
 * tuple 0: got
 *  i = (4 bytes) 2
 *  t = (8 bytes) 'ho there'
 *
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <libpq-fe.h>

/* for ntohl/htonl */
#include <netinet/in.h>
#include <arpa/inet.h>

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

/*
 * This function is used to print out the query results. The results are in binary format
* and fetched from the table created in the comment above.
 */
static void

        cnt = PQntuples(res);
        printf("return %d rows\n", cnt);
        for (i=0; i<cnt; i++)
        {
            printf("row %d: %s\n", i, PQgetvalue(res, i, 0));
        }
        PQclear(res);
    }
    PQfinish(conn);
    return 0;
}
```

## 6.5.4 libpq Interface Reference

For details, see **21.3 libpq Interface Reference**.

## 6.5.5 Link Parameters

**Table 6-14** Link parameters

| Parameter | Description |
| --- | --- |
| host | Name of the host to connect to. If the host name starts with a slash (/), Unix-domain socket communications instead of TCP/IP communications are used. The value is the directory where the socket file is stored. If **host** is not specified, the default behavior is to connect to the Unix-domain socket in the **/tmp** directory (or the socket directory specified during GaussDB installation). On a machine without a Unix-domain socket, the default behavior is to connect to **localhost**. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| hostaddr | IP address of the host to connect to. The value is in standard IPv4 address format, for example, 172.28.40.9. If a non-null character string is specified, TCP/IP communications are used.<br>Replacing **host** with **hostaddr** can prevent applications from querying host names, which may be important for applications with time constraints. However, a host name is required for GSSAPI or SSPI authentication methods. Therefore, the following rules are used:<br>1. If **host** is specified but **hostaddr** is not, a query for the host name will be executed.<br>2. If **hostaddr** is specified but **host** is not, the value of **hostaddr** is the server network address. If the host name is required by authentication, the connection attempt fails.<br>3. If both **host** and **hostaddr** are specified, the value of **hostaddr** is the server network address. The value of **host** is ignored unless it is required by authentication, in which case it is used as the host name.<br>**NOTICE**<br>• If **host** is not the server name in the network address specified by **hostaddr**, the authentication may fail.<br>• If neither **host** nor **hostaddr** is specified, libpq will use a local Unix-domain socket for connection. If the machine does not have a Unix-domain socket, it will attempt to connect to **localhost**. |
| port | Port number of the host server, or the socket file name extension for Unix-domain connections. |
| user | Name of the user to connect as. By default, the username is the same as the operating system name of the user running the application. |
| dbname | Database name. The default value is the same as the username. |
| password | Password to be used if the server requires password authentication. |
| connect_timeout | Maximum timeout period of the connection, in seconds (in decimal integer string). The value **0** or null indicates infinity. You are not advised to set the connection timeout period to a value less than 2 seconds. |
| client_encoding | Client encoding for the connection. In addition to the values accepted by the corresponding server options, you can use **auto** to determine the correct encoding from the current environment in the client (the **LC_CTYPE** environment variable in the Unix system). |
| tty | This parameter can be ignored. (This parameter was used to specify the location to which the debugging output of the server was sent). |
| options | Adds command-line options to send to the server at runtime. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| application_name | Current user identity. |
| fallback_application_name | Specifies a backup value for the **application_name** parameter. This value is used if no value is set for **application_name** through a connection parameter or the *PGAPPNAME* environment variable. It is useful to specify a backup value in a common tool program that wants to set a default application name but does not want it to be overwritten by the user. |
| keepalives | Whether TCP keepalive is enabled on the client side. The default value is **1**, indicating that the function is enabled. The value **0** indicates that the function is disabled. Ignore this parameter for Unix-domain connections. |
| keepalives_idle | The number of seconds of inactivity after which TCP should send a keepalive message to the server. The value **0** indicates that the default value is used. Ignore this parameter for Unix-domain connections or if keep-alive is disabled. |
| keepalives_interval | The number of seconds after which a TCP keepalive message that is not acknowledged by the server should be retransmitted. The value **0** indicates that the default value is used. Ignore this parameter for Unix-domain connections or if keep-alive is disabled. |
| keepalives_count | Controls the number of times that keepalive messages are sent through TCP. The value **0** indicates that the default value is used. Ignore this parameter for Unix-domain connections or if keep-alive is disabled. |
| tcp_user_timeout | Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an operating system that supports the **TCP_USER_TIMEOUT** socket option. The value **0** indicates that the default value is used. Ignore this parameter for Unix-domain connections. |
| rw_timeout | Sets the read and write timeout interval of the client connection. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| sslmode | SSL encryption mode:<br>• **disable**: SSL connection is not enabled.<br>• **allow**: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.<br>• **prefer**: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.<br>• **require**: SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.<br>• **verify-ca**: SSL connection is required. Currently, Windows ODBC does not support cert authentication.<br>• **verify-full**: SSL connection is required. Currently, Windows ODBC does not support cert authentication. |
| sslcompression | If this parameter is set to **1** (default value), the data transmitted over the SSL connection is compressed (this requires that the OpenSSL version be 0.9.8 or later). If set to **0**, compression will be disabled (this requires OpenSSL 1.0.0 or later). If a connection without SSL is established, this parameter is ignored. If the OpenSSL version in use does not support this parameter, it will also be ignored. Compression takes up CPU time, but it increases throughput when the bottleneck is the network. If CPU performance is a limiting factor, disabling compression can improve response time and throughput. |
| sslcert | This parameter specifies the file name of the client SSL certificate. It replaces the default **~/.postgresql/postgresql.crt**. If no SSL connection is established, this parameter is ignored. |
| sslkey | This parameter specifies the location of the key used for the client certificate. It can specify the name of a file used to replace the default **~/.postgresql/postgresql.key**, or specify a key obtained from an external "engine" that is a loadable module of OpenSSL. An external engine description should consist of a colon-separated engine name and an engine-related key identifier. If no SSL connection is established, this parameter is ignored. |
| sslrootcert | This parameter specifies the name of a file that contains the SSL Certificate Authority (CA) certificate. If the file exists, the system authenticates the server certificate issued by one of these authorities. The default value is **~/.postgresql/root.crt**. |
| sslcrl | This parameter specifies the file name of the SSL Certificate Revocation List (CRL). If a certificate listed in this file exists, the server certificate authentication will be rejected. The default value is **~/.postgresql/root.crl**. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| requirepeer | This parameter specifies the OS user of the server, for example, **requirepeer=postgres**. When a Unix-domain socket connection is established, if this parameter is set, the client checks whether the server process is running under the specified user name at the beginning of the connection. If not, the connection will be interrupted by an error. This parameter can be used to provide server authentication similar to that of the SSL certificate on TCP/IP connections. (Note that if the Unix domain socket is in **/tmp** or another public writable location, any user can start a server for listening on the location. Use this parameter to ensure that you are connected to a server that is run by a trusted user.) This option is supported only on platforms that implement the peer authentication method. |
| krbsrvname | This parameter specifies the Kerberos service name used for GSSAPI authentication. For successful Kerberos authentication, this value must match the service name specified in the server configuration. |
| gsslib | This parameter specifies the GSS library used for GSSAPI authentication. It is used only in the Windows OS. If this parameter is set to **gssapi**, the libpq is forced to use the GSSAPI library to replace the default SSPI for authentication. |
| service | This parameter specifies the name of the service for which the additional parameter is used. It specifies a service name in **pg_service.conf** that holds the additional connection parameters. This allows the application to specify only one service name so that the connection parameters can be centrally maintained. |
| authtype | **authtype** is no longer used, so it is marked as a parameter not to be displayed. It is retained in an array so as not to reject the **conninfo** string from old applications that might still try to set it. |
| remote_nodename | Specifies the name of the remote node connected to the local node. |
| localhost | Specifies the local host in a connection channel. |
| localport | Specifies the local port in a connection channel. |
| fencedUdfRPCMode | Specifies whether the fenced udf RPC protocol uses UNIX domain sockets or special socket file names. The default value is **0**, indicating that the UNIX domain socket mode is used and the file type is .s.PGSQL.%d. To use the fenced UDF mode, set this parameter to **1**. In this case, the file type is .s.fencedMaster_unixdomain. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| replication | Specifies whether the connection should use replication protocols instead of common protocols. Protocols with this parameter configured are internal protocols used for PostgreSQL replication connections and tools such as **pg_basebackup**, while they can also be used by third-party applications. The following values, which are case-insensitive, are supported:<br>• **true**, **on**, **yes**, and **1**<br>Specify whether the physical replication mode is connected.<br>• database<br>Specifies that the logical replication mode and the database specified by **dbname** are connected.<br>• **false**, **off**, **no**, and **0**<br>Specify that the connection is a regular connection, which is the default behavior.<br>In physical or logical replication mode, only simple query protocols can be used. |
| backend_version | Specifies the backend version to be passed to the remote end. |
| prototype | Sets the current protocol level. The default value is **PROTO_TCP**. |
| enable_ce | Specifies whether a client is allowed to connect to a fully-encrypted database. The default value is **0**. To enable this function, change the value to **1**. |
| connection_info | The value of **connection_info** is a JSON character string consisting of **driver_name**, **driver_version**, **driver_path**, and **os_user**.<br>If the value is not null, use **connection_info** and ignore **connectionExtraInf**.<br>If the value is null, a connection information string related to **libpq** is generated. When **connectionExtraInf** is set to **false**, the value of **connection_info** consists of only **driver_name** and **driver_version**. |
| connectionExtraInf | Specifies whether the value of **connection_info** contains extension information. The default value is **0**. If the value contains other information, set this parameter to **1**. |

# 6.6 Psycopg-based Development

Psycopg is a Python API used to execute SQL statements and provides a unified access API for PostgreSQL and GaussDB. Applications can perform data operations based on psycopg. Psycopg2 is an encapsulation of libpq and is implemented using the C language, which is efficient and secure. It provides cursors on both clients and servers, asynchronous communication and notification, and the COPY

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

TO and COPY FROM functions. Psycopg2 supports multiple types of Python out-of-the-box and adapts to PostgreSQL data types. Through the flexible object adaptation system, you can extend and customize the adaptation. Psycopg2 is compatible with Unicode and Python 3.

GaussDB supports Psycopg2 features and allows Psycopg2 to be connected in SSL mode.

**Table 6-15** Platforms supported by Psycopg

| OS | Platform |
| --- | --- |
| EulerOS 2.5 | x86_64 |
| EulerOS 2.8 | ARM64 |
| Kylin | x86_64 |
| Kylin | ARM64 |

**NOTICE**

OpenSSL of GaussDB is linked during Psycopg2 compilation. It may be incompatible with OpenSSL of the operating system. If incompatibility occurs, for example, "version 'OPENSSL_1_1_1f' not found" is displayed, use the environment variable **LD_LIBRARY_PATH** to isolate the OpenSSL provided by the operating system and the OpenSSL on which GaussDB depends.

For example, when the application software **client.py** that invokes Psycopg2 is executed, the environment variable is explicitly assigned to the application software.

```
export LD_LIBRARY_PATH=/path/to/gaussdb/libs:$LD_LIBRARY_PATH python client.py
```

In the preceding command, **/path/to/pyscopg2/lib** indicates the directory where the OpenSSL library on which GaussDB depends is located. Change it as required.

## 6.6.1 Psycopg Package

The psycopg package is obtained from the release package. Its name is **GaussDB-Kernel-*VxxxRxxxCxx*-*OS version number*-64bit-Python.tar.gz**.

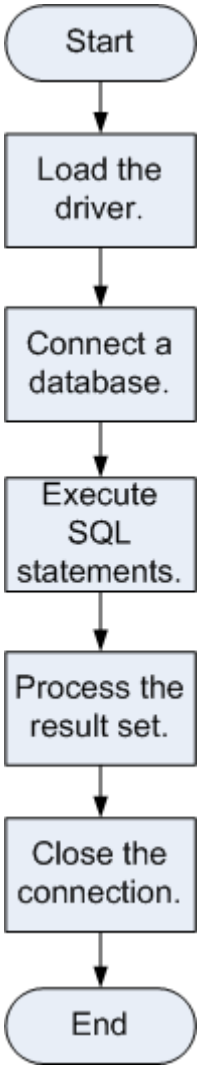
After the decompression, the following folders are generated:

- **psycopg2**: **psycopg2** library file
- **lib**: **lib** library file

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## 6.6.2 Development Process

**Figure 6-4** Application development process based on psycopg2



## 6.6.3 Loading a Driver

- Before using the driver, perform the following operations:
  a. Decompress the driver package of the corresponding version and copy psycopg2 to the **site-packages** folder in the Python installation directory as the **root** user.
  b. Change the **psycopg2** directory permission to **755**.
  c. Add the **psycopg2** directory to the environment variable *$PYTHONPATH* and validate it.
  d. For non-database users, configure the **lib** directory in *LD_LIBRARY_PATH* after decompression.
- Load the database driver before creating a database connection.

```
import  psycopg2
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## 6.6.4 Connecting a Database

1. Use the **psycopg2.connect** function to obtain the connection object.
2. Use the connection object to create a cursor object.

## 6.6.5 Executing SQL Statements

1. Construct an operation statement and use **%s** as a placeholder. During execution, psycopg2 will replace the placeholder with the parameter value. You can add the RETURNING clause to obtain the automatically generated column values.
2. The **cursor.execute** method is used to perform operations on one row, and the **cursor.executemany** method is used to perform operations on multiple rows.

## 6.6.6 Processing the Result Set

1. **cursor.fetchone()**: Fetches the next row in a query result set and returns a sequence. If no data is available, null is returned.
2. **cursor.fetchall()**: Fetches all remaining rows in a query result and returns a list. An empty list is returned when no rows are available.

NOTE

For GaussDB-specific data types, such as tinyint, the corresponding fields in the query result are character strings.

## 6.6.7 Closing the Connection

After you complete required data operations in a database, close the database connection. Call the close method such as **connection.close()** to close the connection.

CAUTION

This method closes the database connection and does not automatically call **commit()**. If you just close the database connection without calling **commit()** first, changes will be lost.

## 6.6.8 Connecting the Database (Using SSL)

When you use psycopy2 to connect to the GaussDB server, you can enable SSL to encrypt the communications between the client and server. To enable SSL, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

1. Use the .ini file (the **configparser** package of Python can parse this type of configuration file) to save the configuration information about the database connection.
2. Add SSL connection parameters **sslmode**, **sslcert**, **sslkey**, and **sslrootcert** to the connection options.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

a. **sslmode**: Table 6-16
b. **sslcert**: client certificate path
c. **sslkey**: client key path
d. **sslrootcert**: root certificate path

3. Use the **psycopg2.connect** function to obtain the connection object.
4. Use the connection object to create a cursor object.

**Table 6-16** sslmode options

| sslmode | Whether SSL Encryption Is Enabled | Description |
| --- | --- | --- |
| disable | No | SSL connection is not enabled. |
| allow | Possible | If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified. |
| prefer | Possible | If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified. |
| require | Yes | SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified. |
| verify-ca | Yes | The SSL connection must be enabled. |
| verify-full | Yes | The SSL connection must be enabled, which is not supported by GaussDB currently. |

## 6.6.9 Example: Common Operations

```
import psycopg2

# Create a connection object.
conn=psycopg2.connect(database="postgres",user="user",password="password",host="localhost",port=port)
cur=conn.cursor() # Create a pointer object.

# Create a connection object (using SSL).
conn = psycopg2.connect(dbname="postgres", user="user", password="password", host="localhost",
port=port,
        sslmode="verify-ca", sslcert="client.crt",sslkey="client.key",sslrootcert="cacert.pem")
Note: If sslcert, sslkey, and sslrootcert are not set, the following files in the .postgresql directory of the
current user are used by default: client.crt,
        client.key, and root.crt.

# Create a table.
cur.execute("CREATE TABLE student(id integer,name varchar,sex varchar);")

# Insert data.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(1,'Aspirin','M'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(2,'Taxol','F'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(3,'Dixheral','M'))

# Obtain the result.
cur.execute('SELECT * FROM student')
results=cur.fetchall()
print (results)

# Close the connection.
conn.commit()
cur.close()
conn.close()

Common connection modes of psycopg2
1. conn = psycopg2.connect(dbname="postgres", user="user", password="password", host="localhost",
port=port)
2. conn = psycopg2.connect("dbname=postgres user=user password=password  host=localhost port=port")
3. Using logs
import logging
import psycopg2
from psycopg2.extras import LoggingConnection

logging.basicConfig(level=logging.DEBUG) # Log level
logger = logging.getLogger(__name__)

db_settings = {
    "user": "user",
    "password": "password",
    "host": "localhost",
    "database": "postgres",
    "port": port
}
conn = psycopg2.connect(connection_factory=LoggingConnection, **db_settings)
conn.initialize(logger)
```

## 6.6.10 Psycopg API Reference

For details, see **21.4 Psycopg API Reference**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 7 Database Security Management

## 7.1 Checking the Number of Database Connections

### Background

If the number of connections reaches its upper limit, new connections cannot be created. Therefore, if a user fails to connect a database, the administrator must check whether the number of connections has reached the upper limit. The following are details about database connections:

- The maximum number of global connections is specified by the **max_connections** parameter.
- The number of a user's connections is specified by **CONNECTION LIMIT connlimit** in the **CREATE ROLE** statement and can be changed using **CONNECTION LIMIT connlimit** in the **ALTER ROLE** statement.
- The number of a database's connections is specified by the **CONNECTION LIMIT connlimit** parameter in the **CREATE DATABASE** statement.
- Some connections need to be reserved for the **gs_clean** tool to remove residual transactions as the residual transactions may affect system operation. In a cluster with *n* CNs, at least *n* connections need to be reserved for the **gs_clean** tool on the CNs.

### Procedure

**Step 1** Connect to a database. For details, see **2.1 Connecting to a Database**.

**Step 2** View the upper limit of the number of global connections.

```
openGauss=# SHOW max_connections;
 max_connections
-----------------
 800
(1 row)
```

**800** is the maximum number of session connections.

**Step 3** View the number of session connections that have been used.

For details, see **Table 7-1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**NOTICE**

Except for database and usernames that are enclosed in double quotation marks (") during creation, uppercase letters are not allowed in the database and usernames in the commands in the following table.

**Table 7-1** Viewing the number of session connections

| Description | Command |
| --- | --- |
| View the maximum number of sessions connected to a specific user. | Run the following command to view the upper limit of the number of user **omm**'s connections. **-1** indicates that no upper limit is set for user **omm**.<br>openGauss=# **SELECT ROLNAME,ROLCONNLIMIT FROM PG_ROLES WHERE ROLNAME='omm';**<br>rolname \| rolconnlimit<br>----------+--------------<br>omm \| -1<br>(1 row) |
| View the number of session connections that have been used by a user. | Run the following command to view the number of session connections that have been used by user **omm**: **1** indicates that one connection has been used by user **omm**.<br>openGauss=# **SELECT COUNT(*) FROM dv_sessions WHERE USERNAME='omm';**<br>count<br>-------<br>1<br>(1 row) |
| View the maximum number of sessions connected to a specific database. | Run the following commands to view the upper limit of the number of **postgres**'s session connections: **-1** indicates that no upper limit is set for the number of **postgres**'s session connections.<br>openGauss=# **SELECT DATNAME,DATCONNLIMIT FROM PG_DATABASE WHERE DATNAME='postgres';**<br>datname \| datconnlimit<br>----------+--------------<br>postgres \| -1<br>(1 row) |
| View the number of session connections that have been used by a specific database. | Run the following commands to view the number of session connections that have been used by **postgres**: **1** indicates the number of session connections that have been used by **postgres**.<br>openGauss=# **SELECT COUNT(*) FROM PG_STAT_ACTIVITY WHERE DATNAME='postgres';**<br>count<br>-------<br>1<br>(1 row) |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Description | Command |
| --- | --- |
| View the number of session connections that have been used by all users. | Run the following commands to view the number of session connections that have been used by all users:<br>openGauss=# **SELECT COUNT(*) FROM dv_sessions;**<br> count<br>-------<br> 10<br>(1 row) |

**----End**

# 7.2 Managing Users and Their Permissions

## 7.2.1 Default Permission Mechanism

A user who creates an object is the owner of this object. By default, **7.2.3 Separation of Duties** is disabled after cluster installation. A database system administrator has the same permissions as object owners. After an object is created, only the object owner or system administrator can query, modify, and delete the object, and grant permissions for the object to other users through **12.14.140 GRANT** by default.

To enable another user to use the object, grant required permissions to the user or the role that contains the user.

GaussDB supports the following permissions: SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, CREATE, CONNECT, EXECUTE, USAGE, ALTER, DROP, COMMENT, INDEX, and VACUUM. Permission types are associated with object types. For permission details, see **12.14.140 GRANT**.

To remove permissions, run **12.14.154 REVOKE**. Object owners have implicit permissions (such as ALTER, DROP, COMMENT, INDEX, VACUUM, GRANT, and REVOKE) on objects. That is, once becoming the owner of an object, the owner is immediately granted the implicit permissions on the object. Object owners can remove their own common permissions, for example, making tables read-only to themselves or others.

System catalogs and views are visible to either system administrators or all users. System catalogs and views that require system administrator permissions can be queried only by system administrators. For details, see **16 Schemas**.

The database provides the object isolation feature. If this feature is enabled, users can view only the objects (tables, views, columns, and functions) that they have the permission to access. System administrators are not affected by this feature. For details, see **12.14.5 ALTER DATABASE**.

You are not advised to modify the permissions on system catalogs or system views.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 7.2.2 Administrator

## Initial User

The account automatically generated during the cluster installation is called the initial user. The initial user is also the system administrator, monitor administrator, O&M administrator, and security policy administrator. It has the highest permissions in the system and can perform all operations. If the initial user name is not set during the installation, the user name is the same as the name of the OS user who installs the cluster. If the password of the initial user is not set during the cluster installation, the password is empty after the installation. In this case, you need to set the password of the initial user on the gsql client before performing other operations. If the initial user password is empty, you cannot perform other SQL operations, such as upgrade, capacity expansion, and node replacement, except changing the password.

An initial user bypasses all permission checks. You are advised to use an initial user as a database administrator only for database management other than service running.

## System Administrator

A system administrator is an account with the SYSADMIN attribute. By default, a system administrator has the same permissions as the object owner but does not have the object permissions in the **dbe_perf** schema or the permission to use Roach to perform backup and restoration.

To create a database administrator, connect to the database as an administrator and run the **12.14.88 CREATE USER** or **12.14.37 ALTER USER** statement with **SYSADMIN** specified.

```
openGauss=# CREATE USER sysadmin WITH SYSADMIN password "xxxxxxxxxx";
```

or

```
openGauss=# ALTER USER joe SYSADMIN;
```

To run the **ALTER USER** statement, the user must exist.

## Monitor Administrator

A monitor administrator is an account with the **MONADMIN** attribute and has the permission to view views and functions in the **dbe_perf** schema. The monitor administrator can also grant or revoke object permissions in the **dbe_perf** schema.

To create a monitor administrator, connect to the database as a system administrator and run the **12.14.88 CREATE USER** or **12.14.37 ALTER USER** statement with **MONADMIN** specified.

```
openGauss=# CREATE USER monadmin WITH MONADMIN password "xxxxxxxxxx";
```

or

```
openGauss=# ALTER USER joe MONADMIN;
```

To run the **ALTER USER** statement, the user must exist.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

### O&M Administrator

An O&M administrator is an account with the **OPRADMIN** attribute and has the permission to use Roach to perform backup and restoration.

To create an O&M administrator, connect to the database as an initial user and run the **12.14.88 CREATE USER** or **12.14.37 ALTER USER** statement with **OPRADMIN** specified.

```
openGauss=# CREATE USER opradmin WITH OPRADMIN password "xxxxxxxxxx";
```

or

```
openGauss=# ALTER USER joe OPRADMIN;
```

To run the **ALTER USER** statement, the user must exist.

### Security Policy Administrator

A security policy administrator is an account with the **POLADMIN** attribute and has the permission to create resource tags, anonymization policies, and unified audit policies.

To create a security policy administrator, connect to the database as an administrator and run the **12.14.88 CREATE USER** or **12.14.37 ALTER USER** statement with **POLADMIN** specified.

```
openGauss=# CREATE USER poladmin WITH POLADMIN password "xxxxxxxxxx";
```

or

```
openGauss=# ALTER USER joe POLADMIN;
```

To run the **ALTER USER** statement, the user must exist.

### Logical Cluster Administrator

Common users in the logical cluster administrator role have the following more permissions than common users: (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)

- Create, modify, and delete resource pools in the associated logical cluster. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)
- Grant the access permission on the associated logical cluster to other users or roles, or revoke the access permission from those users or roles.

For details about logical cluster user and permission management, see section "Logical Cluster Management > Managing Users and Permissions in a Logical Cluster" in *Administrator Guide*.

## 7.2.3 Separation of Duties

Descriptions in **7.2.1 Default Permission Mechanism** and **7.2.2 Administrator** are about the initial situation after a cluster is created. By default, a system administrator with the **SYSADMIN** attribute has the highest-level permissions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

To avoid risks caused by centralized permissions, you can enable separation of duties to assign the system administrator's user management permission to security administrators and audit management permission to audit administrators.

After separation of duties is enabled, the system administrator does not have the **CREATEROLE** attribute (security administrator) or the **AUDITADMIN** attribute (audit administrator). That is, the system administrator can neither create roles or users, nor view or maintain database audit logs. For details about the **CREATEROLE** and **AUDITADMIN** attributes, see **12.14.74 CREATE ROLE**.

Separation of duties does not take effect for an initial user. Therefore, you are advised to use an initial user as a database administrator only for database management other than service running.

To enable separation of duties, set **enableSeparationOfDuty** to **on**.

**WARNING**

If you need to use the separation of duties model, specify it during database initialization. You are not advised to switch the permission management model back and forth. In particular, if you want to switch from a non-separation-of-duties permission management model to the separation-of-duties permission management model, you need to review the permission set of existing users. If a user has the system administrator permission and audit administrator permission, the permissions need to be tailored.

After separation of duties, the system administrator does not have permissions for non-system schemas of other users. Therefore, the system administrator cannot access the objects in other users' schemas before being granted the permissions. For details about permission changes before and after enabling separation of duties, see **Table 7-2** and **Table 7-3**.

**Table 7-2** Default user permissions

| Object Name | Initial User (ID: 10) | System Administrator | Security Administrator | Audit Administrator | Common User |
|---|---|---|---|---|---|
| Tablespaces | Has all permissions except the one to access private tables. | Can create, modify, delete, access, or grant permissions for tablespaces. | Cannot create, modify, delete, or grant permissions for tablespaces and can access tablespaces if the access permission is granted. | | |
| Schemas | | Has all permissions for all schemas except **dbe_perf**. | Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users. | | |
| User-defined functions | | Has all permissions for all user-defined functions. | Has all permissions for their own functions, and has only the call permission for other users' functions. | | |

|---|---|---|---|---|---|
| User-defined tables or views | | Has all permissions for all user-defined tables or views. | Has all permissions for their own tables or views, but does not have permissions for other users' tables or views. | | |

**Table 7-3** Changes in permissions after separation of duties

| Object Name | Initial User (ID: 10) | System Administrator | Security Administrator | Audit Administrator | Common User |
|---|---|---|---|---|---|
| Tablespaces | N/A<br>Has all permissions except the one to access private tables. | N/A | No change | | |
| Schemas | | Permissions reduced<br>Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users. | No change | | |
| User-defined functions | | Cannot access functions in non-system schemas of other users before being granted the permissions. | No change | | |
| User-defined tables or views | | Cannot access tables or views in non-system schemas of other users before being granted the permissions. | No change | | |

**NOTICE**

**PG_STATISTIC** and **PG_STATISTIC_EXT** store sensitive information about statistical objects, such as high-frequency MCVs. After separation of duties is enabled, the system administrator can still access the two system catalogs to obtain the statistics.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 7.2.4 Users

You can use **CREATE USER** and **ALTER USER** to create and manage database users, respectively. A database cluster can have one or more databases. Users and roles are shared within the entire cluster, but their data is not shared. That is, a user can connect to any database, but after the connection is successful, any user can access only the database declared in the connection request.

In non-**separation-of-duties** scenarios, GaussDB user accounts can be created and deleted only by a system administrator or a security administrator with the **CREATEROLE** attribute. In separation-of-duties scenarios, a user account can be created only by an initial user or a security administrator.

When a user logs in, GaussDB authenticates the user. A user can own databases and database objects (such as tables), and grant permissions of these objects to other users and roles. In addition to system administrators, users with the **CREATEDB** attribute can create databases and grant permissions on these databases.

## Adding, Modifying, and Deleting Users

- To create a user, use the SQL statement **12.14.88 CREATE USER**.

  For example, create a user **joe** and set the **CREATEDB** attribute for the user.

  ```
  openGauss=# CREATE USER joe WITH CREATEDB PASSWORD "xxxxxxxxxx";
  CREATE ROLE
  ```

- To create a system administrator, use the **12.14.88 CREATE USER** statement with the **SYSADMIN** parameter.
- To delete an existing user, use **12.14.131 DROP USER**.
- To change a user account (for example, rename the user or change the password), use **12.14.37 ALTER USER**.
- To view a user list, query the **PG_USER** view.

  ```
  openGauss=# SELECT * FROM pg_user;
  ```

- To view user attributes, query the system catalog **15.2.42 PG_AUTHID**.

  ```
  openGauss=# SELECT * FROM pg_authid;
  ```

## Private Users

If multiple service departments use different database user accounts to perform service operations and a database maintenance department at the same level uses database administrator accounts to perform maintenance operations, service departments may require that database administrators, without specific authorization, can perform the DROP, ALTER, and TRUNCATE operations on their data but cannot perform the INSERT, DELETE, UPDATE, SELECT, and COPY operations on the data. That is, the management permissions of database administrators for tables need to be isolated from their access permissions to improve the data security of common users.

In **separation-of-duties** mode, a database administrator does not have permissions for the tables in schemas of other users. In this case, database administrators have neither management permissions nor access permissions, which does not meet the requirements of the service departments mentioned above. Therefore, GaussDB provides private users to solve the problem. That is, create private users with the **INDEPENDENT** attribute in non-separation-of-duties

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

mode. Users with the CREATEROLE permission or the system administrator permission can create private users or change the attributes of common users to private users. Common users can also change their own attributes to private users.

```
openGauss=# CREATE USER user_independent WITH INDEPENDENT IDENTIFIED BY "1234@abc";
```

System administrators can manage (DROP, ALTER, and TRUNCATE) table objects of private users but cannot access (INSERT, DELETE, SELECT, UPDATE, COPY, GRANT, REVOKE, and ALTER OWNER) the objects before being authorized.

**NOTICE**

**PG_STATISTIC** and **PG_STATISTIC_EXT** store sensitive information about statistical objects, such as high-frequency MCVs. The system administrator can still access the two system catalogs to obtain the statistics of the tables to which private users belong.

### Permanent User

GaussDB provides the permanent user solution. That is, create a permanent user with the **PERSISTENCE** attribute.

```
openGauss=# CREATE USER user_persistence WITH PERSISTENCE IDENTIFIED BY "1234@abc";
```

Only the initial user is allowed to create, modify, and delete permanent users with the **PERSISTENCE** attribute.

## 7.2.5 Roles

A role is a set of users. After a role is granted to a user through **GRANT**, the user will have all the permissions of the role. It is recommended that roles be used to efficiently grant permissions. For example, you can create different roles of design, development, and maintenance personnel, grant the roles to users, and then grant specific data permissions required by different users. When permissions are granted or revoked at the role level, these changes take effect on all members of the role.

GaussDB provides an implicitly defined group **PUBLIC** that contains all roles. By default, all new users and roles have the permissions of **PUBLIC**. For details about the default permissions of **PUBLIC**, see **12.14.140 GRANT**. To revoke permissions of **PUBLIC** from a user or role, or re-grant these permissions to them, add the **PUBLIC** keyword in the **REVOKE** or **GRANT** statement.

To view all roles, query the system catalog **PG_ROLES**.

```
SELECT * FROM PG_ROLES;
```

### Adding, Modifying, and Deleting Roles

In non-**separation-of-duties** scenarios, a role can be created, modified, and deleted only by a system administrator or a user with the **CREATEROLE** attribute. In separation-of-duties scenarios, a role can be created, modified, and deleted only by an initial user or a user with the **CREATEROLE** attribute.

- To create a role, use **12.14.74 CREATE ROLE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- To add or delete users in an existing role, use **12.14.22 ALTER ROLE**.
- To delete a role, use **12.14.119 DROP ROLE**. **DROP ROLE** deletes only a role, rather than member users in the role.

## Built-in Roles

GaussDB provides a group of default roles whose names start with **gs_role_**. These roles are provided to access to specific, typically high-privileged operations. You can grant these roles to other users or roles within the database so that they can use specific functions. These roles should be given with great care to ensure that they are used where they are needed. **Table 7-4** describes the permissions of built-in roles.

**Table 7-4** Permission description of built-in roles

| Roles | Permission |
| --- | --- |
| gs_role_copy_files | Permission to run the **copy... to/from filename** command. However, the GUC parameter **enable_copy_server_files** must be set first to enable the function of copying server files. |
| gs_role_signal_backend | Permission to call the **pg_cancel_backend**, **pg_terminate_backend**, and **pg_terminate_session** functions to cancel or terminate other sessions. However, this role cannot perform operations on sessions of the initial user or **PERSISTENCE** user. |
| gs_role_tablespace | Permission to create a tablespace. |
| gs_role_replication | Permission to call logical replication functions, such as **kill_snapshot**, **pg_create_logical_replication_slot**, **pg_create_physical_replication_slot**, **pg_drop_replication_slot**, **pg_replication_slot_advance**, **pg_create_physical_replication_slot_extern**, **pg_logical_slot_get_changes**, **pg_logical_slot_peek_changes**, **pg_logical_slot_get_binary_changes**, and **pg_logical_slot_peek_binary_changes**. |
| gs_role_account_lock | Permission to lock and unlock users. However, this role cannot lock or unlock the initial user or **PERSISTENCE** user. |
| gs_role_pldebugger | Permission to debug functions in **dbe_pldebugger**. |
| gs_role_directory_create | Permission to create directory objects. However, this role needs to enable the GUC parameter **enable_access_server_directory** first. |
| gs_role_directory_drop | Permission to delete directory objects. However, this role needs to enable the GUC parameter **enable_access_server_directory** first. |

The restrictions on built-in roles are as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- The role names starting with **gs_role_** are reserved for built-in roles in the database. Do not create users or roles starting with **gs_role_** or rename existing users or roles starting with **gs_role_**.
- Do not perform **ALTER** or **DROP** operations on built-in roles.
- By default, built-in roles do not have the **LOGIN** permission and do not have preset passwords.
- The **gsql** meta-commands **\du** and **\dg** do not display information about built-in roles. However, if *pattern* is set to a specific built-in role, the information is displayed.
- When separation-of-duty is disabled, the initial user, users with the **SYSADMIN** permission, and users with the **ADMIN OPTION** built-in role permission have the permission to perform **GRANT** and **REVOKE** operations on built-in roles. When separation of duty is enabled, the initial user and users with the **ADMIN OPTION** built-in role permission have the permission to perform **GRANT** and **REVOKE** operations on built-in roles. Example:

```
GRANT gs_role_signal_backend TO user1;
REVOKE gs_role_signal_backend FROM user1;
```

## 7.2.6 Schemas

Schemas allow multiple users to use the same database without interference. In this way, database objects can be organized into logical groups that are easy to manage, and third-party applications can be added to corresponding schemas without causing conflicts.

Each database has one or more schemas. Each schema contains tables and other types of objects. When a database is created, a public schema named **public** is created by default, and all users have the **USAGE** permission on this schema. In addition, each database has a **pg_catalog** schema, which contains system catalogs and all built-in data types, functions, and operators. Only the system administrator and initial user can create functions, stored procedures, and synonyms under the **public** and **pg_catalog** schemas. Other users cannot create these objects even if they are granted with the CREATE permission on the **public** and **pg_catalog** schemas. You can group database objects by schema. A schema is similar to an OS directory but cannot be nested. By default, only the initial user can create objects under the **pg_catalog** schema.

The same database object name can be used in different schemas of the same database without causing conflicts. For example, both **a_schema** and **b_schema** can contain a table named **mytable**. Users with required permissions can access objects across multiple schemas of the same database.

When you run the **CREATE USER** command to create a user, the system creates a schema with the same name as the user in the database where the command is executed.

Database objects are generally created in the first schema in a database search path. For details about the first schema and how to change the schema order, see **Search Path**.

### Creating, Modifying, and Deleting Schemas

- To create a schema, use **12.14.76 CREATE SCHEMA**. By default, the initial user and system administrator can create schemas. Other users can create

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

schemas in the database only when they have the CREATE permission on the database. For details about how to grant the permission, see the syntax in **12.14.140 GRANT**.

- To change the name or owner of a schema, use **12.14.24 ALTER SCHEMA**. The schema owner can change the schema.
- To delete a schema and its objects, use **12.14.121 DROP SCHEMA**. Schema owners can delete schemas.
- To create a table in a schema, use the *schema_name*.*table_name* format to specify the table. If *schema_name* is not specified, the table will be created in the first schema in **search path**.
- To view the owner of a schema, perform the following join query on the system catalogs **PG_NAMESPACE** and **PG_USER**. Replace *schema_name* in the statement with the name of the schema to be queried.

```
openGauss=# SELECT s.nspname,u.usename AS nspowner FROM pg_namespace s, pg_user u WHERE nspname='schema_name' AND s.nspowner = u.usesysid;
```

- To view a list of all schemas, query the system catalog **PG_NAMESPACE**.

```
openGauss=# SELECT * FROM pg_namespace;
```

- To view a list of tables in a schema, query the system catalog **PG_TABLES**. For example, the following query will return a table list from **PG_CATALOG** in the schema.

```
openGauss=# SELECT distinct(tablename),schemaname from pg_tables where schemaname = 'pg_catalog';
```

### Search Path

A search path is defined in the **search_path** parameter. The parameter value is a list of schema names separated by commas (,). If no target schema is specified during object creation, the object will be added to the first schema listed in the search path. If there are objects with the same name across different schemas and no schema is specified for an object query, the object will be returned from the first schema containing the object in the search path.

- To view the current search path, use **12.14.166 SHOW**.

```
openGauss=# SHOW SEARCH_PATH;
 search_path
----------------
 "$user",public
(1 row)
```

  The default value of **search_path** is **"*$user*",public**. *$user* indicates the name of the schema with the same name as the current session user. If the schema does not exist, *$user* will be ignored. By default, after a user connects to a database that has schemas with the same name, objects will be added to all the schemas. If there are no such schemas, objects will be added to only to the **public** schema.

- To change the default schema of the current session, run the **SET** statement.

  Run the following command to set **search_path** to **myschema** and **public** (**myschema** will be searched first):

```
openGauss=# SET SEARCH_PATH TO myschema, public;
SET
```

## 7.2.7 Setting User Permissions

- To grant permissions for an object to a user, use **12.14.140 GRANT**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

When permissions for a table or view in a schema are granted to a user or role, the **USAGE** permission of the schema must be granted together. Otherwise, the user or role can only see these objects but cannot access them.

In the following example, permissions for the schema **tpcds** are first granted to user **joe**, and then the **SELECT** permission for the **tpcds.web_returns** table is also granted.

```
openGauss=# GRANT USAGE ON SCHEMA tpcds TO joe;
openGauss=# GRANT SELECT ON TABLE tpcds.web_returns to joe;
```

- Grant a role to a user to allow the user to inherit the object permissions of the role.

  a. Create a role.

     Create a role **lily** and grant the system permission **CREATEDB** to the role.

     ```
     openGauss=# CREATE ROLE lily WITH CREATEDB PASSWORD "xxxxxxxxxx";
     ```

  b. Grant object permissions to the role by using **12.14.140 GRANT**.

     For example, first grant permissions for the schema **tpcds** to the role **lily**, and then grant the **SELECT** permission of the **tpcds.web_returns** table to **lily**.

     ```
     openGauss=# GRANT USAGE ON SCHEMA tpcds TO lily;
     openGauss=# GRANT SELECT ON TABLE tpcds.web_returns to lily;
     ```

  c. Grant the role permissions to a user.

     ```
     openGauss=# GRANT lily to joe;
     ```

     NOTE

     When the permissions of a role are granted to a user, the attributes of the role are not transferred together.

- To revoke user permissions, use **12.14.154 REVOKE**.

## 7.2.8 Row-Level Access Control

The row-level access control feature enables database access control to be accurate to each row of data tables. In this way, the same SQL query may return different results for different users.

You can create a row-level access control policy for a data table. The policy defines an expression that takes effect only for specific database users and SQL operations. When a database user accesses the data table, if a SQL statement meets the specified row-level access control policies of the data table, the expressions that meet the specified condition will be combined by using **AND** or **OR** based on the attribute type (**PERMISSIVE** | **RESTRICTIVE**) and applied to the execution plan in the query optimization phase.

Row-level access control is used to control the visibility of row-level data in tables. By predefining filters for data tables, the expressions that meet the specified condition can be applied to execution plans in the query optimization phase, which will affect the final execution result. Currently, the SQL statements that can be affected include **SELECT**, **UPDATE**, and **DELETE**.

Scenario 1: A table summarizes the data of different users. Users can view only their own data.

```
-- Create users alice, bob, and peter.
openGauss=# CREATE USER alice PASSWORD 'xxxxxxxxx';
openGauss=# CREATE USER bob PASSWORD 'xxxxxxxxx';
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# CREATE USER peter PASSWORD 'xxxxxxxxx';

-- Create the all_data table that contains user information.
openGauss=# CREATE TABLE all_data(id int, role varchar(100), data varchar(100));

-- Insert data into the data table.
openGauss=# INSERT INTO all_data VALUES(1, 'alice', 'alice data');
openGauss=# INSERT INTO all_data VALUES(2, 'bob', 'bob data');
openGauss=# INSERT INTO all_data VALUES(3, 'peter', 'peter data');

-- Grant the read permission for the all_data table to users alice, bob, and peter.
openGauss=# GRANT SELECT ON all_data TO alice, bob, peter;

-- Enable row-level access control.
openGauss=# ALTER TABLE all_data ENABLE ROW LEVEL SECURITY;

-- Create a row-level access control policy to specify that the current user can view only their own data.
openGauss=# CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role =
CURRENT_USER);

-- View table details.
openGauss=# \d+ all_data
                        Table "public.all_data"
 Column |          Type          | Modifiers | Storage  | Stats target | Description
--------+------------------------+-----------+----------+--------------+-------------
 id     | integer                |           | plain    |              |
 role   | character varying(100) |           | extended |              |
 data   | character varying(100) |           | extended |              |
Row Level Security Policies:
    POLICY "all_data_rls"
      USING (((role)::name = "current_user"()))
Has OIDs: no
Distribute By: HASH(id)
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no, enable_rowsecurity=true

-- Switch to user alice and run SELECT * FROM public.all_data.
openGauss=# SELECT * FROM public.all_data;
 id | role  |    data
----+-------+------------
  1 | alice | alice data
(1 row)

openGauss=# EXPLAIN(COSTS OFF) SELECT * FROM public.all_data;
                        QUERY PLAN
-----------------------------------------------------------------
 Streaming (type: GATHER)

   ->  Seq Scan on all_data
         Filter: ((role)::name = 'peter'::name)
 Notice: This query is influenced by row level security feature
(5 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTICE

PG_STATISTIC and PG_STATISTIC_EXT store sensitive information about statistical objects, such as high-frequency MCVs. If the permission to query the two system catalogs is granted to a common user after the row-level security policy is created, the common user can still access the two system catalogs to obtain the information in the statistical objects.

# 7.2.9 Setting Security Policies

## 7.2.9.1 Setting Account Security Policies

### Background

For data security purposes, GaussDB provides a series of security measures, such as automatically locking and unlocking accounts, manually locking and unlocking abnormal accounts, and deleting accounts that are no longer used.

### Automatically Locking and Unlocking Accounts

- If the number of incorrect password attempts (**failed_login_attempts**) of an account reaches the upper limit (**10** by default), the system automatically locks the account. Smaller parameter values result in higher account security. However, if the value of this parameter is set too small, inconvenience may occur.
- If the time during which a user is locked exceeds the preset value (**password_lock_time**, one day by default), the system automatically unlocks the user. Larger parameter values bring higher account security. However, if the value of this parameter is set too large, inconvenience may occur.

  NOTE

  - The integer part of the **password_lock_time** parameter indicates the number of days, and the decimal part can be converted into hours, minutes, and seconds. For example, **password_lock_time=1.5** indicates one day and 12 hours.
  - If the **failed_login_attempts** parameter is set to **0**, an account is never locked due to incorrect password attempts. If the **password_lock_time** parameter is set to **0**, an account is quickly unlocked after it is locked due to incorrect password attempts. Therefore, only when both parameters are set to positive values, the following operations can be performed: password failure check, account locking, and account unlocking.
  - The default values of the two parameters meet the security requirements. You can change the parameter values as needed for higher security. You are advised to retain the default values.
- The database provides two account locking modes.
  - Single CN mode: During cluster deployment, one CN is configured as an interface to provide external services.
  - Multi-CN mode: During cluster deployment, multiple CNs are configured to work as external interfaces.

  In security mode, a single CN provides the account locking mechanism. In high concurrency mode, each CN provides account locking independently and

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

does not share their locking information. In this mode, you are advised to limit the number of CNs to prevent brute-force attacks. The automatic account unlocking time for each node depends on their system clocks. During cluster deployment, ensure clock synchronization between cluster nodes (for example, use the NTP). If the nodes are out of synchronization, the account unlocking time for each node will be different.

## Manually Locking and Unlocking Accounts

Once detecting that an account is stolen or the account is used to access the database without being authorized, administrators can manually lock the account. Administrators can manually unlock the account if the account becomes normal again.

For details about how to create a user, see **7.2.4 Users**. To manually lock and unlock user **joe**, run commands in the following format:

- To manually lock the account, run the following command:
  ```
  openGauss=# ALTER USER joe ACCOUNT LOCK;
  ALTER ROLE
  ```
- To manually unlock the account, run the following command:
  ```
  openGauss=# ALTER USER joe ACCOUNT UNLOCK;
  ALTER ROLE
  ```

## Deleting Accounts That Are No Longer Used

Administrators can delete an account that is no longer used. This operation cannot be rolled back.

When an account to be deleted is in the active state, it is deleted after the session is disconnected.

For example, if you want to delete account **joe**, run the following command:

```
openGauss=# DROP USER joe  CASCADE;
DROP ROLE
In the scenario where multiple users, databases, and schemas are assigned permissions, if you drop a user, the following error message is displayed because the user has the permissions granted by other users.
openGauss=# drop user test1 cascade;
ERROR: role "test1" cannot be dropped because some objects depend on it
In this scenario, you can drop user only after querying the system catalog to find the permissions granted to the user by other users and logging in to the system as other users to manually delete the permissions. The following is an example:
Log in to the system database and check the user OID.
openGauss=#  select oid from pg_roles where rolname='test1';
  oid
-------
 16386
(1 row)
Check the pg_shdepend view to obtain the permissions granted to the user. You can find that the user has two permissions granted by other users. Handle the first permission first.
openGauss=# select * from pg_shdepend where refobjid='16386';
 dbid  | classid | objid | objsubid | refclassid | refobjid | deptype | objfile
-------+---------+-------+----------+------------+----------+---------+---------
 16394 |     826 | 16400 |        0 |       1260 |    16386 | a       |
 16394 |     2615 | 16399 |        0 |       1260 |    16386 | a       |

Check the pg_database view to obtain the database where the view is located. The test database is displayed.
openGauss=#    select * from pg_database where oid='16394'
 datname | datdba | encoding | datcollate  |  datctype   | datistemplate | datallowconn | datconnlimit |
datlastsysoid | datfrozenxid | dattablespace | datcompatibility |                    datacl
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
            | datfrozenxid64
---------+--------+----------+-------------+-------------+---------------+--------------+--------------+---------------
+-------------+---------------+-----------------+-----------------------------------
-------------+----------------
 test    |    10 |        7 | en_US.UTF-8 | en_US.UTF-8 | f             | t            |           -1 |         16268 |
1985          |          1663 | MYSQL             | {=Tc/test,test=CTc/test,admi
n=c/test} |           1985
(1 row)
```

Log in to the **test** database.

```
[test@euler_phy_194 opengauss]$ gsql -p 3730 -d test
gsql((GaussDB Kernel VxxxRxxxCxx build f521c606) compiled at 2021-09-16 14:55:22 commit 2935 last mr
6385 release)
Non-SSL connection (SSL connection is recommended when requiring high-security)
Type "help" for help.
```

Check the permission type using pg_class. The value of **where oid** is the value of **classid** queried in the pg_shdepend view.

```
test=# select * from pg_class where oid = 826;
    relname     | relnamespace | reltype | reloftype | relowner | relam | relfilenode | reltablespace | relpages |

 pg_default_acl |           11 |   11810 |         0 |       10 |     0 |       16063 |             0 |        0 |         0 |
0 |             0 |             0 |             0 |           0 |
         0 |           0 | t          | f          | p             | r       |        4 |         0 | t          | f          | f           |
f             | f             | 0        | f
 | f             | n        | 0           | {=r/test} |           | n           |           1985 |           |
(1 row)
```

The preceding information indicates that the user has been granted the default ACL permission on the table or view by other users. Check the pg_default_acl view. The value of **oid** is the value of **objid** in the pg_shdepend table.

```
test=#  select * from pg_default_acl oid = 16400;;
 defaclrole | defaclnamespace | defaclobjtype |               defaclacl               |  oid
------------+-----------------+---------------+---------------------------------------+-------
      16395 |           16399 | r             | {test=arwd/admin,test1=arwd/admin} | 16400
(1 row)
```

According to the defaclacl column of the view, user **test1** is granted with the default permission by user **admin**. Then, find the object (table or view) to which the permission is granted.

View the object name using pg_namespace. The value of **oid** is the value of **defaclnamespace** queried in pg_default_acl. The view shows that user **test1** has been granted the schema test_schema_1 permission by user **admin**.

```
test=# select * from pg_namespace where oid = 16399;
    nspname    | nspowner | nsptimeline |                nspacl                 | in_redistribution | nspblockchain
---------------+----------+-------------+---------------------------------------+-------------------+---------------
 test_schema_1 |       10 |           0 | {test=UC/test,admin=UC/test} | n                 | f
(1 row)
```

Log in to the **test** database as user **admin**. To revoke the default schema permission granted by the user **admin** to user **test1**, run **ALTER DEFAULT PRIVILEGES IN SCHEMA test_schema_1 revoke all privileges ON TABLES from test1;**.

```
test=#   ALTER DEFAULT PRIVILEGES IN SCHEMA test_schema_1 revoke all privileges ON TABLES from test1;
ALTER DEFAULT PRIVILEGES
```

Log in to the system database and check the **pg_database** view to obtain the database where the view is located. The **test** database is displayed.

```
openGauss=#   select * from pg_database where oid='16394'
 datname | datdba | encoding | datcollate  |  datctype   | datistemplate | datallowconn | datconnlimit |
datlastsysoid | datfrozenxid | dattablespace | datcompatibility |                    datacl
            | datfrozenxid64
---------+--------+----------+-------------+-------------+---------------+--------------+--------------+---------------
+--------------+---------------+-----------------+-----------------------------------
-------------+----------------
 test    |    10 |        7 | en_US.UTF-8 | en_US.UTF-8 | f             | t            |           -1 |         16268 |
```

```
1985         |          1663 | MYSQL            | {=Tc/test,test=CTc/test,admi
n=c/test} |          1985
(1 row)
Log in to the test database.
[test@euler_phy_194 opengauss]$ gsql -p 3730 -d test

Check the pg_class view. In the view, the value of oid is the value of classid in the second row of the
pg_shdepend table.
openGauss=#  select * from pg_class where oid='2615';
   relname     | relnamespace | reltype | reloftype | relowner | relam | relfilenode | reltablespace | relpages |
reltuples | relallvisible | reltoastrelid | reltoastidxid | reldeltarelid | reldeltaidx | relcu
descrelid | relcudescidx | relhasindex | relisshared | relpersistence | relkind | relnatts | relchecks | relhasoids |
relhaspkey | relhasrules | relhastriggers | relhassubclass | relcmprs | relhasclusterkey |
 relrowmovement | parttype | relfrozenxid |    relacl     | reloptions | relreplident | relfrozenxid64 | relbucket |
relbucketkey
--------------+--------------+---------+-----------+----------+-------+-------------+---------------+----------
+-----------+---------------+---------------+---------------+--------------+-------------+------+------
----------+--------------+-------------+-------------+----------------+---------+----------+-----------+------------
+------------+-------------+----------------+----------------+----------+------------------+
----------------+----------+--------------+--------------+------------+-------------+----------------+-----------
+--------------
 pg_namespace |           11 |   11787 |        0 |       10 |     0 |       15947 |            0 |        1 |        20
|            1 |            0 |            0 |            0 |            0 |
       0 |           0 | t          | f          | p            | r       |       6 |        0 | t         | f         | f          |
f            | f            | 0       | f             |
 f            | n       | 0          | {=r/test} |          | n           |          1985 |          |
(1 row)

The result shows that the type is pg_namespace. Check the pg_namespace system view. The value of oid is
the value of objid in the second line of pg_shdepend.
test=# select * from pg_namespace where oid='16399';
    nspname     | nspowner | nsptimeline |                        nspacl                        | in_redistribution |
nspblockchain
---------------+----------+-------------+------------------------------------------------------+-------------------
+---------------
 test_schema_1 |       10 |           0 | {test=UC/test,admin=UC/test,test1=U/test} | n                 | f
(1 row)

The nspacl column shows that the test_schema_1 view of user test1 is granted permissions by user test. To
revoke the permissions granted to user test1, log in to the test database as user test and run revoke all on
schema test_schema_1 from test1.
test=# revoke all on schema test_schema_1 from test1;
REVOKE

By now, the permissions granted to user test1 by other users have been cleared. You only need to run the
drop user command.
openGauss=# drop user test1 cascade;
DROP ROLE
```

## 7.2.9.2 Setting the Validity Period of an Account

## Precautions

When creating a user, you need to specify the validity period of the user, including the start time and end time.

To enable a user not within the validity period to use its account, set a new validity period.

## Procedure

**Step 1** Connect to a database. For details, see **2.1 Connecting to a Database**.

**Step 2** Run the following command to create a user and specify the start time and end time:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# CREATE USER joe WITH PASSWORD 'xxxxxxxxxx' VALID BEGIN '2015-10-10 08:00:00' VALID UNTIL '2016-10-10 08:00:00';
```

The user is created if the following information is displayed:

```
CREATE ROLE
```

**Step 3** If the user is not within the specified validity period, run the following command to set the start time and end time of a new validity period.

```
openGauss=# ALTER USER joe WITH VALID BEGIN '2016-11-10 08:00:00' VALID UNTIL '2017-11-10 08:00:00';
```

The start time and end time of the new validity period is set successfully if the following information is displayed:

```
ALTER ROLE
```

**----End**

NOTE

If **VALID BEGIN** is not specified in the **CREATE ROLE** or **ALTER ROLE** statement, the start time of the validity period is not limited. If **VALID UNTIL** is not specified, the end time of the validity period is not limited. If both of the parameters are not specified, the user is always valid.

## 7.2.9.3 Setting Password Security Policies

## Procedure

User passwords are stored in the system catalog **pg_authid**. To prevent password leakage, GaussDB encrypts user passwords before storing them. The encryption algorithm is determined by the configuration parameter **password_encryption_type**.

- If the **password_encryption_type** parameter is set to **0**, passwords are encrypted using MD5. The MD5 encryption algorithm is not recommended because it has lower security and poses security risks.
- If the **password_encryption_type** parameter is set to **1**, passwords are encrypted using SHA-256 and MD5. The MD5 encryption algorithm is not recommended because it has lower security and poses security risks.
- If parameter **password_encryption_type** is set to **2**, passwords are encrypted using SHA-256. This is the default configuration.
- If parameter **password_encryption_type** is set to **3**, passwords are encrypted using SM3.

**Step 1** Connect to a database. For details, see **2.1 Connecting to a Database**.

**Step 2** View the configured encryption algorithm.

```
openGauss=# SHOW password_encryption_type;
 password_encryption_type
--------------------------
 2
(1 row)
```

**Step 3** Configure password security parameters.

- Password complexity

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

You need to specify a password when initializing a database, creating a user, or modifying a user. The password must meet the complexity check rules (see **password_policy**). Otherwise, you are prompted to enter the password again.

- If parameter **password_policy** is set to **1**, the default password complexity rule is used to check passwords.
- If **password_policy** is set to **0**, the password complexity rule is not used. However, the password cannot be empty and must contain only valid characters, including uppercase letters (A–Z), lowercase letters (a–z), digits (0–9), and special characters (see **Table 7-5**). You are not advised to set this parameter to **0** because this operation poses security risks. If the setting is required, you must set **password_policy** to **0** on all cluster nodes.

Configure the **password_policy** parameter.

The password complexity and length requirements are as follows:

- Minimum number of uppercase letters (A-Z) (**password_min_uppercase**)
- Minimum number of lowercase letters (a-z) (**password_min_lowercase**)
- Minimum number of digits (0-9) (**password_min_digital**)
- Minimum number of special characters (**password_min_special**) (**Table 7-5** lists special characters.)
- Minimum length of a password (**password_min_length**)
- Maximum length of a password (**password_max_length**)

  NOTE

  For details, see "GUC Parameters" in *Developer Guide*.

- A password must contain at least three types of the characters (uppercase letters, lowercase letters, digits, and special characters).
- A password is case insensitive and cannot be the username or the username spelled backwards.
- A new password cannot be the current password and the current password spelled backwards.
- It must be a strong password.

  - Weak passwords are weak passwords that are easy to crack. The definition of weak passwords may vary with users or user groups. Users can define their own weak passwords.
  - Passwords in the weak password dictionary are stored in the **gs_global_config** system catalog. When a user is created or modified, the password set by the user is compared with the password stored in the weak password dictionary. If the password is matched, a message is displayed, indicating that the password is weak and the password fails to be set.
  - The weak password dictionary is empty by default. You can add or delete weak passwords using the following syntax:

    CREATE WEAK PASSWORD DICTIONARY WITH VALUES ('password1'), ('password2');

    DROP WEAK PASSWORD DICTIONARY;

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Password reuse

  An old password can be reused only when it meets the requirements on reuse days (**password_reuse_time**) and reuse times (**password_reuse_max**). **Table 7-6** lists the parameter configurations.

  NOTE

  The default values of the **password_reuse_time** and **password_reuse_max** parameters are **0**, respectively. Large values of the two parameters bring higher security. However, if the values of the parameters are set too large, inconvenience may occur. The default values of the two parameters meet the security requirements. You can change the parameter values as needed for higher security.

  Configure the **password_reuse_time** parameter.

  Configure the **password_reuse_max** parameter.

- Password validity period

  A validity period (**password_effect_time**) is set for each database user password. If the password is about to expire (**password_notify_time**), the system displays a message to remind the user to change it upon login.

  NOTE

  Considering the usage and service continuity of a database, the database still allows a user to log in after the password expires. A password change notification is displayed every time the user logs in to the database until the password is changed.

  Configure the **password_effect_time** parameter.

  Configure the **password_notify_time** parameter.

- Password change
  - During database installation, an OS user with the same name as the initial user is created. The password of the OS user needs to be periodically changed for account security.

    To change the password of user **user1**, run the following command:

    ```
    passwd user1
    ```

    Change the password as prompted.
  - System administrators and common users need to periodically change their passwords to prevent the accounts from being stolen.

    For example, to change the password of user **user1**, connect to the database as the system administrator and run the following commands:

    ```
    openGauss=# ALTER USER user1 IDENTIFIED BY "1234@abc" REPLACE "5678@def";
    ALTER ROLE
    ```

    NOTE

    **1234@abc** and **5678@def** represent the new password and the original password of user **user1**, respectively. If the new password does not have the required complexity, the change will not take effect.
  - Administrators can change their own and common users' passwords. If common users forget their passwords, they can ask administrators to change the passwords.

    To change the password of user **joe**, run the following command:

    ```
    openGauss=# ALTER USER joe IDENTIFIED BY "abc@1234";
    ALTER ROLE
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- System administrators are not allowed to change passwords for each other.
- A system administrator can change the password of a common user without being required to provide the common user's old password.
- A system administrator can change their own password but is required to provide the old password.

- Password verification

  Password verification is required when you set the user or role in the current session. If the entered password is inconsistent with the stored password of the user, an error is reported.

  If user **joe** needs to be set, run the following command:

```
openGauss=# SET ROLE joe PASSWORD "abc@1234";
ERROR:  Invalid username/password,set role denied.
```

**Table 7-5** Special characters

| No. | Character | No. | Character | No. | Character | No. | Character |
|---|---|---|---|---|---|---|---|
| 1 | ~ | 9 | * | 17 | \| | 25 | < |
| 2 | ! | 10 | ( | 18 | [ | 26 | . |
| 3 | @ | 11 | ) | 19 | { | 27 | > |
| 4 | # | 12 | N/A | 20 | } | 28 | / |
| 5 | $ | 13 | _ | 21 | ] | 29 | ? |
| 6 | % | 14 | = | 22 | ; | N/A | N/A |
| 7 | ^ | 15 | + | 23 | : | N/A | N/A |
| 8 | & | 16 | \ | 24 | , | N/A | N/A |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 7-6** Parameter description for reuse days and reuse times

| Parameter | Value Range | Description |
| --- | --- | --- |
| Number of days during which a password cannot be reused (**password_reuse_time**) | Positive number or **0**. The integral part of a positive number indicates the number of days and its decimal part can be converted into hours, minutes, and seconds.<br>The default value is **0**. | • If the parameter value is changed to a smaller one, new password will be checked based on the new parameter value.<br>• If the parameter value is changed to a larger one (for example, changed from **a** to **b**), the historical passwords before **b** days probably can be reused because these historical passwords may have been deleted. New passwords will be checked based on the new parameter value.<br>**NOTE**<br>The absolute time is used. Historical passwords are recorded using absolute time and unaffected by local time changes. |
| Number of consecutive times that a password cannot be reused (**password_reuse_max**) | Positive integer or **0**.<br>The value **0** indicates that the number of consecutive times that a password cannot be reused is not checked. | • If the parameter value is changed to a smaller one, new password will be checked based on the new parameter value.<br>• If the parameter value is changed to a larger one (for example, changed from **a** to **b**), the historical passwords before the last **b** passwords probably can be reused because these historical passwords may have been deleted. New passwords will be checked based on the new parameter value. |

**Step 4** Set user password expiration.

When creating a user, a user with the CREATEROLE permission can force the user password to expire. After logging in to the database for the first time, a new user can perform query operations only after changing the password. The command format is as follows:

```
openGauss=# CREATE USER joe PASSWORD "abc@1234" EXPIRED;
CREATE ROLE
```

A user with the CREATEROLE permission can force a user password to expire or force a user to change the forcibly expired password. The command format is as follows:

```
openGauss=# ALTER USER joe PASSWORD EXPIRED;
ALTER ROLE
openGauss=# ALTER USER joe PASSWORD "abc@2345" EXPIRED;
ALTER ROLE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- After a user whose password is invalid logs in to the database, the system prompts the user to change the password when the user performs a simple or extended query. The user can then execute the statement after changing the password.
- Only initial users, system administrators (**sysadmin**), and users who have the permission to create users (**CREATEROLE**) can invalidate user passwords. System administrators can invalidate their own passwords or the passwords of other system administrators. The password of initial users cannot be invalidated.

**----End**

# 7.3 Configuring Database Audit

## 7.3.1 Overview

### Background

Database security is essential for a database system. GaussDB writes all user operations in the database into audit logs. Database security administrators can use the audit logs to reproduce a series of events that cause faults in the database and identify unauthorized users, unauthorized operations, and the time when these operations are performed.

You need to know the following about the audit function:

- The overall audit switch **audit_enabled** supports dynamic loading. After you change the switch status when the database is running, the change takes effect immediately and you do not need to restart the database. Its default value is **on**, indicating that the audit function is enabled.
- In addition to the overall audit switch, each audit item has an independent switch. An audit item is available only after its own switch is turned on.
- The switch of each audit supports dynamic loading. After changing the audit switch status when the database is running, the modification takes effect immediately without restarting the database.

Table 7-7 lists the audit items supported by GaussDB. For details, see the GUC parameter description in the links.

**Table 7-7** Audit items

| Parameter | Description |
| --- | --- |
| User login and logout audit | Parameter: **audit_login_logout**<br>Its default value is **7**, which indicates that the function of user login and logout audit is enabled. **0** indicates that the function of user login and logout audit is disabled. Other values are not recommended. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| Database startup, stop, recovery, and switchover audit | Parameter: **audit_database_process**<br>Its default value is **1**, which indicates that the audit of database startup, stop, recovery, and switchover is enabled. |
| User locking and unlocking audit | Parameter: **audit_user_locked**<br>Its default value is **1**, which indicates that the audit of user locking and unlocking is enabled. |
| Unauthorized access audit | Parameter: **audit_user_violation**<br>Its default value is **0**, which indicates that the audit of unauthorized access disabled. |
| Permission granting and revoking audit | Parameter: **audit_grant_revoke**<br>Its default value is **1**, which indicates that the audit of permission granting and revoking is enabled. |
| Audit of CREATE, ALTER, and DROP operations on database objects | Parameter: **audit_system_object**<br>Its default value is **67121159**, which indicates that only the CREATE, ALTER, and DROP operations on databases, schemas, users, data sources, and node groups are audited. |
| Audit of INSERT, UPDATE, and DELETE operations on a specific table | Parameter: **audit_dml_state**<br>Its default value is **0**, which indicates that the audit of DML operations (except SELECT) on a specific table is disabled. |
| SELECT operation audit | Parameter: **audit_dml_state_select**<br>Its default value is **0**, which indicates that the audit of the SELECT operation is disabled. |
| COPY operation audit | Parameter: **audit_copy_exec**<br>Its default value is **1**, which indicates that the audit of the COPY operation is enabled. |
| Execution of stored procedures and customized functions | Parameter: **audit_function_exec**<br>Its default value is **0**, which indicates that no execution audit logs of stored procedures and customized functions are recorded. |
| SET operation audit | Parameter: **audit_set_parameter**<br>Its default value is **0**, which indicates that the audit of the SET operation is disabled. |
| Transaction ID record | Parameter: **audit_xid_info**<br>Its default value is **0**, which indicates that the function of recording transaction IDs in audit logs is disabled. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Table 7-8 lists security-related parameters and their default values.

**Table 7-8** Security-related parameters

| Parameter | Description |
| --- | --- |
| ssl | Specifies whether the SSL connection is enabled. |
| require_ssl | Specifies whether the server requires the SSL connection. |
| ssl_ciphers | Encryption algorithm list supported by the SSL |
| ssl_cert_file | File containing the SSL server certificate |
| ssl_key_file | File containing the SSL private key |
| ssl_ca_file | File containing CA information |
| ssl_crl_file | File containing CRL information |
| ssl_cert_notify_time | Specifies the number of days prior to SSL server certificate expiration that a user will receive a reminder. |
| password_policy | Specifies whether to check the password complexity. |
| password_reuse_time | Specifies whether to check the reuse days of a new password. |
| password_reuse_max | Specifies whether to check the reuse times of a new password. |
| password_lock_time | Duration before a locked account is automatically unlocked |
| failed_login_attempts | If the number of consecutive login attempts with incorrect passwords reaches this value, the account is locked. |
| password_encryption_type | Password storage encryption mode |
| password_min_uppercase | Minimum number of uppercase letters in a password |
| password_min_lowercase | Minimum number of lowercase letters in a password |
| password_min_digital | Minimum number of digits in a password |
| password_min_special | Minimum number of special characters in a password |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| password_min_length | Minimum password length<br>**NOTE**<br>The value of this parameter must be less than or equal to that of **password_max_length**. Otherwise, a password length error message is displayed upon all password-related operations. |
| password_max_length | Maximum password length<br>**NOTE**<br>The value of this parameter must be greater than or equal to that of **password_min_length**. Otherwise, a password length error message is displayed upon all password-related operations. |
| password_effect_time | Password validity period |
| password_notify_time | Number of days prior to account password expiration that a user is notified |
| audit_enabled | Specifies whether the audit process is enabled or disabled. |
| audit_directory | Audit file storage directory |
| audit_data_format | Audit log file format. Currently, only the binary format is supported. |
| audit_rotation_interval | Time interval of creating an audit log file. If the difference between the current time and the time when the previous audit log file is created is greater than the value of this parameter, a new audit log file will be generated. |
| audit_rotation_size | Maximum capacity of an audit log file. If the total number of messages in an audit log exceeds the value of **audit_rotation_size**, the server will generate a new audit log file. |
| audit_resource_policy | Policy for determining whether audit logs are preferentially stored by space or time. **on** indicates that audit logs are preferentially stored by space. |
| audit_file_remain_time | Minimum duration required for recording audit logs. This parameter is valid only when audit_resource_policy is set to **off**. |
| audit_space_limit | Maximum total size of audit log files in a disk |
| audit_file_remain_threshold | Maximum number of audit files in the audit directory |
| audit_login_logout | Specifies whether to audit user logins (including login successes and failures) and logouts. |
| audit_database_process | Specifies whether to audit database startup, stop, switchover, and restoration operations. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| audit_user_locked | Specifies whether to audit database user locking and unlocking. |
| audit_user_violation | Specifies whether to audit beyond-authority operations of a database user. |
| audit_grant_revoke | Specifies whether to audit user permission granting and reclaiming operations. |
| audit_system_object | Specifies whether to audit the CREATE, DROP, and ALTER operations on database objects. |
| audit_dml_state | Specifies whether to audit the INSERT, UPDATE, and DELETE operations on a specific table. |
| audit_dml_state_select | Specifies whether to audit the SELECT operation. |
| audit_copy_exec | Specifies whether to audit the COPY operation. |
| audit_function_exec | Specifies whether to record audit information during execution of stored procedures, anonymous blocks, or customized functions (excluding system functions). |
| audit_set_parameter | Specifies whether to audit the SET operation. |
| enableSeparationOfDuty | Specifies whether the separation of duties is enabled. |
| session_timeout | If the duration of a connection session exceeds the parameter value, the session is automatically disconnected. |
| auth_iteration_count | Number of iterations during the generation of encrypted information for authentication |

## Procedure

**Step 1** Connect to a database. For details, see **2.1 Connecting to a Database**.

**Step 2** Check the status of the overall audit switch.

Run the **show** command to view the value of **audit_enabled**.

```
openGauss=# SHOW audit_enabled;
```

**----End**

# 7.3.2 Querying Audit Results

## Prerequisites

- Audit has been enabled.
- Audit of required items has been enabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- The database is running properly and a series of addition, modification, deletion, and query operations have been executed in the database. Otherwise, no audit result is generated.
- Audit logs are separately recorded on the database nodes.

## Background

- Only users with the **AUDITADMIN** permission can view audit records. For details about database users and how to create users, see **7.2.4 Users**.
- The SQL function **pg_query_audit** is provided by the database for audit query. Its syntax is as follows:

  ```
  pg_query_audit(timestamptz startime,timestamptz endtime,audit_log)
  ```

  **startime** and **endtime** indicate the start time and end time of the audit record, respectively. **audit_log** indicates the physical file path of the queried audit logs. If **audit_log** is not specified, the audit log information of the current instance is queried.

  You can use the SQL function **pgxc_query_audit** to query audit logs of all CNs. Its syntax is as follows:

  ```
  pgxc_query_audit(timestamptz startime,timestamptz endtime)
  ```

  NOTE

  The difference between the values of the **startime** and **endtime** parameters indicates the query period, which can be any value ranging from 00:00:00 of the **startime** parameter to 23:59:59 of the **endtime** parameter. Therefore, the **startime** and **endtime** parameters must be properly set to ensure that the required audit information is displayed.

## Procedure

**Step 1** Connect to a database. For details, see **2.1 Connecting to a Database**.

**Step 2** Run the following command to query the audit record:

```
openGauss=# SELECT * FROM pg_query_audit('2021-03-03 21:30:00', '2021-03-03 22:00:00') where type = 'login_success' and username = 'user1';
```

The command output is similar to the following:

```
         time          |     type      | result | userid | username | database | client_conninfo | object_name
|                  detail_info                   | node_name |
         thread_id           | local_port | remote_port
-----------------------+---------------+--------+--------+----------+----------+-----------------+-------------
+------------------------------------------------+-----------+--
-------------------------------+-------------+-------------
 2021-03-03 21:30:31+08 | login_success | ok     | 16398  | user1    | postgres | gsql@[local]    | postgres    |
login db(postgres) success, SSL=off| cn_5001    | 1
39634608699136@668093431256149 | 18000       | null
(1 row)
```

This record indicates that user **user1** logged in to the **postgres** database at 2021-03-03 21:30:31+08. After the host specified by **log_hostname** is started and a client is connected to its IP address, the host name found by reverse DNS resolution is displayed following the at sign (@) in the value of **client_conninfo**.

**Step 3** Query the audit records of all CNs.

```
openGauss=# SELECT * FROM pgxc_query_audit('2021-03-03 21:30:00', '2021-03-03 22:00:00') where type = 'login_success' and username = 'user1';
```

The command output is similar to the following:

```
         time          |     type      | result | userid | username | database | client_conninfo | object_name
|                 detail_info                  | node_name |
         thread_id           | local_port | remote_port
-----------------------+---------------+--------+--------+----------+----------+-----------------+-------------
+----------------------------------------------------+-----------+--
-------------------------------+------------+-------------
 2021-03-03 21:30:31+08 | login_success | ok     | 16398  | user1    | postgres | gsql@[local]    | postgres    |
login db(postgres) success, SSL=off | cn_5001    | 1
39634608699136@668093431256149 | 18000      | null
 2021-03-03 21:36:09+08 | login_success | ok     | 16398  | user1    | postgres | gsql@[local]    | postgres    |
login db(postgres) success, SSL=off | cn_5003    | 1
39779716937472@668093769836394 | 18000      | null
(2 rows)
```

The query result shows the successful login records of **user1** in to cn_5001 and cn_5003.

NOTE

SSL information is recorded at the end of the audit log **detail_info**. **SSL=on** indicates that the client is connected using SSL, and **SSL=off** indicates that the client is not connected using SSL.

**----End**

## 7.3.3 Maintaining Audit Logs

### Prerequisites

You have the audit permission.

### Background

- Table 7-9 lists the configuration parameters related to audit logs and the parameter descriptions.

**Table 7-9** Configuration parameters of audit logs

| Parameter | Description | Default Value |
| --- | --- | --- |
| audit_directory | Audit file storage directory | $GAUSSLOG/pg_audit |
| audit_resource_policy | Policy for saving audit logs | **on** (indicating that the space configuration policy is used) |
| audit_space_limit | Maximum storage space occupied by audit files | 1 GB |
| audit_file_remain_time | Minimum period for storing audit log files | 90 |
| audit_file_remain_threshold | Maximum number of audit files in the audit directory | 1048576 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

If **gs_om** is used for cluster deployment, audit logs are stored in *$GAUSSLOG*/**pg_audit**.

- The **pg_delete_audit** function is used to delete audit logs and is an internal SQL function of the database. Its syntax is as follows:

```
pg_delete_audit(timestamp startime,timestamp endtime)
```

**startime** and **endtime** indicate the audit record start time and end time, respectively.

- Audit content is commonly recorded to database tables or OS files. **Table 7-10** lists the advantages and disadvantages of the two record methods.

**Table 7-10** Comparison between the two record methods

| Mode | Benefit | Drawback |
| --- | --- | --- |
| Record in tables | Users do not need to maintain audit logs. | Any users having certain permissions to access database objects can access the audit tables. If a user illegally performs operations on the audit tables, the audit records may become inaccurate. |
| Record in OS files | This method has higher security because a user with the permission to access the database may not have the permission to access the OS files. | Users need to maintain audit logs. |

For database security purposes, GaussDB adopts the second method to save audit results for reliability.

## Procedure

**Step 1** Connect to a database. For details, see **2.1 Connecting to a Database**.

**Step 2** Select a method to maintain audit logs.

- Automatic deletion of audit logs

  If the storage space occupied by audit files or the number of audit files reaches the upper limit, the system automatically deletes the oldest audit files and records deletion information to audit logs.

  NOTE

  By default, the allowed maximum storage space that can be occupied by audit files is set to **1024 MB**. Users can set the value as required.

  Configure the allowed maximum size of storage space occupied by audit files (**audit_space_limit**).

  Configure the maximum number of audit files (**audit_file_remain_threshold**).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Manual backup of audit files

  If the storage space occupied by audit files or the number of audit logs exceeds the threshold specified by the configuration file, the system automatically deletes the oldest audit files. Therefore, you are advised to periodically save important audit logs.

  a. Run the **show** command to view the directory (**audit_directory**) where audit files are saved.

  ```
  openGauss=# SHOW audit_directory;
  ```

  b. Copy the entire audit directory elsewhere to save it.

- Manual deletion of audit logs

  Run the **pg_delete_audit** command to manually delete the audit logs generated during a specified period of time.

  For example, manually delete the audit logs generated from September 20, 2020 to September 21, 2020.

  ```
  openGauss=# SELECT pg_delete_audit('2020-09-20 00:00:00','2020-09-21 23:59:59');
  ```

**----End**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 8 Importing Data

You can use **GDS**, **INSERT**, **COPY**, or **\copy** (a **gsql** meta-command) to import data to GaussDB. **GDS** has high efficiency because of its parallel import and is used to import large volume of data. The rest statements and commands are used to import small volume of data. For details, see **Table 8-1**.

**Table 8-1** Import modes

| Method | Feature |
| --- | --- |
| GDS | Multiple DNs are used for parallel import, improving the efficiency. It is recommended for importing a large volume of data. |
| INSERT | Insert one or more rows of data, or insert data from a specified table. |
| COPY | Run the **COPY FROM STDIN** statement to write data into GaussDB.<br>Service data does not need to be stored in files when it is written from other databases to GaussDB through the CopyManager interface driven by JDBC. |
| **\copy**, a **gsql** meta-command | Different from the SQL **COPY** statement, the **\copy** command can read data from or write data into only local files on a **gsql** client.<br>**NOTE**<br>**\copy** applies only to small-scale data import in good format. It does not preprocess invalid characters or provide error tolerance. Therefore, **\copy** cannot be used in scenarios where abnormal data exists. **GDS** or **COPY** is preferred for data import. |

## 8.1 Importing Data in Parallel Using Foreign Tables

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 8.1.1 Parallel Data Import

The INSERT (**8.2 Running the INSERT Statement to Insert Data**) and COPY (**8.3 Running the COPY FROM STDIN Statement to Import Data**) statements can be used only for serially importing a small volume of data. To import a large volume of data to GaussDB, you can import data in parallel through a foreign table. To import foreign tables in parallel, you must enable the stream operator (controlled by the GUC parameter **enable_stream_operator**).

## Overview

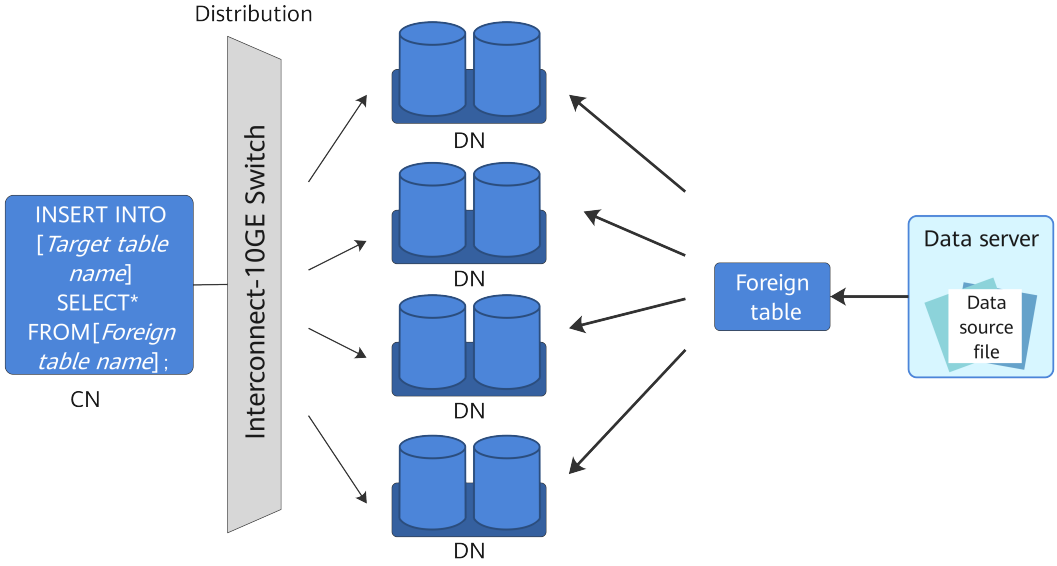
GDS imports data in parallel from the common file system of a server to GaussDB.

Source data files to import are specified based on the import policy and data formats set in a foreign table. Data is imported in parallel through multiple DNs from source data files to the database, which improves overall data import performance. **Figure 8-1** shows an example.

- The CN only plans data import tasks and delivers the tasks to DNs. Then the CN is released to process other tasks.
- In this way, the computing capacities and bandwidths of all the DNs are fully leveraged to import data, improving import efficiency.

You can preprocess data (such as invalid character replacement and fault tolerance processing) by setting parameters in a foreign table. For details, see **12.14.60 CREATE FOREIGN TABLE (for Import and Export)**.

**Figure 8-1** Importing data in parallel



The concepts mentioned in this figure are as follows:

- **CN**: coordinator node of GaussDB. After receiving import SQL requests from an application or client, the CN plans import tasks and delivers the tasks to DNs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- **DN**: data node of GaussDB. After receiving import tasks delivered by the CN, DNs import data from the source data file to the target table in the database through a foreign table.
- **Source data file**: a file that stores data to import.
- **Data server**: a server that stores source data files. For security purposes, it is recommended that the data server and GaussDB cluster be on the same intranet.
- **Foreign table**: a table that stores information, such as the current location, format, destination location, encoding format, and data delimiter of a source data file. It is used to associate source data files with the target table.
- **Target table**: a table in the database. It can be a row-store table or column-store table. Data in the source data files will be imported to this table.

## Loading Policies

To fully use computing resources for parallel import, import tasks are pushed down to DNs. The CN delivers tasks but does not import data. In this case, user data managers, correct and unique data allocation to DNs, and the uniqueness of data imported into databases must be first considered. GaussDB provides the following import policies:

- **Normal**: GDS is used to load source data into DNs. This policy is used for importing data to a cluster from hosts outside the cluster.
- **Shared**: The network file system (NFS) is used to load source data into DNs. After you configure NFS on a data server, mount the data server to the same directory of each DN. This policy is used for importing data to a cluster from hosts outside the cluster. In this policy, the CN scans all data files during task planning and evenly allocates source data files to each DN.
- **Private**: Users upload source data files to each DN. Before uploading data files, create a directory named after the DN name on each DN. Each DN searches for unloaded data files in its corresponding directory and loads them, until all data has been loaded.

As shown in **Table 8-2**, the Normal policy is recommended because it is scalable, easy to prepare, and has no limit on the size of a single row of data to be imported. The foreign tables in Private and Shared modes require the initial user permissions or the O&M administrator permissions in **operation_mode**. This section describes how to use GDS to import data in parallel. For details on the other policies, see **8.1.9.2 Example 2: Importing Data in Shared Mode** and **8.1.9.3 Example 3: Importing Data in Private Mode**.

**Table 8-2** Import policies

| Import Policy | Preparation for Data Import | Data Format |
| --- | --- | --- |
| Normal | Deploy GDS on data servers. Multi-GDS concurrent import is supported. | CSV, TEXT, and FIXED |

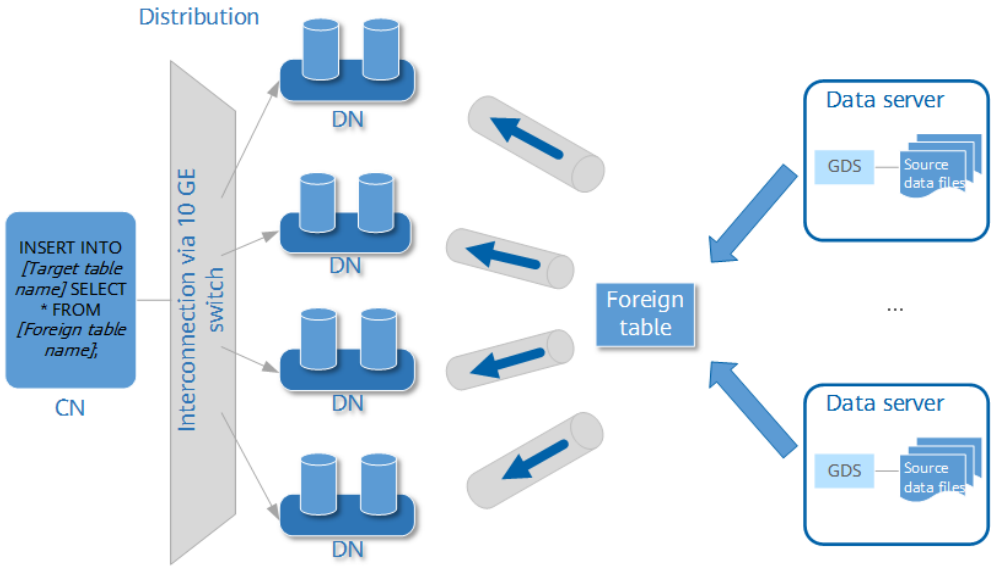
 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Import Policy | Preparation for Data Import | Data Format |
| --- | --- | --- |
| Shared | Configure NFS on data servers and mount the data servers to the same directory of each DN. The mount directory on each DN must be the same. | TEXT<br>The size of data in a single row must be less than 1 GB. |
| Private | Evenly allocate source data files to DN servers.<br>Data files in each folder named after a DN name under the same directory of hosts should not be duplicate. | CSV, TEXT, and FIXED<br>The size of data in a single row must be less than 1 GB. |

## Parallel Import Using GDS

- If a large volume of data is stored on multiple servers, deploy, configure, and start GDS on each server. Then, data on all the servers can be imported in parallel, as shown in **Figure 8-2**.

**Figure 8-2** Parallel import from multiple data servers



**NOTICE**

The number of GDS processes cannot exceed that of DNs. If the number of connections exceeds the maximum, one DN may be connected to multiple GDS processes. As a result, some GDS processes may run abnormally, and the error message "Session doesn't exist" may be displayed. If the number of GDSs involved in an import is greater than the number of DNs, a warning "It is recommended that the number of GDS should not be greater than the number of datanode" is returned when the import starts.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- If data is stored on one data server, and both GaussDB and the data server have available I/O resources, you can use GDS for multi-thread parallel import.

  GDS determines the number of threads based on the number of parallel import transactions. Even if multi-thread import is configured before GDS startup, the import of a single transaction will not be accelerated. By default, an **INSERT** statement is an import transaction.

  Multi-thread parallel import enables you to:

  – Make full use of resources and improve the parallel import efficiency when you import multiple tables to the database.

  – Speed up the import of a table with a large volume of data.

    Table data is split into multiple data files, and multi-thread parallel import is implemented by importing data using multiple foreign tables at the same time. Ensure that a data file is read only by one foreign table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Import Process

**Figure 8-3** Parallel import process

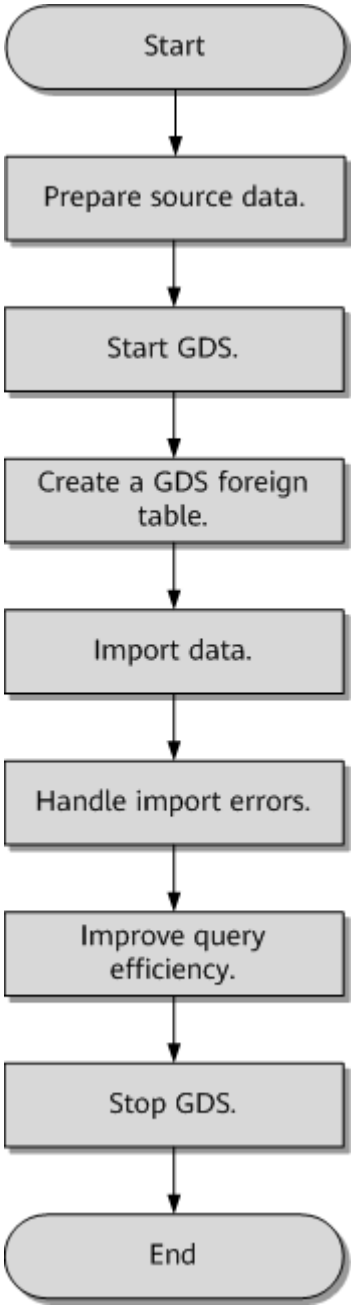


**Table 8-3** Process description

| Process | Description |
| --- | --- |
| Prepare source ata | Prepare source data files to import to the database and upload the files to the data server.<br>For details, see **8.1.3 Preparing Source Data**. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Process | Description |
| --- | --- |
| Start GDS | Install, configure, and enable GDS on the data server.<br>For details, see **8.1.4 Installing, Configuring, and Starting GDS**. |
| Create a foreign table | A foreign table is used to identify data in a source data file. Foreign tables store the location, file format, encoding format, and delimiters information about the data source files.<br>For details, see **8.1.5 Creating a GDS Foreign Table**. |
| Import data | After creating the foreign table, execute the **INSERT** statement to efficiently import data to the target table. For details, see **8.1.6 Importing Data**. |
| Handle import errors | If there are errors during parallel data import, handle errors based on the error information to ensure data integrity.<br>For details, see **8.1.7 Handling Import Errors**. |
| Improve query efficiency | After data is imported, run the **ANALYZE** statement to generate table statistics. The **ANALYZE** statement stores the statistics in the system catalog **PG_STATISTIC**. The statistics data is useful when you run the planner, which provides you with an efficient query execution plan.<br>For details, see **8.8 Analyzing Tables**. |
| Stop GDS | After data import is complete, log in to each data server and stop GDS.<br>For details, see **8.1.8 Stopping GDS**. |

## 8.1.2 Tutorial and Best Practice

**5 Tutorial: Using GDS to Import Data from a Remote Server** guides you through importing data using GDS.

The **Best Practices of GDS Data Import** describes how to maximize system resources to improve import performance. You are advised to read this before planning data import.

## 8.1.3 Preparing Source Data

### Scenarios

Before being imported to a database, data is stored on the related host. The server that stores the data to import is called the data server. In this case, you only need to check the communication between the data server and GaussDB cluster and record the data storage directory on the data server. Check whether the server has robust system resources such as memory, handles, and disk space, based on the load of the import job.

If the data has not been uploaded to the data server, perform the operations described in this section to upload it first.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

### Procedure

**Step 1** Log in to the data server.

**Step 2** Create a file storage directory **/input_data**.

```
mkdir -p /input_data
```

**Step 3** Upload source data files to the created directory.

GDS parallel import supports data only in CSV, TEXT, or FIXED format. Ensure that the source data file meets the format requirements.

**----End**

## 8.1.4 Installing, Configuring, and Starting GDS

### Scenarios

GaussDB uses GDS to allocate source data for parallel data import. GDS needs to be deployed on data servers.

If a large volume of data is stored on multiple servers, deploy, configure, and start GDS on each server. Then, data on all the servers can be imported in parallel. The procedure for installing, configuring, and starting GDS is the same on each data server. This section describes how to perform this procedure on one data server.

### Background

1. GDS can be installed on the following x86/ARM OS: EulerOS 2.5/2.8.
2. The GDS version must be consistent with the database version. Otherwise, the import or export may fail or not respond.

   Therefore, do not use an earlier version of GDS. After the database is upgraded, download the GDS of the new version as instructed in **Procedure**. When the import or export starts, GaussDB checks the GDS version and will display an error message and terminate the import or export if it detects a version mismatch.

   To obtain the GDS version, run the following command in the GDS decompression directory:

   ```
   gds -V
   ```

   To view the database version, run the following SQL statement after connecting to the database:

   ```
   SELECT version();
   ```

- The data server where GDS is deployed must use the recommended OS and communication parameter settings, which are the same as the configuration parameters of the cluster. For proper service running, ensure that the communication between the GDS data server and the cluster is normal.

  To use the inspection package to check system parameters on a data server, perform the following operations:

  a. Copy the inspection package to the GDS data server.

  b. Run the following command to check the system configuration parameters:

  ```
  gs_check -i CheckSysParams -L
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

c. Modify parameter settings as prompted and run the command in the previous steps again.

If the message "Warning reason: variable 'net.ipv4.tcp_retries1' RealValue '3' ExpectedValue '5'." is displayed, run the following commands:

```
vim /etc/sysctl.conf // Set net.ipv4.tcp_retries1=5.
sysctl -p // Make parameter settings take effect.
```

## Procedure

**Step 1** Log in to the data server where GDS is to be installed, and create a GDS user and its user group. This user is used to start GDS and read source data.

```
groupadd gdsgrp
useradd -g gdsgrp gds_user
```

**Step 2** Switch to user **gds_user**.

```
su - gds_user
```

**Step 3** Create the **/opt/bin** directory for storing the GDS package.

```
mkdir -p /opt/bin
```

**Step 4** Change the owner of the GDS package directory and source data file directory to the GDS user.

```
chown -R gds_user:gdsgrp /opt/bin/gds
chown -R gds_user:gdsgrp /input_data
```

**Step 5** Upload the GDS package to the created directory.

Use the SUSE Linux package as an example. Upload the GDS package **GaussDB-Kernel-VxxxRxxxCxx-SUSE11-64bit-Gds.tar.gz** in the software installation package to the newly created directory.

**Step 6** (Optional) If SSL is used, upload the SSL certificates to the directory newly created in Step **Step 1**.

The certificates are stored in the **$GAUSSHOME/share/sslcert/gds** directory of GaussDB. Download and upload the file.

**Step 7** Go to the new directory and decompress the package.

```
cd /opt/bin
tar -zxvf GaussDB-Kernel-VxxxRxxxCxx-SUSE11-64bit-Gds.tar.gz
export LD_LIBRARY_PATH="/opt/bin/lib:$LD_LIBRARY_PATH"  // GDS depends on the Cjson dynamic library. Therefore, you need to configure the path of the dynamic library.
```

**Step 8** Start GDS.

GDS is green software and can be started after being decompressed. You can start it in either of the following ways: One is to run the **gds** command to set startup parameters. The other is to write the startup parameters into the **gds.conf** configuration file and run the **gds_ctl.py** command to start GDS. The **gds** command is recommended when you do not need to import data again. The **gds.conf** configuration file is recommended when you need to import data again.

- Run the **gds** command to start GDS.
  - If data is transmitted in non-SSL mode, run the following command to start GDS:

    ```
    gds -d dir -p ip:port -H address_string -l log_file -D -t worker_num --enable-ssl off
    ```

    Example:

    ```
    /opt/bin/gds/gds -d /input_data/ -p 192.168.0.90:5000 -H 10.10.0.1/24 -l /opt/bin/gds/gds_log.txt -D -t 2 --enable-ssl off
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- If data is transmitted in SSL mode, run the following command to start GDS:
  ```
  gds -d dir -p ip:port -H address_string -l log_file -D
  -t worker_num --enable-ssl on --ssl-dir Cert_file
  ```
  Example:

  Run the following command to upload the SSL certificate mentioned in **Step 6** to **/opt/bin**:
  ```
  /opt/bin/gds/gds -d /input_data/ -p 192.168.0.90:5000 -H 10.10.0.1/24 -l /opt/bin/gds/
  gds_log.txt -D --enable-ssl on --ssl-dir /opt/bin/
  ```

Replace the information in italic as required.

- **-d** *dir*: directory that stores source data files. It is **/input_data/** in this tutorial.
- **-p** *ip:port*: listening IP address and port for GDS. The default value is **127.0.0.1**. Replace it with the IP address of a 10GE network that can communicate with GaussDB. The listening port can be any one ranging from 1024 to 65535. The default port is **8098**. This parameter is set to **192.168.0.90:5000** in this tutorial.
- **-H** *address_string*: network segment for hosts that can connect to and use GDS. The value must be in CIDR format. Set this parameter to enable the GaussDB cluster to access GDS for data import. Ensure that the network segment covers all hosts in the GaussDB cluster.
- **-l** *log_file*: GDS log directory and log file name. This tutorial uses **/opt/bin/gds/gds_log.txt** as an example.
- **-D**: GDS in daemon mode. This parameter is used only in Linux.
- **-t** *worker_num*: number of concurrent GDS threads. If the data server and GaussDB have robust I/O resources, you can increase the number of concurrent GDS threads.

  GDS determines the number of threads based on the number of parallel import transactions. Even if multi-thread import is configured before GDS startup, the import of a single transaction will not be accelerated. By default, an **INSERT** statement is an import transaction.
- **--enable-ssl**: Data transmission in SSL encryption mode. By default, the value **on** is used to enable the SSL encryption mode. If this parameter is not used, you need to add **--ssl-dir** to specify the SSL certificate directory.
- **--ssl-dir** *Cert_file*: SSL certificate directory. Set it to the certificate directory mentioned in **Step 6**.
- For details on how to set more parameters, see **Server Tools** > **GDS** > **Parameter Description** in the *Tool Reference*.

- Run the **gds_ctl.py** command to start GDS.

  a. Run the following command to go to the **config** directory of the GDS package and modify the **gds.conf** configuration file. In this case, GDS is not in SSL mode. For details on the parameters in the **gds.conf** configuration file, see **Table 8-4**.
  ```
  vim /opt/bin/gds/config/gds.conf
  ```
  Example:

  The **gds.conf** configuration file contains the following information:
  ```
  <?xml version="1.0"?>
  <config>
  <gds name="gds1" ip="192.168.0.90" port="5000" data_dir="/input_data/" err_dir="/err"
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
data_seg="100MB" err_seg="100MB" log_file="/log/gds_log.txt" host="10.10.0.1/24"
daemon='true' recursive="true" parallel="32"></gds>
</config>
```

Details are as follows:

- The data server IP address is **192.168.0.90** and the GDS listening port is **5000**.
- Data files are stored in the **/input_data/** directory.
- Error log files are stored in the **/err** directory.
- The size of a single data file is 100 MB.
- The size of a single error log file is 100 MB.
- Run logs are stored in the **/log/gds_log.txt** file.
- Only nodes with the IP address being 10.10.0.* can be connected.
- The GDS process is running in daemon mode.
- Recursive data file directories are used.
- The number of concurrent import threads is 2.

b. Start GDS and check whether it has been started:

```
python3 gds_ctl.py start
```

Example:

```
cd /opt/bin/gds
python3 gds_ctl.py start
Start GDS gds1                  [OK]
gds [options]:
 -d dir            Set data directory.
 -p port           Set GDS listening port.
   ip:port         Set GDS listening ip address and port.
 -l log_file       Set log file.
 -H secure_ip_range
                  Set secure IP checklist in CIDR notation.                  Required for GDS to start.
 -e dir            Set error log directory.
 -E size           Set size of per error log segment.(0 < si                  ze < 1TB)
 -S size           Set size of data segment.(1MB < size < 10                  0TB)
 -t worker_num     Set number of worker thread in multi-thre                  ad mode, the upper
limit is 32. If withou                  t setting, the default value is 1.
 -s status_file    Enable GDS status report.
 -D                Run the GDS as a daemon process.
 -r                Read the working directory recursively.
 -h                Display usage.
```

**----End**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

The binary use of GDSs depends on some common library files. If GDSs are deployed on physical nodes outside the cluster and the physical environment where GDSs reside cannot provide such library files or the versions of related library files are incompatible, an error message similar to "/lib64/libstdc++.so.6: version `GLIBCXX_3.4.20' not found" may be displayed during the startup. Log in to the physical node where the cluster resides, copy the corresponding library file (for example, **libstdc++.so.6** or **libgcc_s.so.1**) from the *$GAUSSHOME*/**lib** directory to the directory in step 4, and repeat step 4 to set environment variables. After the setting is successful, restart GDS.

If the problem persists, GDS does not support the current physical environment or platform. You are advised to switch to a supported physical environment and try again.

## gds.conf Parameter Description

**Table 8-4** Attributes in the gds.conf file

| Attribute | Description | Value Range |
| --- | --- | --- |
| name | Identifier | - |
| ip | Listening IP address | The IP address must be valid.<br>Default value: 127.0.0.1 |
| port | Listening port | Value range: an integer ranging from 1024 to 65535<br>Default value: 8098 |
| data_dir | Data file directory | - |
| err_dir | Error log file directory | Default value: data file directory |
| log_file | Log file path | - |
| host | Host IP address allowed to be connected to GDS (The value must in CIDR format and this parameter is set for the Linux OS only.) | - |
| recursive | Whether the data file directories are recursive | Value range:<br>● **true**: recursive<br>● **false**: not recursive<br>Default value: false |
| daemon | Whether a process is running in daemon mode | Value range:<br>● **true**: The server is running in daemon mode.<br>● **false**: The server is not running in daemon mode.<br>Default value: false |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Attribute | Description | Value Range |
| --- | --- | --- |
| parallel | Number of concurrent data import threads | Value range: an integer ranging form 0 to 32<br>Default value: 1 |

## 8.1.5 Creating a GDS Foreign Table

Source data information and GDS access information are configured in a foreign table. Then, GaussDB can import data from a data server to a database table based on the configuration in the foreign table.

### Procedure

**Step 1** Collect source data information and GDS access information.

You need to collect the following source data information:

- **format**: CSV, TEXT, and FIXED are supported. Check the format of data to import, for example, CSV format.
- **header**: whether a source data file has a header. This parameter is set only for files in CSV or FIXED format.
- **delimiter**: delimiter in the source data file, for example, comma (,).
- **encoding**: encoding format of the source data file, for example, UTF-8.
- **eol**: line break character in the data file. It can be a default character, such as 0x0D0A or 0X0A, or a customized line break character such as a string **!@#**. This parameter can be set only for TEXT import.
- For details on more source data information configured in a foreign table, see **data format parameters**.

You need to collect the following GDS access information:

**location**: GDS URL. GDS information in **8.1.4 Installing, Configuring, and Starting GDS** is used as an example. In non-SSL mode, **location** is set to **gsfs**://*192.168.0.90:5000*|*/input_data/*. In SSL mode, **location** is set to **gsfss**://*192.168.0.90:5000*|*/input_data/*. **192.168.0.90:5000** is the IP address and port number of GDS. **input_data** is the directory for storing source data files on the data server. Replace the values as required.

**Step 2** Design an error tolerance mechanism for data import.

GaussDB supports the following error tolerance in data import:

- **fill_missing_fields**: This parameter specifies whether to report an error when the last column in a row of the source data file is empty, or to fill the column with null.
- **ignore_extra_data**: When the number of columns in the source data file is greater than that specified in the foreign table, this parameter specifies whether to report an error or ignore the extra columns.
- **per node reject_limit**: This parameter specifies the number of data format errors allowed on each DN. If the number of errors recorded in the error table

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

on a DN exceeds the specified value, the import fails and an error message is reported. You can also set it to **unlimited**.

- **compatible_illegal_chars**: When an illegal character is encountered, this parameter specifies whether to import an error, or convert it and proceed with the import.

  The following describes the rules for converting an illegal character:

  - **\0** is converted to a space.
  - Other illegal characters are converted to question marks.
  - If **NULL**, **DELIMITER**, **QUOTE**, or **ESCAPE** is also set to a space or question mark, GaussDB displays an error message, such as "illegal chars conversion may confuse COPY escape 0x20", to prompt you to modify parameter settings that may cause import errors.
- **error_table_name**: This parameter specifies the name of the table that records data format errors. After the parallel import, you can query the table for error details.
- **remote log 'name'**: This parameter specifies whether to store data format errors in files on the GDS server. **name** is the prefix of the error data file.
- For details on more error tolerance parameters, see **error tolerance parameters**.

**Step 3** After connecting to the database using **gsql** or Data Studio, create a GDS foreign table based on the collected and design information.

The command is as follows:

```
openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
)
 SERVER gsmpp_server
 OPTIONS
(
LOCATION 'gsfs://192.168.0.90:5000/input_data | gsfs://192.168.0.91:5000/input_data',
FORMAT 'CSV' ,
DELIMITER ',',
ENCODING 'utf8',
HEADER 'false',
FILL_MISSING_FIELDS 'true',
IGNORE_EXTRA_DATA 'true'
)
LOG INTO product_info_err
PER NODE REJECT LIMIT 'unlimited';
```

The following describes information in this example:

- The columns specified in the foreign table must be the same as those in the target table.
- Retain the value **gsmpp_server** for **SERVER**.
- Set **location** based on the GDS access information collected in **Step 1**. If SSL is used, replace **gsfs** with **gsfss**.
- Set **FORMAT**, **DELIMITER**, **ENCODING**, and **HEADER** based on the source data information collected in **Step 1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Set **FILL_MISSING_FIELDS**, **IGNORE_EXTRA_DATA**, **LOG INTO**, and **PER NODE REJECT LIMIT** based on the error tolerance mechanism designed in **Step 2**. **LOG INTO** specifies the name of the error table.

For details on the **CREATE FOREIGN TABLE** syntax, see **12.14.60 CREATE FOREIGN TABLE (for Import and Export)**.

**----End**

## Examples

For more examples, see **8.1.9 Examples**.

- Example 1: Create a GDS foreign table named **foreign_tpcds_reasons**. The data format is CSV.

```
openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
)
 SERVER gsmpp_server OPTIONS (location 'gsfs://192.168.0.90:5000/* | gsfs://192.168.0.91:5000/*',
FORMAT 'CSV',MODE 'Normal', ENCODING 'utf8', DELIMITER E'\x20', QUOTE E'\x1b', NULL '');
```

- Example 2: Create a GDS foreign table named **foreign_tpcds_reasons_SSL**. SSL is used and the data format is CSV.

```
openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons_SSL
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
)
 SERVER gsmpp_server OPTIONS (location 'gsfss://192.168.0.90:5000/* | gsfss://192.168.0.91:5000/*',
FORMAT 'CSV',MODE 'Normal', ENCODING 'utf8', DELIMITER E'\x20', QUOTE E'\x1b', NULL '');
```

- Example 3: Create a GDS foreign table named **foreign_tpcds_reasons**. The data format is TEXT.

```
openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
) SERVER gsmpp_server OPTIONS (location 'gsfs://192.168.0.90:5000/* | gsfs://192.168.0.91:5000/*',
FORMAT 'TEXT', delimiter E'\x20',  null '',reject_limit '2',EOL '0x0D') WITH err_foreign_tpcds_reasons;
```

- Example 4: Create a GDS foreign table named **foreign_tpcds_reasons**. The data format is FIXED.

```
openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons
(
  r_reason_sk       integer      position(1,2),
  r_reason_id       char(16)     position(3,16),
  r_reason_desc     char(100)    position(19,100)
) SERVER gsmpp_server OPTIONS (location 'gsfs://192.168.0.90:5000/*', FORMAT 'FIXED', ENCODING
'utf8',FIX '119');
```

# 8.1.6 Importing Data

This section describes how to create tables in GaussDB and import data to the tables.

Before importing all the data from a table containing over 10 million records, you are advised to import some of the data and perform operations in **8.7 Checking for Data Skew**. Immediately address data skew problems if any because it is costly to address them after a large amount of data has been imported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Prerequisites

The IP addresses and ports of servers where CNs and DNs reside can connect to those of a GDS server.

## Procedure

**Step 1** Create a target table in GaussDB to store imported data. For details, see **12.14.80 CREATE TABLE**.

**Step 2** (Optional) If the target table has an index, the index information will be incrementally updated during the import, affecting data import performance. You are advised to delete the index from the target table before the import. You can create the indexes again after the import is complete.

1. If there is an ordinary index **product_idx** in the **product_id** column of the target table **product_info**, delete the index from the table before importing data.
   ```
   DROP INDEX product_idx;
   ```
2. After importing the data, create the index again.
   ```
   openGauss=# CREATE INDEX product_idx ON product_info(product_id);
   ```
3. Set **enable_stream_operator** to **on**.
   ```
   openGauss=# set enable_stream_operator=on;
   ```

NOTE

To accelerate the index recreation, add the **maintenance_work_mem** and **psort_work_mem** parameters.

**Step 3** Import data.

```
openGauss=# INSERT INTO [Target table name] SELECT * FROM [Foreign table name]
```

- If information similar to the following is displayed, the data has been imported. Query the error information table to check whether any data format errors occurred. For details, see **8.1.7 Handling Import Errors**.
  ```
  INSERT 0 9
  ```
- If data fails to be loaded, troubleshoot the problem by following the instructions provided in **8.1.7 Handling Import Errors** and try again.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- If a data loading error occurs, the entire data import task will fail.
- Create batch processing scripts to concurrently import data. The degree of parallelism depends on server resource usage. You can test several tables and monitor resource usage to determine whether to increase or reduce the amount. Common resource monitoring commands include **top** for monitoring memory and CPU usage, **iostat** for monitoring I/O usage, and **sar** for monitoring networks. For details on application cases, see **Example: Data Import Using Multiple Threads**.
- If possible, more GDS servers can significantly improve the data import efficiency. For details on application cases, see **Example: Parallel Import from Multiple Data Servers**.
- In a scenario where many GDS servers import data concurrently, you can extend the TCP Keepalive interval for connections between GDS servers and DNs to ensure connection stability. (The recommended interval is 5 minutes.) TCP Keepalive settings of the cluster affect its fault detection response time.
- If **enable_stream_operator** is set to **on**, the performance is affected. If there are other SQL statements to be executed in the session, you are advised to set **enable_stream_operator** to **off**. If there is no SQL statement to be executed in the session, disconnect the session.

**----End**

## Examples

1. Create a target table named **reasons**.
```
openGauss=# CREATE TABLE reasons
(
  r_reason_sk   integer  not null,
  r_reason_id   char(16) not null,
  r_reason_desc char(100)
)
DISTRIBUTE BY HASH (r_reason_sk);
```
2. Delete the index from the target table. Create the indexes again after the import is complete.
   a. If there is an ordinary table index **reasons_idx** in the **r_reason_id** column of the **reasons** table, delete the index from the table before importing data.
   ```
   openGauss=# DROP INDEX reasons_idx;
   ```
   b. After importing the data, create the index again.
   ```
   openGauss=# CREATE INDEX reasons_idx ON reasons(r_reasons_id);
   ```
   c. Set **enable_stream_operator** to **on**.
   ```
   openGauss=# set enable_stream_operator=on;
   ```
3. Import data from source data files through the **foreign_tpcds_reasons** foreign table to the **reasons** table.
```
openGauss=# INSERT INTO reasons SELECT * FROM foreign_tpcds_reasons ;
```

# 8.1.7 Handling Import Errors

## Scenarios

Handle errors that occurred during data import.

## Querying Error Information

Errors that occur when data is imported are divided into data format errors and non-data format errors.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Data format errors

  When creating a foreign table, specify **LOG INTO** *error_table_name*. Data format errors during data import will be written into the specified table. You can run the following SQL statement to query error details:

  ```
  openGauss=# SELECT * FROM error_table_name;
  ```

  **Table 8-5** lists the columns of the *error_table_name* table.

  **Table 8-5** Columns in the error information table

  | Column Name | Type | Description |
  | --- | --- | --- |
  | nodeid | integer | ID of the node where an error is reported |
  | begintime | timestamp with time zone | Time when a data format error was reported |
  | filename | character varying | Name of the source data file where a data format error occurs |
  | rownum | numeric | Number of the row where a data format error occurs in a source data file |
  | rawrecord | text | Raw record of a data format error in the source data file |
  | detail | text | Error details |

- Non-data format errors

  A non-data format error leads to the failure of an entire data import task. You can locate and troubleshoot a non-data format error based on the error message displayed during data import.

## Handling Data Import Errors

Troubleshoot data import errors based on obtained error information and descriptions in **Table 8-6**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 8-6** Handling data import errors

| Error Message | Cause | Solution |
| --- | --- | --- |
| missing data for column "r_reason_desc" | 1. The number of columns in the source data file is less than that in the foreign table.<br>2. In a TEXT-format source data file, an escape character (for example, \) leads to delimiter or quote mislocation. Example: The target table contains three columns, and the following data is imported. The escape character (\) converts the delimiter (\|) into the value of the second column, causing the value of the third column to lose.<br>`BE\|Belgium\\|1` | 1. If an error is reported due to missing columns, perform the following operations:<br>• Add the value of the **r_reason_desc** column to the source data file.<br>• When creating a foreign table, set the parameter **fill_missing_fields** to **on**. In this way, if the last column of a row in the source data file is missing, it will be set to **NULL** and no error will be reported.<br>2. Check whether the row where an error is reported contains the escape character (\). If the row contains such a character, you are advised to set the parameter **noescaping** to **true** when creating a foreign table, indicating that the escape character (\) and the characters following it are not escaped. |
| extra data after last expected column | The number of columns in the source data file is greater than that in the foreign table. | • Delete extra columns from the source data file.<br>• When creating a foreign table, set the parameter **ignore_extra_data** to **on**. In this way, if the number of columns in the source data file is greater than that in the foreign table, the extra columns at the end of rows will not be imported. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Error Message | Cause | Solution |
| --- | --- | --- |
| invalid input syntax for type numeric: "a" | The data type is incorrect. | In the source data file, change the data type of the columns to import. If this error information is displayed, change the data type to **numeric**. |
| null value in column "staff_id" violates not-null constraint | The not-null constraint is violated. | In the source data file, add values to the specified columns. If this error information is displayed, add values to the **staff_id** column. |
| duplicate key value violates unique constraint "reg_id_pk" | The unique constraint is violated. | • Delete duplicate rows from the source data file.<br>• Run the **SELECT** statement with the **DISTINCT** keyword to ensure that all imported rows are unique.<br>openGauss=# **INSERT INTO** reasons **SELECT DISTINCT * FROM** foreign_tpcds_reasons; |
| value too long for type character varying(16) | The column length exceeds the upper limit. | In the source data file, change the column length. If this error information is displayed, reduce the column length to no greater than 16 bytes (VARCHAR2). |

# 8.1.8 Stopping GDS

## Scenarios

Stop GDS after data is imported successfully.

## Procedure

**Step 1** Log in as user **gds_user** to the data server where GDS is installed.

**Step 2** Select the mode of stopping GDS based on the GDS start mode.

- If GDS is started using the **gds** command, perform the following operations to stop GDS:
  a. Query the GDS process ID.
  ```
  ps -ef|grep gds
  ```
  For example, the GDS process ID is 128954.
  ```
  ps -ef|grep gds
  gds_user 128954     1  0 15:03 ?        00:00:00 gds -d /input_data/ -p 192.168.0.90:5000 -l /log/gds_log.txt -D
  gds_user 129003 118723  0 15:04 pts/0    00:00:00 grep gds
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

b. Run the **kill** command to stop GDS. **128954** in the command is the GDS process ID.
```
kill -9 128954
```

- If GDS is started using the **gds_ctl.py** command, run the following commands to stop GDS:
```
cd /opt/bin/gds
python3 gds_ctl.py stop
```

**----End**

# 8.1.9 Examples

## 8.1.9.1 Example 1: Importing Data in Normal Mode

## Example: Parallel Import from Multiple Data Servers

The data servers reside on the same intranet as the cluster. Their IP addresses are 192.168.0.90 and 192.168.0.91. Source data files are in CSV format.

1. Create the target table **tpcds.reasons**.
```
openGauss=# CREATE TABLE tpcds.reasons
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
);
```
2. (Optional) Create a user and its user group. The user is used to start GDS. If the user and user group already exist, skip this step.
```
groupadd gdsgrp
useradd -g gdsgrp gds_user
```
3. Log in to each GDS data server as user **gds_user** and create the **/input_data** directory for storing data files on the servers. The following uses the data server whose IP address is 192.168.0.90 as an example. Operations on the other server are the same.
```
su - gds_user
mkdir -p /input_data
```
4. Evenly distribute source data files to the **/input_data** directories on the data servers.
5. Change the owners of source data files and the **/input_data** directory on each data server to **gds_user**. The data server with the IP address 192.168.0.90 is used as an example.
```
chown -R gds_user:gdsgrp /input_data
```
6. Log in to each data server as user **gds_user** and start GDS.

   The GDS installation path is **/opt/bin/gds**. Source data files are stored in **/input_data/**. The IP addresses of the data servers are 192.168.0.90 and 192.168.0.91. The GDS listening port is 5000. GDS runs in daemon mode.

   Start GDS on the data server whose IP address is 192.168.0.90.
```
/gds/gds -d /input_data -p 192.168.0.90:5000 -H 10.10.0.1/24 -D
```

   Start GDS on the data server whose IP address is 192.168.0.91.
```
/gds/gds -d /input_data -p 192.168.0.91:5000 -H 10.10.0.1/24  -D
```
7. Create the foreign table **tpcds.foreign_tpcds_reasons** for the source data.

   Set import mode parameters as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Set the import mode to **Normal**.
- When GDS is started, the source data file directory is **/input_data** and the GDS listening port is 5000. Therefore, set **location** to **gsfs://192.168.0.90:5000/* | gsfs://192.168.0.91:5000/***.

Information about the data format is set based on data format parameters specified during data export. The parameter settings are as follows:

- **format** is set to **CSV**.
- **encoding** is set to **UTF-8**.
- **delimiter** is set to **E'\x08'**.
- **quote** is set to **0x1b**.
- **null** is set to an empty string without quotation marks.
- **escape** is set to a double quotation mark.
- **header** is set to **false**, indicating that the first row is regarded as a data row when a file is imported.

Set import error tolerance parameters as follows:

- Set **PER NODE REJECT LIMIT** (number of allowed data format errors) to **unlimited**. In this case, all the data format errors detected during data import will be tolerated.
- Set **LOG INTO** to **err_tpcds_reasons**. The data format errors detected during data import will be recorded in the **err_tpcds_reasons** table.

Based on the above settings, the foreign table is created using the following statement:

```
openGauss=# CREATE FOREIGN TABLE tpcds.foreign_tpcds_reasons
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
)
SERVER gsmpp_server OPTIONS (location 'gsfs://192.168.0.90:5000/* | gsfs://192.168.0.91:5000/*',
format 'CSV',mode 'Normal', encoding 'utf8', delimiter E'\x08', quote E'\x1b', null '', fill_missing_fields
'false') LOG INTO err_tpcds_reasons PER NODE REJECT LIMIT 'unlimited';
```

8. Import data through the foreign table **tpcds.foreign_tpcds_reasons** to the target table **tpcds.reasons**.

   ```
   openGauss=# INSERT INTO tpcds.reasons SELECT * FROM tpcds.foreign_tpcds_reasons;
   ```

9. Query data import errors in the **err_tpcds_reasons** table and rectify the errors (if any). For details, see **8.1.7 Handling Import Errors**.

   ```
   openGauss=# SELECT * FROM err_tpcds_reasons;
   ```

10. After data import is complete, log in to each data server as user **gds_user** and stop GDS.

    The data server with the IP address 192.168.0.90 is used as an example. The GDS process ID is 128954.

    ```
    ps -ef|grep gds
    gds_user 128954      1  0 15:03 ?        00:00:00 gds -d /input_data -p 192.168.0.90:5000 -D
    gds_user 129003 118723  0 15:04 pts/0    00:00:00 grep gds
    kill -9 128954
    ```

## Example: Data Import Using Multiple Threads

The data server resides on the same intranet as the cluster. The server IP address is 192.168.0.90. Source data files are in CSV format. Data will be imported to two tables using multiple threads in **Normal** mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

1. In the database, create the target tables **tpcds.reasons1** and **tpcds.reasons2**.
```
openGauss=# CREATE TABLE tpcds.reasons1
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
) ;
openGauss=# CREATE TABLE tpcds.reasons2
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
) ;
```
2. (Optional) Create a user and its user group. The user is used to start GDS. If the user and user group already exist, skip this step.
```
groupadd gdsgrp
useradd -g gdsgrp gds_user
```
3. Log in to the GDS data server as user **gds_user**, and then create the data file directory **/input_data** and its sub-directories **/input_data/import1/** and **/input_data/import2/**.
```
su - gds_user
mkdir -p /input_data
```
4. Store the source data files of the target table **tpcds.reasons1** in **/input_data/import1/** and the source data files of the target table **tpcds.reasons2** in **/input_data/import2/**.
5. Change the owners of source data files and the **/input_data** directory on the data server to **gds_user**.
```
chown -R gds_user:gdsgrp /input_data
```
6. Log in to the data server as user **gds_user** and start GDS.

   The GDS installation path is **/gds**. Source data files are stored in **/input_data/**. The IP address of the data server is 192.168.0.90. The GDS listening port is 5000. GDS runs in daemon mode. The degree of parallelism is 2. A recursive directory is specified.
```
/gds/gds -d /input_data -p 192.168.0.90:5000 -H 10.10.0.1/24  -D -t 2 -r
```
7. In the database, create the foreign tables **tpcds.foreign_tpcds_reasons1** and **tpcds.foreign_tpcds_reasons2** for the source data.

   The foreign table **tpcds.foreign_tpcds_reasons1** is used as an example to describe how to set parameters in a foreign table.

   Set import mode parameters as follows:

   - Set the import mode to **Normal**.
   - When GDS is started, the source data file directory is **/input_data** and the GDS listening port is 5000. However, source data files are actually stored in **/input_data/import1/**. Therefore, set **location** to **gsfs://192.168.0.90:5000/import1/***.

   Information about the data format is set based on data format parameters specified during data export. The parameter settings are as follows:

   - **format** is set to **CSV**.
   - **encoding** is set to **UTF-8**.
   - **delimiter** is set to **E'\x08'**.
   - **quote** is set to **0x1b**.
   - **null** is set to an empty string without quotation marks.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- **escape** is set to a double quotation mark.
- **header** is set to **false**, indicating that the first row is regarded as a data row when a file is imported.

Set import error tolerance parameters as follows:

- Set **PER NODE REJECT LIMIT** (number of allowed data format errors) to **unlimited**. In this case, all the data format errors detected during data import will be tolerated.
- Set **LOG INTO** to **err_tpcds_reasons1**. The data format errors detected during data import will be recorded in the **err_tpcds_reasons1** table.
- If the last column (**fill_missing_fields**) in a source data file is missing, the **NULL** column will be automatically added to the target file.

Based on the above settings, the foreign table **tpcds.foreign_tpcds_reasons1** is created using the following statement:

```
openGauss=# CREATE FOREIGN TABLE tpcds.foreign_tpcds_reasons1
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
) SERVER gsmpp_server OPTIONS (location 'gsfs://192.168.0.90:5000/import1/*', format 'CSV',mode
'Normal', encoding 'utf8', delimiter E'\x20', quote E'\x1b', null '',fill_missing_fields 'on')LOG INTO
err_tpcds_reasons1 PER NODE REJECT LIMIT 'unlimited';
```

Based on the above settings, the foreign table **tpcds.foreign_tpcds_reasons2** is created using the following statement:

```
openGauss=# CREATE FOREIGN TABLE tpcds.foreign_tpcds_reasons2
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
) SERVER gsmpp_server OPTIONS (location 'gsfs://192.168.0.90:5000/import2/*', format 'CSV',mode
'Normal', encoding 'utf8', delimiter E'\x20', quote E'\x1b', null '',fill_missing_fields 'on')LOG INTO
err_tpcds_reasons2 PER NODE REJECT LIMIT 'unlimited';
```

8. Import data through the foreign tables **tpcds. foreign_tpcds_reasons1** and **tpcds. foreign_tpcds_reasons2** to **tpcds.reasons1** and **tpcds.reasons2**, respectively.

   ```
   openGauss=# INSERT INTO tpcds.reasons1 SELECT * FROM tpcds.foreign_tpcds_reasons1;
   openGauss=# INSERT INTO tpcds.reasons2 SELECT * FROM tpcds.foreign_tpcds_reasons2;
   ```

9. Query data import errors in the **err_tpcds_reasons1** and **err_tpcds_reasons2** tables and rectify the errors (if any). For details, see **8.1.7 Handling Import Errors**.

   ```
   openGauss=# SELECT * FROM err_tpcds_reasons1;
   openGauss=# SELECT * FROM err_tpcds_reasons2;
   ```

10. After data import is complete, log in to the data server as user **gds_user** and stop GDS.

    The GDS process ID is 128954.

    ```
    ps -ef|grep gds
    gds_user 128954      1  0 15:03 ?        00:00:00 gds -d /input_data -p 192.168.0.90:5000 -D -t 2 -r
    gds_user 129003 118723  0 15:04 pts/0    00:00:00 grep gds
    kill -9 128954
    ```

## 8.1.9.2 Example 2: Importing Data in Shared Mode

1. Prepare for data import.

   This section assumes that a source data file **foreign_tpcds_reasons.dat.0** in text format is stored in the **/input_data** directory on the 192.168.0.90 server.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

a. Configure the NFS service on the data server. For details, see **SUSE DOC: Administration Guide – Configuring NFS Server**.

> **CAUTION**
>
> The security of the NFS service and data transmission is ensured by users. You are advised to use the NFS service in a trusted domain.

b. Start the NFS service on the data server.
```
service nfs start
```

c. Log in as a common user to each server where GaussDB DNs reside, create the **/input_data** directory on each server, and mount each data server storing source data files to this directory.
```
cd /input_data
mount -t nfs 192.168.0.90:/input_data /input_data
```

2. Log in as the OS user **omm** to the host where the CN is located.
3. Run the following command to connect to the database:
```
gsql -d postgres -p 8000
```
**postgres** is the name of the database, and **8000** is the port number of the CN.

If information similar to the following is displayed, the connection succeeds:
```
gsql((GaussDB Kernel VxxxRxxxCxx build f521c606) compiled at 2021-09-16 14:55:22 commit 2935 last mr 6385 release)
Non-SSL connection (SSL connection is recommended when requiring high-security)
Type "help" for help.

openGauss=#
```
4. Create the target table **reasons**.
```
openGauss=# CREATE TABLE reasons
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
);
```
5. Create the foreign table **foreign_tpcds_reasons** for the source data.
```
openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
) SERVER gsmpp_server OPTIONS (location 'file:///input_data/foreign_tpcds_reasons.dat.0', format 'TEXT', mode 'shared', delimiter E'\x20',  NULL '');
```
6. Import data to the **reasons** table.
```
openGauss=# INSERT INTO reasons SELECT * FROM foreign_tpcds_reasons;
```

### 8.1.9.3 Example 3: Importing Data in Private Mode

A cluster has four hosts and eight primary DNs and every two primary DNs reside on the same host. There are eight data files to import and the size of each file is 50 MB. The files are in CSV format.

1. Log in as the OS user **omm** to the host where the CN is located.
2. Run the following command to connect to the database:
```
gsql -d postgres -p 8000
```
**postgres** is the name of the database, and **8000** is the port number of the CN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

If information similar to the following is displayed, the connection succeeds:

```
gsql((GaussDB Kernel VxxxRxxxCxx build f521c606) compiled at 2021-09-16 14:55:22 commit 2935
last mr 6385 release)
Non-SSL connection (SSL connection is recommended when requiring high-security)
Type "help" for help.

openGauss=#
```

3. Query DN names on each node.

```
openGauss=# SELECT node_name,node_host FROM pgxc_node WHERE node_type='D';
```

Example:

```
openGauss=# SELECT node_name,node_host FROM pgxc_node WHERE node_type='D';
  node_name   |   node_host
--------------+----------------
 dn_6001_6002 | 192.168.0.11
 dn_6003_6004 | 192.168.0.11
 dn_6005_6006 | 192.168.0.12
 dn_6007_6008 | 192.168.0.12
 dn_6009_6010 | 192.168.0.13
 dn_6011_6012 | 192.168.0.13
 dn_6013_6014 | 192.168.0.14
 dn_6015_6016 | 192.168.0.14
(8 rows)
```

4. Upload the source data files to the nodes where DNs are located.

   a. Log in to each cluster node as a common user. Create the **/input_data** directory to store data files and create sub-directories named after DNs on each node.

      The following uses the node with the IP address 192.168.0.11 which is queried in **3** as an example. Two DNs, dn_6001_6002 and dn_6003_6004, are on the node.

      ```
      mkdir -p /input_data
      mkdir -p /input_data/dn_6001_6002
      mkdir -p /input_data/dn_6003_6004
      ```

   b. Evenly distribute source data files to the sub-directories created on each node.

   c. Change the owner of data source files to be imported and the **/input_data** directory on each cluster node to **omm**.

      ```
      chown -R omm:dbgrp /input_data
      ```

5. Create the target table **reasons**.

```
openGauss=# CREATE TABLE reasons
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
);
```

6. Create the foreign table **foreign_tpcds_reasons** for the source data.

   Set import mode parameters as follows:

   - Set the import mode to **Private**.
   - The source data files are stored in sub-directories named after DNs on the nodes, and can be locally accessed. Therefore, set **location** to **file:///input_data/***.

   Information about the data format is set based on data format parameters specified during data export. The parameter settings are as follows:

   - **format** is set to **CSV**.
   - **delimiter** is set to a comma (,).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

  - **quote** is set to **0x1b**.
  - **null** is set to an empty string without quotation marks.

  Set import error tolerance parameters as follows:

  - Set **PER NODE REJECT LIMIT** (number of allowed data format errors) to **unlimited**. In this case, all the data format errors detected during data import will be tolerated.
  - Set **LOG INTO** to **err_tpcds_reasons**. The data format errors detected during data import will be recorded in the **err_tpcds_reasons** table.

```
openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons
(
  r_reason_sk integer not null,
  r_reason_id char(16) not null,
  r_reason_desc char(100)
)
 SERVER gsmpp_server OPTIONS (location 'file:///input_data/*', format 'CSV', mode 'private', delimiter
',', quote E'\x1b', null '')LOG INTO err_tpcds_reasonS PER NODE REJECT LIMIT 'unlimited';
```

7. Import data to the **reasons** table.

```
openGauss=# INSERT INTO reasons SELECT * FROM foreign_tpcds_reasons;
```

8. Query data import errors in the **err_tpcds_reasons** table and rectify the errors (if any). For details, see **8.1.7 Handling Import Errors**.

```
openGauss=# SELECT * FROM err_tpcds_reasons;
```

# 8.2 Running the INSERT Statement to Insert Data

Run the **INSERT** statement to write data into GaussDB in either of the following ways:

- Use the client tool provided by GaussDB to write data into it.

  For details, see **2.6.2 Inserting Data to a Table**.
- Connect to the database using the JDBC or ODBC driver and run the **INSERT** statement to write data into GaussDB.

  For details, see **6.3.4 Connecting to a Database**.

You can add, modify, and delete database transactions for GaussDB. **INSERT** is the simplest way to write data and applies to scenarios with small data volume and low concurrency.

# 8.3 Running the COPY FROM STDIN Statement to Import Data

## 8.3.1 Data Import Using COPY FROM STDIN

This method is applicable to low-concurrency scenarios where a small volume of data is to import.

Run the **COPY FROM STDIN** statement to import data to GaussDB in either of the following ways:

- Write data into GaussDB by typing. For details, see **12.14.50 COPY**.
- Import data from a file or database to GaussDB through the CopyManager interface driven by JDBC. You can use any parameters in the **COPY** syntax.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 8.3.2 Introduction to the CopyManager Class

CopyManager is an API class provided by the JDBC driver in GaussDB. It is used to import data to GaussDB clusters in batches.

## Inheritance Relationship of CopyManager

The CopyManager class is in the **org.postgresql.copy** package and inherits the java.lang.Object class. The declaration of the class is as follows:

```
public class CopyManager
extends Object
```

## Constructor Method

public CopyManager(BaseConnection connection)

throws SQLException

## Common Methods

**Table 8-7** Common methods of CopyManager

| Return Value | Method | Description | throws |
| --- | --- | --- | --- |
| CopyIn | copyIn(String sql) | - | SQLException |
| long | copyIn(String sql, InputStream from) | Uses **COPY FROM STDIN** to quickly import data to tables in a database from InputStream. | SQLException,IOException |
| long | copyIn(String sql, InputStream from, int bufferSize) | Uses **COPY FROM STDIN** to quickly import data to tables in a database from InputStream. | SQLException,IOException |
| long | copyIn(String sql, Reader from) | Uses **COPY FROM STDIN** to quickly import data to tables in a database from Reader. | SQLException,IOException |
| long | copyIn(String sql, Reader from, int bufferSize) | Uses **COPY FROM STDIN** to quickly import data to tables in a database from Reader. | SQLException,IOException |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Return Value | Method | Description | throws |
| --- | --- | --- | --- |
| CopyOut | copyOut(String sql) | - | SQLException |
| long | copyOut(String sql, OutputStream to) | Sends the result set of **COPY TO STDOUT** from the database to the OutputStream class. | SQLException,IOException |
| long | copyOut(String sql, Writer to) | Sends the result set of **COPY TO STDOUT** from the database to the Writer class. | SQLException,IOException |

## 8.3.3 Example 1: Importing and Exporting Data Through Local Files

When the JAVA language is used for secondary development based on GaussDB, you can use the CopyManager interface to export data from the database to a local file or import a local file to the database by streaming. The file can be in CSV or TEXT format.

The sample program is as follows. Load the GaussDB JDBC driver before executing it.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.io.IOException;
import java.io.FileInputStream;
import java.io.FileOutputStream;
import java.sql.SQLException;
import org.postgresql.copy.CopyManager;
import org.postgresql.core.BaseConnection;

public class Copy{

    public static void main(String[] args)
    {
     String urls = new String("jdbc:postgresql://localhost:8000/postgres"); //URL of the database
     String username = new String("username");            //Username
     String password = new String("passwd");             //Password
     String tablename = new String("migration_table"); // Table information
     String tablename1 = new String("migration_table_1"); // Table information
     String driver = "org.postgresql.Driver";
     Connection conn = null;

     try {
         Class.forName(driver);
         conn = DriverManager.getConnection(urls, username, password);
     } catch (ClassNotFoundException e) {
          e.printStackTrace(System.out);
     } catch (SQLException e) {
          e.printStackTrace(System.out);
     }
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
    // Export data from the migration_table table to the d:/data.txt file.
    try {
        copyToFile(conn, "d:/data.txt", "(SELECT * FROM migration_table)");
    } catch (SQLException e) {
        // TODO Auto-generated catch block
        e.printStackTrace();
    } catch (IOException e) {
        // TODO Auto-generated catch block
        e.printStackTrace();
    }
    // Import data from the d:/data.txt file to the migration_table_1 table.
    try {
        copyFromFile(conn, "d:/data.txt", tablename1);
    } catch (SQLException e) {
        // TODO Auto-generated catch block
        e.printStackTrace();
    } catch (IOException e) {
        // TODO Auto-generated catch block
        e.printStackTrace();
    }

    // Export data from the migration_table_1 table to the d:/data1.txt file.
    try {
        copyToFile(conn, "d:/data1.txt", tablename1);
    } catch (SQLException e) {
        // TODO Auto-generated catch block
        e.printStackTrace();
    } catch (IOException e) {
        // TODO Auto-generated catch block
        e.printStackTrace();
    }
}

public static void copyFromFile(Connection connection, String filePath, String tableName)
        throws SQLException, IOException {

    FileInputStream fileInputStream = null;

    try {
        CopyManager copyManager = new CopyManager((BaseConnection)connection);
        fileInputStream = new FileInputStream(filePath);
        copyManager.copyIn("COPY " + tableName + " FROM STDIN ", fileInputStream);
    } finally {
        if (fileInputStream != null) {
            try {
                fileInputStream.close();
            } catch (IOException e) {
                e.printStackTrace();
            }
        }
    }
}
    public static void copyToFile(Connection connection, String filePath, String tableOrQuery)
            throws SQLException, IOException {

     FileOutputStream fileOutputStream = null;

     try {
        CopyManager copyManager = new CopyManager((BaseConnection)connection);
        fileOutputStream = new FileOutputStream(filePath);
        copyManager.copyOut("COPY " + tableOrQuery + " TO STDOUT", fileOutputStream);
    } finally {
        if (fileOutputStream != null) {
            try {
                fileOutputStream.close();
            } catch (IOException e) {
                e.printStackTrace();
            }
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
        }
    }
  }
}
```

## 8.3.4 Example 2: Migrating Data from a MySQL Database

The following example shows how to use CopyManager to migrate data from MySQL.

```
import java.io.StringReader;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;

import org.postgresql.copy.CopyManager;
import org.postgresql.core.BaseConnection;

public class Migration{

    public static void main(String[] args) {
        String url = new String("jdbc:postgresql://localhost:8000/postgres"); //URL of the database
        String user = new String("username");            // GaussDB user name
        String pass = new String("passwd");              // GaussDB password
        String tablename = new String("migration_table_1"); // Table information
        String delimiter = new String("|");              // Delimiter
        String encoding = new String("UTF8");            // Character set
        String driver = "org.postgresql.Driver";
        StringBuffer buffer = new StringBuffer();       // Buffer to store formatted data

        try {
            // Obtain the query result set of the source database.
            ResultSet rs = getDataSet();

            // Traverse the result set and obtain records row by row.
            // The values of columns in each record are separated by the specified delimiter and end with a
linefeed, forming strings.
            // Add the strings to the buffer.
            while (rs.next()) {
                buffer.append(rs.getString(1) + delimiter
                        + rs.getString(2) + delimiter
                        + rs.getString(3) + delimiter
                        + rs.getString(4)
                        + "\n");
            }
            rs.close();

            try {
                // Connect to the target database.
                Class.forName(driver);
                Connection conn = DriverManager.getConnection(url, user, pass);
                BaseConnection baseConn = (BaseConnection) conn;
                baseConn.setAutoCommit(false);

                // Initialize the table.
                String sql = "Copy " + tablename + " from STDIN with (DELIMITER " + "'" + delimiter + "'" +","+ "
ENCODING " + "'" + encoding + "')";

                // Commit data in the buffer.
                CopyManager cp = new CopyManager(baseConn);
                StringReader reader = new StringReader(buffer.toString());
                cp.copyIn(sql, reader);
                baseConn.commit();
                reader.close();
                baseConn.close();
            } catch (ClassNotFoundException e) {
                e.printStackTrace(System.out);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
            } catch (SQLException e) {
                e.printStackTrace(System.out);
            }

        } catch (Exception e) {
            e.printStackTrace();
        }
    }

    //**********************************
    // Return the query result set from the source database.
    //**********************************
    private static ResultSet getDataSet() {
        ResultSet rs = null;
        try {
            Class.forName("com.mysql.jdbc.Driver").newInstance();
            Connection conn = DriverManager.getConnection("jdbc:mysql://10.119.179.227:3306/jack?
useSSL=false&allowPublicKeyRetrieval=true", "jack", "xxxxxxxxx");
            Statement stmt = conn.createStatement();
            rs = stmt.executeQuery("select * from migration_table");
        } catch (SQLException e) {
            e.printStackTrace();
        } catch (Exception e) {
            e.printStackTrace();
        }
        return rs;
    }
}
```

# 8.4 Using a gsql Meta-Command to Import Data

The **gsql** tool provides the **\copy** to import data.

## \copy Command

For the format and description of the **\copy** command, see **Table 8-8**.

**Table 8-8** \copy meta-command

| Syntax | Description |
| --- | --- |
| \copy { table [ ( column_list ) ] \| ( query ) } { from \| to } { filename \| stdin \| stdout \| pstdin \| pstdout } [ with ] [ binary ] [ oids ] [ delimiter [ as ] 'character' ] [ useeof ] [ null [ as ] 'string' ] [ csv [ header ] [ quote [ as ] 'character' ] [ escape [ as ] 'character' ] [ force quote column_list \| * ] [ force not null column_list ] ] | You can run this command to import or export data after logging in to a database on any gsql client. Different from the **COPY** statement in SQL, this command performs read/write operations on local files rather than files on database servers. The accessibility and permissions of the local files are restricted to local users.<br>**NOTE**<br>**\copy** applies only to small-scale data import in good format. It does not preprocess invalid characters or provides error tolerance. Therefore, **\copy** cannot be used in scenarios where abnormal data exists. **GDS** or **COPY** is preferred for data import. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Parameter Description

- table

  Specifies the name (possibly schema-qualified) of an existing table.

  Value range: an existing table name

- column_list

  Indicates an optional list of columns to be copied.

  Value range: any field in the table. If no column list is specified, all columns of the table will be copied.

- query

  Specifies that the results will be copied.

  Value range: a **SELECT** or **VALUES** command in parentheses.

- filename

  Specifies the absolute path of a file. To run the **\copy to** command, you must have the write permission on the path. To run the **\copy from** command, you must have the read permission on the path.

- stdin

  Specifies that input comes from the client application.

- stdout

  Specifies that output goes to the client application.

- pstdin

  Specifies that input comes from the gsql client.

- pstout
- Specifies that output goes to the gsql client.
- binary

  Specifies that data is stored and read in binary mode instead of text mode. In binary mode, you cannot declare **DELIMITER**, **NULL**, or **CSV**. After **binary** is specified, CSV, FIXED, and TEXT cannot be specified through **option** or **copy_option**.

- oid

  Specifies the internal OID to be copied for each row.

  > NOTE
  >
  > An error is raised if OIDs are specified for a table that does not have OIDs, or in the case of copying a query.

  Value range: **true/on** and **false/off**

  Default value: false

- delimiter [ as ] 'character'

  Specifies the character that separates columns within each row (line) of the file.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- The value of **delimiter** cannot be **\r** or **\n**.
- A delimiter cannot be the same as the **null** value. The delimiter for the CSV format cannot be same as the **quote** value.
- The delimiter for the TEXT format data cannot contain backslashes (\), dots (.), lowercase letters, or digits, for example, **\.abcdefghijklmnopqrstuvwxyz0123456789**.
- The data length of a single row should be less than 1 GB. A row that has many columns using long delimiters cannot contain much valid data.
- You are advised to use multi-character delimiters or invisible delimiters. For example, you can use multi-characters (such as $^&) and invisible characters (such as 0x07, 0x08, and 0x1b).

Value range: a multi-character delimiter within 10 bytes

Default value:

- A tab character in text format
- A comma (,) in CSV format
- No delimiter in FIXED format

- null [ as ] 'string'

  Specifies that a string represents a null value in a data file.

  Value range:

  - A null value cannot be **\r** or **\n**. The maximum length is 100 characters.
  - A null value cannot be the same as the **delimiter** or **quote** value.

  Default value:

  - an empty string without quotation marks in CSV format
  - **\N** in text format

- useeof

  Does not report an error for **\.** in the imported data.

  Value range: **true** or **false**

  Default value: false

- header

  Specifies whether a file contains a header with the names of each column in the file. **header** is available only for CSV and FIXED files.

  When data is imported, if **header** is **on**, the first row of the data file will be identified as the header and ignored. If **header** is **off**, the first row will be identified as a data row.

  When data is exported, if header is **on**, **fileheader** must be specified. **fileheader** specifies the content in the header. If **header** is **off**, an exported file does not contain a header.

  Value range: **true/on** and **false/off**

  Default value: false

- quote [ as ] 'character'

  Specifies a quote character for a CSV file.

  Default value: ""

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- The **quote** value cannot be the same as the **delimiter** or **null** value.
- The **quote** value must be a single-byte character.
- Invisible characters are recommended, such as 0x07, 0x08, and 0x1b.

- escape [ as ] 'character'

  Specifies an escape character for a CSV file. The value must be a single-byte character.

  Default value: "" If the value is the same as the **quote** value, it will be replaced with **\0**.

- force quote column_list | *

  In CSV COPY TO mode, forces quoting to be used for all not-null values in each specified column. **NULL** values are not quoted.

  Value range: an existing column

- force not null column_list

  Assigns a value to a specified column in CSV COPY FROM mode.

  Value range: an existing column

## Examples

1. Create a target table **a**.

```
openGauss=# CREATE TABLE a(a int);
```

2. Import data.

   a. Copy data from **stdin** to table **a**.

```
openGauss=# \copy a from stdin;
```

   When the **>>** characters are displayed, enter data. To end your input, enter a backslash and a period (\.).

```
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1
>> 2
>> \.
```

   Query data imported to table **a**.

```
openGauss=# SELECT * FROM a;
 a
---
 1
 2
(2 rows)
```

   b. Copy data from a local file to table **a**. For example, the local file /home/omm/2.csv exists.

      - Commas (,) are used as delimiters.
      - If the number of columns defined in a source data file is greater than that in a foreign table, extra columns will be ignored during import.

```
openGauss=# \copy a FROM '/home/omm/2.csv' WITH (delimiter',',IGNORE_EXTRA_DATA 'on');
```

# 8.5 Updating Data in a Table

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 8.5.1 Updating a Table by Using DML Statements

In GaussDB, you can update a table by running DML statements.

## Procedure

There is a table named **customer_t** and the table structure is as follows:

```
openGauss=# CREATE TABLE customer_t
( c_customer_sk             integer,
  c_customer_id             char(5),
  c_first_name              char(6),
  c_last_name               char(8)
) ;
```

You can run the following DML statements to update data in the table.

- Run the **INSERT** statement to insert data into the table.
  - Insert a row to the **customer_t** table.
    ```
    openGauss=# INSERT INTO customer_t (c_customer_sk, c_customer_id,
    c_first_name,c_last_name) VALUES (3769, 5, 'Grace','White');
    ```
  - Insert multiple rows to the **customer_t** table.
    ```
    openGauss=# INSERT INTO customer_t (c_customer_sk, c_customer_id,
    c_first_name,c_last_name) VALUES
    (6885, 1, 'Joes', 'Hunter'),
    (4321, 2, 'Lily','Carter'),
    (9527, 3, 'James', 'Cook'),
    (9500, 4, 'Lucy', 'Baker');
    ```

    For details on how to use **INSERT**, see **2.6.2 Inserting Data to a Table**.
- Run the **UPDATE** statement to update data in the table. Change the value of the **c_customer_id** column to **0**.
  ```
  openGauss=# UPDATE customer_t SET c_customer_id = 0;
  ```

  For details on how to use **UPDATE**, see **12.14.170 UPDATE**.
- Run the **DELETE** statement to delete rows from the table.

  You can use the **WHERE** clause to specify the rows whose data is to delete. If you do not specify it, all rows in the table are deleted and only the data structure is retained.
  ```
  openGauss=# DELETE FROM customer_t WHERE c_last_name = 'Baker';
  ```

  For details on how to use **DELETE**, see **12.14.95 DELETE**.
- Run the **TRUNCATE** statement to delete all rows from the table.
  ```
  openGauss=# TRUNCATE TABLE customer_t;
  ```

  For details on how to use **TRUNCATE**, see **12.14.169 TRUNCATE**.

  The **DELETE** statement deletes a row of data each time whereas the **TRUNCATE** statement deletes data by releasing the data page stored in the table. Therefore, data can be deleted more quickly by using **TRUNCATE** than using **DELETE**.

  **DELETE** deletes table data but does not release table storage space. **TRUNCATE** deletes table data and releases table storage space.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 8.5.2 Updating and Inserting Data by Using the MERGE INTO Statement

To add all or a large amount of data in a table to an existing table, you can run the **MERGE INTO** statement in GaussDB to merge the two tables so that data can be quickly added to the existing table.

The **MERGE INTO** statement matches data in a source table with that in a target table based on a join condition. If data matches, **UPDATE** will be executed on the target table. Otherwise, **INSERT** will be executed. This statement is a convenient way to combine multiple operations and avoids multiple **INSERT** or **UPDATE** statements.

## Prerequisites

You have the **INSERT** and **UPDATE** permissions for the target table and the **SELECT** permission for the source table.

## Procedure

**Step 1** Create a source table named **products** and insert data.

```
openGauss=# CREATE TABLE products
( product_id INTEGER,
  product_name VARCHAR2(60),
  category VARCHAR2(60)
);

openGauss=# INSERT INTO products VALUES
(1502, 'olympus camera', 'electrncs'),
(1601, 'lamaze', 'toys'),
(1666, 'harry potter', 'toys'),
(1700, 'wait interface', 'books');
```

**Step 2** Create a target table named **newproducts** and insert data.

```
openGauss=# CREATE TABLE newproducts
( product_id INTEGER,
  product_name VARCHAR2(60),
  category VARCHAR2(60)
);

openGauss=# INSERT INTO newproducts VALUES
(1501, 'vivitar 35mm', 'electrncs'),
(1502, 'olympus ', 'electrncs'),
(1600, 'play gym', 'toys'),
(1601, 'lamaze', 'toys'),
(1666, 'harry potter', 'dvd');
```

**Step 3** Run the **MERGE INTO** statement to merge data in the source table **products** into the target table **newproducts**.

```
openGauss=# MERGE INTO newproducts np
USING products p
ON (np.product_id = p.product_id )
WHEN MATCHED THEN
  UPDATE SET np.product_name = p.product_name, np.category = p.category
WHEN NOT MATCHED THEN
  INSERT VALUES (p.product_id, p.product_name, p.category) ;
```

For details on parameters in the statement, see **Table 8-9**. For more information, see **12.14.144 MERGE INTO**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 8-9** Parameters in the MERGE INTO statement

| Parameter | Description | Example Value |
| --- | --- | --- |
| **INTO** clause | Specifies a target table that is to be updated or has data to be inserted.<br>• A table alias is supported.<br>• The target table can be copied, but the copied table cannot contain columns (such as auto-increment columns) that contain volatile functions. If **enable_stream_operator** is set to **off**, the target replication table must contain a primary key or a column must meet the **unique not null** constraint. | Value: newproducts np<br>The table name is **newproducts** and the alias is **np**. |
| **USING** clause | Specifies a source table. A table alias is supported.<br>If the target table is a replication table, the source table must also be a replication table. | Value: products p<br>The table name is **products** and the alias is **p**. |
| **ON** clause | Specifies a join condition between a target table and a source table.<br>Columns in the join condition cannot be updated. | Value: np.product_id = p.product_id<br>The join condition is that the **product_id** column in the target table **newproducts** has equivalent values as the **product_id** column in the source table **products**. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description | Example Value |
| --- | --- | --- |
| **WHEN MATCHED** clause | Performs **UPDATE** if data in the source table matches that in the target table based on the condition.<br>• Only one **WHEN MATCHED** clause can be specified.<br>• The **WHEN MATCHED** clause can be omitted. If it is omitted, no operation will be performed on the rows that meet the condition in the **ON** clause.<br>• Columns involved in the distribution key of the target table cannot be updated. | Value: WHEN MATCHED THEN UPDATE SET np.product_name = p.product_name, np.category = p.category<br>When the condition in the **ON** clause is met, the values of the **product_name** and **category** columns in the target table **newproducts** are replaced with the values in the corresponding columns in the source table **products**. |
| **WHEN NOT MATCHED** clause | Performs **INSERT** if data in the source table does not match that in the target table based on the condition.<br>• Only one **WHEN NOT MATCHED** clause can be specified.<br>• The **WHEN NOT MATCHED** clause can be omitted.<br>• An **INSERT** clause can contain only one **VALUES**.<br>• The **WHEN MATCHED** and **WHEN NOT MATCHED** clauses can be exchanged in sequence. One of them can be omitted, but they cannot be omitted at the same time. | Value: WHEN NOT MATCHED THEN<br>INSERT VALUES (p.product_id, p.product_name, p.category)<br>Insert rows in the source table **products** that do not meet the condition in the **ON** clause into the target table **products**. |

**Step 4** Query the target table **newproducts** after the merge.

```
openGauss=# SELECT * FROM newproducts;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The command output is as follows:

```
 product_id |  product_name  | category
------------+----------------+-----------
       1501 | vivitar 35mm   | electrncs
       1502 | olympus camera | electrncs
       1666 | harry potter   | toys
       1600 | play gym       | toys
       1601 | lamaze         | toys
       1700 | wait interface | books
(6 rows)
```

**----End**

# 8.6 Deep Copy

After data is imported, you can perform a deep copy to modify a distribution key or partition key, change a row-store table to a column-store table, or add a partial cluster key. A deep copy re-creates a table and batch inserts data into the table.

GaussDB provides three deep copy methods.

## 8.6.1 Performing a Deep Copy by Using the CREATE TABLE Statement

Run the **CREATE TABLE** statement to create a copy of the original table, batch insert data of the original table into the copy, and rename the copy to the name of the original table.

When creating the copy, you can specify table and column attributes, including the primary key and foreign key.

### Procedure

Perform the following operations to carry out a deep copy for the **customer_t** table:

**Step 1** Run the **CREATE TABLE** statement to create the copy **customer_t_copy** of the **customer_t** table.

```
openGauss=# CREATE TABLE customer_t_copy
( c_customer_sk             integer,
  c_customer_id             char(5),
  c_first_name              char(6),
  c_last_name               char(8)
) ;
```

**Step 2** Run the **INSERT INTO...SELECT** statement to batch insert data of the original table into the copy.

```
openGauss=# INSERT INTO customer_t_copy (SELECT * FROM customer_t);
```

**Step 3** Delete the original table.

```
openGauss=# DROP TABLE customer_t;
```

**Step 4** Run the **ALTER TABLE** statement to rename the copy to the name of the original table.

```
openGauss=# ALTER TABLE customer_t_copy RENAME TO customer_t;
```

**----End**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## 8.6.2 Performing a Deep Copy by Using the CREATE TABLE LIKE Statement

Run the **CREATE TABLE LIKE** statement to create a copy of the original table, batch insert data of the original table into the copy, and rename the copy to the name of the original table. This method does not inherit the primary key and foreign key of the original table. You can use the **ALTER TABLE** statement to add them.

### Procedure

**Step 1** Run the **CREATE TABLE LIKE** statement to create the copy **customer_t_copy** of the **customer_t** table.

```
openGauss=# CREATE TABLE customer_t_copy (LIKE customer_t);
```

**Step 2** Run the **INSERT INTO...SELECT** statement to batch insert data of the original table into the copy.

```
openGauss=# INSERT INTO customer_t_copy (SELECT * FROM customer_t);
```

**Step 3** Delete the original table.

```
openGauss=# DROP TABLE customer_t;
```

**Step 4** Run the **ALTER TABLE** statement to rename the copy to the name of the original table.

```
openGauss=# ALTER TABLE customer_t_copy RENAME TO customer_t;
```

**----End**

## 8.6.3 Performing a Deep Copy by Creating a Temporary Table and Truncating the Original Table

Run the **CREATE TABLE .... AS** statement to create a temporary table for the original table, truncate the original table, and batch insert data of the temporary data into the original table.

When creating the temporary table, retain the primary key and foreign key of the original table. This method is recommended if the original table has dependency items.

### Procedure

**Step 1** Run the **CREATE TABLE AS** statement to create a temporary table **customer_t_temp** for the **customer_t** table.

```
openGauss=# CREATE TEMP TABLE customer_t_temp AS SELECT * FROM customer_t;
```

NOTE

- Compared with the use of permanent tables, the use of temporary tables can improve performance but may incur data loss. A temporary table is automatically deleted at the end of the session where it is located. If data loss is unacceptable, use a permanent table.
- Temporary tables and common tables are stored in the same location. You can also specify a tablespace to store temporary tables. If too many local temporary tables are used, the system catalog may bloat, but the overall impact is acceptable.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Step 2** Truncate the original table **customer_t**.

```
openGauss=# TRUNCATE customer_t;
```

**Step 3** Run the **INSERT INTO...SELECT** statement to batch insert data of the temporary table into the original table.

```
openGauss=# INSERT INTO customer_t (SELECT * FROM customer_t_temp);
```

**Step 4** Delete the temporary table **customer_t_temp**.

```
openGauss=# DROP TABLE customer_t_temp;
```

**----End**

# 8.7 Checking for Data Skew

## Scenarios

Data skew causes query performance to deteriorate. Before importing all data from a table containing over 10 million records, you are advised to import some of the data and check whether there is data skew and whether the distribution keys need to be changed. Troubleshoot the data skew if any. It is costly to address data skew and change the distribution keys after a large volume of data has been imported.

## Background

GaussDB uses a massively parallel processing (MPP) system of the shared-nothing architecture. MPP performs horizontal partitioning to store tuples in the service data table on all DNs using proper distribution policies.

The current product supports multiple user table distribution policies, such as replication, hash, range, and list.

- Replication: Full table data is stored on each DN. You are advised to use the replication distribution policy for tables with a small volume of data.
- Hash: A distribution key must be specified for a user table. When a record is inserted, the system hashes it based on the distribution key and then stores it on the corresponding DN. You are advised to use the hash distribution policy for tables with a large volume of data.
- Range and List: These modes are used in the scenario where users specify the data distribution rule. The target node of the tuple is determined based on the specified column value and the preset range or specific value.

If an inappropriate distribution key is used, there may be data skew when you use the hash policy. Therefore, after this policy is used, data skew check will be performed on user tables to ensure that data is evenly distributed on each DN. You are advised to use the column with few replicated values as the distribution key.

## Procedure

**Step 1** Analyze source data and select candidate distribution keys.

**Step 2** Select a column from the candidates in **Step 1** as the distribution key to create a target table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
CREATE [ [ GLOBAL | LOCAL ] [ TEMPORARY | TEMP ] | UNLOGGED ] TABLE [ IF NOT EXISTS ] table_name
   ({ column_name data_type [ compress_mode ] [ COLLATE collation ] [ column_constraint [ ... ] ]
   | table_constraint    | LIKE source_table [ like_option [...] ] }
   [, ... ])    [ WITH ( {storage_parameter = value} [, ... ] ) ]
   [ ON COMMIT { PRESERVE ROWS | DELETE ROWS } ]
   [ COMPRESS | NOCOMPRESS ]    [ TABLESPACE tablespace_name ]
   [ DISTRIBUTE BY { REPLICATION
                   | { HASH ( column_name [,...] )
                   | { RANGE ( column_name [, ...] ) SLICE REFERENCES tablename
                      | ( slice_less_than_item [, ...]
                      | slice_start_end_item [, ...] )
                   | { LIST ( column_name [, ...] ) SLICE REFERENCES tablename
                      | ( slice_values_item [, ...] )  }}} } ]
```

**Step 3** Import a small batch of data to the target table.

When importing a single data file, you can evenly split this file and import a part of it to check for the data skew in the target table.

**Step 4** Check for data skew. (Replace *table_name* with the actual table name.)

```
openGauss=# SELECT a.count,b.node_name FROM (SELECT count(*) AS count,xc_node_id FROM
table_name GROUP BY xc_node_id) a, pgxc_node b WHERE a.xc_node_id=b.node_id ORDER BY a.count
desc;
```

**Step 5** If data distribution deviation is less than 10% across DNs, data has been evenly distributed and an appropriate distribution key has been selected. Delete the small batch of imported data and import full data to complete data migration.

If data distribution deviation across DNs is greater than or equal to 10%, data skew occurs. Remove this distribution key from the candidates in step 1, delete the target table, and repeat steps 2 to 5.

**Step 6** (Optional) If you fail to select an appropriate distribution key after performing the above steps, select multiple columns from the candidates as distribution keys.

**----End**

## Examples

To select an appropriate distribution key for the **staffs** table, perform the following operations:

1. Analyze source data for the **staffs** table and select the **staff_ID**, **FIRST_NAME**, and **LAST_NAME** columns as candidate distribution keys.
2. Select the **staff_ID** column as the distribution key and create the target table **staffs**.

```
openGauss=# CREATE TABLE staffs
(
  staff_ID       NUMBER(6) not null,
  FIRST_NAME     VARCHAR2(20),
  LAST_NAME      VARCHAR2(25),
  EMAIL          VARCHAR2(25),
  PHONE_NUMBER   VARCHAR2(20),
  HIRE_DATE      DATE,
  employment_ID  VARCHAR2(10),
  SALARY         NUMBER(8,2),
  COMMISSION_PCT NUMBER(2,2),
  MANAGER_ID     NUMBER(6),
  section_ID     NUMBER(4)
)
DISTRIBUTE BY hash(staff_ID);
```

3. Import a small batch of data to the target table **staffs**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

As queried by the following statement, there are eight DNs in the cluster. You are advised to import 80,000 records.

```
openGauss=# SELECT count(*) FROM pgxc_node where node_type='D';
 count
-------
     8
(1 row)
```

4. Verify the data skew of the target table **staffs** whose distribution key is **staff_ID**.

```
openGauss=# SELECT a.count,b.node_name FROM (select count(*) as count,xc_node_id FROM staffs
GROUP BY xc_node_id) a, pgxc_node b WHERE a.xc_node_id=b.node_id ORDER BY a.count desc;
count | node_name
------+-----------
11010 | datanode4
10000 | datanode3
12001 | datanode2
 8995 | datanode1
10000 | datanode5
 7999 | datanode6
 9995 | datanode7
10000 | datanode8
(8 rows)
```

5. As shown in the above query result, the data distribution deviation across DNs is greater than 10%, indicating data skew. Therefore, delete **staff_ID** from the distribution key candidates and delete the **staffs** table.

```
openGauss=# DROP TABLE staffs;
```

6. Use **staff_ID**, **FIRST_NAME**, and **LAST_NAME** as distribution keys and create the target table **staffs**.

```
openGauss=# CREATE TABLE staffs
(
  staff_ID       NUMBER(6) not null,
  FIRST_NAME     VARCHAR2(20),
  LAST_NAME      VARCHAR2(25),
  EMAIL          VARCHAR2(25),
  PHONE_NUMBER   VARCHAR2(20),
  HIRE_DATE      DATE,
  employment_ID  VARCHAR2(10),
  SALARY         NUMBER(8,2),
  COMMISSION_PCT NUMBER(2,2),
  MANAGER_ID     NUMBER(6),
  section_ID     NUMBER(4)
)
DISTRIBUTE BY hash(staff_ID,FIRST_NAME,LAST_NAME);
```

7. Verify the data skew of the target table **staffs** whose distribution keys are **staff_ID**, **FIRST_NAME**, and **LAST_NAME**.

```
openGauss=# SELECT a.count,b.node_name FROM (select count(*) as count,xc_node_id FROM staffs
GROUP BY xc_node_id) a, pgxc_node b WHERE a.xc_node_id=b.node_id ORDER BY a.count desc;
count | node_name
------+-----------
10010 | datanode4
10000 | datanode3
10001 | datanode2
 9995 | datanode1
10000 | datanode5
 9999 | datanode6
 9995 | datanode7
10000 | datanode8
(8 rows)
```

8. As shown in the above query result, the data distribution deviation across DNs is less than 10%, indicating even data distribution and a proper distribution key.

9. Delete the imported small-batch data.

```
openGauss=# TRUNCATE TABLE staffs;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

10. Import the full data to complete data migration.

# 8.8 Analyzing Tables

The execution plan generator needs to use table statistics to generate the most effective query execution plan to improve query performance. After data is imported, you are advised to run the **ANALYZE** statement to update table statistics. The statistics are stored in the system catalog **PG_STATISTIC**.

## Analyzing Tables

**ANALYZE** supports row-store and column-store tables. **ANALYZE** can also collect statistics on specified columns of a local table. For details on **ANALYZE**, see **12.14.40 ANALYZE | ANALYSE**.

**Step 1** Update table statistics.

Do **ANALYZE** to the **product_info** table.

```
openGauss=# ANALYZE product_info;
ANALYZE
```

**----End**

## Automatically Analyzing a Table

GaussDB provides the GUC parameter **autovacuum** to specify whether to enable the autovacuum function of the database.

If **autovacuum** is set to **on**, the system will start the autovacuum thread to automatically analyze tables when the data volume in the table reaches the threshold. This is the autoanalyze function.

- For an empty table, when the number of rows inserted to it is greater than 50, **ANALYZE** is automatically triggered.
- For a table containing data, the threshold is 50 + 10% x **reltuples**, where **reltuples** indicates the total number of rows in the table.

The autovacuum function also depends on the following two GUC parameters in addition to **autovacuum**:

- **track_counts**: This parameter must be set to **on** to enable statistics collection about the database.
- **autovacuum_max_workers**: This parameter must be set to a value greater than **0** to specify the maximum number of concurrent autovacuum threads.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**NOTICE**

- The autoanalyze function supports the default sampling mode but not percentage sampling.
- The autoanalyze function does not collect multi-column statistics, which only supports percentage sampling. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)
- The autoanalyze function supports row-store and column-store tables but does not support the following: foreign tables, OBS tables (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.), temporary tables, unlogged tables, and TOAST tables.

# 8.9 Doing VACUUM to a Table

If a large number of rows were updated or deleted during import, run **VACUUM FULL** before **ANALYZE**. A large number of UPDATE and DELETE operations generate huge disk page fragments, which reduces query efficiency. **VACUUM FULL** can restore disk page fragments and return them to the OS.

**Step 1** Run the **VACUUM FULL** statement.

Do **VACUUM FULL** to the **product_info** table.

```
openGauss=# VACUUM FULL product_info
VACUUM
```

**----End**

# 8.10 Managing Concurrent Write Operations

## 8.10.1 Transaction Isolation

GaussDB manages transactions based on MVCC and two-phase locks, avoiding conflicts between read and write operations. SELECT is a read-only operation, whereas UPDATE and DELETE are read/write operations.

- There is no conflict between read/write and read-only operations, or between read/write operations. Each concurrent transaction creates a snapshot when it starts. Concurrent transactions cannot detect updates made by each other.
  - At the **READ COMMITTED** level, if transaction T1 is committed, transaction T2 can see changes made by T1.
  - At the **REPEATABLE READ** level, if T2 starts before T1 is committed, T2 will not see changes made by T1 even after T1 is committed. The query results in a transaction are consistent and unaffected by other transactions.
- Read/Write operations use row-level locks. Different transactions can concurrently update the same table but not the same row. A row update transaction will start only after the previous one is committed.
  - **READ COMMITTED**: At this level, a transaction can access only committed data. This is the default level.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

  - **REPEATABLE READ**: Only data committed before transaction start is read. Uncommitted data or data committed in other concurrent transactions cannot be read.

## 8.10.2 Write and Read/Write Operations

Statements for write-only and read/write operations are as follows:

- **INSERT**, used to insert one or more rows of data into a table
- **UPDATE**, used to modify existing data in a table
- **DELETE**, used to delete existing data from a table
- **COPY**, used to import data

INSERT and COPY are write-only operations. Only one of them can be performed at a time. If INSERT or COPY of transaction T1 locks a table, INSERT or COPY of transaction T2 needs to wait until T1 unlocks the table.

UPDATE and DELETE operations are read/write operations. They need to query for the target rows before modifying data. Concurrent transactions cannot see changes made by each other, and UPDATE and DELETE operations read snapshots of data committed before their transactions start. Write operations use row-level locks. If T2 starts after T1 and is to update the same row as T1 does, T2 waits for T1 to finish update. If T1 is not complete within the specified timeout duration, T2 will time out. If T1 and T2 update different rows in a table, they can be concurrently executed.

## 8.10.3 Potential Deadlocks During Concurrent Write

Whenever transactions involve updates of more than one table, there is always the possibility that concurrently running transactions become deadlocked when they both try to write to the same set of tables. A transaction releases all of its locks at once when it either commits or rolls back; it does not relinquish locks one at a time. For example, transactions T1 and T2 start at roughly the same time.

- If T1 starts writing to table A and T2 starts writing to table B, both transactions can proceed without conflict. However, if T1 finishes writing to table A and needs to start writing to the same rows as T2 does in table B, it will not be able to proceed because T2 still holds the lock on B. Conversely, if T2 finishes writing to table B and needs to start writing to the same rows as T1 does in table A, it will not be able to proceed either because T1 still holds the lock on A. In this case, a deadlock occurs. If T1 is committed and releases the lock within the lock timeout duration, subsequent update can proceed. If a lock times out, an error is reported and the corresponding transaction exits.
- If T1 updates rows 1 to 5 and T2 updates rows 6 to 10 in the same table, the two transactions do not conflict. However, if T1 finishes the update and proceeds to update rows 6 to 10, and T2 proceeds to update rows 1 to 5, neither of them can continue. If either of the transactions is committed and releases the lock within the lock timeout duration, subsequent update can proceed. If a lock times out, an error is reported and the corresponding transaction exits.

# 8.10.4 Concurrent Write Examples

This section uses the **test** table as an example to describe how to perform concurrent **INSERT** and **DELETE** in the same table, concurrent **INSERT** in the same table, concurrent **UPDATE** in the same table, and concurrent import and queries.

```
CREATE TABLE test(id int, name char(50), address varchar(255));
```

## 8.10.4.1 Concurrent INSERT and DELETE in the Same Table

Transaction T1:

```
START TRANSACTION;
INSERT INTO test VALUES(1,'test1','test123');
COMMIT;
```

Transaction T2:

```
START TRANSACTION;
DELETE test WHERE NAME='test1';
COMMIT;
```

Scenario 1:

T1 is started but not committed. At this time, T2 is started. After **INSERT** of T1 is complete, **DELETE** of T2 is performed. In this case, **DELETE 0** is displayed, because T1 is not committed and T2 cannot see the data inserted by T1.

Scenario 2:

- **READ COMMITTED** level

  T1 is started but not committed. At this time, T2 is started. After **INSERT** of T1 is complete, T1 is committed and **DELETE** of T2 is executed. In this case, **DELETE 1** is displayed, because T2 can see the data inserted by T1.

- **REPEATABLE READ** level

  T1 is started but not committed. At this time, T2 is started. After **INSERT** of T1 is complete, T1 is committed and **DELETE** of T2 is executed. In this case, **DELETE 0** is displayed, because the data obtained in queries is consistent in a transaction.

## 8.10.4.2 Concurrent INSERT in the Same table

Transaction T1:

```
START TRANSACTION;
INSERT INTO test VALUES(2,'test2','test123');
COMMIT;
```

Transaction T2:

```
START TRANSACTION;
INSERT INTO test VALUES(3,'test3','test123');
COMMIT;
```

Scenario 1:

T1 is started but not committed. At this time, T2 is started. After **INSERT** of T1 is complete, **INSERT** of T2 is executed and succeeds. At the **READ COMMITTED** and **REPEATABLE READ** levels, the **SELECT** statement of T1 cannot see data inserted by T2, and a query in T2 cannot see data inserted by T1.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Scenario 2:

- **READ COMMITTED** level

  T1 is started but not committed. At this time, T2 is started. After **INSERT** of T1 is complete, T1 is committed. In T2, a query executed after **INSERT** can see the data inserted by T1.

- **REPEATABLE READ** level

  T1 is started but not committed. At this time, T2 is started. After **INSERT** of T1 is complete, T1 is committed. In T2, a query executed after **INSERT** cannot see the data inserted by T1.

### 8.10.4.3 Concurrent UPDATE in the Same Table

Transaction T1:

```
START TRANSACTION;
UPDATE test SET address='test1234' WHERE name='test1';
COMMIT;
```

Transaction T2:

```
START TRANSACTION;
UPDATE test SET address='test1234' WHERE name='test2';
COMMIT;
```

Transaction T3:

```
START TRANSACTION;
UPDATE test SET address='test1234' WHERE name='test1';
COMMIT;
```

Scenario 1:

T1 is started but not committed. At this time, T2 is started. **UPDATE** of T1 and then T2 starts, and both of them succeed. This is because the **UPDATE** operations use row-level locks and do not conflict when they update different rows.

Scenario 2:

T1 is started but not committed. At this time, T3 is started. **UPDATE** of T1 and then T3 starts, and **UPDATE** of T1 succeeds. **UPDATE** of T3 times out. This is because T1 and T3 update the same row and the lock is held by T1 at the time of the update.

### 8.10.4.4 Concurrent Data Import and Queries

Transaction T1:

```
START TRANSACTION;
COPY test FROM '...';
COMMIT;
```

Transaction T2:

```
START TRANSACTION;
SELECT * FROM test;
COMMIT;
```

Scenario 1:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

T1 is started but not committed. At this time, T2 is started. **COPY** of T1 and then **SELECT** of T2 starts, and both of them succeed. In this case, T2 cannot see the data added by **COPY** of T1.

Scenario 2:

- **READ COMMITTED** level

  T1 is started but not committed. At this time, T2 is started. **COPY** of T1 is complete and T1 is committed. In this case, T2 can see the data added by **COPY** of T1.

- **REPEATABLE READ** level

  T1 is started but not committed. At this time, T2 is started. **COPY** of T1 is complete and T1 is committed. In this case, T2 cannot see the data added by **COPY** of T1.

# 9 Exporting Data

## 9.1 Exporting Data in Parallel Using a Foreign Table

### 9.1.1 Exporting Data In Parallel

In high-concurrency scenarios, you can use GDS to export a large volume of data from a database to a common file system. To export data in parallel using a foreign table, you must enable the stream operator first.

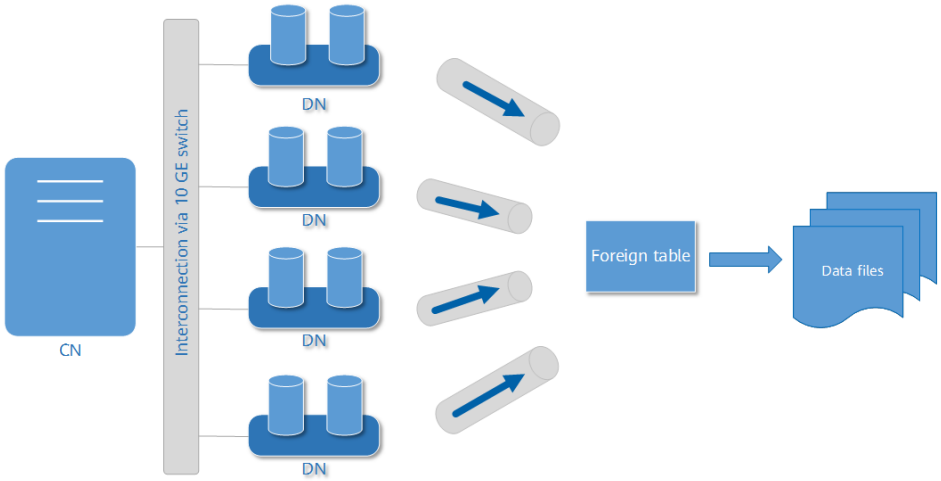
#### Overview

**Using foreign tables**: Data files to export are specified based on the export mode and data formats specified in a foreign table. Data is exported in parallel through multiple DNs from the database to data files, which improves overall data export performance.

- The CN plans data export tasks and delivers the tasks to DNs. Then the CN is released to process other tasks.
- The computing capabilities and bandwidths of all the DNs are fully leveraged to export data.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Figure 9-1** Exporting data using foreign tables



## Concepts

- **Data file**: A TEXT, CSV, or FIXED file that stores data exported from GaussDB.
- **Foreign table**: a table that stores information, such as the format, location, and encoding format of a data file.
- **GDS**: a data service tool. To export data, deploy GDS on the server where data files are stored.
- **Table**: a table in the database, including row-store tables and column-store tables. Data in data files is exported from these tables.
- **Local mode**: Service data in a cluster is exported to hosts in the cluster.
- **Remote mode**: Service data in a cluster is exported to hosts outside the cluster.

## Exporting a Schema

In GaussDB, data can be exported in local or remote mode.

- **Remote mode**: Service data in a cluster is exported to hosts outside the cluster.
  - In this mode, multiple GDSs are used to concurrently export data. One GDS can export data for only one cluster at a time.
  - The data export rate of a GDS that resides on the same intranet as cluster nodes is limited by the network bandwidth. A 10 GE configuration is recommended.
  - Data files in TEXT, CSV, or FIXED format are supported. The size of data in a single row must be less than 1 GB.
- **Local mode**: Service data in a cluster is exported to hosts in the cluster. The local mode is dedicated to exporting data from a large number of small files.
  - In this mode, data is evenly divided and stored in specified directories on cluster nodes, occupying the disk space of these cluster nodes.
  - Data files in TEXT, CSV, or FIXED format are supported. The size of data in a single row must be less than 1 GB.

## Export Process

**Figure 9-2** Process of parallel data export

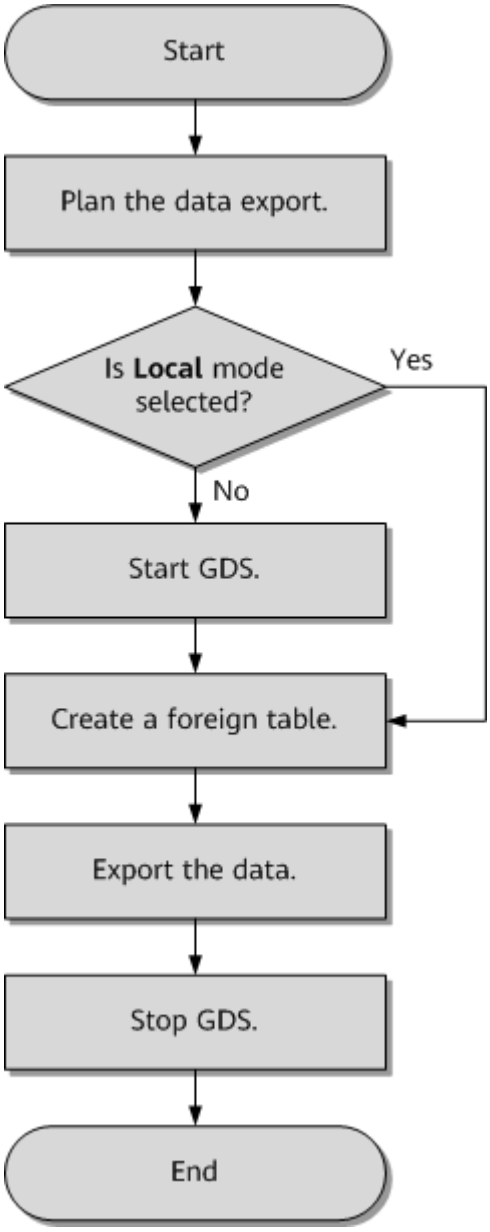

**Table 9-1** Process description

| Process | Description | Sub-task |
| --- | --- | --- |
| Plan data export | Prepare data to export and plan the export path.<br>For details, see **9.1.2 Planning Data Export**. | N/A |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Process | Description | Sub-task |
| --- | --- | --- |
| Check whether the **Local** mode is selected | Check the export mode specified during foreign table creation to determine whether the **Local** mode is selected. | N/A |
| Start GDS | If the **Remote** mode is selected, install, configure, and start GDS on data servers.<br>For details, see **9.1.3 Installing, Configuring, and Starting GDS**. | N/A |
| Create a foreign table | Create a foreign table to help GDS specify information about a data file. The foreign table stores information, such as the location, format, encoding, and inter-data delimiter of a data file.<br>For details, see **9.1.4 Creating a GDS Foreign Table**. | N/A |
| Export data | After the foreign table is created, run the **INSERT** statement to efficiently export data to data files.<br>For details, see **9.1.5 Exporting Data**. | N/A |
| Stop GDS | Stop GDS after data is exported.<br>For details, see **9.1.6 Stopping GDS**. | N/A |

## 9.1.2 Planning Data Export

### Scenarios

Before you use GDS to export data from a cluster, prepare data to export and plan the export path.

### Planning an Export Path

- **Remote** mode

**Step 1** (Optional) Create a user and a user group. The user is used to start GDS and must have the write permission on the directory for storing data files.

```
groupadd gdsgrp
useradd -g gdsgrp gdsuser
```

If the following information is displayed, the user and user group already exist. Skip this step.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
useradd: Account 'gdsuser' already exists.
groupadd: Group 'gdsgrp' already exists.
```

**Step 2** Create the **/output_data** directory for storing exported data files.

```
mkdir -p /output_data
```

**Step 3** Change the directory owner to **gdsuser**.

```
chown -R gdsuser:gdsgrp /output_data
```

**----End**

- **Local** mode

**Step 1** Create the **/output_data** directory for storing data files on each DN in the cluster.

```
mkdir -p /output_data
```

**Step 2** Change the directory owner to **omm**.

```
chown -R omm:dbgrp /output_data
```

**Step 3** Set **location** to a local path. You do not need to specify the file name.

For example, to store data files to the **/output_data/** directory, set the **location** parameter to **file:///output_data/** when you create a foreign table.

**----End**

## 9.1.3 Installing, Configuring, and Starting GDS

GDS is a data service tool provided by GaussDB. Using the foreign table mechanism, this tool helps export data at a high speed. Based on the load of the export job, check whether the server where GDS is located is properly connected to each physical cluster of the GaussDB Kernel clusters and whether there are robust system resources such as memory, handles, and disk space. For details, see **8.1.4 Installing, Configuring, and Starting GDS**.

## 9.1.4 Creating a GDS Foreign Table

### Procedure

**Step 1** Set the **location** parameter for the foreign table based on the path planned in **9.1.2 Planning Data Export**.

- **Remote** mode

  Set the **location** parameter to the URL of the directory that stores the data files.

  - You do not need to specify a file name in the URL.
  - If multiple URLs are configured, only the first URL is effective.

  **Example**:

  The IP address of the GDS data server is 192.168.0.90. The listening port number set during GDS startup is 5000. The directory for storing data files is **/output_data**.

  In this case, set the **location** parameter to **gsfs://192.168.0.90:5000/**.

- **Local** mode

  Set the **location** parameter to the directory for storing the data files. You do not need to specify the file name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Example**:

To store data files in the **/output_data/** directory, set the **location** parameter to **file:///output_data/** when you create a foreign table.

**Step 2** Set data format parameters in the foreign table based on the planned data file formats. For details on format parameters, see **data format parameters**.

**Step 3** Create a GDS foreign table based on the parameter settings in the preceding steps. For details, see **12.14.60 CREATE FOREIGN TABLE (for Import and Export)**.

**----End**

## Examples

- **Example 1**: Create the GDS foreign table **foreign_tpcds_reasons** to receive data from a data server. Data will be exported in CSV format.

  Data export settings are as follows:

  The data server resides on the same intranet as the cluster. The IP address of the data server is 192.168.0.90. Data is to be exported as CSV files. The **Remote** mode is selected for parallel data export.

  If the directory for storing data files is **/output_data/** and the GDS listening port is 5000 when GDS is started, set the **location** parameter to **gsfs://192.168.0.90:5000/**.

  Data format parameter settings are as follows:

  - **format** is set to **CSV**.
  - **encoding** is set to **UTF-8**.
  - **delimiter** is set to **E'\x20'**.
  - **quote** is set to **0x1b**.
  - **null** is set to an empty string without quotation marks.
  - **escape** is set to a double quotation mark.
  - **header** is set to **false**, indicating that the first row is identified as a data row in an exported file.
  - **EOL** is set to **0X0A**.

  The statement for creating the foreign table is as follows:

  ```
  openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons
  (
    r_reason_sk    integer        not null,
    r_reason_id    char(16)       not null,
    r_reason_desc  char(100)
  )
  SERVER gsmpp_server
  OPTIONS (LOCATION 'gsfs://192.168.0.90:5000/',
  FORMAT 'CSV',
  DELIMITER E'\x20',
  QUOTE E'\x1b',
  NULL '',
  EOL '0x0a'
  )
  WRITE ONLY;
  ```

- **Example 2**: The GDS foreign table **foreign_tpcds_reasons** is created for receiving data from a data server. Data will be exported as FIXED files.

  Data export settings are as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The data server resides on the same intranet as the cluster. The IP address of the data server is 192.168.0.90. Data is to be exported as CSV files. The **Remote** mode is selected for parallel data export.

If the directory for storing data files is **/output_data/** and the GDS listening port is 5000 when GDS is started, set the **location** parameter to **gsfs://192.168.0.90:5000/**.

Data format parameter settings are as follows:

- **format** is set to **FIXED**.
- **encoding** is set to **UTF-8**.
- **header** is set to false, indicating that when the file is exported, the first row is regarded as a data row.
- **POSITION(***offset***,***length***)** is set to specify the position of a column in a source data file. **offset** indicates the starting point of a column in the data file. **length** indicates the length (in bytes) of the column.

  In the **r_reason_sk** column, the data type is **integer** and the maximum number of bytes is 2 (as shown in the following statement output). Therefore, *offset* is set to **1** and *length* is set to **2**.

  In the **r_reason_id** column, the data type is **character varying(16)** and the maximum number of bytes is 16 (as shown in the following statement output). Therefore, *offset* is set to **3** (sum of *offset* and *length* of **r_reason_sk**) and *length* is set to **16**.

  In the **r_reason_desc** column, the data type is **character varying(100)** and the maximum number of bytes is 100 (as shown in the following statement output). Therefore, *offset* is set to **19** (sum of *offset* and *length* of **r_reason_id**) and *length* is set to **100**.

  ```
  openGauss=# SELECT
  max(lengthb(r_reason_sk)),max(lengthb(r_reason_id)),max(lengthb(r_reason_desc)) FROM
  reasons;
   max | max | max
  -----+-----+-----
     2 |  16 | 100
  (1 row)
  ```

- **EOL** is set to **0X0A**.

The statement for creating the foreign table is as follows:

```
openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons
( r_reason_sk    integer        position(1,2),
  r_reason_id    char(16)       position(3,16),
  r_reason_desc  char(100)      position(19,100)
)
SERVER gsmpp_server
OPTIONS (LOCATION 'gsfs://192.168.0.90:5000/',
FORMAT 'FIXED',
ENCODING 'utf8',
EOL '0x0a'
)
WRITE ONLY;
```

# 9.1.5 Exporting Data

## Prerequisites

The IP addresses and ports of servers where CNs and DNs reside can connect to those of a GDS server.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Procedure

**Step 1** Export data.

```
INSERT INTO [Foreign table name] SELECT * FROM [Source table name];
```

NOTE

- Create batch processing scripts to export data in parallel. The degree of parallelism depends on server resource usage. You can test several tables and monitor resource usage to determine whether to increase or reduce the amount. Common resource monitoring commands include **top** for monitoring memory and CPU usage, **iostat** for monitoring I/O usage, and **sar** for monitoring networks.
- Only a single internal table can be exported at a time. Multi-table join is not supported during export. Results of the aggregation, sort, subquery, and limit operations on a single table also cannot be exported.
- In this version, GDS export supports CN RETRY. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) CN RETRY is triggered when a network error occurs due to a DN or GTM fault. Ensure that the GDS version is the same as or later than the kernel version.

**----End**

## Examples

- **Example 1**: Export data from the **reasons** table to data files through the foreign table **foreign_tpcds_reasons**.
  ```
  openGauss=# INSERT INTO foreign_tpcds_reasons SELECT * FROM reasons;
  ```
- **Example 2**: Export part of the data to data files by specifying the filter condition **r_reason_sk =1**.
  ```
  openGauss=# INSERT INTO foreign_tpcds_reasons SELECT * FROM reasons WHERE r_reason_sk=1;
  ```
- **Example 3**: Data of a special type, such as RAW, is exported as a binary file, which cannot be recognized by the import tool. You need to use the RAWTOHEX() function to convert it to hexadecimal the format before export.
  ```
  openGauss=# INSERT INTO foreign_blob_type_tab SELECT RAWTOHEX(c) FROM blob_type_tab;
  ```

# 9.1.6 Stopping GDS

GDS is a data service tool provided by GaussDB. Using the foreign table mechanism, this tool helps export data at a high speed.

For details, see **8.1.8 Stopping GDS**.

# 9.1.7 Examples

## Example: Exporting Data in Remote Mode

A data server resides on the same intranet as the cluster, the IP address of the data server is 192.168.0.90, and data files are in CSV format. In this scenario, data is concurrently exported in **Remote** mode.

To concurrently export data in **Remote** mode, perform the following operations:

1. (Optional) Create a user and its user group. The user is used to start GDS. If the user and user group already exist, skip this step.
   ```
   groupadd gdsgrp
   useradd -g gdsgrp gds_user
   ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

2. Switch to user **gds_user**, create the **/output_data** directory for storing data files, and start user **gds_user** and its user group.
   ```
   su - gds_user
   mkdir -p /output_data
   ```
3. Change the owner of the **/output_data** directory on the data server to **gds_user**.
   ```
   chown -R gds_user:gdsgrp /output_data
   ```
4. Log in to the data server as user **gds_user** and start GDS.

   The GDS installation path is **/opt/bin/gds**. Exported data files are stored in **/output_data/**. The IP address of the data server is 192.168.0.90. The GDS monitoring port number is 5000. The GDS runs in the background.
   ```
   /opt/bin/gds/gds -d /output_data -p 192.168.0.90:5000 -H 10.10.0.1/24 -D
   ```
5. In the database, create the foreign table **foreign_tpcds_reasons** for receiving data from the data server.

   Data export mode settings are as follows:

   - The directory for storing exported files is set to **/output_data/** and the GDS listening port number is 5000 while GDS is started. The created directory for storing exported files is **/output_data/**. Therefore, set the **location** parameter to **gsfs://192.168.0.90:5000/**.

   Data format parameter settings are as follows:

   - **format** is set to **CSV**.
   - **encoding** is set to **UTF-8**.
   - **delimiter** is set to **E'\x20'**.
   - **quote** is set to **0x1b**.
   - **null** is set to an empty string without quotation marks.
   - **escape** is set to a double quotation mark.
   - **header** is set to **false**, indicating that the first row is identified as a data row in an exported file.

   Based on the above settings, the foreign table is created using the following statement:
   ```
   openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons
   (
     r_reason_sk    integer        not null,
     r_reason_id    char(16)       not null,
     r_reason_desc  char(100)
   ) SERVER gsmpp_server OPTIONS (LOCATION 'gsfs://192.168.0.90:5000/', FORMAT 'CSV',ENCODING
   'utf8',DELIMITER E'\x20', QUOTE E'\x1b', NULL '') WRITE ONLY;
   ```
6. In the database, export data to data files through the foreign table **foreign_tpcds_reasons**.
   ```
   openGauss=# INSERT INTO foreign_tpcds_reasons SELECT * FROM reasons;
   ```
7. After data export is complete, log in to the data server as user **gds_user** and stop GDS.

   The GDS process ID is 128954.
   ```
   ps -ef|grep gds
   gds_user 128954      1  0 15:03 ?        00:00:00 gds -d /output_data -p 192.168.0.90:5000 -D
   gds_user 129003 118723  0 15:04 pts/0    00:00:00 grep gds
   kill -9 128954
   ```

## Example: Exporting Data Using Multiple Threads

A data server resides on the same intranet as the cluster, the IP address of the data server is 192.168.0.90, and source data files are in CSV format. In this

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

scenario, data is concurrently exported from two tables using multiple threads in **Remote** mode.

To concurrently export data using multiple threads in **Remote** mode, perform the following operations:

1. Log in to the GDS data server and create a database user and its user group.
   ```
   groupadd gdsgrp
   useradd -g gdsgrp gds_user
   ```
2. Switch to user **gds_user** and create the **/output_data** directory for storing exported files.
   ```
   su - gds_user
   mkdir -p /output_data
   ```
3. Change the owner of the **/output_data** directory on the data server to **gds_user**.
   ```
   chown -R gds_user:gdsgrp /output_data
   ```
4. Log in to the data server as user **gds_user** and start GDS.

   The GDS installation path is **/opt/bin/gds**. Exported data files are stored in **/output_data/**. The IP address of the data server is 192.168.0.90. The GDS listening port number is 5000. The GDS runs in the background. The concurrency level is 2.
   ```
   /opt/bin/gds/gds -d /output_data -p 192.168.0.90:5000 -H 10.10.0.1/24 -D -t 2
   ```
5. In GaussDB, create the foreign tables **foreign_tpcds_reasons1** and **foreign_tpcds_reasons2** for receiving data from the data server.
   - Data export mode settings are as follows:
     - The directory for storing exported files is set to **/output_data/** and the GDS listening port number is 5000 while GDS is started. The created directory for storing exported files is **/output_data/**. Therefore, the **location** parameter is set to **gsfs://192.168.0.90:5000/**.
   - Data format parameter settings are as follows:
     - **format** is set to **CSV**.
     - **encoding** is set to **UTF-8**.
     - **delimiter** is set to **E'\x20'**.
     - **quote** is set to **0x1b**.
     - **null** is set to an empty string without quotation marks.
     - **escape** is set to a double quotation mark.
     - **header** is set to **false**, indicating that the first row is identified as a data row in an exported file.

   Based on the above settings, the foreign table **foreign_tpcds_reasons1** is created using the following statement:
   ```
   openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons1
   (
     r_reason_sk    integer      not null,
     r_reason_id    char(16)     not null,
     r_reason_desc  char(100)
   ) SERVER gsmpp_server OPTIONS (LOCATION 'gsfs://192.168.0.90:5000/', FORMAT 'CSV',ENCODING
   'utf8', DELIMITER E'\x20', QUOTE E'\x1b', NULL '') WRITE ONLY;
   ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Based on the above settings, the foreign table **foreign_tpcds_reasons2** is created using the following statement:

```
openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons2
(
  r_reason_sk    integer     not null,
  r_reason_id    char(16)    not null,
  r_reason_desc  char(100)
) SERVER gsmpp_server OPTIONS (LOCATION 'gsfs://192.168.0.90:5000/', FORMAT 'CSV', DELIMITER
E'\x20', QUOTE E'\x1b', NULL '') WRITE ONLY;
```

6. In the database, export data from table **reasons1** through the foreign table **foreign_tpcds_reasons1** and from table **reasons2** through the foreign table **foreign_tpcds_reasons2** to **/output_data**.

   ```
   openGauss=# INSERT INTO foreign_tpcds_reasons1 SELECT * FROM reasons1;
   openGauss=# INSERT INTO foreign_tpcds_reasons2 SELECT * FROM reasons2;
   ```

7. After data export is complete, log in to the data server as user **gds_user** and stop GDS.

   The GDS process ID is 128954.

   ```
   ps -ef|grep gds
   gds_user 128954      1  0 15:03 ?        00:00:00 gds -d /output_data -p 192.168.0.90:5000 -D -t 2
   gds_user 129003 118723  0 15:04 pts/0    00:00:00 grep gds
   kill -9 128954
   ```

## Example: Exporting Data in Local Mode

A cluster contains eight DNs and four physical nodes. Every two DNs reside on the same physical node. The cluster has sufficient disk space and the cluster node I/O performance is satisfactory. In this scenario, data is concurrently exported in **Local** mode.

To concurrently export data in **Local** mode, perform the following operations:

1. Log in to a physical node, create the **/output_data** directory for storing data files, and change the owner of the directory to **omm**.

   All the following operations use a node with the IP address 192.168.0.11 as an example.

   ```
   mkdir -p /output_data
   chown -R omm:dbgrp /output_data
   ```

2. In the database, create the foreign table **foreign_tpcds_reasons**.
   - Data export mode settings are as follows:
     - The directory created in the previous step for storing data files is **/output_data/**. Therefore, the **location** parameter is set to **file:///output_data/**.
   - Data format parameter settings are as follows:
     - **format** is set to **CSV**.
     - **encoding** is set to **UTF-8**.
     - **delimiter** is set to **E'\x20'**.
     - **quote** is set to **0x1b**.
     - **null** is set to an empty string without quotation marks.
     - **escape** is set to a double quotation mark.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- **header** is set to **false**, indicating that the first row is identified as a data row in an exported file.

Based on the above settings, the foreign table **foreign_tpcds_reasons** is created using the following statement:

```
openGauss=# CREATE FOREIGN TABLE foreign_tpcds_reasons
(
  r_reason_sk    integer      not null,
  r_reason_id    char(16)     not null,
  r_reason_desc  char(100)
) SERVER gsmpp_server OPTIONS (LOCATION 'file:///output_data/', FORMAT 'CSV',ENCODING 'utf8',
DELIMITER E'\x20', QUOTE E'\x1b', NULL '') WRITE ONLY;
```

3. Export data in the database.

```
openGauss=# INSERT INTO foreign_tpcds_reasons SELECT * FROM reasons;
```

4. View data files.

   The data files are generated in **/output_data/***YYYYMMDD/DN name* on each cluster node. *YYYYMMDD* indicates the current system date. *DN name* can be found by running the following statement:

```
openGauss=# SELECT node_name,node_host FROM pgxc_node WHERE node_type='D';
  node_name   |   node_host
--------------+---------------
 dn_6001_6002 | 192.168.0.11
 dn_6003_6004 | 192.168.0.11
 dn_6005_6006 | 192.168.0.12
 dn_6007_6008 | 192.168.0.12
 dn_6009_6010 | 192.168.0.13
 dn_6011_6012 | 192.168.0.13
 dn_6013_6014 | 192.168.0.14
 dn_6015_6016 | 192.168.0.14
(8 rows)
```

   On the node whose IP address is 192.168.0.11, the names of DNs are **dn_6001_6002** and **dn_6003_6004**. In this case, data files are generated in **/output_data/20160101/dn_6001_6002** and **/output_data/20160101/dn_6003_6004** on the node.

# 10 Performance Tuning

## 10.1 Overview

To fine-tune GaussDB performance, you need to identify performance bottlenecks, adjust key parameters, and optimize SQL statements. During performance tuning, locate and analyze performance issues based on performance elements, such as system resources, throughput, and loads to achieve required system performance.

Various factors must be considered during GaussDB performance tuning. Therefore, optimization personnel must know well about knowledge, such as system software architecture, hardware and software configuration, database parameter configuration, concurrency control (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.), query processing, and database applications.

**NOTICE**

Performance tuning sometimes require cluster restart, which may interrupt current services. Therefore, after the service goes live and when the cluster needs to be restarted, you must send the request to related management department about the operation time window for approval.

### Tuning Process

**Figure 10-1** shows the procedure of performance tuning.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Figure 10-1** GaussDB performance tuning

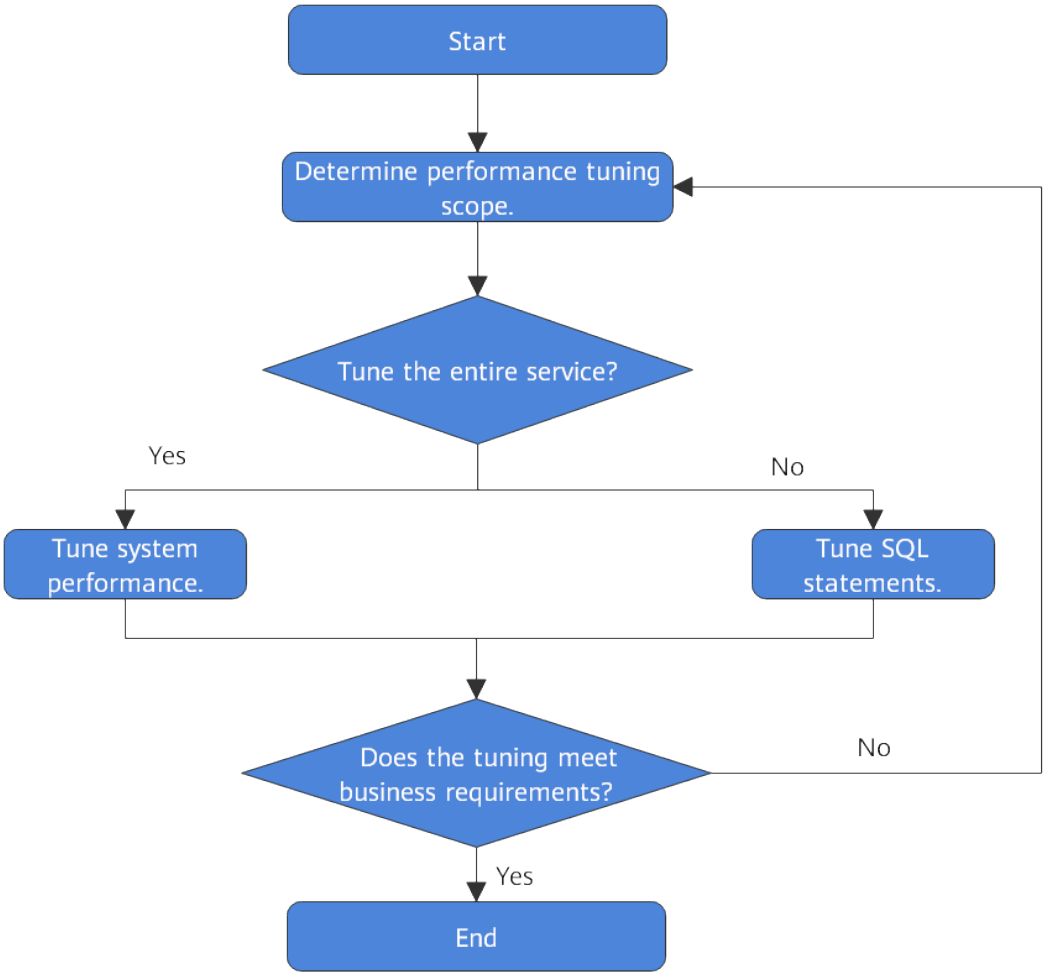

**Table 10-1** lists the details about each phase.

**Table 10-1** GaussDB performance tuning

| Phase | Description |
| --- | --- |
| **10.2 Determining the Scope of Performance Tuning** | The phase where the CPU, memory, I/O, and network resource usage of each cluster node are obtained to check whether these resources are fully used and whether any bottleneck exists |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Phase | Description |
| --- | --- |
| 10.3 SQL Optimization | The phase where the SQL statements used are analyzed to determine whether any optimization can be performed. Analysis of SQL statements comprises:<br>• Generating table statistics using **ANALYZE**: The **ANALYZE** statement collects statistics about the database table content. Statistical results are stored in the system catalog **PG_STATISTIC**. The execution plan generator uses these statistics to determine which one is the most effective execution plan.<br>• Analyzing the execution plan: The **EXPLAIN** statement displays the execution plan of SQL statements, and the **EXPLAIN PERFORMANCE** statement displays the execution time of each operator in SQL statements.<br>• Identifying the root causes of issues: Identifies possible causes by analyzing the execution plan and perform specific optimization by modifying database-level SQL optimization parameters.<br>• Compiling better SQL statements: Compiles better SQL statements in the scenarios, such as cache of intermediate and temporary data for complex queries, result set cache, and result set combination. |

# 10.2 Determining the Scope of Performance Tuning

Database performance tuning often happens when users are not satisfied with the service execution efficiency and want to improve the efficiency. The database performance is affected by many factors as described in section **Performance Elements**. Therefore, performance tuning is a complex process and sometimes cannot be systematically described or explained. It depends more on the database administrator's experience. However, this section still attempts to illustrate the performance tuning methods that can be referred to by application development personnel and new GaussDB database administrators.

## Performance Elements

There are multiple performance factors that affect the database performance. Knowing these factors can help you identify and analyze performance-associated issues.

- System resources

  Database performance greatly relies on disk I/O and memory usage. To accurately set performance counters, you need to have a knowledge of the basic performance of the hardware deployed in the cluster. Performance of hardware, such as the CPU, hard disk, disk controller, memory, and network interfaces, greatly affects database running speed.

- Load

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The load indicates the total database system demands and it changes over time. The overall load contains user queries, applications, concurrent jobs, transactions, and system commands transferred at any time. For example, the system load increases if multiple users are executing multiple queries. The load greatly affects database performance. Identifying load peak hours helps improve resource utilization so that tasks are executed effectively.

- Throughput

  The data processing capability of a database is defined by its throughput. Database throughput is measured by the number of queries or processed transactions per second or by the average response time. The database processing capacity is closely related to the underlying system performance (disk I/O, CPU speed, and storage bandwidth). You need to know about the hardware performance before setting a target throughput.

- Competition

  Competition indicates that two or more load components try to use system resources in a conflicting way. For example, competition occurs when multiple queries attempt to update the same data at the same time, or when a large number of loads compete for system resources. When competition increases, the throughput decreases.

- Optimization

  The database optimization can affect the performance of the whole system. Before executing the SQL statements, configuring database parameters, designing tables, and performing data distribution, enable the database query optimizer can help you obtain the most efficient execution plan.

### Determining the Tuning Scope

Performance tuning depends on the usage of hardware resources, such as the CPU, memory, I/O, and network of each node in the cluster. Check whether these resources are fully utilized, and whether any bottlenecks exist, and then perform performance tuning as required.

- If a resource reaches the bottleneck:
  a. Check whether the key OS parameters and database parameters are properly set.
  b. Find the resource consuming SQL statements by querying the most time-consuming SQL statements and unresponsive SQL statements, and then perform **10.3 SQL Optimization**.
- If no resource reaches the bottleneck, the system performance can be improved. In this case, query the most time-consuming SQL statements and the unresponsive SQL statements, and then perform **10.3 SQL Optimization** as required.

## 10.2.1 Querying SQL Statements That Affect Performance Most

This section describes how to query SQL statements whose execution takes a long time, leading to poor system performance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Procedure

**Step 1** Connect to a database. For details, see **2.1 Connecting to a Database**.

**Step 2** Query the statements that are run for a long time in the database.

```
SELECT current_timestamp - query_start AS runtime, datname, usename, query FROM pg_stat_activity
where state != 'idle' ORDER BY 1 desc;
```

The command output lists the query statements in descending order by their execution duration length. The first record is the query statement that takes the longest time for execution. The returned result contains SQL statements invoked by the system and SQL statements run by users. Find the statements that were run by users and took a long time.

Alternatively, you can set **current_timestamp - query_start** to be greater than a threshold to identify query statements that are executed for a duration longer than this threshold.

```
SELECT query FROM pg_stat_activity WHERE current_timestamp - query_start > interval '1 days';
```

**Step 3** Set the parameter **track_activities** to **on**.

```
SET track_activities = on;
```

The database collects the running information about active queries only if the parameter is set to **on**.

**Step 4** View the running query statements.

The **pg_stat_activity** view is used as an example here.

```
SELECT datname, usename, state FROM pg_stat_activity;
 datname  | usename | state  |
----------+---------+--------+
 postgres |   omm   | idle   |
 postgres |   omm   | active |
(2 rows)
```

If the **state** column is **idle**, the connection is idle and requires a user to enter a command.

To identify only active query statements, run the following command:

```
SELECT datname, usename, state FROM pg_stat_activity WHERE state != 'idle';
```

**Step 5** Analyze the status of the query statements that were run for a long time.

- If the query statement is normal, wait until the execution of the query statement is complete.
- If a query statement is blocked, run the following command to view this query statement:

  ```
  SELECT datname, usename, state, query FROM pg_stat_activity WHERE waiting = true;
  ```

  The query statement is displayed. It is requesting a lock resource that may be held by another session, and is waiting for the lock resource to be released by the session.

  **NOTE**

  Only when the query is blocked by internal lock resources, the **waiting** column is **true**. In most cases, blocks happen when query statements are waiting for lock resources to be released. However, query statements may be blocked due to write and timers operations. Such blocked queries are not displayed in the **pg_stat_activity** view.

**----End**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 10.2.2 Checking Blocked Statements

During database running, query statements are blocked in some service scenarios and run for an excessively long time. In this case, you can forcibly terminate the faulty session.

## Procedure

**Step 1** Connect to a database. For details, see **2.1 Connecting to a Database**.

**Step 2** Check the blocked query statements, the SQL statement that blockes the query, query status, and session ID (applicable when the SQL thread pool is enabled).

```
SELECT w.query AS waiting_query,
w.state as w_state,
w.datname as w_datname,
w.usename as w_user,
w.client_addr as w_client_addr,
l.query AS locking_query,
l.state as l_state,
l.pid AS l_pid,
l.sessionid as l_sessionid
FROM pgxc_stat_activity AS w
JOIN (
    SELECT query_id,block_sessionid,global_sessionid,node_name
    FROM pgxc_thread_wait_status
) AS a ON a.query_id = w.query_id
 JOIN (
    SELECT sessionid,node_name,global_sessionid  FROM pgxc_thread_wait_status
) AS b ON b.sessionid = a.block_sessionid and b.node_name=a.node_name
JOIN (select query,pid,sessionid,global_sessionid,state from pgxc_stat_activity ) l
on substring(l.global_sessionid,0,instr(l.global_sessionid,'#')) ilike
substring(b.global_sessionid,0,instr(b.global_sessionid,'#'))
WHERE a.block_sessionid !=0;
```

This query returns the session ID, user information, query status, and the statement that causes the blocking and its query status and session ID.

**Step 3** Run the following command to terminate the required session, where **139834762094352** is the thread ID:

```
SELECT PG_TERMINATE_BACKEND(139834762094352);
```

If information similar to the following is displayed, the session is successfully terminated:

```
 PG_TERMINATE_BACKEND
----------------------
 t
(1 row)
```

If information similar to the following is displayed, the user is attempting to end the current session:

```
FATAL:  terminating connection due to administrator command
FATAL:  terminating connection due to administrator command
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

1. If the **PG_TERMINATE_BACKEND** function is used to terminate the backend threads of the current session and the user is an initial user, the **gsql** client is reconnected automatically rather than be logged out. The message "The connection to the server was lost. Attempting reset: Succeeded." is returned. Otherwise, the client fails to be reconnected and the error message "The connection to the server was lost. Attempting reset: Failed." is returned because only the initial user can use password-free login.
2. If the **PG_TERMINATE_BACKEND** function is used to terminate inactive backend threads and the thread pool is opened, idle sessions do not have thread IDs and cannot be ended. In non-thread pool mode, ended sessions are not automatically reconnected.

**----End**

# 10.3 SQL Optimization

The aim of SQL optimization is to maximize the utilization of resources, including CPU, memory, disk I/O, and network I/O. All optimization methods are intended for resource utilization. To maximize resource utilization is to run SQL statements as efficiently as possible to achieve the highest performance at a lower cost. For example, when performing a typical point query, you can use a Seq Scan and a filter (that is, read every tuple and point query conditions for match). You can also use an Index Scan, which can be implemented at a lower cost but achieve the same effect.

You can determine a proper cluster deployment solution and table definition based on hardware resources and service characteristics. This is the basis of meeting performance requirements. The following performance tuning sections assume that you have finished installation based on a proper cluster solution in the software installation guide and performed database design based on the guide for database design and development.

## 10.3.1 Query Execution Process

The process from receiving SQL statements to the statement execution by the SQL engine is shown in **Figure 10-2** and described in **Table 10-2**. The texts in red are steps where database administrators can optimize queries.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Figure 10-2** Execution process of query-related SQL statements by the SQL engine

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 10-2** Execution process of query-related SQL statements by the SQL engine

| Step | Description |
| --- | --- |
| 1. Perform syntax and lexical parsing. | Converts the input SQL statements from the string data type to the formatted structure stmt based on the specified SQL statement rules. |
| 2. Perform semantic parsing. | Converts the formatted structure obtained from the previous step into objects that can be recognized by the database. |
| 3. Rewrite the query statements. | Converts the output of the previous step into the structure that optimizes the query execution. |
| 4. Optimize the query. | Determines the execution mode of SQL statements (the execution plan) based on the result obtained from the previous step and the internal database statistics. For details about how the internal database statistics and GUC parameters affect the query optimization (execution plan), see **Optimizing Queries Using Statistics** and **Optimizing Queries Using GUC Parameters**. |
| 5. Perform the query. | Executes the SQL statements based on the execution path specified in the previous step. Selecting a proper underlying storage mode improves the query execution efficiency. For details, see **Optimizing Queries Using the Underlying Storage**. |

## Optimizing Queries Using Statistics

The GaussDB optimizer is a typical Cost-based Optimization (CBO). By using CBO, the database calculates the number of tuples and the execution cost for each execution step under each execution plan based on the number of table tuples, column width, NULL record ratio, and characteristic values, such as distinct, MCV, and HB values, and certain cost calculation methods. The database then selects the execution plan that takes the lowest cost for the overall execution or for the return of the first tuple. These characteristic values are the statistics, which is the core for optimizing a query. Accurate statistics helps the planner select the most appropriate query plan. Generally, you can collect statistics of a table or that of some columns in a table using **ANALYZE**. You are advised to periodically execute **ANALYZE** or execute it immediately after you modified most contents in a table.

## Optimizing Queries Using GUC Parameters

Optimizing queries aims to select an efficient execution mode.

Take the following SQL statement as an example:

```
select count(1)
from customer inner join store_sales on (ss_customer_sk = c_customer_sk);
```

During execution of **customer inner join store_sales**, GaussDB supports nested loop, merge join, and hash join. The optimizer estimates the result set sizes and the execution cost for each join mode based on the statistics on the **customer** and

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**store_sales** tables. It then compares the costs and selects the one costing the least.

As described in the preceding content, the execution cost is calculated based on certain methods and statistics. If the actual execution cost cannot be accurately estimated, you need to optimize the execution plan by setting the GUC parameters.

### Optimizing Queries Using the Underlying Storage

GaussDB supports row- and column-store tables. The selection of an underlying storage mode strongly depends on specific customer service scenarios. You are advised to use column-store tables for computing service scenarios (mainly involving association and aggregation operations) and row-store tables for service scenarios, such as point queries and massive **UPDATE** or **DELETE** executions.

Optimization methods of each storage mode will be described in detail below.

### Optimizing Queries by Rewriting SQL Statements

Besides the preceding methods that improve the performance of the execution plan generated by the SQL engine, database administrators can also enhance SQL statement performance by rewriting SQL statements while retaining the original service logic based on the execution mechanism of the database and abundant practices.

This requires that database administrators know the customer services well and have professional knowledge of SQL statements. Below chapters will describe some common SQL rewriting scenarios.

## 10.3.2 Introduction to the SQL Execution Plan

### 10.3.2.1 Overview

The SQL execution plan is a node tree, which displays detailed procedure when GaussDB runs an SQL statement. A database operator indicates one step.

You can run the **EXPLAIN** command to view the execution plan generated for each query by an optimizer. The output of **EXPLAIN** has one row for each execution node, showing the basic node type and the cost estimation that the optimizer made for the execution of this node, as shown in **Figure 10-3**.

**Figure 10-3** SQL execution plan example

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Nodes at the bottom level are scan nodes. They scan tables and return raw rows. The types of scan nodes (sequential scans and index scans) vary depending on the table access methods. Objects scanned by the bottom layer nodes may not be row-store data (not directly read from a table), such as **VALUES** clauses and functions that return rows, which have their own types of scan nodes.
- If the query requires join, aggregation, sorting, or other operations on the raw rows, there will be other nodes above the scan nodes to perform these operations. In addition, there is more than one way to perform these operations, so different types of execution nodes may be displayed here.
- The first row (the upper-layer node) estimates the total execution cost of the execution plan. Such an estimate indicates the value that the optimizer tries to minimize.

## Execution Plan Display Format

GaussDB provides four display formats: **normal**, **pretty**, **summary**, and **run**.

- **normal** indicates that the default printing format is used, as shown in **Figure 10-3**.
- **pretty** indicates that the optimized display mode of GaussDB is used. A new format contains a plan node ID, directly and effectively analyzing performance, as shown in **Figure 10-4**.
- **summary** indicates that the analysis result on this information is printed in addition to the printed information in the format specified by **pretty**.
- **run** indicates that in addition to the printed information specified by **summary**, the database exports the information as a CSV file.

**Figure 10-4** Example of an execution plan using the pretty format

```
openGauss=# explain select cjxh, count(1) from dwcjk group by cjxh;
 id |               operation                | E-rows | E-memory | E-width | E-costs
----+----------------------------------------+--------+----------+---------+---------
  1 | ->  Row Adapter                        |      1 |          |      52 | 58.42
  2 |    ->  Vector Streaming (type: GATHER) |      1 |          |      52 | 58.42
  3 |       ->  Vector Hash Aggregate        |      1 | 16MB     |      52 | 58.02
  4 |          ->  CStore Scan on dwcjk      |      1 | 1MB      |      44 | 58.00
(4 rows)
```

You can change the display format of execution plans by setting **explain_perf_mode**. Later examples use the pretty format by default.

## Execution Plan Information

In addition to setting different display formats for an execution plan, you can use different **EXPLAIN** syntax to display execution plan information in detail. The following lists the common **EXPLAIN** syntax. For details about more **EXPLAIN** syntax, see **12.14.137 EXPLAIN**.

- EXPLAIN *statement*: only generates an execution plan and does not execute. The *statement* indicates SQL statements.
- EXPLAIN ANALYZE *statement*: generates and executes an execution plan, and displays the execution summary. Then actual execution time statistics are

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

added to the display, including the total elapsed time expended within each plan node (in milliseconds) and the total number of rows it actually returned.

- EXPLAIN PERFORMANCE *statement*: generates and executes the execution plan, and displays all execution information.

To measure the run time cost of each node in the execution plan, the current execution of **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** adds profiling overhead to query execution. Running **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** on a query sometimes takes longer time than executing the query normally. The amount of overhead depends on the nature of the query, as well as the platform being used.

Therefore, if an SQL statement is not finished after being running for a long time, run the **EXPLAIN** statement to view the execution plan and then locate the fault. If the SQL statement has been properly executed, run the **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** statement to check the execution plan and information to locate the fault.

## 10.3.2.2 Description

As described in **10.3.2.1 Overview**, **EXPLAIN** displays the execution plan, but will not actually run SQL statements. **EXPLAIN ANALYZE** and **EXPLAIN PERFORMANCE** both will actually run SQL statements and return the execution information. This section describes the execution plan and execution information in detail.

## Execution Plans

The following SQL statement is used as an example:

```
select
   cjxh,
   count(1)
from dwcjk
group by cjxh;
```

Run the **EXPLAIN** command and the output is as follows:

```
openGauss=# explain select cjxh, count(1) from dwcjk group by cjxh;
 id |               operation                | E-rows | E-memory | E-width | E-costs
----+----------------------------------------+--------+----------+---------+---------
  1 | ->  Row Adapter                        |      1 |          |      52 | 58.42
  2 |    ->  Vector Streaming (type: GATHER) |      1 |          |      52 | 58.42
  3 |       ->  Vector Hash Aggregate        |      1 | 16MB     |      52 | 58.02
  4 |          ->  CStore Scan on dwcjk      |      1 | 1MB      |      44 | 58.00
(4 rows)
```

**Interpretation of the execution plan column (horizontal)**:

- **id**: ID of a node corresponding to each execution operator
- **operation**: name of an execution operator

  An operator prefixed with **Vector** is a vectorized executor operator, usually used in a query containing a column-store table.

  Streaming is a special operator. It implements the core data shuffle function of the distributed architecture. Streaming has three types, which correspond to different data shuffle functions in the distributed architecture:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

  - Streaming (type: GATHER): The CN collects data from DNs.
  - Streaming (type: REDISTRIBUTE): Data is redistributed to all the DNs based on selected columns.
  - Streaming (type: BROADCAST): Data on the current DN is broadcast to other DNs.
- **E-rows**: number of output rows estimated by each operator
- **E-memory**: estimated memory used by each operator on a DN. Only operators executed on DNs are displayed. In certain scenarios, the memory upper limit enclosed in parentheses will be displayed following the estimated memory usage.
- **E-width**: estimated width of an output tuple of each operator
- **E-costs**: execution cost estimated by each operator
  - **E-costs** is measured by the optimizer based on an overhead unit. Usually, fetching a disk page is defined as a unit. Other overhead parameters are set based on the unit.
  - The overhead of each node (specified by **E-costs**) includes the overheads of all its child nodes.
  - Such an overhead reflects only what the optimizer is concerned about, but does not consider the time for transferring result rows to the client. Although the time may play a very important role in the actual total time, it is ignored by the optimizer, because it cannot be changed by modifying the plan.

**Interpretation of the execution plan level (vertical)**:

1. Layer 1: **CStore Scan on dwcjk**

   The table scan operator scans the table **dwcjk** using **CStore Scan**. At this layer, data in the table **dwcjk** is read from a buffer or disk, and then transferred to the upper-layer node for calculation.

2. Layer 2: **Vector Hash Aggregate**

   Aggregation operator. It is used to perform aggregation (**GROUP BY**) on the data transferred from the lower layer.

3. Layer 3: **Vector Streaming (type: GATHER)**

   GATHER-type Shuffle operator. It is used to aggregate data from DNs to the CN.

4. Layer 4: **Row Adapter**

   Storage format conversion operator. It is used to convert memory data from column storage to row storage for client display.

If the operator in the top layer is **Data Node Scan**, set **enable_fast_query_shipping** to **off** to view the detailed execution plan. The following is an example plan.

```
openGauss=# explain select cjxh, count(1) from dwcjk group by cjxh;
                QUERY PLAN
--------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Node/s: All datanodes
(2 rows)
```

After **enable_fast_query_shipping** is set, the execution plan will be displayed as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# set enable_fast_query_shipping=off;
SET
openGauss=# explain select cjxh, count(1) from dwcjk group by cjxh;
 id |               operation                | E-rows | E-memory | E-width | E-costs
----+----------------------------------------+--------+----------+---------+---------
  1 | ->  Row Adapter                        |      1 |          |      52 | 58.42
  2 |    ->  Vector Streaming (type: GATHER) |      1 |          |      52 | 58.42
  3 |       ->  Vector Hash Aggregate        |      1 | 16MB     |      52 | 58.02

(4 rows)
```

**Keywords in the execution plan**:

1. Table access modes
   - Seq Scan

     Scans all rows of the table in sequence.
   - Index Scan

     The optimizer uses a two-step plan: the child plan node visits an index to find the locations of rows matching the index condition, and then the upper plan node actually fetches those rows from the table itself. Fetching rows separately is much more expensive than reading them sequentially, but because not all pages of the table have to be visited, this is still cheaper than a sequential scan. The upper-layer planning node sorts index-identified rows based on their physical locations before reading them. This minimizes the independent capturing overhead.

     If there are separate indexes on multiple columns referenced in **WHERE**, the optimizer might choose to use an **AND** or **OR** combination of the indexes. However, this requires the visiting of both indexes, so it is not necessarily a win compared to using just one index and treating the other condition as a filter.

     The following index scans featured with different sorting mechanisms are involved:

     - Bitmap index scan

       Fetches data pages using a bitmap.
     - Index scan using index_name

       Fetches table rows in index order, which makes them even more expensive to read. However, there are so few rows that the extra cost of sorting the row locations is unnecessary. This plan type is used mainly for queries fetching just a single row and queries having an **ORDER BY** condition that matches the index order, because no extra sorting step is needed to satisfy **ORDER BY**.
2. Table connection modes
   - Nested Loop

     A nested loop is used for queries that have a smaller data set connected. In a nested loop join, the foreign table drives the internal table and each row returned from the foreign table should have a matching row in the internal table. The returned result set of all queries should be less than 10,000. The table that returns a smaller subset will work as a foreign

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

table, and indexes are recommended for connection columns of the internal table.

- (Sonic) Hash Join

  A hash join is used for large tables. The optimizer uses a hash join, in which rows of one table are entered into an in-memory hash table, after which the other table is scanned and the hash table is probed for matches to each row. Sonic and non-Sonic hash joins differ in their hash table structures, which do not affect the execution result set.

- Merge Join

  In most cases, the execution performance of a merge join is lower than that of a hash join. However, if the source data has been pre-sorted and no more sorting is needed during the merge join, its performance excels.

3. Operators
   - sort

     Sorts the result set.

   - filter

     The **EXPLAIN** output shows the **WHERE** clause being applied as a **Filter** condition attached to the **Seq Scan** plan node. This means that the plan node checks the condition for each row it scans, and returns only the ones that meet the condition. The estimated number of output rows has been reduced because of the **WHERE** clause. However, the scan will still have to visit all 10,000 rows, as a result, the cost is not decreased. It increases a bit (by 10,000 x **cpu_operator_cost**) to reflect the extra CPU time spent on checking the **WHERE** condition.

   - LIMIT

     Limits the number of output execution results. If a **LIMIT** condition is added, not all rows are retrieved.

## Execution Information

In SQL optimization process, you can use **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** to check the SQL statement execution information. By comparing estimation differences between actual implementation and the optimizer, basis for service optimization is provided. **EXPLAIN PERFORMANCE** provides the execution information on each DN, whereas **EXPLAIN ANALYZE** does not.

The following SQL statement is used as an example:

```
select count(1) from tb1;
```

The output of running **EXPLAIN PERFORMANCE** is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=#  explain performance select count(1) from tbl;
 id |               operation                |    A-time      | A

This figure shows that the execution information can be classified into the following seven aspects.

1. The plan is displayed as a table, which contains 11 columns: **id**, **operation**, **A-time**, **A-rows**, **E-rows**, **E-distinct**, **Peak Memory**, **E-memory**, **A-width**, **E-width**, and **E-costs**. The definition of the plan-type columns (columns started with id, operation, or E) is the same as that of running **EXPLAIN**. For details, see **Execution Plans**. The definition of **A-time**, **A-rows**, **E-distinct**, **Peak Memory**, and **A-width** are described as follows:
   - **A-time**: execution completion time of the operator. Generally, **A-time** of the operator is two values enclosed with square brackets ([]), indicating the shortest time and longest time for completing the operator on all DNs, respectively.
   - **A-rows**: number of actual output tuples of the operator
   - **E-distinct**: estimated distinct value of the Hash Join operator
   - **Peak Memory**: peak memory of the operator on each DN
   - **A-width**: actual tuple width in each row of the current operator. This parameter is valid only for heavy memory operators, including (Vec)HashJoin, (Vec)HashAgg, (Vec)HashSetOp, (Vec)Sort, and (Vec)Materialize. The (Vec)HashJoin calculation width is the width of its right subtree operator and will be displayed on the right subtree.
2. **Predicate Information (identified by plan id)**:

   This part displays the static information that does not change in the plan execution process, such as some join conditions and filter information.
3. **Memory Information (identified by plan id)**:

   This part displays the memory usage information printed by certain operators (mainly Hash and Sort), including **peak memory**, **control memory**, **operator**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**memory**, **width**, **auto spread num**, and **early spilled**; and spill details, including **spill Time(s)**, **inner/outer partition spill num**, **temp file num**, spilled data volume, and **written disk IO [***min, max***]**.

4. **Targetlist Information (identified by plan id)**:

   This part displays the target columns provided by each operator.

5. **DataNode Information (identified by plan id)**:

   The execution time, CPU, and buffer usage of each operator are printed in this part.

6. **User Define Profiling**:

   This part displays CNs and DNs, DN and DN connection time, and some execution information at the storage layer.

7. **====== Query Summary =====**:

   The total execution time and network traffic, including the maximum and minimum execution time in the initialization and end phases on each DN, the time in the initialization, execution, and end phases on each CN, the system available memory and statement estimation memory information during the current statement execution, are printed in this part.

**NOTICE**

- The difference between **A-rows** and **E-rows** shows the deviation between the optimizer estimation and actual execution. Generally, if the deviation is larger, the plan generated by the optimizer is more improper, and more manual intervention and optimization are required.
- If the difference of the **A-time** values is larger, the operator computing skew (difference between execution time on different DNs) is larger, and more manual intervention and optimization are required.
- **Max Query Peak Memory** is often used to estimate the consumed memory of SQL statements, and is also used as an important basis for setting a running memory parameter during SQL statement optimization. Generally, the output from **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** is provided for the input for further optimization.

## 10.3.3 Optimization Process

You can analyze slow SQL statements to optimize them.

### Procedure

**Step 1** Collect all table statistics associated with the SQL statements. In a database, statistics indicate the source data of a plan generated by a planner. If no collection statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance. According to past experience, about 10% performance problems occurred because no statistics are collected. For details, see **10.3.4 Updating Statistics**.

**Step 2** View the execution plan to find out the cause. If the SQL statements have been running for a long period of time and not ended, run the **EXPLAIN** statement to view the execution plan and then locate the fault. If the SQL statement has been

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

properly executed, run the **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** statement to check the execution plan and information to locate the fault. For details about the execution plan, see **10.3.2 Introduction to the SQL Execution Plan**.

**Step 3** **Review and modify a table definition**.

**Step 4** For details about **EXPLAIN** or **EXPLAIN PERFORMANCE**, the reason why SQL statements are slowly located, and how to solve this problem, see **10.3.6 Typical SQL Optimization Methods**.

**Step 5** Generally, some SQL statements can be converted to its equivalent statements in all or certain scenarios by rewriting queries. SQL statements are simpler after they are rewritten. Some execution steps can be simplified to improve the performance. Query rewriting methods are universal in all databases. **10.3.7 Experience in Rewriting SQL Statements** describes several tuning methods by rewriting SQL statements.

**----End**

# 10.3.4 Updating Statistics

In a database, statistics indicate the source data of a plan generated by a planner. If no statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance.

## Background

The **ANALYZE** statement collects statistic about table contents in databases, which will be stored in the **PG_STATISTIC** system catalog. Then, the query optimizer uses the statistics to work out the most efficient execution plan.

After executing batch insertions and deletions, you are advised to run the **ANALYZE** statement on the table or the entire library to update statistics. By default, 30,000 rows of statistics are sampled. That is, the default value of the GUC parameter **default_statistics_target** is **100**. If the total number of rows in the table exceeds 1,600,000, you are advised to set **default_statistics_target** to **-2**, indicating that 2% of the statistics are collected.

For an intermediate table generated during the execution of a batch script or stored procedure, you also need to run the **ANALYZE** statement.

If there are multiple inter-related columns in a table and the conditions or grouping operations based on these columns are involved in the query, collect statistics about these columns so that the query optimizer can accurately estimate the number of rows and generate an effective execution plan. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)

## Procedure

Run the following commands to update the statistics about a table or the entire database:

```
ANALYZE tablename;                --Update statistics about a table.
ANALYZE;                        ---Update statistics about the entire database.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Run the following statements to perform statistics-related operations on multiple columns:

```
ANALYZE tablename ((column_1, column_2));                    --Collect statistics about column_1 and column_2 of tablename.

ALTER TABLE tablename ADD STATISTICS ((column_1, column_2));    --Declare statistics about column_1 and column_2 of tablename.
ANALYZE tablename;                                           --Collect statistics about one or more columns.

ALTER TABLE tablename DELETE STATISTICS ((column_1, column_2)); --Delete statistics about column_1 and column_2 of tablename or their statistics declaration.
```

**NOTICE**

After the statistics are declared for multiple columns by running the **ALTER TABLE** *tablename* **ADD STATISTICS** statement, the system collects the statistics about these columns next time **ANALYZE** is performed on the table or the entire database.

To collect the statistics, run the **ANALYZE** statement.

**NOTE**

Use **EXPLAIN** to show the execution plan of each SQL statement. If **rows=10** (the default value, probably indicating that the table has not been analyzed) is displayed in the **SEQ SCAN** output of a table, run the **ANALYZE** statement for this table.

## 10.3.5 Reviewing and Modifying a Table Definition

### 10.3.5.1 Overview

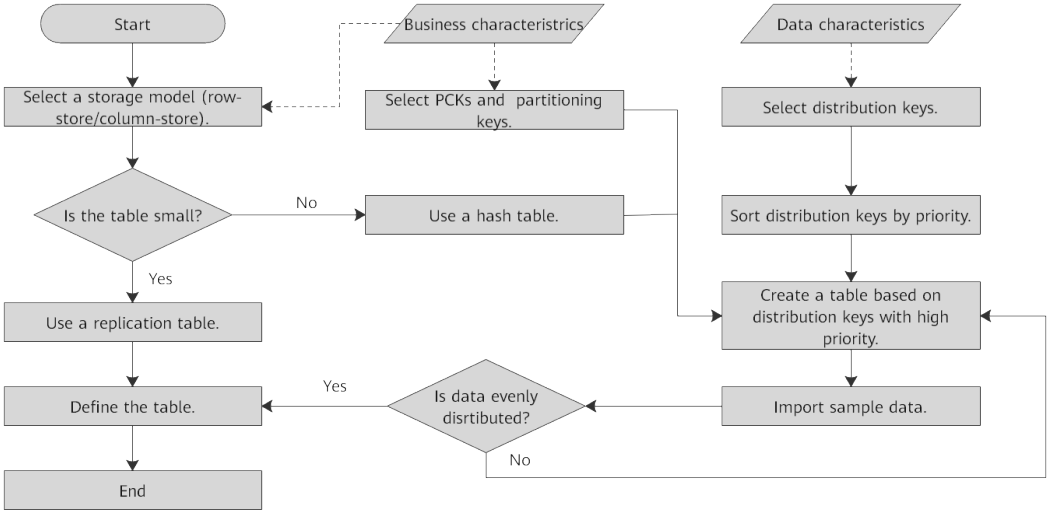
In a distributed framework, data is distributed on DNs. Data on one or more DNs is stored on a physical storage device. To properly define a table, you must:

1. **Evenly distribute data on each DN** to avoid the available capacity decrease of a cluster caused by insufficient storage space of the storage device associated with a DN. Specifically, select a proper distribution key to avoid data skew.
2. **Evenly assign table scanning tasks on each DN** to avoid that a single DN is overloaded by the table scanning tasks. Specifically, do not select columns in the equivalent filter of a base table as the distribution key.
3. **Reduce the data volume scanned** by using the partition pruning mechanism.
4. **Minimize random I/Os** by using clustering or partial clustering.
5. **Avoid data shuffle** to reduce the network pressure by selecting the **join-condition** or **group by** column as the distribution key.

The distribution key is the core for defining a table. **Figure 10-5** shows the procedure of defining a table. The table definition is created during the database design and is reviewed and modified during the SQL statement optimization.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Figure 10-5** Procedure of defining a table



## 10.3.5.2 Selecting a Storage Model

During database design, some key factors about table design will greatly affect the subsequent query performance of the database. Table design affects data storage as well. Scientific table design reduces I/O operations and minimizes memory usage, improving the query performance.

Selecting a model for table storage is the first step of table definition. Select a proper storage model for your service based on the following table.

| Storage Model | Application Scenario |
| --- | --- |
| Row storage | Point queries (simple index-based queries that only return a few records)<br>Scenarios requiring frequent addition, deletion, and modification operations |
| Column storage | Statistics analysis query, in which operations, such as group and join, are performed many times |

## 10.3.5.3 Selecting a Distribution Mode

In replication mode, full data in a table is copied to each DN in the cluster. This mode is used for tables containing a small volume of data. Full data in a table stored on each DN avoids data redistribution during the join operation. This reduces network costs and plan segment (each having a thread), but generates much redundant data. Generally, this mode is only used for small dimension tables.

In hash mode, hash values are generated for one or more columns. You can obtain the storage location of a tuple based on the mapping between DNs and the hash values. In a hash table, I/O resources on each node can be used during data read/write, which improves the read/write speed of a table. Generally, a table containing a large amount data is defined as a hash table.

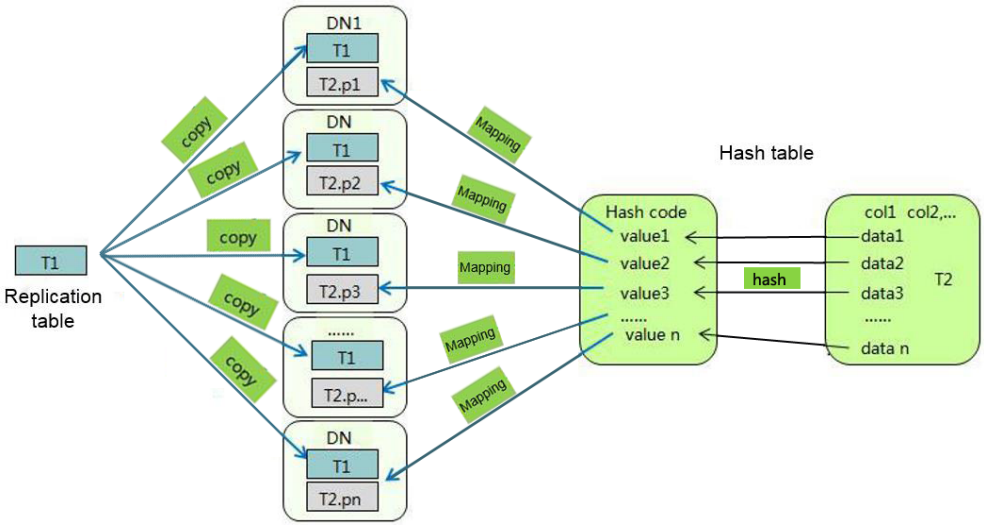
 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Range distribution and list distribution are user-defined distribution policies. Values in a distribution column are within a certain range or fall into a specific value range of the corresponding target DN. The two distribution modes facilitate flexible data management which, however, requires users equipped with certain data abstraction capability.

| Policy | Description | Application Scenario |
| --- | --- | --- |
| Hash | Table data is distributed on all DNs in the cluster. | Fact tables containing a large amount of data |
| Replication | Full data in a table is stored on every DN in the cluster. | Small tables and dimension tables |
| Range | Table data is mapped to specified columns based on the range and distributed to the corresponding DNs. | Users need to customize distribution rules. |
| List | Table data is mapped to specified columns based on specific values and distributed to corresponding DNs. | Users need to customize distribution rules. |

As shown in **Figure 10-6**, **T1** is a replication table and **T2** is a hash table.

**Figure 10-6** Replication tables and hash tables



## 10.3.5.4 Selecting Distribution Keys

Selecting a distribution key for a hash table is essential. Details are as follows:

1. **Ensure that the column values are discrete so that data can be evenly distributed to each DN.** You can select the primary key of the table as the distribution key. For example, for a person information table, choose the ID card number column as the distribution key.
2. **Do not select the column that has a constant filter.** For example, if a constant constraint (for example, zqdh= '000001') exists on the **zqdh** column

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

in some queries on the **dwcjk** table, you are not advised to use **zqdh** as the distribution key.

3. **Select the join condition as the distribution key**, so that join tasks can be pushed down to DNs to execute, reducing the amount of data transferred between the DNs.

For a hash table, an improper distribution key may cause data skew or poor I/O performance on certain DNs. Therefore, you need to check the table to ensure that data is evenly distributed on each DN. You can run the following SQL statement to check for data skew:

```
select
xc_node_id, count(1)
from tablename
group by xc_node_id
order by xc_node_id desc;
```

**xc_node_id** corresponds to a DN. Generally, **over 5% difference between the amount of data on different DNs is regarded as data skew. If the difference is over 10%, choose another distribution key.**

Multiple distribution keys can be selected in GaussDB to evenly distribute data.

You can select the distribution key of the range or list distribution table as required. In addition to selecting a proper distribution key, pay attention to the impact of distribution rules on data distribution.

## 10.3.5.5 Using PCKs

The PCK is the column-store-based technology. It can minimize or maximize sparse indexes to quickly filter base tables. You are advised to select a maximum of two columns as PCKs. Use the following principles to specify PCKs:

1. The selected PCKs must be restricted by simple expressions in base tables. Such constraints are usually represented by *col op const*, in which *col* indicates the column name, *op* indicates operators, (including =, >, >=, <=, and <), and *const* indicates constants.
2. Select columns that are frequently selected (to filter much more undesired data) in simple expressions.
3. List the less frequently selected columns on the top.
4. List the columns of the enumerated type at the top.

## 10.3.5.6 Using Partitioned Tables

Partitioning refers to splitting what is logically one large table into smaller physical pieces based on specific schemes. The table based on the logic is called a partitioned table, and a physical piece is called a partition. Data is stored on these physical partitions, instead of the logical partitioned table. A partitioned table has the following advantages over an ordinary table:

1. High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
2. High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
3. Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

GaussDB supports range partitioned tables.

Range partitioned table: Data in different ranges is mapped to different partitions. The range is determined by the partition key specified during the partitioned table creation. The partition key is usually a date. For example, sales data is partitioned by month.

### 10.3.5.7 Selecting a Data Type

Use the following principles to select efficient data types:

1. **Select data types that facilitate data calculation.**

   Generally, the calculation of integers (including common comparison calculations, such as =, >, <, ≥, ≤, and ≠ and group by) is more efficient than that of strings and floating point numbers. For example, if you need to perform a point query on a column-store table whose numeric column is used as a filter condition, the query will take over 10s. If you change the data type from **NUMERIC** to **INT**, the query duration will be reduced to 1.8s.

2. **Select data types with a short length.**

   Data types with short length reduce both the data file size and the memory used for computing, improving the I/O and computing performance. For example, use **SMALLINT** instead of **INT**, and **INT** instead of **BIGINT**.

3. **Use the same data type for a join.**

   You are advised to use the same data type for a join. To join columns with different data types, the database needs to convert them to the same type, which leads to additional performance overheads.

## 10.3.6 Typical SQL Optimization Methods

SQL optimization involves continuous analysis and trying. Queries are run before they are used for services to determine whether the performance meets requirements. If it does not, queries will be optimized by **checking the execution plan** and identifying the causes. Then, the queries will be run and optimized again until they meet the requirements.

### 10.3.6.1 Optimizing SQL Self-Diagnosis

Performance issues may occur when you query data or run the **INSERT**, **DELETE**, **UPDATE**, or **CREATE TABLE AS** statement. In this case, you can query the **warning** column in the **15.3.88 GS_WLM_SESSION_STATISTICS**, **15.3.83 GS_WLM_SESSION_HISTORY**, and **15.2.33 GS_WLM_SESSION_QUERY_INFO_ALL** views to obtain reference for performance optimization.

Alarms that can trigger SQL self diagnosis depend on the settings of **resource_track_level**. If **resource_track_level** is set to **query**, alarms about the failures in collecting column statistics and pushing down SQL statements will trigger the diagnosis. If **resource_track_level** is set to **operator**, all alarms will trigger the diagnosis.

Whether a SQL plan will be diagnosed depends on the settings of **resource_track_cost**. A SQL plan will be diagnosed only if its execution cost is greater than **resource_track_cost**. You can use the **EXPLAIN** keyword to check the plan execution cost.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The SQL self-diagnosis function is affected by the **enable_analyze_check** parameter. Ensure that the function is enabled before using it.

If a large number of statements are executed, certain data may fail to be collected due to memory control. In this case, you can increase the value of **instr_unique_sql_count**.

## Alarms

Currently, the following performance alarms will be reported:

- Some column statistics are not collected.

An alarm will be reported if some column statistics are not collected. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) For details about the optimization, see **10.3.4 Updating Statistics** and **10.3.6.4 Optimizing Statistics**.

An alarm will also be reported if column statistics are not collected for queries on OBS foreign tables. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) The performance of the **ANALYZE** statement executed for OBS foreign tables is poor and seems inefficient for a simple query. Run this statement as needed.

Example alarms:

No statistics about a table are not collected.

```
Statistic Not Collect:
    schema_test.t1
```

The statistics about a single column are not collected.

```
Statistic Not Collect:
    schema_test.t2(c1,c2)
```

The statistics about multiple columns are not collected.

```
Statistic Not Collect:
    schema_test.t3((c1,c2))
```

The statistics about a single column and multiple columns are not collected.

```
Statistic Not Collect:
    schema_test.t4(c1,c2)    schema_test.t4((c1,c2))
```

- SQL statements are not pushed down.

  The cause details are displayed in the alarms. For details about the optimization, see **10.3.6.2 Optimizing Statement Pushdown**.

  - If the pushdown failure is caused by functions, the function names are displayed in the alarm.
  - If the pushdown failure is caused by syntax, the alarm indicates that the syntax does not support pushdown. For example, the syntax containing the **With Recursive**, **Distinct On**, or **Row** expression, and syntax whose return value is of record type do not support pushdown.

Example alarms:

```
SQL is not plan-shipping, reason : "With Recursive" can not be shipped"
SQL is not plan-shipping, reason : "Function now() can not be shipped"
SQL is not plan-shipping, reason : "Function string_agg() can not be shipped"
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- In a hash join, the larger table is used as the inner table.

An alarm will be reported if the number of rows in the inner table reaches or exceeds 10 times of that in the outer table, more than 100 thousand of inner-table rows are processed on each DN in average, and the join statement has spilled to disks. You can view the **query_plan** column in **15.3.83 GS_WLM_SESSION_HISTORY** to check whether the hash join is used. For details about the optimization, see **10.3.9 Hint-based Tuning**.

Example alarms:

```
PlanNode[7] Large Table is INNER in HashJoin "Vector Hash Aggregate"
```

- **nestloop** is used in a large-table equivalent join.

An alarm will be reported if **nestloop** is used in an equivalent join where more than 100 thousand of the larger-table rows are processed on each DN in average. You can view the **query_plan** column of **15.3.83 GS_WLM_SESSION_HISTORY** to check whether **nestloop** is used. For details about the optimization, see **15.3.83 GS_WLM_SESSION_HISTORY**.

Example alarms:

```
PlanNode[5] Large Table with Equal-Condition use Nestloop"Nested Loop"
```

- A large table is broadcasted.

An alarm will be reported if more than 100 thousand of rows are broadcast on each DN in average. For details about the optimization, see **10.3.9 Hint-based Tuning**.

Example alarms:

```
PlanNode[5] Large Table in Broadcast "Streaming(type: BROADCAST dop: 1/2)"
```

- Data skew occurs.

An alarm will be reported if the number of rows processed on any DN exceeds 100 thousand, and the number of rows processed on a DN reaches or exceeds 10 times of that processed on another DN. For the optimization, see **10.4.1 Case: Selecting an Appropriate Distribution Key** and **10.3.6.6 Optimizing Data Skew**.

Example alarms:

```
PlanNode[6] DataSkew:"Seq Scan", min_dn_tuples:0, max_dn_tuples:524288
```

- Estimation is inaccurate.

An alarm will be reported if the maximum number or the estimated maximum number of rows processed on a DN is over 10 thousand, and the larger number reaches or exceeds 10 times of the smaller one. For details about the optimization, see **10.3.9 Hint-based Tuning**.

Example alarms:

```
PlanNode[5] Inaccurate Estimation-Rows: "Hash Join" A-Rows:0, E-Rows:52488
```

## Restrictions

1. An alarm contains a maximum of 2048 characters. If the length of an alarm exceeds this value (for example, a large number of long table names and column names are displayed in the alarm when their statistics are not collected), a warning instead of an alarm will be reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
WARNING, "Planner issue report is truncated, the rest of planner issues will be skipped"
```

2. If a query statement contains the **Limit** operator, alarms of operators lower than **Limit** will not be reported.
3. For alarms about data skew and inaccurate estimation, only alarms on the lower-layer nodes in a plan tree will be reported. This is because the same alarms on the upper-level nodes may be triggered by problems on the lower-layer nodes. For example, if data skew occurs on the **Scan** node, data skew may also occur in operators (for example, **Hashagg**) at the upper layer.

## 10.3.6.2 Optimizing Statement Pushdown

### Statement Pushdown

Currently, the GaussDB optimizer can use three methods to develop statement execution policies in the distributed framework: generating a statement pushdown plan, a distributed execution plan, or a distributed execution plan for sending statements.

- A statement pushdown plan pushes query statements from a CN down to DNs for execution and returns the execution results to the CN.
- In a distributed execution plan, a CN compiles and optimizes query statements, generates a plan tree, and then sends the plan tree to DNs for execution. After the statements have been executed, execution results will be returned to the CN.
- A distributed execution plan for sending statements pushes queries that can be pushed down (mostly base table scanning statements) to DNs for execution. Then, the plan obtains the intermediate results and sends them to the CN, on which the remaining queries are to be executed.

The third policy sends many intermediate results from DNs to the CN for further execution. In this case, the CN performance bottleneck (in bandwidth, storage, and computing) is caused by statements that cannot be pushed down to DNs. Therefore, you are not advised to use the query statements where only the third policy applies.

Statements cannot be pushed down to DNs if they have **functions that do not support pushdown** or **syntax that does not support pushdown**. Generally, you can rewrite the execution statements to solve the problem.

### Typical Scenarios of Statement Pushdown

In the GaussDB optimizer, if you want to support statement pushdown, set the GUC parameter **enable_fast_query_shipping** to **on**. Generally, no execution plan operator is displayed after the EXPLAIN statement. If the keyword similar to "Data Node Scan on" is displayed in the first line (excluding the plan format), the statement has been pushed down to DNs for execution. The following describes statement pushdown and its supported scope from three scenarios.

**1. Pushdown of single-table query statements**

In a distributed database, to query a single table, whether the current statement can be pushed down depends on whether the CN needs to participate in calculation instead of simply collecting data. If the CN needs to further calculate the DN result, the statement cannot be pushed down. Generally, statements with

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

keywords such as **agg**, **windows function**, **limit/offset**, **sort**, **distinct** cannot be pushed down.

- Pushdown: Simple queries can be pushed down without further calculation on the CN.

```
openGauss=# explain select * from t where c1 > 1;
                            QUERY PLAN
------------------------------------------------------------------------------
 Data Node Scan on "__REMOTE_FQS_QUERY__"  (cost=0.00..0.00 rows=0 width=0)
   Node/s: All datanodes
(2 rows)
```

- Non-pushdown: A CN with the **limit** clause cannot simply send statements to DNs and collect data, which is inconsistent with the semantics of the **limit** clause.

```
openGauss=# explain select * from t limit 1;
                                QUERY PLAN
---------------------------------------------------------------------------------------
 Limit  (cost=0.00..0.00 rows=1 width=12)
   ->  Data Node Scan on "__REMOTE_LIMIT_QUERY__"  (cost=0.00..0.00 rows=1 width=12)
         Node/s: All datanodes
(3 rows)
```

- Non-pushdown: A CN with the **aggregate** function cannot simply push down statements. Instead, it needs to further aggregate the results collected from DNs.

```
openGauss=# explain select sum(c1), count(*) from t;
                                QUERY PLAN
---------------------------------------------------------------------------------------
 Aggregate  (cost=0.10..0.11 rows=1 width=20)
   ->  Data Node Scan on "__REMOTE_GROUP_QUERY__"  (cost=0.00..0.00 rows=20 width=4)
         Node/s: All datanodes
(3 rows)
```

**2. Pushdown of multi-table query statements**

In the multi-table query scenario, whether a statement can be pushed down depends on the **join** condition and distribution columns. That is, if the **join** condition matches the distribution columns of the table, the statement can be pushed down. Otherwise, the statement cannot be pushed down. Generally, a replication table can be pushed down.

- Create two hash distribution tables.

```
openGauss=# create table t(c1 int, c2 int, c3 int)distribute by hash(c1);
CREATE TABLE
openGauss=# create table t1(c1 int, c2 int, c3 int)distribute by hash(c1);
CREATE TABLE
```

- Pushdown: The **join** condition meets the hash distribution column attributes of two tables.

```
openGauss=# explain select * from t1 join t on t.c1 = t1.c1;
                            QUERY PLAN
------------------------------------------------------------------------------
 Data Node Scan on "__REMOTE_FQS_QUERY__"  (cost=0.00..0.00 rows=0 width=0)
   Node/s: All datanodes
(2 rows)
```

- Non-pushdown: The **join** condition does not meet the hash distribution column attribute. That is, **t1.c2** is not the distribution column of **t1**.

```
openGauss=# explain select * from t1 join t on t.c1 = t1.c2;
                                  QUERY PLAN
-------------------------------------------------------------------------------------------
 Hash Join  (cost=0.25..0.53 rows=20 width=24)
   Hash Cond: (t1.c2 = t.c1)
   ->  Data Node Scan on t1 "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=20 width=12)
         Node/s: All datanodes
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
  ->  Hash  (cost=0.00..0.00 rows=20 width=12)
        ->  Data Node Scan on t "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=20 width=12)
              Node/s: All datanodes
(7 rows)
```

**3. Special scenarios**

In some special scenarios, for example, a statement containing the **with recursive** clause or a column-store table cannot be pushed down.

## Checking Whether the Execution Plan Has Been Pushed Down to DNs

Perform the following procedure to quickly determine whether the execution plan can be pushed down to DNs:

**Step 1** Set the GUC parameter **enable_fast_query_shipping** to **off** to use the distributed framework policy for the query optimizer.

```
SET enable_fast_query_shipping = off;
```

**Step 2** View the execution plan.

If the execution plan contains Data Node Scan nodes, the execution plan is a distributed execution plan for sending statements and cannot be pushed down. If the execution plan contains Streaming nodes, the SQL statements can be pushed down to DNs.

For example:

```
select
count(ss.ss_sold_date_sk order by ss.ss_sold_date_sk)c1
from store_sales ss, store_returns sr
where
sr.sr_customer_sk = ss.ss_customer_sk;
```

The execution plan is as follows, which indicates that the SQL statement cannot be pushed down.

```
                            QUERY PLAN
------------------------------------------------------------------------------
Aggregate
->  Hash Join
Hash Cond: (ss.ss_customer_sk = sr.sr_customer_sk)
->  Data Node Scan on store_sales "_REMOTE_TABLE_QUERY_"
Node/s: All datanodes
->  Hash
->  Data Node Scan on store_returns "_REMOTE_TABLE_QUERY_"
Node/s: All datanodes
(8 rows)
```

**----End**

## Syntax That Does Not Support Pushdown

SQL syntax that does not support pushdown is described using the following table definition examples:

```
openGauss=# CREATE TABLE CUSTOMER1
(
    C_CUSTKEY     BIGINT NOT NULL
  , C_NAME        VARCHAR(25) NOT NULL
  , C_ADDRESS     VARCHAR(40) NOT NULL
  , C_NATIONKEY   INT NOT NULL
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
  , C_PHONE       CHAR(15) NOT NULL
  , C_ACCTBAL     DECIMAL(15,2)   NOT NULL
  , C_MKTSEGMENT  CHAR(10) NOT NULL
  , C_COMMENT     VARCHAR(117) NOT NULL
)
DISTRIBUTE BY hash(C_CUSTKEY);
openGauss=# CREATE TABLE test_stream(a int, b float);--float does not support redistribution.
openGauss=# CREATE TABLE sal_emp ( c1 integer[] ) DISTRIBUTE BY replication;
```

- The **returning** statement cannot be pushed down.

```
openGauss=# explain update customer1 set C_NAME = 'a' returning c_name;
                            QUERY PLAN
------------------------------------------------------------------
 Update on customer1  (cost=0.00..0.00 rows=30 width=187)
   Node/s: All datanodes
   Node expr: c_custkey
   ->  Data Node Scan on customer1 "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=30 width=187)
         Node/s: All datanodes
(5 rows)
```

- If a SQL statement contains the aggregate functions using **ORDER BY**, this statement cannot be pushed down.

```
openGauss=# explain verbose select count ( c_custkey order by c_custkey) from customer1;

                        QUERY PLAN
------------------------------------------------------------------- Aggregate  (cost=2.50..2.51 rows=1 width=8)
   Output: count(customer1.c_custkey ORDER BY customer1.c_custkey)
   ->  Data Node Scan on customer1 "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=30 width=8)
         Output: customer1.c_custkey
         Node/s: All datanodes
         Remote query: SELECT c_custkey FROM ONLY public.customer1 WHERE true
(6 rows)
```

- If a SQL statement contains **COUNT(DISTINCT *expr*)** and columns in **COUNT(DISTINCT *expr*)** do not support redistribution, this statement cannot be pushed down.

```
openGauss=# explain verbose select count(distinct b) from test_stream;
                                    QUERY PLAN
------------------------------------------------------------------------- Aggregate  (cost=2.50..2.51 rows=1 width=8)
   Output: count(DISTINCT test_stream.b)
   ->  Data Node Scan on test_stream "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=30 width=8)
         Output: test_stream.b
         Node/s: All datanodes
         Remote query: SELECT b FROM ONLY public.test_stream WHERE true
(6 rows)
```

- A statement containing **DISTINCT ON** cannot be pushed down.

```
openGauss=# explain verbose select distinct on (c_custkey) c_custkey from customer1 order by
c_custkey;
                                    QUERY PLAN
------------------------------------------------------------------------- Unique  (cost=49.83..54.83 rows=30 width=8)
   Output: customer1.c_custkey
   ->  Sort  (cost=49.83..52.33 rows=30 width=8)
         Output: customer1.c_custkey
         Sort Key: customer1.c_custkey
         ->  Data Node Scan on customer1 "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=30
width=8)
               Output: customer1.c_custkey
               Node/s: All datanodes
               Remote query: SELECT c_custkey FROM ONLY public.customer1 WHERE true
(9 rows)
```

- A statement containing array expressions cannot be pushed down.

```
openGauss=# explain verbose select array[c_custkey,1] from customer1 order by c_custkey;

                        QUERY PLAN
------------------------------------------------------------------- Sort  (cost=49.83..52.33 rows=30 width=8)
   Output: (ARRAY[customer1.c_custkey, 1::bigint]), customer1.c_custkey
   Sort Key: customer1.c_custkey
   ->  Data Node Scan on "__REMOTE_SORT_QUERY__"  (cost=0.00..0.00 rows=30 width=8)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
        Output: (ARRAY[customer1.c_custkey, 1::bigint]), customer1.c_custkey
        Node/s: All datanodes
        Remote query: SELECT ARRAY[c_custkey, 1::bigint], c_custkey FROM ONLY public.customer1
WHERE true ORDER BY 2
(7 rows)
```

- The following table describes the scenarios where a statement containing **WITH RECURSIVE** cannot be pushed down in the current version, as well as the causes.

| No. | Scenario | Cause of Not Supporting Pushdown |
| --- | --- | --- |
| 1 | The query contains foreign tables. | LOG: SQL can't be shipped, reason: RecursiveUnion contains ForeignScan is not shippable (In this table, **LOG** describes the cause of not supporting pushdown.)<br>In the current version, queries containing foreign tables do not support pushdown. |
| 2 | Multiple node groups | LOG: SQL can't be shipped, reason: With-Recursive under multi-nodegroup scenario is not shippable<br>In the current version, pushdown is supported only when all base tables are stored and computed in the same node group. |
| 3 | **ALL** is not used for **UNION**. In this case, the return result is deduplicated. | LOG: SQL can't be shipped, reason: With-Recursive does not contain "ALL" to bind recursive & none-recursive branches<br>For example:<br>`WITH recursive t_result AS (`<br>`SELECT dm,sj_dm,name,1 as level`<br>`FROM test_rec_part`<br>`WHERE sj_dm > 10`<br>`UNION`<br>`SELECT t2.dm,t2.sj_dm,t2.name\|\|' > '\|\|`<br>`t1.name,t1.level+1`<br>`FROM t_result t1`<br>`JOIN test_rec_part t2 ON t2.sj_dm = t1.dm`<br>`)`<br>`SELECT * FROM t_result t;` |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| No. | Scenario | Cause of Not Supporting Pushdown |
| --- | --- | --- |
| 4 | A base table contains the system catalog. | LOG: SQL can't be shipped, reason: With-Recursive contains system table is not shippable<br>For example:<br>WITH RECURSIVE x(id) AS<br>(<br>select count(1) from pg_class where oid=1247<br>UNION ALL<br>SELECT id+1 FROM x WHERE id < 5<br>), y(id) AS<br>(<br>select count(1) from pg_class where oid=1247<br>UNION ALL<br>SELECT id+1 FROM x WHERE id < 10<br>)<br>SELECT y.*, x.* FROM y LEFT JOIN x USING (id) ORDER BY 1; |
| 5 | Only **VALUES** is used for scanning base tables. In this case, the statement can be executed on the CN, and DNs are unnecessary. | LOG: SQL can't be shipped, reason: With-Recursive contains only values rte is not shippable<br>For example:<br>WITH RECURSIVE t(n) AS (<br>VALUES (1)<br>UNION ALL<br>SELECT n+1 FROM t WHERE n < 100<br>)<br>SELECT sum(n) FROM t; |
| 6 | Only the recursion part has correlation conditions of correlated subqueries, and the non-recursion part has no correlation condition. | LOG: SQL can't be shipped, reason: With-Recursive recursive term correlated only is not shippable<br>For example:<br>select  a.ID,a.Name,<br>(<br>with recursive cte as (<br>select ID, PID, NAME from b where b.ID = 1<br>union all<br>select parent.ID,parent.PID,parent.NAME from cte as child join b as parent on child.pid=parent.id<br>where child.ID = a.ID<br>)<br>select NAME from cte limit 1<br>) cName<br>from<br>(<br>select id, name, count(*) as cnt<br>from a group by id,name<br>) a order by 1,2; |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| No. | Scenario | Cause of Not Supporting Pushdown |
| --- | --- | --- |
| 7 | The **replicate** plan is used for **limit** in the non-recursion part but the **hash** plan is used in the recursion part, resulting in conflicts. | LOG: SQL can't be shipped, reason: With-Recursive contains conflict distribution in none-recursive(Replicate) recursive(Hash)<br>For example:<br>`WITH recursive t_result AS (`<br>`select * from(`<br>`SELECT dm,sj_dm,name,1 as level`<br>`FROM test_rec_part`<br>`WHERE sj_dm < 10 order by dm limit 6 offset 2)`<br>`UNION all`<br>`SELECT t2.dm,t2.sj_dm,t2.name||' > '|| t1.name,t1.level+1`<br>`FROM t_result t1`<br>`JOIN test_rec_part t2 ON t2.sj_dm = t1.dm`<br>`)`<br>`SELECT * FROM t_result t;` |
| 8 | **recursive** of multiple-layers are nested. That is, a **recursive** is nested in the recursion part of another **recursive**. | LOG: SQL can't be shipped, reason: Recursive CTE references recursive CTE "cte"<br>For example:<br>`with recursive cte as`<br>`(`<br>`select * from rec_tb4 where id<4`<br>`union all`<br>`select h.id,h.parentID,h.name from`<br>`(`<br>`with recursive cte as`<br>`(`<br>`select * from rec_tb4 where id<4`<br>`union all`<br>`select h.id,h.parentID,h.name from rec_tb4 h inner join cte c on h.id=c.parentID`<br>`)`<br>`SELECT id ,parentID,name from cte order by parentID`<br>`) h`<br>`inner join cte  c on h.id=c.parentID`<br>`)`<br>`SELECT id ,parentID,name from cte order by parentID,1,2,3;` |

## Functions That Do Not Support Pushdown

The following describes the volatility of functions. In GaussDB, every function has a volatility classification, with the possibilities being:

- **IMMUTABLE**

  Indicates that the function always returns the same result if the parameter values are the same.

- **STABLE**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same parameter value, but its result varies by SQL statements.

- **VOLATILE**

  Indicates that the function value can change in a single table scan and no optimization is performed.

The volatility of a function can be obtained by querying for its **provolatile** column in **pg_proc**. The value **i** indicates immutable, **s** indicates stable, and **v** indicates volatile. The valid values of the **proshippable** column in **pg_proc** are **t**, **f**, and **NULL**. This column and the **provolatile** column together describe whether a function is pushed down.

- If the **provolatile** of a function is **i**, the function can be pushed down regardless of the value of **proshippable**.
- If the **provolatile** of a function is **s** or **v**, the function can be pushed only if the value of **proshippable** is **t**.
- CTEs containing **random**, **exec_hadoop_sql**, or **exec_on_extension** are not pushed down, because pushdown may lead to incorrect results.

When creating a customized function, you can specify the values of **provolatile** and **proshippable**. For details, see **12.14.61 CREATE FUNCTION**.

In scenarios where a function does not support pushdown, perform one of the following as required:

- If it is a system function, replace it with a functionally equivalent one.
- If it is a customized function, check whether its **provolatile** and **proshippable** are correctly defined.

## Example: Customized Functions

Define a customized function that generates fixed output for a certain input as the **immutable** type.

Take the sales information of TPC Benchmark DS (TPC-DS) as an example. If you want to write a function to calculate the discount data of a product, you can define the function as follows:

```
CREATE FUNCTION func_percent_2 (NUMERIC, NUMERIC) RETURNS NUMERIC
AS 'SELECT $1 / $2 WHERE $2 > 0.01'
LANGUAGE SQL
VOLATILE;
```

Run the following statement:

```
SELECT func_percent_2(ss_sales_price, ss_list_price)
FROM store_sales;
```

The execution plan is as follows:

```
 Data Node Scan on store_sales "_REMOTE_TABLE_QUERY_"
   Output: func_percent_2(store_sales.ss_sales_price, store_sales.ss_list_price)
   Remote query: SELECT ss_sales_price, ss_list_price FROM ONLY store_sales WHERE true
(3 rows)
```

**func_percent_2** is not pushed down, and **ss_sales_price** and **ss_list_price** are executed on a CN. In this case, a large amount of resources on the CN is consumed, and the performance deteriorates as a result.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

In this example, the function generates the same output when the same input is provided. Therefore, we can modify the function to the following one:

```
CREATE FUNCTION func_percent_1 (NUMERIC, NUMERIC) RETURNS NUMERIC
AS 'SELECT $1 / $2 WHERE $2 > 0.01'
LANGUAGE SQL
IMMUTABLE;
```

Run the following statement:

```
SELECT func_percent_1(ss_sales_price, ss_list_price)
FROM store_sales;
```

The execution plan is as follows:

```
 Data Node Scan
   Output: (func_percent_1(store_sales.ss_sales_price, store_sales.ss_list_price))
   Remote query: SELECT func_percent_1(ss_sales_price, ss_list_price) AS func_percent_1 FROM store_sales
(3 rows)
```

**func_percent_1** is pushed down to DNs for quicker execution. (In TPC-DS 1000X, where three CNs and 18 DNs are used, the query efficiency is improved by over 100 times).

## Example 2: Pushing Down the Sorting Operation

For details, see **10.4.4 Case: Pushing Down Sort Operations to DNs**.

## 10.3.6.3 Optimizing Subqueries

## Background

When an application runs a SQL statement to operate the database, a large number of subqueries are used because they are more clear than table join. Especially in complicated query statements, subqueries have more complete and independent semantics, which makes SQL statements clearer and easier to understand. Therefore, subqueries are widely used.

In GaussDB, subqueries can also be called sublinks based on the location of subqueries in SQL statements.

- Subquery: corresponds to a range table (RangeTblEntry) in the query parse tree. That is, a subquery is a **SELECT** statement following immediately after the **FROM** keyword.
- Sublink: corresponds to an expression in the query parsing tree. That is, a sublink is a statement in the **WHERE** or **ON** clause or in the target list.

  In conclusion, a subquery is a RangeTblEntry and a sublink is an expression in the query parsing tree. A sublink can be found in constraint conditions and expressions. In GaussDB, sublinks can be classified into the following types:

  - exist_sublink: corresponds to the **EXIST** and **NOT EXIST** statements.
  - any_sublink: corresponds to the *op* **ANY(SELECT...)** statement. *op* can be the <, >, or = operator. **IN/NOT IN (SELECT...)** also belongs to this type.
  - all_sublink: corresponds to the *op* **ALL(SELECT...)** statement. *op* can be the <, >, or = operator.
  - rowcompare_sublink: corresponds to the **RECORD** *op* **(SELECT...)** statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- expr_sublink: corresponds to the **(SELECT** *with a single target list item...*) statement.
- array_sublink: corresponds to the **ARRAY(SELECT...)** statement.
- cte_sublink: corresponds to the **WITH(...)** query statement.

The exist_sublink and any_sublink are pulled up by the optimization engine of GaussDB. In addition, expr_sublink can also be pulled up. However, because of the flexible use of subqueries in SQL statements, complex subqueries may affect query performance. If you do not want to pull up expr_sublink, set the GUC parameter **rewrite_rule**. For details, see **19.8.4 Other Optimizer Options**. Subqueries are classified into non-correlated subqueries and correlated subqueries.

- **Non-correlated subqueries**

  The execution of a subquery is independent from attributes of the outer query. In this way, a subquery can be executed before outer queries.

  For example:

```
select t1.c1,t1.c2
from t1
where t1.c1 in (
   select c2
   from t2
   where t2.c2 IN (2,3,4)
);
                        QUERY PLAN
------------------------------------------------------------------
Streaming (type: GATHER)
  Node/s: All datanodes
  ->  Hash Right Semi Join
        Hash Cond: (t2.c2 = t1.c1)
        ->  Streaming(type: REDISTRIBUTE)
              Spawn on: All datanodes
              ->  Seq Scan on t2
                    Filter: (c2 = ANY ('{2,3,4}'::integer[]))
        ->  Hash
              ->  Seq Scan on t1
(10 rows)
```

- **Correlated subqueries**

  The execution of a subquery depends on some attributes (used as **AND** conditions of the subquery) of outer queries. In the following example, **t1.c1** in the **t2.c1 = t1.c1** condition is a correlated attribute. Such a subquery depends on outer queries and needs to be executed once for each outer query.

  For example:

```
select t1.c1,t1.c2
from t1
where t1.c1 in (
   select c2
   from t2
   where t2.c1 = t1.c1 AND t2.c2 in (2,3,4)
);
                              QUERY PLAN
-----------------------------------------------------------------------
Streaming (type: GATHER)
  Node/s: All datanodes
  ->  Seq Scan on t1
        Filter: (SubPlan 1)
        SubPlan 1
          ->  Result
                Filter: (t2.c1 = t1.c1)
                ->  Materialize
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
                    ->  Streaming(type: BROADCAST)
                        Spawn on: All datanodes
                        ->  Seq Scan on t2
                            Filter: (c2 = ANY ('{2,3,4}'::integer[]))
(12 rows)
```

## Sublink Optimization on GaussDB

To optimize a sublink, a subquery is pulled up to join with tables in outer queries, preventing the subquery from being converted into a plan involving subplans and broadcast. You can run the **EXPLAIN** statement to check whether a subquery is converted into such a plan.

For example:

```
select t1.c1,t1.c2
from t1
where t1.c1 in (
    select c2
    from t2
    where t2.c1 = t1.c1
);
```

```
QUERY PLAN
-------------------------------------------------------------
Streaming (type: GATHER)
  Node/s: All datanodes
  ->  Seq Scan on t1
        Filter: (SubPlan 1)
        SubPlan 1
          ->  Result
                Filter: (t2.c1 = t1.c1)
                ->  Materialize
                      ->  Streaming(type: BROADCAST)
                            Spawn on: All datanodes
                            ->  Seq Scan on t2
(11 rows)
```

- **Sublink-release scenarios supported by GaussDB**
  - Pulling up the **IN** sublink
    - The subquery cannot contain columns in the outer query (columns in more outer queries are allowed).
    - The subquery cannot contain volatile functions.

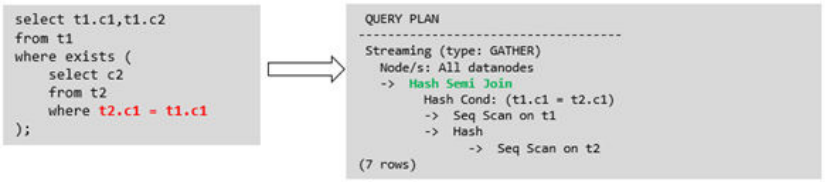
```
select t1.c1,t1.c2
from t1
where t1.c1 in (
    select c2
    from t2
    where t2.c1 = 1
);
```

```
QUERY PLAN
-------------------------------------------------
Streaming (type: GATHER)
  Node/s: All datanodes
  ->  Nested Loop Semi Join
        Join Filter: (t1.c1 = t2.c2)
        ->  Seq Scan on t1
        ->  Materialize
              ->  Streaming(type: REDISTRIBUTE)
                    Spawn on: datanode1
                    ->  Seq Scan on t2
                          Filter: (c1 = 1)
(10 rows)
```

  - Pulling up the **EXISTS** sublink

    The **WHERE** clause must contain a column in the outer query. Other parts of the subquery cannot contain the column. Other restrictions are as follows:
    - The subquery must contain the **FROM** clause.
    - The subquery cannot contain the **WITH** clause.
    - The subquery cannot contain aggregate functions.
    - The subquery cannot contain a **SET**, **SORT**, **LIMIT**, **WindowAgg**, or **HAVING** operation.
    - The subquery cannot contain volatile functions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 



- Pulling up an equivalent correlated query containing aggregate functions

  The **WHERE** condition of the subquery must contain a column from the outer query. Equivalence comparison must be performed between this column and related columns in tables of the subquery. These conditions must be connected using **AND**. Other parts of the subquery cannot contain the column. Other restrictions are as follows:

  - The columns in the expression in the **WHERE** condition of the subquery must exist in tables.
  - After the **SELECT** keyword of the subquery, there must be only one output column. The output column must be an aggregate function (for example, **MAX**), and the parameter (for example, **t2.c2**) of the aggregate function cannot be columns of a table (for example, **t1**) in outer queries. The aggregate function cannot be **COUNT**.

    For example, the following subquery can be pulled up:

    ```
    select * from t1 where c1 >(
        select max(t2.c1) from t2 where t2.c1=t1.c1
    );
    ```

    The following subquery cannot be pulled up because the subquery has no aggregate function:

    ```
    select * from t1 where c1 >(
        select  t2.c1 from t2 where t2.c1=t1.c1
    );
    ```

    The following subquery cannot be pulled up because the subquery has two output columns:

    ```
    select * from t1 where (c1,c2) >(
        select  max(t2.c1),min(t2.c2) from t2 where t2.c1=t1.c1
    );
    ```

  - The subquery must be a **FROM** clause.
  - The subquery cannot contain a **GROUP BY**, **HAVING**, or **SET** operation.
  - The subquery can only be an inner join.

    For example, the following subquery cannot be pulled up:

    ```
    select * from t1 where c1 >(
        select max(t2.c1) from t2 full join t3 on (t2.c2=t3.c2) where t2.c1=t1.c1
    );
    ```

  - The target list of the subquery cannot contain the function that returns a set.
  - The **WHERE** condition of the subquery must contain a column from the outer query. Equivalence comparison must be performed between this column and related columns in tables of the subquery. These conditions must be connected using **AND**. Other parts of the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

subquery cannot contain the column. For example, the following subquery can be pulled up:

```
select * from t3 where t3.c1=(
      select t1.c1
      from t1 where c1 >(
            select max(t2.c1) from t2 where t2.c1=t1.c1
));
```

If another condition is added to the subquery in the previous example, the subquery cannot be pulled up because the subquery references to the column in the outer query. For example:

```
select * from t3 where t3.c1=(
      select t1.c1
      from t1 where c1 >(
            select max(t2.c1) from t2 where t2.c1=t1.c1 and t3.c1>t2.c2

));
```

- Pulling up a sublink in the **OR** clause

  If the **WHERE** condition contains an **EXIST** correlated sublink connected by **OR**:

  Example:

  ```
  select a, c from t1
  where t1.a = (select avg(a) from t3 where t1.b = t3.b) or
  exists (select * from t4 where t1.c = t4.c);
  ```

  The process of pulling up such a sublink is as follows:

  i. Extract **opExpr** from the **OR** clause in the **WHERE** condition. The value is **t1.a = (select avg(a) from t3 where t1.b = t3.b)**.

  ii. The **opExpr** contains a subquery. If the subquery can be pulled up, the subquery is rewritten as **select avg(a), t3.b from t3 group by t3.b**, generating the **NOT NULL** condition **t3.b is not null**. The **opExpr** is replaced with this **NOT NULL** condition. In this case, the SQL statement changes to:

  ```
  select a, c
  from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b)  as t3 on (t1.a = avg and t1.b = t3.b)
  where t3.b is not null or exists (select * from t4 where t1.c = t4.c);
  ```

  iii. Extract the **EXISTS** sublink **exists (select * from t4 where t1.c = t4.c)** from the **OR** clause to check whether the sublink can be pulled up. If it can be pulled up, it is converted into **select t4.c from t4 group by t4.c**, generating the **NOT NULL** condition **t4.c is not null**. In this case, the SQL statement changes to:

  ```
  select t1.a, t1.c from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b) as t3 on (t1.a = avg and t1.b = t3.b) left join (select t5.c from t5 group by t5.c) as t5 on (t1.c = t5.c) where t3.b is not null or t5.c is not null;
  ```

  ```
  select * from t1
  where exists (
      select t2.c1 from t2
      where t2.c1 = t1.c1
  ) OR
  exists (
      select t3.c1 from t3
      where t3.c1 = t1.c1
  );
  ```

  ⇒

  ```
  QUERY PLAN
  ------------------------------------------------------------
  Streaming (type: GATHER)
    Node/s: All datanodes
    ->  Hash Left Join
          Hash Cond: (t1.c1 = t3.c1)
          Filter: ((t2.c1 IS NOT NULL) OR (t3.c1 IS NOT NULL))
          ->  Hash Left Join
                Hash Cond: (t1.c1 = t2.c1)
                ->  Seq Scan on t1
                ->  Hash
                      ->  HashAggregate
                            Group By Key: t2.c1
                            ->  Seq Scan on t2
          ->  Hash
                ->  HashAggregate
                      Group By Key: t3.c1
                      ->  Seq Scan on t3
  (16 rows)
  ```

- **Sublink-release scenarios not supported by GaussDB**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Except the sublinks described above, all the other sublinks cannot be pulled up. In this case, a join subquery is planned as the combination of subplans and broadcast. As a result, if tables in the subquery have a large amount of data, query performance may be poor.

If a correlated subquery joins with two tables in outer queries, the subquery cannot be pulled up. You need to change the outer query into a **WITH** clause and then perform the join.

For example:

```
select distinct t1.a, t2.a
from t1 left join t2 on t1.a=t2.a and not exists (select a,b from test1 where test1.a=t1.a and
test1.b=t2.a);
```

The outer query is changed into:

```
with temp as
(
      select * from (select t1.a as a, t2.a as b from t1 left join t2 on t1.a=t2.a)

)
select distinct a,b
from temp
where not exists (select a,b from test1 where temp.a=test1.a and temp.b=test1.b);
```

– The subquery (without **COUNT**) in the target list cannot be pulled up.

  For example:

  ```
  explain (costs off)
  select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
  from t1
  where t1.c2 > 10;
  ```

  The execution plan is as follows:

  ```
  explain (costs off)
  select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
  from t1
  where t1.c2 > 10;
                    QUERY PLAN
  ------------------------------------------------------------
   Streaming (type: GATHER)
     Node/s: All datanodes
     ->  Seq Scan on t1
           Filter: (c2 > 10)
           SubPlan 1
             ->  Result
                   Filter: (t1.c1 = t2.c1)
                   ->  Materialize
                         ->  Streaming(type: BROADCAST)
                               Spawn on: All datanodes
                               ->  Seq Scan on t2
  (11 rows)
  ```

  The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met. Therefore, use left outer join to join **T1** and **T2** so that SSQ can return padding values when the condition **t1.c1=t2.c1** is not met.

  **NOTE**

  ScalarSubQuery (SSQ) and Correlated-ScalarSubQuery (CSSQ) are described as follows:

  - SSQ: a sublink that returns a scalar value of a single row with a single column
  - CSSQ: an SSQ containing correlation conditions

  The preceding SQL statement can be changed into:

  ```
  with ssq as
  (
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
   select t2.c2 from t2
)
select ssq.c2, t1.c2
from t1 left join ssq on t1.c1 = ssq.c2
where t1.c2 > 10;
```

The execution plan after the change is as follows:

```
                QUERY PLAN
-------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Hash Right Join
         Hash Cond: (t2.c2 = t1.c1)
         ->  Streaming(type: REDISTRIBUTE)
               Spawn on: All datanodes
               ->  Seq Scan on t2
         ->  Hash
               ->  Seq Scan on t1
                     Filter: (c2 > 10)
(10 rows)
```

In the preceding example, the SSQ in the target list is pulled up to right join, preventing poor performance caused by the plan involving subplans and broadcast when the table (**T2**) in the subquery is too large.

- The subquery (with **COUNT**) in the target list cannot be pulled up.

  For example:

```
select (select count(*) from t2 where t2.c1=t1.c1) cnt, t1.c1, t3.c1
from t1,t3
where t1.c1=t3.c1 order by cnt, t1.c1;
```

  The execution plan is as follows:

```
                          QUERY PLAN
-----------------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Sort
         Sort Key: ((SubPlan 1)), t1.c1
         ->  Hash Join
               Hash Cond: (t1.c1 = t3.c1)
               ->  Seq Scan on t1
               ->  Hash
                     ->  Seq Scan on t3
               SubPlan 1
                 ->  Aggregate
                       ->  Result
                             Filter: (t2.c1 = t1.c1)
                             ->  Materialize
                                   ->  Streaming(type: BROADCAST)
                                         Spawn on: All datanodes
                                         ->  Seq Scan on t2
(17 rows)
```

  The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met. Therefore, use left outer join to join **T1** and **T2** so that SSQ can return padding values when the condition **t1.c1=t2.c1** is not met. However, **COUNT** is used, which requires that **0** is returned when the condition is not met. Therefore, **case-when NULL then 0 else count(*)** can be used.

  The preceding SQL statement can be changed into:

```
with ssq as
(
   select count(*) cnt, c1 from t2 group by c1
)
select case when
          ssq.cnt is null then 0
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
          else ssq.cnt
      end cnt, t1.c1, t3.c1
from t1 left join ssq on ssq.c1 = t1.c1,t3
where t1.c1 = t3.c1
order by ssq.cnt, t1.c1;
```

The execution plan after the change is as follows:

```
 QUERY PLAN
-----------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Sort
         Sort Key: (count(*)), t1.c1
         ->  Hash Join
               Hash Cond: (t1.c1 = t3.c1)
               ->  Hash Left Join
                     Hash Cond: (t1.c1 = t2.c1)
                     ->  Seq Scan on t1
                     ->  Hash
                           ->  HashAggregate
                                 Group By Key: t2.c1
                                 ->  Seq Scan on t2
               ->  Hash
                     ->  Seq Scan on t3
(15 rows)
```

– Non-equivalent correlated subqueries cannot be pulled up.

  For example:

```
select t1.c1, t1.c2
from t1
where t1.c1 = (select agg() from t2.c2 > t1.c2);
```

  Non-equivalent correlated subqueries cannot be pulled up. You can perform join twice (one CorrelationKey and one rownum self-join) to rewrite the statement.

  You can rewrite the statement in either of the following ways:

  - Subquery rewriting

```
select t1.c1, t1.c2
from t1, (
   select t1.rowid, agg() aggref
   from t1,t2
   where t1.c2 > t2.c2 group by t1.rowid
) dt /* derived table */
where t1.rowid = dt.rowid AND t1.c1 = dt.aggref;
```

  - CTE rewriting

```
WITH dt as
(
   select t1.rowid, agg() aggref
   from t1,t2
   where t1.c2 > t2.c2 group by t1.rowid
)
select t1.c1, t1.c2
from t1, derived_table
where t1.rowid = derived_table.rowid AND
t1.c1 = derived_table.aggref;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**NOTICE**

- Currently, GaussDB does not have an effective way to provide globally unique row IDs for tables and intermediate result sets. Therefore, the rewriting is difficult. It is recommended that this issue is avoided at the service layer or by using **t1.xc_nodeid + t1.ctid** to associate row IDs. However, the high repetition rate of **xc_nodeid** leads to low association efficiency, and **xc_node_id+ctid** cannot be used as the join condition of a hash join.
- If the AGG type is **COUNT(*)**, **0** is used for data padding when **CASE-WHEN** is not matched. If the type is not **COUNT(*)**, **NULL** is used.
- CTE rewriting works better by using share scan.

## More Optimization Examples

1. Change the base table to a replication table and create an index on the filter column.

```
create table master_table (a int);
create table sub_table(a int, b int);
select a from master_table group by a having a in (select a from sub_table);
```

In this example, a correlated subquery is contained. To improve the query performance, you can change **sub_table** to a replication table and create an index on the **a** column.

2. Modify the **SELECT** statement to change the subquery to a **JOIN** relationship between the primary table and the parent query, or modify the subquery to improve the query performance. Ensure that the subquery to be used is semantically correct.

```
explain (costs off)select * from master_table as t1 where t1.a in (select t2.a from sub_table as t2 where t1.a
= t2.b);
                      QUERY PLAN
-------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Seq Scan on master_table t1
         Filter: (SubPlan 1)
         SubPlan 1
           ->  Result
                 Filter: (t1.a = t2.b)
                 ->  Materialize
                       ->  Streaming(type: BROADCAST)
                             Spawn on: All datanodes
                             ->  Seq Scan on sub_table t2
(11 rows)
```

In the preceding example, a subplan is used. To remove the subplan, you can modify the statement as follows:

```
explain(costs off) select * from master_table as t1 where exists (select t2.a from sub_table as t2 where t1.a
= t2.b and t1.a = t2.a);
                   QUERY PLAN
-------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Hash Semi Join
         Hash Cond: (t1.a = t2.b)
         ->  Seq Scan on master_table t1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
      ->  Hash
            ->  Streaming(type: REDISTRIBUTE)
                  Spawn on: All datanodes
                  ->  Seq Scan on sub_table t2
(9 rows)
```

In this way, the subplan is replaced by the semi-join between the two tables, greatly improving the execution efficiency.

## 10.3.6.4 Optimizing Statistics

## Background

GaussDB generates optimal execution plans based on the cost estimation. Optimizers need to estimate the number of data rows and the cost based on statistics collected using **ANALYZE**. Therefore, the statistics is vital for the estimation of the number of rows and cost. Global statistics are collected using **ANALYZE**: **relpages** and **reltuples** in the **pg_class** table; **stadistinct**, **stanullfrac**, **stanumbersN**, **stavaluesN**, and **histogram_bounds** in the **pg_statistic** table.

## Example 1: Poor Query Performance Due to the Lack of Statistics

In most cases, the lack of statistics about tables or columns involved in the query greatly affects the query performance.

The table structure is as follows:

```
CREATE TABLE LINEITEM
(
L_ORDERKEY        BIGINT        NOT NULL
, L_PARTKEY       BIGINT        NOT NULL
, L_SUPPKEY       BIGINT        NOT NULL
, L_LINENUMBER    BIGINT        NOT NULL
, L_QUANTITY      DECIMAL(15,2) NOT NULL
, L_EXTENDEDPRICE  DECIMAL(15,2) NOT NULL
, L_DISCOUNT      DECIMAL(15,2) NOT NULL
, L_TAX           DECIMAL(15,2) NOT NULL
, L_RETURNFLAG    CHAR(1)       NOT NULL
, L_LINESTATUS    CHAR(1)       NOT NULL
, L_SHIPDATE      DATE          NOT NULL
, L_COMMITDATE    DATE          NOT NULL
, L_RECEIPTDATE   DATE          NOT NULL
, L_SHIPINSTRUCT  CHAR(25)      NOT NULL
, L_SHIPMODE      CHAR(10)      NOT NULL
, L_COMMENT       VARCHAR(44)   NOT NULL
) with (orientation = column, COMPRESSION = MIDDLE) distribute by hash(L_ORDERKEY);

CREATE TABLE ORDERS
(
O_ORDERKEY       BIGINT        NOT NULL
, O_CUSTKEY      BIGINT        NOT NULL
, O_ORDERSTATUS  CHAR(1)       NOT NULL
, O_TOTALPRICE   DECIMAL(15,2) NOT NULL
, O_ORDERDATE    DATE NOT NULL
, O_ORDERPRIORITY CHAR(15)     NOT NULL
, O_CLERK        CHAR(15)      NOT NULL
, O_SHIPPRIORITY  BIGINT       NOT NULL
, O_COMMENT      VARCHAR(79)   NOT NULL
)with (orientation = column, COMPRESSION = MIDDLE) distribute by hash(O_ORDERKEY);
```

The query statements are as follows:

```
explain verbose select
count(*) as numwait
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
from
lineitem l1,
orders
where
o_orderkey = l1.l_orderkey
and o_orderstatus = 'F'
and l1.l_receiptdate > l1.l_commitdate
and not exists (
select
*
from
lineitem l3
where
l3.l_orderkey = l1.l_orderkey
and l3.l_suppkey <> l1.l_suppkey
and l3.l_receiptdate > l3.l_commitdate
)
order by
numwait desc;
```

If such an issue occurs, you can use the following methods to check whether statistics in tables or columns has been collected using **ANALYZE**.

1. Execute **EXPLAIN VERBOSE** to analyze the execution plan and check the warning information:

   ```
   WARNING:Statistics in some tables or columns(public.lineitem.l_receiptdate,
   public.lineitem.l_commitdate, public.lineitem.l_orderkey, public.lineitem.l_suppkey,
   public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.
   HINT:Do analyze for them in order to generate optimized plan.
   ```

2. Check whether the following information exists in the log file in the **pg_log** directory. If it does, the poor query performance was caused by the lack of statistics in some tables or columns.

   ```
   2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] LOG:Statistics in some tables
   or columns(public.lineitem.l_receiptdate, public.lineitem.l_commitdate, public.lineitem.l_orderkey,
   public.linei
   tem.l_suppkey, public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.
   2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] HINT:Do analyze for them in
   order to generate optimized plan.
   ```

By using any of the preceding methods, you can identify tables or columns whose statistics have not been collected using **ANALYZE**. You can execute **ANALYZE** to warnings or tables and columns recorded in logs to resolve the problem.

## Example 2: Setting cost_param to Optimize Query Performance

See **10.4.5 Case: Setting cost_param and Optimizing Query Performance**.

## Example 3: Optimization is Not Accurate When Intermediate Results Exist in the Query Where JOIN Is Used for Multiple Tables

**Symptom**: Query the personnel who have registered in an Internet cafe within 15 minutes before and after the registration of a specified person.

```
SELECT
C.WBM,
C.DZQH,
C.DZ,
B.ZJHM,
B.SWKSSJ,
B.XWSJ
FROM
b_zyk_wbswxx A,
b_zyk_wbswxx B,
b_zyk_wbcs C
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
WHERE
A.ZJHM = '522522******3824'
AND A.WBDM = B.WBDM
AND A.WBDM = C.WBDM
AND abs(to_date(A.SWKSSJ,'yyyymmddHH24MISS') - to_date(B.SWKSSJ,'yyyymmddHH24MISS')) <
INTERVAL '15 MINUTES'
ORDER BY
B.SWKSSJ,
B.ZJHM
limit 10 offset 0
;
```

**Figure 10-7** shows the execution plan. This query takes about 12s.

**Figure 10-7** Using an unlogged table (1)

```
                                                
```

```
A.WBDM,
to_char((to_date(A.SWKSSJ,'yyyymmddHH24MISS') - INTERVAL '15
MINUTES'),'yyyymmddHH24MISS'),
to_char((to_date(A.SWKSSJ,'yyyymmddHH24MISS') + INTERVAL '15
MINUTES'),'yyyymmddHH24MISS'),
B.WBM,B.DZQH,B.DZ,B.IPDZ
FROM
b_zyk_wbswxx A,
b_zyk_wbcs B
WHERE
A.ZJHM='522522******3824' AND A.WBDM = B.WBDM
;

// Query the personnel who have registered in an Internet cafe before and after 15 minutes of the registration of the specified person. Convert their ID card number format to int8 in comparison.
SELECT
A.WBM,
A.DZQH,
A.DZ,
A.IPDZ,
B.ZJHM,
B.XM,
to_date(B.SWKSSJ,'yyyymmddHH24MISS') as SWKSSJ,
to_date(B.XWSJ,'yyyymmddHH24MISS') as XWSJ,
B.SWZDH
FROM temp_tsw A,
b_zyk_wbswxx B
WHERE
A.ZJHM <> B.ZJHM
AND A.WBDM = B.WBDM
AND (B.SWKSSJ)::int8 > (A.swkssj_start)::int8
AND (B.SWKSSJ)::int8 < (A.swkssj_end)::int8
order by
B.SWKSSJ,
B.ZJHM
limit 10 offset 0
;
```

The query takes about 7s. **Figure 10-8** shows the execution plan.

**Figure 10-8** Using an unlogged table (2)

```
                                                
```

**Figure 10-9** shows the execution plan. The query takes about 3s.

**Figure 10-9** Using an unlogged table (3)

```
                                                
```

```
ORDER BY
SWKSSJ,
ZJHM
LIMIT 10 OFFSET 0;
```

**CAUTION**

Collecting more accurate statistics usually improves the query performance, but may also deteriorate the performance. If the performance deteriorates, you can:

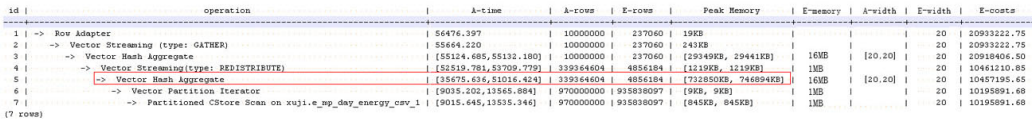
- Restore to the default statistics.
- Use hints to force the optimizer to use the optimal query plan. (For details, see **10.3.9 Hint-based Tuning**.)

## 10.3.6.5 Optimizing Operators

### Background

A query statement needs to go through multiple operator procedures to generate the final result. Sometimes, the overall query performance deteriorates due to long execution time of certain operators, which are regarded as bottleneck operators. In this case, you need to execute the **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** command to view the bottleneck operators, and then perform optimization.

For example, in the following execution process, the execution time of the **Hashagg** operator accounts for about 66% [(51016-13535)/56476 ≈ 66%] of the total execution time. Therefore, the **Hashagg** operator is the bottleneck operator for this query. Optimize this operator first.



### Example

1. Scan the base table. For queries requiring large volume of data filtering, such as point queries or queries that need range scanning, a full table scan using SeqScan will take a long time. To facilitate scanning, you can create indexes on the condition column and select IndexScan for index scanning.

```
openGauss=# explain (analyze on, costs off) select * from store_sales where ss_sold_date_sk = 2450944;
 id |             operation          |       A-time        | A-rows | Peak Memory  | A-width
----+--------------------------------+---------------------+--------+--------------+---------
  1 | ->  Streaming (type: GATHER)   | 3666.020            |   3360 | 195KB        |
  2 |    ->  Seq Scan on store_sales | [3594.611,3594.611] |   3360 | [34KB, 34KB] |
(2 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
   2 --Seq Scan on store_sales
         Filter: (ss_sold_date_sk = 2450944)
         Rows Removed by Filter: 4968936
openGauss=# create index idx on store_sales_row(ss_sold_date_sk);
CREATE INDEX
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# explain (analyze on, costs off) select * from store_sales_row where ss_sold_date_sk = 2450944;
 id |                    operation                     |     A-time      | A-rows | Peak Memory  | A-width
----+--------------------------------------------------+-----------------+--------+--------------+----------
  1 | ->  Streaming (type: GATHER)                     | 81.524          |   3360 | 195KB        |
  2 |    ->  Index Scan using idx on store_sales_row | [13.352,13.352] |   3360 | [34KB, 34KB] |
(2 rows)
```

In this example, the full table scan filters much data and returns 3360 records. After an index has been created on the **ss_sold_date_sk** column, the scanning efficiency is significantly boosted from 3.6s to 13 ms by using **IndexScan**.

2: If NestLoop is used for joining tables with a large number of rows, the join may take a long time. In the following example, NestLoop takes 181s. If **enable_mergejoin** is set to **off** to disable merge join and **enable_nestloop** is set to **off** to disable NestLoop so that the optimizer selects hash join, the join takes more than 200 ms.

```
openGauss=# explain analyze select count(*) from store_sales ss, item i where ss.ss_item_sk = i.i_item_sk;
 id |                       operation                       |         A-time          |  A-rows   | E-rows  |  Peak Memory   | E-memory | A-width | E-width |   E-costs
----+-------------------------------------------------------+-------------------------+-----------+---------+----------------+----------+---------+---------+-------------
  1 | ->  Row Adapter                                       | 184300.301              |         1 |       1 | 11KB           |          |         |       0 | 48629179.77
  2 |    ->  Vector Aggregate                               | 184300.280              |         1 |       1 | 181KB          |          |         |       0 | 48629179.77
  3 |       ->  Vector Streaming (type: GATHER)             | 184300.186              |         4 |       4 | 188KB          |          |         |       0 | 48629179.77

  8 |                   ->  CStore Scan on item i           | [0.234,0.243]           |     18000 |   18000 | [476KB, 476KB] | 1MB      |         |       4 | 3867.50
(8 rows)
```

```
openGauss=# set enable_nestloop=off;
SET
openGauss=# set enable_mergejoin=off;
SET
openGauss=# explain analyze select count(*) fpostgres=# ales ss, item i where ss.ss_item_sk = i.i_item_sk;
 id |                       operation                       |         A-time          | A-rows  | E-rows  |  Peak Memory   | E-memory | A-width | E-width | E-costs
----+-------------------------------------------------------+-------------------------+---------+---------+----------------+----------+---------+---------+-----------
  1 | ->  Row Adapter                                       | 291.066                 |       1 |       1 | 11KB           |          |         |       0 | 32308.66
  2 |    ->  Vector Aggregate                               | 291.052                 |       1 |       1 | 181KB          |          |         |       0 | 32308.66
  3 |       ->  Vector Streaming (type: GATHER)             | 290.973                 |       4 |       4 | 188KB          |          |         |       0 | 32308.66
  4 |          ->  Vector Aggregate                         | [220.792,234.532]       |       4 |       4 | [140KB, 140KB] | 1MB      |         |       0 | 32308.50
  5 |             ->  Vector Hash Join (6,7)                | [209.987,223.345]       | 2880404 | 2880404 | [236KB, 241KB] | 16MB     | [8,8]   |       0 | 30508.24
  6 |                ->  CStore Scan on store_sales ss      | [13.132,13.717]         | 2880404 | 2880404 | [490KB, 490KB] | 1MB      |         |       4 | 16683.10
  7 |                ->  CStore Scan on item i              | [0.214,0.246]           |   18000 |   18000 | [477KB, 477KB] | 1MB      |         |       4 | 3867.50
(7 rows)
```

3. Generally, query performance can be improved by selecting **HashAgg**. If **Sort** and **GroupAgg** are used for a large result set, you need to set **enable_sort** to **off**. **HashAgg** consumes less time than **Sort** and **GroupAgg**.

```
openGauss=#  explain analyze select count(*) from store_sales group by ss_item_sk;
 id |                       operation                       |         A-time          | A-rows  | E-rows  |      Peak Memory      | E-memory | A-width | E-width | E-costs

(4 rows)
```

## 10.3.6.6 Optimizing Data Skew

Data skew breaks the balance among nodes in the distributed MPP architecture. If the amount of data stored or processed by a node is much greater than that by other nodes, the following problems may occur:

- Storage skew severely limits the system capacity. The skew on a single node hinders system storage utilization.
- Computing skew severely affects performance. The data to be processed on the skew node is much more than that on other nodes, deteriorating overall system performance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Data skew severely affects the scalability of the MPP architecture. During storage or computing, data with the same values is often placed on the same node. Therefore, even if we add nodes after a data skew occurs, the skew data (data with the same values) is still placed on the node and affects the system capacity or performance bottleneck.

GaussDB provides a complete solution for data skew, including storage and computing skew.

## Data Skew in the Storage Layer

In the GaussDB database, data is distributed and stored on each DN. You can improve the query efficiency by using distributed execution. However, if data skew occurs, bottlenecks exist on some DNs during distribution execution, affecting the query performance. This is because the distribution key is not properly selected. This can be solved by adjusting the distribution key.

For example:

```
openGauss=# explain performance select count(*) from inventory;
5 --CStore Scan on lmz.inventory

```

In the performance information, the number of scan lines on each DN in the inventory table is displayed. The maximum number of scan lines is 63000000, and the minimum number is 15000000, which is four times of the actual number. This value difference on the performance of data scan is acceptable, but if the join operator exists in the upper-layer, the impact on the performance cannot be ignored.

Generally, the data table is hash distributed on each DN; therefore, it is important to choose a proper distribution key. Run **table_skewness()** to view data skew of each DN in the inventory table. The query result is as follows:

```
openGauss=# select table_skewness('inventory');
              table_skewness
-------------------------------------------
 ("dn_6015_6016         ",63000000,8.046%)
 ("dn_6013_6014         ",60000000,7.663%)
 ("dn_6023_6024         ",60000000,7.663%)
 ("dn_6027_6028         ",60000000,7.663%)
 ("dn_6017_6018         ",54000000,6.897%)
 ("dn_6021_6022         ",54000000,6.897%)
 ("dn_6007_6008         ",51000000,6.513%)
 ("dn_6011_6012         ",51000000,6.513%)
 ("dn_6005_6006         ",45000000,5.747%)
```

(18 rows)
```

The table definition indicates that the table uses the **inv_date_sk** column as the distribution key, which causes a data skew. Based on the data distribution of each column, change the distribution key to **inv_item_sk**. The skew status is as follows:

```
openGauss=# select table_skewness('inventory');
              table_skewness
-----------------------------------------
 ("dn_6001_6002          ",43934200,5.611%)
 ("dn_6007_6008          ",43829420,5.598%)
 ("dn_6003_6004          ",43781960,5.592%)
 ("dn_6031_6032          ",43773880,5.591%)
 ("dn_6033_6034          ",43763280,5.589%)
 ("dn_6011_6012          ",43683600,5.579%)
 ("dn_6013_6014          ",43551660,5.562%)
 ("dn_6027_6028          ",43546340,5.561%)
 ("dn_6009_6010          ",43508700,5.557%)
 ("dn_6023_6024          ",43484540,5.554%)
 ("dn_6019_6020          ",43466800,5.551%)
 ("dn_6021_6022          ",43458500,5.550%)
 ("dn_6017_6018          ",43448040,5.549%)
 ("dn_6015_6016          ",43247700,5.523%)
 ("dn_6005_6006          ",43200240,5.517%)
 ("dn_6029_6030          ",43181360,5.515%)
 ("dn_6025_6026          ",43179700,5.515%)
 ("dn_6035_6036          ",42960080,5.487%)

```

Data skew is solved.

In addition to the **table_skewness()** view, you can use the **table_distribution** function and the **15.3.192 PGXC_GET_TABLE_SKEWNESS** view to efficiently query the data skew status of each table.

## Data Skew in the Computing Layer

Even if data is balanced across nodes after you change the distribution key of a table, data skew may still occur during a query. If data skew occurs in the result set of an operator on a DN, skew will also occur during the computing that involves the operator. Generally, this is caused by data redistribution during the execution.

During a query, **JOIN** keys and **GROUP BY** keys are not used as distribution keys. Data is redistributed among DNs based on the hash values of data on the keys. The redistribution is implemented using the Redistribute operator in an execution plan. Data skew in redistribution columns can lead to data skew during system operation. After the redistribution, some nodes will have much more data, process more data, and will have much lower performance than others.

In the following example, the **s** and **t** tables are joined, and **s.x** and **t.x** columns in the join condition are not their distribution keys. Table data is redistributed using the **REDISTRIBUTE** operator. Data skew occurs in the **s.x** column and not in the **t.x** column. The result set of the **Streaming** operator (**id** being **6**) on datanode2 has data three times that of other DNs and causes a skew.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
select * from skew s,test t where s.x = t.x order by s.a limit 1;
 id |                    operation                    |        A-time

```

Computing skew is more difficult to detect than storage skew. To solve computing skew, GaussDB provides the Runtime Load Balance Technology (RLBT) solution, controlled by the **skew_option** parameter. The RLBT solution addresses how to detect and solve data skew.

1. Detect data skew.

   The solution first checks whether skew data exists in redistribution columns used for computing. RLBT can detect data skew based on statistics, specified hints, or rules.

   - Detection based on statistics

     Run the **ANALYZE** statement to collect statistics on tables. The optimizer will automatically identify skew data on redistribution keys based on the statistics and generate optimization plans for queries having potential skew. When the redistribution key has multiple columns, statistics information can be used for identification only when all columns belong to the same base table.

     The statistics information can only provide the skew of the base table. When a column in the base table is skewed, other columns have filtering conditions, or after the join of other tables, the skewed data may still exist on the skewed column. If **skew_option** is **normal**, it indicates that the skew data still exists, and the base tables will be optimized to solve skew. If **skew_option** is **lazy**, it indicates that no more skew data exists and the optimization will stop.

   - Detection based on specified hints

     The intermediate results of complex queries are difficult to estimate based on statistics. In this case, you can specify hints to provide the skew information based on which the optimizer optimizes queries. For details about the syntax of hints, see **10.3.9.8 Skew Hints**.

   - Detection based on rules

     In a business intelligence (BI) system, a large number of SQL statements having outer joins (including left joins, right joins, and full joins) are generated, and many NULL values will be generated in empty columns that have no match for outer joins. If JOIN or GROUP BY operations are performed on the columns, data skew will occur. RLBT can automatically identify this scenario and generate an optimization plan for NULL value skew.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

2. Solve computing skew.

   **Join** and **Aggregate** operators are optimized to solve skew.

   – **Join** optimization

   Skew and non-skew data is separately processed. Details are as follows:

   a. When redistribution is required on both sides of a join:

      Use **PART_REDISTRIBUTE_PART_ROUNDROBIN** on the side with skew. Specifically, perform round-robin on skew data and redistribution on non-skew data.

      Use **PART_REDISTRIBUTE_PART_BROADCAST** on the side with no skew. Specifically, perform broadcast on skew data and redistribution on non-skew data.

   b. When redistribution is required on only one side of a join:

      Use **PART_REDISTRIBUTE_PART_ROUNDROBIN** on the side where redistribution is required.

      Use **PART_LOCAL_PART_BROADCAST** on the side where redistribution is not required. Specifically, perform broadcast on skew data and retain other data locally.

   c. When a table has NULL values padded:

      Use **PART_REDISTERIBUTE_PART_LOCAL** on the table. Specifically, retain the NULL values locally and perform redistribution on other data.

   In the example query, the **s.x** column contains skewed data and its value is **0**. The optimizer identifies the skew data in statistics and generates the following optimization plan:

```
 id |                                operation                                 |        A-time
----+--------------------------------------------------------------------------+-----------------------
  1 | ->  Limit                                                                | 23642.049
  2 |    ->  Streaming (type: GATHER)                                          | 23642.041
  3 |       ->  Limit                                                          | [23310.768,23618.021]
  4 |          ->  Sort                                                        | [23310.761,23618.012]
  5 |             ->  Hash Join (6,8)                                          | [20898.341,21115.272]
  6 |                ->  Streaming(type: PART REDISTRIBUTE PART ROUNDROBIN)    |
[7125.834,7472.111]
  7 |                   ->  Seq Scan on public.skew s                          | [1837.079,1911.025]
  8 |                ->  Hash                                                  | [2612.484,2640.572]
  9 |                   ->  Streaming(type: PART REDISTRIBUTE PART BROADCAST)  | [1193.548,1297.894]
 10 |                      ->  Seq Scan on public.test t                       | [314.343,328.707]
(10 rows)
   5 --Vector Hash Join (6,8)
       Hash Cond: s.x = t.x
       Skew Join Optimizated by Statistic
   6 --Streaming(type: PART REDISTRIBUTE PART ROUNDROBIN)
       datanode1 (rows=7635968)
       datanode2 (rows=7517184)
       datanode3 (rows=7748608)
       datanode4 (rows=7818240)
```

   In the preceding execution plan, **Skew Join Optimizated by Statistic** indicates that this is an optimized plan used for handling data skew. The **Statistic** keyword indicates that the plan optimization is based on statistics; **Hint** indicates that the optimization is based on hints; **Rule** indicates that the optimization is based on rules. In this plan, skew and non-skew data are separately processed. Non-skew data in the **s** table is redistributed based on its hash values, and skew data (whose value is **0**) is evenly distributed on all nodes in round-robin mode. In this way, data skew is solved.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

To ensure result correctness, the **t** table also needs to be processed. In the **t** table, the data whose value is **0** (skew value in the **s.x** table) is broadcast and other data is redistributed based on its hash values.

In this way, data skew in **JOIN** operations is solved. The above result shows that the output of the **Streaming** operator (**id** being **6**) is balanced and the end-to-end performance of the query is doubled.

– **Aggregate** optimization

For aggregation, data on each DN is deduplicated based on the **GROUP BY** key and then redistributed. After the deduplication on DNs, the global occurrences of each value will not be greater than the number of DNs. Therefore, no serious data skew will occur. Take the following query as an example:

```
select c1, c2, c3, c4, c5, c6, c7, c8, c9, count(*) from t group by c1, c2, c3, c4, c5, c6, c7, c8, c9 limit 10;
```

The command output is as follows:

```
 id |                operation                 |         A-time         | A-rows
----+------------------------------------------+------------------------+----------
  1 | ->  Streaming (type: GATHER)             | 130621.783             |       12
  2 |    ->  GroupAggregate                    | [85499.711,130432.341] |       12
  3 |       ->  Sort                           | [85499.509,103145.632] | 36679237
  4 |         ->  Streaming(type: REDISTRIBUTE) | [25668.897,85499.050]  | 36679237
  5 |           ->  Seq Scan on public.t       | [9835.069,10416.388]   | 36679237
(5 rows)

  4 --Streaming(type: REDISTRIBUTE)
        datanode1 (rows=36678837)
        datanode2 (rows=100)
        datanode3 (rows=100)
        datanode4 (rows=200)
```

A large amount of skew data exists. As a result, after data is redistributed based on its **GROUP BY** key, the data volume of datanode1 is hundreds of thousands of times that of others. After optimization, a **GROUP BY** operation is performed on the DN to deduplicate data. After redistribution, no data skew occurs.

```
 id |                operation                 |         A-time
----+------------------------------------------+------------------------
  1 | ->  Streaming (type: GATHER)             | 10961.337
  2 |    ->  HashAggregate                     | [10953.014,10953.705]
  3 |       ->  HashAggregate                  | [10952.957,10953.632]
  4 |         ->  Streaming(type: REDISTRIBUTE) | [10952.859,10953.502]
  5 |           ->  HashAggregate              | [10084.280,10947.139]
  6 |             ->  Seq Scan on public.t     | [4757.031,5201.168]
(6 rows)

(2 rows)

  4 --Streaming(type: REDISTRIBUTE)
        datanode1 (rows=17)
        datanode2 (rows=8)
        datanode3 (rows=8)
        datanode4 (rows=14)
```

Applicability

– **Join** operator

  - **nest loop**, **merge join**, and **hash join** can be optimized.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

    - If skew data is on the left to the join, **inner join**, **left join**, **semi join**, and **anti join** are supported. If skew data is on the right to the join, **inner join**, **right join**, **right semi join**, and **right anti join** are supported.
    - For an optimization plan generated based on statistics, the optimizer checks whether it is optimal by estimating its cost. Optimization plans based on hints or rules are forcibly generated.
  - **Aggregate** operator
    - **array_agg**, **string_agg**, and **subplan in agg qual** cannot be optimized.
    - A plan generated based on statistics is affected by its cost, the **plan_mode_seed** parameter, and the **best_agg_plan** parameter. A plan generated based on hints or rules are not affected by them.

## 10.3.7 Experience in Rewriting SQL Statements

Based on the SQL execution mechanism and a large number of practices, SQL statements can be optimized by following certain rules to enable the database to execute SQL statements more quickly and obtain correct results. You can comply with these rules to improve service query efficiency.

- Replace **UNION** with **UNION ALL**.

  **UNION** eliminates duplicate rows while merging two result sets but **UNION ALL** merges the two result sets without deduplication. Therefore, replace **UNION** with **UNION ALL** if you are sure that the two result sets do not contain duplicate rows based on the service logic.

- Add **NOT NULL** to the join columns.

  If there are many NULL values in the **JOIN** columns, you can add the filter criterion **IS NOT NULL** to filter data in advance to improve the **JOIN** efficiency.

- Convert **NOT IN** to **NOT EXISTS**.

  **nestloop anti join** must be used to implement **NOT IN**, and **hash anti join** is required for **NOT EXISTS**. If no NULL value exists in the **JOIN** columns, **NOT IN** is equivalent to **NOT EXISTS**. Therefore, if you are sure that no NULL value exists, you can convert **NOT IN** to **NOT EXISTS** to generate **hash join** and to improve the query performance.

  As shown in the following statement, the **t2.d2** column does not contain null values (it is set to **NOT NULL**) and **NOT EXISTS** is used for the query.

  ```
  SELECT * FROM t1 WHERE  NOT EXISTS (SELECT * FROM t2 WHERE t1.c1=t2.d2);
  ```

  The generated execution plan is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Figure 10-10 NOT EXISTS** execution plan

```
 id |                  operation
----+-------------------------------------------
  1 | ->  Streaming (type: GATHER)
  2 |    ->  Hash Anti Join (3, 4)
  3 |       ->  Seq Scan on t1
  4 |       ->  Hash
  5 |          ->  Streaming(type: REDISTRIBUTE)
  6 |             ->  Seq Scan on t2
(6 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
   2 --Hash Anti Join (3, 4)
         Hash Cond: (t1.c1 = t2.d2)
(2 rows)
```

- Use **hashagg**.

  If a plan involving groupAgg and SORT operations generated by the **GROUP BY** statement is poor in performance, you can set **work_mem** to a larger value to generate a **hashagg** plan, which does not require sorting and improves the performance.

- Replace functions with **CASE** statements.

  The GaussDB performance greatly deteriorates if a large number of functions are called. In this case, you can modify the pushdown functions to **CASE** statements.

- Do not use functions or expressions for indexes.

  Using functions or expressions for indexes stops indexing. Instead, it enables scanning on the full table.

- Do not use **!=** or **<>** operators, **NULL**, **OR**, or implicit parameter conversion in **WHERE** clauses.

- Split complex SQL statements.

  You can split an SQL statement into several ones and save the execution result to a temporary table if the SQL statement is too complex to be tuned using the solutions above, including but not limited to the following scenarios:

  - The same subquery is involved in multiple SQL statements of a job and the subquery contains large amounts of data.
  - Incorrect plan cost causes a small hash bucket of subquery. For example, the actual number of rows is 10 million, but only 1000 rows are in hash bucket.
  - Functions such as **substr** and **to_number** cause incorrect measures for subqueries containing large amounts of data.
  - **BROADCAST** subqueries are performed on large tables in multi-DN environment.

## 10.3.8 Configuring Key Parameters for SQL Tuning

This section describes key CN parameters that affect tuning of SQL statements in GaussDB. For details about how to configure the parameters, see **11 Configuring Running Parameters**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 10-3** CN parameters

| Parameter/ Reference Value | Description |
| --- | --- |
| enable_nestloop=on | Specifies how the optimizer uses Nest Loop Join. If this parameter is set to **on**, the optimizer preferentially uses Nest Loop Join. If it is set to **off**, the optimizer preferentially uses other methods, if any.<br>**NOTE**<br>If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement:<br>`SET enable_nestloop to off;`<br>You can determine whether to disable this function based on the actual requirements. Generally, among the three join modes (Nested Loop, Merge Join, and Hash Join), Nested Loop is applicable to scenarios with small data volume or indexes, and Hash Join is applicable to big data analysis scenarios. |
| enable_bitmapscan=on | Specifies whether the optimizer uses bitmap scan. If the value is **on**, bitmap scan is used. If the value is **off**, it is not used.<br>**NOTE**<br>If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement:<br>`SET enable_bitmapscan to off;`<br>The bitmap scan applies only in the query condition **where a > 1 and b > 1** and indexes are created on columns **a** and **b**. However, the performance of bitmapscan is sometimes inferior to that of indexscan. During tuning, if the query performance is poor and bitmapscan operators are in the execution plan, set this parameter to **off** and check whether the performance is improved. |
| enable_fast_query_shipping=on | Specifies whether the optimizer uses a distribution framework to execute quick execution plans. If the value is **on**, the execution plan is generated on both CNs and DNs. If the value is **off**, the distribution framework is used, that is, the execution plan is generated on the CN and then sent to the DN for execution.<br>**NOTE**<br>If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement:<br>`SET enable_fast_query_shipping to off;` |
| enable_hashagg=on | Specifies whether the optimizer uses hash aggregate plans. |
| enable_hashjoin=on | Specifies whether the optimizer uses hash join plans. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter/ Reference Value | Description |
| --- | --- |
| enable_mergejoin=on | Specifies whether the optimizer uses merge join plans. |
| enable_indexscan=on | Specifies whether the optimizer uses index scan plans. |
| enable_indexonlyscan=on | Specifies whether the optimizer uses index-only scan plans. |
| enable_seqscan=on | Specifies whether the optimizer uses sequential scan plans. It is impossible to suppress sequential scans entirely, but setting this variable to **off** encourages the optimizer to choose other methods if available. |
| enable_sort=on | Specifies the optimizer sorting order. It is impossible to fully suppress explicit sorting, but setting this variable to **off** encourages the optimizer to choose other methods if available. |
| enable_broadcast=on | Specifies whether the optimizer uses data broadcast. In data broadcast, a large amount of data is transferred on the network. When the number of transmission nodes (stream) is large and the estimation is inaccurate, set this parameter to **off** and check whether the performance is improved. |
| rewrite_rule | Specifies whether the optimizer enables the LAZYAGG, MAGICSET, PARTIALPUSH, UNIQUECHECK, DISABLEREP, INTARGETLIST, and PREDPUSH rewriting rules. |
| sql_beta_feature | Specifies whether the optimizer enables the SEL_SEMI_POISSON, NO_UNIQUE_INDEX_FIRST, JOIN_SEL_WITH_CAST_FUNC, SEL_EXPR_INSTR, PARAM_PATH_GEN, RAND_COST_OPT, PARAM_PATH_OPT, PAGE_EST_OPT, CANONICAL_PATHKEY, INDEX_COST_WITH_INDEX_COST_WITH_LEAF_PAGES_ONLY, PARTITION_OPFUSION, PREDPUSH_SAME_LEVEL, PARTITION_FDW_ON, or DISABLE_BITMAP_COST_WITH_LOSSY_PAGES beta feature. |

# 10.3.9 Hint-based Tuning

## 10.3.9.1 Plan Hint Optimization

In plan hints, you can specify a join order; join, stream, and scan operations, the number of rows in a result, and redistribution skew information to tune an execution plan, improving query performance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Function

Plan hints are specified in the following format after keywords such as SELECT, INSERT, UPDATE, DELETE, and MERGE:

```
/*+ <plan hint>*/
```

You can specify multiple hints for a query plan and separate them with spaces. A hint specified for a query plan does not apply to its subquery plans. To specify a hint for a subquery, add the hint following the **SELECT** of this subquery.

Example:

```
select /*+ <plan_hint1> <plan_hint2> */ * from t1, (select /*+ <plan_hint3> */ * from t2) where 1=1;
```

In the preceding command, <*plan_hint1*> and <*plan_hint2*> are the hints of a query, and <*plan_hint3*> is the hint of its subquery.

**NOTICE**

If a hint is specified in the **CREATE VIEW** statement, the hint will be applied each time this view is used.

If the random plan function is enabled (**plan_mode_seed** is set to a value other than 0), the specified hint will not be used.

## Scope

Currently, the following hints are supported:

- Join order hints (**leading**)
- Join operation hints, excluding the **semi join**, **anti join**, and **unique plan** hints
- Rows hints
- Stream operation hints
- Scan operation hints, supporting only the **tablescan**, **indexscan**, and **indexonlyscan** hints
- Sublink name hints
- Skew hints, supporting only the skew in the redistribution involving Join or HashAgg
- Hints of the GUC parameter that takes effect in a query. The hints do not take effect if they are used in views.
- Hints that use the custom plan or generic plan. The hints are valid only for query statements executed by PBE.
- Hints specifying not to expand subqueries
- Hints specifying that the current query statement does not enter the global plan cache. The hints are valid only when **enable_global_plancache** is enabled and the current statement is executed by PBE.

## Precautions

- Hints do not support **Agg**, **Sort**, **Setop**, or **Subplan**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Hints do not support SMP or Node Groups.

## Example

The following is the original plan and is used for comparing with the optimized ones:

```
explain
select i_product_name product_name
,i_item_sk item_sk
,s_store_name store_name
,s_zip store_zip
,ad2.ca_street_number c_street_number
,ad2.ca_street_name c_street_name
,ad2.ca_city c_city
,ad2.ca_zip c_zip
,count(*) cnt
,sum(ss_wholesale_cost) s1
,sum(ss_list_price) s2
,sum(ss_coupon_amt) s3
FROM   store_sales
,store_returns
,store
,customer
,promotion
,customer_address ad2
,item
WHERE  ss_store_sk = s_store_sk AND
ss_customer_sk = c_customer_sk AND
ss_item_sk = i_item_sk and
ss_item_sk = sr_item_sk and
ss_ticket_number = sr_ticket_number and
c_current_addr_sk = ad2.ca_address_sk and
ss_promo_sk = p_promo_sk and
i_color in ('maroon','burnished','dim','steel','navajo','chocolate') and
i_current_price between 35 and 35 + 10 and
i_current_price between 35 + 1 and 35 + 15
group by i_product_name
,i_item_sk
,s_store_name
,s_zip
,ad2.ca_street_number
,ad2.ca_street_name
,ad2.ca_city
,ad2.ca_zip
;
```

```
 id |                                operation                                 |   E-rows   | E-memory | E-width |  E-costs

## 10.3.9.2 Join Order Hints

### Function

Theses hints specify the join order and outer/inner tables.

### Syntax

- Specify only the join order.

```
leading(join_table_list)
```

- Specify the join order and outer/inner tables. The outer/inner tables are specified by the outermost parentheses.

```
leading((join_table_list))
```

### Parameter Description

*join_table_list* specifies the tables to be joined. The values can be table names or table aliases. If a subquery is pulled up, the value can also be the subquery alias. Separate the values with spaces. You can add parentheses to specify the join priorities of tables.

**NOTICE**

A table name or alias can only be a string without a schema name.

An alias (if any) is used to represent a table.

To prevent semantic errors, tables in the list must meet the following requirements:

- The tables must exist in the query or its subquery to be pulled up.
- The table names must be unique in the query or subquery to be pulled up. If they are not, their aliases must be unique.
- A table appears only once in the list.
- An alias (if any) is used to represent a table.

For example:

**leading(t1 t2 t3 t4 t5)**: **t1**, **t2**, **t3**, **t4**, and **t5** are joined. The join order and outer/inner tables are not specified.

**leading((t1 t2 t3 t4 t5))**: **t1**, **t2**, **t3**, **t4**, and **t5** are joined in sequence. The table on the right is used as the inner table in each join.

**leading(t1 (t2 t3 t4) t5)**: First, **t2**, **t3**, and **t4** are joined and the outer/inner tables are not specified. Then, the result is joined with **t1** and **t5**, and the outer/inner tables are not specified.

**leading((t1 (t2 t3 t4) t5))**: First, **t2**, **t3**, and **t4** are joined and the outer/inner tables are not specified. Then, the result is joined with **t1**, and **(t2 t3 t4)** is used as the inner table. Finally, the result is joined with **t5**, and **t5** is used as the inner table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**leading((t1 (t2 t3) t4 t5)) leading((t3 t2))**: First, **t2** and **t3** are joined and **t2** is used as the inner table. Then, the result is joined with **t1**, and **(t2 t3)** is used as the inner table. Finally, the result is joined with **t4** and then **t5**, and the table on the right in each join is used as the inner table.

## Example

Hint the query plan in **Example** as follows:

```
explain
select /*+ leading((((((store_sales store) promotion) item) customer) ad2) store_returns) leading((store store_sales))*/ i_product_name product_name ...
```

First, **store_sales** and **store** are joined and **store_sales** is the inner table. Then, the result is joined with **promotion**, **item**, **customer**, **ad2**, and **store_returns** in sequence. The optimized plan is as follows:

```
WARNING:  Duplicated or conflict hint: Leading(store_sales store), will be discarded.
 id |                                operation                                 |   E-rows   | E-memory | E-width |   E-costs
----+--------------------------------------------------------------------------+------------+----------+---------+-------------
  1 | ->  Row Adapter                                                          |          6 |          |     273 | 16308094.34
  2 |    ->  Vector Streaming (type: GATHER)                                   |          6 |          |     273 | 16308094.34
  3 |       ->  Vector Hash Aggregate                                          |          6 | 16MB     |     273 | 16308092.67
  4 |          ->  Vector Hash Join (5,20)                                     |          6 | 585MB    |     169 | 16308092.63

 12 |                                  ->  Vector Hash Join (13,14)            | 2750085660 | 2156MB   |      77 | 14226077.19
 13 |                                     ->  CStore Scan on store             |      24048 | 1MB      |      19 | 2264.00
 14 |                                     ->  Vector Partition Iterator        | 2879987999 | 1MB      |      66 | 2756066.50
 15 |                                        ->  Partitioned CStore Scan on store_sales | 2879987999 | 1MB | 66 | 2756066.50
 16 |                                  ->  CStore Scan on promotion            |      36000 | 1MB      |       4 | 1268.50
 17 |                               ->  CStore Scan on item                    |        158 | 1MB      |      58 | 4051.25
 18 |                         ->  CStore Scan on customer                      |   12000000 | 1MB      |       8 | 12923.00
 19 |                      ->  CStore Scan on customer_address ad2             |    6000000 | 1MB      |      58 | 5770.00
 20 |                ->  Vector Partition Iterator                             |  287999764 | 1MB      |      12 | 227383.99
 21 |                   ->  Partitioned CStore Scan on store_returns           |  287999764 | 1MB      |      12 | 227383.99
(21 rows)
```

For details about the warning at the top of the plan, see **10.3.9.10 Hint Errors, Conflicts, and Other Warnings**.

## 10.3.9.3 Join Operation Hints

## Function

These hints specify the join method, which can be nested loop join, hash join, or merge join.

## Syntax

```
[no] nestloop|hashjoin|mergejoin(table_list)
```

## Parameter Description

- **no** indicates that the specified hint will not be used for a join.
- *table_list* specifies the tables to be joined. The values are the same as those of **join_table_list** but contain no parentheses.

For example:

**no nestloop(t1 t2 t3)**: **nestloop** is not used for joining **t1**, **t2**, and **t3**. The three tables may be joined in either of the two ways: Join **t2** and **t3**, and then **t1**; join **t1**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

and **t2**, and then **t3**. This hint takes effect only for the last join. If necessary, you can hint other joins. For example, you can add **no nestloop(t2 t3)** to join **t2** and **t3** first and to forbid the use of **nestloop**.

## Example

Hint the query plan in **Example** as follows:

```
explain
select /*+ nestloop(store_sales store_returns item) */ i_product_name product_name ...
```

**nestloop** is used for the last join between **store_sales**, **store_returns**, and **item**. The optimized plan is as follows:

```
 id |                                operation                                 |   E-rows   | E-memory | E-width |     E-costs
----+--------------------------------------------------------------------------+------------+----------+---------+-----------------
  1 | ->  Row Adapter                                                          |          6 |          |     273 | 100061693161.06
  2 |    ->  Vector Streaming (type: GATHER)                                   |          6 |          |     273 | 100061693161.06
  3 |       ->  Vector Hash Aggregate                                          |          6 | 16MB     |     273 | 100061693159.40

## 10.3.9.4 Rows Hints

## Function

These hints specify the number of rows in an intermediate result set. Both absolute values and relative values are supported.

## Syntax

```
rows(table_list #|+|-|* const)
```

## Parameter Description

- **#**, **+**, **-**, and ***** are operators used for hinting the estimation. **#** indicates that the original estimation is used without any calculation. **+**, **-**, and ***** indicate that the original estimation is calculated using these operators. The minimum calculation result is 1. *table_list* specifies the tables to be joined. The values are the same as those of **table_list** in **10.3.9.3 Join Operation Hints**.
- *const* can be any non-negative number and supports scientific notation.

For example:

**rows(t1 #5)**: The result set of **t1** is five rows.

**rows(t1 t2 t3 *1000)**: Multiply the result set of joined **t1**, **t2**, and **t3** by 1000.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Suggestion

- The hint using * for two tables is recommended. This hint will be triggered if the two tables appear on two sides of a join. For example, if the hint is **rows(t1 t2 * 3)**, the join result of **(t1 t3 t4)** and **(t2 t5 t6)** will be multiplied by 3 because **t1** and **t2** appear on both sides of the join.
- **rows** hints can be specified for the result sets of a single table, multiple tables, function tables, and subquery scan tables.

## Example

Hint the query plan in **Example** as follows:

```
explain
select /*+ rows(store_sales store_returns *50) */ i_product_name product_name ...
```

Multiply the result set of joined **store_sales** and **store_returns** by 50. The optimized plan is as follows:

```
 id |                                operation                                 |   E-rows   | E-memory | E-width |  E-costs
----+--------------------------------------------------------------------------+------------+----------+---------+------------
  1 | ->  Row Adapter                                                          |        312 |          |     273 | 3401656.58
  2 |    ->  Vector Streaming (type: GATHER)                                   |        312 |          |     273 | 3401656.58
  3 |       ->  Vector Hash Aggregate                                          |        312 | 16MB     |     273 | 3401634.91

 13 |                                     ->  Partitioned CStore Scan on store_returns | 287999764 | 1MB |      12 | 227383.99
 14 |                                  ->  Vector Hash Join (15,17)            |    1516824 | 16MB     |     124 | 3065686.08
 15 |                                     ->  Vector Partition Iterator        | 2879987999 | 1MB      |      66 | 2756066.50
 16 |                                        ->  Partitioned CStore Scan on store_sales | 2879987999 | 1MB |      66 | 2756066.50
 17 |                                     ->  CStore Scan on item              |        158 | 1MB      |      58 | 4051.25
 18 |                                  ->  CStore Scan on store                |      24048 | 1MB      |      19 | 2264.00
 19 |                               ->  CStore Scan on promotion               |      36000 | 1MB      |       4 | 1268.50
 20 |                         ->  CStore Scan on customer                      |   12000000 | 1MB      |       8 | 12923.00
 21 |                   ->  CStore Scan on customer_address ad2                |    6000000 | 1MB      |      58 | 5770.00
(21 rows)
```

The estimation value after the hint in row 11 is **360**, and the original value is rounded off to 7.

## 10.3.9.5 Stream Operation Hints

## Function

These hints specify a stream operation, which can be **broadcast** or **redistribute**. You can also directly specify a method to generate a gather plan.

## Syntax

```
[no] broadcast|redistribute(table_list)
gather(REL|JOIN|ALL)
```

## Parameter Description

- **broadcast** and **redistribute**
  - **no** specifies that the specified hint will not be used for a stream operation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

  - *table_list* specifies the table on which a stream operation is to be performed or the tables to be joined. For details, see **Parameter Description**.

- gather

  The gather hint can specify the following plan generation modes:

  - **REL**: Only the gather path based on the base table is generated, and then the remaining plan is executed on the CN.
  - **JOIN**: A join-based gather path is generated as much as possible and is added to the join subplan that can be pushed down (the join subplan does not contain the redistribution node), and the remaining plan is executed on the CN. For a join plan that requires node redistribution, such a join-based gather path cannot be generated. Instead, a base table-based gather path is generated.

    **CAUTION**

    After **Hint(JOIN)** is specified, the plan expected by **Hint(JOIN)** cannot be generated if the distribution table and replication table are joined, because the optimizer has found a better plan for replacement.

  - **ALL**: The **Gather Rel** or **Gather Join** path is selected based on the optimal mode.

## Example

Hint the query plan in **Example** as follows:

```
explain
select /*+ no redistribute(store_sales store_returns item store) leading(((store_sales store_returns item
store) customer)) */ i_product_name product_name ...
```

In the original plan, the join result of **store_sales**, **store_returns**, **item**, and **store** is redistributed before it is joined with **customer**. After the hinting, the redistribution is disabled and the join order is retained. The optimized plan is as follows:

```
 id |                                operation                                |   E-rows   | E-memory | E-width |  E-costs
----+-------------------------------------------------------------------------+------------+----------+---------+------------
  1 | ->  Row Adapter                                                         |          6 |          |     273 | 5718448.94
  2 |    ->  Vector Streaming (type: GATHER)                                  |          6 |          |     273 | 5718448.94
  3 |       ->  Vector Hash Aggregate                                         |          6 | 16MB     |     273 | 5718447.27
  4 |          ->  Vector Streaming(type: REDISTRIBUTE)                       |          6 | 1MB      |     169 | 5718447.23
  5 |             ->  Vector Hash Join (6,21)                                 |          6 | 16MB     |     169 | 5718446.86

Node/s: All datanodes
->  Seq Scan on t3  (cost=0.00..1.05 rows=10 width=8)
(15 rows)
```

2. Generate the join gather plan **/*+ GATHER(REL)*/** that can be pushed down.

```
openGauss=# explain select /*+ GATHER(JOIN)*/* from t1, t2, t3 where t1.c1 = t2.c1 and t2.c2 = t3.c2;
QUERY PLAN
------------------------------------------------------------------------------
Hash Join  (cost=2.76..4.48 rows=10 width=24)
Hash Cond: (t2.c2 = t3.c2)
->  Streaming (type: GATHER)  (cost=1.43..2.70 rows=10 width=16)
Node/s: All datanodes
->  Hash Join  (cost=1.11..2.23 rows=10 width=16)
Hash Cond: (t1.c1 = t2.c1)
->  Seq Scan on t1  (cost=0.00..1.05 rows=10 width=8)
->  Hash  (cost=1.05..1.05 rows=10 width=8)
->  Seq Scan on t2  (cost=0.00..1.05 rows=10 width=8)
->  Hash  (cost=1.52..1.52 rows=10 width=8)
->  Streaming (type: GATHER)  (cost=0.31..1.52 rows=10 width=8)
Node/s: All datanodes
->  Seq Scan on t3  (cost=0.00..1.05 rows=10 width=8)
(13 rows)
```

3. Generate the gather plan **/*+ GATHER(ALL)*/** based on the optimal mode.

   The **GATHER(REL)** or **GATHER(JOIN)** path is selected based on the optimal mode and rules.

```
openGauss=# explain select /*+ GATHER(ALL)*/* from t1, t2, t3 where t1.c1 = t2.c1 and t2.c2 = t3.c2;
QUERY PLAN
------------------------------------------------------------------------------
Hash Join  (cost=2.76..4.48 rows=10 width=24)
Hash Cond: (t2.c2 = t3.c2)
->  Streaming (type: GATHER)  (cost=1.43..2.70 rows=10 width=16)
Node/s: All datanodes
->  Hash Join  (cost=1.11..2.23 rows=10 width=16)
Hash Cond: (t1.c1 = t2.c1)
->  Seq Scan on t1  (cost=0.00..1.05 rows=10 width=8)
->  Hash  (cost=1.05..1.05 rows=10 width=8)

->  Streaming (type: GATHER)  (cost=0.31..1.52 rows=10 width=8)
Node/s: All datanodes
->  Seq Scan on t3  (cost=0.00..1.05 rows=10 width=8)
(13 rows)
```

## 10.3.9.6 Scan Operation Hints

## Function

These hints specify a scan operation, which can be **tablescan**, **indexscan**, or **indexonlyscan**.

## Syntax

```
[no] tablescan|indexscan|indexonlyscan(table [index])
```

## Parameter Description

- **no** indicates that the specified hint will not be used for a join.
- *table* specifies the table to be scanned. You can specify only one table. Use a table alias (if any) instead of a table name.
- *index* indicates the index for **indexscan** or **indexonlyscan**. You can specify only one index.

NOTE

**indexscan** and **indexonlyscan** hints can be used only when the specified index belongs to the table.

Scan operation hints can be used for row-store tables, column-store tables, OBS tables (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.), and subquery tables.

## Example

To specify an index-based hint for a scan, create an index named **i** on the **i_item_sk** column of the **item** table.

```
create index i on item(i_item_sk);
```

Hint the query plan in **Example** as follows:

```
explain
select /*+ indexscan(item i) */ i_product_name product_name ...
```

**item** is scanned based on an index. The optimized plan is as follows:

```
 id |                                operation                                 |   E-rows   | E-memory | E-width |     E-costs
----+--------------------------------------------------------------------------+------------+----------+---------+-----------------
  1 | ->  Row Adapter                                                          |          6 |          |     273 | 100061674938.26
  2 |    ->  Vector Streaming (type: GATHER)                                   |          6 |          |     273 | 100061674938.26
  3 |       ->  Vector Hash Aggregate                                          |          6 | 16MB     |     273 | 100061674936.59
  4 |          ->  Vector Streaming(type: REDISTRIBUTE)                        |          6 | 1MB      |     169 | 100061674936.55
  5 |             ->  Vector Hash Join (6,21)                                  |          6 | 43MB     |     169 | 100061674936.19
  6 |                ->  Vector Streaming(type: REDISTRIBUTE)                  |          6 | 1MB      |     119 | 100061670368.67
  7 |                   ->  Vector Hash Join (8,20)                            |          6 | 16MB     |     119 | 100061670368.50
  8 |                      ->  Vector Hash Join (9,19)                         |          7 | 27MB     |     123 | 100061669081.23

## 10.3.9.7 Sublink Name Hints

## Function

These hints specify the name of a sublink block.

## Syntax

```
blockname (table)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Parameter Description

- *table* specifies the name you have specified for a sublink block.

  NOTE

  - The **blockname** hint is used by an outer query only when the corresponding sublink is not pulled up. Currently, only the **Agg** equivalent join, **IN**, and **EXISTS** sublinks can be pulled up. This hint is usually used together with the hints described in the previous sections.
  - The subquery after the **FROM** keyword is hinted by using the subquery alias. In this case, **blockname** becomes invalid.
  - If a sublink contains multiple tables, the tables will be joined with the outer-query tables in a random sequence after the sublink is pulled up. In this case, **blockname** also becomes invalid.

## Examples

```
explain select /*+nestloop(store_sales tt) */ * from store_sales where ss_item_sk in (select /*
+blockname(tt)*/ i_item_sk from item group by 1);
```

**tt** indicates the sublink block name. After being pulled up, the sublink is joined with the outer-query table **store_sales** by using **nestloop**. The optimized plan is as follows:

```
 id |                       operation                       |   E-rows   | E-memory | E-width |     E-costs
----+-------------------------------------------------------+------------+----------+---------+-----------------
  1 | ->  Row Adapter                                       | 1439994000 |          |     216 | 325105765847.91
  2 |    ->  Vector Streaming (type: GATHER)                | 1439994000 |          |     216 | 325105765847.91
  3 |       ->  Vector Nest Loop Semi Join (4, 6)           | 1439994000 | 1MB      |     216 | 325026664615.00
  4 |          ->  Vector Partition Iterator                | 2879987999 | 1MB      |     216 | 2756066.50
  5 |             ->  Partitioned CStore Scan on store_sales | 2879987999 | 1MB      |     216 | 2756066.50
  6 |          ->  Vector Materialize                       |     300000 | 16MB     |       4 | 4176.25
  7 |             ->  Vector Hash Aggregate                 |     300000 | 16MB     |       4 | 3988.75
  8 |                ->  CStore Scan on item                |     300000 | 1MB      |       4 | 3832.50
(8 rows)
```

## 10.3.9.8 Skew Hints

## Function

Theses hints specify redistribution keys containing skew data and skew values, and are used to optimize redistribution involving Join or HashAgg.

## Syntax

- Specify single-table skew.
  ```
  skew(table (column) [(value)])
  ```
- Specify intermediate result skew.
  ```
  skew((join_rel) (column) [(value)])
  ```

## Parameter Description

- *table* specifies the table where skew occurs.
- *join_rel* specifies two or more joined tables. For example, **(t1 t2)** indicates that the result of joining **t1** and **t2** tables contains skew data.
- *column* specifies one or more columns where skew occurs.
- *value* specifies one or more skew values.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- Skew hints are used only if redistribution is required and the specified skew information matches the redistribution information.
- Skew hints are controlled by the GUC parameter **skew_option**. If the parameter is disabled, skew hints cannot be used for solving skew.
- Currently, skew hints support only the table relationships of the ordinary table and subquery types. Hints can be specified for base tables, subqueries, and **WITH ... AS** clauses. Unlike other hints, a subquery can be used in skew hints regardless of whether it is pulled up.
- Use an alias (if any) to specify a table where data skew occurs.
- You can use a name or an alias to specify a skew column as long as it is not ambiguous. The columns in skew hints cannot be expressions. If data skew occurs in the redistribution that uses an expression as a redistribution key, set the redistribution key as a new column and specify the column in skew hints.
- The number of skew values must be an integer multiple of the number of columns. Skew values must be grouped based on the column sequence, with each group containing a maximum of 10 values. You can specify duplicate values to group skew columns having different number of skew values. For example, the **c1** and **c2** columns of the **t1** table contain skew data. The skew value of the **c1** column is **a1**, and the skew values of the **c2** column are **b1** and **b2**. In this case, the skew hint is **skew(t1 (c1 c2) ((a1 b1)(a1 b2)))**. **(a1 b1)** is a value group, where **NULL** is allowed as a skew value. Each hint can contain a maximum of 10 groups and the number of groups should be an integer multiple of the number of columns.
- In the redistribution optimization of Join, a skew value must be specified for skew hints. The skew value can be left empty for HashAgg.
- If multiple tables, columns, or values are specified, separate items of the same type with spaces.
- The type of skew values cannot be forcibly converted in hints. To specify a string, enclose it with single quotation marks (' ').

Example:

- Specify single-table skew.

  Each skew hint describes the skew information of one table relationship. To describe the skews of multiple table relationships in a query, specify multiple skew hints.

  Skew hints have the following formats:

  - One skew value in one column: **skew(t (c1) (v1))**

    Description: The **v1** value in the **c1** column of the **t** table relationship causes skew in query execution.
  - Multiple skew values in one column: **skew(t (c1) (v1 v2 v3 ...))**

    Description: Values including **v1, v2**, and **v3** in the **c1** column of the **t** table relationship cause skew in query execution.
  - Multiple columns, each having one skew value: **skew(t (c1 c2) (v1 v2))**

    Description: The **v1** value in the **c1** column and the **v2** value in the **c2** column of the **t** table relationship cause skew in query execution.
  - Multiple columns, each having multiple skew values: **skew(t (c1 c2) ((v1 v2) (v3 v4) (v5 v6) ...))**

    Description: Values including **v1, v3**, and **v5** in the **c1** column and values including **v2, v4**, and **v6** in the **c2** column of the **t** table relationship cause skew in query execution.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**NOTICE**

In the last format, parentheses for skew value groups can be omitted, for example, **skew(t (c1 c2) (v1 v2 v3 v4 v5 v6 ...))**. In a skew hint, either use parentheses for all skew value groups or for none of them.

Otherwise, a syntax error will be generated. For example, **skew(t (c1 c2) (v1 v2 v3 v4 (v5 v6) ...))** will generate an error.

- Specify intermediate result skew.

  If data skew does not occur in base tables but in an intermediate result during query execution, specify skew hints of the intermediate result to solve the skew. skew((t1 t2) (c1) (v1))

  Description: Data skew occurs after the table relationships **t1** and **t2** are joined. The **c1** column of the **t1** table contains skew data and its skew value is **v1**.

  **c1** can exist only in a table relationship of **join_rel**. If there is another column having the same name, use aliases to avoid ambiguity.

## Suggestion

- For a multi-level query, write the hint on the layer where data skew occurs.
- For a listed subquery, you can specify the subquery name in a hint. If you know data skew occurs on which base table, directly specify the table.
- Aliases are preferred when you specify a table or column in a hint.

## Example

Specify single-table skew.

- Specify hints in the original query.

  For example, the original query is as follows:

```
explain
with customer_total_return as
(select sr_customer_sk as ctr_customer_sk
,sr_store_sk as ctr_store_sk
,sum(SR_FEE) as ctr_total_return
from store_returns
,date_dim
where sr_returned_date_sk = d_date_sk
and d_year =2000
group by sr_customer_sk
,sr_store_sk)
 select  c_customer_id
from customer_total_return ctr1
,store
,customer
where ctr1.ctr_total_return > (select avg(ctr_total_return)*1.2
from customer_total_return ctr2
where ctr1.ctr_store_sk = ctr2.ctr_store_sk)
and s_store_sk = ctr1.ctr_store_sk
and s_state = 'NM'
and ctr1.ctr_customer_sk = c_customer_sk
order by c_customer_id
limit 100;
```

 27 |                                              ->  Vector Partition Iterator |       363 | 1MB            |       4 | 910.65
 28 |                                                 ->  Partitioned CStore Scan on date_dim |  363 | 1MB      |       4 | 910.65
 29 |                   ->  CStore Scan on customer                            |  12000000 | 1MB            |      24 | 12923.00
(29 rows)
```

Specify the hints of HashAgg in the inner **with** clause and of the outer Hash Join. The query containing hints is as follows:

```
explain
with customer_total_return as
(select /*+ skew(store_returns(sr_store_sk sr_customer_sk)) */sr_customer_sk as ctr_customer_sk
,sr_store_sk as ctr_store_sk
,sum(SR_FEE) as ctr_total_return
from store_returns
,date_dim
where sr_returned_date_sk = d_date_sk
and d_year =2000
group by sr_customer_sk
,sr_store_sk)
 select  /*+ skew(ctr1(ctr_customer_sk)(11))*/  c_customer_id
from customer_total_return ctr1
,store
,customer
where ctr1.ctr_total_return > (select avg(ctr_total_return)*1.2
from customer_total_return ctr2
where ctr1.ctr_store_sk = ctr2.ctr_store_sk)
and s_store_sk = ctr1.ctr_store_sk
and s_state = 'NM'
and ctr1.ctr_customer_sk = c_customer_sk
order by c_customer_id
limit 100;
```

The hints indicate that the **group by** in the inner **with** clause contains skew data during redistribution by HashAgg, corresponding to the original Hash Agg operators 10 and 21; and that the **ctr_customer_sk** column in the outer **ctr1** table contains skew data during redistribution by Hash Join, corresponding to operator 6 in the original plan. The optimized plan is as follows:

(32 rows)
```

To solve data skew in the redistribution, Hash Agg is changed to double-level Agg operators and the redistribution operators used by Hash Join are changed in the optimized plan.

- Modify the query and then specify hints.

  For example, the original query and its plan are as follows:

```
explain select count(*) from store_sales_1 group by round(ss_list_price);
```

```
 id |                                operation                                 |  E-rows  |  E-memory  | E-width |  E-costs
----+--------------------------------------------------------------------------+----------+------------+---------+----------
  1 | ->  Row Adapter                                                          |    16672 |            |      14 | 62261.28
  2 |    ->  Vector Streaming (type: GATHER)                                   |    16672 |            |      14 | 62261.28
  3 |       ->  Vector Streaming(type: LOCAL GATHER dop: 1/2)                  |    16672 | 32KB       |      14 | 61479.78
  4 |          ->  Vector Hash Aggregate                                       |    16672 | 16MB       |      14 | 61452.00
  5 |             ->  Vector Streaming(type: SPLIT REDISTRIBUTE dop: 2/2)      |  3112836 | 128KB      |       6 | 57498.43
  6 |                ->  CStore Scan on store_sales_1                          |  3112836 | 1MB        |       6 | 21810.25
(6 rows)
```

  Columns in hints do not support expressions. To specify hints, rewrite the query as several subqueries. The rewritten query and its plan are as follows:

```
explain
select count(*)
from (select round(ss_list_price),ss_hdemo_sk
from store_sales_1)tmp(a,ss_hdemo_sk)
group by a;
```

```
 id |                                operation                                 |  E-rows  |  E-memory  | E-width |  E-costs
----+--------------------------------------------------------------------------+----------+------------+---------+----------
  1 | ->  Row Adapter                                                          |    16672 |            |      14 | 62261.28
  2 |    ->  Vector Streaming (type: GATHER)                                   |    16672 |            |      14 | 62261.28
  3 |       ->  Vector Streaming(type: LOCAL GATHER dop: 1/2)                  |    16672 | 32KB       |      14 | 61479.78
  4 |          ->  Vector Hash Aggregate                                       |    16672 | 16MB       |      14 | 61452.00
  5 |             ->  Vector Streaming(type: SPLIT REDISTRIBUTE dop: 2/2)      |  3112836 | 128KB      |       6 | 57498.43
  6 |                ->  CStore Scan on store_sales_1                          |  3112836 | 1MB        |       6 | 21810.25
(6 rows)
```

  Ensure that the service logic is not changed during the rewriting.

  Specify hints in the rewritten query as follows:

```
explain
select /*+ skew(tmp(a)) */ count(*)
from (select round(ss_list_price),ss_hdemo_sk
from store_sales_1)tmp(a,ss_hdemo_sk)
group by a;
```

```
 id |                                operation                                 |  E-rows  | E-memory | E-width |  E-costs
----+--------------------------------------------------------------------------+----------+----------+---------+-----------
  1 | ->  Row Adapter                                                          |    16672 |          |      14 | 27771.82
  2 |    ->  Vector Streaming (type: GATHER)                                   |    16672 |          |      14 | 27771.82
  3 |       ->  Vector Streaming(type: LOCAL GATHER dop: 1/2)                  |    16672 | 32KB     |      14 | 26990.32
  4 |          ->  Vector Hash Aggregate                                       |    16671 | 16MB     |      14 | 26962.54
  5 |             ->  Vector Streaming(type: SPLIT REDISTRIBUTE dop: 2/2)      |    66216 | 128KB    |      14 | 26838.09
  6 |                ->  Vector Hash Aggregate                                 |    66216 | 16MB     |      14 | 25949.61
  7 |                   ->  CStore Scan on store_sales_1                       |  3112836 | 1MB      |       6 | 21810.25
(7 rows)
```

  The plan shows that after Hash Agg is changed to double-layer Agg operators, redistributed data is greatly reduced and redistribution time is shortened.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

You can specify hints in columns in a subquery, for example:

```
explain
select /*+ skew(tmp(b)) */ count(*)
from (select round(ss_list_price) b,ss_hdemo_sk
from store_sales_1)tmp(a,ss_hdemo_sk)
group by a;
```

## 10.3.9.9 Parameterized Path Hint

### Function

Specifies the parameterized path and the conditional predicate pushdown method.

### Syntax

```
predpush(src1 src2)
predpush(src, dest)
```

### Parameter Description

- **src**, **src1**, and **src2** indicate the set of candidates tables pushed down by **predpush**.
- **dest** indicates the specified destination table pushed down by **predpush**.
- If **predpush** does not contain commas (,), all tables are candidates table. If **predpush** contains commas (,), both candidates tables and destination tables are specified.

NOTE

Use the **predpush** hint to move the filter expression as close to the data source as possible to optimize the query.

- Before using the **predpush** hint, ensure that the **rewrite_rule** GUC parameter contains the **PREDPUSH|REDPUSHFORCE|PREDPUSHNORMAL** option.
- **subquery_block** can also be a view or materialized view.

### Examples

Use the **predpush** hint to improve the statement execution efficiency. Example:

```
set rewrite_rule = 'predpushnormal';
explain (costs off) SELECT /*+PREDPUSH(t2, st3)*/ *
FROM t2,
   (SELECT sum(t3.b), t3.a FROM t3, t4 where t3.a = t4.a GROUP BY t3.a) st3
WHERE st3.a = t2.a;
 id |                     operation

```
  8 --Index Scan using t3_a_idx on t3
        Index Cond: (a = t2.a)
(4 rows)
```

If the **predpush** hint is not used, t3 and t4 in the subquery are not processed outside the query block before being joined. As a result, the returned result set is large, causing performance waste.

However, as shown in the preceding plan, after the **predpush** hint is used, condition filtering is performed on t3 and t4 based on t2 before they are joined. The result set returned after joining is small, which effectively improves the performance.

## 10.3.9.10 Hint Errors, Conflicts, and Other Warnings

Plan hints change an execution plan. You can run **EXPLAIN** to view the changes.

Hints containing errors are invalid and do not affect statement execution. The errors will be displayed in different ways based on statement types. Hint errors in an **EXPLAIN** statement are displayed as a warning on the interface. Hint errors in other statements will be recorded in debug1-level logs containing the **PLANHINT** keyword.

Hint error types are as follows:

- Syntax errors

  An error will be reported if the syntax tree fails to be reduced. The No. of the row generating an error is displayed in the error details.

  For example, the hint keyword is incorrect, no table or only one table is specified in the **leading** or **join** hint, or no tables are specified in other hints. The parsing of a hint is terminated immediately after a syntax error is detected. Only the hints that have been parsed successfully are valid.

  Example:

  ```
  leading((t1 t2)) nestloop(t1) rows(t1 t2 #10)
  ```

  The syntax of **nestloop(t1)** is wrong and its parsing is terminated. Only **leading(t1 t2)** that has been successfully parsed before **nestloop(t1)** is valid.
- Semantic errors
  - An error will be reported if the specified tables do not exist, multiple tables are found based on the hint setting, or a table is used more than once in the **leading** or **join** hint.
  - An error will be reported if the index specified in a scan hint does not exist.
  - If multiple tables with the same name exist after a subquery is pulled up and some of them need to be hinted, add aliases for them to avoid name duplication.
- Duplicated or conflicted hints

  If hint duplication or conflicts occur, only the first hint takes effect. A message will be displayed to describe the situation.
  - Hint duplication indicates that a hint is used more than once in the same query, for example, **nestloop(t1 t2) nestloop(t1 t2)**.
  - A hint conflict indicates that the functions of two hints with the same table list conflict with each other.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

For example, if **nestloop (t1 t2) hashjoin (t1 t2)** is used, **hashjoin (t1 t2)** becomes invalid. **nestloop(t1 t2)** does not conflict with **no mergejoin(t1 t2)**.

**NOTICE**

The table list in the **leading** hint is disassembled. For example, **leading ((t1 t2 t3))** will be disassembled as **leading((t1 t2)) leading(((t1 t2) t3))**, which will conflict with **leading((t2 t1))** (if any). In this case, the latter **leading(t2 t1)** becomes invalid. If two hints use duplicated table lists and only one of them has the specified outer/inner table, the one without a specified outer/inner table becomes invalid.

- A hint becomes invalid after a sublink is pulled up.

  In this case, a message will be displayed. Generally, such invalidation occurs when a sublink contains multiple tables to be joined. After the sublink is pulled up, the tables will not be join members.

- Unsupported column types
  - Skew hints are specified to optimize redistribution. They will be invalid if their corresponding columns do not support redistribution.
- Hints are not used.
  - If **hashjoin** or **mergejoin** is specified for non-equivalent joins, it will not be used.
  - If **indexscan** or **indexonlyscan** is specified for a table that does not have an index, it will not be used.
  - If **indexscan hint** or **indexonlyscan** is specified for a full-table scan or for a scan whose filtering conditions are not set on index columns, it will not be used.
  - The specified **indexonlyscan** hint is used only when the output column contains only indexes.
  - In equivalent joins, only the joins containing equivalence conditions are valid. Therefore, the **leading**, **join**, and **rows** hints specified for the joins without an equivalence condition will not be used. For example, **t1**, **t2**, and **t3** are to be joined, and the join between **t1** and **t3** does not contain an equivalence condition. In this case, **leading(t1 t3)** will not be used.
  - To generate a streaming plan, if the distribution key of a table is the same as its join key, **redistribute** specified for this table will not be used. If the distribution key and join key are different for this table but the same for the other table in the join, **redistribute** specified for this table will be used but **broadcast** will not.
  - If no sublink is pulled up, the specified **blockname** hint will not be used.
  - Skew hints are not used possibly because:
    - The plan does not require redistribution.
    - The columns specified by hints contain distribution keys.
    - Skew information specified in hints is incorrect or incomplete, for example, no value is specified for join optimization.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- Skew optimization is disabled by GUC parameters.

## 10.3.9.11 Plan Hint Cases

This section takes the statements in TPC-DS (Q24) as an example to describe how to optimize an execution plan by using hints in 1000X+24DN environments. For example:

```
select avg(netpaid) from
(select c_last_name
,c_first_name
,s_store_name
,ca_state
,s_state
,i_color
,i_current_price
,i_manager_id
,i_units
,i_size
,sum(ss_sales_price) netpaid
from store_sales
,store_returns
,store
,item
,customer
,customer_address
where ss_ticket_number = sr_ticket_number
and ss_item_sk = sr_item_sk
and ss_customer_sk = c_customer_sk
and ss_item_sk = i_item_sk
and ss_store_sk = s_store_sk
and c_birth_country = upper(ca_country)
and s_zip = ca_zip
and s_market_id=7
group by c_last_name
,c_first_name
,s_store_name
,ca_state
,s_state
,i_color
,i_current_price
,i_manager_id
,i_units
,i_size);
```

1. The original plan of this statement is as follows and the statement execution takes 110s:

```
 id |                                operation                                 |        A-time         |  A-rows   |  E-rows
----+--------------------------------------------------------------------------+-----------------------+-----------+-----------
  1 | ->  Row Adapter                                                          | 110324.107            |         1 |         1
  2 |    ->  Vector Aggregate                                                  | 110324.093            |         1 |         1
  3 |       ->  Vector Streaming (type: GATHER)                                | 110323.958            |        24 |        24
  4 |          ->  Vector Aggregate                                            | [110179.302,110309.653] |        24 |        24
  5 |             ->  Vector Hash Aggregate                                    | [110178.388,110308.515] |    647824 |     16656
  6 |                ->  Vector Streaming(type: REDISTRIBUTE)                  | [77616.177,96478.771]   |  666834733 |     16664

 10 |                            ->  Vector Streaming(type: BROADCAST)         | [7940.962,21430.725]    |  591882336 |     51360
 11 |                               ->  Vector Hash Join (12,20)               | [2419.995,5319.606]     |   24661764 |      2140
 12 |                                  ->  Vector Streaming(type: REDISTRIBUTE) | [1750.448,4659.581]     |   25258268 |      2241
 13 |                                     ->  Vector Hash Join (14,18)         | [15240.666,17159.616]   |   25258268 |      2241
 14 |                                        ->  Vector Hash Join (15,17)      | [12112.913,13563.366]   |  252564412 |  472070592
 15 |                                           ->  Vector Partition Iterator  | [11148.731,12473.230]   | 2879987999 | 2879987999
 16 |                                              ->  Partitioned CStore Scan on public.store_sales | [11097.921,12412.596] | 2879987999 | 2879987999
 17 |                                           ->  CStore Scan on public.store | [0.447,0.689]           |      2064 |      2064
 18 |                                        ->  Vector Partition Iterator     | [296.805,319.014]       |  287999764 |  287999764
 19 |                                           ->  Partitioned CStore Scan on public.store_returns | [292.938,314.787] |  287999764 |  287999764
 20 |                                  ->  CStore Scan on public.customer       | [114.358,144.462]       |   12000000 |   12000000
 21 |                               ->  CStore Scan on public.customer_address  | [38.426,56.753]         |    6000000 |    6000000
 22 |                      ->  CStore Scan on public.item                       | [3.160,5.026]           |     300000 |     300000
(22 rows)
```

In this plan, the performance of the layer-10 **broadcast** is poor because the estimation result generated at layer 11 is 2140 rows, much less than the actual

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

number of rows. The inaccurate estimation is mainly caused by the underestimated number of rows in layer-13 hash join. In this layer, **store_sales** and **store_returns** are joined (based on the **ss_ticket_number** and **ss_item_sk** columns in **store_sales** and the **sr_ticket_number** and **sr_item_sk** columns in **store_returns**) but the multi-column correlation is not considered.

2. After the **rows** hint is used for optimization, the plan is as follows and the statement execution takes 318s:

```
select avg(netpaid) from
(select /*+rows(store_sales store_returns * 11270)*/ c_last_name ...
```

```
 id |                                operation                                 |        A-time         |  A-rows   |  E-rows
----+--------------------------------------------------------------------------+-----------------------+-----------+-----------+
  1 | ->  Row Adapter                                                          | 318585.246            |         1 |         1 |
  2 |    ->  Vector Aggregate                                                  | 318585.232            |         1 |         1 |
  3 |       ->  Vector Streaming (type: GATHER)                                | 318585.082            |        24 |        24 |
  4 |          ->  Vector Aggregate                                            | [318323.324,318499.290] |        24 |        24 |
  5 |             ->  Vector Hash Aggregate                                    | [318320.813,318497.054] |    647824 |  187770504 |

 15 |                                     ->  Vector Partition Iterator        | [304.188,403.205]     |  287999764 |  287999764 |
 16 |                                        ->  Partitioned CStore Scan on public.store_returns | [299.838,398.255] |  287999764 |  287999764 |
 17 |                               ->  CStore Scan on public.customer         | [122.246,170.128]     |   12000000 |   12000000 |
 18 |                         ->  Vector Streaming(type: REDISTRIBUTE)         | [57.558,117.461]      |     492915 |     146467 |
 19 |                            ->  Vector Hash Join (20,21)                  | [45.554,96.238]       |     492915 |     146467 |
 20 |                               ->  CStore Scan on public.customer_address | [39.738,89.412]       |    6000000 |    6000000 |
 21 |                               ->  CStore Scan on public.store            | [0.361,1.095]         |       2064 |       2064 |
 22 |                      ->  Vector Streaming(type: BROADCAST)               | [48.986,91.170]       |    7200000 |    7200000 |
 23 |                         ->  CStore Scan on public.item                   | [4.506,6.602]         |     300000 |     300000 |
(23 rows)
```

The execution takes a longer time because layer-9 **redistribute** is slow. Considering that data skew does not occur at layer-9 **redistribute**, the slow redistribution is caused by the slow layer-8 **hashjoin** due to data skew at layer-18 **redistribute**.

3. Data skew occurs at layer-18 **redistribute** because **customer_address** has a few different values in its two join keys. Therefore, plan **customer_address** as the last one to be joined. After the hint is used for optimization, the plan is as follows and the statement execution takes 116s:

```
select avg(netpaid) from
(select /*+rows(store_sales store_returns *11270)
leading((store_sales store_returns store item customer) customer_address)*/
c_last_name ...
```

```
 id |                                operation                                 |        A-time         |  A-rows   |  E-rows
----+--------------------------------------------------------------------------+-----------------------+-----------+-----------+
  1 | ->  Row Adapter                                                          | 116326.597            |         1 |         1 |
  2 |    ->  Vector Aggregate                                                  | 116326.590            |         1 |         1 |
  3 |       ->  Vector Streaming (type: GATHER)                                | 116326.473            |        24 |        24 |

```

Most of the time is spent on layer-6 **redistribute**. The plan needs to be further optimized.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

4. Most of the time is spent on layer-6 **redistribute** because of data skew. To avoid the data skew, plan the **item** table as the last one to be joined because the number of rows is not reduced after **item** is joined. After the hint is used for optimization, the plan is as follows and the statement execution takes 120s:

```
select avg(netpaid) from
(select /*+rows(store_sales store_returns *11270)
leading((customer_address (store_sales store_returns store customer) item))
c_last_name ...
```

```

(23 rows)
```

Data skew occurs after the join of **item** and **customer_address** because **item** is broadcast at layer-22. As a result, layer-6 **redistribute** is still slow.

5. Add a hint to disable **broadcast** for **item** or add a **redistribute** hint for the join result of **item** and **customer_address**. After the hint is used for optimization, the plan is as follows and the statement execution takes 105s:

```
select avg(netpaid) from
(select /*+rows(store_sales store_returns *11270)
leading((customer_address (store_sales store_returns store customer) item))
no broadcast(item)*/
c_last_name ...
```

```

6. The last layer uses single-layer **Agg** and the number of rows is greatly reduced. Set **best_agg_plan** to **3** and change the single-layer **Agg** to a double-layer **Agg**. The plan is as follows and the statement execution takes 94s. The optimization ends.

If the query performance deteriorates due to statistics changes, you can use hints to optimize the query plan. Take TPCH-Q17 as an example. The query performance deteriorates after the value of **default_statistics_target** is changed from the default one to **–2** for statistics collection.

1. If **default_statistics_target** is set to the default value **100**, the plan is as follows:

```

3. After the analysis, the cause is that the stream type is changed from **Broadcast** to **Redistribute** during the join of the **lineitem** and **part** tables. You can use a hint to change the stream type back to **BroadCast**. For example:

```
select /*+ no redistribute(part lineitem) */
    sum(l_extendedprice) / 7.0 as avg_yearly
from
    lineitem,
    part
where
    p_partkey = l_partkey
    and p_brand = 'Brand#23'
    and p_container = 'MED BOX'
    and l_quantity < (
        select
            0.2 * avg(l_quantity)
        from
            lineitem
        where
            l_partkey = p_partkey
    );
```

## 10.3.9.12 Optimizer GUC Parameter Hints

### Function

These hints set GUC parameters related to query optimization that take effect during the query execution. For details about the application scenarios of hints, see the description of each GUC parameter.

### Syntax

```
set(param value)
```

### Parameter Description

- **param** indicates the parameter name.
- **value** indicates the value of a parameter.
- Currently, the following parameters can be set and take effect by using hints:
  - Boolean

    enable_bitmapscan, enable_hashagg, enable_hashjoin, enable_indexscan, enable_indexonlyscan, enable_material, enable_mergejoin, enable_nestloop, enable_index_nestloop, enable_seqscan, enable_sort, enable_tidscan, enable_stream_operator, enable_stream_recursive, enable_broadcast, enable_fast_query_shipping, enable_trigger_shipping, enable_remotejoin, enable_remotegroup, enable_remotelimit, and enable_remotesort
  - Integer

    best_agg_plan and query_dop
  - Floating point

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

cost_weight_index, default_limit_rows, seq_page_cost, random_page_cost, cpu_tuple_cost, cpu_index_tuple_cost, cpu_operator_cost, and effective_cache_size

- Enumerated type

  try_vector_engine_strategy

- Character string

  node_name

  By setting **node_name**, you can deliver the current SQL statement to the DN corresponding to **node_name** for execution.

  Example:

  ```
  select /*+ set(node_name datanode1) */ from table_name;
  ```

  In the preceding command, **datanode1** indicates the name of the DN queried from the **pgxc_node** system catalog (without quotation marks), and **table_name** indicates the table name. This query is directly performed on **datanode1**.

**NOTICE**

- **node_name** can be set only by using the SELECT statement. If it is set by using other statements, it does not take effect.
- **node_name** can only be set to the name of a DN and cannot be set to the name of a CN.
- **node_name** cannot be modified by using the SET statement and can only be used in plan hints.
- **node_name** cannot be modified by using **gs_guc**.
- **node_name** supports only simple query statements and does not support complex query statements (such as UNION and UNION ALL), subqueries, and multi-table associations.
- This operation can be performed by common users.
- This operation cannot be performed together with row-level access control. If they are performed together, an error will be reported.

**NOTE**

- If you set a parameter that is not in the whitelist and the parameter value is invalid or the hint syntax is incorrect, the query execution is not affected. Run **explain(verbose on)**. An error message is displayed, indicating that hint parsing fails.
- The GUC parameter hint takes effect only in the outermost query. That is, the GUC parameter hint in the subquery does not take effect.
- The GUC parameter hint in the view definition does not take effect.
- CREATE TABLE ... AS ... The GUC parameter hint in the outermost query takes effect.

## 10.3.9.13 Hints for Selecting the Custom Plan or Generic Plan

## Function

For query statements and DML statements executed in PBE mode, the optimizer generates a custom plan or generic plan based on factors such as rules, costs, and

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

parameters. You can use the hint of **use_cplan** or **use_gplan** to specify the plan to execute.

## Syntax

- To select the custom plan, run the following statement:
  ```
  use_cplan
  ```
- To select the generic plan, run the following statement:
  ```
  use_gplan
  ```

  NOTE

  - For SQL statements that are executed in non-PBE mode, setting this hint does not affect the execution mode.
  - This hint has a higher priority than cost-based selection and the **plan_cache_mode** parameter. That is, this hint does not take effect for statements for which **plan_cache_mode** cannot be forcibly set to specify an execution mode.

## Example

Forcibly use the custom plan.

```
set enable_fast_query_shipping = off;
create table t (a int, b int, c int);
prepare p as select /*+ use_cplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filtering condition is the actual value of the input parameter, that is, the plan is a custom plan.

```
                              QUERY PLAN
-----------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..13.26 rows=1 width=12)
   Node/s: datanode1
   ->  Seq Scan on t  (cost=0.00..13.16 rows=1 width=12)
         Filter: (a = 1)
(4 rows)
```

Forcibly use the generic plan.

```
deallocate p;
prepare p as select /*+ use_gplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filtering condition is the input parameter to be added, that is, the plan is a generic plan.

```
                              QUERY PLAN
-----------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..13.26 rows=1 width=12)
   Node/s: All datanodes
   ->  Seq Scan on t  (cost=0.00..13.16 rows=1 width=12)
         Filter: (a = $1)
(4 rows)
```

## 10.3.9.14 Hints Specifying Not to Expand Subqueries

### Function

When the database optimizes the query logic, some subqueries can be promoted to the upper layer to avoid nested execution. However, for some subqueries that have a low selection rate and can use indexes to filter access pages, nested execution does not cause too much performance deterioration, while after the promotion, the query search scope is expanded, which may cause performance deterioration. In this case, you can use the **no_expand** hint for debugging. This hint is not recommended in most cases.

### Syntax

```
no_expand
```

### Example

Normal query execution:

```
explain select * from t1 where t1.a in (select t2.a from t2);
```

Plan:

```
                              QUERY PLAN
-----------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..2.13 rows=2 width=12)
   Node/s: All datanodes
   ->  Nested Loop Semi Join  (cost=0.00..2.03 rows=2 width=12)
         Join Filter: (t1.a = t2.a)
         ->  Seq Scan on t1  (cost=0.00..1.01 rows=1 width=12)
         ->  Seq Scan on t2  (cost=0.00..1.01 rows=1 width=4)
(6 rows)
```

After **no_expand** is added:

```
explain select * from t1 where t1.a in (select /*+ no_expand*/ t2.a from t2);
```

Plan:

```
                                    QUERY PLAN
-------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=1.09..2.13 rows=1 width=12)
   Node/s: All datanodes
   ->  Seq Scan on t1  (cost=1.02..2.04 rows=1 width=12)
         Filter: (hashed SubPlan 1)
         SubPlan 1
           ->  Materialize  (cost=0.00..1.02 rows=4 width=4)
                 ->  Streaming(type: BROADCAST)  (cost=0.00..1.01 rows=2 width=4)
                       Spawn on: All datanodes
                       ->  Seq Scan on t2  (cost=0.00..1.01 rows=1 width=4)
(9 rows)
```

## 10.3.9.15 Hints Specifying Not to Use Global Plan Cache

### Function

When global plan cache is enabled, you can use the **no_gpc** hint to force a single query statement not to share the plan cache globally. Only the plan cache within the current session lifecycle is retained.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The current feature is a lab feature. Contact Huawei technical support before using it.

## Syntax

```
no_gpc
```

NOTE

This parameter takes effect only for statements executed by PBE when **enable_global_plancache** is set to **on**.

## Example

```
openGauss=# deallocate all;
DEALLOCATE ALL
openGauss=# prepare insert_nogpc as insert /*+ no_gpc */ into t1 select c1, c2 from t2 where c1 = $1;
PREPARE
openGauss=# execute insert_nogpc(1);
INSERT 0 1
openGauss=# select * from dbe_perf.global_plancache_status where schema_name = 'schema_hint_iud' order by 1,2;
 nodename | query | refcount | valid | databaseid | schema_name | params_num | func_id
----------+-------+----------+-------+------------+-------------+------------+---------
(0 rows)
```

No result exists in the **dbe_perf.global_plancache_status** view, that is, no plan is cached globally.

## 10.3.9.16 Hint of Parameterized Paths at the Same Level

## Function

The **predpush_same_level** hint is used to specify the generation of parameterized paths between tables or materialized views at the same level.

For details about cross-layer parameterized path hints, see **10.3.9.9 Parameterized Path Hint**.

## Syntax

```
predpush_same_level(src, dest)
predpush_same_level(src1 src2 ..., dest)
```

NOTE

This parameter takes effect only when the **predpushforce** option in **rewrite_rule** is enabled.

## Examples

Prepare parameters, tables, and indexes.

```
openGauss=# set rewrite_rule = 'predpushforce';
SET
openGauss=# create table t1(a int, b int) distribute by hash(a);
CREATE TABLE
openGauss=# create table t2(a int, b int) distribute by hash(a);
CREATE TABLE
openGauss=# create index idx1 on t1(a);
CREATE INDEX
openGauss=# create index idx2 on t2(a);
CREATE INDEX
```

Run the following statement to view the plan:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# explain select * from t1, t2 where t1.a = t2.a;
                           QUERY PLAN
--------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=18.25..77.00 rows=1000 width=16)
   Node/s: All datanodes
   ->  Hash Join  (cost=14.25..30.12 rows=1000 width=16)
         Hash Cond: (t1.a = t2.a)
         ->  Seq Scan on t1  (cost=0.00..9.00 rows=1000 width=8)
         ->  Hash  (cost=8.00..8.00 rows=1000 width=8)
               ->  Seq Scan on t2  (cost=0.00..8.00 rows=1000 width=8)
(7 rows)
```

The filter condition **t1.a = t2.a** is displayed on **Join**. In this case, **predpush_same_level(t1, t2)** can be used to push the condition down to the scan operator of t2.

```
openGauss=# explain select /*+predpush_same_level(t1, t2)*/ * from t1, t2 where t1.a = t2.a;
                           QUERY PLAN
--------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..263.88 rows=1000 width=16)
   Node/s: All datanodes
   ->  Nested Loop  (cost=0.00..217.00 rows=1000 width=16)
         ->  Seq Scan on t1  (cost=0.00..9.00 rows=1000 width=8)
         ->  Index Scan using idx2 on t2  (cost=0.00..0.41 rows=1 width=8)
               Index Cond: (a = t1.a)
(6 rows)
```

**NOTICE**

- **predpush_same_level** can specify multiple **src** parameters in the same condition.
- If the specified **src** and **dest** conditions do not exist or do not meet the parameterized path requirements, this hint does not take effect.
- If a stream operator exists on the **dest** scanning operator, this hint does not take effect.

## 10.3.10 Checking the Implicit Conversion Performance

In some scenarios, implicit data type conversion may cause performance problems. For example:

```
SET enable_fast_query_shipping = off;
CREATE TABLE t1(c1 VARCHAR, c2 VARCHAR);
CREATE INDEX on t1(c1);
EXPLAIN verbose SELECT * FROM t1 WHERE c1 = 10;
```

The execution plan of the preceding query is as follows:

```
                            QUERY PLAN
------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..13.29 rows=1 width=64)
   Output: c1, c2
   Node/s: All datanodes
   ->  Seq Scan on public.t1  (cost=0.00..13.20 rows=1 width=64)
         Output: c1, c2
         Distribute Key: c1
         Filter: ((t1.c1)::bigint = 10)
(7 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The data type of **c1** is **varchar**. When the filter criterion is **c1 = 10**, the optimizer implicitly converts the data type of **c1** to **bigint** by default. As a result, the following two consequences occur:

- DN tailoring is not allowed. The plan is delivered to all DNs for execution.
- The Index Scan mode cannot be used to scan data in the plan.

These may cause performance problems.

After knowing the causes, you can rewrite the SQL statements. In the preceding scenario, you only need to convert the constant display in the filter criteria to the **varchar** type. The result is as follows:

```
EXPLAIN verbose SELECT * FROM t1 WHERE c1 = 10::varchar;
```

```
                                    QUERY PLAN
-----------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..8.36 rows=1 width=64)
   Output: c1, c2
   Node/s: datanode2
   ->  Index Scan using t1_c1_idx on public.t1  (cost=0.00..8.27 rows=1 width=64)
         Output: c1, c2
         Distribute Key: c1
         Index Cond: ((t1.c1)::text = '10'::text)
(7 rows)
```

To identify the performance impact of implicit type conversion in advance, you can use the GUC parameter **check_implicit_conversions**. After this parameter is enabled, the system checks the index columns that are implicitly converted in the query in the path generation phase. If no candidate index scan path is generated for the index columns, an error message is displayed. For example:

```
SET check_implicit_conversions = on;
SELECT * FROM t1 WHERE c1 = 10;
ERROR:  There is no optional index path for index column: "t1"."c1".
Please check for potential performance problem.
```

**NOTE**

- The **check_implicit_conversions** parameter is used only to check for potential performance problems caused by implicit type conversion. In the formal production environment, set this parameter to **off** (default value) to disable it.
- When enabling **check_implicit_conversions**, you must disable **enable_fast_query_shipping**. Otherwise, you cannot view the result of restoring the implicit type conversion.
- A candidate path of a table may include multiple possible data scan modes such as sequential scanning and index scanning. A table scan mode used in the final execution plan is determined by the cost of the execution plan. Therefore, even if a candidate path for index scan is generated, other scan modes may also be used in the final execution plan.

## 10.3.11 Using the Vectorized Executor for Tuning

The GaussDB database supports row executors and vectorized executors for processing row-store tables and column-store tables, respectively. Column-store tables and vectorized executors have the following advantages:

- More data is read in one batch at a time, saving I/O resources.
- There are a large number of records in a batch, and the CPU cache hit rate increases.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- The number of function calls is small in pipeline mode.
- A batch of data is processed at a time, which is efficient.

GaussDB achieves better query performance in complex analytical queries. However, column-store tables do not perform well in data insertion and update. Therefore, column-store tables cannot be used for services with frequent data insertion and update.

To improve the query performance of row-store tables in complex analytical queries, GaussDB provides vectorized executors for processing row-store tables. You can set **try_vector_engine_strategy** to convert query statements containing row-store tables into vectorized execution plans for execution.

The conversion is not applicable to all query scenarios. If a query statement contains operations such as expression calculation, multi-table join, and aggregation, the performance can be improved by converting the statement to a vectorized execution plan. Theoretically, converting a row-store table to a vectorized execution plan causes conversion overheads and performance deterioration. After the foregoing expression calculation, join operation, and aggregation operations are converted into vectorized execution plans, performance can be improved. The performance improvement must be higher than the overheads generated by the conversion. This determines whether the conversion is required.

Take TPCH Q1 as an example. When a row executor is used, the execution time of the scan operators is 405210 ms, and the execution time of the aggregation operation is 2618964 ms. After a vectorized executor is used, the execution time of the scan operators (SeqScan and VectorAdapter) is 470840 ms, and the execution time of the aggregation operation is 212384 ms. As such, the query performance is improved.

Execution plan of the TPCH Q1 row executor:

```
                                                
```

```
      ->  Vector Sonic Hash Aggregate  (cost=43825807.98..43825808.08 rows=6 width=298) (actual
time=683224.837..683224.837 rows=4 loops=1)
            Group By Key: l_returnflag, l_linestatus
            ->  Vector Adapter(type: BATCH MODE)  (cost=19966853.54..19966853.54 rows=596473861
width=66) (actual time=0.982..470840.274 rows=596140342 loops=1)
                  Filter: (l_shipdate <= '1998-10-01 00:00:00'::timestamp without time zone)
                  Rows Removed by Filter: 3897560
                  ->  Seq Scan on lineitem  (cost=0.00..19966853.54 rows=596473861 width=66) (actual
time=0.364..199301.737 rows=600037902 loops=1)
 Total runtime: 683225.564 ms
(11 rows)
```

# 10.4 Optimization Cases

## 10.4.1 Case: Selecting an Appropriate Distribution Key

### Symptom

Tables are defined as follows:

```
CREATE TABLE t1 (a int, b int);
CREATE TABLE t2 (a int, b int);
```

The following query is executed:

```
SELECT * FROM t1, t2 WHERE t1.a = t2.b;
```

### Optimization Analysis

If **a** is the distribution key of **t1** and **t2**:

```
CREATE TABLE t1 (a int, b int) DISTRIBUTE BY HASH (a);
CREATE TABLE t2 (a int, b int) DISTRIBUTE BY HASH (a);
```

Then **Streaming** exists in the execution plan and the data volume is heavy among DNs, as shown in **Figure 10-11**.

**Figure 10-11** Selecting an appropriate distribution key (1)

```
openGauss => explain select * from t1, t2 where t1.a = t2.b;
                                  QUERY PLAN
-------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=245.40..582.15 rows=240 width=16)
   Node/s: All datanodes
   ->  Hash Join  (cost=10.22..24.26 rows=10 width=16)
         Hash Cond: (t1.a = t2.b)
         ->  Seq Scan on t1  (cost=0.00..10.10 rows=10 width=8)
         ->  Hash  (cost=3.79..3.79 rows=10 width=8)
               ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..3.79 rows=10 width=8)
                     Spawn on: All datanodes
                     ->  Seq Scan on t2  (cost=0.00..10.10 rows=10 width=8)
(9 rows)
```

If **a** is the distribution key of **t1** and **b** is the distribution key of **t2**:

```
CREATE TABLE t1 (a int, b int) DISTRIBUTE BY HASH (a);
CREATE TABLE t2 (a int, b int) DISTRIBUTE BY HASH (b);
```

Then **Streaming** does not exist in the execution plan, and the data volume among DNs is decreasing and the query performance is increasing, as shown in **Figure 10-12**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Figure 10-12** Selecting an appropriate distribution key (2)

```
openGauss=> explain select * from t1, t2 where t1.a = t2.b;
                                  QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=245.40..491.10 rows=240 width=16)
   Node/s: All datanodes
   ->  Hash Join  (cost=10.22..20.46 rows=10 width=16)
         Hash Cond: (t1.a = t2.b)
         ->  Seq Scan on t1  (cost=0.00..10.10 rows=10 width=8)
         ->  Hash  (cost=10.10..10.10 rows=10 width=8)
               ->  Seq Scan on t2  (cost=0.00..10.10 rows=10 width=8)
(7 rows)
```

## 10.4.2 Case: Creating an Appropriate Index

### Symptom

Query the information about all personnel in the sales department.

```
SELECT staff_id,first_name,last_name,employment_id,state_name,city
FROM staffs,sections,states,places
WHERE sections.section_name='Sales'
AND staffs.section_id = sections.section_id
AND sections.place_id = places.place_id
AND places.state_id = states.state_id
ORDER BY staff_id;
```

### Optimization Analysis

The original execution plan is as follows before creating the **places.place_id** and **states.state_id** indexes:

```
 id |                           operation                           |     A-time      | A-rows | E-rows | Peak Memory  | E-memory | A-width | E-width | E-costs
----+---------------------------------------------------------------+-----------------+--------+--------+--------------+----------+---------+---------+---------
  1 | ->  Streaming (type: GATHER)                                  | 69.801          |     34 |      2 |212KB         |          |         |     354 | 53.67
  2 |    ->  Sort                                                   | [21.508,23.283] |     34 |      2 |[30KB, 36KB]  | 16MB     | [380,380] |     354 | 53.32
  3 |       ->  Hash Join (4,5)                                     | [21.483,23.153] |     34 |      2 |[7KB, 7KB]    | 1MB      |         |     354 | 53.31
  4 |          ->  Seq Scan on hr.states                            | [0.007,0.022]   |     17 |     20 |[12KB, 12KB]  | 1MB      |         |     110 | 13.13
  5 |          ->  Hash                                             | [21.026,22.663] |     34 |      2 |[262KB, 294KB]| 16MB     | [284,284] |     268 | 40.08
  6 |             ->  Streaming(type: REDISTRIBUTE)                 | [21.024,22.458] |     34 |      2 |[85KB, 86KB]  | 1MB      |         |     268 | 40.08
  7 |                ->  Hash Join (8,9)                            | [13.814,14.827] |     34 |      2 |[8KB, 8KB]    | 1MB      |         |     268 | 39.80

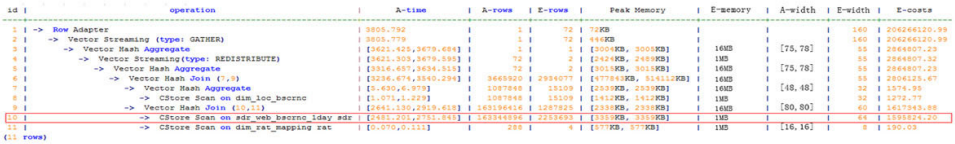
**Figure 10-13** Adding NOT NULL for JOIN columns (1)



## Optimization Analysis

1. As shown in **Figure 10-13**, the sequential scan phase is time consuming.
2. The JOIN performance is poor because a large number of null values exist in the JOIN column **BSCRNC_ID** of the **PS.SDR_WEB_BSCRNC_1DAY** table.

   Therefore, you are advised to manually add **NOT NULL** for **JOIN** columns in the statement, as shown below:

```
SELECT
 *
FROM
( ( SELECT
  STARTTIME STTIME,
  SUM(NVL(PAGE_DELAY_MSEL,0)) PAGE_DELAY_MSEL,
  SUM(NVL(PAGE_SUCCEED_TIMES,0)) PAGE_SUCCEED_TIMES,
  SUM(NVL(FST_PAGE_REQ_NUM,0)) FST_PAGE_REQ_NUM,
  SUM(NVL(PAGE_AVG_SIZE,0)) PAGE_AVG_SIZE,
  SUM(NVL(FST_PAGE_ACK_NUM,0)) FST_PAGE_ACK_NUM,
  SUM(NVL(DATATRANS_DW_DURATION,0)) DATATRANS_DW_DURATION,
  SUM(NVL(PAGE_SR_DELAY_MSEL,0)) PAGE_SR_DELAY_MSEL
 FROM
  PS.SDR_WEB_BSCRNC_1DAY SDR
  INNER JOIN (SELECT
      BSCRNC_ID,
      BSCRNC_NAME,
      ACCESS_TYPE,
      ACCESS_TYPE_ID
     FROM
      nethouse.DIM_LOC_BSCRNC
     GROUP BY
      BSCRNC_ID,
      BSCRNC_NAME,
      ACCESS_TYPE,
      ACCESS_TYPE_ID) DIM
  ON SDR.BSCRNC_ID = DIM.BSCRNC_ID
  AND DIM.ACCESS_TYPE_ID IN (0,1,2)
  INNER JOIN nethouse.DIM_RAT_MAPPING RAT
  ON (RAT.RAT = SDR.RAT)
 WHERE
  ( (STARTTIME >= 1461340800
  AND STARTTIME < 1461427200) )
  AND RAT.ACCESS_TYPE_ID IN (0,1,2)
  and SDR.BSCRNC_ID is not null
 GROUP BY
  STTIME ) ) A;
```

**Figure 10-14** shows the execution plan.

# 10.4.4 Case: Pushing Down Sort Operations to DNs

## Symptom

In an execution plan, more than 95% of the execution time is spent on **window agg** performed on the CN. In this case, **sum** is performed for the two columns separately, and then another **sum** is performed for the separate sum results of the two columns. After this, **trunc** and **sort** are performed in sequence.

The table structure is as follows:

```
CREATE TABLE public.test(imsi int,L4_DW_THROUGHPUT int,L4_UL_THROUGHPUT int)
with (orientation = column) DISTRIBUTE BY hash(imsi);
```

The query statements are as follows:

```
SELECT COUNT(1) over() AS DATACNT,
IMSI AS IMSI_IMSI,
CAST(TRUNC(((SUM(L4_UL_THROUGHPUT) + SUM(L4_DW_THROUGHPUT))), 0) AS
DECIMAL(20)) AS TOTAL_VOLOME_KPIID
FROM public.test AS test
GROUP BY IMSI
order by TOTAL_VOLOME_KPIID DESC;
```

The execution plan is as follows:

```
Row Adapter  (cost=10.70..10.70 rows=10 width=12)
  ->  Vector Sort  (cost=10.68..10.70 rows=10 width=12)
        Sort Key: ((trunc((((sum(l4_ul_throughput)) + (sum(l4_dw_throughput))))::numeric,
0))::numeric(20,0))
        ->  Vector WindowAgg  (cost=10.09..10.51 rows=10 width=12)
              ->  Vector Streaming (type: GATHER)  (cost=242.04..246.84 rows=240 width=12)
                    Node/s: All datanodes
                    ->  Vector Hash Aggregate  (cost=10.09..10.29 rows=10 width=12)
                          Group By Key: imsi
                          ->  CStore Scan on test  (cost=0.00..10.01 rows=10 width=12)
```

As we can see, both **window agg** and **sort** are performed on the CN, which is time consuming.

## Optimization Analysis

Modify the statement to a subquery statement, as shown below:

```
SELECT COUNT(1) over() AS DATACNT, IMSI_IMSI, TOTAL_VOLOME_KPIID
FROM (SELECT IMSI AS IMSI_IMSI,
CAST(TRUNC(((SUM(L4_UL_THROUGHPUT) + SUM(L4_DW_THROUGHPUT))),
0) AS DECIMAL(20)) AS TOTAL_VOLOME_KPIID
FROM public.test AS test
GROUP BY IMSI
ORDER BY TOTAL_VOLOME_KPIID DESC);
```

Perform **sum** on the **trunc** results of the two columns, take it as a subquery, and then perform **window agg** for the subquery to push down the sorting operation to DNs, as shown below:

```
Row Adapter  (cost=10.70..10.70 rows=10 width=24)
  ->  Vector WindowAgg  (cost=10.45..10.70 rows=10 width=24)
        ->  Vector Streaming (type: GATHER)  (cost=250.83..253.83 rows=240 width=24)
              Node/s: All datanodes
              ->  Vector Sort  (cost=10.45..10.48 rows=10 width=12)
                    Sort Key: ((trunc(((sum(test.l4_ul_throughput) + sum(test.l4_dw_throughput)))::numeric,
0))::numeric(20,0))
                    ->  Vector Hash Aggregate  (cost=10.09..10.29 rows=10 width=12)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
                Group By Key: test.imsi
                ->  CStore Scan on test  (cost=0.00..10.01 rows=10 width=12)
```

The optimized SQL statement greatly improves the performance by reducing the execution time from 120s to 7s.

## 10.4.5 Case: Setting cost_param and Optimizing Query Performance

### Symptom 1

If **bit0** of **cost_param** is set to **1** (**set cost_param=1**), an improved mechanism is used for estimating the selection rate of non-equi-joins. This method is more accurate for estimating the selection rate of joins between two identical tables. The following example describes the optimization scenario when **bit0** of **cost_param** is set to **1**. At present, if **cost_param & 1** is set to a value other than 0, the path is not used. That is, an optimized formula is selected for calculation.

**Note**: The selection rate indicates the percentage for which the number of rows meeting the join conditions account of the **JOIN** results when the **JOIN** relationship is established between two tables.

The table structure is as follows:

```
CREATE TABLE LINEITEM
(
L_ORDERKEY BIGINT NOT NULL
, L_PARTKEY BIGINT NOT NULL
, L_SUPPKEY BIGINT NOT NULL
, L_LINENUMBER BIGINT NOT NULL
, L_QUANTITY DECIMAL(15,2) NOT NULL
, L_EXTENDEDPRICE DECIMAL(15,2) NOT NULL
, L_DISCOUNT DECIMAL(15,2) NOT NULL
, L_TAX DECIMAL(15,2) NOT NULL
, L_RETURNFLAG CHAR(1) NOT NULL
, L_LINESTATUS CHAR(1) NOT NULL
, L_SHIPDATE DATE NOT NULL
, L_COMMITDATE DATE NOT NULL
, L_RECEIPTDATE DATE NOT NULL
, L_SHIPINSTRUCT CHAR(25) NOT NULL
, L_SHIPMODE CHAR(10) NOT NULL
, L_COMMENT VARCHAR(44) NOT NULL
) with (orientation = column, COMPRESSION = MIDDLE) distribute by hash(L_ORDERKEY);

CREATE TABLE ORDERS
(
O_ORDERKEY BIGINT NOT NULL
, O_CUSTKEY BIGINT NOT NULL
, O_ORDERSTATUS CHAR(1) NOT NULL
, O_TOTALPRICE DECIMAL(15,2) NOT NULL
, O_ORDERDATE DATE NOT NULL
, O_ORDERPRIORITY CHAR(15) NOT NULL
, O_CLERK CHAR(15) NOT NULL
, O_SHIPPRIORITY BIGINT NOT NULL
, O_COMMENT VARCHAR(79) NOT NULL
)with (orientation = column, COMPRESSION = MIDDLE) distribute by hash(O_ORDERKEY);
```

The query statements are as follows:

```
explain verbose select
count(*) as numwait
from
lineitem l1,
orders
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
where
o_orderkey = l1.l_orderkey
and o_orderstatus = 'F'
and l1.l_receiptdate > l1.l_commitdate
and not exists (
select
*
from
lineitem l3
where
l3.l_orderkey = l1.l_orderkey
and l3.l_suppkey <> l1.l_suppkey
and l3.l_receiptdate > l3.l_commitdate
)
order by
numwait desc;
```

The following figure shows the execution plan. (When **verbose** is used, **distinct** is added for column selection which is controlled by **cost off/on**. The hash join rows show the estimated number of **distinct** values and the other rows do not.)

```
 id |                        operation                        | E-rows | E-distinct | E-width | E-costs
----+---------------------------------------------------------+--------+------------+---------+---------
  1 | ->  Row Adapter                                         |      1 |            |       8 | 39.36
  2 |    ->  Vector Sort                                      |      1 |            |       8 | 39.36
  3 |       ->  Vector Aggregate                              |      1 |            |       8 | 39.34
  4 |          ->  Vector Streaming (type: GATHER)            |      2 |            |       8 | 39.34
  5 |             ->  Vector Aggregate                        |      2 |            |       8 | 39.25
  6 |                ->  Vector Hash Anti Join (7, 10)        |      2 | 4, 5       |       0 | 39.24
  7 |                   ->  Vector Hash Join (8,9)            |      2 | 200, 1     |      16 | 26.12
  8 |                      ->  CStore Scan on public.lineitem l1 |      7 |            |      16 | 13.05
  9 |                      ->  CStore Scan on public.orders   |      1 |            |       8 | 13.05
 10 |                   ->  CStore Scan on public.lineitem l3 |      7 |            |      16 | 13.05
(10 rows)
```

## Optimization Analysis 1

These queries are from Anti Join connected in the **lineitem** table. When **bit0** of **cost_param** is set to **1**, the estimated number of Anti Join rows greatly differ from that of the actual number of rows so that the query performance deteriorates. You can estimate the number of Anti Join rows more accurately by setting **bit0** of **cost_param** to **1** to improve the query performance. The optimized execution plan is as follows:

```
id |                        operation                        |  E-rows  | E-memory | E-width |  E-costs
---+---------------------------------------------------------+----------+----------+---------+-----------
 1 |  -> Row Adapter                                         |        1 |          |       0 | 9104892.37
 2 |    -> Vector Sort                                       |        1 |          |       0 | 9104892.37
 3 |      -> Vector Aggregate                                |        1 |          |       0 | 9104892.35
 4 |        -> Vector Streaming (type: GATHER)               |       48 |          |       0 | 9104892.35
 5 |          -> Vector Aggregate                            |       48 | 1MB      |       0 | 9104890.82
 6 |            -> Vector Hash Join (7,12)                   | 2526630903 | 929MB    |       0 | 8973295.45
 7 |              -> Vector Hash Anti Join (8, 10)           | 1999996587 | 3178MB   |       8 | 7198231.14
 8 |                -> Vector Partition Iterator             | 1999996587 | 1MB      |      16 | 3000158.25
 9 |                  -> Partitioned CStore Scan on public.lineitem 11 | 1999996587 | 1MB | 16 | 3000158.25
10 |                -> Vector Partition Iterator             | 1999996587 | 1MB      |      16 | 3000158.25
11 |                  -> Partitioned CStore Scan on public.lineitem 13 | 1999996587 | 1MB | 16 | 3000158.25
12 |                -> Vector Partition Iterator             |  730839014 | 1MB      |       8 | 589611.00
13 |                  -> Partitioned CStore Scan on public.orders | 730839014 | 1MB | 8 | 589611.00
(13 rows)
```

## Symptom 2

If **bit1** of **cost_param** is set to **1** (**set cost_param=2**), the selection rate is estimated based on multiple filter criteria. The lowest selection rate among all

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

filter criteria, but not the product of the selection rates for two tables under a specific filter criterion, is used as the total selection rate. This method is more accurate when a close correlation exists between the columns to be filtered. The following example describes the optimization scenario when **bit1** of **cost_param** is set to **1**.

The table structure is as follows:

```
CREATE TABLE NATION
(
  N_NATIONKEY INT NOT NULL
, N_NAME      CHAR(25) NOT NULL
, N_REGIONKEY INT NOT NULL
, N_COMMENT   VARCHAR(152)
) distribute by replication;
CREATE TABLE SUPPLIER
(
  S_SUPPKEY   BIGINT NOT NULL
, S_NAME      CHAR(25) NOT NULL
, S_ADDRESS   VARCHAR(40) NOT NULL
, S_NATIONKEY INT NOT NULL
, S_PHONE     CHAR(15) NOT NULL
, S_ACCTBAL   DECIMAL(15,2) NOT NULL
, S_COMMENT   VARCHAR(101) NOT NULL
) distribute by hash(S_SUPPKEY);
CREATE TABLE PARTSUPP
(
  PS_PARTKEY    BIGINT NOT NULL
, PS_SUPPKEY    BIGINT NOT NULL
, PS_AVAILQTY   BIGINT NOT NULL
, PS_SUPPLYCOST DECIMAL(15,2)NOT NULL
, PS_COMMENT    VARCHAR(199) NOT NULL
)distribute by hash(PS_PARTKEY);
```

The query statements are as follows:

```
set cost_param=2;
explain verbose select
nation,
sum(amount) as sum_profit
from
(
select
n_name as nation,
l_extendedprice * (1 - l_discount) - ps_supplycost * l_quantity as amount
from
supplier,
lineitem,
partsupp,
nation
where
s_suppkey = l_suppkey
and ps_suppkey = l_suppkey
and ps_partkey = l_partkey
and s_nationkey = n_nationkey
) as profit
group by nation
order by nation;
```

When **bit1** of **cost_param** is set to **0**, the execution plan is shown as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 id |                           operation                           | E-rows | E-distinct | E-width | E-costs
----+---------------------------------------------------------------+--------+------------+---------+---------
  1 | ->  Sort                                                      |      1 |            |     208 | 61.52
  2 |    ->  HashAggregate                                          |      1 |            |     208 | 61.51
  3 |       ->  Streaming (type: GATHER)                            |      2 |            |     208 | 61.51
  4 |          ->  HashAggregate                                    |      2 |            |     208 | 61.36
  5 |             ->  Hash Join (6,7)                               |      2 | 20, 15     |     176 | 61.33
  6 |                ->  Seq Scan on public.nation                  |     40 |            |     108 | 20.20
  7 |                ->  Hash                                       |      2 |            |      76 | 41.04
  8 |                   ->  Hash Join (9,16)                        |      2 | 10, 13     |      76 | 41.04
  9 |                      ->  Streaming(type: REDISTRIBUTE)        |      2 |            |      88 | 27.73
 10 |                         ->  Hash Join (11,14)                 |      2 | 10, 13     |      88 | 27.62
 11 |                            ->  Streaming(type: REDISTRIBUTE)  |     20 |            |      70 | 14.19
 12 |                               ->  Row Adapter                 |     21 |            |      70 | 13.01
 13 |                                  ->  CStore Scan on public.lineitem |     20 |            |      70 | 13.01
 14 |                            ->  Hash                           |     21 |            |      34 | 13.13
 15 |                               ->  Seq Scan on public.partsupp |     20 |            |      34 | 13.13
 16 |                      ->  Hash                                 |     21 |            |      12 | 13.13
 17 |                         ->  Seq Scan on public.supplier       |     20 |            |      12 | 13.13
(17 rows)
```

## Optimization Analysis 2

In the preceding queries, the hash join criteria of the **supplier**, **lineitem**, and **partsupp** tables are setting **lineitem.l_suppkey** to **supplier.s_suppkey** and **lineitem.l_partkey** to **partsupp.ps_partkey**. Two filter criteria exist in the hash join conditions. **lineitem.l_suppkey** in the first filter criterion and **lineitem.l_partkey** in the second filter criterion are two columns with strong relationship of the **lineitem** table. In this situation, when you estimate the rate of the hash join conditions, if **bit1** of **cost_param** is set to **0**, the selection rate is estimated based on multiple filter criteria. The lowest selection rate among all filter criteria, but not the product of the selection rates for two tables under a specific filter criterion, is used as the total selection rate. Therefore, you need to set **bit1** of **cost_param** to **2** and select the lowest selection rate as the total selection rate to optimize the query performance. The optimized query plan is shown as follows:

```
 id |                           operation                           | E-rows | E-distinct | E-width | E-costs
----+---------------------------------------------------------------+--------+------------+---------+---------
  1 | ->  Sort                                                      |     10 |            |     208 | 64.42
  2 |    ->  HashAggregate                                          |     10 |            |     208 | 64.23
  3 |       ->  Streaming (type: GATHER)                            |     20 |            |     208 | 64.23
  4 |          ->  HashAggregate                                    |     20 |            |     208 | 62.71
  5 |             ->  Hash Join (6,7)                               |     20 | 20, 10     |     176 | 62.46
  6 |                ->  Seq Scan on public.nation                  |     40 |            |     108 | 20.20

(11 rows)

According to the execution information, Hash Join becomes the performance bottleneck of the whole plan. Based on the execution time of Hash Join **[2657.406,93339.924]** (for details about the value, see **10.3.2.2 Description**), it can be seen that severe skew occurs on different DNs during the Hash Join operation.

In the memory information (as shown in the following figure), it can be seen that the data skew occurs in the memory usage of each node.

```
Memory Information (identified by plan id)
--------------------------------------------------------------------------------
Coordinator:
  Query Peak Memory: 4MB
Datanode:
  Max Query Peak Memory: 118MB
  Min Query Peak Memory: 24MB
 12 --Hash
        Max Buckets: 131072  Max Batches: 1  Max Memory Usage: 91857kB
        Min Buckets: 131072  Min Batches: 1  Min Memory Usage: 0kB
(8 rows)
```

## Optimization Analysis

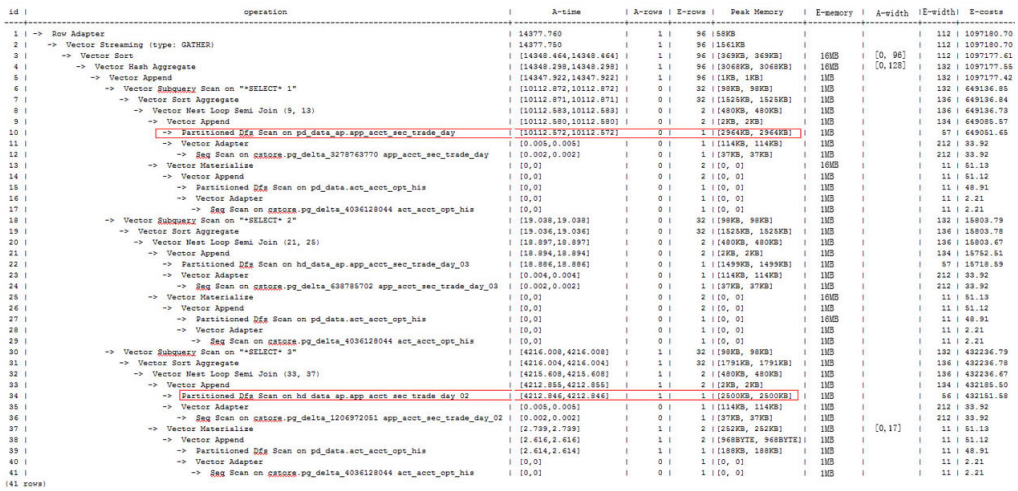
The preceding two features indicate that this SQL statement has extremely serious computing unbalance. The further lower-layer analysis on the Hash Join operator shows that serious computing skew **[38.885,2940.983]** occurs in **Seq Scan on s_riskrate_setting**. Based on the description of the Scan, we can infer that the performance problems of this plan lie in data skew occurred in the **s_riskrate_setting** table. Later, it is proved that serious data skew occurred in the **s_riskrate_setting** table. After performance optimization, the execution time is reduced from 94s to 50s.

# 10.4.7 Case: Adjusting Partial Clustering Keys

## Symptom

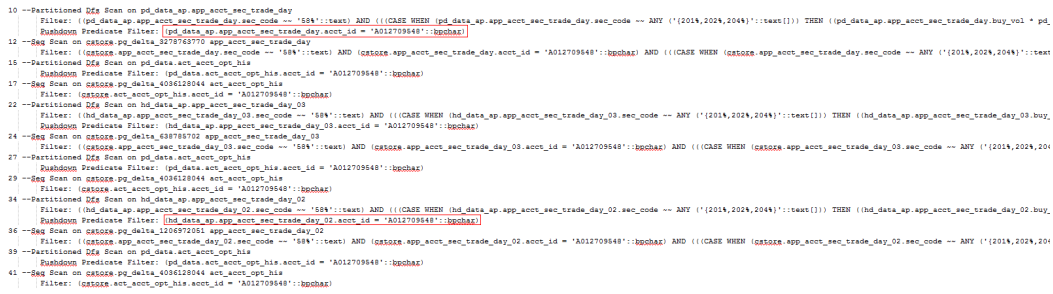
Information on the **EXPLAIN PERFORMANCE** at a site is as follows: As shown in the red boxes, two performance bottlenecks are scan operations in a table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 



## Optimization Analysis

Based on further analysis, the filter condition **acct_id = 'A012709548'::bpchar** exists in **Scan** of two tables.



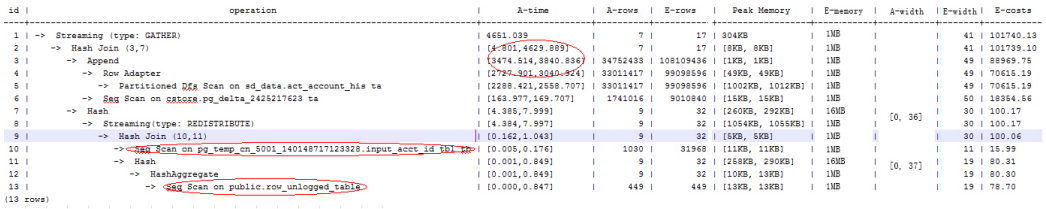
Try to add the partial clustering key in the **acct_id** column of the two tables, and run the **VACUUM FULL** statement to make the local clustering take effect. The table performance is improved.

# 10.4.8 Case: Adjusting the Table Storage Model in a Medium Table

## Symptom

In the GaussDB database, row-store tables use row execution engine, and column-store tables use column execution engine. If both row-store tables and column-store tables exist in a SQL statement, the system will automatically select the row execution engine. The performance of a column execution engine (except for the index scan related operators) is much better than that of a row execution engine. Therefore, a column-store table is recommended. This is important for some intermediate result set dumping tables, and you need to select a proper table storage model.

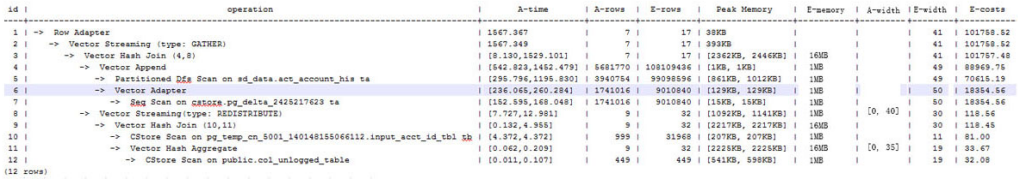
During the test at a site, if the following execution plan is performed, the customer expects that the performance can be improved and the result can be returned within 3s.



## Optimization Analysis

It is found that the row execution engine is used after analysis, because both the temporary plan table **input_acct_id_tbl** and the intermediate result dumping table **row_unlogged_table** use row storage.

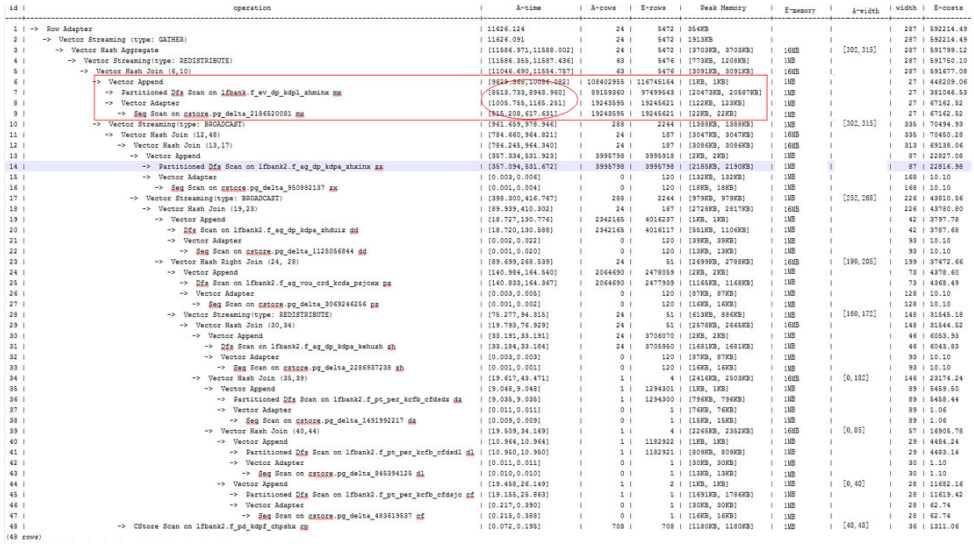
After the two tables are changed into column-store tables, the system performance is improved and the result is returned by 1.6s.



# 10.4.9 Case: Adjusting Partial Clustering Keys

## Symptom

During the test at a site, if the following execution plan is performed, the customer expects that the performance can be improved and the result can be returned within 3s.



## Optimization Analysis

The analysis shows that the performance bottleneck of this plan is the scan operation on the **lfbank.f_ev_dp_kdpl_zhminx** table. The scan condition of this table is as follows:

```
                                Predicate Information (identified by plan id)
-------------------------------------------------------------------------------------------------------------------------------------------------------
  5 --Vector Hash Join (6,10)
      Hash Cond: (((mx.zhanghao)::text = (dd.zhanghao)::text) AND ((mx.farendma)::text = (cf.farendma)::text))
  7 --Partitioned Dfs Scan on lfbank.f_ev_dp_kdpl_zhminx mx
      Pushdown Predicate Filter: ((mx.yezdminc)::text = 'DPLDGBAL'::text)
  9 --Seq Scan on cstore.pg_delta_21865ZUU81 mx
      Filter: ((mx.yezdminc)::text = 'DPLDGBAL'::text)
      Rows Removed by Filter: 489
```

Try to change the **lfbank.f_ev_dp_kdpl_zhminx** table to a column-store table. Then, create the PCK (local clustering) in the **yezdminc** column, and set **PARTIAL_CLUSTER_ROWS** to **100000000**. The execution plan after optimization is as follows:

```
id |                                operation                                |          A-time          | A-rows |  E-rows   |  Peak Memory   | E-memory | A-width | E-width | E-costs

(42 rows)
```

**NOTE**

- This method actually sacrifices the performance during data import to improve the query performance.
- The number of local sorting tuples is increased, and you need to increase the value of **psort_work_mem** to improve the sorting efficiency.

# 10.4.10 Case: Modifying a Partitioned Table

## Symptom

In the following simple SQL statements, the performance bottlenecks exist in the scan operation of the **dwcjk** table.

```
openGauss=#    explain performance select zqdh, count(1) from dwcjk where cjrq = '2015-05-02 00:00:00' group by zqdh;
 id |                  operation                  |        A-time         | A-rows  | E-rows  |    Peak Memory    | E-memory | A-width | E-width | E-costs
----+---------------------------------------------+-----------------------+---------+---------+-------------------+----------+---------+---------+---------
  1 | ->  Row Adapter                             | 1599.794              |      58 |      12 | 19KB              |          |         |       7 | 771106.83
  2 |   ->  Vector Streaming (type: GATHER)       | 1599.781              |      58 |      12 | 210KB             |          |         |       7 | 771106.83
  3 |     ->  Vector Hash Aggregate               | [1445.092,1446.332]   |      58 |       2 | [2315KB, 2315KB]  | 16MB     | [16,16] |       7 | 128517.80
  4 |       ->  Vector Streaming(type: REDISTRIBUTE) | [1444.996,1446.259]   |     340 |      12 | [247KB, 247KB]    | 1MB      |         |       7 | 128518.09
  5 |         ->  Vector Hash Aggregate           | [573.150,1261.354]    |     340 |      12 | [2297KB, 2297KB]  | 16MB     | [16,16] |       7 | 128517.80
  6 |           ->  CStore Scan on public.dwcjk   | [330.178,1021.695]    | 10000000 | 1623137 | [786KB, 786KB]    | 1MB      |         |       7 | 120402.00
(6 rows)
```

## Optimization Analysis

Obviously, there are date features in the **cjrq** column of table data in the service layer, and this meet the features of a partitioned table. Replan the table definition of the **dwcjk** table. Set the **cjrq** column as a partition key, and day as an interval unit. Define the partitioned table **dwcjk_part**. The modified result is as follows, and the performance is nearly doubled.

# 10.4.11 Case: Adjusting the GUC Parameter best_agg_plan

## Symptom

The **t1** table is defined as follows:

```
create table t1(a int, b int, c int) distribute by hash(a);
```

Assume that the distribution key of the result set provided by the agg lower-layer operator is **setA**, and the **group by** column of the agg operation is **setB**, the agg operations can be performed in two scenarios in the Stream framework.

1. **setA** is a subset of **setB**.

   In this scenario, the aggregation result of the lower-layer is correct and can be directly used by upper-level operators. Example:

   ```
   openGauss=# explain select a, count(1) from t1 group by a;
    id |          operation           | E-rows | E-width | E-costs
   ----+------------------------------+--------+---------+---------
     1 | ->  Streaming (type: GATHER) |     30 |       4 | 15.56
     2 |    ->  HashAggregate         |     30 |       4 | 14.31
     3 |       ->  Seq Scan on t1     |     30 |       4 | 14.14
   (3 rows)
   ```

2. **setA** is not a subset of **setB**.

   In this scenario, the Stream execution framework is classified into the following three plans:

   hashagg+gather(redistribute)+hashagg

   redistribute+hashagg(+gather)

   hashagg+redistribute+hashagg(+gather)

   GaussDB provides the GUC parameter **best_agg_plan** to intervene the execution plan, and forces the plan to generate the corresponding execution plan. This parameter can be set to **0**, **1**, **2**, **3**.

   - When the parameter is set to **1**, the first plan is forcibly generated.
   - When the parameter is set to **2** and if the **group by** column can be redistributed, the second plan is forcibly generated. Otherwise, the first plan is generated.
   - When the parameter is set to **3** and if the **group by** column can be redistributed, the third plan is generated. Otherwise, the first plan is generated.
   - When the parameter is set to **0**, the query optimizer chooses the most optimal plan by the three preceding plans' evaluation cost.

   For details, see the following figure.

   ```
   openGauss=# set best_agg_plan to 1;
   SET
   openGauss=# explain select b,count(1) from t1 group by b;
    id |          operation           | E-rows | E-width | E-costs
   ----+------------------------------+--------+---------+---------
     1 | ->  HashAggregate            |      8 |       4 | 15.83
     2 |    ->  Streaming (type: GATHER) |     25 |       4 | 15.83
   ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 3 |       ->  HashAggregate        |     25 |       4 | 14.33
 4 |         ->  Seq Scan on t1     |     30 |       4 | 14.14
(4 rows)
openGauss=# set best_agg_plan to 2;
SET
openGauss=# explain select b,count(1) from t1 group by b;
 id |              operation               | E-rows | E-width | E-costs
----+--------------------------------------+--------+---------+---------
 1 | ->  Streaming (type: GATHER)         |     30 |       4 | 15.85
 2 |    ->  HashAggregate                 |     30 |       4 | 14.60
 3 |       ->  Streaming(type: REDISTRIBUTE) |     30 |       4 | 14.45
 4 |         ->  Seq Scan on t1           |     30 |       4 | 14.14
(4 rows)
openGauss=# set best_agg_plan to 3;
SET
openGauss=# explain select b,count(1) from t1 group by b;
 id |              operation               | E-rows | E-width | E-costs
----+--------------------------------------+--------+---------+---------
 1 | ->  Streaming (type: GATHER)         |     30 |       4 | 15.84
 2 |    ->  HashAggregate                 |     30 |       4 | 14.59
 3 |       ->  Streaming(type: REDISTRIBUTE) |     25 |       4 | 14.59
 4 |         ->  HashAggregate            |     25 |       4 | 14.33
 5 |           ->  Seq Scan on t1         |     30 |       4 | 14.14
(5 rows)
```

## Optimization

Generally, the optimizer chooses an optimal execution plan, but the cost estimation, especially that of the intermediate result set, has large deviations, which may result in large deviations in agg calculation. In this case, you need to use **best_agg_plan** to adjust the agg calculation model.

When the aggregation convergence ratio is very small, that is, the number of result sets does not become small obviously after the agg operation (5 times is a critical point), you can select the redistribute+hashagg or hashagg+redistribute +hashagg execution mode.

# 10.4.12 Case: Rewriting SQL and Deleting Subqueries (1)

## Symptom

```
select
   1,
   (select count(*) from customer_address_001 a4 where a4.ca_address_sk = a.ca_address_sk) as GZCS
from customer_address_001 a;
```

This SQL performance is poor. SubPlan exists in the execution plan as follows:

```
openGauss=# explain select 1,(select count(*)
openGauss(#           from customer_address_001 a4
openGauss(#          where a4.ca_address_sk = a.ca_address_sk
openGauss(#         ) as GZCS from customer_address_001 a;
 id |                          operation                          | E-rows | E-width | E-costs
----+-------------------------------------------------------------+--------+---------+---------
  1 | ->  Streaming (type: GATHER)                                |    320 |       4 | 4529.27
  2 |    ->  Seq Scan on customer_address_001 a                   |    320 |       4 | 4496.27
  3 |       ->  Aggregate  [2, SubPlan 1]                         |     32 |       4 | 139.50
  4 |          ->  Result                                         |  10240 |       4 | 138.69
  5 |             ->  Materialize                                 |  10240 |       4 | 138.69
  6 |                ->  Streaming(type: BROADCAST)               |  10240 |       4 | 137.09
  7 |                   ->  Seq Scan on customer_address_001 a4   |    320 |       4 | 32.32
(7 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Optimization

The core of this optimization is to eliminate subqueries. Based on the service scenario analysis, **a.ca_address_sk** is not null. In terms of SQL syntax, you can rewrite the SQL statement as follows:

```
select
count(*)
from customer_address_001 a4, customer_address_001 a
where a4.ca_address_sk = a.ca_address_sk
group by  a.ca_address_sk;
```

NOTE

To ensure that the modified statements have the same functions, **not null** is added to **customer_address_001. ca_address_sk**.

# 10.4.13 Case: Rewriting SQL and Deleting Subqueries (2)

## Symptom

On a site, the customer gave the feedback saying that the execution time of the following SQL statements lasted over one day and did not end:

```
UPDATE calc_empfyc_c_cusr1 t1
SET ln_rec_count =
 (
   SELECT CASE WHEN current_date - ln_process_date + 1 <= 12 THEN 0 ELSE t2.ln_rec_count END
   FROM calc_empfyc_c1_policysend_tmp t2
   WHERE t1.ln_branch = t2.ln_branch AND t1.ls_policyno_cusr1 = t2.ls_policyno_cusr1
)
WHERE dsign = '1'
AND flag = '1'
AND EXISTS
   (SELECT 1
   FROM calc_empfyc_c1_policysend_tmp t2
   WHERE t1.ln_branch = t2.ln_branch AND t1.ls_policyno_cusr1 = t2.ls_policyno_cusr1
   );
```

The corresponding execution plan is as follows:

```
Streaming (type: GATHER)  (cost=44693.26..19548819558.34 rows=4058158 width=1061)
  Node/s: All datanodes
  ->  Update on channel.calc_empfyc_c_cusr1 t1  (cost=44689.26..19546717163.01 rows=4058158 width=1061)
        ->  Hash Join  (cost=44689.26..19546717163.01 rows=4058158 width=1061)
              Hash Cond: (((t1.ln_branch)::text = ((t2.ln_branch)::text)) AND ((t1.ls_policyno_cusr1)::text = ((t2.ls_policyno_cusr1)::text)))
              ->  Seq Scan on channel.calc_empfyc_c_cusr1 t1  (cost=0.00..28692.39 rows=7105667 width=1055)
                    Filter: ((t1.dsign = '1'::bpchar) AND (t1.flag = '1'::bpchar))
              ->  Hash  (cost=2112.16..2112.16 rows=108998016 width=37)
                    ->  Unique  (cost=2112.06..2112.16 rows=108998016 width=37)
                          ->  Sort  (cost=2112.06..2112.09 rows=775 width=37)
                                Sort Key: ((t2.ln_branch)::text), ((t2.ls_policyno_cusr1)::text)
                                ->  Streaming(type: BROADCAST)  (cost=2109.81..2111.85 rows=775 width=37)
                                      Spawn on: All datanodes
                                      ->  HashAggregate  (cost=2109.81..2109.82 rows=12 width=37)
                                            Group By Key: (t2.ln_branch)::text, (t2.ls_policyno_cusr1)::text
                                            ->  Seq Scan on channel.calc_empfyc_c1_policysend_tmp t2  (cost=0.00..1406.87 rows=1703094 width=37)
              SubPlan 1
                ->  Result  (cost=0.00..308262.89 rows=108998016 width=44)
                      Filter: (((t1.ln_branch)::text = (t2.ln_branch)::text) AND ((t1.ls_policyno_cusr1)::text = (t2.ls_policyno_cusr1)::text))
                      ->  Materialize  (cost=0.00..295489.68 rows=108998016 width=44)
                            ->  Streaming(type: BROADCAST)  (cost=0.00..286974.21 rows=108998016 width=44)
                                  Spawn on: All datanodes
                                  ->  Seq Scan on channel.calc_empfyc_c1_policysend_tmp t2  (cost=0.00..1406.87 rows=1703094 width=44)
```

## Optimization

SubPlan exists in the execution plan, and the calculation accounts for a large proportion in the SubPlan query. That is, SubPlan is a performance bottleneck.

Based on the SQL syntax, you can rewrite the SQL statements and delete SubPlan as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
UPDATE calc_empfyc_c_cusr1 t1
SET ln_rec_count = CASE WHEN current_date - ln_process_date + 1 <= 12 THEN 0 ELSE t2.ln_rec_count END
FROM calc_empfyc_c1_policysend_tmp t2
WHERE
t1.dsign = '1' AND t1.flag = '1'
AND t1.ln_branch = t2.ln_branch AND t1.ls_policyno_cusr1 = t2.ls_policyno_cusr1;
```

After the rewriting, the execution of this SQL statement is complete within 50s.

# 10.4.14 Case: Rewriting SQL Statements to Eliminate Pruning Interference

## Symptom

In a test at a site, **ddw_f10_op_cust_asset_mon** is a partitioned table and the partitioning key is **year_mth** whose value is a combined string of month and year values.

The following figure shows the tested SQL statements:

```
select
    count(1)
from t_ddw_f10_op_cust_asset_mon b1
where b1.year_mth between to_char(add_months(to_date(''20170222'','yyyymmdd'), -11),'yyyymm') and
substr(''20170222'',1 ,6 );
```

The test result shows the Scan operation on the tables in the SQL statement takes 135s. This may be the performance bottleneck.

NOTE

**add_months** is a local adaptation function.

```
CREATE OR REPLACE FUNCTION ADD_MONTHS(date, integer) RETURNS date
   AS $$
   SELECT
   CASE
   WHEN (EXTRACT(day FROM $1) = EXTRACT(day FROM (date_trunc('month', $1) + INTERVAL '1
month - 1 day'))) THEN
       date_trunc('month', $1) + CAST($2 + 1 || ' month - 1 day' as interval)
   ELSE
       $1 + CAST($2 || ' month' as interval)
   END
   $$
   LANGUAGE SQL
   IMMUTABLE;
```

## Optimization

According to the statement execution plan, the base table filter is displayed as follows:

```
Filter: (((year_mth)::text <= '201702'::text) AND ((year_mth)::text >=
to_char(add_months(to_date('20170222'::text, 'YYYYMMDD'::text), (-11)), 'YYYYMM'::text)))
```

The query condition expression to_char(add_months(to_date(''20170222'','yyyymmdd'),-11),'yyyymm') exists in the filter condition, and this non-constant expression cannot be used for pruning. Therefore, all data of query statements in the partitioned tables is scanned.

**to_date** and **to_char** are stable functions as queried in **pg_proc**. According to the function behavior described in PostgreSQL, this type of functions cannot be

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

converted to Const values in the preprocessing phase, which is the root cause why partition pruning cannot be performed.

Based on the preceding analysis, the optimization expression can be used for partition pruning, which is the key to performance optimization. The original SQL statements can be written to as follows:

```
select
   count(1)
from t_ddw_f10_op_cust_asset_mon b1
where b1.year_mth between(substr(ADD_MONTHS('20170222'::date, -11), 1, 4)||
substr(ADD_MONTHS('20170222'::date, -11), 6, 2)) and substr(''20170222'',1 ,6 );
```

The execution time of modified SQL statements is reduced from 135s to 18s.

# 10.4.15 Case: Rewriting SQL Statements and Deleting in-clause

## Symptom

in-clause/any-clause is a common SQL statement constraint. Sometimes, the clause following **in** or **any** is a constant. For example:

```
select
count(1)
from calc_empfyc_c1_result_tmp_t1
where ls_pid_cusr1 in ('20120405', '20130405')
```

or

```
select
count(1)
from calc_empfyc_c1_result_tmp_t1
where ls_pid_cusr1 in any('20120405', '20130405');
```

Sometimes, the **in** or **any** clause is used as follows:

```
SELECT
ls_pid_cusr1,COALESCE(max(round((current_date-bthdate)/365)),0)
FROM calc_empfyc_c1_result_tmp_t1 t1,p10_md_tmp_t2 t2
WHERE t1.ls_pid_cusr1 = any(values(id),(id15))
GROUP BY ls_pid_cusr1;
```

**id** and **id15** are columns in **p10_md_tmp_t2**, and **t1.ls_pid_cusr1 = any(values(id),(id15))** is equivalent to **t1.ls_pid_cusr1 = id or t1.ls_pid_cusr1 = id15**.

Therefore, join-condition is essentially an inequality, and nestloop must be used for this join operation. The execution plan is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Optimization

The test result shows that both result sets are too large. As a result, nestloop is time-consuming with more than one hour to return results. Therefore, the key to performance optimization is to eliminate nestloop, using more efficient hash join. From the perspective of semantic equivalence, the SQL statements can be written as follows:

```
select
ls_pid_cusr1,COALESCE(max(round(ym/365)),0)
from
(
	(
		SELECT
			ls_pid_cusr1,(current_date-bthdate) as ym
		FROM calc_empfyc_c1_result_tmp_t1 t1,p10_md_tmp_t2 t2
		WHERE t1.ls_pid_cusr1 = t2.id and t1.ls_pid_cusr1 != t2.id15
	)
	union all
	(
		SELECT
			ls_pid_cusr1,(current_date-bthdate) as ym
		FROM calc_empfyc_c1_result_tmp_t1 t1,p10_md_tmp_t2 t2
		WHERE t1.ls_pid_cusr1 = id15
	)
)
GROUP BY ls_pid_cusr1;
```

The optimized SQL query consists of two equivalent join subqueries, and each subquery can be used for hash join in this scenario. The optimized execution plan is as follows:

```
 id |                                operation                                |          A-time          | A-rows  | E-rows  |   Peak Memory   | E-memory | A-width
----+-------------------------------------------------------------------------+--------------------------+---------+---------+-----------------+----------+---------
  1 | ->  Streaming (type: GATHER)                                            | 6737.281                 |       0 |     192 | 292KB           |          |
  2 |    ->  Insert on channel.calc_empfyc_c1_result_age_tmp                  | [4665.024,4990.666]      |       0 |     192 | [1108KB, 1108KB] | 1MB      |
  3 |       ->  HashAggregate                                                 | [4664.996,4990.641]      |       0 |     192 | [12KB, 12KB]    | 16MB     |

  7 |                   ->  Hash Join (8,9)                                   | [2011.226,3080.697]      |       0 |    3947 | [6KB, 6KB]      | 1MB      |
  8 |                      ->  Seq Scan on channel.p10_md_tmp_t2 t2           | [803.782,1238.984]       | 443525717 | 443523360 | [12KB, 12KB]    | 1MB      |
  9 |                      ->  Hash                                           | [4.357,328.979]          |  252608 |  252608 | [482KB, 482KB]  | 16MB     | [35,39]
 10 |                         ->  Streaming(type: BROADCAST)                  | [2.345,326.320]          |  252608 |  252608 | [2090KB, 2090KB] | 1MB      |
 11 |                            ->  Seq Scan on channel.calc_empfyc_c1_result_tmp_t1 t1 | [0.011,0.030]    |    3947 |    3947 | [11KB, 11KB]    | 1MB      |
 12 |                   ->  Hash Join (13,14)                                 | [1376.258,2066.110]      |       0 |      64 | [5KB, 5KB]      | 1MB      |
 13 |                      ->  Seq Scan on channel.p10_md_tmp_t2 t2           | [777.552,1388.499]       | 443525717 | 443523360 | [12KB, 12KB]    | 1MB      |
 14 |                      ->  Hash                                           | [2.812,4.217]            |  252608 |  252608 | [482KB, 482KB]  | 16MB     | [23,27]
 15 |                         ->  Streaming(type: BROADCAST)                  | [1.276,1.868]            |  252608 |  252608 | [2090KB, 2090KB] | 1MB      |
 16 |                            ->  Seq Scan on channel.calc_empfyc_c1_result_tmp_t1 t1 | [0.010,0.033]    |    3947 |    3947 | [11KB, 11KB]    | 1MB      |
(16 rows)
```

Before the optimization, no result is returned for more than 1 hour. After the optimization, the result is returned within 7s.

# 10.4.16 Case: Setting Partial Cluster Keys

You can add **PARTIAL CLUSTER KEY**(*column_name*[,...]) to the definition of a column-store table to set one or more columns of this table as PCKs. In this way, every 70 CUs (4.2 million rows) will be sorted based on the cluster keys by default during data import and the value range is narrowed down for each of the new 70 CUs. If the **where** condition in the query statement contains these columns, the filtering performance will be improved.

1. Use PCKs.

```
CREATE TABLE lineitem
(
 L_ORDERKEY    BIGINT NOT NULL
, L_PARTKEY     BIGINT NOT NULL
, L_SUPPKEY     BIGINT NOT NULL
, L_LINENUMBER  BIGINT NOT NULL
, L_QUANTITY    DECIMAL(15,2) NOT NULL
, L_EXTENDEDPRICE  DECIMAL(15,2) NOT NULL
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
, L_DISCOUNT    DECIMAL(15,2) NOT NULL
, L_TAX         DECIMAL(15,2) NOT NULL
, L_RETURNFLAG  CHAR(1) NOT NULL
, L_LINESTATUS  CHAR(1) NOT NULL
, L_SHIPDATE    DATE NOT NULL
, L_COMMITDATE  DATE NOT NULL
, L_RECEIPTDATE DATE NOT NULL
, L_SHIPINSTRUCT CHAR(25) NOT NULL
, L_SHIPMODE     CHAR(10) NOT NULL
, L_COMMENT      VARCHAR(44) NOT NULL
)
with (orientation = column)
distribute by hash(L_ORDERKEY);

select
sum(l_extendedprice * l_discount) as revenue
from
lineitem
where
l_shipdate >= '1994-01-01'::date
and l_shipdate < '1994-01-01'::date + interval '1 year'
and l_discount between 0.06 - 0.01 and 0.06 + 0.01
and l_quantity < 24;
```

In the **where** condition, both the **l_shipdate** and **l_quantity** columns have a few distinct values, and their values can be used for **min**/**max** filtering. Therefore, modify the table definition as follows:

```
CREATE TABLE lineitem
(
  L_ORDERKEY    BIGINT NOT NULL
, L_PARTKEY     BIGINT NOT NULL
, L_SUPPKEY     BIGINT NOT NULL
, L_LINENUMBER  BIGINT NOT NULL
, L_QUANTITY    DECIMAL(15,2) NOT NULL
, L_EXTENDEDPRICE  DECIMAL(15,2) NOT NULL
, L_DISCOUNT    DECIMAL(15,2) NOT NULL
, L_TAX         DECIMAL(15,2) NOT NULL
, L_RETURNFLAG  CHAR(1) NOT NULL
, L_LINESTATUS  CHAR(1) NOT NULL
, L_SHIPDATE    DATE NOT NULL
, L_COMMITDATE  DATE NOT NULL
, L_RECEIPTDATE DATE NOT NULL
, L_SHIPINSTRUCT CHAR(25) NOT NULL
, L_SHIPMODE     CHAR(10) NOT NULL
, L_COMMENT      VARCHAR(44) NOT NULL
, partial cluster key(l_shipdate, l_quantity)
)
with (orientation = column)
distribute by hash(L_ORDERKEY);
```

Import the data again and run the query statement. Then, compare the execution time before and after PCKs are used.

**Figure 10-15** PCKs not used

```
 id |                 operation                 |       A-time       | A-rows | E-rows |  Peak Memory   | A-width | E-width |  E-costs

```
 5 --CStore Scan on public.lineitem
       datanode1 (actual time=23.017..249.757 rows=114160 loops=1)
       datanode1 (RoughCheck CU: CUNone: 84, CUSome: 17)
       datanode1 (LLVM Optimized)
       datanode1 (Buffers: shared hit=2853 read=23)
       datanode1 (CPU: ex c/r=5673, ex cyc=647656146, inc cyc=647656146)
```

After PCKs are used, the execution time of **5 --CStore Scan on public.lineitem** decreases by 1.2s because 84 CUs are filtered out.

2. Select PCKs.
   - The following data types support cluster keys: character varying(n), varchar(n), character(n), char(n), text, nvarchar2, timestamp with time zone, timestamp without time zone, date, time without time zone, and time with time zone.
   - Smaller number of distinct values in a PCK generates higher filtering performance.
   - Columns that can filter out larger amount of data is preferentially selected as PCKs.
   - If multiple columns are selected as PCKs, the columns are used in sequence to sort data. You are advised to select a maximum of three columns.
3. Modify parameters to reduce the impact of PCKs on the import performance.

   After PCKs are used, data will be sorted when they are imported, affecting the import performance. If all the data can be sorted in the memory, the keys have little impact on import. If some data cannot be sorted in the memory and is written into a temporary file for collation, the import performance will be greatly affected.

   The memory used for sorting is specified by the GUC parameter **psort_work_mem**. You can set it to a larger value so that the collation has less impact on the import performance.

   The volume of data to be sorted is specified by the **PARTIAL_CLUSTER_ROWS** parameter of the table. Decreasing the value of this parameter reduces the amount of data to be sorted at a time. **PARTIAL_CLUSTER_ROWS** is usually used along with the **MAX_BATCHROW** parameter. The value of **PARTIAL_CLUSTER_ROWS** must be an integer multiple of the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**MAX_BATCHROW** value. **MAX_BATCHROW** specifies the maximum number of rows in a CU.

# 10.4.17 Case: Modifying the GUC Parameter rewrite_rule

**rewrite_rule** contains multiple query rewriting rules: magicset, partialpush, uniquecheck, disablerep, intargetlist, and predpush. The following describes the application scenarios of some important rules:

## partialpush: Partial Pushdown

Queries are pushed down to DNs for distributed execution, greatly accelerating queries. If a query statement contains a factor that cannot be pushed down, the entire statement cannot be pushed down. As a result, a stream plan cannot be generated and executed on DNs for the distributed execution, and the performance is poor.

The following is an example:

```
yshen=# set rewrite_rule='none';
SET
yshen=# explain (verbose on, costs off)  select two_sum(tt.c1, tt.c2) from (select t1.c1,t2.c2 from t1,t2
where t1.c1=t2.c2) tt(c1,c2);
                          QUERY PLAN
------------------------------------------------------------------------
 Hash Join
   Output: two_sum(t1.c1, t2.c2)
   Hash Cond: (t1.c1 = t2.c2)
   ->  Data Node Scan on t1 "_REMOTE_TABLE_QUERY_"
         Output: t1.c1
         Node/s: All datanodes
         Remote query: SELECT c1 FROM ONLY public.t1 WHERE true
   ->  Hash
         Output: t2.c2
         ->  Data Node Scan on t2 "_REMOTE_TABLE_QUERY_"
               Output: t2.c2
               Node/s: All datanodes
               Remote query: SELECT c2 FROM ONLY public.t2 WHERE true
(13 rows)
```

The **two_sum()** function cannot be pushed down. As a result, the remote query plan is executed:

1. Deliver the **select c1 from t1 where true** statement to DNs to read all data in the **t1** table.
2. Deliver the **select c2 from t2 where true** statement to DNs to read all data in the **t2** table.
3. Perform HASH JOIN on the CN.
4. Perform the two_sum calculation and return the final result.

This plan is slow because a large amount of data is transmitted over the network and then HASH JOIN is executed on the CN. As a result, cluster resources cannot be fully used.

**partialpush** is added to push the preceding 1, 2, and 3 operations down to DNs for distributed execution, greatly improving statement performance.

```
yshen=# set rewrite_rule='partialpush';
SET
yshen=# explain (verbose on, costs off) select two_sum(tt.c1, tt.c2) from (select t1.c1,t2.c2 from t1,t2 where
t1.c1=t2.c2) tt(c1,c2);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
                    QUERY PLAN
------------------------------------------------------------
 Subquery Scan on tt
   Output: two_sum(tt.c1, tt.c2)
   ->  Streaming (type: GATHER) --The Gather plan is executed on DNs in a distributed manner:
         Output: t1.c1, t2.c2
         Node/s: All datanodes
         ->  Nested Loop
               Output: t1.c1, t2.c2
               Join Filter: (t1.c1 = t2.c2)
               ->  Seq Scan on public.t1
                     Output: t1.c1, t1.c2, t1.c3
                     Distribute Key: t1.c1
               ->  Materialize
                     Output: t2.c2
                     ->  Streaming(type: REDISTRIBUTE)
                           Output: t2.c2
                           Distribute Key: t2.c2
                           Spawn on: All datanodes
                           Consumer Nodes: All datanodes
                           ->  Seq Scan on public.t2
                                 Output: t2.c2
                                 Distribute Key: t2.c1
(21 rows)
```

## intargetlist: Target Column Subquery Performance Improvement

The query performance can be greatly improved by converting the subquery in the target column to JOIN. The following is an example:

```
yshen=# set rewrite_rule='none';
SET
yshen=# explain (verbose on, costs off) select c1,(select avg(c2) from t2 where t2.c2=t1.c2) from t1 where
t1.c1<100 order by t1.c2;
                          QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)
   Output: t1.c1, ((SubPlan 1)), t1.c2
   Merge Sort Key: t1.c2
   Node/s: All datanodes
   ->  Sort
         Output: t1.c1, ((SubPlan 1)), t1.c2
         Sort Key: t1.c2
         ->  Seq Scan on public.t1
               Output: t1.c1, (SubPlan 1), t1.c2
               Distribute Key: t1.c1
               Filter: (t1.c1 < 100)
               SubPlan 1
                 ->  Aggregate
                       Output: avg(t2.c2)
                       ->  Result
                             Output: t2.c2
                             Filter: (t2.c2 = t1.c2)
                             ->  Materialize
                                   Output: t2.c2
                                   ->  Streaming(type: BROADCAST)
                                         Output: t2.c2
                                         Spawn on: All datanodes
                                         Consumer Nodes: All datanodes
                                         ->  Seq Scan on public.t2
                                               Output: t2.c2
                                               Distribute Key: t2.c1
(26 rows)
```

Because the subquery **(select avg(c2) from t2 where t2.c2=t1.c2)** in the target column cannot be pulled up, execution of the subquery is triggered each time a row of data of **t1** is scanned, and the query efficiency is low. If the **intargetlist**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

parameter is enabled, the subquery is converted to JOIN to improve the query performance.

```
yshen=# set rewrite_rule='intargetlist';
SET
yshen=# explain (verbose on, costs off) select c1,(select avg(c2) from t2 where t2.c2=t1.c2) from t1 where
t1.c1<100 order by t1.c2;
                        QUERY PLAN
------------------------------------------------------------------
 Streaming (type: GATHER)
   Output: t1.c1, (avg(t2.c2)), t1.c2
   Merge Sort Key: t1.c2
   Node/s: All datanodes
   ->  Sort
         Output: t1.c1, (avg(t2.c2)), t1.c2
         Sort Key: t1.c2
         ->  Hash Right Join
               Output: t1.c1, (avg(t2.c2)), t1.c2
               Hash Cond: (t2.c2 = t1.c2)
               ->  Streaming(type: BROADCAST)
                     Output: (avg(t2.c2)), t2.c2
                     Spawn on: All datanodes
                     Consumer Nodes: All datanodes
                     ->  HashAggregate
                           Output: avg(t2.c2), t2.c2
                           Group By Key: t2.c2
                           ->  Streaming(type: REDISTRIBUTE)
                                 Output: t2.c2
                                 Distribute Key: t2.c2
                                 Spawn on: All datanodes
                                 Consumer Nodes: All datanodes
                                 ->  Seq Scan on public.t2
                                       Output: t2.c2
                                       Distribute Key: t2.c1
               ->  Hash
                     Output: t1.c1, t1.c2
                     ->  Seq Scan on public.t1
                           Output: t1.c1, t1.c2
                           Distribute Key: t1.c1
                           Filter: (t1.c1 < 100)
(31 rows)
```

## uniquecheck: Performance Improvement of Subqueries Without Aggregate Functions

Ensure that each condition has only one line of output. The subqueries with aggregate functions can be automatically pulled up. For subqueries without aggregate functions, the following is an example:

select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c2) ;

Rewrite as follows:

select t1.c1 from t1 join (select t2.c1 from t2 where t2.c1 is not null group by t2.c1(unique check)) tt(c1) on tt.c1=t1.c1;

To ensure semantic equivalence, the subquery **tt** must ensure that each **group by t2.c1** has only one line of output. Enable the **uniquecheck** query rewriting parameter to ensure that the query can be pulled up and equivalent. If more than one row of data is output at run time, an error is reported.

```
yshen=# set rewrite_rule='uniquecheck';
SET
yshen=# explain verbose select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c1) ;
                          QUERY PLAN
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
--------------------------------------------------------------------------------
 Streaming (type: GATHER)
   Output: t1.c1
   Node/s: All datanodes
   ->  Nested Loop
         Output: t1.c1
         Join Filter: (t1.c1 = subquery."?column?")
         ->  Seq Scan on public.t1
               Output: t1.c1, t1.c2, t1.c3
               Distribute Key: t1.c1
         ->  Materialize
               Output: subquery."?column?", subquery.c1
               ->  Subquery Scan on subquery
                     Output: subquery."?column?", subquery.c1
                     ->  HashAggregate
                           Output: t2.c1, t2.c1
                           Group By Key: t2.c1
                           Filter: (t2.c1 IS NOT NULL)
                           Unique Check Required -- If more than one row of data is output during running, an
error is reported.
                           ->  Index Only Scan using t2idx on public.t2
                                 Output: t2.c1
                                 Distribute Key: t2.c1
(21 rows)
```

Note: Because **group by t2.c1 unique check** occurs before the filter condition **tt.c1=t1.c1**, an error may be reported after the query that does not report an error is rewritten. An example is as follows:

There are tables **t1** and **t2**. The data in the tables is as follows:

```
yshen=# select * from t1 order by c2;
 c1 | c2 | c3
----+----+----
  1 |  1 |  1
  2 |  2 |  2
  3 |  3 |  3

```

## predpush, predpushnormal, and predpushforce: Condition Pushdown to Subqueries

Generally, the optimizer performs optimization by query block, and different query blocks are independently optimized. If a predicate condition involving cross-query blocks exists, it is difficult to consider the location of a predicate application from a global perspective. The predpush may push down the predicate to the subquery block, so that performance can be improved in a scenario in which the data volume in the parent query block is relatively small and an index can be used in the subquery. There are three rewriting rules related to predpush:

- predpushnormal: attempts to push predicates down to subqueries. The STREAM operators, such as BROADCAST, are used to implement distributed plans.
- predpushforce: attempts to push down predicates to subqueries and uses the index of the parameterized path for scanning as much as possible.
- predpush: selects an optimal distributed plan from predpushnormal and predpushforce at a cost, but increases optimization time.

The following is an example of a plan for disabling and enabling the query rewriting rule:

```
openGauss=# show rewrite_rule;
 rewrite_rule
--------------
 magicset
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1
= t1.c1;
            QUERY PLAN
--------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Nested Loop
         Join Filter: (t1.c1 = t2.c1)
         ->  HashAggregate
               Group By Key: t2.c1
               ->  Seq Scan on t2
         ->  Seq Scan on t1
(8 rows)

openGauss=# set rewrite_rule='predpushnormal';
SET
openGauss=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1
= t1.c1;

(12 rows)
```

# 10.4.18 Case: Using DN Gather to Reduce Stream Nodes in the Plan

The DN Gather is used to remove the stream nodes from the distribution plan and send data to a node for calculation. This reduces the cost of data redistribution during the execution of the distribution plan and improves the single query performance and the overall throughput capability of the system. However, DN Gather is oriented to small-data-volume scenarios of TP. For small-data-volume queries, performance can be improved because the cost of data redistribution is reduced and the computing power of a single node is sufficient. Multi-node parallel computing is more advantageous for large-data-volume computing. You need to enable and disable DN Gather to determine which one is faster. (The default value of **dngather_min_rows** is 500. The following uses the default value.) Some cases are provided as follows:

## Gather Join

To converge the join results to a single DN, the following conditions must be met:

- The number of data rows estimated by the optimizer before and after join is less than the threshold.
- The subnodes of Join are all stream nodes.

For example, the subnodes of Join are all stream nodes, and broadcast is disabled.

```
openGauss=# set enable_broadcast=false;
SET
openGauss=# set explain_perf_mode=pretty;
SET
openGauss=# set enable_dngather=false;
SET
openGauss=# explain select count(*) from t1, t2 where t1.b = t2.b;
 id |                    operation                    | E-rows | E-width | E-costs
----+-------------------------------------------------+--------+---------+---------
  1 | ->  Aggregate                                   |      1 |       8 | 31.46
  2 |    ->  Streaming (type: GATHER)                 |      3 |       8 | 31.46
  3 |       ->  Aggregate                             |      3 |       8 | 31.34
  4 |          ->  Hash Join (5,7)                    |     30 |       0 | 31.30
  5 |             ->  Streaming(type: REDISTRIBUTE)   |     30 |       4 | 15.49
  6 |                ->  Seq Scan on t1               |     30 |       4 | 14.14

## Gather Groupby/Agg

To converge the GroupBy/Agg results to a single DN, the following conditions must be met:

- The number of data rows estimated by the optimizer before and after GroupBy/Agg is less than the threshold.
- All agg subnodes are stream nodes.

```

## Union/Union all

To converge union/union all results to a single DN, the following conditions must be met:

- Subnodes must meet conditions of at least one of the preceding three cases.

For example, all the subnodes of Join are stream nodes, and broadcast is disabled.

```
openGauss=# set explain_perf_mode=pretty;
SET
openGauss=# set enable_broadcast=false;
SET
openGauss=# set enable_dngather=false;
SET
openGauss=# explain select t1.a, t2.b from t1, t2 where t1.b = t2.b union all select t3.a, t3.b from t3, t4
where t3.b = t4.b;
 id |                  operation                   | E-rows | E-width | E-costs

# 10.4.19 Case: Adjusting I/O Parameters to Reduce the Log Bloat Rate

- Parameter values before adjustment:
  - pagewriter_sleep=2000ms
  - bgwriter_delay=2000ms
  - max_io_capacity=500MB
- Parameter values after adjustment:
  - pagewriter_sleep=100ms
  - bgwriter_delay=1s
  - max_io_capacity=300MB

NOTE

- The **max_io_capacity** parameter is set to a small value because the I/O does not use the maximum value of the previous parameter. This parameter is used to limit the upper limit of the I/O usage of the backend write process.
- Log recycling is triggered only when the number of logs reaches a certain value. The formula for calculating the value is as follows: Value of **wal_keep_segments** + Value of **checkpoint_segments** x 2 + 1. If **checkpoint_segments** is set to **128** and **wal_keep_segments** is set to **128**, the number of logs is (128 + 128 x 2 + 1) x 16 MB = 6 GB.
- Before the parameters are adjusted, the Xlogs of different data volumes bloat in different degrees in the TPC-C data export phase. As a result, GB-level logs bloat. The main cause is that dirty pages are not flushed to disks, the recovery point cannot be pushed forward, and logs cannot be recycled in time. After the parameters are adjusted, the log bloat rate decreases significantly.
- Take the 2000 warehouses as an example. Before the parameter adjustment, the log size bloats by 10 GB in the data export phase. After the parameter adjustment, the log size remains within the range of the minimum xlog value calculated based on the parameter setting.

# 11 Configuring Running Parameters

## 11.1 Viewing Parameter Values

GaussDB uses a set of default running parameters after it is installed. You can modify the parameters to better fit your application scenarios and data volume.

### Procedure

**Step 1** Connect to a database. For details, see **2.1 Connecting to a Database**.

**Step 2** View the parameter values in the database.

- Method 1: Run the **SHOW** command.
  - Run the following command to view the value of a certain parameter:
    ```
    openGauss=# SHOW server_version;
    ```
    *server_version* indicates the database version.
  - Run the following command to view values of all parameters:
    ```
    openGauss=# SHOW ALL;
    ```
- Method 2: Query the **pg_settings** view.
  - Run the following command to view the value of a certain parameter:
    ```
    openGauss=# SELECT * FROM pg_settings WHERE NAME='server_version';
    ```
  - Run the following command to view values of all parameters:
    ```
    openGauss=# SELECT * FROM pg_settings;
    ```

**----End**

### Example

View the server version.

```
openGauss=# SHOW server_version;
 server_version
----------------
 9.2.4
(1 row)
```

# 11.2 Resetting Parameters

## Background

GaussDB provides multiple methods to set GUC parameters for databases, users, or sessions.

- Parameter names are case-insensitive.
- The parameter values can be integers, floating points, strings, Boolean values, or enumerated values.
  - The Boolean values can be **on**/**off**, **true**/**false**, **yes**/**no**, or **1**/**0**, and are case-insensitive.
  - The enumerated value range is specified in the **enumvals** column of the system catalog **pg_settings**.
- For parameters using units, specify their units during the setting. Otherwise, default units are used.
  - The default units are specified in the **unit** column of **pg_settings**.
  - The unit of memory can be KB, MB, or GB.
  - The unit of time can be ms, s, min, h, or d.
- You can set parameters about CNs and DNs at a time, but cannot do the same to other parameters.

For details about parameters in the hosts configuration template, see **19 GUC Parameters**.

## Setting GUC Parameters

GaussDB provides six types of GUC parameters. For details about parameter types and their setting methods, see **Table 11-1**.

**Table 11-1** GUC parameter types

| Parameter Type | Description | Setting Method |
| --- | --- | --- |
| INTERNAL | Fixed parameter. It is set during database creation and cannot be modified. Users can only view the parameter by running the **SHOW** command or in the **pg_settings** view. | None |
| POSTMASTER | Database server parameter. It can be set when the database is started or in the configuration file. | Method 1 in **Table 11-2**. |
| SIGHUP | Global database parameter. It can be set when the database is started or be modified later. | Method 1 or 2 in **Table 11-2**. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter Type | Description | Setting Method |
| --- | --- | --- |
| BACKEND | Session connection parameter. It is specified during session connection creation and cannot be modified after that. The parameter setting becomes invalid when the session is disconnected. This is an internal parameter and not recommended for users to set it. | Method 1 or 2 in **Table 11-2**.<br>**NOTE**<br>The parameter setting takes effect when the next session is created. |
| SUSET | Database administrator parameter. It can be set by common users when or after the database is started. It can also be set by database administrators using SQL statements. | Method 1 or 2 by a common user, or method 3 by a database administrator in **Table 11-2**. |
| USERSET | Common user parameter. It can be set by any user at any time. | Method 1, 2, or 3 in **Table 11-2**.<br>**NOTE**<br>When you set parameters of the USERSET type, the parameter value set using **ALTER DATABASE** takes precedence over that set using **gs_guc**. To make the parameter settings of **gs_guc** take effect, run the **alter database** *xxx* **reset** *xxx* command to reset the parameters. |

You can set GUC parameters in GaussDB using the methods listed in **Table 11-2**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 11-2** Methods for setting GUC parameters

| No. | Setting Method |
| --- | --- |
| Method 1 | 1. Run the following command to set a parameter:<br>**gs_guc set -Z** *nodetype* **-D** *datadir* **-c** "*paraname=value*"<br>**NOTE**<br>If the parameter is a string variable, use **-c** *parameter*="'*value*'" or **-c** "*parameter* = '*value*'".<br>Run the following command to set a parameter for CNs and DNs at the same time:<br>**gs_guc set -Z coordinator -Z datanode -N *all* -I *all* -c "*paraname=value*"**<br>Run the following command to set a cm_agent parameter for CN and DN:<br>**gs_guc set -Z cmagent -N *all* -I *all* -c "paraname=value"**<br>**gs_guc set -Z cmagent -c "paraname=value"**<br>Run the following command to set a cm_server parameter for CN and DN:<br>**gs_guc set -Z cmserver -N *all* -I *all* -c "paraname=value"**<br>**gs_guc set -Z cmserver -c "paraname=value"**<br>2. Restart the database to make the setting take effect.<br>**NOTE**<br>Restarting the database cluster results in operation interruption. Properly plan the restart to avoid affecting users.<br>**gs_om -t stop gs_om -t start** |
| Method 2 | **gs_guc reload -Z** *nodetype* **-D** *datadir* **-c** *"paraname=value*"<br>**NOTE**<br>Run the following command to set a parameter for CNs and DNs at the same time:<br>**gs_guc reload -Z coordinator -Z datanode -N *all* -I *all* -c "*paraname=value*"**<br>Run the following command to set a cm_agent parameter for CN and DN:<br>**gs_guc reload -Z cmagent -N *all* -I *all* -c "paraname=value"**<br>**gs_guc reload -Z cmagent -c "paraname=value"**<br>Run the following command to set a cm_server parameter for CN and DN:<br>**gs_guc reload -Z cmserver -N *all* -I *all* -c "paraname=value"**<br>**gs_guc reload -Z cmserver -c "paraname=value"** |
| Method 3 | Modify a session-level parameter.<br>• Set a session-level parameter.<br>openGauss=# **SET** *paraname* **TO** *value;*<br>Parameter value in the current session is changed. After you exit the session, the setting becomes invalid. |

**CAUTION**

If you use method 1 or 2 to set a parameter that does not belong to the current environment, the database displays a message indicating that the parameter is not supported.

# 12 SQL Reference

## 12.1 GaussDB SQL

### What Is SQL?

SQL is a standard computer language used to control the access to databases and manage data in databases.

SQL provides different statements to enable you to:

- Query data.
- Insert, update, and delete rows.
- Create, replace, modify, and delete objects.
- Control the access to a database and its objects.
- Maintain the consistency and integrity of a database.

SQL consists of commands and functions that are used to manage databases and database objects. SQL can also forcibly implement the rules for data types, expressions, and texts. Therefore, **12 SQL Reference** describes data types, expressions, functions, and operators in addition to SQL syntax.

### Development of SQL Standards

Released SQL standards are as follows:

- 1986: ANSI X3.135-1986, ISO/IEC 9075:1986, SQL-86
- 1989: ANSI X3.135-1989, ISO/IEC 9075:1989, SQL-89

### SQL Standards Supported by GaussDB

GaussDB is compatible with Postgres-XC and supports major SQL2, SQL3, and SQL4 features by default.

## 12.2 Keywords

The SQL contains reserved words and non-reserved words. Standards require that reserved keywords not be used as other identifiers. Non-reserved keywords have special meanings only in a specific environment and can be used as identifiers in other environments.

**Table 12-1** SQL keywords

| Keyword | GaussDB | SQL:1999 | SQL-92 |
| --- | --- | --- | --- |
| ABORT | Non-reserved | N/A | N/A |
| ABS | N/A | Non-reserved | N/A |

| | | | | |
|---|---|---|---|---|
| CTID | XMIN | CMIN | XMAX | CMAX |
| TABLEOID | XC_NODE_ID | TID | OID | GS_TUPLE_UID |
| TABLEBUCKETID | N/A | N/A | N/A | N/A |

# 12.3 Data Type

Data type is a basic attribute of data that used to distinguish different types of data. Different data types occupy different storage space and support different operations. Data is stored in data tables in the database. Each column of a data table defines the data type. During storage, data must be stored according to data types.

GaussDB supports implicit conversions between certain data types. For details, see **15.2.45 PG_CAST**.

## 12.3.1 Numeric Types

**Table 12-2** lists all available types. For arithmetic operators and related built-in functions, see **12.5.7 Arithmetic Functions and Operators**.

**Table 12-2** Integer types

| Name | Description | Storage Space | Range |
|---|---|---|---|
| TINYINT | Tiny integer, also called INT1 | 1 byte | 0 to 255 |
| SMALLINT | Small integer, also called INT2 | 2 bytes | –32,768 to +32,767 |
| INTEGER | Typical choice for integers, also called INT4 | 4 bytes | –2,147,483,648 to +2,147,483,647 |
| BINARY_INTEGER | INTEGER alias, compatible with Oracle | 4 bytes | –2,147,483,648 to +2,147,483,647 |
| BIGINT | Big integer, also called INT8 | 8 bytes | –9,223,372,036,854,775,808 to +9,223,372,036,854,775,807 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
-- Create a table containing TINYINT data.
openGauss=# CREATE TABLE int_type_t1
         (
          IT_COL1 TINYINT
         );

-- Insert data.
openGauss=# INSERT INTO int_type_t1 VALUES(10);

-- View data.
openGauss=# SELECT * FROM int_type_t1;
 it_col1
---------
 10
(1 row)

-- Drop the table.
openGauss=# DROP TABLE int_type_t1;
-- Create a table containing TINYINT, INTEGER, and BIGINT data.
openGauss=# CREATE TABLE int_type_t2
(
    a TINYINT,
    b TINYINT,
    c INTEGER,
    d BIGINT
);

-- Insert data.
openGauss=# INSERT INTO int_type_t2 VALUES(100, 10, 1000, 10000);

-- View data.
openGauss=# SELECT * FROM int_type_t2;
  a  | b  |  c   |   d
-----+----+------+-------
 100 | 10 | 1000 | 10000
(1 row)

-- Drop the table.
openGauss=# DROP TABLE int_type_t2;
```

**NOTE**

- The TINYINT, SMALLINT, INTEGER, and BIGINT types store whole numbers, that is, numbers without fractional components, of various ranges. Saving a number with a decimal in any of the data types will result in errors.
- The INTEGER type is the common choice, as it offers the best balance between range, storage size, and performance. Generally, use the SMALLINT type only if you are sure that the value range is within the SMALLINT value range. The storage speed of INTEGER is much faster. BIGINT is used only when the range of INTEGER is not large enough.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-3** Arbitrary precision types

| Name | Description | Storage Space | Range |
| --- | --- | --- | --- |
| NUMERIC[(p[,s])], DECIMAL[(p[,s])] | The value range of **p** is [1,1000], and the value range of **s** is [0,*p*].<br>**NOTE**<br>**p** indicates the total digits, and **s** indicates the decimal digit. | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified. |
| NUMBER[(p[,s])] | Alias for type NUMERIC, compatible with Oracle | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified. |

Example:

```
-- Create a table.
openGauss=# CREATE TABLE decimal_type_t1
(
    DT_COL1 DECIMAL(10,4)
);

-- Insert data.
openGauss=# INSERT INTO decimal_type_t1 VALUES(123456.122331);

-- Query data in the table.
openGauss=# SELECT * FROM decimal_type_t1;
   dt_col1
-------------
 123456.1223
(1 row)

-- Drop the table.
openGauss=# DROP TABLE decimal_type_t1;
-- Create a table.
openGauss=# CREATE TABLE numeric_type_t1
(
    NT_COL1 NUMERIC(10,4)
);

-- Insert data.
openGauss=# INSERT INTO numeric_type_t1 VALUES(123456.12354);

-- Query data in the table.
openGauss=# SELECT * FROM numeric_type_t1;
   nt_col1
-------------
 123456.1235
(1 row)

-- Drop the table.
openGauss=# DROP TABLE numeric_type_t1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- Compared to the integer types, the arbitrary precision numbers require larger storage space and have lower storage efficiency, operation efficiency, and poorer compression ratio results. The INTEGER type is the common choice when number types are defined. Arbitrary precision numbers are used only when numbers exceed the maximum range indicated by the integers.
- When NUMERIC/DECIMAL is used for defining a column, you are advised to specify the precision (p) and scale (s) for the column.

**Table 12-4** Sequence integer

| Name | Description | Storage Space | Range |
| --- | --- | --- | --- |
| SMALLSERIAL | Two-byte serial integer | 2 bytes | –32,768 to +32,767 |
| SERIAL | Four-byte serial integer | 4 bytes | –2,147,483,648 to +2,147,483,647 |
| BIGSERIAL | Eight-byte serial integer | 8 bytes | –9,223,372,036,854,775,808 to +9,223,372,036,854,775,807 |

Example:

```
-- Create a table.
openGauss=# CREATE TABLE smallserial_type_tab(a SMALLSERIAL);

-- Insert data.
openGauss=# INSERT INTO smallserial_type_tab VALUES(default);

-- Insert data again.
openGauss=# INSERT INTO smallserial_type_tab VALUES(default);

-- View data.
openGauss=# SELECT * FROM smallserial_type_tab;
 a
---
 1
 2
(2 rows)

-- Create a table.
openGauss=# CREATE TABLE serial_type_tab(b SERIAL);

-- Insert data.
openGauss=# INSERT INTO serial_type_tab VALUES(default);

-- Insert data again.
openGauss=# INSERT INTO serial_type_tab VALUES(default);

-- View data.
openGauss=# SELECT * FROM serial_type_tab;
 b
---
 1
 2
(2 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
-- Create a table.
openGauss=# CREATE TABLE bigserial_type_tab(c BIGSERIAL);

-- Insert data.
openGauss=# INSERT INTO bigserial_type_tab VALUES(default);

-- Insert data.
openGauss=# INSERT INTO bigserial_type_tab VALUES(default);

-- View data.
openGauss=# SELECT * FROM bigserial_type_tab;
 c
---
 1
 2
(2 rows)

-- Drop the table.
openGauss=# DROP TABLE smallserial_type_tab;

openGauss=# DROP TABLE serial_type_tab;

openGauss=# DROP TABLE bigserial_type_tab;
```

**NOTE**

SMALLSERIAL, SERIAL, and BIGSERIAL are not real types. They are concepts used for setting a unique identifier for a table. Therefore, an integer column is created and its default value plans to be read from a sequencer. A NOT NULL constraint is used to ensure NULL is not inserted. In most cases you would also want to attach a **UNIQUE** or **PRIMARY KEY** constraint to prevent duplicate values from being inserted unexpectedly, but this is not automatic. The sequencer is set so that it belongs to the column. In this case, when the column or the table is deleted, the sequencer is also deleted. Currently, the **SERIAL** column can be specified only when you create a table. You cannot add the **SERIAL** column in an existing table. In addition, **SERIAL** columns cannot be created in temporary tables. Because SERIAL is not a data type, columns cannot be converted to this type.

**Table 12-5** Floating point types

| Name | Description | Storage Space | Range |
| --- | --- | --- | --- |
| REAL,<br>FLOAT4 | Single precision floating points, inexact | 4 bytes | –3.402E+38 to 3.402E+38,<br>6-bit decimal digits |
| DOUBLE PRECISION,<br>FLOAT8 | Double precision floating points, inexact | 8 bytes | –1.79E+308 to 1.79E+308,<br>15-bit decimal digits |
| FLOAT[(p)] | Floating points, inexact The value range of precision (p) is [1,53].<br>**NOTE**<br>**p** is the precision, indicating the total number of binary bits. | 4 bytes or 8 bytes | **REAL** or **DOUBLE PRECISION** is selected as an internal identifier based on precision (p). If no precision is specified, **DOUBLE PRECISION** is used as the internal identifier. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Description | Storage Space | Range |
| --- | --- | --- | --- |
| BINARY_DOUBLE | DOUBLE PRECISION alias, compatible with Oracle | 8 bytes | –1.79E+308 to 1.79E+308, 15-bit decimal digits |
| DEC[(p[,s])] | The value range of **p** (precision) is [1,1000], and the value range of **s** (scale) is [0,*p*].<br>**NOTE**<br>**p** indicates the total digits, and **s** indicates the decimal digit. | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified. |
| INTEGER[(p[,s])] | The value range of **p** (precision) is [1,1000], and the value range of **s** (scale) is [0,*p*]. | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | - |

**NOTE**

For the precision of the floating-point type, only the number of precision bits can be ensured when the data is directly read. When distributed computing is involved, the computation is executed on each DN and is finally aggregated to a CN. Therefore, the error may be amplified as the number of compute nodes increases.

Example:

```
-- Create a table.
openGauss=# CREATE TABLE float_type_t2
(
    FT_COL1 INTEGER,
    FT_COL2 FLOAT4,
    FT_COL3 FLOAT8,
    FT_COL4 FLOAT(3),
    FT_COL5 BINARY_DOUBLE,
    FT_COL6 DECIMAL(10,4),
    FT_COL7 INTEGER(6,3)
)DISTRIBUTE BY HASH ( ft_col1);

-- Insert data.
openGauss=# INSERT INTO float_type_t2 VALUES(10,10.365456,123456.1234,10.3214, 321.321, 123.123654,
123.123654);

-- View data.
openGauss=# SELECT * FROM float_type_t2 ;
 ft_col1 | ft_col2 |   ft_col3   | ft_col4 | ft_col5 | ft_col6  | ft_col7
---------+---------+-------------+---------+---------+----------+---------
      10 | 10.3655 | 123456.1234 | 10.3214 | 321.321 | 123.1237 | 123.124
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
-- Drop the table.
openGauss=# DROP TABLE float_type_t2;
```

## 12.3.2 Monetary Types

The money type stores a currency amount with fixed fractional precision.

The range shown in **Table 12-6** assumes there are two fractional digits. Input is accepted in a variety of formats, including integer and floating-point literals, as well as typical currency formatting, such as "$1,000.00". Output is generally in the last format but depends on the locale.

**Table 12-6** Monetary type

| Name | Storage Space | Description | Range |
| --- | --- | --- | --- |
| money | 8 bytes | Currency amount | –92233720368547758.08 to +92233720368547758.07 |

Values of the numeric, int, and bigint data types can be cast to money. Conversion from the real and double precision data types can be done by casting to numeric first, for example:

```
openGauss=# SELECT '12.34'::float8::numeric::money;
```

However, this is not recommended. Floating point numbers should not be used to handle money due to the potential for rounding errors.

A money value can be cast to numeric without loss of precision. Conversion to other types could potentially lose precision, and must also be done in two stages:

```
openGauss=# SELECT '52093.89'::money::numeric::float8;
```

When a money value is divided by another money value, the result is of the double precision type (that is, a pure number, not money); the currency units cancel each other out in the division.

## 12.3.3 Boolean Types

**Table 12-7** Boolean type

| Name | Description | Storage Space | Value |
| --- | --- | --- | --- |
| BOOLEAN | Boolean | 1 byte | • **true**<br>• **false**<br>• **null**: unknown |

Valid literal values for the "true" state are:

**TRUE**, **'t'**, **'true'**, **'y'**, **'yes'**, **'1'**, and all non-zero integers.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Valid literal values for the "false" state include:

**FALSE**, **'f'**, **'false'**, **'n'**, **'no'**, **'0'**, and **0**.

**TRUE** and **FALSE** are standard expressions, compatible with SQL statements.

## Examples

Boolean values are displayed using the letters t and f.

```
-- Create a table.
openGauss=# CREATE TABLE bool_type_t1
(
    BT_COL1 BOOLEAN,
    BT_COL2 TEXT
)DISTRIBUTE BY HASH(BT_COL2);

-- Insert data.
openGauss=# INSERT INTO bool_type_t1 VALUES (TRUE, 'sic est');

openGauss=# INSERT INTO bool_type_t1 VALUES (FALSE, 'non est');

-- View data.
openGauss=# SELECT * FROM bool_type_t1;
 bt_col1 | bt_col2
---------+---------
 t       | sic est
 f       | non est
(2 rows)

openGauss=# SELECT * FROM bool_type_t1 WHERE bt_col1 = 't';
 bt_col1 | bt_col2
---------+---------
 t       | sic est
(1 row)

-- Drop the table.
openGauss=# DROP TABLE bool_type_t1;
```

# 12.3.4 Character Types

Table 12-8 lists the character data types supported by GaussDB. For string operators and related built-in functions, see 12.5.3 Character Processing Functions and Operators.

**Table 12-8** Character types

| Name | Description | Storage Space |
| --- | --- | --- |
| CHAR(n)<br>CHARACTER(n)<br>NCHAR(n) | Fixed-length character string, blank padded. **n** indicates the string length. If it is not specified, the default precision **1** is used. | The maximum value of **n** is **10485760** (10 MB). |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Description | Storage Space |
| --- | --- | --- |
| VARCHAR(n)<br>CHARACTER VARYING(n) | Variable-length string. In PostgreSQL-compatible mode, **n** indicates the string length. In other compatibility modes, **n** indicates the byte length. | The maximum value of **n** is **10485760** (10 MB).<br>If **n** is not contained, the maximum storage length is 1 GB – 85 – Length of the first *n* columns. For example, the maximum length (of a int, b varchar) is 1 GB – 85 – 4 = 1,073,741,735. |
| VARCHAR2(n) | Variable-length string. It is an alias for VARCHAR(n) type, compatible with Oracle. **n** indicates the string length. | The maximum value of **n** is **10485760** (10 MB).<br>If **n** is not contained, the maximum storage length is 1 GB – 85 – Length of the first *n* columns. For example, the maximum length (of a int, b varchar) is 1 GB – 85 – 4 = 1,073,741,735. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Description | Storage Space |
| --- | --- | --- |
| NVARCHAR2(n) | Variable-length string. **n** indicates the string length. | The maximum value of **n** is **10485760** (10 MB).<br>If **n** is not contained, the maximum storage length is 1 GB – 85 – Length of the first *n* columns. For example, the maximum length (of a int, b varchar) is 1 GB – 85 – 4 = 1,073,741,735. |
| CLOB | Big text object. It is compatible with the Oracle database. | The maximum storage length is 1 GB – 85 – Length of the first *n* columns. For example, the maximum length (of a int, b varchar) is 1 GB – 85 – 4 = 1,073,741,735. |
| TEXT | Variable-length string. | The maximum storage length is 1 GB – 85 – Length of the first *n* columns. For example, the maximum length (of a int, b varchar) is 1 GB – 85 – 4 = 1,073,741,735. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

1. In addition to the size limitation on each column, the total size of each tuple is 1,073,741,739 bytes (1 GB – 85 bytes).
2. NCHAR is the alias of the bpchar type, and VARCHAR2(n) is the alias of the VARCHAR(n) type.

GaussDB has two other fixed-length character types, as shown in **Table 12-9**. The **name** type exists only for the storage of identifiers in the internal system catalogs and is not intended for use by general users. Its length is currently defined as 64 bytes (63 usable characters plus terminator). The type **"char"** only uses one byte of storage. It is internally used in the system catalogs as a simplistic enumeration type.

**Table 12-9** Special character types

| Name | Description | Storage Space |
| --- | --- | --- |
| name | Internal type for object names | 64 bytes |
| "char" | Single-byte internal type | 1 byte |

## Examples

```
-- Create a table.
openGauss=# CREATE TABLE char_type_t1
(
    CT_COL1 CHARACTER(4)
)DISTRIBUTE BY HASH (CT_COL1);

-- Insert data.
openGauss=# INSERT INTO char_type_t1 VALUES ('ok');

-- Query data in the table.
openGauss=# SELECT ct_col1, char_length(ct_col1) FROM char_type_t1;
 ct_col1 | char_length
---------+-------------
 ok      |           4
(1 row)

-- Delete the table.
openGauss=# DROP TABLE char_type_t1;
-- Create a table.
openGauss=# CREATE TABLE char_type_t2
(
    CT_COL1 VARCHAR(5)
)DISTRIBUTE BY HASH (CT_COL1);

-- Insert data.
openGauss=# INSERT INTO char_type_t2 VALUES ('ok');

openGauss=# INSERT INTO char_type_t2 VALUES ('good');

-- Specify the type length. An error is reported if an inserted string exceeds this length.
openGauss=# INSERT INTO char_type_t2 VALUES ('too long');
ERROR:  value too long for type character varying(5)
CONTEXT:  referenced column: ct_col1

-- Specify the type length. A string exceeding this length is truncated.
openGauss=# INSERT INTO char_type_t2 VALUES ('too long'::varchar(5));

-- Query data.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT ct_col1, char_length(ct_col1) FROM char_type_t2;
 ct_col1 | char_length
---------+-------------
 ok      |           2
 good    |           4
 too l   |           5
(3 rows)

-- Delete data.
openGauss=# DROP TABLE char_type_t2;
```

## 12.3.5 Binary Types

Table 12-10 lists the binary types supported by GaussDB.

**Table 12-10** Binary types

| Name | Description | Storage Space |
| --- | --- | --- |
| BLOB | Binary large object (BLOB).<br>Currently, BLOB only supports the following external access interfaces:<br>• DBE_LOB.GET_LENGTH<br>• DBE_LOB.READ<br>• DBE_LOB.WRITE<br>• DBE_LOB.WRITE_APPEND<br>• DBE_LOB.COPY<br>• DBE_LOB.ERASE<br>For details about the APIs, see 13.12.2.1 DBE_LOB.<br>**NOTE**<br>Column storage cannot be used for the BLOB type. | The maximum value is 1,073,741,818 bytes (that is,1 GB minus 6 bytes). |
| RAW | Variable-length hexadecimal string.<br>**NOTE**<br>Column storage cannot be used for the RAW type. | The maximum value is 1,073,741,818 bytes (that is,1 GB minus 6 bytes). |
| BYTEA | Variable-length binary string. | The maximum value is calculated as follows: 1 GB – (56 + 24 + 5 + 1 + Total number of bytes in the first *n* columns). For example, if the table is (a int, b bytea), the maximum storage length is 1 GB – 56 – 24 – 5 – 1 – 4(int) = 1073741735. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Description | Storage Space |
| --- | --- | --- |
| BYTEAWITHOUTORDERWITHEQUALCOL | Variable-length binary character string (new type for the encryption feature. If the encryption type of the encrypted column is specified as deterministic encryption, the column type is BYTEAWITHOUTORDERWITHEQUALCOL). The original data type is displayed when the encryption table is printed by running the meta command. | 4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes). |
| BYTEAWITHOUTORDERCOL | Variable-length binary character string (new type for the encryption feature. If the encryption type of the encrypted column is specified as random encryption, the column type is BYTEAWITHOUTORDERCOL). The original data type is displayed when the encryption table is printed by running the meta command. | 4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes). |
| _BYTEAWITHOUTORDERWITHEQUALCOL | Variable-length binary string, which is a new type for the encryption feature. | 4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes). |
| _BYTEAWITHOUTORDERCOL | Variable-length binary string, which is a new type for the encryption feature. | 4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes). |

**NOTE**

- In addition to the size limitation on each column, the total size of each tuple is 1,073,741,771 bytes (1 GB minus 53 bytes).
- BYTEAWITHOUTORDERWITHEQUALCOL, BYTEAWITHOUTORDERCOL, _BYTEAWITHOUTORDERWITHEQUALCOL, and _BYTEAWITHOUTORDERCOL cannot be directly used to create a table.

Example:

```
-- Create a table.
openGauss=# CREATE TABLE blob_type_t1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
(
    BT_COL1 INTEGER,
    BT_COL2 BLOB,
    BT_COL3 RAW,
    BT_COL4 BYTEA
) DISTRIBUTE BY REPLICATION;

-- Insert data.
openGauss=# INSERT INTO blob_type_t1 VALUES(10,empty_blob(),
HEXTORAW('DEADBEEF'),E'\\xDEADBEEF');

-- Query data in the table.
openGauss=# SELECT * FROM blob_type_t1;
 bt_col1 | bt_col2 | bt_col3  |  bt_col4
---------+---------+----------+------------
      10 |         | DEADBEEF | \xdeadbeef
(1 row)

-- Drop the table.
openGauss=# DROP TABLE blob_type_t1;
```

## 12.3.6 Date/Time Types

Table 12-11 lists the date/time types that can be used in GaussDB. For the operators and built-in functions of the types, see 12.5.8 Date and Time Processing Functions and Operators.

NOTE

If the time format of another database is different from that of GaussDB, modify the value of the **DateStyle** parameter to keep them consistent.

**Table 12-11** Date/Time types

| Name | Description | Storage Space |
| --- | --- | --- |
| DATE | Date.<br>Minimum value: 4713-01-01 B.C.<br>Maximum value: 5874897-12-31 A.D.<br>**NOTE**<br>For ORA compatibility, the database treats empty strings as **NULL** and replaces **DATE** with **TIMESTAMP(0) WITHOUT TIME ZONE**. | 4 bytes (The actual storage space is 8 bytes.) |
| TIME [(p)] [WITHOUT TIME ZONE] | Time within one day.<br>**p** indicates the precision after the decimal point. The value ranges from **0** to **6**.<br>Minimum value: 00:00:00.<br>Maximum value: 24:00:00. | 8 bytes |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Description | Storage Space |
| --- | --- | --- |
| TIME [(p)] [WITH TIME ZONE] | Time within one day (with time zone).<br>**p** indicates the precision after the decimal point. The value ranges from **0** to **6**.<br>Minimum value: 00:00:00 + 1559. Maximum value: 24:00:00. | 12 bytes |
| TIMESTAMP[(p)] [WITHOUT TIME ZONE] | Date and time.<br>**p** indicates the precision after the decimal point. The value ranges from **0** to **6**.<br>Minimum: 4713 B.C., 4713-11-24 B.C. 00:00:00.000000. Maximum value: 294277 A.D., 294277-01-09 A.D. 00:00:00.000000. | 8 bytes |
| TIMESTAMP[(p)] [WITH TIME ZONE] | Date and time (with time zone). TIMESTAMP is also called TIMESTAMPTZ.<br>**p** indicates the precision after the decimal point. The value ranges from **0** to **6**.<br>Minimum: 00:00:00.000000, 4713-11-24 B.C. Maximum value: 00:00:00.000000, 294277-01-09 A.D. | 8 bytes |
| SMALLDATETIME | Date and time (without time zone).<br>The precision level is minute. 31s to 59s are rounded into 1 minute.<br>Minimum: 4713 B.C., 4713-11-24 B.C. 00:00:00.000000. Maximum value: 294277 A.D., 294277-01-09 A.D. 00:00:00.000000. | 8 bytes |
| INTERVAL DAY (l) TO SECOND (p) | Specifies the time interval (*X* days *X* hours *X* minutes *X* seconds).<br>• **l**: indicates the precision of days. The value ranges from 0 to 6. To adapt to Oracle syntax, the precision functions are not supported.<br>• **p**: indicates the precision of seconds. The value ranges from 0 to 6. The digit 0 at the end of a decimal number is not displayed. | 16 bytes |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Description | Storage Space |
| --- | --- | --- |
| INTERVAL [FIELDS] [ (p) ] | Time interval.<br>• **FIELDS**: **YEAR**, **MONTH**, **DAY**, **HOUR**, **MINUTE**, **SECOND**, **DAY TO HOUR**, **DAY TO MINUTE**, **DAY TO SECOND**, **HOUR TO MINUTE**, **HOUR TO SECOND**, or **MINUTE TO SECOND**.<br>• **p**: indicates the precision of seconds. The value ranges from 0 to 6. **p** takes effect only when **FIELDS** is set to **SECOND**, **DAY TO SECOND**, **HOUR TO SECOND**, or **MINUTE TO SECOND**. The digit 0 at the end of a decimal number is not displayed. | 12 bytes |
| reltime | Relative time interval. The format is as follows:<br>*X* years *X* mons *X* days *XX:XX:XX*<br>• The Julian calendar is used. It specifies that a year has 365.25 days and a month has 30 days. The relative time interval needs to be calculated based on the input value. The output format is POSTGRES. | 4 bytes |
| abstime | Date and time. The format is as follows:<br>YYYY-MM-DD hh:mm:ss+timezone<br>The value range is from 1901-12-13 20:45:53 GMT to 2038-01-18 23:59:59 GMT. The precision is second. | 4 bytes |

**NOTE**

1. The data of the time type automatically ignores all zeros at the end of the data when it is displayed.

2. The default value of **p** is **6**.

3. For the INTERVAL type, the date and time are stored in the int32 and double types in the system. Therefore, the value ranges of the two types are the same as those of the corresponding data type.

4. If the insertion time is out of the range, the system may not report an error, but may not ensure that the operation is normal.

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
-- Create a table.
openGauss=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
openGauss=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.
openGauss=# SELECT * FROM date_type_tab;
    coll
------------
  2010-12-10
(1 row)

-- Drop the table.
openGauss=# DROP TABLE date_type_tab;

-- Create a table.
openGauss=# CREATE TABLE time_type_tab (da time without time zone ,dai time with time zone,dfgh
timestamp without time zone,dfga timestamp with time zone, vbg smalldatetime);

-- Insert data.
openGauss=# INSERT INTO time_type_tab VALUES ('21:21:21','21:21:21 pst','2010-12-12','2013-12-11
pst','2003-04-12 04:05:06');

-- View data.
openGauss=# SELECT * FROM time_type_tab;
    da    |     dai     |        dfgh         |          dfga          |         vbg
----------+-------------+---------------------+------------------------+---------------------
 21:21:21 | 21:21:21-08 | 2010-12-12 00:00:00 | 2013-12-11 16:00:00+08 | 2003-04-12 04:05:00

## Date Input

Date and time input is accepted in almost any reasonable formats, including ISO 8601, SQL-compatible, and traditional POSTGRES. The system allows you to customize the sequence of day, month, and year in the date input. Set the **DateStyle** parameter to **MDY** to select month-day-year interpretation, **DMY** to select day-month-year interpretation, or **YMD** to select year-month-day interpretation.

Remember that any date or time literal input needs to be enclosed with single quotation marks ('), and the syntax is as follows:

type [ ( p ) ] 'value'

The **p** that can be selected in the precision statement is an integer, indicating the number of fractional digits in the **seconds** column. Table 12-12 shows some possible inputs for the **date** type.

**Table 12-12** Date input

| Example | Description |
| --- | --- |
| 1999-01-08 | ISO 8601 (recommended format). January 8, 1999 in any mode |
| January 8, 1999 | Unambiguous in any **datestyle** input mode |
| 1/8/1999 | January 8 in **MDY** mode. August 1 in **DMY** mode |
| 1/18/1999 | January 18 in **MDY** mode, rejected in other modes |
| 01/02/03 | • January 2, 2003 in **MDY** mode<br>• February 1, 2003 in **DMY** mode<br>• February 3, 2001 in **YMD** mode |
| 1999-Jan-08 | January 8 in any mode |
| Jan-08-1999 | January 8 in any mode |
| 08-Jan-1999 | January 8 in any mode |
| 99-Jan-08 | January 8 in **YMD** mode, else error |
| 08-Jan-99 | January 8, except error in **YMD** mode |
| Jan-08-99 | January 8, except error in **YMD** mode |
| 19990108 | ISO 8601. January 8, 1999 in any mode |
| 990108 | ISO 8601. January 8, 1999 in any mode |
| 1999.008 | Year and day of year |
| J2451187 | Julian date |
| January 8, 99 BC | Year 99 BC |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
-- Create a table.
openGauss=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
openGauss=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.
openGauss=# SELECT * FROM date_type_tab;
        coll
---------------------
 2010-12-10
(1 row)

-- View the date format.
openGauss=# SHOW datestyle;
 DateStyle
-----------
 ISO, MDY
(1 row)

-- Set the date format.
openGauss=# SET datestyle='YMD';
SET

-- Insert data.
openGauss=# INSERT INTO date_type_tab VALUES(date '2010-12-11');

-- View data.
openGauss=# SELECT * FROM date_type_tab;
        coll
---------------------
 2010-12-10
 2010-12-11
(2 rows)

-- Drop the table.
openGauss=# DROP TABLE date_type_tab;
```

## Time

The time-of-day types are **TIME [(p)] [WITHOUT TIME ZONE]** and **TIME [(p)] [WITH TIME ZONE]**. **TIME** alone is equivalent to **TIME WITHOUT TIME ZONE**.

If a time zone is specified in the input for **TIME WITHOUT TIME ZONE**, it is silently ignored.

For details about the time input types, see **Table 12-13**. For details about time zone input types, see **Table 12-14**.

**Table 12-13** Time input types

| Example | Description |
| --- | --- |
| 05:06.8 | ISO 8601 |
| 4:05:06 | ISO 8601 |
| 4:05 | ISO 8601 |
| 40506 | ISO 8601 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Example | Description |
| --- | --- |
| 4:05 AM | Same as 04:05. AM does not affect value. |
| 4:05 PM | Same as 16:05. Input hours must be less than or equal to 12. |
| 04:05:06.789-8 | ISO 8601 |
| 04:05:06-08:00 | ISO 8601 |
| 04:05-08:00 | ISO 8601 |
| 040506-08 | ISO 8601 |
| 04:05:06 PST | Time zone specified by abbreviation |
| 2003-04-12 04:05:06 America/New_York | Time zone specified by full name |

**Table 12-14** Time zone input types

| Example | Description |
| --- | --- |
| PST | Abbreviation (for Pacific Standard Time) |
| America/New_York | Full time zone name |
| -8:00 | ISO-8601 offset for PST |
| -800 | ISO-8601 offset for PST |
| -8 | ISO-8601 offset for PST |

Example:

```
openGauss=# SELECT time '04:05:06';
   time
----------
 04:05:06
(1 row)

openGauss=# SELECT time '04:05:06 PST';
   time
----------
 04:05:06
(1 row)

openGauss=# SELECT time with time zone '04:05:06 PST';
   timetz
-------------
 04:05:06-08
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Special Values

The special values supported by GaussDB are converted to common date/time values when being read. For details, see **Table 12-15**.

**Table 12-15** Special values

| Input String | Applicable Type | Description |
| --- | --- | --- |
| epoch | date and timestamp | 1970-01-01 00:00:00+00 (Unix system time zero) |
| infinity | timestamp | Later than any other timestamps |
| -infinity | timestamp | Earlier than any other timestamps |
| now | date, time, and timestamp | Start time of the current transaction |
| today | date and timestamp | Midnight today |
| tomorrow | date and timestamp | Midnight tomorrow |
| yesterday | date and timestamp | Midnight yesterday |
| allballs | time | 00:00:00.00 UTC |

## Interval Input

The input of **reltime** can be any valid interval in text format. It can be a number (negative numbers and decimals are also allowed) or a specific time, which must be in SQL standard format, ISO-8601 format, or POSTGRES format. In addition, the text input needs to be enclosed with single quotation marks ('').

For details, see **Table 6 Interval input types**.

**Table 12-16** Interval input types

| Input | Output | Description |
| --- | --- | --- |
| 60 | 2 mons | Numbers are used to indicate intervals. The default unit is day. Decimals and negative numbers are allowed. Particularly, a negative interval syntactically means how long before. |
| 31.25 | 1 mons 1 days 06:00:00 | |
| -365 | -12 mons -5 days | |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Input | Output | Description |
| --- | --- | --- |
| 1 years 1 mons 8 days 12:00:00 | 1 years 1 mons 8 days 12:00:00 | Intervals are in POSTGRES format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input. |
| -13 months -10 hours | -1 years -25 days -04:00:00 | |
| -2 YEARS +5 MONTHS 10 DAYS | -1 years -6 mons -25 days -06:00:00 | |
| P-1.1Y10M | -3 mons -5 days -06:00:00 | Intervals are in ISO-8601 format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input. |
| -12H | -12:00:00 | |

Example:

```
-- Create a table.
openGauss=# CREATE TABLE reltime_type_tab(col1 character(30), col2 reltime);

-- Insert data.
openGauss=# INSERT INTO reltime_type_tab VALUES ('90', '90');
openGauss=# INSERT INTO reltime_type_tab VALUES ('-366', '-366');
openGauss=# INSERT INTO reltime_type_tab VALUES ('1975.25', '1975.25');
openGauss=# INSERT INTO reltime_type_tab VALUES ('-2 YEARS +5 MONTHS 10 DAYS', '-2 YEARS +5
MONTHS 10 DAYS');
openGauss=# INSERT INTO reltime_type_tab VALUES ('30 DAYS 12:00:00', '30 DAYS 12:00:00');
openGauss=# INSERT INTO reltime_type_tab VALUES ('P-1.1Y10M', 'P-1.1Y10M');

-- View data.
openGauss=# SELECT * FROM reltime_type_tab;
              col1              |                col2
--------------------------------+-------------------------------------
 1975.25                        | 5 years 4 mons 29 days
 -2 YEARS +5 MONTHS 10 DAYS     | -1 years -6 mons -25 days -06:00:00
 P-1.1Y10M                      | -3 mons -5 days -06:00:00
 -366                           | -1 years -18:00:00
 90                             | 3 mons
 30 DAYS 12:00:00               | 1 mon 12:00:00
(6 rows)

-- Drop the table.
openGauss=# DROP TABLE reltime_type_tab;
```

## 12.3.7 Geometric Types

**Table 12-17** lists the geometric types that can be used in GaussDB. The most fundamental type, the point, forms the basis for all of the other types.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-17** Geometric types

| Name | Storage Space | Description | Representation |
| --- | --- | --- | --- |
| point | 16 bytes | Point on a plane | (x,y) |
| lseg | 32 bytes | Finite line segment | ((x1,y1),(x2,y2)) |
| box | 32 bytes | Rectangle | ((x1,y1),(x2,y2)) |
| path | 16 + 16*n* bytes | Closed path (similar to polygon) | ((x1,y1),...) |
| path | 16 + 16*n* bytes | Open path | [(x1,y1),...] |
| polygon | 40 + 16*n* bytes | Polygon (similar to closed paths) | ((x1,y1),...) |
| circle | 24 bytes | Circle | <(x,y),r> (center point and radius) |

A rich set of functions and operators is available in GaussDB to perform various geometric operations, such as scaling, translation, rotation, and determining intersections. For details, see **12.5.10 Geometric Functions and Operators**.

## Points

Points are the fundamental two-dimensional building block for geometric types. Values of the **point** type are specified using either of the following syntax:

```
( x , y )
x , y
```

**x** and **y** are the respective coordinates, as floating-point numbers. The value type of the points is float8.

Points are output using the first syntax.

Example:

```
openGauss=# select point(1.1, 2.2);
   point
-----------
 (1.1,2.2)
(1 row)
```

## Line Segments

Line segments (**lseg**) are represented by pairs of points. Values of the **lseg** type are specified using any of the following syntax:

```
[ ( x1 , y1 ) , ( x2 , y2 ) ]
( ( x1 , y1 ) , ( x2 , y2 ) )
( x1 , y1 ) , ( x2 , y2 )
x1 , y1   ,   x2 , y2
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**(x1,y1)** and **(x2,y2)** are the end points of the line segment. The value type of the points is float8.

Line segments are output using the first syntax.

Example:

```
openGauss=# select lseg(point(1.1, 2.2), point(3.3, 4.4));
        lseg
----------------------
 [(1.1,2.2),(3.3,4.4)]
(1 row)
```

## Rectangles

Rectangles are represented by pairs of points that are opposite corners of a rectangle. Values of the **box** type are specified using any of the following syntax:

```
( ( x1 , y1 ) , ( x2 , y2 ) )
( x1 , y1 ) , ( x2 , y2 )
x1 , y1   ,   x2 , y2
```

**(x1,y1)** and **(x2,y2)** are any two opposite corners of the rectangle. The value type of the points is float8.

Rectangles are output using the second syntax.

Any two opposite corners can be supplied on input, but in this order, the values will be reordered as needed to store the upper right and lower left corners.

Example:

```
openGauss=# select box(point(1.1, 2.2), point(3.3, 4.4));
         box
----------------------
 (3.3,4.4),(1.1,2.2)
(1 row)
```

## Paths

Paths are represented by lists of connected points. Paths can be open, where the first and last points in the list are considered not connected, or closed, where the first and last points are considered connected.

Values of the **path** type are specified using any of the following syntax:

```
[ ( x1 , y1 ) , ... , ( xn , yn ) ]
( ( x1 , y1 ) , ... , ( xn , yn ) )
( x1 , y1 ) , ... , ( xn , yn )
( x1 , y1   , ... ,   xn , yn )
x1 , y1   , ... ,   xn , yn
```

The points are the end points of the line segments comprising the path. The value type of the points is float8. Square brackets ([]) indicate an open path, while parentheses (()) indicate a closed path. When the outermost parentheses are omitted, as in the third through fifth syntax, a closed path is assumed.

Paths are output using the first or second syntax.

Example:

```
openGauss=# select path(polygon '((0,0),(1,1),(2,0))');
        path
---------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 ((0,0),(1,1),(2,0))
(1 row)
```

## Polygons

Polygons are represented by lists of points (the vertexes of the polygon). Polygons are very similar to closed paths, but are stored differently and have their own set of support functions.

Values of the **polygon** type are specified using any of the following syntax:

```
( ( x1 , y1 ) , ... , ( xn , yn ) )
( x1 , y1 ) , ... , ( xn , yn )
( x1 , y1   , ... ,   xn , yn )
x1 , y1   , ... ,   xn , yn
```

The points are the end points of the line segments comprising the polygon. The value type of the points is float8.

Polygons are output using the first syntax.

Example:

```
openGauss=# select polygon(box '((0,0),(1,1))');
          polygon
----------------------------
 ((0,0),(0,1),(1,1),(1,0))
(1 row)
```

## Circles

Circles are represented by a center point and radius. Values of the **circle** type are specified using any of the following syntax:

```
< ( x , y ) , r >
( ( x , y ) , r )
( x , y ) , r
x , y   , r
```

**(x,y)** is the center point and **r** is the radius of the circle. The value type of the points is float8.

Circles are output using the first syntax.

Example:

```
openGauss=# select circle(point(0,0),1);
  circle
----------
 <(0,0),1>
(1 row)
```

# 12.3.8 Network Address Types

GaussDB offers data types to store IPv4 and MAC addresses.

It is better to use these types instead of plain text types to store network addresses, because these types offer input error checking and specialized operators and functions (see **12.5.11 Network Address Functions and Operators**).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-18** Network address types

| Name | Storage Space | Description |
| --- | --- | --- |
| cidr | 7 bytes | IPv4 networks |
| inet | 7 bytes | IPv4 hosts and networks |
| macaddr | 6 bytes | MAC address |

## cidr

The **cidr** type (Classless Inter-Domain Routing) holds an IPv4 network address. The format for specifying networks is **address/y** where **address** is the network represented as an IPv4 address, and **y** is the number of bits in the netmask. If **y** is omitted, it is calculated using assumptions from the older classful network numbering system, except it will be at least large enough to include all of the octets written in the input.

**Table 12-19** cidr type input examples

| cidr Input | cidr Output | abbrev(cidr) |
| --- | --- | --- |
| 192.168.100.128/25 | 192.168.100.128/25 | 192.168.100.128/25 |
| 192.168/24 | 192.168.0.0/24 | 192.168.0/24 |
| 192.168/25 | 192.168.0.0/25 | 192.168.0.0/25 |
| 192.168.1 | 192.168.1.0/24 | 192.168.1/24 |
| 192.168 | 192.168.0.0/24 | 192.168.0/24 |
| 10.1.2 | 10.1.2.0/24 | 10.1.2/24 |
| 10.1 | 10.1.0.0/16 | 10.1/16 |
| 10 | 10.0.0.0/8 | 10/8 |
| 10.1.2.3/32 | 10.1.2.3/32 | 10.1.2.3/32 |

## inet

The **inet** type holds an IPv4 host address, and optionally its subnet, all in one field. The subnet is represented by the number of network address bits present in the host address (the "netmask"). If the netmask is 32 and the address is an IPv4 address, then the value does not indicate a subnet, only a single host.

The input format for this type is **address/y** where **address** is an IPv4 address and **y** is the number of bits in the netmask. If the **/y** portion is omitted, the netmask is 32 for an IPv4 address, and the value represents just a single host. On display, the **/y** portion is suppressed if the netmask specifies a single host.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The essential difference between the **inet** and **cidr** data types is that **inet** accepts values with nonzero bits to the right of the netmask, whereas **cidr** does not.

### macaddr

The **macaddr** type stores MAC addresses, known for example from Ethernet card hardware addresses (although MAC addresses are used for other purposes as well). Input is accepted in the following formats:

```
'08:00:2b:01:02:03'
'08-00-2b-01-02-03'
'08002b:010203'
'08002b-010203'
'0800.2b01.0203'
'08002b010203'
```

These examples would all specify the same address. Upper and lower cases are accepted for the digits a through f. Output is always in the first of the forms shown.

## 12.3.9 Bit String Types

Bit strings are strings of 1's and 0's. They can be used to store bit masks.

GaussDB supports two bit string types: bit(n) and bit varying(n). Here, *n* is a positive integer. The maximum value of *n* is **83886080**, which is equivalent to 10 MB.

The **bit** type data must match the length *n* exactly. It is an error to attempt to store shorter or longer bit strings. The **bit varying** data is of variable length up to the maximum length *n*; longer strings will be rejected. Writing **bit** without a length is equivalent to **bit(1)**, while **bit varying** without a length limit means unlimited length.

**NOTE**

If one explicitly casts a bit-string value to **bit(n)**, it will be truncated or zero-padded on the right to be exactly *n* bits, without raising an error.

Similarly, if one explicitly casts a bit-string value to **bit varying(n)**, it will be truncated on the right if it is more than *n* bits.

When the ADMS platform driver 8.1.3-200 or earlier is used, use **::bit varying** to convert the bit type. Otherwise, an error may occur.

```
-- Create a table.
openGauss=# CREATE TABLE bit_type_t1
(
    BT_COL1 INTEGER,
    BT_COL2 BIT(3),
    BT_COL3 BIT VARYING(5)
) DISTRIBUTE BY REPLICATION;

-- Insert data.
openGauss=# INSERT INTO bit_type_t1 VALUES(1, B'101', B'00');

-- Specify the type length. An error is reported if an inserted string exceeds this length.
openGauss=# INSERT INTO bit_type_t1 VALUES(2, B'10', B'101');
ERROR:  bit string length 2 does not match type bit(3)
CONTEXT:  referenced column: bt_col2

-- Specify the type length. Data is converted if it exceeds this length.
openGauss=# INSERT INTO bit_type_t1 VALUES(2, B'10'::bit(3), B'101');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
-- View data.
openGauss=# SELECT * FROM bit_type_t1;
 bt_col1 | bt_col2 | bt_col3
---------+---------+---------
       1 | 101     | 00
       2 | 100     | 101
(2 rows)

-- Delete the table.
openGauss=# DROP TABLE bit_type_t1;
```

# 12.3.10 Text Search Types

GaussDB offers two data types that are designed to support full text search. The **tsvector** type represents a document in a form optimized for text search. The **tsquery** type similarly represents a text query.

## tsvector

The **tsvector** type represents a retrieval unit, usually a textual column within a row of a database table, or a combination of such columns. A **tsvector** value is a sorted list of distinct lexemes, which are words that have been normalized to merge different variants of the same word. Sorting and deduplication are done automatically during input. The maximum length is 2046 bytes. The **to_tsvector** function is used to parse and normalize a document string.

A **tsvector** value is a sorted list of distinct lexemes, which are words that have been formatted different entries. During segmentation, **tsvector** automatically performs duplicate-elimination to the entries for input in a certain order. Example:

```
openGauss=# SELECT 'a fat cat sat on a mat and ate a fat rat'::tsvector;
                    tsvector
-----------------------------------------------------
 'a' 'and' 'ate' 'cat' 'fat' 'mat' 'on' 'rat' 'sat'
(1 row)
```

It can be seen from the preceding example that **tsvector** segments a string by spaces, and segmented lexemes are sorted based on their length and alphabetical order. To represent lexemes containing whitespace or punctuation, surround them with quotation marks:

```
openGauss=# SELECT $$the lexeme '    ' contains spaces$$::tsvector;
                tsvector
-------------------------------------------
 '    ' 'contains' 'lexeme' 'spaces' 'the'
(1 row)
```

Use double dollar signs ($$) to mark entries containing single quotation marks ('').

```
openGauss=# SELECT $$the lexeme 'Joe''s' contains a quote$$::tsvector;
                   tsvector
-------------------------------------------------
 'Joe''s' 'a' 'contains' 'lexeme' 'quote' 'the'
(1 row)
```

Optionally, integer positions can be attached to lexemes:

```
openGauss=# SELECT 'a:1 fat:2 cat:3 sat:4 on:5 a:6 mat:7 and:8 ate:9 a:10 fat:11 rat:12'::tsvector;
                                tsvector
-------------------------------------------------------------------------------
 'a':1,6,10 'and':8 'ate':9 'cat':3 'fat':2,11 'mat':7 'on':5 'rat':12 'sat':4
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

A position normally indicates the source word's location in the document. Positional information can be used for proximity ranking. Position values range from 1 to 255. The default maximum value is **255**. Duplicate positions for the same lexeme are discarded.

Lexemes that have positions can further be labeled with a weight, which can be **A**, **B**, **C**, or **D**. **D** is the default and hence is not shown on output:

```
openGauss=# SELECT 'a:1A fat:2B,4C cat:5D'::tsvector;
          tsvector
-----------------------------
 'a':1A 'cat':5 'fat':2B,4C
(1 row)
```

Weights are typically used to reflect document structure, for example, by marking title words differently from body words. Text search ranking functions can assign different priorities to the different weight markers.

The following example is the standard usage of the **tsvector** type. Example:

```
openGauss=# SELECT 'The Fat Rats'::tsvector;
      tsvector
--------------------
 'Fat' 'Rats' 'The'
(1 row)
```

For most English-text-searching applications the above words would be considered non-normalized, which should usually be passed through **to_tsvector** to normalize the words appropriately for searching:

```
openGauss=# SELECT to_tsvector('english', 'The Fat Rats');
   to_tsvector
-----------------
 'fat':2 'rat':3
(1 row)
```

## tsquery

The **tsquery** type represents a retrieval condition. A **tsquery** value stores lexemes that are to be searched for, and combines them honoring the **Boolean** operators **& (AND)**, **| (OR)**, and **! (NOT)**. Parentheses can be used to enforce grouping of the operators. The **to_tsquery** and **plainto_tsquery** functions will normalize lexemes before the lexemes are converted to the **tsquery** type. The maximum length supported by the **tsquery** type is not limited.

```
openGauss=# SELECT 'fat & rat'::tsquery;
    tsquery
----------------
 'fat' & 'rat'
(1 row)

openGauss=# SELECT 'fat & (rat | cat)'::tsquery;
          tsquery
-----------------------------
 'fat' & ( 'rat' | 'cat' )
(1 row)

openGauss=# SELECT 'fat & rat & ! cat'::tsquery;
        tsquery
------------------------
 'fat' & 'rat' & !'cat'
(1 row)
```

In the absence of parentheses, **! (NOT)** binds most tightly, and **& (AND)** binds more tightly than **| (OR)**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Lexemes in a **tsquery** can be labeled with one or more weight letters, which restrict them to match only **tsvector** lexemes with matching weights:

```
openGauss=# SELECT 'fat:ab & cat'::tsquery;
     tsquery
------------------
 'fat':AB & 'cat'
(1 row)
```

Also, lexemes in a **tsquery** can be labeled with * to specify prefix matching:

```
openGauss=# SELECT 'super:*'::tsquery;
  tsquery
-----------
 'super':*
(1 row)
```

This query will match any word in a **tsvector** that begins with "super".

Note that prefixes are first processed by text search configurations, which means the following example returns true:

```
openGauss=# SELECT to_tsvector( 'postgraduate' ) @@ to_tsquery( 'postgres:*' ) AS RESULT;
  result
----------
 t
(1 row)
```

This is because **postgres** gets stemmed to **postgr**:

```
openGauss=# SELECT to_tsquery('postgres:*');
 to_tsquery
------------
 'postgr':*
(1 row)
```

It then matches **postgraduate**.

**'Fat:ab & Cats'** is normalized to the **tsquery** type as follows:

```
openGauss=# SELECT to_tsquery('Fat:ab & Cats');
    to_tsquery
------------------
 'fat':AB & 'cat'
(1 row)
```

# 12.3.11 UUID Type

The data type **UUID** stores Universally Unique Identifiers (UUID) as defined by RFC 4122, ISO/IEF 9834-8:2005, and related standards. This identifier is a 128-bit quantity that is generated by an algorithm chosen to make it very unlikely that the same identifier will be generated by anyone else in the known universe using the same algorithm.

Therefore, for distributed systems, these identifiers provide a better uniqueness guarantee than sequence generators, which are only unique within a single database.

A UUID is written as a sequence of lower-case hexadecimal digits, in several groups separated by hyphens, specifically a group of 8 digits followed by three groups of 4 digits followed by a group of 12 digits, for a total of 32 digits representing the 128 bits. An example of a UUID in this standard form is:

```
a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

GaussDB also accepts the following alternative forms for input: use of upper-case letters and digits, the standard format surrounded by braces, omitting some or all hyphens, adding a hyphen after any group of four digits. An example is provided as follows:

```
A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11
{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}
a0eebc999c0b4ef8bb6d6bb9bd380a11
a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11
```

Output is always in the standard form.

# 12.3.12 JSON/JSONB Types

JavaScript Object Notation (JSON) data can be a single scalar, an array, or a key-value pair object. The array and object can be called a container:

- Scalar: a number, Boolean, string, or null
- Array: defined in a pair of square brackets ([]), in which elements can be any type of JSON data, and are not necessarily of the same type.
- Object: defined in a pair of braces ({}), in which objects are stored in the format of key:value. Each key must be a string enclosed by a pair of double quotation marks (""), and its value can be any type of JSON data. In case of duplicate keys, the last key-value pair will be used.

GaussDB offers two types for storing JSON data: JSON and JSONB. The JSON data type stores a complete copy of the input, retaining the entered spaces, duplicate keys, and sequence, while the JSONB data type stores data in a decomposed binary form, removing semantic-irrelevant details and duplicate keys, and sorting key-values. Therefore, the JSONB data does not need to be parsed.

It can be found that both are of JSON type, and the same strings can be entered as input. The main difference between them is the efficiency. Because JSON data type stores an exact copy of the input text, the data must be parsed on every execution. In contrast, JSONB data is stored in a decomposed binary form and can be processed faster, though this makes it slightly slower to input due to the conversion mechanism. In addition, because the JSONB data type is normalized, it supports more operations, for example, comparing sizes according to a specific rule. JSONB also supports indexing, which is a significant advantage.

## Input Format

An input must be a JSON-compliant string, which is enclosed in single quotation marks ('').

null (null-json): The value can only be **null** in lowercase.

```
select 'null'::json;   -- suc
select 'NULL'::jsonb;  -- err
```

Number (num-json): The value can be a positive or negative integer, decimal fraction, or 0. The scientific notation is supported.

```
select '1'::json;select '-1.5'::json;select '-1.5e-5'::jsonb, '-1.5e+2'::jsonb;select '001'::json, '+15'::json, 'NaN'::json;
-- Redundant leading zeros, plus signs (+), NaN, and infinity are not supported.
```

Boolean (bool-json): The value can only be **true** or **false** in lowercase.

```
select 'true'::json;select 'false'::jsonb;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

String (str-json): The value must be a string enclosed in double quotation marks ("").

```
select '"a"'::json;select '"abc"'::jsonb;
```

Array (array-json): Arrays are enclosed in square brackets ([]). Elements in the array can be any valid JSON data, and are unnecessarily of the same type.

```
select '[1, 2, "foo", null]'::json;select '[]'::json;select '[1, 2, "foo", null, [[]], {}]'::jsonb;
```

Object (object-json): The value is enclosed in braces ({}). The key must be a JSON-compliant string, and the value can be any valid JSON string.

```
select '{}'::json;select '{"a": 1, "b": {"a": 2,  "b": null}}'::json;select '{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}'::jsonb;
```

**CAUTION**

- Note that **'null'::json** and **null::json** are different, which are similar to the strings **str=""** and **str=null**.
- For numbers, when scientific notation is used, JSONB expands them, while JSON stores an exact copy of the input text.

## JSONB Advanced Features

- Precautions
  - Row-store tables are not supported.
  - It cannot be used as a partition key.
  - Foreign tables and MOTs are not supported.

The main difference between JSON and JSONB lies in the storage mode. JSONB stores parsed binary data, which reflects the JSON hierarchy and facilitates direct access. Therefore, JSONB has many advanced features that JSON does not have.

- Format normalization
  - After the input object-json string is parsed into JSONB binary, semantically irrelevant details are naturally discarded, for example, spaces:

    ```
    openGauss=# select '   [1, " a ", {"a"   :1    }]  '::jsonb;
          jsonb
    ----------------------
     [1, " a ", {"a": 1}]
    (1 row)
    ```

  - For object-json, duplicate key-values are deleted and only the last key-value is retained. For example:

    ```
    openGauss=# select '{"a" : 1, "a" : 2}'::jsonb;
      jsonb
    ----------
     {"a": 2}
    (1 row)
    ```

  - For object-json, key-values will be re-sorted. The sorting rule is as follows: 1. Longer key-values are sorted last. 2. If the key-values are of the same length, the key-values with a larger ASCII code are sorted after the key-values with a smaller ASCII code:

    ```
    openGauss=# select '{"aa" : 1, "b" : 2, "a" : 3}'::jsonb;
              jsonb
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
----------------------------
{"a": 3, "b": 2, "aa": 1}
(1 row)
```

- Size comparison

  Format normalization ensures that only one form of JSONB data exists in the same semantics. Therefore, sizes may be compared according to a specific rule.

  - First, type comparison: **object-jsonb** > **array-jsonb** > **bool-jsonb** > **num-jsonb** > **str-jsonb** > **null-jsonb**
  - Content comparison if the data type is the same:
    - **str-json**: The default text sorting rule of the database is used for comparison. A positive value indicates greater than, a negative value indicates less than, and **0** indicates equal.
    - **num-json**: numeric comparison
    - **bool-json**: **true** > **false**
    - **array-jsonb**: long elements > short elements. If the lengths are the same, compare each element in sequence.
    - **object-jsonb**: If the length of a key-value pair is longer than that of a short key-value pair, the key is compared first, and then the value is compared.

  **CAUTION**

  For comparison within the **object-jsonb** type, the final result after format sorting is used for comparison. Therefore, the comparison result may not be intuitive compared with the direct input.

- Creating indexes, primary keys, and foreign keys
  - B-tree index

    B-tree indexes, primary keys, and foreign keys can be created for the **JSONB** type.
  - GIN index

    GIN indexes can be used to effectively search for keys or key-value pairs that appear in a large number of JSONB documents (datums). Two GIN operator classes (**jsonb_ops** and **jsonb_hash_ops**) are provided for different performance and flexibility choices. The default GIN operator class supports **@>**, **<@**, **?**, **?&** and **?|** operator query. The non-default GIN operator class **jsonb_path_ops** supports only the **@>** and **<@** operators.

    For details about the operators, see **12.5.13 JSON/JSONB Functions and Operators**.
- Inclusion and existence

  Querying whether a JSON contains some elements or whether some elements exist in a JSON is an important capability of JSONB.

  ```
  -- A simple scalar/original value contains only the same value: SELECT '"foo"'::jsonb @> '"foo"'::jsonb; -- The array on the left contains the string on the right. SELECT' [ 1, "aa", 3 ] '::jsonb?
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**'aa';** -- The array on the left contains all elements in the array on the right. The sequence and repetition are not specified. **SELECT '[1, 2, 3]'::jsonb @> '[1, 3, 1]'::jsonb;** -- The **object-json** on the left contains all key-values of the **object-json** on the right. **SELECT '{"product": "PostgreSQL", "version": 9.4, "jsonb":true}'::jsonb @> '{"version":9.4}'::jsonb;** -- The array on the left does not contain all elements of the array on the right, because the three elements of the array on the left are **1**, **2**, and **[1,3]**, and the elements on the right are **1** and **3**. **SELECT'[1, 2, [1, 3] ]. '::jsonb @>' [1, 3] '::jsonb;** -- Produces a **false**. **SELECT '{"foo": {"bar": "baz"}}'::jsonb @> '{"bar": "baz"}'::jsonb;** -- Similarly, **false** is produced.

For details about the operators, see **12.5.13 JSON/JSONB Functions and Operators**.

- Functions and operators

  For details about the functions and operators supported by the JSON/JSONB type, see **12.5.13 JSON/JSONB Functions and Operators**.

## 12.3.13 HLL

HyperLoglog (HLL) is an approximation algorithm for efficiently counting the number of distinct values in a dataset. It features faster computing and lower space usage. You only need to store HLL data structures, instead of data sets. When new data is added to a dataset, make hash calculation on the data and insert the result to an HLL. Then, you can obtain the final result based on the HLL.

**Table 12-20** compares HLL with other algorithms.

**Table 12-20** Comparison between HLL and other algorithms

| Item | Sorting Algorithm | Hash Algorithm | HLL |
| --- | --- | --- | --- |
| Time complexity | O(nlogn) | O(n) | O(n) |
| Space complexity | O(n) | O(n) | log(logn) |
| Error rate | 0 | 0 | ≈0.8% |
| Storage space requirement | Size of original data | Size of original data | The maximum size is 16 KB by default. |

HLL has advantages over others in the computing speed and storage space requirement. In terms of time complexity, the sorting algorithm needs O(nlogn) time for sorting, and the hash algorithm and HLL need O(n) time for full table scanning. In terms of storage space, the sorting algorithm and hash algorithm need to store raw data before collecting statistics, whereas the HLL algorithm needs to store only the HLL data structures rather than the raw data, and thereby occupies a fixed space of about 16 KB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**NOTICE**

- In the current default specifications, the maximum number of distinct values that can be calculated is about 1.1e + 15, and the error rate is 0.8%. If the calculation result exceeds the maximum, the error rate of the calculation result will increase, or the calculation will fail and an error will be reported.
- When using this feature for the first time, you need to evaluate the distinct values of the service, properly select configuration parameters, and perform verification to ensure that the accuracy meets requirements.
  - By default, the distinct value is 1.1e + 15. If the distinct value is NaN, you need to adjust log2m or use another algorithm to calculate the distinct value.
  - The hash algorithm has an extremely low probability of collision. However, you are still advised to select 2 or 3 hash seeds for verification when using the hash algorithm for the first time. If there is only a small difference between the distinct values, you can select any one of the seeds as the hash seed.

**Table 12-21** describes main HLL data structures.

**Table 12-21** Main HLL data structures

| Data Type | Description |
| --- | --- |
| hll | The HLL header is a 27-byte field. By default, the data length ranges from 0 KB to 16 KB. The distinct value can be obtained. |

When you create an HLL data type, 0 to 4 input parameters are supported. The parameter meanings and specifications are the same as those of the **hll_empty** function. The first parameter is **log2m**, indicating the logarithm of the number of buckets, and its value ranges from 10 to 16. The second parameter is **log2explicit**, indicating the threshold in explicit mode, and its value ranges from 0 to 12. The third parameter is **log2sparse**, indicating the threshold of the Sparse mode, and its value ranges from 0 to 14. The fourth parameter is **duplicatecheck**, indicating whether to enable duplicatecheck, and its value ranges from 0 to 1. When the input parameter is set to **–1**, the default value of the HLL parameter is used. You can run the **\d** or **\d+** command to view the parameters of the HLL type.

**NOTE**

When the HLL data type is created, the result varies depending on the input parameter behavior:

- When creating an HLL type, do not set the input parameter or set it to **–1**. Use the default value of the corresponding HLL parameter.
- If a valid value is set for the input parameter, the corresponding HLL parameter uses the input value.
- If the input value is invalid, an error is reported when the HLL type is created.

```
-- Create an HLL table without specifying input parameters.
openGauss=# create table t1 (id integer, set hll);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# \d t1
      Table "public.t1"
 Column |  Type   | Modifiers
--------+---------+-----------
 id     | integer |
 set    | hll     |

-- Create an HLL table, specify the first two input parameters, and use the default values for the last two
input parameters.
openGauss=# create table t2 (id integer, set hll(12,4));
openGauss=# \d t2
          Table "public.t2"
 Column |      Type      | Modifiers
--------+----------------+-----------
 id     | integer        |
 set    | hll(12,4,12,0) |

-- Create an HLL table, specify the third input parameter, and use default values for other parameters.
openGauss=# create table t3(id int, set hll(-1,-1,8,-1));
openGauss=# \d t3
          Table "public.t3"
 Column |      Type      | Modifiers
--------+----------------+-----------
 id     | integer        |
 set    | hll(14,10,8,0) |

-- When a user creates an HLL table and specifies an invalid input parameter, an error is reported.
openGauss=# create table t4(id int, set hll(5,-1));
ERROR:  log2m = 5 is out of range, it should be in range 10 to 16, or set -1 as default
```

**NOTE**

When inserting an HLL object to an HLL table, ensure that the parameters of the HLL type are the same as those of the inserted object. Otherwise, an error is reported.

```
-- Create an HLL table:
openGauss=# create table t1(id integer, set hll(14));

-- Insert an HLL object to a table. The insertion succeeds because parameter types are consistent.
openGauss=# insert into t1 values (1, hll_empty(14,-1));

-- Insert an HLL object to a table. The insertion fails because parameter types are inconsistent.
openGauss=# insert into t1(id, set) values (1, hll_empty(14,5));
ERROR:  log2explicit does not match: source is 5 and dest is 10
```

The following describes HLL application scenarios.

- Scenario 1: "Hello World"

  The following example shows how to use the HLL data type:

  ```
  -- Create a table with the HLL type:
  openGauss=# create table helloworld (id integer, set hll);

  -- Insert an empty HLL to the table:
  openGauss=# insert into helloworld(id, set) values (1, hll_empty());

  -- Add a hashed integer to the HLL:
  openGauss=# update helloworld set set = hll_add(set, hll_hash_integer(12345)) where id = 1;

  -- Add a hashed string to the HLL:
  openGauss=# update helloworld set set = hll_add(set, hll_hash_text('hello world')) where id = 1;

  -- Obtain the number of distinct values of the HLL:
  openGauss=# select hll_cardinality(set) from helloworld where id = 1;
   hll_cardinality
  -----------------
                 2
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
-- Delete the table.
openGauss=# drop table helloworld;
```

- Scenario 2: Collect statistics about website visitors.

  The following example shows how an HLL collects statistics on the number of users visiting a website within a period of time:

```
-- Create a raw data table to show that a user has visited the website at a certain time:
openGauss=# create table facts (
        date            date,
        user_id         integer
);

 -- Create a raw data table to show that a user has visited the website at a certain time:
openGauss=# insert into facts values ('2019-02-20', generate_series(1,100));
openGauss=# insert into facts values ('2019-02-21', generate_series(1,200));
openGauss=# insert into facts values ('2019-02-22', generate_series(1,300));
openGauss=# insert into facts values ('2019-02-23', generate_series(1,400));
openGauss=# insert into facts values ('2019-02-24', generate_series(1,500));
openGauss=# insert into facts values ('2019-02-25', generate_series(1,600));
openGauss=# insert into facts values ('2019-02-26', generate_series(1,700));
openGauss=# insert into facts values ('2019-02-27', generate_series(1,800));

-- Create another table and specify an HLL column:
openGauss=# create table daily_uniques (
    date            date UNIQUE,
    users           hll
);

-- Group data by date and insert the data into the HLL:
openGauss=# insert into daily_uniques(date, users)
    select date, hll_add_agg(hll_hash_integer(user_id))
    from facts
    group by 1;

-- Calculate the numbers of users visiting the website every day:
openGauss=# select date, hll_cardinality(users) from daily_uniques order by date;
    date    | hll_cardinality
------------+------------------
 2019-02-20 |              100
 2019-02-21 | 200.217913059312
 2019-02-22 |  301.76494508014
 2019-02-23 | 400.862858326446
 2019-02-24 | 502.626933349694
 2019-02-25 | 601.922606454213
 2019-02-26 | 696.602316769498
 2019-02-27 | 798.111731634412
(8 rows)

-- Calculate the number of users who had visited the website in the week from February 20, 2019 to
February 26, 2019:
openGauss=# select hll_cardinality(hll_union_agg(users)) from daily_uniques where date >=
'2019-02-20'::date and date <= '2019-02-26'::date;
 hll_cardinality
------------------
 696.602316769498
(1 row)

-- Calculate the number of users who had visited the website yesterday but have not visited the
website today:
openGauss=# SELECT date, (#hll_union_agg(users) OVER two_days) - #users AS lost_uniques FROM
daily_uniques WINDOW two_days AS (ORDER BY date ASC ROWS 1
PRECEDING);
    date    | lost_uniques
------------+--------------
 2019-02-20 |            0
 2019-02-21 |            0
 2019-02-22 |            0
 2019-02-23 |            0
 2019-02-24 |            0
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 2019-02-25 |          0
 2019-02-26 |          0
 2019-02-27 |          0
(8 rows)

-- Delete the table.
openGauss=# drop table facts;
openGauss=# drop table daily_uniques;
```

- Scenario 3: The data to be inserted does not meet the requirements of the HLL data structure.

  When inserting data into a column of the HLL type, ensure that the data meets the requirements of the HLL data structure. If the data does not meet the requirements after being parsed, an error will be reported. In the following example, **E\\1234** to be inserted does not meet the requirements of the HLL data structure after being parsed. As a result, an error is reported.

```
openGauss=# create table test(id integer, set hll);
openGauss=# insert into test values(1, 'E\\1234');
ERROR:  not a hll type, size=6 is not enough
openGauss=# drop table test;
```

# 12.3.14 Range

A range type is a data type that represents the range of a value of an element type (called the *subtype* of a range). For example, the range of timestamp may be used to express a time range in which a conference room is reserved. In this case, the data type is tsrange (short for timestamp range), and timestamp is the subtype. The subtype must have an overall order so that the element value can be clearly specified within a range, before, or after.

Range types are useful because they can express multiple element values in a single range value and can clearly express concepts such as range overlapping. The time and date range used for scheduling is the best example, as the range of an instrument are also examples of range type.

## Built-in Range

The following built-in ranges are available:

- int4range: integer range.
- int8range: bigint range.
- numrange: numeric range.
- tsrange: range of timestamp without the time zone.
- tstzrange: range of timestamp with the time zone
- daterange: date range.

In addition, you can define your own range types. For details, see **12.14.87 CREATE TYPE**.

## Example

```
CREATE TABLE reservation (room int, during tsrange);
INSERT INTO reservation VALUES (1108, '[2010-01-01 14:30, 2010-01-01 15:30)');
-- Inclusion
SELECT int4range(10, 20) @> 3;
-- Determine whether the two ranges overlap.
SELECT numrange(11.1, 22.2) && numrange(20.0, 30.0);
-- Upper bound extraction
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
SELECT upper(int8range(15, 25));
-- Intersection set
SELECT int4range(10, 20) * int4range(15, 25);
-- Determine whether the range is empty.
SELECT isempty(numrange(1, 5));
```

See the complete list of operators and functions on a range type in **12.5.17 Range Functions and Operators**.

## Including and Excluding Bounds

Each non-empty range has two bounds, a lower bound and an upper bound. All values between the two bounds are included in the range. An inclusion bound means that the bound value itself is included in the range, while an exclusion bound means that the bound value is not included in the range.

In a textual form of a range, an inclusion lower bound is expressed as "[" and an exclusion lower bound is expressed as "(". Similarly, one including the upper bound is expressed as "]" and one excluding the upper bound is expressed as ")" (for details, see **Range Input/Output**).

The lower_inc and upper_inc functions test the upper and lower bounds of a range value, respectively.

## Infinite (Unbounded) Range

When the lower bound of a range is unbounded, it means that all values less than the upper bound are included in the range, for example, (,3] meaning all values less than the upper bound 3 are included in the range. Similarly, when the upper bound of a range is unbounded, all values greater than the upper bound are included in the range. When both the upper and lower bounds are unbounded, all values of the element type are considered within the range. The missing bounds are automatically converted to exclusions, for example, [,] is converted to (,). You can think of these missing values as positive infinity or negative infinity, but they are special range type values and are considered to be positive and negative infinity values that go beyond any range element type.

Element types with the infinity values can be used as explicit bound values. For example, in the timestamp range, [today, infinity) does not include a special timestamp value infinity.

The lower_inf and upper_inf functions test the infinite upper and lower bounds of a range, respectively.

## Range Input/Output

The input of a range value must follow one of the following formats:

```
(lower-bound, upper-bound)
(lower-bound, upper-bound]
[lower-bound, upper-bound)
[lower-bound, upper-bound]
Empty
```

Parentheses () or square brackets [] indicate whether the upper and lower bounds are excluded or included. Note that the last format is empty, which represents an empty range (a range that does not contain values).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The value of *lower-bound* can be a valid input string of the subtype or null, indicating that there is no lower bound. Similarly, *upper-bound* can be a valid input string of the subtype or null, indicating that there is no upper bound.

Each bound value can be referenced using the quotation marks("") character. This is necessary if the bounds value contains parentheses (), square brackets [], commas (,), quotation marks (""), or backslashes (\), because otherwise those characters will be considered part of the range syntax. To put the quotation mark or backslash in a referenced bound value, put a backslash in front of it (and a pair of double quotation marks in its quoted bound value represents one quotation mark character, which is similar to the single quotation mark rule in SQL character strings). In addition, you can avoid referencing and use backslash escapes to protect all data characters, otherwise they will be used as part of the return syntax. Also, if you want to write a bound value that is an empty string, write **""**, indicating infinite bounds.

Spaces are allowed before and after a range value, but any space between parentheses() or square brackets[] is used as part of the upper or lower bound value (depending on the element type, the space may or may not represent a value).

Example:

```
-- 3 is included, 7 is not included, and all values between 3 and 7 are included.
SELECT '[3,7)'::int4range;
-- Neither 3 nor 7 is included, but all values between them are included.
SELECT '(3,7)'::int4range;
-- Only value 4 is included.
SELECT '[4,4]'::int4range;
-- Exclude any value (and will be normalized to empty).
SELECT '[4,4)'::int4range;
```

## Constructing Range

Each range type has a constructor function with the same name. Using constructor functions is often more convenient than writing a range literal constant because it avoids extra references to bound values. Constructor functions accept two or three parameters. Two parameters form a range in the standard form, where the lower bound is included and the upper bound is excluded, and three parameters form a range according to the bound specified by the third parameter. The third parameter must be one of the following character strings: (), (], [), or []. For example:

```
-- The complete format is: lower bound, upper bound, and textual parameters indicating the inclusion/
exclusion of bounds.
SELECT numrange(1.0, 14.0, '(]');
-- If the third parameter is ignored, it is assumed to be '[)'.
SELECT numrange(1.0, 14.0);
-- Although '(]' is specified here, the value will be converted to the standard format when displayed,
because int8range is a discrete range type (see below).
SELECT int8range(1, 14, '(]');
-- Using NULL for a bound causes the range to be unbounded on that side.
SELECT numrange(NULL, 2.2);
```

## Discrete Range

A range element type has a well-defined "step" such as integer or date. In these types, if there is no valid value between two elements, they can be said to be adjacent. This is in contrast to a continuous range in which other element values

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

can always be identified between two given values. For example, the numeric type range is continuous, and the timestamp range is also continuous. (Although timestamp has limited precision and can be considered as discrete in theory, it is better to consider it as continuous because the step is not normally considered.)

Another way to consider discrete range types is to have a clear "next" or "previous" value for each element value. With this idea in mind, you can switch between inclusion and exclusion expressions of a range bound by replacing it with the original given next or previous element value. For example, in an integer range type, [4,8] and (3,9) represent the same set of values, but not for numeric ranges.

A discrete range type should have a *regularization* function that knows the expected step size of the element type. The regularization function can convert the equivalents of the range type to the same expression, in particular consistent with the inclusion or exclusion bounds. If you do not specify a regularization function, ranges with different formats will always be considered as unequal, even if they actually express the same set of values.

The built-in range types int4range, int8range, and daterange use a regularized form that includes the lower bound and excludes the upper bound, that is, [). However, user-defined range types can use other conventions.

### Index

GiST and SP-GiST indexes can be created for table columns of the range type. For example, to create a GiST index, run the following command:

```
CREATE INDEX reservation_idx ON reservation USING GIST (during);
```

A GiST or SP-GiST index can accelerate queries involving the following range operators: =, &&, <@, @>, <<, >>, -|-, &<, and &> (see **12.5.17 Range Functions and Operators**).

In addition, the B-tree and hash index can be created on table columns of the range type. For these index types, basically the only useful range operation is equivalence. Using the corresponding < and > operators, there is a B-tree sort oder for range value definitions, but that order is fairly arbitrary and is often less useful in the reality. The B-tree and hash support for range types is primarily designed to allow sorting and hashing within a query, rather than creating an index.

## 12.3.15 Object Identifier Types

Object identifiers (OIDs) are used internally by GaussDB as primary keys for various system catalogs. OIDs are not added to user-created tables by the system. The **OID** type represents an object identifier.

The **OID** type is currently implemented as an unsigned four-byte integer. So, using a user-created table's **OID** column as a primary key is discouraged.

**Table 12-22** Object identifier types

| Name | Reference | Description | Example |
| --- | --- | --- | --- |
| OID | N/A | Numeric object identifier | 564182 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Reference | Description | Example |
| --- | --- | --- | --- |
| CID | N/A | Command identifier. This is the data type of the system columns **cmin** and **cmax**. Command identifiers are 32-bit quantities. | N/A |
| XID | N/A | A transaction identifier. This is the data type of the system columns **xmin** and **xmax**. Transaction identifiers are also 64-bit quantities. | N/A |
| TID | N/A | Row identifier. This is the data type of the system column **ctid**. A row ID is a pair (block number, tuple index within block) that identifies the physical location of the row within its table. | N/A |
| REGCONFIG | pg_ts_config | Text search configuration | english |
| REGDICTIONARY | pg_ts_dict | Text search dictionary | simple |
| REGOPER | pg_operator | Operator name | N/A |
| REGOPERATOR | pg_operator | Operator with argument types | *(integer,integer) or -(NONE,integer) |
| REGPROC | pg_proc | Function name | sum |
| REGPROCEDURE | pg_proc | Function with argument types | sum(int4) |
| REGCLASS | pg_class | Relation name | pg_type |
| REGTYPE | pg_type | Data type name | integer |

The **OID** type is used for a column in the database system catalog.

Example:

```
openGauss=# SELECT oid FROM pg_class WHERE relname = 'pg_type';
 oid
------
 1247
(1 row)
```

The alias type for **OID** is **REGCLASS** which allows simplified search for **OID** values.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# SELECT attrelid,attname,atttypid,attstattarget FROM pg_attribute WHERE attrelid =
'pg_type'::REGCLASS;
 attrelid |  attname   | atttypid | attstattarget
----------+------------+----------+---------------
     1247 | xc_node_id     |       23 |             0
     1247 | tableoid       |       26 |             0
     1247 | cmax           |       29 |             0
     1247 | xmax           |       28 |             0
     1247 | cmin           |       29 |             0
     1247 | xmin           |       28 |             0
     1247 | oid            |       26 |             0
     1247 | ctid           |       27 |             0
     1247 | typname        |       19 |            -1
     1247 | typnamespace   |       26 |            -1
     1247 | typowner       |       26 |            -1
     1247 | typlen         |       21 |            -1
     1247 | typbyval       |       16 |            -1
     1247 | typtype        |       18 |            -1
     1247 | typcategory    |       18 |            -1
     1247 | typispreferred |       16 |            -1
     1247 | typisdefined   |       16 |            -1
     1247 | typdelim       |       18 |            -1
     1247 | typrelid       |       26 |            -1
     1247 | typelem        |       26 |            -1
     1247 | typarray       |       26 |            -1
     1247 | typinput       |       24 |            -1
     1247 | typoutput      |       24 |            -1
     1247 | typreceive     |       24 |            -1
     1247 | typsend        |       24 |            -1
     1247 | typmodin       |       24 |            -1
     1247 | typmodout      |       24 |            -1
     1247 | typanalyze     |       24 |            -1
     1247 | typalign       |       18 |            -1
     1247 | typstorage     |       18 |            -1
     1247 | typnotnull     |       16 |            -1
     1247 | typbasetype    |       26 |            -1

     1247 | typacl         |     1034 |            -1
(38 rows)
```

## 12.3.16 Pseudo-Types

GaussDB type system contains a number of special-purpose entries that are collectively called pseudo-types. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type.

Each of the available pseudo-types is useful in situations where a function's behavior does not correspond to simply taking or returning a value of a specific SQL data type. **Table 12-23** lists all pseudo-types.

**Table 12-23** Pseudo-types

| Name | Description |
| --- | --- |
| any | Indicates that a function accepts any input data type. |
| anyelement | Indicates that a function accepts any data type. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Description |
| --- | --- |
| anyarray | Indicates that a function accepts any array data type. |
| anynonarray | Indicates that a function accepts any non-array data type. |
| anyenum | Indicates that a function accepts any enum data type. |
| anyrange | Indicates that a function accepts any range data type. |
| cstring | Indicates that a function accepts or returns a null-terminated C string. |
| internal | Indicates that a function accepts or returns a server-internal data type. |
| language_handler | Indicates that a procedural language call handler is declared to return **language_handler**. |
| fdw_handler | Indicates that a foreign-data wrapper handler is declared to return **fdw_handler**. |
| record | Identifies a function returning an unspecified row type. |
| trigger | Indicates that a trigger function is declared to return **trigger**. |
| void | Indicates that a function returns no value. |
| opaque | Indicates an obsolete type name that formerly served all the above purposes. |

Functions coded in C (whether built in or dynamically loaded) can be declared to accept or return any of these pseudo data types. It is up to the function author to ensure that the function will behave safely when a pseudo-type is used as an argument type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. At present the procedural languages all forbid use of a pseudo-type as argument type, and allow only **void** and **record** as a result type. Some also support polymorphic functions using the **anyelement**, **anyarray**, **anynonarray**, **anyenum**, and **anyrange** types.

The **internal** pseudo-type is used to declare functions that are meant only to be called internally by the database system, and not by direct invocation in an SQL query. If a function has at least one **internal**-type argument then it cannot be called from SQL. You are advised not to create any function that is declared to return internal unless it has at least one **internal** argument.

Example:

```
-- Create a table.
openGauss=# create table t1 (a int);

-- Insert two data records.
openGauss=# insert into t1 values(1),(2);

-- Create the showall() function.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# CREATE OR REPLACE FUNCTION showall() RETURNS SETOF record
AS $$ SELECT count(*) from t1; $$
LANGUAGE SQL;

-- Invoke the showall() function.
openGauss=# SELECT showall();
 showall
---------
 (2)
(1 row)

-- Delete the function.
openGauss=# DROP FUNCTION showall();

-- Drop the table.
openGauss=# drop table t1;
```

## 12.3.17 Data Types Supported by Column-store Tables

Table 12-24 lists the data types supported by column-store tables.

**Table 12-24** Data types supported by column-store tables

| Category | Data Type | Length | Supported or Not |
| --- | --- | --- | --- |
| Numeric Types | smallint | 2 | Supported |
| | integer | 4 | Supported |
| | bigint | 8 | Supported |
| | decimal | -1 | Supported |
| | numeric | -1 | Supported |
| | real | 4 | Supported |
| | double precision | 8 | Supported |
| | smallserial | 2 | Supported |
| | serial | 4 | Supported |
| | bigserial | 8 | Supported |
| Monetary Types | money | 8 | Supported |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Category | Data Type | Length | Supported or Not |
| --- | --- | --- | --- |
| Character Types | character varying(n), varchar(n) | -1 | Supported |
| | character(n), char(n) | n | Supported |
| | character, char | 1 | Supported |
| | text | -1 | Supported |
| | nvarchar2 | -1 | Supported |
| | name | 64 | Not supported |
| Date/Time Types | timestamp with time zone | 8 | Supported |
| | timestamp without time zone | 8 | Supported |
| | date | 4 | Supported |
| | time without time zone | 8 | Supported |
| | time with time zone | 12 | Supported |
| | interval | 16 | Supported |
| big object | clob | -1 | Supported |
| | blob | -1 | Not supported |
| other types | ... | ... | Not supported |

## 12.3.18 Data Types Used by the Ledger Database

The ledger database uses the hash16 data type to store row-level hash digests or table-level hash digests, and uses the hash32 data type to store global hash

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

digests or history table verification hashes. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)

**Table 12-25** Hash type of the ledger database

| Name | Description | Storage Space | Range |
| --- | --- | --- | --- |
| HASH16 | Stored as an unsigned 64-bit integer | 8 bytes | 0 to +18446744073709551615 |
| HASH32 | Stored as an unsigned integer array of 16 elements | 16 bytes | Value range of an unsigned integer array of 16 elements |

The hash16 data type is used to store row-level or table-level hash digests in the ledger database. After obtaining the hash sequence of a 16-character hexadecimal string, the system invokes the **hash16in** function to convert the sequence into an unsigned 64-bit integer and stores the integer in a hash16 variable. Example:

```
Hexadecimal string: e697da2eaa3a775b; corresponding 64-bit unsigned integer: 16615989244166043483
Hexadecimal string: ffffffffffffffff; corresponding 64-bit unsigned integer: 18446744073709551615
```

The hash32 data type is used to store the global hash digest or history table verification hash in the ledger database. After obtaining the hash sequence of a 32-character hexadecimal string, the system invokes the **hash32in** function to convert the sequence to an unsigned integer array of 16 elements. Example:

```
Hexadecimal string: 685847ed1fe38e18f6b0e2b18c00edee
Corresponding hash32 array: [104,88,71,237,31,227,142,24,246,176,226,177,140,0,237,238]
```

## 12.3.19 ACLItem

The ACLItem data type is used to store object permission information. Its internal implementation is of the int type and supports the '*user1*=*privs*|*user2*' format.

The aclitem[] data type is an array consisting of ACL items. The supported format is {*user1*=*privs1*|*user3*, *user2*=*privs2*|*user3*}.

In the preceding command, *user1*, *user2*, and *user3* indicate the existing users or roles in the database, and *privs* indicates the permissions supported by the database. For details, see **Table 15-43**.

Example:

```
openGauss=# create table table_acl (id int,priv aclitem,privs aclitem[]);
-- Create a data table table_acl that contains three fields of the int, aclitem, and aclitem[] types.
openGauss=# insert into table_acl values (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}');
-- Insert a record whose content is (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}') into the table_acl table.
openGauss=# insert into table_acl values (2,'user1=aw/omm','{omm=d/user2}');
-- Insert a record whose content is (2,'user1=aw/omm','{omm=d/user2}') into the table_acl table.
openGauss=# select * from  table_acl;
 id |     priv      |          privs
----+---------------+-------------------------
  1 | user1=arw/omm | {omm=d/user2,omm=w/omm}
  2 | user1=aw/omm  | {omm=d/user2}
(2 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 12.4 Constant and Macro

Table 12-26 lists the constants and macros that can be used in GaussDB.

**Table 12-26** Constant and macro

| Parameter | Description | Example |
| --- | --- | --- |
| CURRENT_CATALOG | Specifies the current database. | openGauss=# SELECT CURRENT_CATALOG;<br>current_database<br>----------<br>postgres<br>(1 row) |
| CURRENT_ROLE | Specifies the current user. | openGauss=# SELECT CURRENT_ROLE;<br>current_user<br>----------<br>omm<br>(1 row) |
| CURRENT_SCHEMA | Specifies the current database mode. | openGauss=# SELECT CURRENT_SCHEMA;<br>current_schema<br>----------<br>public<br>(1 row) |
| CURRENT_USER | Specifies the current user. | openGauss=# SELECT CURRENT_USER;<br>current_user<br>----------<br>omm<br>(1 row) |
| LOCALTIMESTAMP | Specifies the current session time (without time zone). | openGauss=# SELECT LOCALTIMESTAMP;<br>timestamp<br>----------<br>2015-10-10 15:37:30.968538<br>(1 row) |
| NULL | This parameter is left blank. | N/A |
| SESSION_USER | Specifies the current system user. | openGauss=# SELECT SESSION_USER;<br>session_user<br>----------<br>omm<br>(1 row) |
| SYSDATE | Specifies the current system date. | openGauss=# SELECT SYSDATE;<br>sysdate<br>----------<br>2015-10-10 15:48:53<br>(1 row) |
| USER | Specifies the current user, also called **CURRENT_USER**. | openGauss=# SELECT USER;<br>current_user<br>----------<br>omm<br>(1 row) |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 12.5 Functions and Operators

Operators can be used to process one or more operands and can be placed before, after, or between operands. Results are returned after the processing.

Functions encapsulate service logic to implement specific functions. A function may or may not have parameters. After a function is executed, the result is returned.

Users can modify system functions. However, after the modification, the meaning of the functions may change, which results in disorder in system control. Therefore, users are not allowed to manually modify system functions.

## 12.5.1 Logical Operators

The usual logical operators include AND, OR, and NOT. SQL uses a three-valued logical system with true, false, and null, which represents "unknown". Their priorities are NOT > AND > OR.

Table 12-27 lists the calculation rules, where a and b represent logical expressions.

**Table 12-27** Operation rules

| a | b | a AND b Result | a OR b Result | NOT a Result |
|---|---|---|---|---|
| TRUE | TRUE | TRUE | TRUE | FALSE |
| TRUE | FALSE | FALSE | TRUE | FALSE |
| TRUE | NULL | NULL | TRUE | FALSE |
| FALSE | FALSE | FALSE | FALSE | TRUE |
| FALSE | NULL | FALSE | NULL | TRUE |
| NULL | NULL | NULL | NULL | NULL |

NOTE

The operators AND and OR are commutative, that is, you can switch the left and right operand without affecting the result.

## 12.5.2 Comparison Operators

Comparison operators are available for all data types and return Boolean values.

All comparison operators are binary operators. Only data types that are the same or can be implicitly converted can be compared using comparison operators.

Table 12-28 describes comparison operators provided by GaussDB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-28** Comparison operations

| Operator | Description |
| --- | --- |
| < | Less than |
| > | Greater than |
| <= | Less than or equal to |
| >= | Greater than or equal to |
| = | Equal to |
| <>, !=, or ^= | Not equal to |

Comparison operators are available for all relevant data types. All comparison operators are binary operators that returned values of Boolean type. Expressions like **1 < 2 < 3** are invalid. (Because there is no comparison operator to compare a Boolean value with **3**.)

Besides, each comparison operator has a corresponding function in the **pg_proc** system catalog. If the value of proleakproof attribute of the corresponding function is **f**, the function is not used to prevent data leakage. If a user only has the permission for a system view, but does not have the permission for the corresponding table, the query plan may not be optimal when the user searches the system view.

## 12.5.3 Character Processing Functions and Operators

String functions and operators provided by GaussDB are for concatenating strings with each other, concatenating strings with non-strings, and matching the patterns of strings.

- bit_length(string)

  Description: Specifies the number of bits occupied by a string.

  Return type: int

  Example:

  ```
  openGauss=# SELECT bit_length('world');
   bit_length
  ------------
          40
  (1 row)
  ```

- btrim(string text [, characters text])

  Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start and end of **string**.

  Return type: text

  Example:

  ```
  openGauss=# SELECT btrim('sring' , 'ing');
   btrim
  -------
   sr
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- char_length(string) or character_length(string)

  Description: Specifies the number of characters in a string.

  Return type: int

  Example:

```
openGauss=# SELECT char_length('hello');
 char_length
-------------
           5
(1 row)
```

- instr(text,text,int,int)

  Description: **instr(string1,string2,int1,int2)** returns the text from **int1** to **int2** in **string1**. The first **int** indicates the start position for matching, and the second **int** indicates the number of matching times.

  Return type: int

  Example:

```
openGauss=# SELECT instr( 'abcdabcdabcd', 'bcd', 2, 2 );
 instr
-------
     6
(1 row)
```

- lengthb(text/bpchar)

  Description: Obtains the number of bytes of a specified string.

  Return type: int

  Example:

```
openGauss=# SELECT lengthb('hello');
 lengthb
---------
       5
(1 row)
```

- left(str text, n int)

  Description: Returns the first *n* characters in a string. When *n* is negative, all but the last **|n|** characters are returned.

  Return type: text

  Example:

```
openGauss=# SELECT left('abcde', 2);
 left
------
 ab
(1 row)
```

- length(string bytea, encoding name )

  Description: Specifies the number of characters in **string** in the given **encoding**. The **string** must be valid in this encoding.

  Return type: int

  Example:

```
openGauss=# SELECT length('jose', 'UTF8');
 length
--------
      4
(1 row)
```

> **NOTE**
>
> If the length of the bytea type is queried and UTF8 encoding is specified, the maximum length can only be **536870888**.

- lpad(string text, length int [, fill text])

  Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

  Return type: text

  Example:

```
openGauss=# SELECT lpad('hi', 5, 'xyza');
 lpad
-------
 xyzhi
(1 row)
```

- notlike(x bytea name text, y bytea text)

  Description: Compares x and y to check whether they are inconsistent.

  Return type: Boolean

  Example:

```
openGauss=# SELECT notlike(1,2);
   notlike
--------------
           t
(1 row)
openGauss=# SELECT notlike(1,1);
   notlike
--------------
           f
(1 row)
```

- octet_length(string)

  Description: Specifies the number of bytes in a string.

  Return type: int

  Example:

```
openGauss=# SELECT octet_length('jose');
 octet_length
--------------
           4
(1 row)
```

- overlay(string placing string FROM int [for int])

  Description: Replaces substrings. **FROM int** indicates the start position of the replacement in the first string. **for int** indicates the number of characters replaced in the first string.

  Return type: text

  Example:

```
openGauss=# SELECT overlay('hello' placing 'world' from 2 for 3 );
 overlay
---------
 hworldo
(1 row)
```

- position(substring in string)

  Description: Specifies the position of a substring.

  Return type: int

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT position('ing' in 'string');
 position
----------
        4
(1 row)
```

- pg_client_encoding()

  Description: Specifies the current client encoding name.

  Return type: name

  Example:

```
openGauss=# SELECT pg_client_encoding();
 pg_client_encoding
--------------------
 UTF8
(1 row)
```

- quote_ident(string text)

  Description: Converts the given value to text and then quotes it as a literal. Quotation marks are added only if necessary (that is, if the string contains non-identifier characters or would be case-folded). Embedded quotation marks are properly doubled.

  Return type: text

  Example:

```
openGauss=# SELECT quote_ident('hello world');
 quote_ident
--------------
 "hello world"
(1 row)
```

- quote_literal(string text)

  Description: Converts the given value to text and then quotes it as a literal.

  Return type: text

  Example:

```
openGauss=# SELECT quote_literal('hello');
 quote_literal
---------------
 'hello'
(1 row)
```

  If a command similar to the following exists, the text will be escaped.

```
openGauss=# SELECT quote_literal(E'O\'hello');
 quote_literal
---------------
 'O''hello'
(1 row)
```

  If a command similar to the following exists, the backslash will be properly doubled.

```
openGauss=# SELECT quote_literal('O\hello');
 quote_literal
---------------
 E'O\\hello'
(1 row)
```

  If the parameter is null, **NULL** is returned. If the parameter may be null, you are advised to use **quote_nullable**.

```
openGauss=# SELECT quote_literal(NULL);
 quote_literal
---------------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- quote_literal(value anyelement)

  Description: Converts the given value to text and then quotes it as a literal.

  Return type: text

  Example:

```
openGauss=# SELECT quote_literal(42.5);
 quote_literal
---------------
 '42.5'
(1 row)
```

  If a command similar to the following exists, the given value will be escaped.

```
openGauss=# SELECT quote_literal(E'O\'42.5');
 quote_literal
---------------
 '0''42.5'
(1 row)
```

  If a command similar to the following exists, the backslash will be properly doubled.

```
openGauss=# SELECT quote_literal('O\42.5');
 quote_literal
---------------
 E'O\\42.5'
(1 row)
```

- quote_nullable(string text)

  Description: Converts the given value to text and then quotes it as a literal.

  Return type: text

  Example:

```
openGauss=# SELECT quote_nullable('hello');
 quote_nullable
----------------
 'hello'
(1 row)
```

  If a command similar to the following exists, the text will be escaped.

```
openGauss=# SELECT quote_nullable(E'O\'hello');
 quote_nullable
----------------
 'O''hello'
(1 row)
```

  If a command similar to the following exists, the backslash will be properly doubled.

```
openGauss=# SELECT quote_nullable('O\hello');
 quote_nullable
----------------
 E'O\\hello'
(1 row)
```

  If the parameter is null, **NULL** is returned.

```
openGauss=# SELECT quote_nullable(NULL);
 quote_nullable
----------------
 NULL
(1 row)
```

- quote_nullable(value anyelement)

  Description: Converts the given value to text and then quotes it as a literal.

  Return type: text

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT quote_nullable(42.5);
 quote_nullable
----------------
 '42.5'
(1 row)
```

If a command similar to the following exists, the given value will be escaped.

```
openGauss=# SELECT quote_nullable(E'O\'42.5');
 quote_nullable
----------------
 'O''42.5'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
openGauss=# SELECT quote_nullable('O\42.5');
 quote_nullable
----------------
 E'O\\42.5'
(1 row)
```

If the parameter is null, **NULL** is returned.

```
openGauss=# SELECT quote_nullable(NULL);
 quote_nullable
----------------
 NULL
(1 row)
```

- similar_escape(pat text, esc text)

  Description: Converts a regular expression of the SQL:2008 style to the POSIX style.

  Return type: text

  Example:

- substring_inner(string [from int] [for int])

  Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of characters truncated.

  Return type: text

  Example:

```
openGauss=# select substring_inner('adcde', 2,3);
 substring_inner
-----------------
 dcd
(1 row)
```

- substring(string [from int] [for int])

  Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of characters truncated.

  Return type: text

  Example:

```
openGauss=# SELECT substring('Thomas' from 2 for 3);
 substring
-----------
 hom
(1 row)
```

- substring(string from *pattern*)

  Description: Extracts substrings matching the POSIX regular expression. It returns the text that matches the pattern. If no match record is found, a null value is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: text

Example:

```
openGauss=# SELECT substring('Thomas' from '...$');
 substring
-----------
 mas
(1 row)
openGauss=# SELECT substring('foobar' from 'o(.)b');
 result
--------
 o
(1 row)
openGauss=# SELECT substring('foobar' from '(o(.)b)');
 result
--------
 oob
(1 row)
```

NOTE

If the POSIX pattern contains any parentheses, the portion of the text that matched the first parenthesized sub-expression (the one whose left parenthesis comes first) is returned. You can put parentheses around the whole expression if you want to use parentheses within it without triggering this exception.

- substring(string from *pattern* for *escape*)

  Description: Extracts substrings matching the SQL regular expression. The declared schema must match the entire data string; otherwise, the function fails and returns a null value. To indicate the part of the pattern that should be returned on success, the pattern must contain two occurrences of the escape character followed by a double quotation mark ("). The text matching the portion of the pattern between these marks is returned.

  Return type: text

  Example:

  ```
  openGauss=# SELECT substring('Thomas' from '%#"o_a#"_' for '#');
   substring
  -----------
   oma
  (1 row)
  ```

- rawcat(raw,raw)

  Description: Indicates the string concatenation function.

  Return type: raw

  Example:

  ```
  openGauss=# SELECT rawcat('ab','cd');
   rawcat
  --------
   ABCD
  (1 row)
  ```

- regexp_like(text,text,text)

  Description: Indicates the mode matching function of a regular expression.

  Return type: Boolean

  Example:

  ```
  openGauss=# SELECT regexp_like('str','[ac]');
   regexp_like
  -------------
   f
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- regexp_substr(string text, pattern text [, position int [, occurrence int [, flags text]]])

  Description: Extracts substrings from a regular expression. Its function is similar to **substr**. When a regular expression contains multiple parallel brackets, it also needs to be processed.

  Parameter description:

  **string**: source character string used for matching.

  **pattern**: regular expression pattern string used for matching.

  **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.

  **occurrence**: sequence number of the matched substring to be extracted. This parameter is optional. The default value is **1**.

  **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. **m** indicates multi-line matching. If the SQL syntax is compatible with products A and B and the value of the GUC parameter **behavior_compat_options** contains **aformat_regexp_match**, the option **n** indicates that the period (.) can match the **'\n'** character. If **n** is not specified in flags, the period (.) cannot match the **'\n'** character by default. If the value does not contain **aformat_regexp_match**, the period (.) matches the **'\n'** character by default. The meaning of option **n** is the same as that of option **m**.

  Return type: text

  Example:

  ```
  openGauss=# SELECT regexp_substr('str','[ac]');
   regexp_substr
  ---------------

  (1 row)

  openGauss=# SELECT regexp_substr('foobarbaz', 'b(..)', 3, 2) AS RESULT;
   result
  --------
   baz
  (1 row)
  ```

- regexp_count(string text, pattern text [, position int [, flags text]])

  Description: obtains the number of substrings used for matching.

  Parameter description:

  **string**: source character string used for matching.

  **pattern**: regular expression pattern string used for matching.

  **position**: sequence number of the character to be matched from the source character string. This parameter is optional. The default value is **1**.

  **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. **m** indicates multi-line matching. If the SQL syntax is compatible with products A and B and the value of the GUC parameter **behavior_compat_options** contains **aformat_regexp_match**, the option **n** indicates that the period (.) can match the **'\n'** character. If **n** is not specified in flags, the period (.) cannot match the **'\n'** character by default. If the value does not contain **aformat_regexp_match**, the period (.) matches the **'\n'** character by default. The meaning of option **n** is the same as that of option **m**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: int

Example:

```
openGauss=# SELECT regexp_count('foobarbaz','b(..)', 5) AS RESULT;
result
--------
1
(1 row)
```

- regexp_instr(string text, pattern text [, position int [, occurrence int [, return_opt int [, flags text]]]])

  Description: obtains the position (starting from 1) of the substring that meets the matching condition. If no substring is matched, **0** is returned.

  Parameter description:

  **string**: source character string used for matching.

  **pattern**: regular expression pattern string used for matching.

  **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.

  **occurrence**: sequence number of the matched substring to be replaced. This parameter is optional. The default value is **1**.

  **return_opt**: specifies whether to return the position of the first or last character of the matched substring. This parameter is optional. If the value is **0**, the position of the first character (starting from 1) of the matched substring is returned. If the value is greater than 0, the position of the next character of the end character of the matched substring is returned. The default value is **0**.

  **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. **m** indicates multi-line matching. If the SQL syntax is compatible with products A and B and the value of the GUC parameter **behavior_compat_options** contains **aformat_regexp_match**, the option **n** indicates that the period (.) can match the **'\n'** character. If **n** is not specified in flags, the period (.) cannot match the **'\n'** character by default. If the value does not contain **aformat_regexp_match**, the period (.) matches the **'\n'** character by default. The meaning of option **n** is the same as that of option **m**.

  Return type: int

  Example:

  ```
  openGauss=# SELECT regexp_instr('foobarbaz','b(..)', 1, 1, 0) AS RESULT;
  result
  --------
  4
  (1 row)

  openGauss=# SELECT regexp_instr('foobarbaz','b(..)', 1, 2, 0) AS RESULT;
  result
  --------
  7
  (1 row)
  ```

- regexp_matches(string text, pattern text [, flags text])

  Description: Returns all captured substrings resulting from matching a POSIX regular expression against **string**. If the pattern does not match, the function returns no rows. If the pattern contains no parenthesized sub-expressions, then each row returned is a single-element text array containing the substring matching the whole pattern. If the pattern contains parenthesized sub-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

expressions, the function returns a text array whose *n*th element is the substring matching the *n*th parenthesized sub-expression of the pattern.

The optional **flags** argument contains zero or multiple single-letter flags that change function behavior. **i** indicates that the matching is not related to uppercase and lowercase. **g** indicates that each matching substring is replaced, instead of replacing only the first one.

**NOTICE**

If the last parameter is provided but the parameter value is an empty string ('') and the SQL compatibility mode of the database is set to ORA, the returned result is an empty set. This is because the ORA compatible mode treats the empty string ('') as **NULL**. To resolve this problem, you can:

- Change the database SQL compatibility mode to TD.
- Do not provide the last parameter or do not set the last parameter to an empty string.

Return type: SETOF text[]

Example:

```
openGauss=# SELECT regexp_matches('foobarbequebaz', '(bar)(beque)');
 regexp_matches
----------------
 {bar,beque}
(1 row)
openGauss=# SELECT regexp_matches('foobarbequebaz', 'barbeque');
 regexp_matches
----------------
 {barbeque}
(1 row)
openGauss=# SELECT regexp_matches('foobarbequebazilbarfbonk', '(b[^b]+)(b[^b]+)', 'g');
    result
--------------
 {bar,beque}
 {bazil,barf}
(2 rows)
```

- regexp_split_to_array(string text, pattern text [, flags text ])

  Description: Splits **string** using a POSIX regular expression as the delimiter. The **regexp_split_to_array** function behaves the same as **regexp_split_to_table**, except that **regexp_split_to_array** returns its result as an array of text.

  Return type: text[]

  Example:

  ```
  openGauss=# SELECT regexp_split_to_array('hello world', E'\\s+');
   regexp_split_to_array
  -----------------------
   {hello,world}
  (1 row)
  ```

- regexp_split_to_table(string text, pattern text [, flags text])

  Description: Splits **string** using a POSIX regular expression as the delimiter. If there is no match to the pattern, the function returns the string. If there is at least one match, for each match it returns the text from the end of the last match (or the beginning of the string) to the beginning of the match. When there are no more matches, it returns the text from the end of the last match to the end of the string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The **flags** parameter is a text string containing zero or more single-letter flags that change the function's behavior. **i** indicates that the matching is not related to uppercase and lowercase. **g** indicates that each matching substring is replaced, instead of replacing only the first one.

Return type: SETOF text

Example:

```
openGauss=# SELECT regexp_split_to_table('hello world', E'\\s+');
 regexp_split_to_table
-----------------------
 hello
 world
(2 rows)
```

- repeat(string text, number int )

  Description: Repeats **string** the specified number of times.

  Return type: text

  Example:

  ```
  openGauss=# SELECT repeat('Pg', 4);
    repeat
  ----------
   PgPgPgPg
  (1 row)
  ```

  NOTE

  The maximum size of memory allocated at a time cannot exceed 1 GB due to the memory allocation mechanism of the database. Therefore, the maximum value of **number** cannot exceed (1 GB – **x**)/**lengthb** (**string**) – 1. **x** indicates the length of the header information, which is usually greater than 4 bytes. The value varies among different scenarios.

- replace(string text, from text, to text)

  Description: Replaces all occurrences in **string** of substring **from** with substring **to**.

  Return type: text

  Example:

  ```
  openGauss=# SELECT replace('abcdefabcdef', 'cd', 'XXX');
     replace
  ----------------
   abXXXefabXXXef
  (1 row)
  ```

- replace(string, substring)

  Description: Deletes all substrings in a string.

  String type: text

  Substring type: text

  Return type: text

  Example:

  ```
  openGauss=# SELECT replace('abcdefabcdef', 'cd');
     replace
  ----------------
   abefabef
  (1 row)
  ```

- reverse(str)

  Description: Returns the reversed string.

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# SELECT reverse('abcde');
 reverse
---------
 edcba
(1 row)
```

- right(str text, n int)

  Description: Returns the last *n* characters in a string. When *n* is negative, all but the first **|n|** characters are returned.

  Return type: text

  Example:

```
openGauss=# SELECT right('abcde', 2);
 right
-------
 de
(1 row)

openGauss=# SELECT right('abcde', -2);
 right
-------
 cde
(1 row)
```

- rpad(string text, length int [, fill text])

  Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

  Return type: text

  Example:

```
openGauss=# SELECT rpad('hi', 5, 'xy');
 rpad
-------
 hixyx
(1 row)
```

- rtrim(string text [, characters text])

  Description: Removes the longest string containing only characters from characters (a space by default) from the end of string.

  Return type: text

  Example:

```
openGauss=# SELECT rtrim('trimxxxx', 'x');
 rtrim
-------
 trim
(1 row)
```

- substrb(text,int,int)

  Description: Extracts a substring. The first **int** indicates the start position of the subtraction. The second **int** indicates the number of characters extracted.

  Return type: text

  Example:

```
openGauss=# SELECT substrb('string',2,3);
 substrb
---------
 tri
(1 row)
```

- substrb(text,int)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Extracts a substring. **int** indicates the start position of the extraction.

Return type: text

Example:

```
openGauss=# SELECT substrb('string',2);
 substrb
---------
 tring
(1 row)
```

- substr(bytea,from,count)

  Description: Extracts a substring from **bytea**. **from** specifies the position where the extraction starts. **count** specifies the length of the extracted substring.

  Return type: text

  Example:

  ```
  openGauss=# SELECT substr('string',2,3);
   substr
  --------
   tri
  (1 row)
  ```

- string || string

  Description: Concatenates strings.

  Return type: text

  Example:

  ```
  openGauss=# SELECT 'MPP'||'DB' AS RESULT;
   result
  --------
   MPPDB
  (1 row)
  ```

- string || non-string or non-string || string

  Description: Concatenates strings and non-strings.

  Return type: text

  Example:

  ```
  openGauss=# SELECT 'Value: '||42 AS RESULT;
    result
  -----------
   Value: 42
  (1 row)
  ```

- split_part(string text, delimiter text, field int)

  Description: Splits **string** on **delimiter** and returns the **field**th column (counting from text of the first appeared delimiter).

  Return type: text

  Example:

  ```
  openGauss=# SELECT split_part('abc~@~def~@~ghi', '~@~', 2);
   split_part
  ------------
   def
  (1 row)
  ```

- strpos(string, substring)

  Description: Specifies the position of a substring. It is the same as **position(substring in string)**. However, the parameter sequences of them are reversed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: int

Example:

```
openGauss=# SELECT strpos('source', 'rc');
 strpos
--------
      4
(1 row)
```

- to_hex(number int or bigint)

  Description: Converts a number to a hexadecimal expression.

  Return type: text

  Example:

  ```
  openGauss=# SELECT to_hex(2147483647);
    to_hex
  ----------
   7fffffff
  (1 row)
  ```

- translate(string text, from text, to text)

  Description: Any character in **string** that matches a character in the **from** set is replaced by the corresponding character in the **to** set. If **from** is longer than **to**, extra characters occurred in **from** are removed.

  Return type: text

  Example:

  ```
  openGauss=# SELECT translate('12345', '143', 'ax');
   translate
  -----------
   a2x5
  (1 row)
  ```

- length(string)

  Description: Obtains the number of characters in a string.

  Return type: integer

  Example:

  ```
  openGauss=# SELECT length('abcd');
   length
  --------
       4
  (1 row)
  ```

- lengthb(string)

  Description: Obtains the number of characters in a string. The value depends on character sets (GBK and UTF8).

  Return type: integer

  Example:

  ```
  openGauss=# SELECT lengthb('Chinese');
   lengthb
  ---------
        7
  (1 row)
  ```

- substr(string,from)

  Description:

  Extracts substrings from a string.

  **from** indicates the start position of the extraction.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

  - If **from** starts at 0, the value **1** is used.
  - If the value of **from** is positive, all characters from **from** to the end are extracted.
  - If the value of **from** is negative, the last *n* characters in the string are extracted, in which **n** indicates the absolute value of **from**.

  Return type: varchar

  Example:

  If the value of **from** is positive:

```
openGauss=# SELECT substr('ABCDEF',2);
 substr
--------
 BCDEF
(1 row)
```

  If the value of **from** is negative:

```
openGauss=# SELECT substr('ABCDEF',-2);
 substr
--------
 EF
(1 row)
```

- substr(string,from,count)

  Description:

  Extracts substrings from a string.

  **from** indicates the start position of the extraction.

  **count** indicates the length of the extracted substring.

  - If **from** starts at 0, the value **1** is used.
  - If the value of **from** is positive, extract **count** characters starting from **from**.
  - If the value of **from** is negative, extract the last **n count** characters in the string, in which **n** indicates the absolute value of **from**.
  - If the value of **count** is smaller than **1**, **null** is returned.

  Return type: varchar

  Example:

  If the value of **from** is positive:

```
openGauss=# SELECT substr('ABCDEF',2,2);
 substr
--------
 BC
(1 row)
```

  If the value of **from** is negative:

```
openGauss=# SELECT substr('ABCDEF',-3,2);
 substr
--------
 DE
(1 row)
```

- substrb(string,from)

  Description: The functionality of this function is the same as that of **SUBSTR(string,from)**. However, the calculation unit is byte.

  Return type: bytea

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT substrb('ABCDEF',-2);
 substrb
---------
 EF
(1 row)
```

- substrb(string,from,count)

  Description: The functionality of this function is the same as that of **SUBSTR(string,from,count)**. However, the calculation unit is byte.

  Return type: bytea

  Example:

```
openGauss=# SELECT substrb('ABCDEF',2,2);
 substrb
---------
 BC
(1 row)
```

- trim([leading |trailing |both] [characters] from string)

  Description: Removes the longest string containing only the characters (a space by default) from the start/end/both ends of the string.

  Return type: text

  Example:

```
openGauss=# SELECT trim(BOTH 'x' FROM 'xTomxx');
 btrim
-------
 Tom
(1 row)
openGauss=# SELECT trim(LEADING 'x' FROM 'xTomxx');
 ltrim
-------
 Tomxx
(1 row)
openGauss=# SELECT trim(TRAILING 'x' FROM 'xTomxx');
 rtrim
-------
 xTom
(1 row)
```

- rtrim(string [, characters])

  Description: Removes the longest string containing only characters from characters (a space by default) from the end of string.

  Return type: text

  Example:

```
openGauss=# SELECT rtrim('TRIMxxxx','x');
 rtrim
-------
 TRIM
(1 row)
```

- ltrim(string [, characters])

  Description: Removes the longest string containing only characters from characters (a space by default) from the start of string.

  Return type: text

  Example:

```
openGauss=# SELECT ltrim('xxxxTRIM','x');
 ltrim
-------
 TRIM
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- upper(string)

  Description: Converts the string into the uppercase.

  Return type: text

  Example:

  ```
  openGauss=# SELECT upper('tom');
   upper
  -------
   TOM
  (1 row)
  ```

- lower(string)

  Description: Converts the string into the lowercase.

  Return type: text

  Example:

  ```
  openGauss=# SELECT lower('TOM');
   lower
  -------
   tom
  (1 row)
  ```

- rpad(string varchar, length int [, fill varchar])

  Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

  **length** in GaussDB indicates the character length. One Chinese character is counted as one character.

  Return type: text

  Example:

  ```
  openGauss=# SELECT rpad('hi',5,'xyza');
   rpad
  -------
   hixyx
  (1 row)
  openGauss=# SELECT rpad('hi',5,'abcdefg');
   rpad
  -------
   hiabc
  (1 row)
  ```

- instr(string,substring[,position,occurrence])

  Description: Queries and returns the value of the substring position that occurs the **occurrence** (1 by default) times from the **position** (1 by default) in the string.

  - If the value of **position** is **0**, **0** is returned.
  - If the value of **position** is negative, searches backwards from the last *n*th character in the string, in which *n* indicates the absolute value of **position**.

  In this function, the calculation unit is character. One Chinese character is one character.

  Return type: integer

  Example:

  ```
  openGauss=# SELECT instr('corporate floor','or', 3);
   instr
  -------
       5
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT instr('corporate floor','or',-3,2);
 instr
-------
     2
(1 row)
```

- initcap(string)

  Description: Converts the first letter of each word in the string into the uppercase and the other letters into the lowercase.

  Return type: text

  Example:

```
openGauss=# SELECT initcap('hi THOMAS');
  initcap
-----------
 Hi Thomas
(1 row)
```

- ascii(string)

  Description: Indicates the ASCII code of the first character in the string.

  Return type: integer

  Example:

```
openGauss=# SELECT ascii('xyz');
 ascii
-------
   120
(1 row)
```

- replace(string varchar, search_string varchar, replacement_string varchar)

  Description: Replaces all **search_string** in the string with **replacement_string**.

  Return type: varchar

  Example:

```
openGauss=# SELECT replace('jack and jue','j','bl');
    replace
----------------
 black and blue
(1 row)
```

- lpad(string varchar, length int[, repeat_string varchar])

  Description: Adds a series of **repeat_string** (a space by default) on the left of the string to generate a new string with the total length of *n*.

  If the length of the string is longer than the specified length, the function truncates the string and returns the substrings with the specified length.

  Return type: varchar

  Example:

```
openGauss=# SELECT lpad('PAGE 1',15,'*.');
      lpad
-----------------
 *.*.*.*.*PAGE 1
(1 row)
openGauss=# SELECT lpad('hello world',5,'abcd');
 lpad
-------
 hello
(1 row)
```

- concat(str1,str2)

  Description: Concatenates **str1** and **str2** and returns the concatenated string. If **str1** or **str2** is set to **NULL**, **NULL** is returned. Note: **concat** calls the output

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

function of the data type and the return value is uncertain. As a result, the optimizer cannot calculate the result in advance when generating a plan. If there are performance requirements, you are advised to use the operator **||**.

Return type: varchar

Example:

```
openGauss=# SELECT concat('Hello', ' World!');
    concat
--------------
 Hello World!
(1 row)
openGauss=# SELECT concat('Hello', NULL);
 concat
--------

(1 row)
```

- chr(integer)

  Description: Specifies the character of the ASCII code.

  Return type: varchar

  Example:

  ```
  openGauss=# SELECT chr(65);
   chr
  -----
   A
  (1 row)
  ```

- regexp_substr(source_char, pattern)

  Description: Extracts substrings from a regular expression.

  Return type: text

  Example:

  ```
  openGauss=# SELECT regexp_substr('500 Hello World, Redwood Shores, CA', ',[^,]+,')
  "REGEXPR_SUBSTR";
    REGEXPR_SUBSTR
  -------------------
   , Redwood Shores,
  (1 row)
  ```

- regexp_replace(string, pattern, replacement [,flags ])

  Description: Replaces substrings matching the POSIX regular expression. The source string is returned unchanged if there is no match to the pattern. If there is a match, the source string is returned with the replacement string substituted for the matching substring.

  The replacement string can contain \n, where n is 1 through 9, to indicate that the source substring matching the *n*th parenthesized sub-expression of the pattern should be inserted, and it can contain \& to indicate that the substring matching the entire pattern should be inserted.

  The optional **flags** argument contains zero or multiple single-letter flags that change function behavior. **i** indicates that the matching is not related to uppercase and lowercase. **g** indicates that each matching substring is replaced, instead of replacing only the first one.

  Return type: varchar

  Example:

  ```
  openGauss=# SELECT regexp_replace('Thomas', '.[mN]a.', 'M');
   regexp_replace
  ----------------
   ThM
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
(1 row)
openGauss=# SELECT regexp_replace('foobarbaz','b(..)', E'X\\1Y', 'g') AS
RESULT;
   result
-------------
 fooXarYXazY
(1 row)
```

- concat_ws(sep text, str"any" [, str"any" [, ...] ])

  Description: Uses the first parameter as the separator, which is associated with all following parameters.

  Return type: text

  Example:

```
openGauss=# SELECT concat_ws(',', 'ABCDE', 2, NULL, 22);
 concat_ws
------------
 ABCDE,2,22
(1 row)
```

- nlssort(string text, sort_method text)

  Description: Returns the encoding value of a string in the sorting mode specified by **sort_method**. The encoding value can be used for sorting and determines the sequence of the string in the sorting mode. Currently, **sort_method** can be set to **nls_sort=schinese_pinyin_m** or **nls_sort=generic_m_ci**. **nls_sort=generic_m_ci** supports only the case-insensitive order for English characters.

  String type: text

  sort_method type: text

  Return type: text

  Example:

```
openGauss=# create table test(a text);

openGauss=# insert into test(a) values('abC not');

openGauss=# insert into test(a) values('abC a');

openGauss=# insert into test(a) values('abC a');

openGauss=# select * from test order by nlssort(a,'nls_sort=schinese_pinyin_m');
   a
--------
 abc 啊
 abC 啊
 abC 不
(3 rows)

openGauss=# select * from test order by nlssort(a, 'nls_sort=generic_m_ci');
   a
--------
 abC 啊
 abc 啊
 abC 不
(3 rows)
```

- convert(string bytea, src_encoding name, dest_encoding name)

  Description: Converts the bytea string to **dest_encoding**. **src_encoding** specifies the source code encoding. The string must be valid in this encoding.

  Return type: bytea

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT convert('text_in_utf8', 'UTF8', 'GBK');
         convert
--------------------------
 \x746578745f696e5f75746638
(1 row)
```

**NOTE**

If the rule for converting between source to target encoding (for example, GBK and LATIN1) does not exist, the string is returned without conversion. See the **pg_conversion** system catalog for details.

Example:

```
openGauss=# show server_encoding;
 server_encoding
-----------------
 LATIN1
(1 row)

openGauss=# SELECT convert_from('some text', 'GBK');
 convert_from
--------------
 some text
(1 row)

db_latin1=# SELECT convert_to('some text', 'GBK');
      convert_to
----------------------
 \x736f6d652074657874
(1 row)

db_latin1=# SELECT convert('some text', 'GBK', 'LATIN1');
       convert
----------------------
 \x736f6d652074657874
(1 row)
```

- convert_from(string bytea, src_encoding name)

  Description: Converts the long bytea using the coding mode of the database.

  **src_encoding** specifies the source code encoding. The string must be valid in this encoding.

  Return type: text

  Example:

  ```
  openGauss=# SELECT convert_from('text_in_utf8', 'UTF8');
   convert_from
  --------------
   text_in_utf8
  (1 row)
  ```

- convert_to(string text, dest_encoding name)

  Description: Converts a string to **dest_encoding**.

  Return type: bytea

  Example:

  ```
  openGauss=# SELECT convert_to('some text', 'UTF8');
      convert_to
  ----------------------
   \x736f6d652074657874
  (1 row)
  ```

- string [NOT] LIKE pattern [ESCAPE escape-character]

  Description: Specifies the pattern matching function.

  If the pattern does not include a percentage sign (%) or an underscore (_), this mode represents itself only. In this case, the behavior of LIKE is the same

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

as the equal operator. The underscore (_) in the pattern matches any single character while one percentage sign (%) matches no or multiple characters.

To match with underscores (_) or percent signs (%), corresponding characters in **pattern** must lead escape characters. The default escape character is a backward slash (\) and can be specified using the **ESCAPE** clause. To match with escape characters, enter two escape characters.

Return type: Boolean

Example:

```
openGauss=# SELECT 'AA_BBCC' LIKE '%A@_B%' ESCAPE '@' AS RESULT;
 result
--------
 t
(1 row)
openGauss=# SELECT 'AA_BBCC' LIKE '%A@_B%' AS RESULT;
 result
--------
 f
(1 row)
openGauss=# SELECT 'AA@_BBCC' LIKE '%A@_B%' AS RESULT;
 result
--------
 t
(1 row)
```

- REGEXP_LIKE(source_string, pattern [, match_parameter])

  Description: Indicates the mode matching function of a regular expression.

  **source_string** indicates the source string and **pattern** indicates the matching pattern of the regular expression. **match_parameter** indicates the matching items and the values are as follows:

  – 'i': case-insensitive
  – 'c': case-sensitive
  – 'n': allowing the metacharacter "." in a regular expression to be matched with a linefeed.
  – 'm': allows **source_string** to be regarded as multiple rows.

  If **match_parameter** is ignored, **case-sensitive** is enabled by default, "." is not matched with a linefeed, and **source_string** is regarded as a single row.

  Return type: Boolean

  Example:

```
openGauss=# SELECT regexp_like('ABC', '[A-Z]');
 regexp_like
-------------
 t
(1 row)
openGauss=# SELECT regexp_like('ABC', '[D-Z]');
 regexp_like
-------------
 f
(1 row)
openGauss=# SELECT regexp_like('ABC', '[A-Z]','i');
 regexp_like
-------------
 t
(1 row)
openGauss=# SELECT regexp_like('ABC', '[A-Z]');
 regexp_like
-------------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- format(formatstr text [, str"any" [, ...] ])

  Description: Formats a string.

  Return type: text

  Example:

```
openGauss=# SELECT format('Hello %s, %1$s', 'World');
      format
-------------------
 Hello World, World
(1 row)
```

- md5(string)

  Description: Encrypts a string in MD5 mode and returns a value in hexadecimal form.

  **NOTE**

  The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

  Return type: text

  Example:

```
openGauss=# SELECT md5('ABC');
              md5
----------------------------------
 902fbdd2b1df0c4f70b4a5d23525e932
(1 row)
```

- decode(string text, format text)

  Description: Decodes binary data from textual representation.

  Return type: bytea

  Example:

```
openGauss=# SELECT decode('MTIzAAE=', 'base64');
   decode
--------------
 \x3132330001
(1 row)
```

- similar_escape(pat text, esc text)

  Description: Converts a regular expression of the SQL:2008 style to the POSIX style.

  Return type: text

  Example:

```
openGauss=# select similar_escape('\s+ab','2');
 similar_escape
----------------
 ^(?:\\s+ab)$
(1 row)
```

- svals(hstore)

  Description: Obtains the value of the hstore type.

  Return type: SETOF text

  Example:

```
openGauss=# select svals('"aa"=>"bb"');
 svals
-------
 bb
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- tconvert(key text, value text)

  Description: Converts character strings to the hstore format.

  Return type: hstore

  Example:

```
openGauss=# select tconvert('aa', 'bb');
  tconvert
------------
 "aa"=>"bb"
(1 row)
```

- encode(data bytea, format text)

  Description: Encodes binary data into a textual representation.

  Return type: text

  Example:

```
openGauss=# SELECT encode(E'123\\000\\001', 'base64');
  encode
----------
 MTIzAAE=
(1 row)
```

NOTE

- For a string containing newline characters, for example, a string consisting of a newline character and a space, the value of **length** and **lengthb** in GaussDB is **2**.
- In GaussDB, *n* in the CHAR(n) type indicates the number of characters. Therefore, for multiple-octet coded character sets, the length returned by the LENGTHB function may be longer than *n*.

# 12.5.4 Binary String Functions and Operators

## String Operators

SQL defines some string functions that use keywords, rather than commas, to separate arguments.

- octet_length(string)

  Description: Specifies the number of bytes in a binary string.

  Return type: int

  Example:

```
openGauss=# SELECT octet_length(E'jo\\000se'::bytea) AS RESULT;
 result
--------
      5
(1 row)
```

- overlay(string placing string from int [for int])

  Description: Replaces substrings.

  Return type: bytea

  Example:

```
openGauss=# SELECT overlay(E'Th\\000omas'::bytea placing E'\\002\\003'::bytea from 2 for 3) AS
RESULT;
    result
----------------
 \x5402036d6173
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- position(substring in string)

  Description: Specifies the location of the specified substring.

  Return type: int

  Example:

```
openGauss=# SELECT position(E'\\000om'::bytea in E'Th\\000omas'::bytea) AS RESULT;
 result
--------
      3
(1 row)
```

- substring(string [from int] [for int])

  Description: Truncates substrings.

  Return type: bytea

  Example:

```
openGauss=# SELECT substring(E'Th\\000omas'::bytea from 2 for 3) AS RESULT;
  result
----------
 \x68006f
(1 row)
```

- substr(bytea [from int] [for int])

  Description: Truncates substrings.

  Return type: bytea

  Example:

```
openGauss=# select substr(E'Th\\000omas'::bytea,2, 3) as result;
  result
----------
 \x68006f
(1 row)
```

- trim([both] bytes from string)

  Description: Removes the longest string containing only bytes from **bytes** from the start and end of **string**.

  Return type: bytea

  Example:

```
openGauss=# SELECT trim(E'\\000'::bytea from E'\\000Tom\\000'::bytea) AS RESULT;
  result
----------
 \x546f6d
(1 row)
```

## Other Binary String Functions

GaussDB provides common syntax used for calling functions.

- btrim(string bytea,bytes bytea)

  Description: Removes the longest string containing only bytes from **bytes** from the start and end of **string**.

  Return type: bytea

  Example:

```
openGauss=# SELECT btrim(E'\\000trim\\000'::bytea, E'\\000'::bytea) AS RESULT;
   result
------------
 \x7472696d
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- get_bit(string, offset)

  Description: Extracts bits from a string.

  Return type: int

  Example:

```
openGauss=# SELECT get_bit(E'Th\\000omas'::bytea, 45) AS RESULT;
 result
--------
      1
(1 row)
```

- get_byte(string, offset)

  Description: Extracts bytes from a string.

  Return type: int

  Example:

```
openGauss=# SELECT get_byte(E'Th\\000omas'::bytea, 4) AS RESULT;
 result
--------
    109
(1 row)
```

- set_bit(string,offset, newvalue)

  Description: Sets bits in a string.

  Return type: bytea

  Example:

```
openGauss=# SELECT set_bit(E'Th\\000omas'::bytea, 45, 0) AS RESULT;
      result
------------------
 \x5468006f6d4173
(1 row)
```

- set_byte(string,offset, newvalue)

  Description: Sets bytes in a string.

  Return type: bytea

  Example:

```
openGauss=# SELECT set_byte(E'Th\\000omas'::bytea, 4, 64) AS RESULT;
      result
------------------
 \x5468006f406173
(1 row)
```

- rawcmp

  Description: Specifies the raw data type comparison function.

  Parameter: raw, raw

  Return type: integer

- raweq

  Description: Specifies the raw data type comparison function.

  Parameter: raw, raw

  Return type: Boolean

- rawge

  Description: Specifies the raw data type comparison function.

  Parameter: raw, raw

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- rawgt
  Description: Specifies the raw data type comparison function.
  Parameter: raw, raw
  Return type: Boolean
- rawin
  Description: Specifies the raw data type parsing function.
  Parameter: cstring
  Return type: bytea
- rawle
  Description: Specifies the raw data type parsing function.
  Parameter: raw, raw
  Return type: Boolean
- rawlike
  Description: Specifies the raw data type parsing function.
  Parameter: raw, raw
  Return type: Boolean
- rawlt
  Description: Specifies the raw data type parsing function.
  Parameter: raw, raw
  Return type: Boolean
- rawne
  Description: Compares whether the raw types are the same.
  Parameter: raw, raw
  Return type: Boolean
- rawnlike
  Description: Checks whether the raw type matches the mode.
  Parameter: raw, raw
  Return type: Boolean
- rawout
  Description: Specifies the RAW output API.
  Parameter: bytea
  Return type: cstring
- rawsend
  Description: Converts bytea to the binary type.
  Parameter: raw
  Return type: bytea
- rawtohex
  Description: Converts the raw format to the hexadecimal format.
  Parameter: text
  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 12.5.5 Bit String Functions and Operators

## Bit String Operators

Aside from the usual comparison operators, the following operators can be used. Bit string operands of **&**, **|**, and **#** must be of equal length. In case of bit shifting, the original length of the string is preserved by zero padding (if necessary).

- ||

  Description: Connects bit strings.

  Example:

  ```
  openGauss=# SELECT B'10001' || B'011' AS RESULT;
   result
  ----------
   10001011
  (1 row)
  ```

  NOTE

  A column can have a maximum of 180 consecutive internal joins. A column with excessive joins will be split into joined consecutive strings.

  Example: **str1||str2||str3||str4** is split into **(str1||str2)||(str3||str4)**.

- &

  Description: Specifies the AND operation between bit strings.

  Example:

  ```
  openGauss=# SELECT B'10001' & B'01101' AS RESULT;
   result
  --------
   00001
  (1 row)
  ```

- |

  Description: Specifies the OR operation between bit strings.

  Example:

  ```
  openGauss=# SELECT B'10001' | B'01101' AS RESULT;
   result
  --------
   11101
  (1 row)
  ```

- #

  Description: Specifies the OR operation between bit strings if they are inconsistent. If the same positions in the two bit strings are both 1 or 0, the position returns **0**.

  Example:

  ```
  openGauss=# SELECT B'10001' # B'01101' AS RESULT;
   result
  --------
   11100
  (1 row)
  ```

- ~

  Description: Specifies the NOT operation between bit strings.

  Example:

  ```
  openGauss=# SELECT ~B'10001'AS RESULT;
   result
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
----------
 01110
(1 row)
```

- <<

  Description: Shifts left in a bit string.

  Example:

```
openGauss=# SELECT B'10001' << 3 AS RESULT;
 result
----------
 01000
(1 row)
```

- >>

  Description: Shifts right in a bit string.

  Example:

```
openGauss=# SELECT B'10001' >> 2 AS RESULT;
 result
----------
 00100
(1 row)
```

The following SQL-standard functions work on bit strings as well as strings: **length**, **bit_length**, **octet_length**, **position**, **substring**, and **overlay**.

The following functions work on bit strings as well as binary strings: **get_bit** and **set_bit**. When working with a bit string, these functions number the first (leftmost) bit of the string as bit 0.

In addition, it is possible to convert between integral values and type **bit**. Example:

```
openGauss=# SELECT 44::bit(10) AS RESULT;
   result
------------
 0000101100
(1 row)

openGauss=# SELECT 44::bit(3) AS RESULT;
 result
--------
 100
(1 row)

openGauss=# SELECT cast(-44 as bit(12)) AS RESULT;
    result
--------------
 111111010100
(1 row)

openGauss=# SELECT '1110'::bit(4)::integer AS RESULT;
 result
--------
     14
(1 row)

openGauss=# select substring('10101111'::bit(8), 2);
 substring
-----------
 0101111
(1 row)
```

**NOTE**

Casting to just "bit" means casting to bit(1), and so will deliver only the least significant bit of the integer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## 12.5.6 Pattern Matching Operators

The database provides three independent methods for implementing pattern matching: SQL LIKE operator, SIMILAR TO operator, and POSIX-style regular expressions. Besides these basic operators, functions can be used to extract or replace matching substrings and to split a string at matching locations.

- LIKE

  Description: Specifies whether the string matches the pattern string following LIKE. The LIKE expression returns true if the string matches the supplied pattern. (As expected, the NOT LIKE expression returns false if LIKE returns true, and vice versa.)

  Matching rules:

  a. This operator can succeed only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.
  b. The underscore (_) represents (matching) any single character. Percentage (%) indicates the wildcard character of any string.
  c. To match a literal underscore or percent sign, the respective character in pattern must be preceded by the escape character. The default escape character is one backslash but a different one can be selected by using the ESCAPE clause.
  d. To match with escape characters, enter two escape characters. For example, to write a pattern constant containing a backslash (\), you need to enter two backslashes in SQL statements.

     NOTE

     When **standard_conforming_strings** is set to **off**, any backslashes you write in literal string constants will need to be doubled. Therefore, writing a pattern matching a single backslash is actually going to write four backslashes in the statement. You can avoid this by selecting a different escape character by using ESCAPE, so that the backslash is no longer a special character of LIKE. But the backslash is still the special character of the character text analyzer, so you still need two backslashes. You can also select no escape character by writing **ESCAPE ''**. This effectively disables the escape mechanism, but it does not eliminate the special meaning of underscore and percent signs in the pattern.
  e. The keyword ILIKE can be used instead of LIKE to make the match case-insensitive.
  f. Operator **~~** is equivalent to LIKE, and operator **~~*** corresponds to ILIKE.

  Example:

```
openGauss=# SELECT 'abc' LIKE 'abc' AS RESULT;
 result
------------
 t
(1 row)
openGauss=# SELECT 'abc' LIKE 'a%' AS RESULT;
 result
------------
 t
(1 row)
openGauss=# SELECT 'abc' LIKE '_b_' AS RESULT;
 result
------------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT 'abc' LIKE 'c' AS RESULT;
 result
-----------
 f
(1 row)
```

- SIMILAR TO

  Description: Returns true or false depending on whether the pattern matches the given string. It is similar to LIKE, but differs in that SIMILAR TO uses the regular expression understanding pattern defined by the SQL standard.

  Matching rules:

  a. Similar to LIKE, this operator succeeds only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.

  b. The underscore (_) represents (matching) any single character. Percentage (%) indicates the wildcard character of any string.

  c. SIMILAR TO supports these pattern-matching metacharacters borrowed from POSIX-style regular expressions:

| Metacharacter | Description |
| --- | --- |
| \| | Specifies alternation (either of two alternatives). |
| * | Specifies repetition of the previous item zero or more times. |
| + | Specifies repetition of the previous item one or more times. |
| ? | Specifies repetition of the previous item zero or one time. |
| {m} | Specifies repetition of the previous item exactly *m* times. |
| {m,} | Specifies repetition of the previous item *m* or more times. |
| {m,n} | Specifies repetition of the previous item at least *m* times and does not exceed *n* times. |
| () | Specifies that parentheses () can be used to group items into a single logical item. |
| [...] | Specifies a character class, just as in POSIX-style regular expressions. |

  d. A preamble escape character disables the special meaning of any of these metacharacters. The rules for using escape characters are the same as those for LIKE.

  Regular expressions:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The **substring(stringfrompatternforescape)** function extracts a substring that matches an SQL regular expression pattern.

Example:

```
openGauss=# SELECT 'abc' SIMILAR TO 'abc' AS RESULT;
 result
-----------
 t
(1 row)
openGauss=# SELECT 'abc' SIMILAR TO 'a' AS RESULT;
 result
-----------
 f
(1 row)
openGauss=# SELECT 'abc' SIMILAR TO '%(b|d)%' AS RESULT;
 result
-----------
 t
(1 row)
openGauss=# SELECT 'abc' SIMILAR TO '(b|c)%'  AS RESULT;
 result
-----------
 f
(1 row)
```

- POSIX-style regular expressions

  Description: A regular expression is a character sequence that is an abbreviated definition of a set of strings (a regular set). If a string is a member of a regular expression described by a regular expression, the string matches the regular expression. POSIX-style regular expressions provide a more powerful means for pattern matching than the LIKE and SIMILAR TO operators. **Table 1 Regular expression match operators** lists all available operators for pattern matching using POSIX-style regular expressions.

  **Table 12-29** Regular expression match operators

| Operator | Description | Example |
| --- | --- | --- |
| ~ | Matches a regular expression, which is case-sensitive. | 'thomas' ~ '.*thomas.*' |
| ~* | Matches a regular expression, which is case-insensitive. | 'thomas' ~* '.*Thomas.*' |
| ! ~ | Does not match a regular expression, which is case-sensitive. | 'thomas' !~ '.*Thomas.*' |
| ! ~* | Does not match a regular expression, which is case-insensitive. | 'thomas' !~* '.*vadim.*' |

  Matching rules:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

a. Unlike LIKE patterns, a regular expression is allowed to match anywhere within a string, unless the regular expression is explicitly anchored to the beginning or end of the string.

b. Besides the metacharacters mentioned above, POSIX-style regular expressions also support the following pattern matching metacharacters:

| Metacharacter | Description |
| --- | --- |
| ^ | Specifies the match starting with a string. |
| $ | Specifies the match at the end of a string. |
| . | Matches any single character. |

Regular expressions:

POSIX-style regular expressions support the following functions:

- The **substring(string from pattern)** function provides a method for extracting a substring that matches the POSIX-style regular expression pattern.
- The **regexp_count(string tex....** function counts the number of substrings that match the POSIX-style regular expression pattern.
- The **regexp_instr(string text...** function obtains the position of a substring that matches the POSIX-style regular expression pattern.
- The **regexp_substr(string tex...** function extracts a substring that matches the POSIX-style regular expression pattern.
- The **regexp_replace(string, pattern, replacement [,flags ])** function replaces the substring matching the POSIX-style regular expression pattern with the new text.
- The **regexp_matches(string text, pattern text [, flags text])** function returns a text array consisting of all captured substrings that match a POSIX-style regular expression pattern.
- The **regexp_split_to_table(string text, pattern text [, flags text])** function splits a string using a POSIX-style regular expression pattern as a delimiter.
- The **regexp_split_to_array(string text, pattern text [, flags text ])** function behaves the same as **regexp_split_to_table**, except that **regexp_split_to_array** returns its result as an array of text.

  NOTE

  The regular expression split functions ignore zero-length matches, which occur at the beginning or end of a string or after the previous match. This is contrary to the strict definition of regular expression matching. The latter is implemented by **regexp_matches**, but the former is usually the most commonly used behavior in practice.

Example:

```
openGauss=# SELECT 'abc' ~ 'Abc' AS RESULT;
result
--------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 f
(1 row)
openGauss=# SELECT 'abc' ~* 'Abc' AS RESULT;
 result
--------
 t
(1 row)
openGauss=# SELECT 'abc' !~ 'Abc' AS RESULT;
 result
--------
 t
(1 row)
openGauss=# SELECT 'abc'!~* 'Abc' AS RESULT;
 result
--------
 f
(1 row)
openGauss=# SELECT 'abc' ~ '^a' AS RESULT;
 result
--------
 t
(1 row)
openGauss=# SELECT 'abc' ~ '(b|d)'AS RESULT;
 result
--------
 t
(1 row)
openGauss=# SELECT 'abc' ~ '^(b|c)'AS RESULT;
 result
--------
 f
(1 row)
```

Although most regular expression searches can be executed quickly, regular expressions can still be artificially made up of memory that takes a long time and any amount of memory. It is not recommended that you accept the regular expression search pattern from the non-security pattern source. If you must do this, you are advised to add the statement timeout limit. The search with the SIMILAR TO pattern has the same security risks as the SIMILAR TO provides many capabilities that are the same as those of the POSIX-style regular expression. The LIKE search is much simpler than the other two options. Therefore, it is more secure to accept the non-secure pattern source search.

# 12.5.7 Arithmetic Functions and Operators

## Arithmetic Operators

- +

  Description: Addition

  Example:

  ```
  openGauss=# SELECT 2+3 AS RESULT;
   result
  --------
       5
  (1 row)
  ```

- -

  Description: Subtraction

  Example:

  ```
  openGauss=# SELECT 2-3 AS RESULT;
   result
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
--------
    -1
(1 row)
```

- *

  Description: Multiplication

  Example:

  ```
  openGauss=# SELECT 2*3 AS RESULT;
   result
  --------
       6
  (1 row)
  ```

- /

  Description: Division (The result is not rounded.)

  Example:

  ```
  openGauss=# SELECT 4/2 AS RESULT;
   result
  --------
       2
  (1 row)
  openGauss=# SELECT 4/3 AS RESULT;
        result
  ------------------
   1.33333333333333
  (1 row)
  ```

- +/-

  Description: Positive/Negative

  Example:

  ```
  openGauss=# SELECT -2 AS RESULT;
   result
  --------
      -2
  (1 row)
  ```

- %

  Description: Model (to obtain the remainder)

  Example:

  ```
  openGauss=# SELECT 5%4 AS RESULT;
   result
  --------
       1
  (1 row)
  ```

- @

  Description: Absolute value

  Example:

  ```
  openGauss=# SELECT @ -5.0 AS RESULT;
   result
  --------
     5.0
  (1 row)
  ```

- ^

  Description: Power (exponent calculation)

  Example:

  ```
  openGauss=# SELECT 2.0^3.0 AS RESULT;
         result
  --------------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 8.0000000000000000
(1 row)
```

- |/

  Description: Square root

  Example:

```
openGauss=# SELECT |/ 25.0 AS RESULT;
 result
--------
      5
(1 row)
```

- ||/

  Description: Cubic root

  Example:

```
openGauss=# SELECT ||/ 27.0 AS RESULT;
 result
--------
      3
(1 row)
```

- !

  Description: Factorial

  Example:

```
openGauss=# SELECT 5! AS RESULT;
 result
--------
    120
(1 row)
```

- !!

  Description: Factorial (prefix operator)

  Example:

```
openGauss=# SELECT !!5 AS RESULT;
 result
--------
    120
(1 row)
```

- &

  Description: Binary AND

  Example:

```
openGauss=# SELECT 91&15  AS RESULT;
 result
--------
     11
(1 row)
```

- |

  Description: Binary OR

  Example:

```
openGauss=# SELECT 32|3  AS RESULT;
 result
--------
     35
(1 row)
```

- #

  Description: Binary XOR

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT 17#5  AS RESULT;
 result
--------
     20
(1 row)
```

- ~

  Description: Binary NOT

  Example:

```
openGauss=# SELECT ~1 AS RESULT;
 result
--------
     -2
(1 row)
```

- <<

  Description: Binary shift left

  Example:

```
openGauss=# SELECT 1<<4 AS RESULT;
 result
--------
     16
(1 row)
```

- >>

  Description: Binary shift right

  Example:

```
openGauss=# SELECT 8>>2 AS RESULT;
 result
--------
      2
(1 row)
```

## Arithmetic Functions

- abs(x)

  Description: Absolute value

  Return type: same as the input

  Example:

```
openGauss=# SELECT abs(-17.4);
 abs
------
 17.4
(1 row)
```

- acos(x)

  Description: Arc cosine

  Return type: double precision

  Example:

```
openGauss=# SELECT acos(-1);
       acos
------------------
 3.14159265358979
(1 row)
```

- asin(x)

  Description: Arc sine

  Return type: double precision

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# SELECT asin(0.5);
       asin
------------------
 .523598775598299
(1 row)
```

- atan(x)

  Description: Arc tangent

  Return type: double precision

  Example:

  ```
  openGauss=# SELECT atan(1);
        atan
  ------------------
   .785398163397448
  (1 row)
  ```

- atan2(y, x)

  Description: Arc tangent of y/x

  Return type: double precision

  Example:

  ```
  openGauss=# SELECT atan2(2, 1);
       atan2
  ------------------
   1.10714871779409
  (1 row)
  ```

- bitand(integer, integer)

  Description: Performs AND (&) operation on two integers.

  Return type: bigint

  Example:

  ```
  openGauss=# SELECT bitand(127, 63);
   bitand
  --------
      63
  (1 row)
  ```

- cbrt(dp)

  Description: Cubic root

  Return type: double precision

  Example:

  ```
  openGauss=# SELECT cbrt(27.0);
   cbrt
  ------
     3
  (1 row)
  ```

- ceil(x)

  Description: Minimum integer greater than or equal to the parameter

  Return type: integer

  Example:

  ```
  openGauss=# SELECT ceil(-42.8);
   ceil
  ------
    -42
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- ceiling(dp or numeric)

  Description: Minimum integer (alias of ceil) greater than or equal to the parameter

  Return type: same as the input

  Example:

```
openGauss=# SELECT ceiling(-95.3);
 ceiling
---------
     -95
(1 row)
```

- cos(x)

  Description: Cosine

  Return type: double precision

  Example:

```
openGauss=# SELECT cos(-3.1415927);
        cos
--------------------
 -.999999999999999
(1 row)
```

- cot(x)

  Description: Cotangent

  Return type: double precision

  Example:

```
openGauss=# SELECT cot(1);
       cot
------------------
 .642092615934331
(1 row)
```

- degrees(dp)

  Description: Converts radians to angles.

  Return type: double precision

  Example:

```
openGauss=# SELECT degrees(0.5);
     degrees
------------------
 28.6478897565412
(1 row)
```

- div(y numeric, x numeric)

  Description: Integer part of y/x

  Return type: numeric

  Example:

```
openGauss=# SELECT div(9,4);
 div
-----
   2
(1 row)
```

- exp(x)

  Description: Natural exponent

  Return type: same as the input

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT exp(1.0);
        exp
--------------------
 2.7182818284590452
(1 row)
```

- floor(x)

  Description: Not larger than the maximum integer of the parameter

  Return type: same as the input

  Example:

```
openGauss=# SELECT floor(-42.8);
 floor
-------
   -43
(1 row)
```

- int1(in)

  Description: Converts the input text parameter to a value of the int1 type and returns the value.

  Return type: int1

  Example:

```
openGauss=# select int1('123');
 int1
------
 123
(1 row)
openGauss=# select int1('a');
 int1
------
   0
(1 row)
```

- int2(in)

  Description: Converts the input parameter to a value of the int2 type and returns the value. The supported input parameter types include bigint, float4, float8, int16, integer, numeric, real, and text.

  Return type: int2

  Example:

```
openGauss=# select int2('1234');
 int2
------
 1234
(1 row)
openGauss=# select int2(25.3);
 int2
------
   25
(1 row)
```

- int4(in)

  Description: Converts the input parameter to a value of the int4 type and returns the value. The supported input parameter types include bit, boolean, char, double precision, int16, numeric, real, smallint, and text

  Return type: int4

  Example:

```
openGauss=# select int4('789');
 int4
------
 789
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
(1 row)
openGauss=# select int4(99.9);
 int4
------
   99
(1 row)
```

- int8(in)

  Description: Converts the input parameter to a value of the int8 type and returns the value. The supported input parameter types include bit, double precision, int16, integer, numeric, oid, real, smallint, and text.

  Return type: int8

  Example:

```
openGauss=# select int8('789');
 int8
------
 789
(1 row)
openGauss=# select int8(99.9);
 int8
------
   99
(1 row)
```

- float4(in)

  Description: Converts the input parameter to a value of the float4 type and returns the value. The supported input parameter types include bigint, double precision, int16, integer, numeric, smallint, and text.

  Return type: float4

  Example:

```
openGauss=# select float4('789');
 float4
--------
    789
(1 row)

openGauss=# select float4(99.9);
 float4
--------
   99.9
(1 row)
```

- float8(in)

  Description: Converts the input parameter to a value of the float8 type and returns the value. The supported input parameter types include bigint, int16, integer, numeric, real, smallint, and text.

  Return type: float8

  Example:

```
openGauss=# select float8('789');
 float8
--------
    789
(1 row)

openGauss=# select float8(99.9);
 float8
--------
   99.9
(1 row)
```

- int16(in)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Converts the input parameter to a value of the int16 type and returns the value. The supported input parameter types include bigint, boolean, double precision, integer, numeric, oid, real, smallint, and tinyint.

Return type: int16

Example:

```
openGauss=# select int16('789');
 int16
--------
    789
(1 row)

openGauss=# select int16(99.9);
 int16
--------
   99
(1 row)
```

- numeric(in)

  Description: Converts the input parameter to a value of the numeric type and returns the value. The supported input parameter types include bigint, boolean, double precision, int16, integer, money, real, and smallint.

  Return type: numeric

  Example:

  ```
  openGauss=# select "numeric"('789');
   numeric
  ---------
      789
  (1 row)

  openGauss=# select "numeric"(99.9);
   numeric
  ---------
    99.9
  (1 row)
  ```

- oid(in)

  Description: Converts the input parameter to a value of the oid type and returns the value. The supported input parameter types include bigint and int16.

  Return type: oid

- radians(dp)

  Description: Converts angles to radians.

  Return type: double precision

  Example:

  ```
  openGauss=# SELECT radians(45.0);
      radians
  ------------------
   .785398163397448
  (1 row)
  ```

- random()

  Description: Random number between 0.0 and 1.0

  Return type: double precision

  Example:

  ```
  openGauss=# SELECT random();
       random
  ------------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 .824823560658842
(1 row)
```

- multiply(x double precision or text, y double precision or text)

  Description: product of x and y.

  Return type: double precision

  Example:

```
openGauss=# SELECT multiply(9.0, '3.0');
    multiply
-------------------
              27
(1 row)
openGauss=# SELECT multiply('9.0', 3.0);
    multiply
-------------------
              27
(1 row)
```

- ln(x)

  Description: Natural logarithm

  Return type: same as the input

  Example:

```
openGauss=# SELECT ln(2.0);
        ln
-------------------
 .6931471805599453
(1 row)
```

- log(x)

  Description: Logarithm with 10 as the base

  Return type: same as the input

  Example:

```
openGauss=# SELECT log(100.0);
        log
--------------------
 2.0000000000000000
(1 row)
```

- log(b numeric, x numeric)

  Description: Logarithm with b as the base

  Return type: numeric

  Example:

```
openGauss=# SELECT log(2.0, 64.0);
        log
--------------------
 6.0000000000000000
(1 row)
```

- mod(x,y)

  Description:

  Remainder of x/y (model)

  If x equals to 0, y is returned.

  Return type: same as the parameter type

  Example:

```
openGauss=# SELECT mod(9,4);
 mod
-----
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
  1
(1 row)
openGauss=# SELECT mod(9,0);
 mod
-----
   9
(1 row)
```

- pi()

  Description: π constant value

  Return type: double precision

  Example:

```
openGauss=# SELECT pi();
        pi
------------------
 3.14159265358979
(1 row)
```

- power(a double precision, b double precision)

  Description: b power of a

  Return type: double precision

  Example:

```
openGauss=# SELECT power(9.0, 3.0);
        power
----------------------
 729.0000000000000000
(1 row)
```

- round(x)

  Description: Integer closest to the input parameter

  Return type: same as the input

  Example:

```
openGauss=# SELECT round(42.4);
 round
-------
    42
(1 row)

openGauss=# SELECT round(42.6);
 round
-------
    43
(1 row)
```

- round(v numeric, s int)

  Description: **s** digits are kept after the decimal point.

  Return type: numeric

  Example:

```
openGauss=# SELECT round(42.4382, 2);
 round
-------
 42.44
(1 row)
```

- setseed(dp)

  Description: Sets seed for the following random() invoking (between –1.0 and 1.0, inclusive).

  Return type: void

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT setseed(0.54823);
 setseed
---------

(1 row)
```

- sign(x)

  Description: Returns symbols of this parameter.

  Return type: **–1** indicates negative numbers. **0** indicates 0, and **1** indicates positive numbers.

  Example:

```
openGauss=# SELECT sign(-8.4);
 sign
------
   -1
(1 row)
```

- sin(x)

  Description: Sine

  Return type: double precision

  Example:

```
openGauss=# SELECT sin(1.57079);
       sin
------------------
 .999999999979986
(1 row)
```

- sqrt(x)

  Description: Square root

  Return type: same as the input

  Example:

```
openGauss=# SELECT sqrt(2.0);
       sqrt
-------------------
 1.414213562373095
(1 row)
```

- tan(x)

  Description: Tangent

  Return type: double precision

  Example:

```
openGauss=# SELECT tan(20);
       tan
------------------
 2.23716094422474
(1 row)
```

- trunc(x)

  Description: Truncates (the integral part).

  Return type: same as the input

  Example:

```
openGauss=# SELECT trunc(42.8);
 trunc
-------
    42
(1 row)
```

- trunc(v numeric, s int)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Truncates a number with **s** digits after the decimal point.

Return type: numeric

Example:

```
openGauss=# SELECT trunc(42.4382, 2);
 trunc
-------
 42.43
(1 row)
```

- width_bucket(op numeric, b1 numeric, b2 numeric, count int)

  Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.

  Return type: int

  Example:

  ```
  openGauss=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
   width_bucket
  --------------
             3
  (1 row)
  ```

- width_bucket(op dp, b1 dp, b2 dp, count int)

  Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.

  Return type: int

  Example:

  ```
  openGauss=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
   width_bucket
  --------------
             3
  (1 row)
  ```

- int1abs

  Description: Returns the absolute value of data of the uint8 type.

  Parameter: tinyint

  Return type: tinyint

- int1and

  Description: Returns the bitwise AND result of two data records of the uint8 type.

  Parameter: tinyint, tinyint

  Return type: tinyint

- int1cmp

  Description: Returns the comparison result of two data records of the uint8 type. If the value of the first parameter is greater, **1** is returned. If the value of the second parameter is greater, **–1** is returned. If they are the same, **0** is returned.

  Parameter: tinyint, tinyint

  Return type: integer

- int1div

  Description: Returns the result of dividing two data records of the uint8 type. The result is of the float8 type.

  Parameter: tinyint, tinyint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: tinyint

- int1eq

  Description: Compares two pieces of data of the uint8 type to check whether they are the same.

  Parameter: tinyint, tinyint

  Return type: Boolean

- int1ge

  Description: Determines whether the value of the first parameter is greater than or equal to the value of the second parameter in two data records of the uint8 type.

  Parameter: tinyint, tinyint

  Return type: Boolean

- int1gt

  Description: Performs the greater-than operation on an unsigned 1-byte integer.

  Parameter: tinyint, tinyint

  Return type: Boolean

- int1larger

  Description: Returns the larger value of unsigned one-byte integers.

  Parameter: tinyint, tinyint

  Return type: tinyint

- int1le

  Description: Determines whether the unsigned 1-byte integer is less than or equal to.

  Parameter: tinyint, tinyint

  Return type: Boolean

- int1lt

  Description: Determines whether the unsigned 1-byte integer is less than.

  Parameter: tinyint, tinyint

  Return type: Boolean

- int1smaller

  Description: Returns the smaller of two unsigned one-byte integers.

  Parameter: tinyint, tinyint

  Return type: tinyint

- int1inc

  Description: Performs an addition operation on an unsigned 1-byte integer.

  Parameter: tinyint

  Return type: tinyint

- int1mi

  Description: Performs a minus operation on an unsigned 1-byte integer.

  Parameter: tinyint, tinyint

  Return type: tinyint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- int1mod

  Description: Performs a reminder operation on an unsigned 1-byte integer.

  Parameter: tinyint, tinyint

  Return type: tinyint

- int1mul

  Description: Performs a multiplication operation on an unsigned 1-byte integer.

  Parameter: tinyint, tinyint

  Return type: tinyint

- int1ne

  Description: Performs a not-equal-to operation on an unsigned 1-byte integer.

  Parameter: tinyint, tinyint

  Return type: Boolean

- int1pl

  Description: Performs an addition operation on an unsigned 1-byte integer.

  Parameter: tinyint, tinyint

  Return type: tinyint

- int1um

  Description: Returns an unsigned 2-byte integer after subtracting the opposite number from the unsigned 1-byte integer.

  Parameter: tinyint

  Return type: smallint

- int1xor

  Description: Performs an exclusive OR operation on an unsigned 1-byte integer.

  Parameter: tinyint, tinyint

  Return type: tinyint

- cash_div_int1

  Description: Performs a division operation on the money type.

  Parameter: money, tinyint

  Return type: money

- cash_mul_int1

  Description: Performs a multiplication operation on the money type.

  Parameter: money, tinyint

  Return type: money

- int1not

  Description: Reverts binary bits of an unsigned 1-byte integer.

  Parameter: tinyint

  Return type: tinyint

- int1or

  Description: Performs an OR operation on an unsigned 1-byte integer.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Parameter: tinyint, tinyint

Return type: tinyint

- int1shl

  Description: Shifts an unsigned 1-byte integer leftwards by a specified number of bits.

  Parameter: tinyint, integer

  Return type: tinyint

- int1shr

  Description: Shifts an unsigned 1-byte integer rightwards by a specified number of bits.

  Parameter: tinyint, integer

  Return type: tinyint

# 12.5.8 Date and Time Processing Functions and Operators

## Date and Time Operators

**WARNING**

When the user uses date and time operators, explicit type prefixes are modified for corresponding operands to ensure that the operands parsed by the database are consistent with what the user expects, and no unexpected results occur.

For example, abnormal mistakes will occur in the following example without an explicit data type.

```
SELECT date '2001-10-01' - '7' AS RESULT;
```

**Table 12-30** Time and date operators

| Operator | Example |
| --- | --- |
| + | openGauss=# SELECT date '2001-9-28' + integer '7' AS RESULT;<br>  result<br>------------<br> 2001-10-05<br>(1 row) |
| | openGauss=# SELECT date '2001-09-28' + interval '1 hour' AS RESULT;<br>  result<br>---------------------<br> 2001-09-28 01:00:00<br>(1 row) |

## Time and Date Functions

- age(timestamp, timestamp)

  Description: Subtracts parameters, producing a result in YYYY-MM-DD format. If the result is negative, the returned result is also negative. The input parameters can contain timezone or not.

  Return type: interval

  Example:

  ```
  openGauss=# SELECT age(timestamp '2001-04-10', timestamp '1957-06-13');
           age
  --------------------------
   43 years 9 mons 27 days
  (1 row)
  ```

- age(timestamp)

  Description: Minuses the current time with the parameter. The input parameter can contain timezone or not.

  Return type: interval

  Example:

  ```
  openGauss=# SELECT age(timestamp '1957-06-13');
           age
  --------------------------
   60 years 2 mons 18 days
  (1 row)
  ```

- clock_timestamp()

  Description: Specifies the current timestamp of the real-time clock. The volatile function obtains the latest timestamp for each scan. Therefore, the result of each call in a query is different.

  Return type: timestamp with time zone

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# SELECT clock_timestamp();
       clock_timestamp
-------------------------------
 2017-09-01 16:57:36.636205+08
(1 row)
```

- current_date

  Description: Specifies the current date.

  Return type: date

  Example:

  ```
  openGauss=# SELECT current_date;
     date
  ------------
   2017-09-01
  (1 row)
  ```

- current_time

  Description: Specifies the current time.

  Return type: time with time zone

  Example:

  ```
  openGauss=# SELECT current_time;
       timetz
  --------------------
   16:58:07.086215+08
  (1 row)
  ```

- current_timestamp

  Description: Specifies the current date and time. This is a statement-level timestamp. The returned results within the same statement remain unchanged.

  Return type: timestamp with time zone

  Example:

  ```
  openGauss=# SELECT current_timestamp;
       pg_systimestamp
  -------------------------------
   2017-09-01 16:58:19.22173+08
  (1 row)
  ```

- date_part(text, timestamp)

  Description:

  Retrieves subcolumns such as year or hour from date/time values.

  It is equivalent to **extract(field from timestamp)**.

  Timestamp types: abstime, date, interval, reltime, time with time zone, time without time zone, timestamp with time zone, timestamp without time zone

  Return type: double precision

  Example:

  ```
  openGauss=# SELECT date_part('hour', timestamp '2001-02-16 20:38:40');
   date_part
  -----------
          20
  (1 row)
  ```

- date_part(text, interval)

  Description: Obtains the month. If the value is greater than 12, obtain the remainder after it is divided by 12. It is equivalent to **extract(field from timestamp)**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: double precision

Example:

```
openGauss=# SELECT date_part('month', interval '2 years 3 months');
 date_part
-----------
         3
(1 row)
```

- date_trunc(text, timestamp)

  Description: Truncates to the precision specified by **text**.

  Return type: interval, timestamp with time zone, timestamp without time zone

  Example:

```
openGauss=# SELECT date_trunc('hour', timestamp  '2001-02-16 20:38:40');
     date_trunc
---------------------
 2001-02-16 20:00:00
(1 row)
```

- trunc(timestamp)

  Description: Truncates to day by default.

  Example:

```
openGauss=# SELECT trunc(timestamp  '2001-02-16
20:38:40');
                        trunc
---------------------
2001-02-16 00:00:00
(1 row)
```

- trunc(arg1, arg2)

  Description: Truncates to the precision specified by **arg2**.

  Type of **arg1**: interval, timestamp with time zone, timestamp without time zone

  Type of **arg2**: text

  Return type: interval, timestamp with time zone, timestamp without time zone

  Example:

```
openGauss=# SELECT trunc(timestamp  '2001-02-16 20:38:40',
'hour');
                     trunc
---------------------
2001-02-16 20:00:00
(1 row)
```

- daterange(arg1, arg2)

  Description: Obtains time boundary information.

  **arg1** type: date

  **arg2** type: date

  Return type: daterange

  Example:

```
openGauss=# select daterange('2000-05-06','2000-08-08');
       daterange
-------------------------
 [2000-05-06,2000-08-08)
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- daterange(arg1, arg2, text)

  Description: Obtains time boundary information.

  **arg1** type: date

  **arg2** type: date

  **text** type: text

  Return type: daterange

  Example:

```
openGauss=# select daterange('2000-05-06','2000-08-08','[]');
       daterange
-------------------------
 [2000-05-06,2000-08-09)
(1 row)
```

- extract(field from timestamp)

  Description: Obtains the hour.

  Return type: double precision

  Example:

```
openGauss=# SELECT extract(hour from timestamp '2001-02-16 20:38:40');
 date_part
-----------
        20
(1 row)
```

- extract(field from interval)

  Description: Obtains the month. If the value is greater than 12, obtain the remainder after it is divided by 12.

  Return type: double precision

  Example:

```
openGauss=# SELECT extract(month from interval '2 years 3 months');
 date_part
-----------
         3
(1 row)
```

- isfinite(date)

  Description: Tests for a valid date.

  Return type: Boolean

  Example:

```
openGauss=# SELECT isfinite(date '2001-02-16');
 isfinite
----------
 t
(1 row)
```

- isfinite(timestamp)

  Description: Tests for a valid timestamp.

  Return type: Boolean

  Example:

```
openGauss=# SELECT isfinite(timestamp '2001-02-16 21:28:30');
 isfinite
----------
 t
(1 row)
```

- isfinite(interval)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Tests for a valid interval.

Return type: Boolean

Example:

```
openGauss=# SELECT isfinite(interval '4 hours');
 isfinite
----------
 t
(1 row)
```

- justify_days(interval)

  Description: Adjusts intervals to 30-day time periods, which are represented as months.

  Return type: interval

  Example:

  ```
  openGauss=# SELECT justify_days(interval '35 days');
   justify_days
  --------------
   1 mon 5 days
  (1 row)
  ```

- justify_hours(interval)

  Description: Sets the time interval in days (24 hours is one day).

  Return type: interval

  Example:

  ```
  openGauss=# SELECT JUSTIFY_HOURS(INTERVAL '27 HOURS');
   justify_hours
  ----------------
   1 day 03:00:00
  (1 row)
  ```

- justify_interval(interval)

  Description: Adjusts **interval** using **justify_days** and **justify_hours**.

  Return type: interval

  Example:

  ```
  openGauss=# SELECT JUSTIFY_INTERVAL(INTERVAL '1 MON -1 HOUR');
   justify_interval
  ------------------
   29 days 23:00:00
  (1 row)
  ```

- localtime

  Description: Specifies the current time.

  Return type: time

  Example:

  ```
  openGauss=# SELECT localtime AS RESULT;
      result
  ----------------
   16:05:55.664681
  (1 row)
  ```

- localtimestamp

  Description: Specifies the current date and time.

  Return type: timestamp

  Example:

  ```
  openGauss=# SELECT localtimestamp;
          timestamp
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
----------------------------
 2017-09-01 17:03:30.781902
(1 row)
```

- now()

  Description: Specifies the current date and time. This is a transaction-level timestamp. The results returned within the same transaction remain unchanged.

  Return type: timestamp with time zone

  Example:

```
openGauss=# SELECT now();
              now
-------------------------------
 2017-09-01 17:03:42.549426+08
(1 row)
```

- timenow()

  Description: Specifies the current date and time.

  Return type: timestamp with time zone

  Example:

```
openGauss=# select timenow();
       timenow
------------------------
 2020-06-23 20:36:56+08
(1 row)
```

- numtodsinterval(num, interval_unit)

  Description: Converts a number to the interval type. **num** is a numeric-typed number. **interval_unit** is a string in the following format: 'DAY' | 'HOUR' | 'MINUTE' | 'SECOND'

  You can set the **IntervalStyle** parameter to **oracle** to be compatible with the interval output format of the function in the Oracle database.

  Example:

```
openGauss=# SELECT numtodsinterval(100, 'HOUR');
 numtodsinterval
-----------------
 100:00:00
(1 row)

openGauss=# SET intervalstyle = oracle;
SET
openGauss=# SELECT numtodsinterval(100, 'HOUR');
       numtodsinterval
------------------------------
 +000000004 04:00:00.000000000
(1 row)
```

- pg_sleep(seconds)

  Description: Specifies the delay time of the server thread in unit of second. Note that when the database invokes this function, the corresponding transaction snapshot is obtained, which is equivalent to a long transaction. If the input parameter time is too long, the database **oldestxmin** may fail to be executed, affecting the table recycling and query performance.

  Return type: void

  Example:

```
openGauss=# SELECT pg_sleep(10);
 pg_sleep
----------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
(1 row)
```

- statement_timestamp()

  Description: Specifies the current date and time.

  Return type: timestamp with time zone

  Example:

  ```
  openGauss=# SELECT statement_timestamp();
       statement_timestamp
  -------------------------------
   2017-09-01 17:04:39.119267+08
  (1 row)
  ```

- sysdate

  Description: Specifies the current date and time.

  Return type: timestamp

  Example:

  ```
  openGauss=# SELECT sysdate;
        sysdate
  ---------------------
   2017-09-01 17:04:49
  (1 row)
  ```

- timeofday()

  Description: Specifies the current date and time (like **clock_timestamp**, but returned as a **text** string)

  Return type: text

  Example:

  ```
  openGauss=# SELECT timeofday();
               timeofday
  -------------------------------------
   Fri Sep 01 17:05:01.167506 2017 CST
  (1 row)
  ```

- transaction_timestamp()

  Description: Specifies the current date and time (equivalent to **current_timestamp**)

  Return type: timestamp with time zone

  Example:

  ```
  openGauss=# SELECT transaction_timestamp();
      transaction_timestamp
  -------------------------------
   2017-09-01 17:05:13.534454+08
  (1 row)
  ```

- add_months(d,n)

  Description: Returns the date *date* plus *integer* months.

  **d**: indicates the value of the timestamp type and the value that can be implicitly converted to the timestamp type.

  **n**: indicates the value of the INTEGER type and the value that can be implicitly converted to the INTEGER type.

  Return type: timestamp

  Example:

  ```
  openGauss=# SELECT add_months(to_date('2017-5-29', 'yyyy-mm-dd'), 11) FROM sys_dummy;
      add_months
  ---------------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 2018-04-29 00:00:00
(1 row)
```

- last_day(d)

  Description: Returns the date of the last day of the month that contains *date*.

  Return type: timestamp

  Example:

  ```
  openGauss=# select last_day(to_date('2017-01-01', 'YYYY-MM-DD')) AS cal_result;
      cal_result
  ---------------------
   2017-01-31 00:00:00
  (1 row)
  ```

- next_day(x,y)

  Description: Calculates the time of the next week y started from x.

  Return type: timestamp

  Example:

  ```
  openGauss=# select next_day(timestamp '2017-05-25 00:00:00','Sunday')AS cal_result;
      cal_result
  ---------------------
   2017-05-28 00:00:00
  (1 row)
  ```

- tinterval(abstime, abstime)

  Description: Creates a time interval with two pieces of absolute time.

  Return type: tinterval

  Example:

  ```
  openGauss=# call tinterval(abstime 'May 10, 1947 23:59:12', abstime 'Mon May  1 00:30:30 1995');
                       tinterval
  ------------------------------------------------------
   ["1947-05-10 23:59:12+08" "1995-05-01 00:30:30+08"]
  (1 row)
  ```

- tintervalend(tinterval)

  Description: Returns the end time of tinterval.

  Return type: abstime

  Example:

  ```
  openGauss=# select tintervalend('["Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"]');
       tintervalend
  ------------------------
   1983-10-04 23:59:12+08
  (1 row)
  ```

- tintervalrel(tinterval)

  Description: Calculates and returns the relative time of **tinterval**.

  Return type: reltime

  Example:

  ```
  openGauss=# select tintervalrel('["Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"]');
   tintervalrel
  --------------
   1 mon
  (1 row)
  ```

- smalldatetime_ge

  Description: Determines whether the first parameter is greater than the second.

  Parameter: smalldatetime, smalldatetime

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: Boolean

- smalldatetime_cmp

  Description: Compares two smalldatetime values to check whether they are the same.

  Parameter: smalldatetime, smalldatetime

  Return type: integer

- smalldatetime_eq

  Description: Compares two smalldatetime values to check whether they are the same.

  Parameter: smalldatetime, smalldatetime

  Return type: Boolean

- smalldatetime_gt

  Description: Determines whether the first parameter is less than the second parameter.

  Parameter: smalldatetime, smalldatetime

  Return type: Boolean

- smalldatetime_hash

  Description: Calculates the hash value corresponding to a timestamp.

  Parameter: smalldatetime

  Return type: integer

- smalldatetime_in

  Description: Inputs a timestamp.

  Parameter: cstring, oid, integer

  Return type: smalldatetime

- smalldatetime_larger

  Description: Returns a larger timestamp.

  Parameter: smalldatetime, smalldatetime

  Return type: smalldatetime

- smalldatetime_le

  Description: Determines whether the first parameter is less than the second parameter.

  Parameter: smalldatetime, smalldatetime

  Return type: Boolean

- smalldatetime_lt

  Description: Determines whether the first parameter is greater than the second.

  Parameter: smalldatetime, smalldatetime

  Return type: Boolean

- smalldatetime_ne

  Description: Compares two timestamps to check whether they are different.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Parameter: smalldatetime, smalldatetime
Return type: Boolean

- smalldatetime_out
  Description: Converts a timestamp into the external form.
  Parameter: smalldatetime
  Return type: cstring
- smalldatetime_send
  Description: Converts a timestamp to the binary format.
  Parameter: smalldatetime
  Return type: bytea
- smalldatetime_smaller
  Description: Returns a smaller smalldatetime.
  Parameter: smalldatetime, smalldatetime
  Return type: smalldatetime
- smalldatetime_to_abstime
  Description: Converts smalldatetime to abstime.
  Parameter: smalldatetime
  Return type: abstime
- smalldatetime_to_time
  Description: Converts smalldatetime to time.
  Parameter: smalldatetime
  Return type: time without time zone
- smalldatetime_to_timestamp
  Description: Converts smalldatetime to timestamp.
  Parameter: smalldatetime
  Return type: timestamp without time zone
- smalldatetime_to_timestamptz
  Description: Converts smalldatetime to timestamptz.
  Parameter: smalldatetime
  Return type: timestamp with time zone
- smalldatetime_to_varchar2
  Description: Converts smalldatetime to varchar2.
  Parameter: smalldatetime
  Return type: character varying

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

There are multiple methods for obtaining the current time. Select an appropriate API based on the actual service scenario.

(1) The following APIs return values based on the start time of the current transaction:

```
CURRENT_DATE CURRENT_TIME CURRENT_TIME(precision) CURRENT_TIMESTAMP(precision)
LOCALTIME LOCALTIMESTAMP LOCALTIME(precision) LOCALTIMESTAMP(precision)
```

The values transferred by **CURRENT_TIME** and **CURRENT_TIMESTAMP(precision)** contain time zone information. The values transferred by **LOCALTIME** and **LOCALTIMESTAMP** do not contain time zone information. **CURRENT_TIME**, **LOCALTIME**, and **LOCALTIMESTAMP** can be optionally attached with a precision parameter, which rounds the second field of the result to the specified decimal place. If there is no precision parameter, the result is given the full precision that can be obtained.

Because these functions all return results by the start time of the current transaction, their values do not change throughout the transaction. We think this is a feature with the purpose to allow a transaction to have a consistent concept at the "current" time, so that multiple modifications in the same transaction can maintain the same timestamp.

(2) The following APIs return the start time of the current statement:

```
transaction_timestamp() statement_timestamp() now()
```

**transaction_timestamp()** is equivalent to **CURRENT_TIMESTAMP(precision)**, and its name clearly reflects its return value. **statement_timestamp()** returns the start time of the current statement (more accurately, the time when the last instruction is received from the client). The return values of **statement_timestamp()** and **transaction_timestamp()** are the same during the execution of the first instruction of a transaction, but may be different in subsequent commands.

**now()** is equivalent to **transaction_timestamp()**.

(3) The following APIs return the actual "current" time when the function is called:

```
clock_timestamp() timeofday()
```

**clock_timestamp()** returns the actual current time, and its value changes even in the same SQL command. Similar to **clock_timestamp()**, **timeofday()** also returns the actual current time. However, the result of **timeofday()** is a formatted text string instead of a timestamp with time zone information.

**Table 12-31** shows the templates for truncating date/time values.

**Table 12-31** Truncating date/time values

| Item | Format | Description |
| --- | --- | --- |
| Microsecond | MICROSECON | Truncates date/time values, accurate to the microsecond (000000–999999). |
| | US | |
| | USEC | |
| | USECOND | |
| Millisecond | MILLISECON | Truncates date/time values, accurate to the millisecond (000–999). |
| | MS | |
| | MSEC | |
| | MSECOND | |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Item | Format | Description |
| --- | --- | --- |
| Second | S | Truncates date/time values, accurate to the second (00–59). |
| | SEC | |
| | SECOND | |
| Minute | M | Truncates date/time values, accurate to the minute (00–59). |
| | MI | |
| | MIN | |
| | MINUTE | |
| Hour | H | Truncates date/time values, accurate to the hour (00–23). |
| | HH | |
| | HOUR | |
| | HR | |
| Day | D | Truncates date/time values, accurate to the day (01-01 to 12–31) |
| | DAY | |
| | DD | |
| | DDD | |
| | J | |
| Week | W | Truncates date/time values, accurate to the week (the first day of the current week). |
| | WEEK | |
| Month | MM | Truncates date/time values, accurate to the month (the first day of the current month). |
| | MON | |
| | MONTH | |
| Quarter | Q | Truncates date/time values, accurate to the quarter (the first day of the current quarter). |
| | QTR | |
| | QUARTER | |
| Year | Y | Truncates date/time values, accurate to the year (the first day of the current year). |
| | YEAR | |
| | YR | |
| | YYYY | |
| Decade | DEC | Truncates date/time values, accurate to the decade (the first day of the current decade). |
| | DECADE | |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Item | Format | Description |
| --- | --- | --- |
| Century | C | Truncates date/time values, accurate to the century (the first day of the current century). |
| | CC | |
| | CENT | |
| | CENTURY | |
| Millennium | MIL | Truncates date/time values, accurate to the millennium (the first day of the current millennium). |
| | MILLENNIA | |
| | MILLENNIUM | |

## TIMESTAMPDIFF

- **TIMESTAMPDIFF(***unit , timestamp_expr1, timestamp_expr2***)**

  The **timestampdiff** function returns the result of **timestamp_expr2** - **timestamp_expr1** in the specified unit. **timestamp_expr1** and **timestamp_expr2** must be value expressions of the **timestamp**, **timestamptz**, or **date** type. **unit** specifies the unit of the difference between two dates.

  NOTE

  This function is valid only when GaussDB is compatible with MySQL (that is, **dbcompatibility** is set to **'MYSQL'**).

- year

  Year.

  ```
  openGauss=# SELECT TIMESTAMPDIFF(YEAR, '2018-01-01', '2020-01-01');
   timestamp_diff
  ----------------
                2
  (1 row)
  ```

- quarter

  Quarter.

  ```
  openGauss=# SELECT TIMESTAMPDIFF(QUARTER, '2018-01-01', '2020-01-01');
   timestamp_diff
  ----------------
                8
  (1 row)
  ```

- month

  Month.

  ```

- timestamp_expr with the time zone

```
openGauss=# SELECT TIMESTAMPDIFF(HOUR,'2020-05-01 10:10:10-01','2020-05-01 10:10:10-03');
 timestamp_diff
----------------
             2
(1 row)
```

## EXTRACT

- **EXTRACT(***field* **FROM** *source***)**

  The **extract** function retrieves subcolumns such as year or hour from date/time values. **source** must be a value expression of type **timestamp**, **time**, or **interval**. (Expressions of type **date** are cast to **timestamp** and can therefore be used as well.) **field** is an identifier or string that selects what column to extract from the source value. The **extract** function returns values of type **double precision**. The following are valid **field** names:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- century

  Century.

  The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0. You go from **-1** century to **1** century.

  Example:

  ```
  openGauss=# SELECT EXTRACT(CENTURY FROM TIMESTAMP '2000-12-16 12:21:13');
   date_part
  -----------
         20
  (1 row)
  ```

- day
  - For **timestamp** values, the day (of the month) column (1–31)

    ```
    openGauss=# SELECT EXTRACT(DAY FROM TIMESTAMP '2001-02-16 20:38:40');
     date_part
    -----------
          16
    (1 row)
    ```

  - For **interval** values, the number of days

    ```
    openGauss=# SELECT EXTRACT(DAY FROM INTERVAL '40 days 1 minute');
     date_part
    -----------
          40
    (1 row)
    ```

- decade

  Year column divided by 10

  ```
  openGauss=# SELECT EXTRACT(DECADE FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
        200
  (1 row)
  ```

- dow

  Day of the week as Sunday (**0**) to Saturday (**6**)

  ```
  openGauss=# SELECT EXTRACT(DOW FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
          5
  (1 row)
  ```

- doy

  Day of the year (1–365 or 366)

  ```
  openGauss=# SELECT EXTRACT(DOY FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
        47
  (1 row)
  ```

- epoch
  - For **timestamp with time zone** values, the number of seconds since 1970-01-01 00:00:00-00 UTC (can be negative).

    For **date** and **timestamp** values, the number of seconds since 1970-01-01 00:00:00-00 local time.

    For **interval** values, the total number of seconds in the interval.

    ```
    openGauss=# SELECT EXTRACT(EPOCH FROM TIMESTAMP WITH TIME ZONE '2001-02-16
    20:38:40.12-08');
      date_part
    --------------
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 982384720.12
(1 row)
openGauss=# SELECT EXTRACT(EPOCH FROM INTERVAL '5 days 3 hours');
 date_part
-----------
    442800
(1 row)
```

  - Way to convert an epoch value back to a timestamp

```
openGauss=# SELECT TIMESTAMP WITH TIME ZONE 'epoch' + 982384720.12 * INTERVAL '1
second' AS RESULT;
          result
---------------------------
 2001-02-17 12:38:40.12+08
(1 row)
```

- hour

  Hour column (0–23)

```
openGauss=# SELECT EXTRACT(HOUR FROM TIMESTAMP '2001-02-16 20:38:40');
 date_part
-----------
        20
(1 row)
```

- isodow

  Day of the week (1–7)

  Monday is 1 and Sunday is 7.

  **NOTE**

  This is identical to **dow** except for Sunday.

```
openGauss=# SELECT EXTRACT(ISODOW FROM TIMESTAMP '2001-02-18 20:38:40');
 date_part
-----------
         7
(1 row)
```

- isoyear

  The ISO 8601 year that the date falls in (not applicable to intervals).

  Each ISO year begins with the Monday of the week containing January 4, so in early January or late December the ISO year may be different from the Gregorian year. See the **week** column for more information.

```
openGauss=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
 date_part
-----------
      2005
(1 row)
openGauss=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
 date_part
-----------
      2006
(1 row)
```

- microseconds

  The seconds column, including fractional parts, is multiplied by 1,000,000.

```
openGauss=# SELECT EXTRACT(MICROSECONDS FROM TIME '17:12:28.5');
 date_part
-----------
  28500000
(1 row)
```

- millennium

  Millennium.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Years in the 1900s are in the second millennium. The third millennium started from January 1, 2001.

```
openGauss=# SELECT EXTRACT(MILLENNIUM FROM TIMESTAMP '2001-02-16 20:38:40');
 date_part
-----------
         3
(1 row)
```

- milliseconds

  Seconds column, including fractional parts, is multiplied by 1000. Note that this includes full seconds.

```
openGauss=# SELECT EXTRACT(MILLISECONDS FROM TIME '17:12:28.5');
 date_part
-----------
     28500
(1 row)
```

- minute

  Minutes column (0–59).

```
openGauss=# SELECT EXTRACT(MINUTE FROM TIMESTAMP '2001-02-16 20:38:40');
 date_part
-----------
        38
(1 row)
```

- month

  For **timestamp** values, the specific month in the year (1–12).

```
openGauss=# SELECT EXTRACT(MONTH FROM TIMESTAMP '2001-02-16 20:38:40');
 date_part
-----------
         2
(1 row)
```

  For **interval** values, the number of months, modulo 12 (0–11).

```
openGauss=# SELECT EXTRACT(MONTH FROM INTERVAL '2 years 13 months');
 date_part
-----------
         1
(1 row)
```

- quarter

  Quarter of the year (1–4) that the date is in.

```
openGauss=# SELECT EXTRACT(QUARTER FROM TIMESTAMP '2001-02-16 20:38:40');
 date_part
-----------
         1
(1 row)
```

- second

  Seconds column, including fractional parts (0–59).

```
openGauss=# SELECT EXTRACT(SECOND FROM TIME '17:12:28.5');
 date_part
-----------
      28.5
(1 row)
```

- timezone

  Time zone offset from UTC, measured in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.

- timezone_hour

  Hour component of the time zone offset.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- timezone_minute

  Minute component of the time zone offset.

- week

  Number of the week of the year that the day is in. By definition (ISO 8601), the first week of a year contains January 4 of that year. (The ISO-8601 week starts on Monday.) In other words, the first Thursday of a year is in week 1 of that year.

  Because of this, it is possible for early January dates to be part of the 52nd or 53rd week of the previous year, and late December dates to be part of the 1st week of the next year. For example, **2005-01-01** is part of the 53rd week of year 2004, **2006-01-01** is part of the 52nd week of year 2005, and **2012-12-31** is part of the 1st week of year 2013. You are advised to use the columns **isoyear** and **week** together to ensure consistency.

  ```
  openGauss=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
           7
  (1 row)
  ```

- year

  Year column.

  ```
  openGauss=# SELECT EXTRACT(YEAR FROM TIMESTAMP '2001-02-16 20:38:40');
   date_part
  -----------
        2001
  (1 row)
  ```

## date_part

The **date_part** function is modeled on the traditional Ingres equivalent to the SQL-standard function **extract**:

**date_part('***field***',** *source***)**

Note that here the **field** parameter needs to be a string value, not a name. The valid field names for **date_part** are the same as for **extract**. For details, see **EXTRACT**.

Example:

```
openGauss=# SELECT date_part('day', TIMESTAMP '2001-02-16 20:38:40');
 date_part
-----------
          16
(1 row)
openGauss=# SELECT date_part('hour', INTERVAL '4 hours 3 minutes');
 date_part
-----------
           4
(1 row)
```

**Table 12-32** specifies the schema for formatting date and time values.

**Table 12-32** Schema for formatting date and time

| Category | Format | Description |
| --- | --- | --- |
| Hour | HH | Number of hours in one day (01–12) |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Category | Format | Description |
| --- | --- | --- |
| | HH12 | Number of hours in one day (01–12) |
| | HH24 | Number of hours in one day (00–23) |
| Minute | MI | Minute (00–59) |
| Second | SS | Second (00–59) |
| | FF | Microsecond (000000–999999) |
| | SSSSS | Second after midnight (0–86399) |
| Morning and afternoon | AM or A.M. | Morning identifier |
| | PM or P.M. | Afternoon identifier |
| Year | Y,YYY | Year with comma (with four digits or more) |
| | SYYYY | Year with four digits BC |
| | YYYY | Year (with four digits or more) |
| | YYY | Last three digits of a year |
| | YY | Last two digits of a year |
| | Y | Last one digit of a year |
| | IYYY | ISO year (with four digits or more) |
| | IYY | Last three digits of an ISO year |
| | IY | Last two digits of an ISO year |
| | I | Last one digit of an ISO year |
| | RR | Last two digits of a year (A year of the 20th century can be stored in the 21st century.) |
| | RRRR | Capable of receiving a year with four digits or two digits. If there are 2 digits, the value is the same as the returned value of RR. If there are 4 digits, the value is the same as YYYY. |
| | • BC or B.C.<br>• AD or A.D. | Era indicator Before Christ (BC) and After Christ (AD) |
| Month | MONTH | Full spelling of a month in uppercase (9 characters are filled in if the value is empty.) |
| | MON | Month in abbreviated format in uppercase (with three characters) |
| | MM | Month (01–12) |
| | RM | Month in Roman numerals (I–XII; I=JAN) and uppercase |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Category | Format | Description |
| --- | --- | --- |
| Day | DAY | Full spelling of a date in uppercase (9 characters are filled in if the value is empty.) |
| | DY | Day in abbreviated format in uppercase (with three characters) |
| | DDD | Day in a year (001–366) |
| | DD | Day in a month (01–31) |
| | D | Day in a week (1–7). |
| Week | W | Week in a month (1–5) (The first week starts from the first day of the month.) |
| | WW | Week in a year (1–53) (The first week starts from the first day of the year.) |
| | IW | Week in an ISO year (The first Thursday is in the first week.) |
| Century | CC | Century (with two digits) (The 21st century starts from 2001-01-01.) |
| Julian date | J | Julian date (starting from January 1 of 4712 BC) |
| Quarter | Q | Quarter |

**NOTE**

In the table, the rules for RR to calculate years are as follows:

- If the range of the input two-digit year is between 00 and 49:

  If the last two digits of the current year are between 00 and 49, the first two digits of the returned year are the same as the first two digits of the current year.

  If the last two digits of the current year are between 50 and 99, the first two digits of the returned year equal to the first two digits of the current year plus 1.
- If the range of the input two-digit year is between 50 and 99:

  If the last two digits of the current year are between 00 and 49, the first two digits of the returned year equal to the first two digits of the current year minus 1.

  If the last two digits of the current year are between 50 and 99, the first two digits of the returned year are the same as the first two digits of the current year.

# 12.5.9 Type Conversion Functions

## Type Conversion Functions

- cash_words(money)

  Description: Type conversion function, which converts money into text.

  Example:

```
openGauss=# SELECT cash_words('1.23');
        cash_words
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
-----------------------------------
 One dollar and twenty three cents
(1 row)
```

- cast(x as y)

  Description: Converts x into the type specified by y.

  Example:

```
openGauss=# SELECT cast('22-oct-1997' as timestamp);
      timestamp
---------------------
 1997-10-22 00:00:00
(1 row)
```

- hextoraw(raw)

  Description: Converts a string in hexadecimal format into binary format.

  Return type: raw

  Example:

```
openGauss=# SELECT hextoraw('7D');
 hextoraw
----------
 7D
(1 row)
```

- numtoday(numeric)

  Description: Converts values of the number type into the timestamp of the specified type.

  Return type: timestamp

  Example:

```
openGauss=# SELECT numtoday(2);
 numtoday
----------
 2 days
(1 row)
```

- pg_systimestamp()

  Description: Obtains the system timestamp.

  Return type: timestamp with time zone

  Example:

```
openGauss=# SELECT pg_systimestamp();
        pg_systimestamp
-------------------------------
 2015-10-14 11:21:28.317367+08
(1 row)
```

- rawtohex(string)

  Description: Converts a string in binary format into hexadecimal format.

  The result is the ACSII code of the input characters in hexadecimal format.

  Return type: varchar

  Example:

```
openGauss=# SELECT rawtohex('1234567');
    rawtohex
----------------
 31323334353637
(1 row)
```

- to_bigint(varchar)

  Description: Converts the character type to the bigint type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: bigint

Example:

```
openGauss=# SELECT to_bigint('123364545554455');
    to_bigint
----------------
 123364545554455
(1 row)
```

- to_char (datetime/interval [, fmt])

  Description: Converts a DATETIME or INTERVAL value of the DATE/TIMESTAMP/TIMESTAMP WITH TIME ZONE/TIMESTAMP WITH LOCAL TIME ZONE type into the VARCHAR type according to the format specified by **fmt**.

  – The optional parameter **fmt** allows for the following types: date, time, week, quarter, and century. Each type has a unique template. The templates can be combined together. Common templates include: HH, MM, SS, YYYY, MM, and DD.

  – A template may have a modification word. FM is a common modification word and is used to suppress the preceding zero or the following blank spaces.

  Return type: varchar

  Example:

```
openGauss=# SELECT to_char(current_timestamp,'HH12:MI:SS');
 to_char
----------
 10:19:26
(1 row)
openGauss=# SELECT to_char(current_timestamp,'FMHH12:FMMI:FMSS');
 to_char
----------
 10:19:46
(1 row)
```

- to_char(double precision/real, text)

  Description: Converts the values of the floating point type into the strings in the specified format.

  Return type: text

  Example:

```
openGauss=# SELECT to_char(125.8::real, '999D99');
 to_char
---------
  125.80
(1 row)
```

- to_char (numeric/smallint/integer/bigint/double precision/real[, fmt])

  Descriptions: Converts an integer or a value in floating point format into a string in specified format.

  – The optional parameter **fmt** allows for the following types: decimal characters, grouping characters, positive/negative sign and currency sign. Each type has a unique template. The templates can be combined together. Common templates include: 9, 0, millesimal sign (,), and decimal point (.).

  – A template can have a modification word, similar to FM. However, FM does not suppress 0 which is output according to the template.

  – Use the template X or x to convert an integer value into a string in hexadecimal format.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: varchar

Example:

```
openGauss=# SELECT to_char(1485,'9,999');
 to_char
---------
  1,485
(1 row)
openGauss=# SELECT to_char( 1148.5,'9,999.999');
  to_char
------------
  1,148.500
(1 row)
openGauss=# SELECT to_char(148.5,'990999.909');
   to_char
--------------
    0148.500
(1 row)
openGauss=# SELECT to_char(123,'XXX');
 to_char
---------
   7B
(1 row)
```

- to_char(interval, text)

  Description: Converts the values of the time interval type into the strings in the specified format.

  Return type: text

  Example:

  ```
  openGauss=# SELECT to_char(interval '15h 2m 12s', 'HH24:MI:SS');
   to_char
  ----------
   15:02:12
  (1 row)
  ```

- to_char(integer, text)

  Description: Converts the values of the integer type into the strings in the specified format.

  Return type: text

  Example:

  ```
  openGauss=# SELECT to_char(125, '999');
   to_char
  ---------
   125
  (1 row)
  ```

- to_char(numeric, text)

  Description: Converts the values of the numeric type into the strings in the specified format.

  Return type: text

  Example:

  ```
  openGauss=# SELECT to_char(-125.8, '999D99S');
   to_char
  ---------
   125.80-
  (1 row)
  ```

- to_char (string)

  Description: Converts the CHAR/VARCHAR/VARCHAR2/CLOB type into the VARCHAR type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

If this function is used to convert data of the CLOB type, and the value to be converted exceeds the value range of the target type, an error is returned.

Return type: varchar

Example:

```
openGauss=# SELECT to_char('01110');
 to_char
---------
 01110
(1 row)
```

- to_nvarchar2

  Description: Converts to the nvarchar2 type.

  Parameter: numeric

  Return type: nvarchar2

- to_char(timestamp, text)

  Description: Converts the values of the timestamp type into the strings in the specified format.

  Return type: text

  Example:

```
openGauss=# SELECT to_char(current_timestamp, 'HH12:MI:SS');
 to_char
----------
 10:55:59
(1 row)
```

- to_clob(char/nchar/varchar/nvarchar/varchar2/nvarchar2/text/raw)

  Description: Converts the RAW type or text character set type CHAR/NCHAR/VARCHAR/VARCHAR2/NVARCHAR2/TEXT into the CLOB type.

  Return type: clob

  Example:

```
openGauss=# SELECT to_clob('ABCDEF'::RAW(10));
 to_clob
---------
 ABCDEF
(1 row)
openGauss=# SELECT to_clob('hello111'::CHAR(15));
 to_clob
----------
 hello111
(1 row)
openGauss=# SELECT to_clob('gauss123'::NCHAR(10));
 to_clob
----------
 gauss123
(1 row)
openGauss=# SELECT to_clob('gauss234'::VARCHAR(10));
 to_clob
----------
 gauss234
(1 row)
openGauss=# SELECT to_clob('gauss345'::VARCHAR2(10));
 to_clob
----------
 gauss345
(1 row)
openGauss=# SELECT to_clob('gauss456'::NVARCHAR2(10));
 to_clob
----------
 gauss456
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT to_clob('World222!'::TEXT);
 to_clob
-----------
 World222!
(1 row)
```

- to_date(text)

  Description: Converts values of the text type into the timestamp in the specified format.

  Return type: timestamp without time zone

  Example:

```
openGauss=# SELECT to_date('2015-08-14');
      to_date
---------------------
 2015-08-14 00:00:00
(1 row)
```

- to_date(text, text)

  Description: Converts the values of the string type into the dates in the specified format.

  Return type: timestamp without time zone

  Example:

```
openGauss=# SELECT to_date('05 Dec 2000', 'DD Mon YYYY');
      to_date
---------------------
 2000-12-05 00:00:00
(1 row)
```

- to_number ( expr [, fmt])

  Description: Converts **expr** into a value of the NUMBER type according to the specified format.

  For details about the type conversion formats, see **Table 12-33**.

  If a hexadecimal string is converted into a decimal number, the hexadecimal string can include a maximum of 16 bytes if it is to be converted into a sign-free number.

  During the conversion from a hexadecimal string to a decimal digit, the format string cannot have a character other than x or X. Otherwise, an error is reported.

  Return type: number

  Example:

```
openGauss=# SELECT to_number('12,454.8-', '99G999D9S');
 to_number
-----------
  -12454.8
(1 row)
```

- to_number(text, text)

  Description: Converts the values of the string type into the numbers in the specified format.

  Return type: numeric

  Example:

```
openGauss=# SELECT to_number('12,454.8-', '99G999D9S');
 to_number
-----------
  -12454.8
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- to_timestamp(double precision)

  Description: Converts a UNIX century into a timestamp.

  Return type: timestamp with time zone

  Example:

```
openGauss=# SELECT to_timestamp(1284352323);
     to_timestamp
------------------------
 2010-09-13 12:32:03+08
(1 row)
```

- to_timestamp(string [,fmt])

  Description: Converts a string into a value of the timestamp type according to the format specified by **fmt**. When **fmt** is not specified, perform the conversion according to the format specified by **nls_timestamp_format**.

  In **to_timestamp** in GaussDB,

  – If the input year *YYYY* is 0, an error will be reported.

  – If the input year *YYYY* is less than 0, specify *SYYYY* in **fmt**. The year with the value of n (an absolute value) BC will be output correctly.

  Characters in the **fmt** must match the schema for formatting the data and time. Otherwise, an error is reported.

  Return type: timestamp without time zone

  Example:

```
openGauss=# SHOW nls_timestamp_format;
    nls_timestamp_format
----------------------------
 DD-Mon-YYYY HH:MI:SS.FF AM
(1 row)

openGauss=# SELECT to_timestamp('12-sep-2014');
    to_timestamp
---------------------
 2014-09-12 00:00:00
(1 row)
openGauss=# SELECT to_timestamp('12-Sep-10 14:10:10.123000','DD-Mon-YY HH24:MI:SS.FF');
      to_timestamp
-------------------------
 2010-09-12 14:10:10.123
(1 row)
openGauss=# SELECT to_timestamp('-1','SYYYY');
      to_timestamp
-----------------------
 0001-01-01 00:00:00 BC
(1 row)
openGauss=# SELECT to_timestamp('98','RR');
    to_timestamp
---------------------
 1998-01-01 00:00:00
(1 row)
openGauss=# SELECT to_timestamp('01','RR');
    to_timestamp
---------------------
 2001-01-01 00:00:00
(1 row)
```

- to_timestamp(text, text)

  Description: Converts values of the string type into the timestamp of the specified type.

  Return type: timestamp

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT to_timestamp('05 Dec 2000', 'DD Mon YYYY');
   to_timestamp
---------------------
 2000-12-05 00:00:00
(1 row)
```

**Table 12-33** Template patterns for numeric formatting

| Pattern | Description |
| --- | --- |
| 9 | Value with specified digits |
| 0 | Values with leading zeros |
| Period (.) | Decimal point |
| Comma (,) | Group (thousand) separator |
| PR | Negative values in angle brackets |
| S | Sign anchored to number (uses locale) |
| L | Currency symbol (uses locale) |
| D | Decimal point (uses locale) |
| G | Group separator (uses locale) |
| MI | Minus sign in the specified position (if the number is less than 0) |
| PL | Plus sign in the specified position (if the number is greater than 0) |
| SG | Plus or minus sign in the specified position |
| RN | Roman numerals (the input values are between 1 and 3999) |
| TH or th | Ordinal number suffix |
| V | Shifts specified number of digits (decimal) |
| x or X | Hexadecimal-to-decimal conversion identifier |

- abstime_text
  Description: Converts abstime to text.
  Parameter: abstime
  Return type: text
- abstime_to_smalldatetime
  Description: Converts abstime to smalldatatime.
  Parameter: abstime
  Return type: smalldatetime
- bigint_tid
  Description: Converts bigint to tid.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Parameter: bigint
Return type: tid

- bool_int1
  Description: Converts bool to int1.
  Parameter: Boolean
  Return type: tinyint
- bool_int2
  Description: Converts bool to int2.
  Parameter: Boolean
  Return type: smallint
- bool_int8
  Description: Converts bool to int8.
  Parameter: Boolean
  Return type: bigint
- bpchar_date
  Description: Converts a string to a date.
  Parameter: character
  Return type: date
- bpchar_float4
  Description: Converts a string to float4.
  Parameter: character
  Return type: real
- bpchar_float8
  Description: Converts a string to float8.
  Parameter: character
  Return type: double precision
- bpchar_int4
  Description: Converts a string to int4.
  Parameter: character
  Return type: integer
- bpchar_int8
  Description: Converts a string to int8.
  Parameter: character
  Return type: bigint
- bpchar_numeric
  Description: Converts a string to numeric.
  Parameter: character
  Return type: numeric
- bpchar_timestamp
  Description: Converts a string to a timestamp.
  Parameter: character

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: timestamp without time zone

- bpchar_to_smalldatetime
  Description: Converts a string to smalldatetime.
  Parameter: character
  Return type: smalldatetime
- complex_array_in
  Description: Converts the external complex_array type to the internal anyarray array type.
  Parameter: cstring, oid, int2vector
  Return type: anyarray
- cupointer_bigint
  Description: Converts the column-store CU pointer type to the bigint type.
  Parameter: text
  Return type: bigint
- date_bpchar
  Description: Converts the date type to bpchar.
  Parameter: date
  Return type: character
- date_text
  Description: Converts date to text.
  Parameter: date
  Return type: text
- date_varchar
  Description: Converts date to varchar.
  Parameter: date
  Return type: character varying
- f4toi1
  Description: Forcibly converts float4 to uint8.
  Parameter: real
  Return type: tinyint
- f8toi1
  Description: Forcibly converts float8 to uint8.
  Parameter: double precision
  Return type: tinyint
- float4_bpchar
  Description: Converts float4 to bpchar.
  Parameter: real
  Return type: character
- float4_text
  Description: Converts float4 to text.
  Parameter: real

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: text

- float4_varchar
  Description: Converts float4 to varchar.
  Parameter: real
  Return type: character varying
- float8_bpchar
  Description: Converts float4 to bpchar.
  Parameter: double precision
  Return type: character
- float8_interval
  Description: Converts float4 to interval.
  Parameter: double precision
  Return type: interval
- float8_text
  Description: Converts float8 to text.
  Parameter: double precision
  Return type: text
- float8_varchar
  Description: Converts float8 to varchar.
  Parameter: double precision
  Return type: character varying
- i1tof4
  Description: Converts uint8 to float4.
  Parameter: tinyint
  Return type: real
- i1tof8
  Description: Converts uint8 to float8.
  Parameter: tinyint
  Return type: double precision
- i1toi2
  Description: Converts uint8 to int16.
  Parameter: tinyint
  Return type: smallint
- i1toi4
  Description: Converts uint8 to int32.
  Parameter: tinyint
  Return type: integer
- i1toi8
  Description: Converts uint8 to int64.
  Parameter: tinyint
  Return type: bigint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- i2toi1

  Description: Converts int16 to uint8.

  Parameter: smallint

  Return type: tinyint
- i4toi1

  Description: Converts int32 to uint8.

  Parameter: integer

  Return type: tinyint
- i8toi1

  Description: Converts int64 to uint8.

  Parameter: bigint

  Return type: tinyint
- int1_avg_accum

  Description: Adds the second parameter of the uint8 type to the first parameter. The first parameter is an array of the bigint type.

  Parameter: bigint[], tinyint

  Return type: bigint[]
- int1_bool

  Description: Converts uint8 to bool.

  Parameter: tinyint

  Return type: Boolean
- int1_bpchar

  Description: Converts uint8 to bpchar.

  Parameter: tinyint

  Return type: character
- int1_mul_cash

  Description: Returns the product of a parameter of the int8 type and a parameter of the cash type. The return type is cash.

  Parameter: tinyint, money

  Return type: money
- int1_numeric

  Description: Converts uint8 to numeric.

  Parameter: tinyint

  Return type: numeric
- int1_nvarchar2

  Description: Converts uint8 to nvarchar2.

  Parameter: tinyint

  Return type: nvarchar2
- int1_text

  Description: Converts uint8 to text.

  Parameter: tinyint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: text

- int1_varchar
  Description: Converts uint8 to varchar.
  Parameter: tinyint
  Return type: character varying
- int1in
  Description: Converts a string into an unsigned 1-byte integer.
  Parameter: cstring
  Return type: tinyint
- int1out
  Description: Converts an unsigned 1-byte integer into a string.
  Return type: cstring
- int1up
  Description: Converts an input integer to an unsigned 1-byte integer.
  Parameter: tinyint
  Return type: tinyint
- int2_bool
  Description: Converts a signed two-byte integer to the bool type.
  Parameter: smallint
  Return type: Boolean
- int2_bpchar
  Description: Converts a signed two-byte integer to the bpchar type.
  Parameter: smallint
  Return type: character
- int2_text
  Description: Converts a signed two-byte integer to the text type.
  Parameter: smallint
  Return type: text
- int2_varchar
  Description: Converts a signed two-byte integer to the varchar type.
  Parameter: smallint
  Return type: character varying
- int4_bpchar
  Description: Converts a signed four-byte integer to bpchar.
  Parameter: integer
  Return type: character
- int4_text
  Description: Converts a signed four-byte integer to the text type.
  Parameter: integer
  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- int4_varchar
  Description: Converts a signed four-byte integer into varchar.
  Parameter: integer
  Return type: character varying
- int8_bool
  Description: Converts an eight-byte signed integer to a Boolean value.
  Parameter: bigint
  Return type: Boolean
- int8_bpchar
  Description: Converts an 8-byte signed integer to bpchar.
  Parameter: bigint
  Return type: character
- int8_text
  Description: Converts an eight-byte signed integer to the text type.
  Parameter: bigint
  Return type: text
- int8_varchar
  Description: Converts an eight-byte signed integer to varchar.
  Parameter: bigint
  Return type: character varying
- intervaltonum
  Description: Converts the internal dats type date to numeric.
  Parameter: interval
  Return type: numeric
- numeric_bpchar
  Description: Converts numeric to bpchar.
  Parameter: numeric
  Return type: character
- numeric_int1
  Description: Converts numeric to a signed one-byte integer.
  Parameter: numeric
  Return type: tinyint
- numeric_text
  Description: Converts numeric to text.
  Parameter: numeric
  Return type: text
- numeric_varchar
  Description: Converts numeric to varchar.
  Parameter: numeric
  Return type: character varying

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- nvarchar2in
  Description: Converts c string to varchar.
  Parameter: cstring, oid, integer
  Return type: nvarchar2
- nvarchar2out
  Description: Converts text into a c string.
  Parameter: nvarchar2
  Return type: cstring
- nvarchar2send
  Description: Converts varchar to binary.
  Parameter: nvarchar2
  Return type: bytea
- oidvectorin_extend
  Description: Converts a string to oidvector.
  Parameter: cstring
  Return type: oidvector_extend
- oidvectorout_extend
  Description: Converts oidvector to a string.
  Parameter: oidvector_extend
  Return type: cstring
- oidvectorsend_extend
  Description: Converts oidvector to a string.
  Parameter: oidvector_extend
  Return type: bytea
- reltime_text
  Description: Converts reltime to text.
  Parameter: reltime
  Return type: text
- text_date
  Description: Converts the text type to the date type.
  Parameter: text
  Return type: date
- text_float4
  Description: Converts text to float4.
  Parameter: text
  Return type: real
- text_float8
  Description: Converts the text type to float8.
  Parameter: text
  Return type: double precision

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- text_int1
  Description: Converts the text type to int1.
  Parameter: text
  Return type: tinyint
- text_int2
  Description: Converts the text type to the int2 type.
  Parameter: text
  Return type: smallint
- text_int4
  Description: Converts the text type to int4.
  Parameter: text
  Return type: integer
- text_int8
  Description: Converts the text type to the int8 type.
  Parameter: text
  Return type: bigint
- text_numeric
  Description: Converts the text type to the numeric type.
  Parameter: text
  Return type: numeric
- text_timestamp
  Description: Converts the text type to the timestamp type.
  Parameter: text
  Return type: timestamp without time zone
- time_text
  Description: Converts the time type to the text type.
  Parameter: time without time zone
  Return type: text
- timestamp_text
  Description: Converts the timestamp type to the text type.
  Parameter: timestamp without time zone
  Return type: text
- timestamp_to_smalldatetime
  Description: Converts the timestamp type to the smalldatetime type.
  Parameter: timestamp without time zone
  Return type: smalldatetime
- timestamp_varchar
  Description: Converts the timestamp type to varchar.
  Parameter: timestamp without time zone
  Return type: character varying

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- timestamptz_to_smalldatetime
  Description: Converts timestamptz to smalldatetime.
  Parameter: timestamp with time zone
  Return type: smalldatetime
- timestampzone_text
  Description: Converts the timestampzone type to the text type.
  Parameter: timestamp with time zone
  Return type: text
- timetz_text
  Description: Converts the timetz type to the text type.
  Parameter: time with time zone
  Return type: text
- to_integer
  Description: Converts data to the integer type.
  Parameter: character varying
  Return type: integer
- to_interval
  Description: Converts to the interval type.
  Parameter: character varying
  Return type: interval
- to_numeric
  Description: Converts to the numeric type.
  Parameter: character varying
  Return type: numeric
- to_text
  Description: Converts to the text type.
  Parameter: smallint
  Return type: text
- to_ts
  Description: Converts to the ts type.
  Parameter: character varying
  Return type: timestamp without time zone
- to_varchar2
  Description: Converts to the varchar2 type.
  Parameter: timestamp without time zone
  Return type: character varying
- varchar_date
  Description: Converts varchar to date.
  Parameter: character varying
  Return type: date

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- varchar_float4
  Description: Converts varchar to float4.
  Parameter: character varying
  Return type: real
- varchar_float8
  Description: Converts the varchar type to the float8 type.
  Parameter: character varying
  Return type: double precision
- varchar_int4
  Description: Converts the type from varchar to int4.
  Parameter: character varying
  Return type: integer
- varchar_int8
  Description: Converts the varchar type to the int8 type.
  Parameter: character varying
  Return type: bigint
- varchar_numeric
  Description: Converts varchar to numeric.
  Parameter: character varying
  Return type: numeric
- varchar_timestamp
  Description: Converts varchar to timestamp.
  Parameter: character varying
  Return type: timestamp without time zone
- varchar2_to_smlldatetime
  Description: Converts varchar2 to smlldatetime.
  Parameter: character varying
  Return type: smalldatetime
- xidout4
  Description: The xid output is a four-byte number.
  Parameter: xid32
  Return type: cstring
- xidsend4
  Description: Converts xid to the binary format.
  Parameter: xid32
  Return type: bytea

## Encoding Type Conversion

convert_to_nocase(text, text)

Description: Converts a string into a specified encoding type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: bytea

Example:

```
openGauss=# SELECT convert_to_nocase('12345', 'GBK');
 convert_to_nocase
-------------------
 \x3132333435
(1 row)
```

# 12.5.10 Geometric Functions and Operators

## Geometric Operators

- +

  Description: Translation

  Example:

  ```
  openGauss=# SELECT box '((0,0),(1,1))' + point '(2.0,0)' AS RESULT;
    result
  -------------
   (3,1),(2,0)
  (1 row)
  ```

- -e

  Description: Translation

  Example:

  ```
  openGauss=# SELECT box '((0,0),(1,1))' - point '(2.0,0)' AS RESULT;
     result
  ---------------
   (-1,1),(-2,0)
  (1 row)
  ```

- *

  Description: Scaling out/Rotation

  Example:

  ```
  openGauss=# SELECT box '((0,0),(1,1))' * point '(2.0,0)' AS RESULT;
    result
  -------------
   (2,2),(0,0)
  (1 row)
  ```

- /

  Description: Scaling in/Rotation

  Example:

  ```
  openGauss=# SELECT box '((0,0),(2,2))' / point '(2.0,0)' AS RESULT;
    result
  -------------
   (1,1),(0,0)
  (1 row)
  ```

- #

  Description: Intersection of two figures

  Example:

  ```
  openGauss=# SELECT box '((1,-1),(-1,1))' # box '((1,1),(-2,-2))' AS RESULT;
   result
  ---------------
   (1,1),(-1,-1)
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- #

  Description: Number of paths or polygon vertexes

  Example:

```
openGauss=# SELECT # path'((1,0),(0,1),(-1,0))' AS RESULT;
 result
--------
      3
(1 row)
```

- @-@

  Description: Length or circumference

  Example:

```
openGauss=# SELECT @-@ path '((0,0),(1,0))' AS RESULT;
 result
--------
      2
(1 row)
```

- @@

  Description: Center of box

  Example:

```
openGauss=# SELECT @@ circle '((0,0),10)' AS RESULT;
 result
--------
 (0,0)
(1 row)
```

- <->

  Description: Distance between the two figures

  Example:

```
openGauss=# SELECT circle '((0,0),1)' <-> circle '((5,0),1)' AS RESULT;
 result
--------
      3
(1 row)
```

- &&

  Description: Overlaps? (One point in common makes this true.)

  Example:

```
openGauss=# SELECT box '((0,0),(1,1))' && box '((0,0),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- <<

  Description: Is strictly left of (no common horizontal coordinate)?

  Example:

```
openGauss=# SELECT circle '((0,0),1)' << circle '((5,0),1)' AS RESULT;
 result
--------
 t
(1 row)
```

- >>

  Description: Is strictly right of (no common horizontal coordinate)?

  Example:

```
openGauss=# SELECT circle '((5,0),1)' >> circle '((0,0),1)' AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
--------
 t
(1 row)
```

- &<

  Description: Does not extend to the right of?

  Example:

```
openGauss=# SELECT box '((0,0),(1,1))' &< box '((0,0),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- &>

  Description: Does not extend to the left of?

  Example:

```
openGauss=# SELECT box '((0,0),(3,3))' &> box '((0,0),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- <<|

  Description: Is strictly below (no common horizontal coordinate)?

  Example:

```
openGauss=# SELECT box '((0,0),(3,3))' <<| box '((3,4),(5,5))' AS RESULT;
 result
--------
 t
(1 row)
```

- |>>

  Description: Is strictly above (no common horizontal coordinate)?

  Example:

```
openGauss=# SELECT box '((3,4),(5,5))' |>> box '((0,0),(3,3))' AS RESULT;
 result
--------
 t
(1 row)
```

- &<|

  Description: Does not extend above?

  Example:

```
openGauss=# SELECT box '((0,0),(1,1))' &<| box '((0,0),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- |&>

  Description: Does not extend below?

  Example:

```
openGauss=# SELECT box '((0,0),(3,3))' |&> box '((0,0),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- <^

  Description: Is below (allows touching)?

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# SELECT box '((0,0),(-3,-3))' <^ box '((0,0),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- >^

  Description: Is above (allows touching)?

  Example:

```
openGauss=# SELECT box '((0,0),(2,2))' >^ box '((0,0),(-3,-3))'  AS RESULT;
 result
--------
 t
(1 row)
```

- ?#

  Description: Intersect?

  Example:

```
openGauss=# SELECT lseg '((-1,0),(1,0))' ?# box '((-2,-2),(2,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- ?-

  Description: Is horizontal?

  Example:

```
openGauss=# SELECT ?- lseg '((-1,0),(1,0))' AS RESULT;
 result
--------
 t
(1 row)
```

- ?-

  Description: Are horizontally aligned?

  Example:

```
openGauss=# SELECT point '(1,0)' ?- point '(0,0)' AS RESULT;
 result
--------
 t
(1 row)
```

- ?|

  Description: Is vertical?

  Example:

```
openGauss=# SELECT ?| lseg '((-1,0),(1,0))' AS RESULT;
 result
--------
 f
(1 row)
```

- ?|

  Description: Are vertically aligned?

  Example:

```
openGauss=# SELECT point '(0,1)' ?| point '(0,0)' AS RESULT;
 result
--------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- ?-|

  Description: Are perpendicular?

  Example:

```
openGauss=# SELECT lseg '((0,0),(0,1))' ?-| lseg '((0,0),(1,0))' AS RESULT;
 result
--------
 t
(1 row)
```

- ?||

  Description: Are parallel?

  Example:

```
openGauss=# SELECT lseg '((-1,0),(1,0))' ?|| lseg '((-1,2),(1,2))' AS RESULT;
 result
--------
 t
(1 row)
```

- @>

  Description: Contains?

  Example:

```
openGauss=# SELECT circle '((0,0),2)' @> point '(1,1)' AS RESULT;
 result
--------
 t
(1 row)
```

- <@

  Description: Contained in or on?

  Example:

```
openGauss=# SELECT point '(1,1)' <@ circle '((0,0),2)' AS RESULT;
 result
--------
 t
(1 row)
```

- ~=

  Description: Same as?

  Example:

```
openGauss=# SELECT polygon '((0,0),(1,1))' ~= polygon '((1,1),(0,0))' AS RESULT;
 result
--------
 t
(1 row)
```

## Geometric Functions

- area(object)

  Description: Area calculation

  Return type: double precision

  Example:

```
openGauss=# SELECT area(box '((0,0),(1,1))') AS RESULT;
 result
--------
      1
(1 row)
```

- center(object)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Figure center calculation

Return type: point

Example:

```
openGauss=# SELECT center(box '((0,0),(1,2))') AS RESULT;
 result
---------
 (0.5,1)
(1 row)
```

- diameter(circle)

  Description: Circle diameter calculation

  Return type: double precision

  Example:

```
openGauss=# SELECT diameter(circle '((0,0),2.0)') AS RESULT;
 result
--------
      4
(1 row)
```

- height(box)

  Description: Vertical size of box

  Return type: double precision

  Example:

```
openGauss=# SELECT height(box '((0,0),(1,1))') AS RESULT;
 result
--------
      1
(1 row)
```

- isclosed(path)

  Description: A closed path?

  Return type: Boolean

  Example:

```
openGauss=# SELECT isclosed(path '((0,0),(1,1),(2,0))') AS RESULT;
 result
--------
 t
(1 row)
```

- isopen(path)

  Description: An open path?

  Return type: Boolean

  Example:

```
openGauss=# SELECT isopen(path '[(0,0),(1,1),(2,0)]') AS RESULT;
 result
--------
 t
(1 row)
```

- length(object)

  Description: Length calculation

  Return type: double precision

  Example:

```
openGauss=# SELECT length(path '((-1,0),(1,0))') AS RESULT;
 result
--------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
     4
(1 row)
```

- npoints(path)

  Description: Number of points in path

  Return type: int

  Example:

```
openGauss=# SELECT npoints(path '[(0,0),(1,1),(2,0)]') AS RESULT;
 result
--------
      3
(1 row)
```

- npoints(polygon)

  Description: Number of points in polygon

  Return type: int

  Example:

```
openGauss=# SELECT npoints(polygon '((1,1),(0,0))') AS RESULT;
 result
--------
      2
(1 row)
```

- pclose(path)

  Description: Converts path to closed.

  Return type: path

  Example:

```
openGauss=# SELECT pclose(path '[(0,0),(1,1),(2,0)]') AS RESULT;
       result
---------------------
 ((0,0),(1,1),(2,0))
(1 row)
```

- popen(path)

  Description: Converts path to open.

  Return type: path

  Example:

```
openGauss=# SELECT popen(path '((0,0),(1,1),(2,0))') AS RESULT;
       result
---------------------
 [(0,0),(1,1),(2,0)]
(1 row)
```

- radius(circle)

  Description: Circle diameter calculation

  Return type: double precision

  Example:

```
openGauss=# SELECT radius(circle '((0,0),2.0)') AS RESULT;
 result
--------
      2
(1 row)
```

- width(box)

  Description: Horizontal size of box

  Return type: double precision

  Example:

```
openGauss=# SELECT width(box '((0,0),(1,1))') AS RESULT;
 result
--------
      1
(1 row)
```

## Geometric Type Conversion Functions

- box(circle)

  Description: Circle to box

  Return type: box

  Example:

  ```
  openGauss=# SELECT box(circle '((0,0),2.0)') AS RESULT;
                                  result
  ---------------------------------------------------------------------------
   (1.41421356237309,1.41421356237309),(-1.41421356237309,-1.41421356237309)
  (1 row)
  ```

- box(point, point)

  Description: Points to box

  Return type: box

  Example:

  ```
  openGauss=# SELECT box(point '(0,0)', point '(1,1)') AS RESULT;
    result
  -------------
   (1,1),(0,0)
  (1 row)
  ```

- box(polygon)

  Description: Polygon to box

  Return type: box

  Example:

  ```
  openGauss=# SELECT box(polygon '((0,0),(1,1),(2,0))') AS RESULT;
    result
  -------------
   (2,1),(0,0)
  (1 row)
  ```

- circle(box)

  Description: Box to circle

  Return type: circle

  Example:

  ```
  openGauss=# SELECT circle(box '((0,0),(1,1))') AS RESULT;
              result
  -------------------------------
   <(0.5,0.5),0.707106781186548>
  (1 row)
  ```

- circle(point, double precision)

  Description: Center and radius to circle

  Return type: circle

  Example:

  ```
  openGauss=# SELECT circle(point '(0,0)', 2.0) AS RESULT;
    result
  -----------
   <(0,0),2>
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- circle(polygon)

  Description: Polygon to circle

  Return type: circle

  Example:

```
openGauss=# SELECT circle(polygon '((0,0),(1,1),(2,0))') AS RESULT;
                result
-----------------------------------------
 <(1,0.333333333333333),0.924950591148529>
(1 row)
```

- lseg(box)

  Description: Box diagonal to line segment

  Return type: lseg

  Example:

```
openGauss=# SELECT lseg(box '((-1,0),(1,0))') AS RESULT;
    result
----------------
 [(1,0),(-1,0)]
(1 row)
```

- lseg(point, point)

  Description: Points to line segment

  Return type: lseg

  Example:

```
openGauss=# SELECT lseg(point '(-1,0)', point '(1,0)') AS RESULT;
    result
----------------
 [(-1,0),(1,0)]
(1 row)
```

- slope(point, point)

  Description: Calculates the slope of a straight line formed by two points.

  Return type: double

  Example:

```
openGauss=# SELECT slope(point '(1,1)', point '(0,0)') AS RESULT;
 result
--------
      1
(1 row)
```

- path(polygon)

  Description: Polygon to path

  Return type: path

  Example:

```
openGauss=# SELECT path(polygon '((0,0),(1,1),(2,0))') AS RESULT;
      result
--------------------
 ((0,0),(1,1),(2,0))
(1 row)
```

- point(double precision, double precision)

  Description: Points

  Return type: point

  Example:

```
openGauss=# SELECT point(23.4, -44.5) AS RESULT;
   result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
--------------
 (23.4,-44.5)
(1 row)
```

- point(box)

  Description: Center of box

  Return type: point

  Example:

```
openGauss=# SELECT point(box '((-1,0),(1,0))') AS RESULT;
 result
--------
 (0,0)
(1 row)
```

- point(circle)

  Description: Center of circle

  Return type: point

  Example:

```
openGauss=# SELECT point(circle '((0,0),2.0)') AS RESULT;
 result
--------
 (0,0)
(1 row)
```

- point(lseg)

  Description: Center of line segment

  Return type: point

  Example:

```
openGauss=# SELECT point(lseg '((-1,0),(1,0))') AS RESULT;
 result
--------
 (0,0)
(1 row)
```

- point(polygon)

  Description: Center of polygon

  Return type: point

  Example:

```
openGauss=# SELECT point(polygon '((0,0),(1,1),(2,0))') AS RESULT;
       result
-----------------------
 (1,0.333333333333333)
(1 row)
```

- polygon(box)

  Description: Box to 4-point polygon

  Return type: polygon

  Example:

```
openGauss=# SELECT polygon(box '((0,0),(1,1))') AS RESULT;
          result
---------------------------
 ((0,0),(0,1),(1,1),(1,0))
(1 row)
```

- polygon(circle)

  Description: Circle to 12-point polygon

  Return type: polygon

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# SELECT polygon(circle '((0,0),2.0)') AS RESULT;

result

------------------------------------------------------------------------------------------------------------------------
------------------------------------------------------------------------------------------------------------------------
----------
 ((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),
(1.73205080756888,-0.999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),
(-0.999999999999999,-1.73205080756888),(-1.73205080756888,-1))
(1 row)
```

- polygon(npts, circle)

  Description: Circle to **npts**-point polygon

  Return type: polygon

  Example:

```
openGauss=# SELECT polygon(12, circle '((0,0),2.0)') AS RESULT;

result

------------------------------------------------------------------------------------------------------------------------
------------------------------------------------------------------------------------------------------------------------
----------
 ((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),
(1.73205080756888,-0.999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),
(-0.999999999999999,-1.73205080756888),(-1.73205080756888,-1))
(1 row)
```

- polygon(path)

  Description: Path to polygon

  Return type: polygon

  Example:

```
openGauss=# SELECT polygon(path '((0,0),(1,1),(2,0))') AS RESULT;
      result
--------------------
 ((0,0),(1,1),(2,0))
(1 row)
```

# 12.5.11 Network Address Functions and Operators

## cidr and inet Operators

The operators **<<**, **<<=**, **>>**, and **>>=** test for subnet inclusion. They consider only the network parts of the two addresses (ignoring any host part) and determine whether one network is identical to or a subnet of the other.

- <

  Description: Is less than

  Example:

```
openGauss=# SELECT inet '192.168.1.5' < inet '192.168.1.6' AS RESULT;
 result
--------
 t
(1 row)
```

- <=

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Is less than or equals

Example:

```
openGauss=# SELECT inet '192.168.1.5' <= inet '192.168.1.5' AS RESULT;
 result
--------
 t
(1 row)
```

- =

  Description: Equals

  Example:

```
openGauss=# SELECT inet '192.168.1.5' = inet '192.168.1.5' AS RESULT;
 result
--------
 t
(1 row)
```

- >=

  Description: Is greater than or equals

  Example:

```
openGauss=# SELECT inet '192.168.1.5' >= inet '192.168.1.5' AS RESULT;
 result
--------
 t
(1 row)
```

- >

  Description: Is greater than

  Example:

```
openGauss=# SELECT inet '192.168.1.5' > inet '192.168.1.4' AS RESULT;
 result
--------
 t
(1 row)
```

- <>

  Description: Does not equal to

  Example:

```
openGauss=# SELECT inet '192.168.1.5' <> inet '192.168.1.4' AS RESULT;
 result
--------
 t
(1 row)
```

- <<

  Description: Is contained in

  Example:

```
openGauss=# SELECT inet '192.168.1.5' << inet '192.168.1/24' AS RESULT;
 result
--------
 t
(1 row)
```

- <<=

  Description: Is contained in or equals

  Example:

```
openGauss=# SELECT inet '192.168.1/24' <<= inet '192.168.1/24' AS RESULT;
 result
--------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 t
(1 row)
```

- >>

  Description: Contains

  Example:

```
openGauss=# SELECT inet '192.168.1/24' >> inet '192.168.1.5' AS RESULT;
 result
--------
 t
(1 row)
```

- >>=

  Description: Contains or equals

  Example:

```
openGauss=# SELECT inet '192.168.1/24' >>= inet '192.168.1/24' AS RESULT;
 result
--------
 t
(1 row)
```

- ~

  Description: Bitwise NOT

  Example:

```
openGauss=# SELECT ~ inet '192.168.1.6' AS RESULT;
    result
---------------
 63.87.254.249
(1 row)
```

- &

  Description: Performs an AND operation on each bit of the two network addresses.

  Example:

```
openGauss=# SELECT inet '192.168.1.6' & inet '10.0.0.0' AS RESULT;
 result
---------
 0.0.0.0
(1 row)
```

- |

  Description: Performs an OR operation on each bit of the two network addresses.

  Example:

```
openGauss=# SELECT inet '192.168.1.6' | inet '10.0.0.0' AS RESULT;
   result
-------------
 202.168.1.6
(1 row)
```

- +

  Description: Addition

  Example:

```
openGauss=# SELECT inet '192.168.1.6' + 25 AS RESULT;
    result
--------------
 192.168.1.31
(1 row)
```

- -

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Subtraction

Example:

```
openGauss=# SELECT inet '192.168.1.43' - 36 AS RESULT;
   result
-------------
 192.168.1.7
(1 row)
```

- -

  Description: Subtraction

  Example:

```
openGauss=# SELECT inet '192.168.1.43' - inet '192.168.1.19' AS RESULT;
 result
--------
     24
(1 row)
```

## cidr and inet Functions

The **abbrev**, **host**, and **text** functions are primarily intended to offer alternative display formats.

- abbrev(inet)

  Description: Abbreviated display format as text

  Return type: text

  Example:

```
openGauss=# SELECT abbrev(inet '10.1.0.0/16') AS RESULT;
   result
-------------
 10.1.0.0/16
(1 row)
```

- abbrev(cidr)

  Description: Abbreviated display format as text

  Return type: text

  Example:

```
openGauss=# SELECT abbrev(cidr '10.1.0.0/16') AS RESULT;
 result
---------
 10.1/16
(1 row)
```

- broadcast(inet)

  Description: Broadcast address for networks

  Return type: inet

  Example:

```
openGauss=# SELECT broadcast('192.168.1.5/24') AS RESULT;
      result
------------------
 192.168.1.255/24
(1 row)
```

- family(inet)

  Description: Extracts family of addresses, **4** for IPv4.

  Return type: int

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT family('127.0.01') AS RESULT;
 result
--------
      4
(1 row)
```

- host(inet)

  Description: Extracts IP addresses as text.

  Return type: text

  Example:

```
openGauss=# SELECT host('192.168.1.5/24') AS RESULT;
   result
-------------
 192.168.1.5
(1 row)
```

- hostmask(inet)

  Description: Constructs the host mask for a network.

  Return type: inet

  Example:

```
openGauss=# SELECT hostmask('192.168.23.20/30') AS RESULT;
 result
---------
 0.0.0.3
(1 row)
```

- masklen(inet)

  Description: Extracts subnet mask length.

  Return type: int

  Example:

```
openGauss=# SELECT masklen('192.168.1.5/24') AS RESULT;
 result
--------
     24
(1 row)
```

- netmask(inet)

  Description: Constructs the subnet mask for a network.

  Return type: inet

  Example:

```
openGauss=# SELECT netmask('192.168.1.5/24') AS RESULT;
    result
---------------
 255.255.255.0
(1 row)
```

- network(inet)

  Description: Extracts the network part of an address.

  Return type: cidr

  Example:

```
openGauss=# SELECT network('192.168.1.5/24') AS RESULT;
     result
----------------
 192.168.1.0/24
(1 row)
```

- set_masklen(inet, int)

  Description: Sets subnet mask length for the **inet** value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: inet

Example:

```
openGauss=# SELECT set_masklen('192.168.1.5/24', 16) AS RESULT;
    result
----------------
 192.168.1.5/16
(1 row)
```

- set_masklen(cidr, int)

  Description: Sets subnet mask length for the **cidr** value.

  Return type: cidr

  Example:

  ```
  openGauss=# SELECT set_masklen('192.168.1.0/24'::cidr, 16) AS RESULT;
      result
  ----------------
   192.168.0.0/16
  (1 row)
  ```

- text(inet)

  Description: Extracts IP addresses and subnet mask length as text.

  Return type: text

  Example:

  ```
  openGauss=# SELECT text(inet '192.168.1.5') AS RESULT;
      result
  ----------------
   192.168.1.5/32
  (1 row)
  ```

Any **cidr** value can be cast to **inet** implicitly or explicitly; therefore, the functions shown above as operating on **inet** also work on **cidr** values. An **inet** value can be cast to **cidr**. After the conversion, any bits to the right of the subnet mask are silently zeroed to create a valid **cidr** value. In addition, you can cast a text string to **inet** or **cidr** using normal casting syntax. For example, **inet(expression)** or **colname::cidr**.

## macaddr Functions

The function **trunc(macaddr)** returns a MAC address with the last 3 bytes set to zero.

trunc(macaddr)

Description: Sets last 3 bytes to zero.

Return type: macaddr

Example:

```
openGauss=# SELECT trunc(macaddr '12:34:56:78:90:ab') AS RESULT;
     result
-------------------
 12:34:56:00:00:00
(1 row)
```

The **macaddr** type also supports the standard relational operators (such as **>** and **<=**) for lexicographical ordering, and the bitwise arithmetic operators (**~**, **&** and **|**) for NOT, AND and OR.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

# 12.5.12 Text Search Functions and Operators

## Text Search Operators

- @@

  Description: Specifies whether the **tsvector**-typed words match the **tsquery**-typed words.

  Example:

```
openGauss=# SELECT to_tsvector('fat cats ate rats') @@ to_tsquery('cat & rat') AS RESULT;
 result
--------
 t
(1 row)
```

- @@@

  Description: Synonym for @@

  Example:

```
openGauss=# SELECT to_tsvector('fat cats ate rats') @@@ to_tsquery('cat & rat') AS RESULT;
 result
--------
 t
(1 row)
```

- ||

  Description: Connects two **tsvector**-typed words.

  Example:

```
openGauss=# SELECT 'a:1 b:2'::tsvector || 'c:1 d:2 b:3'::tsvector AS RESULT;
          result
----------------------------
 'a':1 'b':2,5 'c':3 'd':4
(1 row)
```

- &&

  Description: Performs the AND operation on two **tsquery**-typed words.

  Example:

```
openGauss=# SELECT 'fat | rat'::tsquery && 'cat'::tsquery AS RESULT;
          result
----------------------------
 ( 'fat' | 'rat' ) & 'cat'
(1 row)
```

- ||

  Description: Performs the OR operation on two **tsquery**-typed words.

  Example:

```
openGauss=# SELECT 'fat | rat'::tsquery || 'cat'::tsquery AS RESULT;
          result
----------------------------
 ( 'fat' | 'rat' ) | 'cat'
(1 row)
```

- !!

  Description: **NOT** a **tsquery**

  Example:

```
openGauss=# SELECT !! 'cat'::tsquery AS RESULT;
 result
--------
 !'cat'
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- @>

  Description: Specifies whether a **tsquery**-typed word contains another **tsquery**-typed word.

  Example:

```
openGauss=# SELECT 'cat'::tsquery @> 'cat & rat'::tsquery AS RESULT;
 result
--------
 f
(1 row)
```

- <@

  Description: Specifies whether a **tsquery**-typed word is contained in another **tsquery**-typed word.

  Example:

```
openGauss=# SELECT 'cat'::tsquery <@ 'cat & rat'::tsquery AS RESULT;
 result
--------
 t
(1 row)
```

In addition to the preceding operators, the ordinary B-tree comparison operators (including = and <) are defined for types **tsvector** and **tsquery**.

## Text Search Functions

- get_current_ts_config()

  Description: Obtains default text search configurations.

  Return type: regconfig

  Example:

```
openGauss=# SELECT get_current_ts_config();
 get_current_ts_config
-----------------------
 english
(1 row)
```

- length(tsvector)

  Description: Specifies the number of lexemes in a **tsvector**-typed word.

  Return type: integer

  Example:

```
openGauss=# SELECT length('fat:2,4 cat:3 rat:5A'::tsvector);
 length
--------
      3
(1 row)
```

- numnode(tsquery)

  Description: Specifies the number of lexemes plus **tsquery** operators.

  Return type: integer

  Example:

```
openGauss=# SELECT numnode('(fat & rat) | cat'::tsquery);
 numnode
---------
       5
(1 row)
```

- plainto_tsquery([ config regconfig , ] query text)

  Description: Generates **tsquery** lexemes without punctuation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: tsquery

Example:

```
openGauss=# SELECT plainto_tsquery('english', 'The Fat Rats');
 plainto_tsquery
-----------------
 'fat' & 'rat'
(1 row)
```

- querytree(query tsquery)

  Description: Obtains the indexable part of a **tsquery**.

  Return type: text

  Example:

```
openGauss=# SELECT querytree('foo & ! bar'::tsquery);
 querytree
-----------
 'foo'
(1 row)
```

- setweight(tsvector, "char")

  Description: Assigns weight to each element of **tsvector**.

  Return type: tsvector

  Example:

```
openGauss=# SELECT setweight('fat:2,4 cat:3 rat:5B'::tsvector, 'A');
           setweight
-------------------------------
 'cat':3A 'fat':2A,4A 'rat':5A
(1 row)
```

- strip(tsvector)

  Description: Removes positions and weights from **tsvector**.

  Return type: tsvector

  Example:

```
openGauss=# SELECT strip('fat:2,4 cat:3 rat:5A'::tsvector);
       strip
--------------------
 'cat' 'fat' 'rat'
(1 row)
```

- to_tsquery([ config regconfig , ] query text)

  Description: Normalizes words and converts them to **tsquery**.

  Return type: tsquery

  Example:

```
openGauss=# SELECT to_tsquery('english', 'The & Fat & Rats');
  to_tsquery
---------------
 'fat' & 'rat'
(1 row)
```

- to_tsvector([ config regconfig , ] document text)

  Description: Reduces document text to **tsvector**.

  Return type: tsvector

  Example:

```
openGauss=# SELECT to_tsvector('english', 'The Fat Rats');
   to_tsvector
-----------------
 'fat':2 'rat':3
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- to_tsvector_for_batch([ config regconfig , ] document text)

  Description: Reduces document text to **tsvector**.

  Return type: tsvector

  Example:

```
openGauss=# SELECT to_tsvector_for_batch('english', 'The Fat Rats');
   to_tsvector
-----------------
 'fat':2 'rat':3
(1 row)
```

- ts_headline([ config regconfig, ] document text, query tsquery [, options text ])

  Description: Highlights a query match.

  Return type: text

  Example:

```
openGauss=# SELECT ts_headline('x y z', 'z'::tsquery);
 ts_headline
--------------
 x y <b>z</b>
(1 row)
```

- ts_rank([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ])

  Description: Ranks document for query.

  Return type: float4

  Example:

```
openGauss=# SELECT ts_rank('hello world'::tsvector, 'world'::tsquery);
 ts_rank
----------
 .0607927
(1 row)
```

- ts_rank_cd([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ])

  Description: Ranks document for query using cover density.

  Return type: float4

  Example:

```
openGauss=# SELECT ts_rank_cd('hello world'::tsvector, 'world'::tsquery);
 ts_rank_cd
------------
          .0
(1 row)
```

- ts_rewrite(query tsquery, target tsquery, substitute tsquery)

  Description: Replaces **tsquery**-typed word.

  Return type: tsquery

  Example:

```
openGauss=# SELECT ts_rewrite('a & b'::tsquery, 'a'::tsquery, 'foo|bar'::tsquery);
       ts_rewrite
-------------------------
 'b' & ( 'foo' | 'bar' )
(1 row)
```

- ts_rewrite(query tsquery, select text)

  Description: Replaces **tsquery** data in the target with the result of a **SELECT** command.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: tsquery

Example:

```
openGauss=# SELECT ts_rewrite('world'::tsquery, 'select ''world''::tsquery, ''hello''::tsquery');
 ts_rewrite
------------
 'hello'
(1 row)
```

## Text Search Debugging Functions

- ts_debug([ config regconfig, ] document text, OUT alias text, OUT description text, OUT token text, OUT dictionaries regdictionary[], OUT dictionary regdictionary, OUT lexemes text[])

  Description: Tests a configuration.

  Return type: SETOF record

  Example:

  ```
  openGauss=# SELECT ts_debug('english', 'The Brightest supernovaes');
                                  ts_debug
  -------------------------------------------------------------------------------
   (asciiword,"Word, all ASCII",The,{english_stem},english_stem,{})
   (blank,"Space symbols"," ",{},,)
   (asciiword,"Word, all ASCII",Brightest,{english_stem},english_stem,{brightest})
   (blank,"Space symbols"," ",{},,)
   (asciiword,"Word, all ASCII",supernovaes,{english_stem},english_stem,{supernova})
  (5 rows)
  ```

- ts_lexize(dict regdictionary, token text)

  Description: Tests a data dictionary.

  Return type: text[]

  Example:

  ```
  openGauss=# SELECT ts_lexize('english_stem', 'stars');
   ts_lexize
  -----------
   {star}
  (1 row)
  ```

- ts_parse(parser_name text, document text, OUT tokid integer, OUT token text)

  Description: Tests a parser.

  Return type: SETOF record

  Example:

  ```
  openGauss=# SELECT ts_parse('default', 'foo - bar');
   ts_parse
  -----------
   (1,foo)
   (12," ")
   (12,"- ")
   (1,bar)
  (4 rows)
  ```

- ts_parse(parser_oid oid, document text, OUT tokid integer, OUT token text)

  Description: Tests a parser.

  Return type: SETOF record

  Example:

  ```
  openGauss=# SELECT ts_parse(3722, 'foo - bar');
   ts_parse
  -----------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 (1,foo)
 (12," ")
 (12,"- ")
 (1,bar)
(4 rows)
```

- ts_token_type(parser_name text, OUT tokid integer, OUT alias text, OUT description text)

  Description: Obtains token types defined by a parser.

  Return type: SETOF record

  Example:

```
openGauss=# SELECT ts_token_type('default');
                      ts_token_type
------------------------------------------------------------
 (1,asciiword,"Word, all ASCII")
 (2,word,"Word, all letters")
 (3,numword,"Word, letters and digits")
 (4,email,"Email address")
 (5,url,URL)
 (6,host,Host)
 (7,sfloat,"Scientific notation")
 (8,version,"Version number")
 (9,hword_numpart,"Hyphenated word part, letters and digits")
 (10,hword_part,"Hyphenated word part, all letters")
 (11,hword_asciipart,"Hyphenated word part, all ASCII")
 (12,blank,"Space symbols")
 (13,tag,"XML tag")
 (14,protocol,"Protocol head")
 (15,numhword,"Hyphenated word, letters and digits")
 (16,asciihword,"Hyphenated word, all ASCII")
 (17,hword,"Hyphenated word, all letters")
 (18,url_path,"URL path")
 (19,file,"File or path name")
 (20,float,"Decimal notation")
 (21,int,"Signed integer")
 (22,uint,"Unsigned integer")
 (23,entity,"XML entity")
(23 rows)
```

- ts_token_type(parser_oid oid, OUT tokid integer, OUT alias text, OUT description text)

  Description: Obtains token types defined by a parser.

  Return type: SETOF record

  Example:

```
openGauss=# SELECT ts_token_type(3722);
                      ts_token_type
------------------------------------------------------------
 (1,asciiword,"Word, all ASCII")
 (2,word,"Word, all letters")
 (3,numword,"Word, letters and digits")
 (4,email,"Email address")
 (5,url,URL)
 (6,host,Host)
 (7,sfloat,"Scientific notation")
 (8,version,"Version number")
 (9,hword_numpart,"Hyphenated word part, letters and digits")
 (10,hword_part,"Hyphenated word part, all letters")
 (11,hword_asciipart,"Hyphenated word part, all ASCII")
 (12,blank,"Space symbols")
 (13,tag,"XML tag")
 (14,protocol,"Protocol head")
 (15,numhword,"Hyphenated word, letters and digits")
 (16,asciihword,"Hyphenated word, all ASCII")
 (17,hword,"Hyphenated word, all letters")
 (18,url_path,"URL path")
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 (19,file,"File or path name")
 (20,float,"Decimal notation")
 (21,int,"Signed integer")
 (22,uint,"Unsigned integer")
 (23,entity,"XML entity")
(23 rows)
```

- ts_stat(sqlquery text, [ weights text, ] OUT word text, OUT ndoc integer, OUT nentry integer)

  Description: Obtains statistics of a **tsvector** column.

  Return type: SETOF record

  Example:

```
openGauss=# SELECT ts_stat('select ''hello world''::tsvector');
   ts_stat
-------------
 (world,1,1)
 (hello,1,1)
(2 rows)
```

## 12.5.13 JSON/JSONB Functions and Operators

For details about the JSON/JSONB data type, see **12.3.12 JSON/JSONB Types**.

**Table 12-34** JSON/JSONB common operators

| Operators | Left Operand Type | Right Operand Type | Return Type | Description | Example | Example Result |
| --- | --- | --- | --- | --- | --- | --- |
| -> | Array-json(b) | int | json(b) | Obtains the **array-json** element. If the subscript does not exist, **NULL** is returned. | '[{"a":"foo"}, {"b":"bar"}, {"c":"baz"}]'::json->2 | {"c":"baz"} |
| -> | object-json(b) | text | json(b) | Obtains the value by a key. If no record is found, **NULL** is returned. | '{"a": {"b":"foo"}}'::json->'a' | {"b":"foo"} |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Operators | Left Operand Type | Right Operand Type | Return Type | Description | Example | Example Result |
| --- | --- | --- | --- | --- | --- | --- |
| ->> | Array-json(b) | int | text | Obtains the JSON array element. If the subscript does not exist, **NULL** is returned. | '[1,2,3]'::json->>2 | 3 |
| ->> | object-json(b) | text | text | Obtains the value by a key. If no record is found, **NULL** is returned. | '{"a":1,"b":2}'::json->>'b' | 2 |
| #> | container-json (b) | text[] | json(b) | Obtains the JSON object in the specified path. If the path does not exist, **NULL** is returned. | '{"a": {"b":{"c": "foo"}}}'::json #>'{a,b}' | {"c": "foo"} |
| #>> | container-json (b) | text[] | text | Obtains the JSON object in the specified path. If the path does not exist, **NULL** is returned. | '{"a": [1,2,3],"b": [4,5,6]}'::json #>>'{a,2}' | 3 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**CAUTION**

For the **#>** and **#>>** operators, if no data can be found in the specified path, no error is reported and a **NULL** value is returned.

**Table 12-35** Additional JSONB support for operators

| Operators | Right Operand Type | Description | Example |
| --- | --- | --- | --- |
| @> | jsonb | Whether the top layer of the JSON on the left contains all items of the top layer of the JSON on the right. | '{"a":1, "b":2}'::jsonb @> '{"b":2}'::jsonb |
| <@ | jsonb | Whether all items in the JSON file on the left exist at the top layer of the JSON file on the right. | '{"b":2}'::jsonb <@ '{"a":1, "b":2}'::jsonb |
| ? | text | Whether the string of the key or element exists at the top layer of the JSON value. | '{"a":1, "b":2}'::jsonb ? 'b' |
| ?\| | text[] | Whether any of these array strings exists as top-layer keys. | '{"a":1, "b":2, "c":3}'::jsonb ?\| array['b', 'c'] |
| ?& | text[] | Whether all these array strings exist as top-layer keys. | '["a", "b"]'::jsonb ?& array['a', 'b'] |
| = | jsonb | Determines the size between two **JSONB** files, which is the same as the **jsonb_eq** function. | / |
| <> | jsonb | Determines the size between two **JSONB** files, which is the same as the **jsonb_ne** function. | / |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Operators | Right Operand Type | Description | Example |
| --- | --- | --- | --- |
| < | jsonb | Determines the size between two **JSONB** files, which is the same as the **jsonb_lt** function. | / |
| > | jsonb | Determines the size between two **JSONB** files, which is the same as the **jsonb_gt** function. | / |
| <= | jsonb | Determines the size between two **JSONB** files, which is the same as the **jsonb_le** function. | / |
| >= | jsonb | Determines the size between two **JSONB** files, which is the same as the **jsonb_ge** function. | / |

## Functions Supported by JSON/JSONB

- array_to_json\(anyarray \[, pretty_bool\]\)

  Description: Returns the array as JSON. A multi-dimensional array becomes a JSON array of arrays. If the value of **pretty_bool** is **true**, a newline character is added between one-dimensional elements.

  Return type: json

  Example:

  ```
  openGauss=# SELECT array_to_json('{{1,5},{99,100}}'::int[]);
    array_to_json
    ------------------
    [[1,5],[99,100]]
    (1 row)
  ```

- row_to_json\(record \[, pretty_bool\]\)

  Description: Returns the row as JSON. If the value of **preretty_bool** is **true**, a newline character is added between one-dimensional elements.

  Return type: json

  Example:

  ```
  openGauss=# SELECT row_to_json(row(1,'foo'));
        row_to_json
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 ---------------------
  {"f1":1,"f2":"foo"}    (1 row)
```

- json_array_element(array-json, integer), jsonb_array_element(array-jsonb, integer)

  Description: Same as the operator **`->`**, which returns the element with the specified subscript in the array.

  Return type: json, jsonb

  Example:

```
openGauss=# select json_array_element('[1,true,[1,[2,3
]],null]',2);
 json_array_element
 --------------------
 [1,[2,3]]
 (1 row)
```

- json_array_element_text(array-json, integer), jsonb_array_element_text(array-jsonb, integer)

  Description: Same as the operator **`->>`**, which returns the element with the specified subscript in the array.

  Return type: text, text

  Example:

```
openGauss=# select json_array_element_text('[1,true,[1,[2,3]],null]',2);
json_array_element_text
------------------------
 [1,[2,3]]
 (1 row)
```

- json_object_field(object-json, text), jsonb_object_field(object-jsonb, text)

  Description: Same as the operator **`->`**, which returns the value of a specified key in an object.

  Return type: json, json

  Example:

```
 openGauss=# select json_object_field('{"a": {"b":"foo"}}','a');
 json_object_field
 -------------------
 {"b":"foo"}
 (1 row)
```

- json_object_field_text(object-json, text), jsonb_object_field_text(object-jsonb, text)

  Description: Same as the operator **`->`**, which returns the value of a specified key in an object.

  Return type: text, text

  Example:

```
 openGauss=# select json_object_field_text('{"a": {"b":"foo"}}','a');
 json_object_field_text
 ------------------------
 {"b":"foo"}
 (1 row)
```

- json_extract_path(json, VARIADIC text[]), jsonb_extract_path((jsonb, VARIADIC text[])

  Description: Equivalent to the operator **`#>`** searches for JSON based on the path specified by *$2* and returns the result.

  Return type: json, jsonb

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# select json_extract_path('{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}', 'f4','f6');
 json_extract_path
-------------------
 "stringy"
(1 row)
```

- json_extract_path_op(json, text[]), jsonb_extract_path_op(jsonb, text[])

  Description: Same as the operator **`#>`**, searches for JSON based on the path specified by *$2* and returns the result.

  Return type: json, jsonb

  Example:

```
 openGauss=# select json_extract_path_op('{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}',
ARRAY['f4','f6']);
  json_extract_path_op
----------------------
 "stringy"
(1 row)
```

- json_extract_path_text(json, VARIADIC text[]), jsonb_extract_path_text((jsonb, VARIADIC text[])

  Description: Equivalent to the operator **`#>`**, searches for JSON based on the path specified by $2 and return the result.

  Return type: text, text

  Example:

```
openGauss=# select json_extract_path_text('{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}', 'f4','f6');
  json_extract_path_text
------------------------
 "stringy"
(1 row)
```

- json_extract_path_text_op(json, text[]), jsonb_extract_path_text_op(jsonb, text[])

  Description: Same as the operator **`#>`**, searches for JSON based on the path specified by $2 and return the result.

  Return type: text, text

  Example:

```
 openGauss=# select json_extract_path_text_op('{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}',
ARRAY['f4','f6']);
  json_extract_path_text_op
---------------------------
 "stringy"
(1 row)
```

- json_array_elements(array-json), jsonb_array_elements(array-jsonb)

  Description: Splits an array. Each element returns a row.

  Return type: json, jsonb

  Example:

```
openGauss=# select json_array_elements('[1,true,[1,[2,3]],null]');
  json_array_elements
----------------------
 1
 true
 [1,[2,3]]
 null
(4 rows)
```

- json_array_elements_text(array-json), jsonb_array_elements_text(array-jsonb)

  Description: Splits an array. Each element returns a row.

  Return type: text, text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# select * from  json_array_elements_text('[1,true,[1,[2,3]],null]');
    value
-----------
 1
 true
 [1,[2,3]]

 (4 rows)
```

- json_array_length(array-json), jsonb_array_length(array-jsonb)

  Description: Returns the array length.

  Return type: integer

  Example:

  ```
  openGauss=# SELECT json_array_length('[1,2,3,{"f1":1,"f2":[5,6]},4,null]');
   json_array_length
  -------------------
                   6
  (1 row)
  ```

- json_each(object-json), jsonb_each(object-jsonb)

  Description: Splits each key-value pair of an object into one row and two columns.

  Return type: setof(key text, value json), setof(key text, value jsonb)

  Example:

  ```
  openGauss=# select * from  json_each('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
   key |  value
  -----+----------
   f1  | [1,2,3]
   f2  | {"f3":1}
   f4  | null
  (3 rows)
  ```

- json_each_text(object-json), jsonb_each_text(object-jsonb)

  Description: Splits each key-value pair of an object into one row and two columns.

  Return type: setof(key text, value text), setof(key text, value text)

  Example:

  ```
  openGauss=# select * from  json_each_text('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
   key |  value
  -----+----------
   f1  | [1,2,3]
   f2  | {"f3":1}
   f4  |
  (3 rows)
  ```

- json_object_keys(object-json), jsonb_object_keys(object-jsonb)

  Description: Returns all keys at the top layer of the object.

  Return type: SETOF text

  Example:

  ```
  openGauss=# select json_object_keys('{"f1":"abc","f2":{"f3":"a", "f4":"b"}, "f1":"abcd"}');
   json_object_keys
  ------------------
   f1
   f2
   f1
  (3 rows)
  ```

- JSONB deduplication operations:

  ```
  openGauss=# select jsonb_object_keys('{"f1":"abc","f2":{"f3":"a", "f4":"b"}, "f1":"abcd"}');
   jsonb_object_keys
  -------------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 f1
 f2
(2 rows)
```

- json_populate_record(anyelement, object-json [, bool]), jsonb_populate_record(anyelement, object-jsonb [, bool])

  Description: *$1* must be a compound parameter. Each key-value in the **object-json** file is split. The key is used as the column name to match the column name in *$1* and fill in the *$1* format.

  Return type: anyelement, anyelement

  Example:

```
openGauss=# create type jpop as (a text, b int, c bool);
CREATE TYPE
postgres=# select * from json_populate_record(null::jpop,'{"a":"blurfl","x":43.2}');
   a    | b | c
--------+---+---
 blurfl |   |
(1 row)
```

```
openGauss=# select * from json_populate_record((1,1,null)::jpop,'{"a":"blurfl","x":43.2}');
   a    | b | c
--------+---+---
 blurfl | 1 |
(1 row)
```

- json_populate_record_set(anyelement, array-json [, bool]), jsonb_populate_record_set(anyelement, array-jsonb [, bool])

  Description: Performs the preceding operations on each element in the *$2* array by referring to the **json_populate_record** and **jsonb_populate_record** functions. Therefore, each element in the *$2* array must be of the **object-json** type.

  Return type: setof anyelement, setof anyelement

  Example:

```
openGauss=# create type jpop as (a text, b int, c bool);
CREATE TYPE
postgres=# select * from json_populate_recordset(null::jpop, '[{"a":1,"b":2},{"a":3,"b":4}]');
 a | b | c
---+---+---
 1 | 2 |
 3 | 4 |
(2 rows)
```

- json_typeof(json), jsonb_typeof(jsonb)

  Description: Checks the JSON type.

  Return type: text, text

  Example:

```
openGauss=# select value, json_typeof(value)
 postgres-# from (values (json '123.4'), (json '"foo"'), (json 'true'), (json 'null'), (json '[1, 2, 3]'), (json
'{"x":"foo", "y":123}'), (NULL::json))  as data(value);
         value          | json_typeof
------------------------+-------------
 123.4                  | number
 "foo"                  | string
 true                   | boolean
 null                   | null
 [1, 2, 3]              | array
 {"x":"foo", "y":123} | object
                        |
(7 rows)
```

- json_build_array( [VARIADIC "any"] )

  Description: Constructs a JSON array from a variable parameter list.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: array-json

Example:

```
openGauss=# select json_build_array('a',1,'b',1.2,'c',true,'d',null,'e',json '{"x": 3, "y": [1,2,3]}','');
                      json_build_array
------------------------------------------------------------------------------
 ["a", 1, "b", 1.2, "c", true, "d", null, "e", {"x": 3, "y": [1,2,3]}, ""]
(1 row)
```

- json_build_object( [VARIADIC "any"] )

  Description: Constructs a JSON object from a variable parameter list. The number of input parameters must be an even number. Every two input parameters form a key-value pair. Note that the value of a key cannot be null.

  Return type: object-json

  Example:

  ```
  openGauss=# select json_build_object(1,2);
    json_build_object
  --------------------
   {"1" : 2}
  (1 row)
  ```

- json_to_record(object-json, bool)

  Description: Like all functions that return **record**, the caller must explicitly define the structure of the record with an AS clause. The key-value pair of **object-json** is split and reassembled. The key is used as a column name to match and fill in the structure of the specified record.

  Return type: record

  Example:

  ```
  openGauss=# select * from json_to_record('{"a":1,"b":"foo","c":"bar"}',true) as x(a int, b text, d text);
    a |  b  | d
  ---+-----+---
    1 | foo |
  (1 row)
  ```

- json_to_recordset(array-json, bool)

  Description: Executes the preceding function on each element in the array by referring to the **json_to_record** function. Therefore, each element in the array must be **object-json**.

  Return type: SETOF record

  Example:

  ```
  openGauss=# select * from json_to_recordset(
   openGauss(#    '[{"a":1,"b":"foo","d":false},{"a":2,"b":"bar","c":true}]',
  openGauss(#    false
  openGauss(# ) as x(a int, b text, c boolean);
    a |  b  | c
  ---+-----+---
    1 | foo |
    2 | bar | t
  (2 rows)
  ```

- json_object(text[]), json_object(text[], text[])

  Description: Constructs an **object-json** from a text array. This is an overloaded function. When the input parameter is a text array, the array length must be an even number, and members are considered as alternate key-value pairs. When two text arrays are used, the first array is considered as a key, and the second array a value. The lengths of the two arrays must be the same. Note that the value of a key cannot be null.

  Return type: object-json

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# select json_object('{a,1,b,2,3,NULL,"d e f","a b c"}');
                       json_object
-----------------------------------------------------
 {"a" : "1", "b" : "2", "3" : null, "d e f" : "a b c"}
(1 row)
postgres=# select json_object('{a,b,"a b c"}', '{a,1,1}');
              json_object
---------------------------------------
 {"a" : "a", "b" : "1", "a b c" : "1"}
(1 row)
```

- json_agg(any)

  Description: Aggregates values into a JSON array.

  Return type: array-json

  Example:

```
openGauss=# select * from classes;
 name | score
------+-------
A    |     2
A    |     3
D    |     5
D    |
(4 rows)
openGauss=# select name, json_agg(score) score from classes group by name order by name;
name |      score
-----+-----------------
A    | [2, 3]
D    | [5, null]
     | [null]
(3 rows)
```

- json_object_agg(any, any)

  Description: Aggregates values into a JSON object.

  Return type: object-json

  Example:

```
openGauss=# select * from classes;
name | score
-----+-------
A    |     2
A    |     3
D    |     5
D    |
(4 rows)
```

```
openGauss=# select json_object_agg(name, score) from classes group by name order by name;
    json_object_agg
-------------------------
 { "A" : 2, "A" : 3 }
 { "D" : 5, "D" : null }
(2 rows)
```

- - jsonb_contained(jsonb, jsonb)

  Description: Same as the operator **`<@`**, determines whether all elements in *$1* exist at the top layer of *$2*.

  Return type: Boolean

  Example:

```
openGauss=# select jsonb_contained('[1,2,3]', '[1,2,3,4]');
 jsonb_contained
-----------------
 t
(1 row)
```

- - jsonb_contains(jsonb, jsonb)

  Description: Same as the operator **`@>`**, checks whether all top-layer elements in *$1* are contained in *$2*.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: Boolean

Example:

```
openGauss=# select jsonb_contains('[1,2,3,4]', '[1,2,3]');
 jsonb_contains
----------------
 t
(1 row)
```

- - jsonb_exists(jsonb, text)

  Description: Same as the operator **`?`**, determines whether all elements in the string array *$2* exist at the top layer of *$1* in the form of **key\elem\scalar**.

  Return type: Boolean

  Example:

  ```
  openGauss=# select jsonb_exists('["1",2,3]', '1');
   jsonb_exists
  --------------
   t
  (1 row)
  ```

- - jsonb_exists_all(jsonb, text[])

  Description: Same as the operator **`?&`**, checks whether all elements in the string array *$2* exist at the top layer of *$1* in the form of **key\elem\scalar**.

  Return type: Boolean

  Example:

  ```
  openGauss=# select jsonb_exists_all('["1","2",3]', '{1, 2}');
   jsonb_exists_all
  ------------------
   t
  (1 row)
  ```

- - jsonb_exists_any(jsonb, text[])

  Description: Same as the operator **`?|`**, checks whether all elements in the string array *$2* exist at the top layer of *$1* in the form of **key\elem\scalar**.

  Return type: Boolean

  Example:

  ```
  openGauss=# select jsonb_exists_any('["1","2",3]', '{1, 2, 4}');
   jsonb_exists_any
  ------------------
   t
  (1 row)
  ```

- - jsonb_cmp(jsonb, jsonb)

  Description: Compares values. A positive value indicates greater than, a negative value indicates less than, and **0** indicates equal.

  Return type: integer

  Example:

  ```
  openGauss=# select jsonb_cmp('["a", "b"]', '{"a":1, "b":2}');
   jsonb_cmp
  -----------
          -1
  (1 row)
  ```

- - jsonb_eq(jsonb, jsonb)

  Description: Same as the operator **`=`**, compares two values.

  Return type: Boolean

  Example:

  ```
  openGauss=# select jsonb_eq('["a", "b"]', '{"a":1, "b":2}');
   jsonb_eq
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
----------
 f
(1 row)
```

- - jsonb_ne(jsonb, jsonb)

  Description: Same as the operator **`<>`**, compares two values.

  Return type: Boolean

  Example:

```
openGauss=# select jsonb_ne('["a", "b"]', '{"a":1, "b":2}');
 jsonb_ne
----------
 t
(1 row)
```

- - jsonb_gt(jsonb, jsonb)

  Description: Same as the operator **`>`**, compares two values.

  Return type: Boolean

  Example:

```
openGauss=# select jsonb_gt('["a", "b"]', '{"a":1, "b":2}');
 jsonb_gt
----------
 f
(1 row)
```

- - jsonb_ge(jsonb, jsonb)

  Description: Same as the operator **`>=`**, compares two values.

  Return type: Boolean

  Example:

```
openGauss=# select jsonb_ge('["a", "b"]', '{"a":1, "b":2}');
 jsonb_ge
----------
 f
(1 row)
```

- - jsonb_lt(jsonb, jsonb)

  Description: Same as the operator **`<`**, compares two values.

  Return type: Boolean

  Example:

```
openGauss=# select jsonb_lt('["a", "b"]', '{"a":1, "b":2}');
 jsonb_lt
----------
 t
(1 row)
```

- - jsonb_le(jsonb, jsonb)

  Description: Same as the operator **`<=`**, compares two values.

  Return type: Boolean

  Example:

```
openGauss=# select jsonb_le('["a", "b"]', '{"a":1, "b":2}');
 jsonb_le
----------
 t
(1 row)
```

- - to_json(anyelement)

  Description: Converts parameters to **`json`**.

  Return type: json

  Example:

```
openGauss=# select to_json('{1,5}'::text[]);
   to_json
 -----------
  ["1","5"]
 (1 row)
```

- - jsonb_hash(jsonb)

  Description: Performs the hash operation on JSONB.

  Return type: integer

  Example:

```
openGauss=# select jsonb_hash('[1,2,3]');
   josnb_hash
 --------------
  -55996848
 (1 row)
```

- Other functions

  Description: Internal functions used by GIN indexes and JSON and JSONB aggregate functions.

```
gin_compare_jsonb
gin_consistent_jsonb
gin_consistent_jsonb_hash
gin_extract_jsonb
gin_extract_jsonb_hash
gin_extract_jsonb_query
gin_extract_jsonb_query_hash
gin_triconsistent_jsonb
gin_triconsistent_jsonb_hash
json_agg_transfn
json_agg_finalfn
json_object_agg_transfn
json_object_agg_finalfn
```

# 12.5.14 HLL Functions and Operators

## Hash Functions

- hll_hash_boolean(bool)

  Description: Hashes data of the bool type.

  Return type: hll_hashval

  Example:

```
openGauss=# SELECT hll_hash_boolean(FALSE);
  hll_hash_boolean
----------------------
 -5451962507482445012
(1 row)
```

- hll_hash_boolean(bool, int32)

  Description: Configures a hash seed (that is, change the hash policy) and hashes data of the bool type.

  Return type: hll_hashval

  Example:

```
openGauss=# SELECT hll_hash_boolean(FALSE, 10);
  hll_hash_boolean
--------------------
 -1169037589280886076
(1 row)
```

- hll_hash_smallint(smallint)

  Description: Hashes data of the smallint type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: hll_hashval

Example:

```
openGauss=# SELECT hll_hash_smallint(100::smallint);
 hll_hash_smallint
---------------------
 962727970174027904
(1 row)
```

NOTE

If parameters with the same numeric value are hashed using different data types, the data will differ, because hash functions select different calculation policies for each type.

- hll_hash_smallint(smallint, int32)

  Description: Configures a hash seed (that is, change the hash policy) and hashes data of the smallint type.

  Return type: hll_hashval

  Example:

  ```
  openGauss=# SELECT hll_hash_smallint(100::smallint, 10);
   hll_hash_smallint
  ---------------------
   -9056177146160443041
  (1 row)
  ```

- hll_hash_integer(integer)

  Description: Hashes data of the integer type.

  Return type: hll_hashval

  Example:

  ```
  openGauss=# SELECT hll_hash_integer(0);
    hll_hash_integer
  ----------------------
   5156626420896634997
  (1 row)
  ```

- hll_hash_integer(integer, int32)

  Description: Hashes data of the integer type and configures a hash seed (that is, change the hash policy).

  Return type: hll_hashval

  Example:

  ```
  openGauss=# SELECT hll_hash_integer(0, 10);
   hll_hash_integer
  ---------------------
   -5035020264353794276
  (1 row)
  ```

- hll_hash_bigint(bigint)

  Description: Hashes data of the bigint type.

  Return type: hll_hashval

  Example:

  ```
  openGauss=# SELECT hll_hash_bigint(100::bigint);
    hll_hash_bigint
  ---------------------
   -2401963681423227794
  (1 row)
  ```

- hll_hash_bigint(bigint, int32)

  Description: Hashes data of the bigint type and configures a hash seed (that is, change the hash policy).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: hll_hashval

Example:

```
openGauss=# SELECT hll_hash_bigint(100::bigint, 10);
  hll_hash_bigint
---------------------
 -2305749404374433531
(1 row)
```

- hll_hash_bytea(bytea)

  Description: Hashes data of the bytea type.

  Return type: hll_hashval

  Example:

  ```
  openGauss=# SELECT hll_hash_bytea(E'\\x');
   hll_hash_bytea
  ----------------
   0
  (1 row)
  ```

- hll_hash_bytea(bytea, int32)

  Description: Hashes data of the bytea type and configures a hash seed (that is, change the hash policy).

  Return type: hll_hashval

  Example:

  ```
  openGauss=# SELECT hll_hash_bytea(E'\\x', 10);
    hll_hash_bytea
  ---------------------
   7233188113542599437
  (1 row)
  ```

- hll_hash_text(text)

  Description: Hashes data of the text type.

  Return type: hll_hashval

  Example:

  ```
  openGauss=# SELECT hll_hash_text('AB');
     hll_hash_text
  ---------------------
   -5666002586880275174
  (1 row)
  ```

- hll_hash_text(text, int32)

  Description: Hashes data of the text type and configures a hash seed (that is, change the hash policy).

  Return type: hll_hashval

  Example:

  ```
  openGauss=# SELECT hll_hash_text('AB', 10);
  hll_hash_text
  ---------------------
  -2215507121143724132
  (1 row)
  ```

- hll_hash_any(anytype)

  Description: Hashes data of any type.

  Return type: hll_hashval

  Example:

  ```
  openGauss=# select hll_hash_any(1);
     hll_hash_any
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
----------------------
 -1316670585935156930
(1 row)

openGauss=# select hll_hash_any('08:00:2b:01:02:03'::macaddr);
     hll_hash_any
----------------------
 -3719950434455589360
(1 row)
```

- hll_hash_any(anytype, int32)

  Description: Hashes data of any type and configures a hash seed (that is, change the hash policy).

  Return type: hll_hashval

  Example:

```
openGauss=# select hll_hash_any(1, 10);
     hll_hash_any
----------------------
 7048553517657992351
(1 row)
```

- hll_hashval_eq(hll_hashval, hll_hashval)

  Description: Compares two pieces of data of the hll_hashval type to check whether they are the same.

  Return type: Boolean

  Example:

```
openGauss=# select hll_hashval_eq(hll_hash_integer(1), hll_hash_integer(1));
 hll_hashval_eq
----------------
 t
(1 row)
```

- hll_hashval_ne(hll_hashval, hll_hashval)

  Description: Compares two pieces of data of the hll_hashval type to check whether they are different.

  Return type: Boolean

  Example:

```
openGauss=# select hll_hashval_ne(hll_hash_integer(1), hll_hash_integer(1));
 hll_hashval_ne
----------------
 f
(1 row)
```

## HLL Functions

There are three HLL modes: explicit, sparse, and full. When the data size is small, the explicit mode is used. In this mode, distinct values are calculated without errors. As the number of distinct values increases, the HLL mode is switched to the sparse and full modes in sequence. The two modes have no difference in the calculation result, but vary in the calculation efficiency of HLL functions and the storage space of HLL objects. The following functions can be used to view some HLL parameters:

- hll_print(hll)

  Description: Prints some debugging parameters of an HLL.

  Example:

```
openGauss=# select hll_print(hll_empty());
                                hll_print
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
--------------------------------------------------------------------------------
 type=1(HLL_EMPTY), log2m=14, log2explicit=10, log2sparse=12, duplicatecheck=0
(1 row)
```

- hll_type(hll)

  Description: Checks the type of the current HLL. The return values are described as follows: **0** indicates **HLL_UNINIT**, an HLL object that is not initialized. **1** indicates **HLL_EMPTY**, an empty HLL object. **2** indicates **HLL_EXPLICIT**, an HLL object in explicit mode. **3** indicates **HLL_SPARSE**, an HLL object in sparse mode. **4** indicates **HLL_FULL**, an HLL object in full mode. **5** indicates **HLL_UNDEFINED**, an invalid HLL object.

  Example:

```
openGauss=# select hll_type(hll_empty());
 hll_type
----------
        1
(1 row)
```

- hll_log2m(hll)

  Description: Checks the value of **log2m** in the current HLL data structure. **log2m** is the logarithm of the number of buckets. This value affects the error rate of calculating distinct values by HLL. The error rate = ±1.04/√(2^log2m). If the value of **log2m** ranges from 10 to 16, HLL sets the number of buckets to $2^{log2m}$. When the value of **log2explicit** is explicitly set to **–1**, the built-in default value is used.

  Example:

```
openGauss=# select hll_log2m(hll_empty());
 hll_log2m
-----------
        14
(1 row)

openGauss=# select hll_log2m(hll_empty(10));
 hll_log2m
-----------
        10
(1 row)

openGauss=# select hll_log2m(hll_empty(-1));
 hll_log2m
-----------
        14
(1 row)
```

- hll_log2explicit(hll)

  Description: Queries the value of **log2explicit** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can change the value of **log2explicit** to change the policy. For example, if the value of **log2explicit** is **0**, the HLL will skip the **explicit** mode and directly enter the **sparse** mode. When the value of **log2explicit** is explicitly set to a value ranging from 1 to 12, the HLL will switch to the sparse mode when the length of the data segment exceeds $2^{log2explicit}$. When the value of **log2explicit** is explicitly set to **–1**, the built-in default value is used.

  Example:

```
openGauss=# select hll_log2explicit(hll_empty());
 hll_log2explicit
------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
           10
(1 row)

openGauss=# select hll_log2explicit(hll_empty(12, 8));
 hll_log2explicit
------------------
            8
(1 row)

openGauss=# select hll_log2explicit(hll_empty(12, -1));
 hll_log2explicit
------------------
           10
(1 row)
```

- hll_log2sparse(hll)

  Description: Queries the value of **log2sparse** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can adjust the value of **log2sparse** to change the policy. For example, if the value of **log2sparse** is **0**, the system skips the sparse mode and directly enters the full mode. If the value of **log2sparse** is explicitly set to a value ranging from 1 to 14, the HLL will switch to the full mode when the length of the data segment exceeds $2^{log2sparse}$. When the value of **log2sparse** is explicitly set to **–1**, the built-in default value is used.

  Example:

```
openGauss=# select hll_log2sparse(hll_empty());
 hll_log2sparse
----------------
          12
(1 row)

openGauss=# select hll_log2sparse(hll_empty(12, 8, 10));
 hll_log2sparse
----------------
          10
(1 row)

openGauss=# select hll_log2sparse(hll_empty(12, 8, -1));
 hll_log2sparse
----------------
          12
(1 row)
```

- hll_duplicatecheck(hll)

  Description: Specifies whether duplicate check is enabled. **0**: disable; **1**: enable. This function is disabled by default. If there are many duplicate values, you can enable this function to improve efficiency. When the value of **duplicatecheck** is explicitly set to **–1**, the built-in default value is used.

  Example:

```
openGauss=# select hll_duplicatecheck(hll_empty());
 hll_duplicatecheck
--------------------
                 0
(1 row)

openGauss=# select hll_duplicatecheck(hll_empty(12, 8, 10, 1));
 hll_duplicatecheck
--------------------
                 1
(1 row)

openGauss=# select hll_duplicatecheck(hll_empty(12, 8, 10, -1));
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 hll_duplicatecheck
--------------------
                  0
(1 row)
```

## Functional Functions

- hll_empty()

  Description: Creates an empty HLL.

  Return type: hll

  Example:

  ```
  openGauss=# select hll_empty();
                                hll_empty
  ------------------------------------------------------------
   \x484c4c00000000002b050000000000000000000000000000000000000000
  (1 row)
  ```

- hll_empty(int32 log2m)

  Description: Creates an empty HLL and sets the **log2m** parameter. The parameter value ranges from 10 to 16. If the input is **–1**, the built-in default value is used.

  Return type: HLL

  Example:

  ```
  openGauss=# select hll_empty(10);
                                hll_empty
  ------------------------------------------------------------
   \x484c4c00000000002b040000000000000000000000000000000000000000
  (1 row)

  openGauss=# select hll_empty(-1);
                                hll_empty
  ------------------------------------------------------------
   \x484c4c00000000002b050000000000000000000000000000000000000000
  (1 row)
  ```

- hll_empty(int32 log2m, int32 log2explicit)

  Description: Creates an empty HLL and sets the **log2m** and **log2explicit** parameters in sequence. The value of **log2explicit** ranges from 0 to 12. The value **0** indicates that the explicit mode is skipped. This parameter is used to set the threshold of the explicit mode. When the length of the data segment reaches $2^{log2explicit}$, the mode is switched to the sparse or full mode. If the input is **–1**, the built-in default value of **log2explicit** is used.

  Return type: HLL

  Example:

  ```
  openGauss=# select hll_empty(10, 4);
                                hll_empty
  ------------------------------------------------------------
   \x484c4c0000000000130400000000000000000000000000000000000000
  (1 row)

  openGauss=# select hll_empty(10, -1);
                                hll_empty
  ------------------------------------------------------------
   \x484c4c00000000002b040000000000000000000000000000000000000000
  (1 row)
  ```

- hll_empty(int32 log2m, int32 log2explicit, int64 log2sparse)

  Description: Creates an empty HLL and sets the **log2m**, **log2explicit** and **log2sparse** parameters in sequence. The value of **log2sparse** ranges from 0

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

to 14. The value **0** indicates that the sparse mode is skipped. This parameter is used to set the threshold of the sparse mode. When the length of the data segment reaches $2^{log2sparse}$, the mode is switched to the full mode. If the input is **–1**, the built-in default value of **log2sparse** is used.

Return type: HLL

Example:

```
openGauss=# select hll_empty(10, 4, 8);
                      hll_empty
------------------------------------------------------------
 \x484c4c0000000000120400000000000000000000000000000000000000
(1 row)

openGauss=# select hll_empty(10, 4, -1);
                      hll_empty
------------------------------------------------------------
 \x484c4c0000000000130400000000000000000000000000000000000000
(1 row)
```

- hll_empty(int32 log2m, int32 log2explicit, int64 log2sparse, int32 duplicatecheck)

  Description: Creates an empty HLL and sets the **log2m**, **log2explicit**, **log2sparse**, and **duplicatecheck** parameters in sequence. The value of **duplicatecheck** is **0** or **1**, indicating whether the duplicate check mode is enabled. By default, this mode is disabled. If the input is **–1**, the built-in default value of **duplicatecheck** is used.

  Return type: HLL

  Example:

```
openGauss=# select hll_empty(10, 4, 8, 0);
                      hll_empty
------------------------------------------------------------
 \x484c4c0000000000120400000000000000000000000000000000000000
(1 row)

openGauss=# select hll_empty(10, 4, 8, -1);
                      hll_empty
------------------------------------------------------------
 \x484c4c0000000000120400000000000000000000000000000000000000
(1 row)
```

- hll_add(hll, hll_hashval)

  Description: Adds hll_hashval to an HLL.

  Return type: HLL

  Example:

```
openGauss=# select hll_add(hll_empty(), hll_hash_integer(1));
                                hll_add
------------------------------------------------------------------------------
 \x484c4c08000002002b0900000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)
```

- hll_add_rev(hll_hashval, hll)

  Description: Adds **hll_hashval** to an HLL. This function works the same as **hll_add**, except that the positions of parameters are switched.

  Return type: HLL

  Example:

```
openGauss=# select hll_add_rev(hll_hash_integer(1), hll_empty());
                              hll_add_rev
------------------------------------------------------------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 \x484c4c08000002002b0900000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)
```

- hll_eq(hll, hll)

  Description: Compares two HLLs to check whether they are the same.

  Return type: Boolean

  Example:

```
openGauss=# select hll_eq(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
 hll_eq
--------
 f
(1 row)
```

- hll_ne(hll, hll)

  Description: Compares two HLLs to check whether they are different.

  Return type: Boolean

  Example:

```
openGauss=# select hll_ne(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
 hll_ne
--------
 t
(1 row)
```

- hll_cardinality(hll)

  Description: Calculates the number of distinct values of an HLL.

  Return type: int

  Example:

```
openGauss=# select hll_cardinality(hll_empty() || hll_hash_integer(1));
 hll_cardinality
-----------------
               1
(1 row)
```

- hll_union(hll, hll)

  Description: Performs the UNION operation on two HLL data structures to obtain one HLL.

  Return type: HLL

  Example:

```
openGauss=# select hll_union(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
                                    hll_union
------------------------------------------------------------------------------------------------

\x484c4c10002000002b0900000000000000004000000000000000000b3ccc49320cca1ae3e2921ff133fba
ed00
(1 row)
```

## Aggregate Functions

- hll_add_agg(hll_hashval)

  Description: Groups hashed data into HLL.

  Return type: HLL

  Example:

```
-- Prepare data:
openGauss=# create table t_id(id int);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# insert into t_id values(generate_series(1,500));
openGauss=# create table t_data(a int, c text);
openGauss=# insert into t_data select mod(id,2), id from t_id;

-- Create a table and specify an HLL column:
openGauss=# create table t_a_c_hll(a int, c hll);

-- Use GROUP BY on column a to group data, and insert the data to the HLL:
openGauss=# insert into t_a_c_hll select a, hll_add_agg(hll_hash_text(c)) from t_data group by a;

-- Calculate the number of distinct values for each group in the HLL:
openGauss=# select a, #c as cardinality from t_a_c_hll order by a;
 a |   cardinality
---+------------------
 0 | 247.862354346299
 1 | 250.908710610377
(2 rows)
```

- hll_add_agg(hll_hashval, int32 log2m)

  Description: Groups hashed data into HLL and specifies the **log2m** parameter. The value ranges from 10 to 16. If the input is **–1** or **NULL**, the built-in default value is used.

  Return type: HLL

  Example:

  ```
  openGauss=# select hll_cardinality(hll_add_agg(hll_hash_text(c), 12)) from t_data;
   hll_cardinality
  ------------------
   497.965240179228
  (1 row)
  ```

- hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit)

  Description: Groups hashed data into HLL and specifies the **log2m** and **log2explicit** parameters in sequence. The value of **log2explicit** ranges from 0 to 12. The value **0** indicates that the explicit mode is skipped. This parameter is used to set the threshold of the explicit mode. When the length of the data segment reaches $2^{log2explicit}$, the mode is switched to the sparse or full mode. If the input is **–1** or **NULL**, the built-in default value of **log2explicit** is used.

  Return type: HLL

  Example:

  ```
  openGauss=# select hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 1)) from t_data;
   hll_cardinality
  ------------------
   498.496062953313
  (1 row)
  ```

- hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse)

  Description: Groups hashed data into HLL and sets the **log2m**, **log2explicit**, and **log2sparse** parameters in sequence. The value of **log2sparse** ranges from 0 to 14. The value **0** indicates that the sparse mode is skipped. This parameter is used to set the threshold of the sparse mode. When the length of the data segment reaches $2^{log2sparse}$, the mode is switched to the full mode. If the input is **–1** or **NULL**, the built-in default value of **log2sparse** is used.

  Return type: HLL

  Example:

  ```
  openGauss=# select hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10)) from t_data;
   hll_cardinality
  ------------------
   498.496062953313
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse, int32 duplicatecheck)

  Description: Groups hashed data into HLL and sets the **log2m**, **log2explicit**, **log2sparse**, and **duplicatecheck** parameters. The value of **duplicatecheck** can be **0** or **1**, indicating whether to enable this mode. By default, this mode is disabled. If the input is **–1** or **NULL**, the built-in default value of **duplicatecheck** is used.

  Return type: HLL

  Example:

```
openGauss=# select hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10, -1)) from t_data;
 hll_cardinality
------------------
 498.496062953313
(1 row)
```

- hll_union_agg(hll)

  Description: Performs the UNION operation on multiple pieces of data of the HLL type to obtain one HLL.

  Return type: HLL

  Example:

```
-- Perform the UNION operation on data of the HLL type in each group to obtain one HLL, and calculate the number of distinct values:
openGauss=# select #hll_union_agg(c) as cardinality from t_a_c_hll;
   cardinality
------------------
 498.496062953313
(1 row)
```

  NOTE

  To perform the UNION operation on data in multiple HLLs, ensure that the HLLs have the same precision. Otherwise, **UNION** cannot be performed. This constraint also applies to the **hll_union(hll, hll)** function.

## Obsolete Functions

Some old HLL functions are discarded due to version upgrade. You can replace them with similar functions.

- hll_schema_version(hll)

  Description: Checks the schema version in the current HLL. In earlier versions, the schema version is fixed at **1**, which is used to verify the header of the HLL field. After refactoring, the HLL field is added to the header for verification. The schema version is no longer used.

- hll_regwidth(hll)

  Description: Queries the bucket size in the HLL data structure. In earlier versions, the value of **regwidth** ranges from 1 to 5, which has a large error and limits the upper limit of the cardinality estimation. After refactoring, the value of *regwidth* is fixed at **6** and the variable is not used.

- hll_expthresh(hll)

  Description: Obtains the value of **expthresh** in the current HLL. The **hll_log2explicit(hll)** function is used to replace similar functions.

- hll_sparseon(hll)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Specifies whether the sparse mode is enabled. Use **hll_log2sparse(hll)** to replace similar functions. The value **0** indicates that the sparse mode is disabled.

## Built-In Functions

HLL has a series of built-in functions for internal data processing. Generally, users do not need to know how to use these functions. For details, see **Table 12-36**.

**Table 12-36** Built-in functions

| Function | Description |
| --- | --- |
| hll_in | Receives hll data in string format. |
| hll_out | Sends hll data in string format. |
| hll_recv | Receives hll data in bytea format. |
| hll_send | Sends hll data in bytea format. |
| hll_trans_in | Receives hll_trans_type data in string format. |
| hll_trans_out | Sends hll_trans_type data in string format. |
| hll_trans_recv | Receives hll_trans_type data in bytea format. |
| hll_trans_send | Sends hll_trans_type data in bytea format. |
| hll_typmod_in | Receives typmod data. |
| hll_typmod_out | Sends typmod data. |
| hll_hashval_in | Receives hll_hashval data. |
| hll_hashval_out | Sends hll_hashval data. |
| hll_add_trans0 | Works similar to **hll_add**. No input parameter is specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations. |
| hll_add_trans1 | Works similar to **hll_add**. An input parameter is specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations. |
| hll_add_trans2 | Works similar to **hll_add**. Two input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations. |
| hll_add_trans3 | Works similar to **hll_add**. Three input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations. |
| hll_add_trans4 | Works similar to **hll_add**. Four input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Function | Description |
| --- | --- |
| hll_union_trans | Works similar to **hll_union** and is used on the first phase of DNs in distributed aggregation operations. |
| hll_union_collect | Works similar to **hll_union** and is used on the second phase of CNs in distributed aggregation operations to summarize the results of each DN. |
| hll_pack | Is used on the third phase of CNs in distributed aggregation operations to convert a user-defined type hll_trans_type to the hll type. |
| hll | Converts a hll type to another hll type. Input parameters can be specified. |
| hll_hashval | Converts the bigint type to the hll_hashval type. |
| hll_hashval_int4 | Converts the int4 type to the hll_hashval type. |

## Operators

- =

  Description: Compares the values of the hll or hll_hashval type to check whether they are the same.

  Return type: Boolean

  Example:

```
--hll
openGauss=# select (hll_empty() || hll_hash_integer(1)) = (hll_empty() || hll_hash_integer(1));
column
----------
 t
(1 row)

--hll_hashval
openGauss=# select hll_hash_integer(1) = hll_hash_integer(1);
 ?column?
----------
 t
(1 row)
```

- <> or !=

  Description: Compares the values of the hll or hll_hashval type to check whether they are different.

  Return type: Boolean

  Example:

```
--hll
openGauss=# select (hll_empty() || hll_hash_integer(1)) <> (hll_empty() || hll_hash_integer(2));
 ?column?
----------
 t
(1 row)

--hll_hashval
openGauss=# select hll_hash_integer(1) <> hll_hash_integer(2);
 ?column?
----------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 t
(1 row)
```

- ||

  Description: Represents the functions of **hll_add**, **hll_union**, and **hll_add_rev**.

  Return type: HLL

  Example:

```
--hll_add
openGauss=# select hll_empty() || hll_hash_integer(1);
                                ?column?
--------------------------------------------------------------------------------
 \x484c4c08000002002b0900000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_add_rev
openGauss=# select hll_hash_integer(1) || hll_empty();
                                ?column?
--------------------------------------------------------------------------------
 \x484c4c08000002002b0900000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_union
openGauss=# select (hll_empty() || hll_hash_integer(1)) || (hll_empty() || hll_hash_integer(2));
                                      ?column?
-----------------------------------------------------------------------------------------------

\x484c4c10002000002b0900000000000000004000000000000000000b3ccc49320cca1ae3e2921ff133fba
ed00
(1 row)
```

- #

  Description: Calculates the number of distinct values of an HLL. It works the same as the **hll_cardinality** function.

  Return type: int

  Example:

```
openGauss=# select #(hll_empty() || hll_hash_integer(1));
 ?column?
----------
        1
(1 row)
```

## 12.5.15 SEQUENCE Functions

The sequence functions provide a simple method to ensure security of multiple users for users to obtain sequence values from sequence objects.

- nextval(regclass)

  Description: Specifies an increasing sequence and returns a new value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- To avoid blocking of concurrent transactions that obtain numbers from the same sequence, a nextval operation is never rolled back; that is, once a value has been fetched it is considered used, even if the transaction that did the nextval later aborts. This means that aborted transactions may leave unused "holes" in the sequence of assigned values. Therefore, sequences in GaussDB cannot be used to obtain sequence without gaps.
- If the nextval function is pushed to DNs, each DN will automatically connect to the GTM and requests the next value. For example, in the **insert into t1 select xxx** statement, a column in table **t1** needs to invoke the nextval function. If maximum number of connections on the GTM is 8192, this type of pushed statements occupies too many GTM connections. Therefore, the number of concurrent connections for these statements is limited to 7000 divided by the number of cluster DNs. The other 1192 connections are reserved for other statements.

Return type: numeric

The **nextval** function can be invoked in either of the following ways: (In example 2, the Oracle syntax is supported. Currently, the sequence name cannot contain a dot.)

Example 1:

```
openGauss=# select nextval('seqDemo');
 nextval
---------
       2
(1 row)
```

Example 2:

```
openGauss=# select seqDemo.nextval;
 nextval
---------
       2
(1 row)
```

- currval(regclass)

  Returns the last value of **nextval** for a specified sequence in the current session. If **nextval** has not been invoked for the specified sequence in the current session, an error is reported when **currval** is invoked. By default, **currval** is disabled. To enable it, set **enable_beta_features** to **true**. After **enable_beta_features** is set to **true**, **nextval** will not be pushed down.

  Return type: numeric

  The **currval** function can be invoked in either of the following ways: (In example 2, the Oracle syntax is supported. Currently, the sequence name cannot contain a dot.)

  Example 1:

```
openGauss=# select currval('seq1');
 currval
---------
       2
(1 row)
```

  Example 2:

```
openGauss=# select seq1.currval seq1;
 currval
---------
       2
(1 row)
```

- lastval()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Returns the last value of **nextval** in the current session. This function is equivalent to **currval**, but **lastval** does not have a parameter. If **nextval** has not been invoked in the current session, invoking **lastval** will report an error.

By default, **lastval** is disabled. To enable it, set **enable_beta_features** or **lastval_supported** to **true**. After **lastval** is enabled, **nextval** will not be pushed down.

Return type: numeric

Example:

```
openGauss=# select lastval();
 lastval
---------
       2
(1 row)
```

- setval(regclass, bigint)

  Sets the current value of a sequence.

  Return type: numeric

  Example:

  ```
  openGauss=# select setval('seqDemo',1);
   setval
  --------
       1
  (1 row)
  ```

- setval(regclass, numeric, Boolean)

  Sets the current value of a sequence and the is_called sign.

  Return type: numeric

  Example:

  ```
  openGauss=# select setval('seqDemo',1,true);
   setval
  --------
       1
  (1 row)
  ```

  **NOTE**

  The current session and GTM will take effect immediately after **setval** is performed. If other sessions have buffered sequence values, **setval** will take effect only after the values are used up. Therefore, to prevent sequence value conflicts, you are advised to use **setval** with caution.

  Because the sequence is non-transactional, changes made by **setval** will not be canceled when a transaction rolled back.

- pg_sequence_last_value(sequence_oid oid, OUT cache_value int16, OUT last_value int16)

  Description: Obtains the parameters of a specified sequence, including the cache value and current value.

  Return type: int16, int16

# 12.5.16 Array Functions and Operators

## Array Operators

- =

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Specifies whether two arrays are equal.

Example:

```
openGauss=# SELECT ARRAY[1.1,2.1,3.1]::int[] = ARRAY[1,2,3] AS RESULT ;
 result
--------
 t
(1 row)
```

- <>

  Description: Specifies whether two arrays are not equal.

  Example:

  ```
  openGauss=# SELECT ARRAY[1,2,3] <> ARRAY[1,2,4] AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- <

  Description: Specifies whether an array is less than another.

  Example:

  ```
  openGauss=# SELECT ARRAY[1,2,3] < ARRAY[1,2,4] AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- >

  Description: Specifies whether an array is greater than another.

  Example:

  ```
  openGauss=# SELECT ARRAY[1,4,3] > ARRAY[1,2,4] AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- <=

  Description: Specifies whether an array is less than or equal to another.

  Example:

  ```
  openGauss=# SELECT ARRAY[1,2,3] <= ARRAY[1,2,3] AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- >=

  Description: Specifies whether an array is greater than or equal to another.

  Example:

  ```
  openGauss=# SELECT ARRAY[1,4,3] >= ARRAY[1,4,3] AS RESULT;
   result
  --------
   t
  (1 row)
  ```

- @>

  Description: Specifies whether an array contains another.

  Example:

  ```
  openGauss=# SELECT ARRAY[1,4,3] @> ARRAY[3,1] AS RESULT;
   result
  --------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 t
(1 row)
```

- <@

  Description: Specifies whether an array is contained in another.

  Example:

```
openGauss=# SELECT ARRAY[2,7] <@ ARRAY[1,7,4,2,6] AS RESULT;
 result
--------
 t
(1 row)
```

- &&

  Description: Specifies whether an array overlaps another (have common elements).

  Example:

```
openGauss=# SELECT ARRAY[1,4,3] && ARRAY[2,1] AS RESULT;
 result
--------
 t
(1 row)
```

- ||

  Description: Specifies array-to-array concatenation.

  Example:

```
openGauss=# SELECT ARRAY[1,2,3] || ARRAY[4,5,6] AS RESULT;
    result
---------------
 {1,2,3,4,5,6}
(1 row)
openGauss=# SELECT ARRAY[1,2,3] || ARRAY[[4,5,6],[7,8,9]] AS RESULT;
          result
---------------------------
 {{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

- ||

  Description: Specifies element-to-array concatenation.

  Example:

```
openGauss=# SELECT 3 || ARRAY[4,5,6] AS RESULT;
  result
-----------
 {3,4,5,6}
(1 row)
```

- ||

  Description: Specifies array-to-element concatenation.

  Example:

```
openGauss=# SELECT ARRAY[4,5,6] || 7 AS RESULT;
  result
-----------
 {4,5,6,7}
(1 row)
```

Array comparisons compare the array contents element-by-element, using the default B-tree comparison function for the element data type. In multidimensional arrays, the elements are accessed in row-major order. If the contents of two arrays are equal but the number of dimensions is different, the first difference in the dimensionality information determines the sort order.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

## Array Functions

- array_append(anyarray, anyelement)

  Description: Appends an element to the end of an array. Only one-dimensional arrays are supported.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_append(ARRAY[1,2], 3) AS RESULT;
 result
---------
 {1,2,3}
(1 row)
```

- array_prepend(anyelement, anyarray)

  Description: Appends an element to the beginning of an array. Only one-dimensional arrays are supported.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_prepend(1, ARRAY[2,3]) AS RESULT;
 result
---------
 {1,2,3}
(1 row)
```

- array_cat(anyarray, anyarray)

  Description: Concatenates two arrays, and supports multi-dimensional arrays.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_cat(ARRAY[1,2,3], ARRAY[4,5]) AS RESULT;
   result
-------------
 {1,2,3,4,5}
(1 row)

openGauss=# SELECT array_cat(ARRAY[[1,2],[4,5]], ARRAY[6,7]) AS RESULT;
       result
---------------------
 {{1,2},{4,5},{6,7}}
(1 row)
```

- array_union(anyarray, anyarray)

  Description: Concatenates two arrays. Only one-dimensional arrays are supported.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_union(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
   result
-------------
 {1,2,3,3,4,5}
(1 row)
```

- array_union_distinct(anyarray, anyarray)

  Description: Concatenates two arrays and deduplicates them. Only one-dimensional arrays are supported.

  Return type: anyarray

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT array_union_distinct(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
  result
-------------
 {1,2,3,4,5}
(1 row)
```

- array_intersect(anyarray, anyarray)

  Description: Intersects two arrays. Only one-dimensional arrays are supported.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_intersect(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
  result
-------------
 {3}
(1 row)
```

- array_intersect_distinct(anyarray, anyarray)

  Description: Intersects two arrays and deduplicates them. Only one-dimensional arrays are supported.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_intersect_distinct(ARRAY[1,2,2], ARRAY[2,2,4,5]) AS RESULT;
  result
-------------
 {2}
(1 row)
```

- array_except(anyarray, anyarray)

  Description: Calculates the difference between two arrays. Only one-dimensional arrays are supported.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_except(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
  result
-------------
 {1,2}
(1 row)
```

- array_except_distinct(anyarray, anyarray)

  Description: Calculates the difference between two arrays and deduplicates them. Only one-dimensional arrays are supported.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_except_distinct(ARRAY[1,2,2,3], ARRAY[3,4,5]) AS RESULT;
  result
-------------
 {1,2}
(1 row)
```

- array_ndims(anyarray)

  Description: Returns the number of dimensions of an array.

  Return type: int

  Example:

```
openGauss=# SELECT array_ndims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
 result
--------
      2
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- array_dims(anyarray)

  Description: Returns a text representation of array dimensions.

  Return type: text

  Example:

```
openGauss=# SELECT array_dims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
   result
------------
 [1:2][1:3]
(1 row)
```

- array_length(anyarray, int)

  Description: Returns the length of the array dimensions.

  Return type: int

  Example:

```
openGauss=# SELECT array_length(array[1,2,3], 1) AS RESULT;
 result
--------
      3
(1 row)
```

- array_lower(anyarray, int)

  Description: Returns lower bound of the array dimensions.

  Return type: int

  Example:

```
openGauss=# SELECT array_lower('[0:2]={1,2,3}'::int[], 1) AS RESULT;
 result
--------
      0
(1 row)
```

- array_sort(anyarray)

  Description: Returns an array in ascending order.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_sort(ARRAY[5,1,3,6,2,7]) AS RESULT;
 result
-------------
{1,2,3,5,6,7}
(1 row)
```

- array_upper(anyarray, int)

  Description: Returns upper bound of the array dimensions.

  Return type: int

  Example:

```
openGauss=# SELECT array_upper(ARRAY[1,8,3,7], 1) AS RESULT;
 result
--------
      4
(1 row)
```

- array_to_string(anyarray, text [, text])

  Description: Uses the first **text** as the new delimiter and the second **text** to replace **NULL** values.

  Return type: text

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT array_to_string(ARRAY[1, 2, 3, NULL, 5], ',', '*') AS RESULT;
 result
-----------
 1,2,3,*,5
(1 row)
```

- array_delete(anyarray)

  Description: Clears elements in an array and returns an empty array of the same type.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_delete(ARRAY[1,8,3,7]) AS RESULT;
 result
--------
 {}
(1 row)
```

- array_deleteidx(anyarray, int)

  Description: Deletes specified subscript elements from an array and returns an array consisting of the remaining elements.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_deleteidx(ARRAY[1,2,3,4,5], 1) AS RESULT;
 result
-----------
 {2,3,4,5}
(1 row)
```

- array_extendnull(anyarray, int)

  Description: Adds a specified number of null elements to the end of an array.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_extend(ARRAY[1,8,3,7],1) AS RESULT;
   result
--------------
{1,8,3,7,null}
(1 row)
```

- array_trim(anyarray, int)

  Description: Deletes a specified number of elements from the end of an array.

  Return type: anyarray

  Example:

```
openGauss=# SELECT array_trim(ARRAY[1,8,3,7],1) AS RESULT;
 result
---------
 {1,8,3}
(1 row)
```

- array_exists(anyarray, int)

  Description: Checks whether the second parameter is a valid subscript of an array.

  Return type: Boolean

  Example:

```
openGauss=# SELECT array_exists(ARRAY[1,8,3,7],1) AS RESULT;
 result
--------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- array_next(anyarray, int)

  Description: Returns the subscript of the element following a specified subscript in an array based on the second input parameter.

  Return type: int

  Example:

```
openGauss=# SELECT array_next(ARRAY[1,8,3,7],1) AS RESULT;
 result
--------
      2
(1 row)
```

- array_prior(anyarray, int)

  Description: Returns the subscript of the element followed by a specified subscript in an array based on the second input parameter.

  Return type: int

  Example:

```
openGauss=# SELECT array_prior(ARRAY[1,8,3,7],2) AS RESULT;
 result
--------
  1
(1 row)
```

- string_to_array(text, text [, text])

  Description: Uses the second **text** as the new delimiter and the third **text** as the substring to be replaced by **NULL** values. A substring can be replaced by **NULL** values only when it is the same as the third **text**.

  Return type: text[]

  Example:

```
openGauss=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'yy') AS RESULT;
    result
--------------
 {xx,NULL,zz}
(1 row)
openGauss=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'y') AS RESULT;
   result
------------
 {xx,yy,zz}
(1 row)
```

- unnest(anyarray)

  Description: Expands an array to a set of rows.

  Return type: setof anyelement

  Example:

```
openGauss=# SELECT unnest(ARRAY[1,2]) AS RESULT;
 result
--------
      1
      2
(2 rows)
```

In **string_to_array**, if the delimiter parameter is NULL, each character in the input string will become a separate element in the resulting array. If the delimiter is an empty string, then the entire input string is returned as a one-element array. Otherwise the input string is split at each occurrence of the delimiter string.

In **string_to_array**, if the null-string parameter is omitted or NULL, none of the substrings of the input will be replaced by NULL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

In **array_to_string**, if the null-string parameter is omitted or NULL, any null elements in the array are simply skipped and not represented in the output string.

- _pg_keysequal

  Description: Checks whether two smallint arrays are the same.

  Parameter: smallint[], smallint[]

  Return type: Boolean

# 12.5.17 Range Functions and Operators

## Range Operators

- =

  Description: Equals

  Example:

```
openGauss=# SELECT int4range(1,5) = '[1,4]'::int4range AS RESULT;
 result
--------
 t
(1 row)
```

- <>

  Description: Does not equal to

  Example:

```
openGauss=# SELECT numrange(1.1,2.2) <> numrange(1.1,2.3) AS RESULT;
 result
--------
 t
(1 row)
```

- <

  Description: Is less than

  Example:

```
openGauss=# SELECT int4range(1,10) < int4range(2,3) AS RESULT;
 result
--------
 t
(1 row)
```

- >

  Description: Is greater than

  Example:

```
openGauss=# SELECT int4range(1,10) > int4range(1,5) AS RESULT;
 result
--------
 t
(1 row)
```

- <=

  Description: Is less than or equals

  Example:

```
openGauss=# SELECT numrange(1.1,2.2) <= numrange(1.1,2.2) AS RESULT;
 result
--------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- >=

  Description: Is greater than or equals

  Example:

```
openGauss=# SELECT numrange(1.1,2.2) >= numrange(1.1,2.0) AS RESULT;
 result
--------
 t
(1 row)
```

- @>

  Description: Contains range

  Example:

```
openGauss=# SELECT int4range(2,4) @> int4range(2,3) AS RESULT;
 result
--------
 t
(1 row)
```

- @>

  Description: Contains element

  Example:

```
openGauss=# SELECT '[2011-01-01,2011-03-01)'::tsrange @> '2011-01-10'::timestamp AS RESULT;
 result
--------
 t
(1 row)
```

- <@

  Description: Range is contained by

  Example:

```
openGauss=# SELECT int4range(2,4) <@ int4range(1,7) AS RESULT;
 result
--------
 t
(1 row)
```

- <@

  Description: Element is contained by

  Example:

```
openGauss=# SELECT 42 <@ int4range(1,7) AS RESULT;
 result
--------
 f
(1 row)
```

- &&

  Description: Overlap (have points in common)

  Example:

```
openGauss=# SELECT int8range(3,7) && int8range(4,12) AS RESULT;
 result
--------
 t
(1 row)
```

- <<

  Description: Strictly left of

  Example:

```
openGauss=# SELECT int8range(1,10) << int8range(100,110) AS RESULT;
 result
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
--------
 t
(1 row)
```

- >>

  Description: Strictly right of

  Example:

```
openGauss=# SELECT int8range(50,60) >> int8range(20,30) AS RESULT;
 result
--------
 t
(1 row)
```

- &<

  Description: Does not extend to the right of

  Example:

```
openGauss=# SELECT int8range(1,20) &< int8range(18,20) AS RESULT;
 result
--------
 t
(1 row)
```

- &>

  Description: Does not extend to the left of

  Example:

```
openGauss=# SELECT int8range(7,20) &> int8range(5,10) AS RESULT;
 result
--------
 t
(1 row)
```

- -|-

  Description: Is adjacent to

  Example:

```
openGauss=# SELECT numrange(1.1,2.2) -|- numrange(2.2,3.3) AS RESULT;
 result
--------
 t
(1 row)
```

- +

  Description: Union

  Example:

```
openGauss=# SELECT numrange(5,15) + numrange(10,20) AS RESULT;
 result
--------
 [5,20)
(1 row)
```

- *

  Description: Intersection

  Example:

```
openGauss=# SELECT int8range(5,15) * int8range(10,20) AS RESULT;
 result
---------
 [10,15)
(1 row)
```

- -

  Description: Difference

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# SELECT int8range(5,15) - int8range(10,20) AS RESULT;
 result
--------
 [5,10)
(1 row)
```

The simple comparison operators **<**, **>**, **<=**, and **>=** compare the lower bounds first, and only if those are equal, compare the upper bounds.

The **<<**, **>>**, and **-|-** operators always return false when an empty range is involved; that is, an empty range is not considered to be either before or after any other range.

The union and difference operators will fail if the resulting range would need to contain two disjoint sub-ranges.

## Range Functions

- numrange(numeric, numeric, [text])

  Description: Specifies a range.

  Return type: Range's element type

  Example:

  ```
  openGauss=# SELECT numrange(1.1,2.2) AS RESULT;
   result
  --------
  [1.1,2.2)
  (1 row)
  openGauss=# SELECT numrange(1.1,2.2, '()') AS RESULT;
   result
  --------
  (1.1,2.2)
  (1 row)
  ```

- lower(anyrange)

  Description: Lower bound of range

  Return type: Range's element type

  Example:

  ```
  openGauss=# SELECT lower(numrange(1.1,2.2)) AS RESULT;
   result
  --------
     1.1
  (1 row)
  ```

- upper(anyrange)

  Description: Upper bound of range

  Return type: Range's element type

  Example:

  ```
  openGauss=# SELECT upper(numrange(1.1,2.2)) AS RESULT;
   result
  --------
     2.2
  (1 row)
  ```

- isempty(anyrange)

  Description: Is the range empty?

  Return type: Boolean

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT isempty(numrange(1.1,2.2)) AS RESULT;
 result
--------
 f
(1 row)
```

- lower_inc(anyrange)

  Description: Is the lower bound inclusive?

  Return type: Boolean

  Example:

```
openGauss=# SELECT lower_inc(numrange(1.1,2.2)) AS RESULT;
 result
--------
 t
(1 row)
```

- upper_inc(anyrange)

  Description: Is the upper bound inclusive?

  Return type: Boolean

  Example:

```
openGauss=# SELECT upper_inc(numrange(1.1,2.2)) AS RESULT;
 result
--------
 f
(1 row)
```

- lower_inf(anyrange)

  Description: Is the lower bound infinite?

  Return type: Boolean

  Example:

```
openGauss=# SELECT lower_inf('(,)'::daterange) AS RESULT;
 result
--------
 t
(1 row)
```

- upper_inf(anyrange)

  Description: Is the upper bound infinite?

  Return type: Boolean

  Example:

```
openGauss=# SELECT upper_inf('(,)'::daterange) AS RESULT;
 result
--------
 t
(1 row)
```

The **lower** and **upper** functions return null if the range is empty or the requested bound is infinite. The **lower_inc**, **upper_inc**, **lower_inf**, and **upper_inf** functions all return false for an empty range.

- elem_contained_by_range(anyelement, anyrange)

  Description: Determines whether an element is within the range.

  Return type: Boolean

  Example:

```
openGauss=# SELECT elem_contained_by_range('2', numrange(1.1,2.2));
 elem_contained_by_range
-------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 t
(1 row)
```

# 12.5.18 Aggregate Functions

## Aggregate Functions

- sum(expression)

  Description: Sum of expression across all input values

  Return type:

  Generally, same as the argument data type. In the following cases, type conversion occurs:

  – **BIGINT** for **SMALLINT** or **INT** arguments

  – **NUMBER** for **BIGINT** arguments

  – **DOUBLE PRECISION** for floating-point arguments

  Example:

  ```
  openGauss=# SELECT SUM(ss_ext_tax) FROM tpcds.STORE_SALES;
    sum
  --------------
   213267594.69
  (1 row)
  ```

- max(expression)

  Description: Specifies the maximum value of expression across all input values.

  Parameter type: any array, numeric, string, or date/time type

  Return type: same as the parameter type

  Example:

  ```
  openGauss=# SELECT MAX(inv_quantity_on_hand) FROM tpcds.inventory;
  ```

- min(expression)

  Description: Minimum value of expression across all input values

  Parameter type: any array, numeric, string, or date/time type

  Return type: same as the parameter type

  Example:

  ```
  openGauss=# SELECT MIN(inv_quantity_on_hand) FROM tpcds.inventory;
   min
  -----
    0
  (1 row)
  ```

- avg(expression)

  Description: Average (arithmetic mean) of all input values

  Return type:

  **NUMBER** for any integer-type argument.

  **DOUBLE PRECISION** for floating-point parameters.

  otherwise the same as the argument data type.

  Example:

  ```
  openGauss=# SELECT AVG(inv_quantity_on_hand) FROM tpcds.inventory;
          avg
  ----------------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 500.0387129084044604
(1 row)
```

- count(expression)

  Description: Returns the number of input rows for which the value of expression is not null.

  Return type: bigint

  Example:

```
openGauss=# SELECT COUNT(inv_quantity_on_hand) FROM tpcds.inventory;
  count
----------
 11158087
(1 row)
```

- count(*)

  Description: Returns the number of input rows.

  Return type: bigint

  Example:

```
openGauss=# SELECT COUNT(*) FROM tpcds.inventory;
  count
----------
 11745000
(1 row)
```

- array_agg(expression)

  Description: Input values, including nulls, concatenated into an array

  Return type: array of the parameter type

  Example:

```
openGauss=# SELECT ARRAY_AGG(sr_fee) FROM tpcds.store_returns WHERE sr_customer_sk = 2;
   array_agg
---------------
 {22.18,63.21}
(1 row)
```

- string_agg(expression, delimiter)

  Description: Input values concatenated into a string, separated by delimiter

  Return type: same as the parameter data type.

  Example:

```
openGauss=# SELECT string_agg(sr_item_sk, ',') FROM tpcds.store_returns where sr_item_sk < 3;
        string_agg
--------------------------------------------------------------------------------
--------------------------------
 1,2,1,2,2,1,1,2,2,1,2,1,2,1,1,1,2,1,1,1,1,1,2,1,1,1,1,1,2,2,1,1,1,1,1,1,1,1,2,
2,1,1,1,1,1,1,2,2,1,1,2,1,1,1
(1 row)
```

- listagg(expression [, delimiter]) WITHIN GROUP(ORDER BY order-list)

  Description: Aggregation column data sorted according to the mode specified by **WITHIN GROUP**, and concatenated to a string using the specified delimiter

  - **expression**: Mandatory. It specifies an aggregation column name or a column-based, valid expression. It does not support the **DISTINCT** keyword and the **VARIADIC** parameter.
  - **delimiter**: Optional. It specifies a delimiter, which can be a string constant or a deterministic expression based on a group of columns. The default value is empty.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

– **order-list**: Mandatory. It specifies the sorting mode in a group.

Return type: text

> **NOTE**
>
> **listagg** is a column-to-row aggregation function, compatible with Oracle Database 11g Release 2. You can specify the **OVER** clause as a window function. When **listagg** is used as a window function, the **OVER** clause does not support the window sorting or framework of **ORDER BY**, to avoid ambiguity in **listagg** and **ORDER BY** of the **WITHIN GROUP** clause.

Example:

The aggregation column is of the text character set type.

```
openGauss=# SELECT deptno, listagg(ename, ',') WITHIN GROUP(ORDER BY ename) AS employees
FROM emp GROUP BY deptno;
 deptno |              employees
--------+---------------------------------------
     10 | CLARK,KING,MILLER
     20 | ADAMS,FORD,JONES,SCOTT,SMITH
     30 | ALLEN,BLAKE,JAMES,MARTIN,TURNER,WARD
(3 rows)
```

The aggregation column is of the integer type.

```
openGauss=# SELECT deptno, listagg(mgrno, ',') WITHIN GROUP(ORDER BY mgrno NULLS FIRST) AS
mgrnos FROM emp GROUP BY deptno;
 deptno |            mgrnos
--------+------------------------------
     10 | 7782,7839
     20 | 7566,7566,7788,7839,7902
     30 | 7698,7698,7698,7698,7698,7839
(3 rows)
```

The aggregation column is of the floating point type.

```
openGauss=# SELECT job, listagg(bonus, '($); ') WITHIN GROUP(ORDER BY bonus DESC) || '($)' AS
bonus FROM emp GROUP BY job;
    job     |                    bonus
------------+-----------------------------------------------
 CLERK      | 10234.21($); 2000.80($); 1100.00($); 1000.22($)
 PRESIDENT  | 23011.88($)
 ANALYST    | 2002.12($); 1001.01($)
 MANAGER    | 10000.01($); 2399.50($); 999.10($)
 SALESMAN   | 1000.01($); 899.00($); 99.99($); 9.00($)
(5 rows)
```

The aggregation column is of the time type.

```
openGauss=# SELECT deptno, listagg(hiredate, ', ') WITHIN GROUP(ORDER BY hiredate DESC) AS
hiredates FROM emp GROUP BY deptno;
 deptno |                                                hiredates
--------
+-----------------------------------------------------------------------------------------------------------------------
---------
     10 | 1982-01-23 00:00:00, 1981-11-17 00:00:00, 1981-06-09 00:00:00
     20 | 2001-04-02 00:00:00, 1999-12-17 00:00:00, 1987-05-23 00:00:00, 1987-04-19 00:00:00,
1981-12-03 00:00:00
     30 | 2015-02-20 00:00:00, 2010-02-22 00:00:00, 1997-09-28 00:00:00, 1981-12-03 00:00:00,
1981-09-08 00:00:00, 1981-05-01 00:00:00
(3 rows)
```

The aggregation column is of the time interval type.

```
openGauss=# SELECT deptno, listagg(vacationTime, '; ') WITHIN GROUP(ORDER BY vacationTime
DESC) AS vacationTime FROM emp GROUP BY deptno;
 deptno |                              vacationtime
--------+-------------------------------------------------------------------------------
     10 | 1 year 30 days; 40 days; 10 days
     20 | 70 days; 36 days; 9 days; 5 days
     30 | 1 year 1 mon; 2 mons 10 days; 30 days; 12 days 12:00:00; 4 days 06:00:00; 24:00:00
(3 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

By default, the delimiter is empty.

```
openGauss=# SELECT deptno, listagg(job) WITHIN GROUP(ORDER BY job) AS jobs FROM emp
GROUP BY deptno;
 deptno |                  jobs
--------+-----------------------------------------------
     10 | CLERKMANAGERPRESIDENT
     20 | ANALYSTANALYSTCLERKCLERKMANAGER
     30 | CLERKMANAGERSALESMANSALESMANSALESMANSALESMAN
(3 rows)
```

When **listagg** is used as a window function, the **OVER** clause does not support the window sorting of **ORDER BY**, and the **listagg** column is an ordered aggregation of the corresponding groups.

```
openGauss=# SELECT deptno, mgrno, bonus, listagg(ename,'; ') WITHIN GROUP(ORDER BY hiredate)
OVER(PARTITION BY deptno) AS employees FROM emp;
 deptno | mgrno |  bonus   |                 employees
--------+-------+----------+-------------------------------------------

     30 |  7698 |     9.00 | BLAKE; TURNER; JAMES; MARTIN; WARD; ALLEN
     30 |  7698 |  1000.22 | BLAKE; TURNER; JAMES; MARTIN; WARD; ALLEN
     30 |  7698 |    99.99 | BLAKE; TURNER; JAMES; MARTIN; WARD; ALLEN
     30 |  7698 |  1000.01 | BLAKE; TURNER; JAMES; MARTIN; WARD; ALLEN
     30 |  7698 |   899.00 | BLAKE; TURNER; JAMES; MARTIN; WARD; ALLEN
(14 rows)
```

- covar_pop(Y, X)

  Description: Overall covariance

  Return type: double precision

  Example:

  ```
  openGauss=# SELECT COVAR_POP(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE
  sr_customer_sk < 1000;
     covar_pop
  ------------------
   829.749627587403
  (1 row)
  ```

- covar_samp(Y, X)

  Description: Sample covariance

  Return type: double precision

  Example:

  ```
  openGauss=# SELECT COVAR_SAMP(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE
  sr_customer_sk < 1000;
     covar_samp
  ------------------
   830.052235037289
  (1 row)
  ```

- stddev_pop(expression)

  Description: Overall standard difference

  Return type: **double precision** for floating-point arguments, otherwise **numeric**

  Example:

  ```
  openGauss=# SELECT STDDEV_POP(inv_quantity_on_hand) FROM tpcds.inventory WHERE
  inv_warehouse_sk = 1;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
   stddev_pop
------------------
 289.224294957556
(1 row)
```

- stddev_samp(expression)

  Description: Sample standard deviation of the input values

  Return type: **double precision** for floating-point arguments, otherwise **numeric**

  Example:

```
openGauss=# SELECT STDDEV_SAMP(inv_quantity_on_hand) FROM tpcds.inventory WHERE
inv_warehouse_sk = 1;
  stddev_samp
------------------
 289.224359757315
(1 row)
```

- var_pop(expression)

  Description: Population variance of the input values (square of the population standard deviation)

  Return type: **double precision** for floating-point arguments, otherwise **numeric**

  Example:

```
openGauss=# SELECT VAR_POP(inv_quantity_on_hand) FROM tpcds.inventory WHERE
inv_warehouse_sk = 1;
      var_pop
--------------------
 83650.692793695475
(1 row)
```

- var_samp(expression)

  Description: Sample variance of the input values (square of the sample standard deviation)

  Return type: **double precision** for floating-point arguments, otherwise **numeric**

  Example:

```
openGauss=# SELECT VAR_SAMP(inv_quantity_on_hand) FROM tpcds.inventory WHERE
inv_warehouse_sk = 1;
      var_samp
--------------------
 83650.730277028768
(1 row)
```

- bit_and(expression)

  Description: The bitwise AND of all non-null input values, or null if none

  Return type: same as the parameter data type.

  Example:

```
openGauss=# SELECT BIT_AND(inv_quantity_on_hand) FROM tpcds.inventory WHERE
inv_warehouse_sk = 1;
 bit_and
---------
       0
(1 row)
```

- bit_or(expression)

  Description: The bitwise OR of all non-null input values, or null if none

  Return type: same as the parameter data type.

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT BIT_OR(inv_quantity_on_hand) FROM tpcds.inventory WHERE
inv_warehouse_sk = 1;
 bit_or
--------
   1023
(1 row)
```

- bool_and(expression)

  Description: Its value is **true** if all input values are **true**, otherwise **false**.

  Return type: Boolean

  Example:

```
openGauss=# SELECT bool_and(100 <2500);
 bool_and
----------
 t
(1 row)
```

- bool_or(expression)

  Description: Its value is **true** if at least one input value is **true**, otherwise **false**.

  Return type: Boolean

  Example:

```
openGauss=# SELECT bool_or(100 <2500);
 bool_or
----------
 t
(1 row)
```

- corr(Y, X)

  Description: Correlation coefficient

  Return type: double precision

  Example:

```
openGauss=# SELECT CORR(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE sr_customer_sk <
1000;
       corr
--------------------
 .0381383624904186
(1 row)
```

- every(expression)

  Description: Equivalent to **bool_and**

  Return type: Boolean

  Example:

```
openGauss=# SELECT every(100 <2500);
 every
-------
 t
(1 row)
```

- rank(expression)

  Description: The tuples in different groups are sorted non-consecutively by **expression**.

  Return type: bigint

  Example:

```
openGauss=# SELECT d_moy, d_fy_week_seq, rank() OVER(PARTITION BY d_moy ORDER BY
d_fy_week_seq) FROM tpcds.date_dim WHERE d_moy < 4 AND d_fy_week_seq < 7 ORDER BY 1,2;
  d_moy | d_fy_week_seq | rank
-------+---------------+------
```

   2 |           6 |   6
(42 rows)
```

- regr_avgx(Y, X)

  Description: Average of the independent variable (**sum(X)/N**)

  Return type: double precision

  Example:

```
openGauss=# SELECT REGR_AVGX(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE
sr_customer_sk < 1000;
    regr_avgx
------------------
 578.606576740795
(1 row)
```

- regr_avgy(Y, X)

  Description: Average of the dependent variable (**sum(Y)/N**)

  Return type: double precision

  Example:

```
openGauss=# SELECT REGR_AVGY(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE
sr_customer_sk < 1000;
    regr_avgy
------------------
 50.0136711629602
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- regr_count(Y, X)

  Description: Specifies the number of input rows in which both expressions are non-null.

  Return type: bigint

  Example:

```
openGauss=# SELECT REGR_COUNT(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE
sr_customer_sk < 1000;
 regr_count
------------
       2743
(1 row)
```

- regr_intercept(Y, X)

  Description: y-intercept of the least-squares-fit linear equation determined by the (X, Y) pairs

  Return type: double precision

  Example:

```
openGauss=# SELECT REGR_INTERCEPT(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE
sr_customer_sk < 1000;
  regr_intercept
------------------
 49.2040847848607
(1 row)
```

- regr_r2(Y, X)

  Description: Square of the correlation coefficient

  Return type: double precision

  Example:

```
openGauss=# SELECT REGR_R2(sr_fee, sr_net_loss) FROM store_returns WHERE sr_customer_sk <
1000;
      regr_r2
--------------------
 .00145453469345058
(1 row)
```

- regr_slope(Y, X)

  Description: Slope of the least-squares-fit linear equation determined by the (X, Y) pairs

  Return type: double precision

  Example:

```
openGauss=# SELECT REGR_SLOPE(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE
sr_customer_sk < 1000;
     regr_slope
--------------------
 .00139920009665259
(1 row)
```

- regr_sxx(Y, X)

  Description: **sum(X^2) - sum(X)^2/N** (sum of squares of the independent variables)

  Return type: double precision

  Example:

```
openGauss=# SELECT REGR_SXX(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE sr_customer_sk
< 1000;
     regr_sxx
------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 1626645991.46135
(1 row)
```

- regr_sxy(Y, X)

  Description: **sum(X*Y) - sum(X) * sum(Y)/N** ("sum of products" of independent times dependent variable)

  Return type: double precision

  Example:

```
openGauss=# SELECT REGR_SXY(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE sr_customer_sk
< 1000;
     regr_sxy
------------------
 2276003.22847225
(1 row)
```

- regr_syy(Y, X)

  Description: **sum(Y^2) - sum(Y)^2/N** ("sum of squares" of the dependent variable)

  Return type: double precision

  Example:

```
openGauss=# SELECT REGR_SYY(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE sr_customer_sk
< 1000;
    regr_syy
-----------------
 2189417.6547314
(1 row)
```

- stddev(expression)

  Description: Alias of **stddev_samp**

  Return type: **double precision** for floating-point arguments, otherwise **numeric**

  Example:

```
openGauss=# SELECT STDDEV(inv_quantity_on_hand) FROM tpcds.inventory WHERE
inv_warehouse_sk = 1;
      stddev
------------------
 289.224359757315
(1 row)
```

- variance(expexpression,ression)

  Description: Alias of **var_samp**

  Return type: **double precision** for floating-point arguments, otherwise **numeric**

  Example:

```
openGauss=# SELECT VARIANCE(inv_quantity_on_hand) FROM tpcds.inventory WHERE
inv_warehouse_sk = 1;
      variance
--------------------
 83650.730277028768
(1 row)
```

- spread

  Description: Calculates the difference between the maximum value and minimum value in a certain period.

  Parameter: real

  Return type: real

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- checksum(expression)

  Description: Returns the CHECKSUM value of all input values. This function can be used to check whether the data in the tables is the same before and after the backup, restoration, or migration of the GaussDB database (databases other than GaussDB are not supported). Before and after database backup, database restoration, or data migration, you need to manually run SQL commands to obtain the execution results. Compare the obtained execution results to check whether the data in the tables before and after the backup or migration is the same.

  NOTE

  - For large tables, the execution of CHECKSUM function may take a long time.
  - If the CHECKSUM values of two tables are different, it indicates that the contents of the two tables are different. Using the hash function in the CHECKSUM function may incur conflicts. There is low possibility that two tables with different contents may have the same CHECKSUM value. The same problem may occur when CHECKSUM is used for columns.
  - If the time type is timestamp, timestamptz, or smalldatetime, ensure that the time zone settings are the same when calculating the CHECKSUM value.

  – If the CHECKSUM value of a column is calculated and the column type can be changed to TEXT by default, set *expression* to the column name.
  – If the CHECKSUM value of a column is calculated and the column type cannot be converted to TEXT by default, set *expression* to *Column name*::**TEXT**.
  – If the CHECKSUM value of all columns is calculated, set *expression* to *Table name*::**TEXT**.

  The following types of data can be converted into TEXT types by default: char, name, int8, int2, int1, int4, raw, pg_node_tree, float4, float8, bpchar, varchar, nvarchar2, date, timestamp, timestamptz, numeric, and smalldatetime. Other types need to be forcibly converted to TEXT.

  Return type: numeric

  Example:

  The following shows the CHECKSUM value of a column that can be converted to the TEXT type by default:

  ```
  openGauss=# SELECT CHECKSUM(inv_quantity_on_hand) FROM tpcds.inventory;
      checksum
  -------------------
   24417258945265247
  (1 row)
  ```

  The following shows the CHECKSUM value of a column that cannot be converted to the TEXT type by default. Note that the CHECKSUM parameter is set to *Column name*::**TEXT**.

  ```
  openGauss=# SELECT CHECKSUM(inv_quantity_on_hand::TEXT) FROM tpcds.inventory;
      checksum
  -------------------
   24417258945265247
  (1 row)
  ```

  The following shows the CHECKSUM value of all columns in a table. Note that the CHECKSUM parameter is set to *Table name*::**TEXT**. The table name is not modified by its schema.

  ```
  openGauss=# SELECT CHECKSUM(inventory::TEXT) FROM tpcds.inventory;
      checksum
  ```

```
-------------------
 25223696246875800
(1 row)
```

# 12.5.19 Window Functions

## Window Functions

Currently, column-store tables only support **rank(expression)** and **row_number(expression)** functions.

This statement is used together with the window function. The **OVER** clause is used for grouping data and sorting the elements in a group. Window functions are used for generating sequence numbers for the values in the group.

NOTE

**order by** in a window function must be followed by a column name. If it is followed by a number, the number is processed as a constant value and the target column is not ranked.

- RANK()

  Description: The **RANK** function is used for generating non-consecutive sequence numbers for the values in each group. The same values have the same sequence number.

  Return type: bigint

  Example:

```
openGauss=# SELECT d_moy, d_fy_week_seq, rank() OVER(PARTITION BY d_moy ORDER BY
d_fy_week_seq) FROM tpcds.date_dim WHERE d_moy < 4 AND d_fy_week_seq < 7 ORDER BY 1,2;
  d_moy | d_fy_week_seq | rank
-------+---------------+------
     1 |             1 |    1
     1 |             1 |    1
     1 |             1 |    1
     1 |             1 |    1
     1 |             1 |    1
     1 |             1 |    1
     1 |             1 |    1
     1 |             2 |    8
     1 |             2 |    8
     1 |             2 |    8
     1 |             2 |    8
     1 |             2 |    8
     1 |             2 |    8
     1 |             2 |    8
     1 |             3 |   15
     1 |             3 |   15
     1 |             3 |   15
     1 |             3 |   15
     1 |             3 |   15
     1 |             3 |   15
     1 |             3 |   15
     1 |             4 |   22
     1 |             4 |   22
     1 |             4 |   22
     1 |             4 |   22
     1 |             4 |   22
     1 |             4 |   22
     1 |             4 |   22
     1 |             5 |   29
     1 |             5 |   29
     2 |             5 |    1
     2 |             5 |    1
     2 |             5 |    1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
   2 |           5 |   1
   2 |           5 |   1
   2 |           6 |   6
   2 |           6 |   6
   2 |           6 |   6
   2 |           6 |   6
   2 |           6 |   6
   2 |           6 |   6
   2 |           6 |   6
(42 rows)
```

- ROW_NUMBER()

  Description: The **ROW_NUMBER** function is used for generating consecutive sequence numbers for the values in each group. The same values have different sequence numbers.

  Return type: bigint

  Example:

```
openGauss=# SELECT d_moy, d_fy_week_seq, Row_number() OVER(PARTITION BY d_moy ORDER BY d_fy_week_seq) FROM tpcds.date_dim  WHERE d_moy < 4 AND d_fy_week_seq < 7 ORDER BY 1,2;
 d_moy | d_fy_week_seq | row_number
-------+---------------+------------
   1 |           1 |         1
   1 |           1 |         2
   1 |           1 |         3
   1 |           1 |         4
   1 |           1 |         5
   1 |           1 |         6
   1 |           1 |         7
   1 |           2 |         8
   1 |           2 |         9
   1 |           2 |        10
   1 |           2 |        11
   1 |           2 |        12
   1 |           2 |        13
   1 |           2 |        14
   1 |           3 |        15
   1 |           3 |        16
   1 |           3 |        17
   1 |           3 |        18
   1 |           3 |        19
   1 |           3 |        20
   1 |           3 |        21

- DENSE_RANK()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: The **DENSE_RANK** function is used for generating consecutive sequence numbers for the values in each group. The same values have the same sequence number.

Return type: bigint

Example:

```
openGauss=# SELECT d_moy, d_fy_week_seq, dense_rank() OVER(PARTITION BY d_moy ORDER BY
d_fy_week_seq) FROM tpcds.date_dim WHERE d_moy < 4 AND d_fy_week_seq < 7 ORDER BY 1,2;
 d_moy | d_fy_week_seq | dense_rank
-------+---------------+------------
     1 |             1 |          1
     1 |             1 |          1
     1 |             1 |          1
     1 |             1 |          1
     1 |             1 |          1
     1 |             1 |          1
     1 |             1 |          1
     1 |             2 |          2
     1 |             2 |          2
     1 |             2 |          2
     1 |             2 |          2
     1 |             2 |          2
     1 |             2 |          2
     1 |             2 |          2
     1 |             3 |          3
     1 |             3 |          3
     1 |             3 |          3
     1 |             3 |          3
     1 |             3 |          3
     1 |             3 |          3
     1 |             3 |          3
     1 |             4 |          4
     1 |             4 |          4
     1 |             4 |          4
     1 |             4 |          4
     1 |             4 |          4
     1 |             4 |          4
     1 |             4 |          4
     1 |             5 |          5
     1 |             5 |          5
     2 |             5 |          1
     2 |             5 |          1
     2 |             5 |          1
     2 |             5 |          1
     2 |             5 |          1
     2 |             6 |          2
     2 |             6 |          2
     2 |             6 |          2
     2 |             6 |          2
     2 |             6 |          2
     2 |             6 |          2
     2 |             6 |          2
(42 rows)
```

- PERCENT_RANK()

  Description: The **PERCENT_RANK** function is used for generating corresponding sequence numbers for the values in each group. That is, the function calculates the value according to the formula Sequence number = (**rank** - 1) / (**total rows** - 1). **rank** is the corresponding sequence number generated based on the **RANK** function for the value and **totalrows** is the total number of elements in a group.

  Return type: double precision

  Example:

  ```
  openGauss=# SELECT d_moy, d_fy_week_seq, percent_rank() OVER(PARTITION BY d_moy ORDER BY
  d_fy_week_seq) FROM tpcds.date_dim WHERE d_moy < 4 AND d_fy_week_seq < 7 ORDER BY 1,2;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 d_moy | d_fy_week_seq |   percent_rank
-------+---------------+------------------
     1 |             1 |                0
     1 |             1 |                0
     1 |             1 |                0
     1 |             1 |                0

```

- CUME_DIST()

  Description: The **CUME_DIST** function is used for generating accumulative distribution sequence numbers for the values in each group. That is, the function calculates the value according to the following formula: Sequence number = Number of rows preceding or peer with current row/Total rows.

  Return type: double precision

  Example:

```
openGauss=# SELECT d_moy, d_fy_week_seq, cume_dist() OVER(PARTITION BY d_moy ORDER BY
d_fy_week_seq) FROM tpcds.date_dim e_dim WHERE d_moy < 4 AND d_fy_week_seq < 7 ORDER BY
1,2;
 d_moy | d_fy_week_seq |    cume_dist

- NTILE(num_buckets integer)

  Description: The **NTILE** function is used for equally allocating sequential data sets to the buckets whose quantity is specified by **num_buckets** according to **num_buckets integer** and allocating the bucket number to each row. Divide the partition as evenly as possible.

  Return type: integer

  Example:

```
openGauss=# SELECT d_moy, d_fy_week_seq, ntile(3) OVER(PARTITION BY d_moy ORDER BY
d_fy_week_seq) FROM tpcds.date_dim WHERE d_moy < 4 AND d_fy_week_seq < 7 ORDER BY 1,2;
 d_moy | d_fy_week_seq | ntile

- LAG(value any [, offset integer [, default any ]])

  Description: The **LAG** function is used for generating lag values for the corresponding values in each group. That is, the value of the row obtained by moving forward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row does not exist after the moving, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **NULL**. The type of the **default** value must be the same as that of **value**.

  Return type: same as the parameter type

  Example:

```
openGauss=# SELECT d_moy, d_fy_week_seq, lag(d_moy,3,null) OVER(PARTITION BY d_moy ORDER BY d_fy_week_seq) FROM tpcds.date_dim WHERE d_moy < 4 AND d_fy_week_seq < 7 ORDER BY 1,2;
 d_moy | d_fy_week_seq | lag

- LEAD(value any [, offset integer [, default any ]])

  Description: The **LEAD** function is used for generating leading values for the corresponding values in each group. That is, the value of the row obtained by moving backward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row after the moving exceeds the total number of rows for the current group, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **NULL**. The type of the **default** value must be the same as that of **value**.

  Return type: same as the parameter type

  Example:

```
openGauss=# SELECT d_moy, d_fy_week_seq, lead(d_fy_week_seq,2) OVER(PARTITION BY d_moy
ORDER BY d_fy_week_seq) FROM  tpcds.date_dim WHERE d_moy < 4 AND d_fy_week_seq < 7 ORDER
BY 1,2;                d_moy | d_fy_week_seq | lead

     2 |             6 |           5
     2 |             6 |           5
     2 |             6 |           5
(42 rows)
```

- LAST_VALUE(value any)

  Description: Returns the last value of each group.

  Return type: same as the parameter type

  Example:

```
openGauss=# SELECT d_moy, d_fy_week_seq, last_value(d_moy) OVER(PARTITION BY d_moy ORDER BY d_fy_week_seq) FROM tpcds.date_dim WHERE d_moy < 4 AND d_fy_week_seq < 6 ORDER BY 1,2;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 d_moy | d_fy_week_seq | last_value
-------+---------------+------------
     1 |             1 |          1
     1 |             1 |          1
     1 |             1 |          1

     2 |             5 |          2
(35 rows)
```

- NTH_VALUE(value any, nth integer)

  Description: The *n*th row for a group is the returned value. If the row does not exist, **NULL** is returned by default.

  Return type: same as the parameter type

  Example:

```
openGauss=# SELECT d_moy, d_fy_week_seq, nth_value(d_fy_week_seq,6) OVER(PARTITION BY
d_moy ORDER BY d_fy_week_seq) FROM tpcds.date_dim WHERE d_moy < 4 AND d_fy_week_seq < 6
ORDER BY 1,2;
 d_moy | d_fy_week_seq | nth_value
-------+---------------+-----------
     1 |             1 |         1
     1 |             1 |         1
     1 |             1 |         1
     1 |             1 |         1
     1 |             1 |         1
     1 |             1 |         1
     1 |             1 |         1
     1 |             2 |         1
     1 |             2 |         1
     1 |             2 |         1
     1 |             2 |         1
     1 |             2 |         1

   2 |           5 |
   2 |           5 |
(35 rows)
```

- delta

  Description: Returns the difference between the current row and the previous row.

  Parameter: numeric

  Return type: numeric

- spread

  Description: Calculates the difference between the maximum value and minimum value in a certain period.

  Parameter: real

  Return type: real

# 12.5.20 Security Functions

## Security Functions

- gs_encrypt_aes128(encryptstr,keystr)

  Description: Encrypts **encryptstr** strings using the key derived from **keystr** and returns encrypted strings. The value of **keystr** ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters. Currently, the following types of data can be encrypted: numerals supported in the database; character type; RAW in binary type; and DATE, TIMESTAMP, and SMALLDATETIME in date/time type.

  Return type: text

  Length of the return value: At least 92 bytes and no more than (4*[*Len*/3]+68) bytes, where *Len* indicates the length of the data before encryption (unit: byte).

  Example:

```
openGauss=# SELECT gs_encrypt_aes128('MPPDB','1234@abc');
                                gs_encrypt_aes128
-----------------------------------------------------------------------------------
 OF1g3+70oeqFfyKiWlpxfYxPnpeitNc6+7nAe02Ttt37fZF8Q+bbEYhdw/YG+0c9tHKRWM6OcTzlB3HnqvX
+1d8Bflo=
(1 row)
```

> **NOTE**
>
> A password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- gs_decrypt_aes128(decryptstr,keystr)

  Description: Decrypts **decrypt** strings using the key derived from **keystr** and returns decrypted strings. The **keystr** used for decryption must be consistent with that used for encryption. **keystr** cannot be empty.

  > **NOTE**
  >
  > This function needs to be used with the **gs_encrypt_aes128** encryption function.

  Return type: text

  Example:

  ```
  openGauss=# SELECT gs_decrypt_aes128('OF1g3+70oeqFfyKiWlpxfYxPnpeitNc6+7nAe02Ttt37fZF8Q
  +bbEYhdw/YG+0c9tHKRWM6OcTzlB3HnqvX+1d8Bflo=','1234@abc');
   gs_decrypt_aes128
  -------------------
   MPPDB
  (1 row)
  ```

  > **NOTE**
  >
  > A password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- gs_password_deadline()

  Description: Indicates the number of remaining days before the password of the current user expires.

  Return type: interval

  Example:

  ```
  openGauss=# SELECT gs_password_deadline();
    gs_password_deadline
  -------------------------
   83 days 17:44:32.196094
  (1 row)
  ```

- gs_password_notifytime()

  Description: Specifies the number of days prior to password expiration that a user will receive a reminder.

  Return type: int32

- login_audit_messages(BOOLEAN)

  Description: Queries login information about a login user.

  Return type: tuple

  Example:

  – Check the date, time, and IP address of the last successful login.

    ```
    openGauss=> select * from login_audit_messages(true);
     username | database |       logintime        |    mytype     | result | client_conninfo
    ----------+----------+------------------------+---------------+--------+-----------------
     omm      | postgres | 2020-06-29 21:56:40+08 | login_success | ok     | gsql@[local]
    (1 row)
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

  - Check the number, date, and time of failed attempts since the previous successful login.

```
openGauss=>  select * from login_audit_messages(false);
 username | database |       logintime        |    mytype    | result |  client_conninfo
----------+----------+------------------------+--------------+--------+-------------------
 omm      | postgres | 2020-06-29 21:57:55+08 | login_failed | failed | [unknown]@[local]
 omm      | postgres | 2020-06-29 21:57:53+08 | login_failed | failed | [unknown]@[local]
(2 rows)
```

- login_audit_messages_pid(BOOLEAN)

  Description: Queries login information about a login user. Different from **login_audit_messages**, this function queries login information based on **backendid**. Information about subsequent logins of the same user does not alter the query result of previous logins and cannot be found using this function.

  Return type: tuple

  NOTE

  When the thread pool is enabled, the **backendid** obtained in the same session may change due to thread switchover. As a result, the return values are different when the function is called for multiple times. You are not advised to call this function when the thread pool is enabled.

  Example:

  - Check the date, time, and IP address of the last successful login.

```
openGauss=> SELECT * FROM login_audit_messages_pid(true);
 username | database |       logintime        |    mytype     | result | client_conninfo |    backendid
----------+----------+------------------------+---------------+--------+-----------------+-----------------
 omm      | postgres | 2020-06-29 21:56:40+08 | login_success | ok     | gsql@[local]    |
139823109633792
(1 row)
```

  - Check the number, date, and time of failed attempts since the previous successful login.

```
openGauss=> SELECT * FROM login_audit_messages_pid(false);
 username | database |       logintime        |    mytype    | result |  client_conninfo  |    backendid
----------+----------+------------------------+--------------+--------+-------------------+-----------------
 omm      | postgres | 2020-06-29 21:57:55+08 | login_failed | failed | [unknown]@[local] |
139823109633792
 omm      | postgres | 2020-06-29 21:57:53+08 | login_failed | failed | [unknown]@[local] |
139823109633792
(2 rows)
```

- inet_server_addr()

  Description: Displays the server IP address.

  Return type: inet

  Example:

```
openGauss=# SELECT inet_server_addr();
 inet_server_addr
------------------
 10.10.0.13
(1 row)
```

  NOTE

  - The client IP address 10.10.0.50 and server IP address 10.10.0.13 are used as an example.
  - If the database is connected to the local PC, the value is empty.

- inet_client_addr()

  Description: Displays the client IP address.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: inet

Example:

```
openGauss=# SELECT inet_client_addr();
 inet_client_addr
------------------
 10.10.0.50
(1 row)
```

NOTE

- The client IP address 10.10.0.50 and server IP address 10.10.0.13 are used as an example.
- If the database is connected to the local PC, the value is empty.

- pg_query_audit**(timestamptz** *startime*,**timestamptz** *endtime*,*audit_log*)

  Description: Displays audit logs of the current CN.

  Return type: record

  The following table describes return fields.

| Name | Type | Description |
| --- | --- | --- |
| time | timestamp with time zone | Operation time |
| type | text | Operation |
| result | text | Operation result |
| userid | oid | User ID |
| username | text | Name of the user who performs the operation |
| database | text | Database name |
| client_conninfo | text | Client connection information |
| object_name | text | Object name |
| detail_info | text | Operation details |
| node_name | text | Node name |
| thread_id | text | Thread ID |
| local_port | text | Local port |
| remote_port | text | Remote port |

  For details about how to use the function and details about function examples, see **7.3.2 Querying Audit Results**.

- pgxc_query_audit**(timestamptz** *startime*,**timestamptz** *endtime*)

  Description: Displays audit logs of all CNs.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The return fields of this function are the same as those of the **pg_query_audit** function.

For details about how to use the function and details about function examples, see **7.3.2 Querying Audit Results**.

- pg_delete_audit**(timestamp** *startime*,**timestamp** *endtime***)**Description: Deletes audit logs in a specified period. Return type: void For details about how to use the function and details about function examples, see 7.3.3 Maintaining Audit Logs.
- alldigitsmasking

  Description: Specifies the internal function of the masking policy, which is used to anonymize all characters.

  Parameter: col text, letter character default '0'

  Return type: text
- creditcardmasking

  Description: Specifies the internal function of the masking policy, which is used to anonymize all credit card information.

  Parameter: col text, letter character default 'x'

  Return type: text
- randommasking

  Description: Specifies the internal function of the masking policy. The random policy is used.

  Parameter: col text

  Return type: text
- fullemailmasking

  Description: Specifies the internal function of the masking policy, which is used to anonymize the text (except **@**) before the last period (.).

  Parameter: col text, letter character default 'x'

  Return type: text
- basicemailmasking

  Description: Specifies the internal function of the masking policy, which is used to anonymize the text before the first at sign (@).

  Parameter: col text, letter character default 'x'

  Return type: text
- shufflemasking

  Description: Specifies the internal function of the masking policy, which is used to sort characters out of order.

  Parameter: col text

  Return type: text
- regexpmasking

  Description: Specifies the internal function of the masking policy, which is used to replace characters using a regular expression.

  Parameter: col text, reg text, replace_text text, pos INTEGER default 0, reg_len INTEGER default -1

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- gs_encrypt(encryptstr,keystr, encrypttype)

  Description: Encrypts **encryptstr** strings using **keystr** as the key and returns encrypted strings based on **encrypttype**. The value of **keystr** contains 8 to 16 bytes and at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters. The value of **encrypttype** can be **aes128** or **sm4**.

  Return type: text

  Example:

```
openGauss=#  SELECT gs_encrypt('MPPDB','Asdf1234','sm4');
       gs_encrypt
 ------------------------------
 ZBzOmaGA4Bb+coyucJ0B8AkIShqc
(1 row)
```

  NOTE

  A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- gs_decrypt(decryptstr, keystr, decrypttype)

  Description: Decrypts **decrypt** strings using **keystr** as the key and returns decrypted strings based on **decrypttype**. The **decrypttype** and **keystr** used for decryption must be consistent with **encrypttype** and **keystr** used for encryption. The value of **keystr** cannot be empty. The value of **decrypttype** can be **aes128** or **sm4**.

  This function needs to be used with the **gs_encrypt** encryption function.

  Return type: text

  Example:

```
openGauss=# select gs_decrypt('ZBzOmaGA4Bb+coyucJ0B8AkIShqc','Asdf1234','sm4');
 gs_decrypt
------------
 MPPDB
(1 row)
```

  NOTE

  A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

## 12.5.21 Ledger Database Functions

The current feature is a lab feature. Contact Huawei technical support before using it.

- get_dn_hist_relhash(text, text)

  Description: Returns the hash value of table-level data in a specified tamper-proof user table. This function can be invoked only between distributed nodes. A message indicating insufficient permission is displayed when all users invoke this function.

  Parameter type: text

  Return type: hash16

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- ledger_hist_check(text, text)

  Description: Verifies the consistency between the hash value of table-level data in a specified tamper-proof user table and that in the corresponding history table.

  Parameter type: text

  Return type: Boolean

- ledger_hist_repair(text, text)

  Description: Restores the hash value of the history table corresponding to the specified tamper-proof user table to be the same as that of the user table, and returns the hash difference.

  Parameter type: text

  Return type: hash16

- ledger_hist_archive(text, text)

  Description: Archives the history table corresponding to a specified tamper-proof user table to the **hist_back** folder in the audit log directory.

  Parameter type: text

  Return type: Boolean

- ledger_gchain_check(text, text)

  Description: Verifies the consistency between the history table hash corresponding to the specified tamper-proof user table and the **relhash** corresponding to the global history table.

  Parameter type: text

  Return type: Boolean

- ledger_gchain_repair(text, text)

  Description: Restores **relhash** of a specified tamper-proof user table in the global history table so that the hash is the same as that in the history table, and returns the hash difference.

  Parameter type: text

  Return type: hash16

- ledger_gchain_archive(void)

  Description: Archives global history tables to the **hist_back** folder in the audit log directory.

  Parameter type: void

  Return type: Boolean

- hash16in(cstring)

  Description: Converts the input hexadecimal string into the internal hash16 format.

  Parameter type: cstring

  Return type: hash16

- hash16out(uint64)

  Description: Converts internal hash16 data to hexadecimal cstring data.

  Parameter type: hash16

  Return type: cstring

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- hash32in(cstring)

  Description: Converts the input hexadecimal string (32 characters) into the internal type hash32.

  Parameter type: cstring

  Return type: hash32
- hash32out(hash32)

  Description: Converts internal hash32 data to hexadecimal cstring data.

  Parameter type: cstring

  Return type: hash32

## 12.5.22 Encrypted Equality Functions

- byteawithoutorderwithequalcolin(cstring)

  Description: Converts input data to the internal byteawithoutorderwithequalcol format.

  Parameter type: cstring

  Return type: byteawithoutorderwithequalcol
- byteawithoutorderwithequalcolout(byteawithoutorderwithequalcol)

  Description: Converts internal data of the byteawithoutorderwithequalcol type to data of the cstring type.

  Parameter type: byteawithoutorderwithequalcol

  Return type: cstring
- byteawithoutorderwithequalcolsend(byteawithoutorderwithequalcol)

  Description: Converts data of the byteawithoutorderwithequalcol type to data of the bytea type.

  Parameter type: byteawithoutorderwithequalcol

  Return type: bytea
- byteawithoutorderwithequalcolrecv(internal)

  Description: Converts data of the byteawithoutorderwithequalcol type to data of the byteawithoutorderwithequalcol type.

  Parameter type: internal

  Return type: byteawithoutorderwithequalcol
- byteawithoutorderwithequalcoltypmodin(_cstring)

  Description: Converts data of the byteawithoutorderwithequalcol type to data of the byteawithoutorderwithequalcol type.

  Parameter type: _cstring

  Return type: int4
- byteawithoutorderwithequalcoltypmodout(int4)

  Description: Converts data of the int4 type into data of the cstring type.

  Parameter type: int4

  Return type: cstring
- byteawithoutordercolin(cstring)

  Description: Converts input data to the internal byteawithoutordercolin format.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Parameter type: cstring

Return type: byteawithoutordercol

- byteawithoutordercolout(byteawithoutordercol)

  Description: Converts internal data of the byteawithoutordercol type to data of the cstring type.

  Parameter type: byteawithoutordercol

  Return type: cstring

- byteawithoutordercolsend(byteawithoutordercol)

  Description: Converts data of the byteawithoutordercol type to data of the bytea type.

  Parameter type: byteawithoutordercol

  Return type: bytea

- byteawithoutordercolrecv(internal)

  Description: Converts data of the byteawithoutordercol type to data of the byteawithoutordercol type.

  Parameter type: internal

  Return type: byteawithoutordercol

- byteawithoutorderwithequalcolcmp(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)

  Description: Compares two byteawithoutorderwithequalcol data sizes. If the first data size is smaller than the second one, **–1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

  Parameter type: byteawithoutorderwithequalcol, byteawithoutorderwithequalcol

  Return type: int4

- byteawithoutorderwithequalcolcmpbytear(byteawithoutorderwithequalcol, bytea)

  Description: Compares the byteawithoutorderwithequalcol and bytea data sizes. If the first data size is smaller than the second one, **–1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

  Parameter type: byteawithoutorderwithequalcol or bytea

  Return type: int4

- byteawithoutorderwithequalcolcmpbyteal(bytea, byteawithoutorderwithequalcol)

  Description: Compares the bytea and byteawithoutorderwithequalcol data sizes. If the first data size is smaller than the second one, **–1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

  Parameter type: byteawithoutorderwithequalcol or bytea

  Return type: int4

- byteawithoutorderwithequalcoleq(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Compares two byteawithoutorderwithequalcol data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: byteawithoutorderwithequalcol or bytea

Return type: Boolean

- byteawithoutorderwithequalcoleqbyteal(bytea, byteawithoutorderwithequalcol)

  Description: Compares the bytea and byteawithoutorderwithequalcol data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

  Parameter type: bytea or byteawithoutorderwithequalcol

  Return type: Boolean

- byteawithoutorderwithequalcoleqbytear(byteawithoutorderwithequalcol, bytea)

  Description: Compares the byteawithoutorderwithequalcol and bytea data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

  Parameter type: byteawithoutorderwithequalcol, bytea

  Return type: Boolean

- byteawithoutorderwithequalcolne(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)

  Description: Compares two byteawithoutorderwithequalcol data records. If they are different, **true** is returned. Otherwise, **false** is returned.

  Parameter type: byteawithoutorderwithequalcol, byteawithoutorderwithequalcol

  Return type: Boolean

- byteawithoutorderwithequalcolnebyteal(bytea, byteawithoutorderwithequalcol)

  Description: Compares the bytea and byteawithoutorderwithequalcol data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

  Parameter type: bytea, byteawithoutorderwithequalcol

  Return type: Boolean

- byteawithoutorderwithequalcolnebytear(byteawithoutorderwithequalcol, bytea)

  Description: Compares the byteawithoutorderwithequalcol and bytea data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

  Parameter type: byteawithoutorderwithequalcol, bytea

  Return type: Boolean

- hll_hash_byteawithoutorderwithequalcol(byteawithoutorderwithequalcol)

  Description: Returns the hll hash value of byteawithoutorderwithequalcol.

  Parameter type: byteawithoutorderwithequalcol

  Return type: hll_hashval

## Example

Functions such as byteawithoutorderwithequalcolin and byteawithoutorderwithequalcolout are read/write format conversion functions such as in, out, send, and recv specified by the data type

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

byteawithoutorderwithequalcol in the database kernel. For details, see the byteain and byteaout functions of the bytea type. However, the local CEK must be verified, and the function can be successfully executed only when the encrypted column contains a CEK OID that can be found on the local host.

```
-- In this example, there is an encrypted table int_type, and int_col2 is the encrypted column.

-- Use a non-encrypted client to connect to the database and query the ciphertext of the encrypted column.
openGauss=# select int_col2 from int_type;
                                                
```

Parameter type: int, bigint, numeric

Return type: setof int, setof bigint, setof numeric (same as the parameter type)

- generate_series(start, stop, step)

  Description: Generates a series of values, from **start** to **stop** with a step size of **step**.

  Parameter type: int, bigint, numeric

  Return type: setof int, setof bigint, setof numeric (same as the parameter type)

- generate_series(start, stop, step interval)

  Description: Generates a series of values, from **start** to **stop** with a step size of **step**.

  Parameter type: timestamp or timestamp with time zone

  Return type: setof timestamp or setof timestamp with time zone (same as parameter type)

When **step** is positive, zero rows are returned if **start** is greater than **stop**. Conversely, when **step** is negative, zero rows are returned if **start** is less than **stop**. Zero rows are also returned for **NULL** inputs. It is an error for **step** to be zero.

Example:

```
openGauss=# SELECT * FROM generate_series(2,4);
 generate_series
-----------------
               2
               3
               4
(3 rows)

openGauss=# SELECT * FROM generate_series(5,1,-2);
 generate_series
-----------------
               5
               3
               1
(3 rows)

openGauss=# SELECT * FROM generate_series(4,3);
 generate_series
-----------------
(0 rows)

-- This example applies to the date-plus-integer operator.
openGauss=# SELECT current_date + s.a AS dates FROM generate_series(0,14,7) AS s(a);
   dates
------------
 2017-06-02
 2017-06-09
 2017-06-16
(3 rows)

openGauss=# SELECT * FROM generate_series('2008-03-01 00:00'::timestamp, '2008-03-04 12:00', '10
hours');
   generate_series
---------------------
 2008-03-01 00:00:00
 2008-03-01 10:00:00
 2008-03-01 20:00:00
 2008-03-02 06:00:00
 2008-03-02 16:00:00
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 2008-03-03 02:00:00
 2008-03-03 12:00:00
 2008-03-03 22:00:00
 2008-03-04 08:00:00
(9 rows)
```

### Subscript Generating Functions

- generate_subscripts(array anyarray, dim int)

  Description: Generates a series comprising the given array's subscripts.

  Return type: setof int

- generate_subscripts(array anyarray, dim int, reverse boolean)

  Description: Generates a series comprising the given array's subscripts. When **reverse** is true, the series is returned in reverse order.

  Return type: setof int

**generate_subscripts** is a function that generates the set of valid subscripts for the specified dimension of the given array. Zero rows are returned for arrays that do not have the requested dimension, or for NULL arrays (but valid subscripts are returned for NULL array elements). Example:

```
-- Basic usage
openGauss=# SELECT generate_subscripts('{NULL,1,NULL,2}'::int[], 1) AS s;
 s
---
 1
 2
 3
 4
(4 rows)
-- Unnest a 2D array.
openGauss=# CREATE OR REPLACE FUNCTION unnest2(anyarray)
RETURNS SETOF anyelement AS $$
SELECT $1[i][j]
   FROM generate_subscripts($1,1) g1(i),
        generate_subscripts($1,2) g2(j);
$$ LANGUAGE sql IMMUTABLE;

openGauss=# SELECT * FROM unnest2(ARRAY[[1,2],[3,4]]);
 unnest2
---------
       1
       2
       3
       4
(4 rows)

-- Delete the function.
openGauss=# DROP FUNCTION unnest2;
```

## 12.5.24 Conditional Expression Functions

### Conditional Expression Functions

- coalesce(expr1, expr2, ..., exprn)

  Description:

  Returns the first of its arguments that are not null.

  **COALESCE(expr1, expr2)** is equivalent to **CASE WHEN expr1 IS NOT NULL THEN expr1 ELSE expr2 END**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# SELECT coalesce(NULL,'hello');
 coalesce
----------
 hello
(1 row)
```

Note:

- Null is returned only if all parameters are null.
- This value is replaced by the default value when data is displayed.
- Like a **CASE** expression, **COALESCE** only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first not-**NULL** parameter are not evaluated.

- decode(base_expr, compare1, value1, Compare2,value2, ... default)

  Description: Compares **base_expr** with each **compare(n)** and **returns value(n)** if they are matched. If **base_expr** does not match each **compare(n)**, the default value is returned.

  Example:

  ```
  openGauss=# SELECT decode('A','A',1,'B',2,0);
   case
  ------
   1
  (1 row)
  ```

- nullif(expr1, expr2)

  Description: Returns **NULL** only when **expr1** is equal to **expr2**. Otherwise, **expr1** is returned.

  **nullif(expr1, expr2)** is equivalent to **CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END**.

  Example:

  ```
  openGauss=# SELECT nullif('hello','world');
   nullif
  --------
   hello
  (1 row)
  ```

  Note:

  Assume the two parameter data types are different:

  - If implicit conversion exists between the two data types, implicitly convert the parameter of lower priority to this data type using the data type of higher priority. If the conversion succeeds, computation is performed. Otherwise, an error is returned. Example:

    ```
    openGauss=# SELECT nullif('1234'::VARCHAR,123::INT4);
     nullif
    --------
       1234
    (1 row)
    openGauss=# SELECT nullif('1234'::VARCHAR,'2012-12-24'::DATE);
    ERROR:  invalid input syntax for type timestamp: "1234"
    ```

  - If implicit conversion is not applied between two data types, an error is displayed. Example:

    ```
    openGauss=# SELECT nullif(TRUE::BOOLEAN,'2012-12-24'::DATE);
    ERROR:  operator does not exist: boolean = timestamp without time zone
    LINE 1: SELECT nullif(TRUE::BOOLEAN,'2012-12-24'::DATE) FROM sys_dummy;
    ^
    HINT:  No operator matches the given name and argument type(s). You might need to add explicit type casts.
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- nvl( expr1 , expr2 )

  Description:

  – If the value of **expr1** is **NULL**, the value of **expr2** is returned.
  – If the value of **expr1** is not **NULL**, the value of **expr1** is returned.

  Example:

```
openGauss=# SELECT nvl('hello','world');
  nvl
-------
 hello
(1 row)
```

  Parameters **expr1** and **expr2** can be of any data type. If **expr1** and **expr2** are of different data types, NVL checks whether **expr2** can be implicitly converted to **expr1**. If it can, the **expr1** data type is returned. If **epr2** cannot be implicitly converted to **expr1** but **epr1** can be implicitly converted to **expr2**, the **expr2** data type is returned. If no implicit type conversion exists between the two parameters and the parameters are different data types, an error is reported.

- greatest(expr1 [, ...])

  Description: Selects the largest value from a list of any number of expressions.

  Return type:

  Example:

```
openGauss=# SELECT greatest(1*2,2-3,4-1);
 greatest
----------
        3
(1 row)
openGauss=# SELECT greatest('HARRY', 'HARRIOT', 'HAROLD');
 greatest
----------
 HARRY
(1 row)
```

- least(expr1 [, ...])

  Description: Selects the smallest value from a list of any number of expressions.

  Example:

```
openGauss=# SELECT least(1*2,2-3,4-1);
 least
-------
    -1
(1 row)
openGauss=# SELECT least('HARRY','HARRIOT','HAROLD');
 least
--------
 HAROLD
(1 row)
```

- EMPTY_BLOB()

  Description: Initiates a BLOB variable in an **INSERT** or an **UPDATE** statement to a **NULL** value.

  Return type: BLOB

  Example:

```
-- Create a table.
openGauss=# CREATE TABLE blob_tb(b blob,id int) DISTRIBUTE BY REPLICATION;
-- Insert data.
openGauss=# INSERT INTO blob_tb VALUES (empty_blob(),1);
-- Drop the table.
openGauss=# DROP TABLE blob_tb;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Note: The length is 0 obtained using **DBE_LOB.GET_LENGTH**.

# 12.5.25 System Information Functions

## Session Information Functions

- current_catalog

  Description: Name of the current database (called "catalog" in the SQL standard)

  Return type: name

  Example:

  ```
  openGauss=# SELECT current_catalog;
   current_database
  ------------------
   postgres
  (1 row)
  ```

- current_database()

  Description: Name of the current database

  Return type: name

  Example:

  ```
  openGauss=# SELECT current_database();
   current_database
  ------------------
   postgres
  (1 row)
  ```

- current_query()

  Description: Text of the currently executing query committed by the client (which might contain more than one statement)

  Return type: text

  Example:

  ```
  openGauss=# SELECT current_query();
       current_query
  -------------------------
   SELECT current_query();
  (1 row)
  ```

- current_schema[()]

  Description: Name of the current schema

  Return type: name

  Example:

  ```
  openGauss=# SELECT current_schema();
   current_schema
  ----------------
   public
  (1 row)
  ```

  Note: **current_schema** returns the first valid schema name in the search path. (If the search path is empty or contains no valid schema name, **NULL** is returned.) This is the schema that will be used for any tables or other named objects that are created without specifying a target schema.

- current_schemas(Boolean)

  Description: Name of a schema in the search path

  Return type: name[]

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# SELECT current_schemas(true);
  current_schemas
--------------------
 {pg_catalog,public}
(1 row)
```

Note:

**current_schemas(Boolean)** returns an array of the names of all schemas in the search path. The Boolean option specifies whether implicitly included system schemas such as **pg_catalog** are included in the returned search path.

NOTE

The search path can be altered at the run time. The command is as follows:

```
SET search_path TO schema [, schema, ...]
```

- current_user

  Description: Username in the current execution environment

  Return type: name

  Example:

  ```
  openGauss=# SELECT current_user;
   current_user
  --------------
   omm
  (1 row)
  ```

  Note: **current_user** is the user identifier used for permission check. Normally it is equal to the session user, but it can be changed by using **12.14.163 SET ROLE**. It also changes during the execution of functions with the **SECURITY DEFINER** attribute.

- definer_current_user

  Description: Username in the current execution environment

  Return type: name

  Example:

  ```
  openGauss=# SELECT definer_current_user();
   definer_current_user
  ----------------------
   omm
  (1 row)
  ```

  Note: In most cases, the results of **definer_current_user** and **current_user** are the same. However, when this function is executed in a stored procedure, the name of user who defines the current stored procedure is returned.

- pg_current_sessionid()

  Description: Session ID in the current execution environment

  Return type: text

  Example:

  ```
  openGauss=# SELECT pg_current_sessionid();
     pg_current_sessionid
  ---------------------------
   1579228402.140190434944768
  (1 row)
  ```

  Note: **pg_current_sessionid()** is used to obtain the session ID in the current execution environment. The format of the value is *Timestamp.Session ID*. When **enable_thread_pool** is set to **off**, the actual session ID is the thread ID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_current_sessid

  Description: Session ID in the current execution environment

  Return type: text

  Example:

  ```
  openGauss=# select pg_current_sessid();
  pg_current_sessid
  -------------------
  140308875015936
  (1 row)
  ```

  Note: In thread pool mode, the ID of the current session is obtained. In non-thread pool mode, the backend thread ID of the current session is obtained.

- pg_current_userid

  Description: Current user ID

  Return type: text

  Example:

  ```
  openGauss=# SELECT pg_current_userid();
  pg_current_userid
  -------------------
  10
  (1 row)
  ```

- tablespace_oid_name()

  Description: Queries the tablespace name based on the tablespace OID.

  Return type: text

  Example:

  ```
  openGauss=# select tablespace_oid_name(1663);
   tablespace_oid_name
  ---------------------
   pg_default
  (1 row)
  ```

- inet_client_addr()

  Description: Remote connection address. **inet_client_addr** returns the IP address of the current client.

  NOTE

  This function is valid only in remote connection mode.

  Return type: inet

  Example:

  ```
  openGauss=# SELECT inet_client_addr();
   inet_client_addr
  ------------------
   10.10.0.50
  (1 row)
  ```

- inet_client_port()

  Description: Remote connection port. **inet_client_port** returns the port number of the current client.

  NOTE

  This function is valid only in remote connection mode.

  Return type: int

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# SELECT inet_client_port();
 inet_client_port
------------------
            33143
(1 row)
```

- inet_server_addr()

  Description: Local connection address. **inet_server_addr** returns the IP address on which the server accepts the current connection.

  NOTE

  This function is valid only in remote connection mode.

  Return type: inet

  Example:

```
openGauss=# SELECT inet_server_addr();
 inet_server_addr
------------------
 10.10.0.13
(1 row)
```

- inet_server_port()

  Description: Local connection port. **inet_server_port** returns the number of the port receiving the current connection. All these functions return **NULL** if the current connection is via a Unix-domain socket.

  NOTE

  This function is valid only in remote connection mode.

  Return type: int

  Example:

```
openGauss=# SELECT inet_server_port();
 inet_server_port
------------------
             8000
(1 row)
```

- pg_backend_pid()

  Description: Process ID of the service process attached to the current session.

  Return type: int

  Example:

```
openGauss=# SELECT pg_backend_pid();
 pg_backend_pid
-----------------
 140229352617744
(1 row)
```

- pg_conf_load_time()

  Description: Configures load time. **pg_conf_load_time** returns the timestamp when the server configuration files were last loaded.

  Return type: timestamp with time zone

  Example:

```
openGauss=# SELECT pg_conf_load_time();
      pg_conf_load_time
-------------------------------
 2017-09-01 16:05:23.89868+08
(1 row)
```

- pg_my_temp_schema()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: OID of the temporary schema of a session. The value is **0** if the OID does not exist.

Return type: oid

Example:

```
openGauss=# SELECT pg_my_temp_schema();
 pg_my_temp_schema
-------------------
                 0
(1 row)
```

Note: **pg_my_temp_schema** returns the OID of the current session's temporary schema, or **0** if it has no temporary schemas (because no temporary tables are created). **pg_is_other_temp_schema** returns **true** if the given OID is the OID of another session's temporary schema.

- pg_is_other_temp_schema(oid)

  Description: Specifies whether the schema is the temporary schema of another session.

  Return type: Boolean

  Example:

  ```
  openGauss=# SELECT pg_is_other_temp_schema(25356);
   pg_is_other_temp_schema
  -------------------------
   f
  (1 row)
  ```

- pg_listening_channels()

  Description: Name of the channel that the session is currently listening on.

  Return type: setof text

  Example:

  ```
  openGauss=# SELECT pg_listening_channels();
   pg_listening_channels
  -----------------------
  (0 rows)
  ```

  Note: **pg_listening_channels** returns a set of names of channels that the current session is currently listening on.

- pg_postmaster_start_time()

  Description: Server start time. **pg_postmaster_start_time** returns the **timestamp with time zone** when the server is started.

  Return type: timestamp with time zone

  Example:

  ```
  openGauss=# SELECT pg_postmaster_start_time();
    pg_postmaster_start_time
  -------------------------------
   2017-08-30 16:02:54.99854+08
  (1 row)
  ```

- sessionid2pid()

  Description: Obtains PID information from a session ID (for example, the **sessid** column in **pv_session_stat**).

  Return type: int8

  Example:

  ```
  openGauss=# select sessionid2pid(sessid::cstring) from pv_session_stat limit 2;
   sessionid2pid
  -----------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 139973107902208
 139973107902208
(2 rows)
```

- session_context( 'namespace' , 'parameter')

  Description: Obtains and returns the parameter values of a specified namespace.

  Return type: VARCHAR

  Example:

  ```
  openGauss=# SELECT session_context('USERENV', 'CURRENT_SCHEMA');
   session_context
  -----------------
   public
  (1 row)
  ```

  The result varies according to the current actual schema.

  Note: Currently, only the SESSION_CONTEXT('USERENV', 'CURRENT_SCHEMA') and SESSION_CONTEXT('USERENV', 'CURRENT_USER') formats are supported.

- pg_trigger_depth()

  Description: Nesting level of triggers.

  Return type: int

  Example:

  ```
  openGauss=# SELECT pg_trigger_depth();
   pg_trigger_depth
  ------------------
                 0
  (1 row)
  ```

- opengauss_version()

  Description: Referenced openGauss kernel version.

  Return type: text

  Example:

  ```
  openGauss=# SELECT opengauss_version();
   opengauss_version
  -------------------
   2.0.0
  (1 row)
  ```

- gs_deployment()

  Description: Deployment mode of the current system. For a distributed system, **Distribute** is returned.

  Return type: text

  Example:

  ```
  openGauss=# select gs_deployment();
   gs_deployment
  ---------------
   Distribute
  (1 row)
  ```

- session_user

  Description: Session username.

  Return type: name

  Example:

  ```
  openGauss=# SELECT session_user;
   session_user
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
--------------
 omm
(1 row)
```

Note: **session_user** usually specifies the initial user connected to the current database, but the system administrator can change this setting by using **12.14.164 SET SESSION AUTHORIZATION**.

- user

  Description: Equivalent to current_user.

  Return type: name

  Example:

```
openGauss=# SELECT user;
 current_user
--------------
 omm
(1 row)
```

- get_shard_oids_byname

  Description: Returns the OID of the node when the node name is entered.

  Return type: oid

  Example:

```
openGauss=# select get_shard_oids_byname('datanode1');
 get_shard_oids_byname
-----------------------
 {16385}
(1 row)
```

- getpgusername()

  Description: Obtains the database username.

  Return type: name

  Example:

```
openGauss=# select getpgusername();
 getpgusername
---------------
 GaussDB_userna
(1 row)
```

- getdatabaseencoding()

  Description: Obtains the database encoding mode.

  Return type: name

  Example:

```
openGauss=# select getdatabaseencoding();
 getdatabaseencoding
---------------------
 SQL_ASCII
(1 row)
```

- version()

  Description: Version information. **version** returns a string describing a server's version.

  Return type: text

  Example:

```
openGauss=# SELECT version();
                                                
```

```
2935 last mr 6385 release
(1 row)
```

- working_version_num()

  Description: Returns a version number regarding system compatibility.

  Return type: int

  Example:

```
openGauss=# SELECT working_version_num();
 working_version_num
---------------------
               92231
(1 row)
```

- get_hostname()

  Description: Returns the host name of the current node.

  Return type: text

  Example:

```
openGauss=# SELECT get_hostname();
 get_hostname
--------------
 linux-user
(1 row)
```

- get_nodename()

  Description: Returns the name of the current node.

  Return type: text

  Example:

```
openGauss=# SELECT get_nodename();
 get_nodename
--------------
 coordinator1
(1 row)
```

- get_schema_oid(cstring)

  Description: Returns the OID of the queried schema.

  Return type: oid

  Example:

```
openGauss=# SELECT get_schema_oid('public');
 get_schema_oid
----------------
           2200
(1 row)
```

- pgxc_parse_clog(OUT xid int8, OUT nodename text, OUT status text)

  Description: Returns the status of all transactions in the current cluster.

  Return type: set of record

  Example:

```
openGauss=# SELECT pgxc_parse_clog();
 pgxc_parse_clog
----------------
(0,dn_6004_6005_6006,INPROGRESS)
(1,dn_6004_6005_6006,COMMITTED)
(2,dn_6004_6005_6006,INPROGRESS)
(3 row)
```

- pgxc_prepared_xact( )

  Description: Returns the list of transaction GIDs at the prepared stage in the cluster.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: set of text

Example:

```
openGauss=# SELECT pgxc_prepared_xact();
 pgxc_prepared_xact
--------------------
(0 row)
```

- pgxc_xacts_iscommitted()

  Description: Returns the status of the transaction with the specified XID in the cluster. **t** indicates the committed state, **f** indicates the aborted state, and **null** indicates other states. To execute this function, you must have the **sysadmin** or **monadmin** permission.

  Return type: set of record

  Example:

```
openGauss=# SELECT pgxc_xacts_iscommitted(1);
 pgxc_xacts_iscommitted
--------------------
(dn_6004_6005_6006,t)
(cn_5001,t)
(cn_5002,t)
(dn_6001_6002_6003,t)
(4 row)
```

- pgxc_total_memory_detail()

  Description: Displays the memory usage in the cluster. To execute this function, you must have the **sysadmin** or **monadmin** permission.

  NOTE

  If **enable_memory_limit** is set to **off**, this function cannot be used.

  Return type: set of pv_total_memory_detail

  Example:

```
openGauss=# SELECT pgxc_total_memory_detail();
pgxc_total_memory_detail
--------------------
(dn_6004_6005_6006,max_process_memory,81920)
(dn_6004_6005_6006,process_used_memory,72747)
(dn_6004_6005_6006,max_dynamic_memory,12096)
(dn_6004_6005_6006,dynamic_used_memory,1530)
(4 row)
```

- pv_total_memory_detail

  Description: Collects statistics on memory usage of the current database node in the unit of MB.

  NOTE

  If **enable_memory_limit** is set to **off**, this function cannot be used.

  Return type: record

**Table 12-37** Return value description

| Name | Type | Description |
| --- | --- | --- |
| nodename | text | Node name |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Type | Description |
| --- | --- | --- |
| memorytype | text | Memory type. The value must be one of the following:<br>• **max_process_memory**: memory occupied by a GaussDB cluster instance<br>• **process_used_memory**: memory occupied by a GaussDB process<br>• **max_dynamic_memory**: maximum dynamic memory<br>• **dynamic_used_memory**: used dynamic memory<br>• **dynamic_peak_memory**: dynamic peak memory<br>• **dynamic_used_shrctx**: maximum dynamic shared memory context<br>• **dynamic_peak_shrctx**: dynamic peak value of the shared memory context<br>• **max_shared_memory**: maximum shared memory<br>• **shared_used_memory**: used shared memory<br>• **max_cstore_memory**: maximum memory allowed for column storage<br>• **cstore_used_memory**: memory used by column storage<br>• **max_sctpcomm_memory**: maximum memory allowed for the communication library<br>• **sctpcomm_used_memory**: memory used by the communication library<br>• **sctpcomm_peak_memory**: memory peak of the communication library<br>• **other_used_memory**: other used memory |
| memorymbytes | integer | Size of allocated memory |

- get_client_info()

  Description: Returns client information.

  Return type: record

## Access Permission Query Functions

The DDL permissions, including ALTER, DROP, COMMENT, INDEX, and VACUUM, are inherent permissions implicitly owned by the owner.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The following access permission query function only indicates whether a user has a certain permission on an object. That is, the permission on the object recorded in the **acl** column of the system catalog is returned.

- has_any_column_privilege(user, table, privilege)

  Description: Queries whether a specified user has permissions on any column of a table.

  **Table 12-38** Parameter types

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name, oid | Username | Username or ID |
| table | text, oid | Table | Table name or ID |
| privilege | text | Permission | • **SELECT**: allows the **SELECT** statement to be executed on any column of a specified table.<br>• **INSERT**: allows the **INSERT** statement to be executed on any column of a specified table.<br>• **UPDATE**: allows the **UPDATE** statement to be executed on any column of a specified table.<br>• **REFERENCES**: allows users to create a foreign key constraint.<br>• **COMMENT**: allows the **COMMENT** statement to be executed on any column of a specified table. |

  Return type: Boolean

- has_any_column_privilege(table, privilege)

  Description: Queries whether the current user has the permission to access any column of a table. For details about the valid parameter types, see **Table 12-38**.

  Return type: Boolean

  Note: **has_any_column_privilege** checks whether a user can access any column of a table in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**, except that the desired access permission type must be some combination of **SELECT**, **INSERT**, **UPDATE**, or **REFERENCES**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table. Therefore, **has_any_column_privilege** always returns **true** if **has_table_privilege** has the same parameters. But **has_any_column_privilege** also returns **true** if a column-level permission is granted for at least one column.

- has_column_privilege(user, table, column, privilege)

  Description: Specifies whether a specified user has the permission to access columns.

  **Table 12-39** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name, oid | User | Username or ID |
| table | text, oid | Table name | Table name or ID |
| column | text, smallint | Column name | Name or attribute number of a column |
| privilege | text | Permission | • **SELECT**: allows the **SELECT** statement to be executed on specified columns of a table.<br>• **INSERT**: allows the **INSERT** statement to be executed on specified columns of a table.<br>• **UPDATE**: allows the **UPDATE** statement to be executed on specified columns of a table.<br>• **REFERENCES**: allows users to create a foreign key constraint.<br>• **COMMENT**: allows the **COMMENT** statement to be executed on specified columns of a table. |

  Return type: Boolean

- has_column_privilege(table, column, privilege)

  Description: Specifies whether the current user has the permission to access columns. For details about the valid parameter types, see **Table 12-39**.

  Return type: Boolean

  **has_column_privilege** checks whether a user can access a column in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. Columns can be added either by name or by attribute

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

number. The desired access permission type must be some combination of **SELECT**, **INSERT**, **UPDATE**, or **REFERENCES**.

NOTE

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table.

- has_cek_privilege(user, cek, privilege)

  Description: Specifies whether a specified user has permissions on CEKs.

  **Table 12-40** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name, oid | User | Username or ID |
| cek | text, oid | CEK | Name or ID of a CEK |
| privilege | text | Permission | • **USAGE**: allows users to use the specified CEK.<br>• **DROP**: allows users to delete the specified CEK. |

  Return type: Boolean

- has_cmk_privilege(user, cmk, privilege)

  Description: Specifies whether a specified user has permissions on CMKs.

  **Table 12-41** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name, oid | User | Username or ID |
| cmk | text, oid | CMK | Name or ID of the CMK |
| privilege | text | Permission | • **USAGE**: allows users to use the specified CMK.<br>• **DROP**: allows users to delete the specified CMK. |

  Return type: Boolean

- has_database_privilege(user, database, privilege)

  Description: Specifies whether a specified user has permissions on databases.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-42** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name, oid | User | Username or ID |
| database | text, oid | Database | Database name or ID |
| privilege | text | Permission | • **CREATE**: For databases, allows new schemas to be created within the database.<br>• **TEMPORARY**: allows users to create temporary tables when the database is used.<br>• **TEMP**: allows users to create temporary tables when the database is used.<br>• **CONNECT**: allows users to access specified databases.<br>• **ALTER**: allows users to modify the attributes of a specified object.<br>• **DROP**: allows users to delete specified objects.<br>• **COMMENT**: allows users to define or modify comments of a specified object. |

Return type: Boolean

- has_database_privilege(database, privilege)

  Description: Queries whether the current user has the permission to access a database. For details about the valid parameter types, see **Table 12-42**.

  Return type: Boolean

  Note: **has_database_privilege** checks whether a user can access a database in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The desired access permission type must be some combination of **CREATE**, **CONNECT**, **TEMPORARY**, or **TEMP** (which is equivalent to **TEMPORARY**).

- has_directory_privilege(user, directory, privilege)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-43** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name, oid | User | Username or ID |
| directory | text, oid | Directory | Directory name or OID |
| privilege | text | Permission | • **READ**: allows read operations on the directory.<br>• **WRITE**: allows write operations on the directory. |

Description: Specifies whether a specified user has permissions on directories.

Return type: Boolean

- has_directory_privilege(directory, privilege)

  Description: Queries whether the current user has the permission to access a directory. For details about the valid parameter types, see **Table 12-43**.

  Return type: Boolean

- has_foreign_data_wrapper_privilege(user, fdw, privilege)

**Table 12-44** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name, oid | User | Username or ID |
| fdw | text, oid | Foreign data wrapper | Name or ID of the foreign data wrapper |
| privilege | text | Permission | **USAGE**: allows access to the foreign data wrapper. |

Description: Specifies whether a specified user has permissions on foreign data wrappers.

Return type: Boolean

- has_foreign_data_wrapper_privilege(fdw, privilege)

  Description: Queries whether the current user has permissions on foreign data wrappers. For details about the valid parameter types, see **Table 12-44**.

  Return type: Boolean

  Note: **has_foreign_data_wrapper_privilege** checks whether a user can access a foreign data wrapper in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The desired access permission type must be **USAGE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- has_function_privilege(user, function, privilege)

  **Table 12-45** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name, oid | User | Username or ID |
| function | text, oid | Function | Function name or ID |
| privilege | text | Permission | **EXECUTE**: allows users to use specified functions and the operators that are realized by the functions.<br>• **ALTER**: allows users to modify the attributes of a specified object.<br>• **DROP**: allows users to delete a specified object.<br>• **COMMENT**: allows users to define or modify comments of a specified object. |

  Description: Specifies whether a specified user has permissions on functions.

  Return type: Boolean

- has_function_privilege(function, privilege)

  Description: Specifies whether the current user has permissions on functions. For details about valid parameter types, see **Table 12-45**.

  Return type: Boolean

  Note: **has_function_privilege** checks whether a user can access a function in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. When a function is specified by a text string rather than by an OID, the allowed input is the same as that for the **regprocedure** data type (see **12.3.15 Object Identifier Types**). The desired access permission type must be **EXECUTE**.

- has_language_privilege(user, language, privilege)

  **Table 12-46** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name, oid | User | Username or ID |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| language | text, oid | Language | Language name or ID |
| privilege | text | Permission | **USAG**: allows users to specify a procedural language when creating a function. |

Description: Specifies whether a specified user has permissions on languages.

Return type: Boolean

- has_language_privilege(language, privilege)

  Description: Specifies whether the current user has permissions on languages. For details about valid parameter types, see **Table 12-46**.

  Return type: Boolean

  Note: **has_language_privilege** checks whether a user can access a procedural language in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The desired access permission type must be **USAGE**.

- has_nodegroup_privilege(user, nodegroup, privilege)

  Description: Checks whether a user has the permission to access a cluster node.

  Return type: Boolean

**Table 12-47** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name, oid | User | Existing username or ID |
| nodegroup | text, oid | Cluster node | Existing cluster node |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| privilege | text | Permission | • **USAGE**: For sub-clusters, allows users who can access objects contained in the schema to access tables in the sub-cluster.<br>• **CREATE**: For sub-clusters, allows users to create tables within the sub-cluster.<br>• **COMPUTE**: allows users to perform elastic computing in the sub-cluster.<br>• **ALTER**: allows users to modify the attributes of a specified object.<br>• **DROP**: allows users to delete a specified object. |

- has_nodegroup_privilege(nodegroup, privilege)

  Description: Checks whether a user has the permission to access a cluster node.

  Return type: Boolean
- has_schema_privilege(user, schema, privilege)

  Description: Specifies whether a specified user has permissions on schemas.

  Return type: Boolean
- has_schema_privilege(schema, privilege)

  Description: Specifies whether the current user has permissions on schemas.

  Return type: Boolean

  Note: **has_schema_privilege** checks whether a user can access a schema in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The desired access permission type must be **CREATE**, **USAGE**, **ALTER**, **DROP**, or **COMMENT**.
- has_sequence_privilege(user, sequence, privilege)

  Description: Queries whether a specified user has permissions on sequences.

  Return type: Boolean

**Table 12-48** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name, oid | User | Existing username or ID |
| sequence | text, oid | Sequence | Existing sequence name or ID |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| privilege | text | Permission | • **USAGE**: For sequences, allows users to use the **nextval** function.<br>• **SELECT**: allows users to create a sequence.<br>• **UPDATE**: allows users to execute the **UPDATE** statement.<br>• **ALTER**: allows users to modify the attributes of a specified object.<br>• **DROP**: allows users to delete a specified object.<br>• **COMMENT**: allows users to define or modify comments of a specified object. |

- has_sequence_privilege(sequence, privilege)

  Description: Queries whether the current user has permissions on sequences.

  Return type: Boolean

- has_server_privilege(user, server, privilege)

  Description: Specifies whether a specified user has permissions on foreign servers.

  Return type: Boolean

- has_server_privilege(server, privilege)

  Description: Specifies whether the current user has permissions on foreign servers.

  Return type: Boolean

  Note: **has_server_privilege** checks whether a user can access a foreign server in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The access permission type must be **USAGE**, **ALTER**, **DROP**, or **COMMENT**.

- has_table_privilege(user, table, privilege)

  Description: Specifies whether a specified user has permissions on tables.

  Return type: Boolean

- has_table_privilege(table, privilege)

  Description: Specifies whether the current user has permissions on tables.

  Return type: Boolean

  Note: **has_table_privilege** checks whether a user can access a table in a particular way. The user can be specified by name or by OID (**pg_authid.oid**), or be set to **public** which indicates public pseudo roles. If this parameter is omitted, **current_user** is used. The table can be specified by name or by OID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

When it is specified by name, the name can be schema-qualified if necessary. If the desired access permission type is specified by a text string, the text string must be one of the values **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE**, **REFERENCESTRIGGER**, **ALTER**, **DROP**, **COMMENT**, **INDEX**, or **VACUUM**. Optionally, **WITH GRANT OPTION** can be added to a permission type to test whether the permission is held with the grant option. Also, multiple permission types can be listed separated by commas, in which case the result will be **true** if any of the listed permissions is held.

Example:

```
openGauss=# SELECT has_table_privilege('tpcds.web_site', 'select');
 has_table_privilege
---------------------
 t
(1 row)

openGauss=# SELECT has_table_privilege('omm', 'tpcds.web_site', 'select,INSERT WITH GRANT
OPTION ');
 has_table_privilege
---------------------
 t
(1 row)
```

- has_tablespace_privilege(user, tablespace, privilege)

  Description: Specifies whether a specified user has permissions on tablespaces.

  Return type: Boolean

- has_tablespace_privilege(tablespace, privilege)

  Description: Specifies whether the current user has permissions on tablespaces.

  Return type: Boolean

  Note: **has_tablespace_privilege** checks whether a user can access a tablespace in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The access permission type must be **CREATE**, **ALTER**, **DROP**, or **COMMENT**.

- pg_has_role(user, role, privilege)

  Description: Specifies whether a specified user has permissions on roles.

  Return type: Boolean

- pg_has_role(role, privilege)

  Description: Specifies whether the current user has permissions on roles.

  Return type: Boolean

  Note: **pg_has_role** checks whether a user can access a role in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**, except that **public** cannot be used as a username. The desired access permission type must be some combination of **MEMBER** or **USAGE**. **MEMBER** denotes direct or indirect membership in the role (that is, permission **SET ROLE**), while **USAGE** denotes the usage permission on the role that is available without the **SET ROLE** permission.

- has_any_privilege(user, privilege)

  Description: Queries whether a specified user has certain ANY permission. If multiple permissions are queried at the same time, **true** is returned as long as one permission is obtained.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-49** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range |
| --- | --- | --- | --- |
| user | name | User | Existing username |
| privilege | text | ANY permission | Available values:<br>CREATE ANY TABLE [WITH ADMIN OPTION]<br>ALTER ANY TABLE [WITH ADMIN OPTION]<br>DROP ANY TABLE [WITH ADMIN OPTION]<br>SELECT ANY TABLE [WITH ADMIN OPTION]<br>INSERT ANY TABLE [WITH ADMIN OPTION]<br>UPDATE ANY TABLE [WITH ADMIN OPTION]<br>DELETE ANY TABLE [WITH ADMIN OPTION]<br>CREATE ANY SEQUENCE [WITH ADMIN OPTION]<br>CREATE ANY INDEX [WITH ADMIN OPTION]<br>CREATE ANY FUNCTION [WITH ADMIN OPTION]<br>EXECUTE ANY FUNCTION [WITH ADMIN OPTION]<br>CREATE ANY PACKAGE [WITH ADMIN OPTION]<br>EXECUTE ANY PACKAGE [WITH ADMIN OPTION]<br>CREATE ANY TYPE [WITH ADMIN OPTION] |

## Schema Visibility Query Functions

Each function performs the visibility check on one type of database objects. For functions and operators, an object in the search path is visible if there is no object of the same name and parameter data type earlier in the path. For operator classes, both name and associated index access methods are considered.

All these functions require object OIDs to identify the object to be checked. If you want to test an object by name, it is convenient to use the OID alias type (**regclass**, **regtype**, **regprocedure**, **regoperator**, **regconfig**, or **regdictionary**).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

For example, a table is said to be visible if the schema where the table is located is in the search path and no table of the same name appears earlier in the search path. This is equivalent to the statement that the table can be referenced by name without explicit schema qualification. For example, to list the names of all visible tables, run the following command:

```
openGauss=# SELECT relname FROM pg_class WHERE pg_table_is_visible(oid);
```

- pg_collation_is_visible(collation_oid)

  Description: Specifies whether the collation is visible in the search path.

  Return type: Boolean
- pg_conversion_is_visible(conversion_oid)

  Description: Specifies whether the conversion is visible in the search path.

  Return type: Boolean
- pg_function_is_visible(function_oid)

  Description: Specifies whether the function is visible in the search path.

  Return type: Boolean
- pg_opclass_is_visible(opclass_oid)

  Description: Specifies whether the operator class is visible in the search path.

  Return type: Boolean
- pg_operator_is_visible(operator_oid)

  Description: Specifies whether the operator is visible in the search path.

  Return type: Boolean
- pg_opfamily_is_visible(opclass_oid)

  Description: Specifies whether the operator family is visible in the search path.

  Return type: Boolean
- pg_table_is_visible(table_oid)

  Description: Specifies whether the table is visible in the search path.

  Return type: Boolean
- pg_ts_config_is_visible(config_oid)

  Description: Specifies whether the text search configuration is visible in the search path.

  Return type: Boolean
- pg_ts_dict_is_visible(dict_oid)

  Description: Specifies whether the text search dictionary is visible in the search path.

  Return type: Boolean
- pg_ts_parser_is_visible(parser_oid)

  Description: Specifies whether the text search parser is visible in the search path.

  Return type: Boolean
- pg_ts_template_is_visible(template_oid)

  Description: Specifies whether the text search template is visible in the search path.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_type_is_visible(type_oid)

  Description: Specifies whether the type (or domain) is visible in the search path.

  Return type: Boolean

## System Catalog Information Functions

- format_type(type_oid, typemod)

  Description: Obtains the SQL name of a data type.

  Return type: text

  Note: **format_type** returns the SQL name of a data type that is identified by its type OID and possible type modifier. **NULL** is passed for the type modifier if no specific modifier is known. Certain type modifiers are passed for data types with length limitations. The SQL name returned by **format_type** contains the length of the data type, which can be calculated by taking sizeof(int32) from actual storage length [actual storage len - sizeof(int32)] in the unit of bytes. 32-bit space is required to store the customized length set by users. Therefore, the actual storage length contains 4 bytes more than the customized length. In the following example, the SQL name returned by **format_type** is character varying(6), indicating the length of the varchar type is 6 bytes. Therefore, the actual storage length of the varchar type is 10 bytes.

  ```
  openGauss=# SELECT format_type((SELECT oid FROM pg_type WHERE typname='varchar'), 10);
      format_type
  ----------------------
   character varying(6)
  (1 row)
  ```

- pg_check_authid(role_oid)

  Description: Checks whether a role name with a given OID exists.

  Return type: Boolean

  ```
  openGauss=# select pg_check_authid(1);
  pg_check_authid
  -----------------
  f
  (1 row)
  ```

- pg_describe_object(catalog_id, object_id, object_sub_id)

  Description: Obtains the description of a database object.

  Return type: text

  Note: **pg_describe_object** returns the description of a database object specified by a catalog OID, an object OID, and a (possibly zero) sub-object ID. This is useful to determine the identity of an object stored in the **pg_depend** catalog.

- pg_get_constraintdef(constraint_oid)

  Description: Obtains the definition of a constraint.

  Return type: text

- pg_get_constraintdef(constraint_oid, pretty_bool)

  Description: Obtains the definition of a constraint.

  Return type: text

  Note: **pg_get_constraintdef** and **pg_get_indexdef** respectively reconstruct the creation command for a constraint and an index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_get_expr(pg_node_tree, relation_oid)

  Description: Decompiles the internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.

  Return type: text

- pg_get_expr(pg_node_tree, relation_oid, pretty_bool)

  Description: Decompiles the internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.

  Return type: text

  Note: **pg_get_expr** decompiles the internal form of an individual expression, such as the default value of a column. It can be useful when the content of system catalogs is checked. If the expression might contain Vars, specify the OID of the relationship they refer to as the second parameter; if no Vars are expected, zero is sufficient.

- pg_get_functiondef(func_oid)

  Description: Obtains the definition of a function.

  Return type: text

  Example:

```
openGauss=# select * from pg_get_functiondef(598);
 headerlines |                    definition
-------------+-----------------------------------------------------
           4 | CREATE OR REPLACE FUNCTION pg_catalog.abbrev(inet)+
             |  RETURNS text                                     +
             |  LANGUAGE internal                                +
             |  IMMUTABLE STRICT NOT FENCED NOT SHIPPABLE        +
             | AS $function$inet_abbrev$function$                +
             |
(1 row)
```

- pg_get_function_arguments(func_oid)

  Description: Obtains the parameter list of the function's definition (with default values).

  Return type: text

  Note: **pg_get_function_arguments** returns the parameter list of a function, in the form it would need to appear in **CREATE FUNCTION**.

- pg_get_function_identity_arguments(func_oid)

  Description: Obtains the parameter list to identify a function (without default values).

  Return type: text

  Note: **pg_get_function_identity_arguments** returns the parameter list required to identify a function, in the form it would need to appear in **ALTER FUNCTION**. This form omits default values.

- pg_get_function_result(func_oid)

  Description: Obtains the **RETURNS** clause for a function.

  Return type: text

  Note: **pg_get_function_result** returns the appropriate **RETURNS** clause for the function.

- pg_get_indexdef(index_oid)

  Description: Obtains the **CREATE INDEX** command for an index.

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# select * from pg_get_indexdef(16416);
                          pg_get_indexdef
------------------------------------------------------------------------
 CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
```

- pg_get_indexdef(index_oid, dump_schema_only)

  Description: Obtains the **CREATE INDEX** command for indexes in dump scenarios. In the current version, the value of **dump_schema_only** does not affect the function output.

  Return type: text

  Example:

```
openGauss=# select * from pg_get_indexdef(16416, true);
                          pg_get_indexdef
------------------------------------------------------------------------
 CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
```

- pg_get_indexdef(index_oid, column_no, pretty_bool)

  Description: Obtains the **CREATE INDEX** command for an index, or definition of just one index column when the value of **column_no** is not zero.

  Return type: text

  Example:

```
openGauss=# select * from pg_get_indexdef(16416, 0, false);
                          pg_get_indexdef
------------------------------------------------------------------------
 CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
openGauss=# select * from pg_get_indexdef(16416, 1, false);
 pg_get_indexdef
-----------------
 b
(1 row)
```

  Note: **pg_get_functiondef** returns a complete **CREATE OR REPLACE FUNCTION** statement for a function.

- pg_get_keywords()

  Description: Obtains the list of SQL keywords and their categories.

  Return type: setof record

  Note: **pg_get_keywords** returns a set of records describing the SQL keywords recognized by the server. The **word** column contains the keywords. The **catcode** column contains a category code: **U** for unreserved, **C** for column name, **T** for type or function name, or **R** for reserved. The **catdesc** column contains a possibly-localized string describing the category.

- pg_get_ruledef(rule_oid)

  Description: Obtains the **CREATE RULE** command for a rule.

  Return type: text

- pg_get_ruledef(rule_oid, pretty_bool)

  Description: Obtains the **CREATE RULE** command for a rule.

  Return type: text

- pg_get_userbyid(role_oid)

  Description: Obtains the role name with a given OID.

  Return type: name

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Note: **pg_get_userbyid** extracts a role's name given its OID.

- pg_check_authid(role_id)

  Description: Checks whether a user exists based on **role_id**.

  Return type: text

```
openGauss=# select pg_check_authid(20);
pg_check_authid
-----------------
f
(1 row)
```

- pg_get_viewdef(view_name)

  Description: Obtains the underlying **SELECT** command for a view.

  Return type: text

- pg_get_viewdef(view_name, pretty_bool)

  Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to 80 columns if **pretty_bool** is set to **true**.

  Return type: text

  Note: **pg_get_viewdef** reconstructs the **SELECT** query that defines a view. Most of these functions come in two forms. When the function has the **pretty_bool** parameter and the value is **true**, it can optionally "pretty-print" the result. The pretty-printed format is more readable. The other one is the default format which is more likely to be interpreted in the same way by future versions. Avoid using pretty-printed output for dump purposes. Passing **false** for the pretty-print parameter yields the same result as the variant that does not have the parameter.

- pg_get_viewdef(view_oid)

  Description: Obtains the underlying **SELECT** command for a view.

  Return type: text

- pg_get_viewdef(view_oid, pretty_bool)

  Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to 80 columns if **pretty_bool** is set to **true**.

  Return type: text

- pg_get_viewdef(view_oid, wrap_column_int)

  Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to the specified number of columns and printing is implicit.

  Return type: text

- pg_get_tabledef(table_oid)

  Description: Obtains the definition of a table based on **table_oid**.

  Return type: text

  Example:

```
openGauss=# select * from pg_get_tabledef(16384);
                  pg_get_tabledef
-----------------------------------------------------
 SET search_path = public;                          +
 CREATE  TABLE t1 (                                 +
        c1 bigint DEFAULT nextval('serial'::regclass)+
 )                                                  +
 WITH (orientation=row, compression=no)             +
 DISTRIBUTE BY HASH(c1)                             +
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 TO GROUP group1;
(1 row)
```

- pg_get_tabledef(table_name)

  Description: Obtains the definition of a table based on **table_name**.

  Return type: text

  Example:

```
openGauss=# select * from pg_get_tabledef('t1');
                  pg_get_tabledef
------------------------------------------------------------
 SET search_path = public;                          +
 CREATE  TABLE t1 (                                +
        c1 bigint DEFAULT nextval('serial'::regclass)+
 )                                                  +
 WITH (orientation=row, compression=no)             +
 DISTRIBUTE BY HASH(c1)                             +
 TO GROUP group1;
(1 row)
```

  Note: **pg_get_tabledef** reconstructs the **CREATE** statement of the definition of the table, including the table definition, index information, and comments. Users need to create the dependent objects of the table, such as groups, schemas, tablespaces, and servers. The table definition does not include the statements for creating these dependent objects.

- pg_options_to_table(reloptions)

  Description: Obtains the set of storage option name/value pairs.

  Return type: setof record

  Note: **pg_options_to_table** returns the set of storage option name/value pairs (**option_name**/**option_value**) when **pg_class.reloptions** or **pg_attribute.attoptions** is passed.

- pg_tablespace_databases(tablespace_oid)

  Description: Obtains the set of database OIDs that have objects in the specified tablespace.

  Return type: setof oid

  Note: **pg_tablespace_databases** allows a tablespace to be checked. It returns the set of OIDs of databases that have objects stored in the tablespace. If this function returns any rows of data, the tablespace is not empty and cannot be dropped. To display the specific objects in the tablespace, you need to connect to the databases identified by **pg_tablespace_databases** and query their **pg_class** catalogs.

- pg_tablespace_location(tablespace_oid)

  Description: Obtains the path in the file system that this tablespace is located in.

  Return type: text

- pg_typeof(any)

  Description: Obtains the data type of any value.

  Return type: regtype

  Note: **pg_typeof** returns the OID of the data type of the value that is passed to it. This can be helpful for troubleshooting or dynamically constructing SQL queries. It is declared that the function returns **regtype**, which is an OID alias type (see **12.3.15 Object Identifier Types**). This means that it is the same as an OID for comparison purposes but displays as a type name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Example:

```
openGauss=# SELECT pg_typeof(33);
 pg_typeof
-----------
 integer
(1 row)

openGauss=# SELECT typlen FROM pg_type WHERE oid = pg_typeof(33);
 typlen
--------
      4
(1 row)
```

- collation for (any)

  Description: Obtains the collation of the parameter.

  Return type: text

  Note: The expression **collation for** returns the collation of the value that is passed to it. Example:

  ```
  openGauss=# SELECT collation for (description) FROM pg_description LIMIT 1;
   pg_collation_for
  ------------------
   "default"
  (1 row)
  ```

  The value might be quoted and schema-qualified. If no collation is derived for the parameter expression, then a null value is returned. If the parameter is not of a collectable data type, then an error is thrown.

- getdistributekey(table_name)

  Description: Obtains a distribution column for a hash table.

  Return type: text

  Example:

  ```
  openGauss=# SELECT getdistributekey('item');
   getdistributekey
  ------------------
   i_item_sk
  (1 row)
  ```

- pg_extension_update_paths(name)

  Description: Returns the version update path of the specified extension. This function can be called only by the system administrator. The current feature is a lab feature. Contact Huawei technical support before using it.

  Return type: text (source text), text (target text), text (path text)

- pg_get_serial_sequence(tablename, colname)

  Description: Obtains the sequence of the corresponding table name and column name.

  Return type: text

  Example:

  ```
  openGauss=# select * from pg_get_serial_sequence('t1', 'c1');
   pg_get_serial_sequence
  ------------------------
   public.serial
  (1 row)
  ```

- pg_sequence_parameters(sequence_oid)

  Description: Obtains the parameters of a specified sequence, including the start value, minimum value, maximum value, and incremental value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: int16, int16, int16, int16, Boolean

Example:

```
openGauss=# select * from pg_sequence_parameters(16420);
 start_value | minimum_value |     maximum_value     | increment | cycle_option
-------------+---------------+-----------------------+-----------+--------------
         101 |             1 | 9223372036854775807 |         1 | f
(1 row)
```

- pgxc_get_variable_info( )

  Description: Obtains variable values on the node, including **nodeName**, **nextOid**, **nextXid**, **oldestXid**, **xidVacLimit**, **oldestXidDB**, **lastExtendCSNLogpage**, **startExtendCSNLogpage**, **nextCommitSeqNo**, **latestCompleteXid**, and **startupMaxXid**.

  Return type: set of pg_variable_info

  Example:

  ```
  openGauss=# select pgxc_get_variable_info( );
                      pgxc_get_variable_info
  ---------------------------------------------------------------------------
  (dn_6004_6005_6006,25617,141396349,2073,20000002073,15808,138111,0,127154152,141396348,104
  433004)
  (1 row)
  ```

- gs_get_index_status(schema_name, index_name)

  Description: Obtains the index status information on all nodes, including whether an index can be inserted and whether an index is available. This function is mainly used to check the index status during online index creation or when the index creation fails. The return values include **node_name**, **indisready**, and **indisvalid**. Only when **indisready** and **indisvalid** of indexes on all nodes are set to **true** and the index state is not changed to unusable, the current index is available.

  Return type: text, Boolean, Boolean

  Example:

  ```
  openGauss=# select * from gs_get_index_status('public', 'index1');
    node_name    | indisready | indisvalid
  ----------------+------------+------------
   datanode1      | t          | t
   datanode2      | t          | t
   coordinator1   | t          | t
  (3 row)
  ```

## Comment Information Functions

- col_description(table_oid, column_number)

  Description: Obtains the comment for a table column.

  Return type: text

  Note: **col_description** returns the comment for a table column, which is specified by the OID of its table and its column number.

- obj_description(object_oid, catalog_name)

  Description: Obtains the comment for a database object.

  Return type: text

  Note: The two-parameter form of **obj_description** returns the comment for a database object specified by its OID and the name of the system catalog to which it belongs. For example, **obj_description(123456,'pg_class')** would retrieve the comment for the table with OID 123456. The one-parameter form of **obj_description** requires only the OID.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**obj_description** cannot be used for table columns since columns do not have OIDs of their own.

- obj_description(object_oid)

  Description: Obtains the comment for a database object.

  Return type: text

- shobj_description(object_oid, catalog_name)

  Description: Obtains the comment for a shared database object.

  Return type: text

  Note: **shobj_description** is used just like **obj_description**, except that the former is used for shared objects. Some system catalogs are global to all databases in the cluster, and the comments for objects in them are stored globally as well.

## XIDs and Snapshots

Internal XIDs are 64 bits. **txid_snapshot**, data type used by these functions, stores information about XID visibility at a particular moment in time. **Table 12-50** describes its components.

**Table 12-50** Snapshot components

| Name | Description |
| --- | --- |
| xmin | Earliest XID (**txid**) that is still active. All earlier transactions will either be committed and visible, or rolled back. |
| xmax | First as-yet-unassigned **txid**. All **txids** greater than or equal to this are not yet started as of the time of the snapshot, so they are invisible. |
| xip_list | Active **txids** at the time of the snapshot. The list includes only those active **txids** between **xmin** and **xmax**; there might be active **txids** higher than **xmax**. A **txid** that is greater than or equal to **xmin** and less than **xmax** and that is not in this list was already completed at the time of the snapshot, and is either visible or rolled back according to its commit status. The list does not include **txids** of subtransactions. |

The textual representation of **txid_snapshot** is **xmin:xmax:xip_list**.

For example, **10:20:10,14,15** means **xmin=10, xmax=20, xip_list=10, 14, 15**.

The following functions provide server transaction information in an exportable form. These functions are mainly used to determine which transactions were committed between two snapshots.

- pgxc_is_committed(transaction_id)

  Description: Specifies whether the given XID is committed or ignored. **NULL** indicates an unknown state (such as running, preparing, or freezing).

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- txid_current()

  Description: Obtains the current XID.

  Return type: bigint

- gs_txid_oldestxmin()

  Description: Obtains the minimum XID (specified by **oldesxmin**).

  Return type: bigint

- txid_current_snapshot()

  Description: Obtains the current snapshot.

  Return type: txid_snapshot

- txid_snapshot_xip(txid_snapshot)

  Description: Obtains in-progress XIDs in a snapshot.

  Return type: setof bigint

- txid_snapshot_xmax(txid_snapshot)

  Description: Obtains **xmax** of snapshots.

  Return type: bigint

- txid_snapshot_xmin(txid_snapshot)

  Description: Obtains **xmin** of snapshots.

  Return type: bigint

- txid_visible_in_snapshot(bigint, txid_snapshot)

  Description: Specifies whether the XID is visible in a snapshot (do not use subtransaction IDs).

  Return type: Boolean

- get_local_prepared_xact()

  Description: Obtains the two-phase residual transaction information of the current node, including the XID, GID of the two-phase transaction, prepared time, owner OID, database OID, and node name of the current node.

  Return type: xid, text, timestamptz, oid, oid, text

- get_remote_prepared_xacts()

  Description: Obtains the two-phase residual transaction information of all remote nodes, including the XID, GID of the two-phase transaction, prepared time, owner name, database name, and node name.

  Return type: xid, text, timestamptz, name, name, text

- global_clean_prepared_xacts(text, text)

  Description: Concurrently cleans two-phase residual transactions. Only the gs_clean tool can call this function for cleaning. In other situations, **false** is returned.

  Return type: Boolean

- pgxc_stat_get_wal_senders()

  Description: Returns the sent logs of all primary DNs and the received logs of their corresponding standby DNs in the cluster. Only users with the **system admin** or **monitor admin** permission can use this function.

  The return values are as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-51** pgxc_stat_get_wal_senders parameter description

| Parameter | Description |
| --- | --- |
| nodename | Instance name |
| sender_pid | PID of the thread for sending logs |
| local_role | Instance role |
| peer_role | Role of the instance on the receiver |
| peer_state | Status of the instance on the receiver |
| state | Synchronization status between instances |
| sender_sent_location | Location where the sender sends logs |
| sender_write_location | Location where the sender writes logs |
| sender_flush_location | Location where the sender flushes logs to disks |
| sender_replay_location | Location of the instance logs. For a primary DN, the value is the same as that of **sender_flush_location**. Otherwise, the value is the location where the sender replays the instance logs. |
| receiver_received_location | Location where the receiver receives logs |
| receiver_write_location | Location where the receiver writes logs |
| receiver_flush_location | Location where the receiver flushes logs to disks |
| receiver_replay_location | Location where the receiver replays logs |

- pgxc_stat_get_wal_senders_status()

  Description: Returns the receiving status of transaction logs on all nodes. Only users with the **system admin** or **monitor admin** permission can use this function.

  The return values are as follows:

  **Table 12-52** pgxc_stat_get_wal_senders_status parameter description

| Parameter | Description |
| --- | --- |
| nodename | Name of the primary node |
| source_ip | IP address of the primary node |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Description |
| --- | --- |
| source_port | Port number of the primary node |
| dest_ip | IP address of the standby node |
| dest_port | Port number of the standby node |
| sender_pid | PID of the sender thread |
| local_role | Type of the primary node |
| peer_role | Type of the standby node |
| peer_state | Status of the standby node |
| state | WAL sender status |
| sender_sent_location | Sending position of the primary node |
| sender_write_location | Writing position of the primary node |
| sender_replay_location | Redo position of the primary node |
| receiver_received_location | Receiving position of the standby node |
| receiver_write_location | Writing position of the standby node |
| receiver_flush_location | Flushing location of the standby node |
| receiver_replay_location | Redo location of the standby node |

- gs_get_next_xid_csn()

  Description: Returns the values of **next_xid** and **next_csn** on all nodes globally.

  The return values are as follows:

  **Table 12-53** gs_get_next_xid_csn parameter description

| Parameter | Description |
| --- | --- |
| nodename | Node name |
| next_xid | ID of the next transaction on the current node. |
| next_csn | Next CSN of the current node. |

- slice(hstore, text[])

  Description: Extracts the subset of the hstore type.

  Return type: hstore

  Example:

```
openGauss=# select slice('a=>1,b=>2,c=>3'::hstore, ARRAY['b','c','x']);
      slice
--------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 "b"=>"2", "c"=>"3"
(1 row)
```

- slice_array(hstore, text[])

  Description: Extracts the set of values of the hstore type.

  Return type: value array

  Example:

```
openGauss=# select slice_array('a=>1,b=>2,c=>3'::hstore, ARRAY['b','c','x']);
 slice_array
-------------
 {2,3,NULL}
(1 row)
```

- skeys(hstore)

  Description: Returns the set of all keys of the hstore type.

  Return type: a set of keys

  Example:

```
openGauss=# select skeys('a=>1,b=>2');
 skeys
-------
 a
 b
(2 rows)
```

- simsearch_lib_load_status()

  Description: Queries the dynamic library loading status (success or failure).

  Return type: SETOF record

- simsearch_gpu_vector_status()

  Description: Queries whether there is a vector in the status of searchlet.

  Return type: SETOF record

  > NOTE
  >
  > This function is no longer supported in the current version due to specification changes. Do not use this function.

- pg_control_system()

  Description: Returns the status of the system control file.

  Return type: SETOF record

- pg_control_checkpoint()

  Description: Returns the system checkpoint status.

  Return type: SETOF record

- get_delta_info

  Description: Obtains the data storage status in the delta table of a column-store table.

  Parameter: rel text

  Return type: part_name text, total_live_tuple bigint, total_data_size bigint, max_blocknum bigint

- get_prepared_pending_xid

  Description: Returns **nextxid** when restoration is complete.

  Parameter: nan

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_clean_region_info

  Description: Clears the region map.

  Parameter: nan

  Return type: character varying

- pg_get_delta_info

  Description: Obtains delta information from a single DN.

  Parameter: rel text, schema_name text

  Return type: part_name text, live_tuple bigint, data_size bigint, blocknum bigint

- pgxc_get_delta_info

  Description: Obtains delta information from all DNs. Only users with the **sysadmin** or **monitor admin** permission can access the information.

  Parameter: rel text, schema_name text

  Return type: part_name text, live_tuple bigint, data_size bigint, blocknum bigint

- pg_get_replication_slot_name

  Description: Obtains the slot name.

  Parameter: nan

  Return type: text

- pg_get_running_xacts

  Description: Obtains running **xact**.

  Parameter: nan

  Return type: handle integer, gxid xid, state tinyint, node text, xmin xid, vacuum boolean, timeline bigint, prepare_xid xid, pid bigint, next_xid xid

- pg_get_variable_info

  Description: Obtains the shared memory variable cache.

  Parameter: nan

  Return type: node_name text, nextOid oid, nextXid xid, oldestXid xid, xidVacLimit xid, oldestXidDB oid, lastExtendCSNLogpage xid, startExtendCSNLogpage xid, nextCommitSeqNo xid, latestCompletedXid xid, startupMaxXid xid

- pg_get_xidlimit

  Description: Obtains XID information from the shared memory.

  Parameter: nan

  Return type: nextXid xid, oldestXid xid, xidVacLimit xid, xidWarnLimit xid, xidStopLimit xid, xidWrapLimit xid, oldestXidDB oid

- pg_relation_compression_ratio

  Description: Queries the compression rate of a table. By default, **1.0** is returned.

  Parameter: text

  Return type: real

- pg_relation_with_compression

  Description: Specifies whether a table is compressed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Parameter: text

Return type: Boolean

- pg_stat_file_recursive

  Description: Lists all files in a path.

  Parameter: location text

  Return type: path text, filename text, size bigint, isdir boolean

- pg_stat_get_activity_for_temptable

  Description: Returns records of background processes related to the temporary table.

  Parameter: nan

  Return type: datid oid, timelineid integer, tempid integer, sessionid bigint

- pg_stat_get_activity_ng

  Description: Returns records of background processes related to the node group.

  Parameter: pid bigint

  Return type: datid oid, pid bigint, sessionid bigint, node_group text

- pg_stat_get_cgroup_info

  Description: Returns Cgroup information.

  Parameter: nan

  Return type: cgroup_name text, percent integer, usage_percent integer, shares bigint, usage bigint, cpuset text, relpath text, valid text, node_group text

- pg_stat_get_realtime_info_internal

  Description: Returns real-time information. Currently, this API is unavailable. **FailedToGetSessionInfo** is returned.

  Parameter: oid, oid, bigint, cstring, oid

  Return type: text

- pg_stat_get_session_wlmstat

  Description: Returns the load information of the current session.

  Parameter: pid integer

  Return type: datid oid, threadid bigint, sessionid bigint, threadpid integer, usesysid oid, appname text, query text, priority bigint, block_time bigint, elapsed_time bigint, total_cpu_time bigint, skew_percent integer, statement_mem integer, active_points integer, dop_value integer, current_cgroup text, current_status text, enqueue_state text, attribute text, is_plana boolean, node_group text, srespool name

- pg_stat_get_wlm_ec_operator_info

  Description: Obtains the operator information of the EC execution plan from the internal hash table.

  Parameter: nan

  Return type: queryid bigint, plan_node_id integer, plan_node_name text, start_time timestamp with time zone, duration bigint, tuple_processed bigint, min_peak_memory integer, max_peak_memory integer, average_peak_memory integer, ec_operator integer, ec_status text, ec_execute_datanode text, ec_dsn text, ec_username text, ec_query text, ec_libodbc_type text, ec_fetch_count bigint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_stat_get_wlm_instance_info

  Description: Returns the load information of the current instance.

  Parameter: nan

  Return type: instancename text, timestamp, timestamp with time zone, used_cpu integer, free_memory integer, used_memory integer, io_await double precision, io_util double precision, disk_read double precision, disk_write double precision, process_read bigint, process_write bigint, logical_read bigint, logical_write bigint, read_counts bigint, write_counts bigint

- pg_stat_get_wlm_instance_info_with_cleanup

  Description: Returns the load information of the current instance and saves the information to the system catalog.

  Parameter: nan

  Return type: instancename text, timestamp, timestamp with time zone, used_cpu integer, free_memory integer, used_memory integer, io_await double precision, io_util double precision, disk_read double precision, disk_write double precision, process_read bigint, process_write bigint, logical_read bigint, logical_write bigint, read_counts bigint, write_counts bigint

- pg_stat_get_wlm_node_resource_info

  Description: Obtains the resource information of the current node.

  Parameter: nan

  Return type: min_mem_util integer, max_mem_util integer, min_cpu_util integer, max_cpu_util integer, min_io_util integer, max_io_util integer, used_mem_rate integer

- pg_stat_get_wlm_operator_info

  Description: Obtains the operator information of the execution plan from the internal hash table.

  Parameter: nan

  Return type: queryid bigint, pid bigint, plan_node_id integer, plan_node_name text, start_time timestamp with time zone, duration bigint, query_dop integer, estimated_rows bigint, tuple_processed bigint, min_peak_memory integer, max_peak_memory integer, average_peak_memory integer, memory_skew_percent integer, min_spill_size integer, max_spill_size integer, average_spill_size integer, spill_skew_percent integer, min_cpu_time bigint, max_cpu_time bigint, total_cpu_time bigint, cpu_skew_percent integer, warning text

- pg_stat_get_wlm_realtime_ec_operator_info

  Description: Obtains the operator information of the EC execution plan from the internal hash table.

  Parameter: nan

  Return type: queryid bigint, plan_node_id integer, plan_node_name text, start_time timestamp with time zone, ec_operator integer, ec_status text, ec_execute_datanode text, ec_dsn text, ec_username text, ec_query text, ec_libodbc_type text, ec_fetch_count bigint

- pg_stat_get_wlm_realtime_operator_info

  Description: Obtains the operator information of the real-time execution plan from the internal hash table.

  Parameter: nan

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: queryid bigint, pid bigint, plan_node_id integer, plan_node_name text, start_time timestamp with time zone, duration bigint, status text, query_dop integer, estimated_rows bigint, tuple_processed bigint, min_peak_memory integer, max_peak_memory integer, average_peak_memory integer, memory_skew_percent integer, min_spill_size integer, max_spill_size integer, average_spill_size integer, spill_skew_percent integer, min_cpu_time bigint, max_cpu_time bigint, total_cpu_time bigint, cpu_skew_percent integer, warning text

- pg_stat_get_wlm_realtime_session_info

  Description: Returns the load information of the real-time session.

  Parameter: nan

  Return type: nodename text, threadid bigint, block_time bigint, duration bigint, estimate_total_time bigint, estimate_left_time bigint, schemaname text, query_band text, spill_info text, control_group text, estimate_memory integer, min_peak_memory integer, max_peak_memory integer, average_peak_memory integer, memory_skew_percent integer, min_spill_size integer, max_spill_size integer, average_spill_size integer, spill_skew_percent integer, min_dn_time bigint, max_dn_time bigint, average_dn_time bigint, dntime_skew_percent integer, min_cpu_time bigint, max_cpu_time bigint, total_cpu_time bigint, cpu_skew_percent integer, min_peak_iops integer, max_peak_iops integer, average_peak_iops integer, iops_skew_percent integer, warning text, query text, query_plan text, cpu_top1_node_name text, cpu_top2_node_name text, cpu_top3_node_name text, cpu_top4_node_name text, cpu_top5_node_name text, mem_top1_node_name text, mem_top2_node_name text, mem_top3_node_name text, mem_top4_node_name text, mem_top5_node_name text, cpu_top1_value bigint, cpu_top2_value bigint, cpu_top3_value bigint, cpu_top4_value bigint, cpu_top5_value bigint, mem_top1_value bigint, mem_top2_value bigint, mem_top3_value bigint, mem_top4_value bigint, mem_top5_value bigint, top_mem_dn text, top_cpu_dn text

- pg_stat_get_wlm_session_info_internal

  Description: Returns the session load information.

  Parameter: oid, bigint, bigint, oid

  Return type: SETOF text

- pg_stat_get_wlm_session_iostat_info

  Description: Returns the session load I/O information.

  Parameter: nan

  Return type: threadid bigint, maxcurr_iops integer, mincurr_iops integer, maxpeak_iops integer, minpeak_iops integer, iops_limits integer, io_priority integer, curr_io_limits integer

- pg_stat_get_wlm_statistics

  Description: Returns session load statistics.

  Parameter: nan

  Return type: statement text, block_time bigint, elapsed_time bigint, total_cpu_time bigint, qualification_time bigint, skew_percent integer, control_group text, status text, action text

- pg_stat_get_workload_struct_info

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Returns the load management data structure. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)

Parameter: nan

Return type: text

- pg_test_err_contain_err

  Description: Tests the error type and return information.

  Parameter: integer

  Return type: void

- pv_session_memory_detail_tp

  Description: Returns the memory usage of the session. For details, see **pv_session_memory_detail**.

  Parameter: nan

  Return type: sessid text, sesstype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint

- gs_get_table_distribution

  Description: Returns the distribution of table data on each DN.

  Parameter: table_name text, schema_name text

  Return type: text

- pv_builtin_functions

  Description: Displays information about all built-in system functions.

  Parameter: nan

  Return type: proname name, pronamespace oid, proowner oid, prolang oid, procost real, prorows real, provariadic oid, protransform regproc, proisagg boolean, proiswindow boolean, prosecdef boolean, proleakproof boolean, proisstrict boolean, proretset boolean, provolatile "char", pronargs smallint, pronargdefaults smallint, prorettype oid, proargtypes oidvector, proallargtypes integer[], proargmodes "char"[], proargnames text[], proargdefaults pg_node_tree, prosrc text, probin text, proconfig text[], proacl aclitem[], prodefaultargpos int2vector, fencedmode boolean, proshippable boolean, propackage boolean, oid oid

- pv_thread_memory_detail

  Description: Returns the memory information of each thread.

  Parameter: nan

  Return type: threadid text, tid bigint, thrdtype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint

- pg_shared_memory_detail

  Description: Returns usage information about all generated shared memory contexts. For details about each column, see **16.2.3.4 SHARED_MEMORY_DETAIL**.

  Parameter: nan

  Return type: contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint

- pgxc_get_running_xacts

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Returns information about running transactions on each node in the cluster. The field content is the same as that in **15.3.196 PGXC_RUNNING_XACTS**. Only users with the **system admin** or **monitor admin** permission can view the information.

Parameter: nan

Return type: setof record

- pgxc_snapshot_status()

  Description: Returns the status of key memory information in the GTM in GTM mode for fault locating. GTM-Free and GTM-Lite do not support this function.

  Parameter: nan

  Return type: xmin xid, xmax xid, xcnt int, oldestxmin xid, next_xid xid, timeline int, active_thread_num int, max_active_thread_num int, snapshot_num int, snapshot_totalsize bigint

  The return values are described as follows:

  **Table 12-54** get_gtm_lite_status parameter description

| Parameter | Description |
| --- | --- |
| xmin | Minimum active XID in the GTM. |
| xmax | Largest XID committed in the GTM plus 1. Transactions whose IDs are greater than or equal to this value are active. |
| xcnt | Number of active transactions in the GTM. |
| oldestxmin | ID of the earliest accessed transaction in the GTM. |
| next_xid | ID of the next transaction allocated by the GTM. |
| timeline | Current time line in the GTM. |
| active_thread_num | Number of active worker threads in the GTM. |
| max_active_thread_num | Peak number of worker threads in the GTM within one minute. |
| snapshot_num | Number of snapshots delivered by the GTM within one minute. |
| snapshot_totalsize | Total size of snapshots delivered by the GTM within one minute. |

- get_gtm_lite_status()

  Description: Returns the backup XID and CSN in the GTM for fault locating. This system function is not supported in GTM-Free mode.

  The return values are as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-55** get_gtm_lite_status parameter description

| Parameter | Description |
| --- | --- |
| backup_xid | Backup XID in the GTM. |
| csn | Latest CSN issued by the GTM. |

# 12.5.26 System Administration Functions

## 12.5.26.1 Configuration Settings Functions

Configuration setting functions are used for querying and modifying configuration parameters during running.

- current_setting(setting_name)

  Description: Specifies the current setting.

  Return type: text

  Note: **current_setting** obtains the current setting of **setting_name** by query. It is equivalent to the **SHOW** statement. For example:

  ```
  openGauss=# SELECT current_setting('datestyle');

   current_setting
  -----------------
   ISO, MDY
  (1 row)
  ```

- set_working_grand_version_num_manually(tmp_version)

  Description: Upgrades new features of GaussDB by switching the authorization version.

  Return type: void

- shell_in(type)

  Description: Inputs a route for the shell type that has not yet been filled.

  Return type: void

- shell_out(type)

  Description: Outputs a route for the shell type that has not yet been filled.

  Return type: void

- set_config(setting_name, new_value, is_local)

  Description: Sets the parameter and returns a new value.

  Return type: text

  Note: **set_config** sets the parameter **setting_name** to **new_value**. If **is_local** is **true**, the new value will only apply to the current transaction. If you want the new value to apply for the current session, use **false** instead. The function corresponds to the **SET** statement.

  Example:

  ```
  openGauss=# SELECT set_config('log_statement_stats', 'off', false);

   set_config
  ------------
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
 off
(1 row)
```

## 12.5.26.2 Universal File Access Functions

Universal file access functions provide local access interfaces for files on a database server. Only files in the database cluster directory and the **log_directory** directory can be accessed. Use a relative path for files in the database cluster directory, and a path matching the **log_directory** configuration setting for log files. Only database initialization users can use these functions.

- pg_ls_dir(dirname text)

  Description: Lists files in a directory.

  Return type: setof text

  Note: **pg_ls_dir** returns all the names in the specified directory, except the special entries "." and "..".

  Example:

```
openGauss=# SELECT pg_ls_dir('./');
      pg_ls_dir
----------------------
 .postgresql.conf.swp
 postgresql.conf
 pg_tblspc
 PG_VERSION
 pg_ident.conf
 core
 server.crt
 pg_serial
 pg_twophase
 postgresql.conf.lock
 pg_stat_tmp
 pg_notify
 pg_subtrans
 pg_ctl.lock
 pg_xlog
 pg_clog
 base
 pg_snapshots
 postmaster.opts
 postmaster.pid
 server.key.rand
 server.key.cipher
 pg_multixact
 pg_errorinfo
 server.key
 pg_hba.conf
 pg_replslot
 .pg_hba.conf.swp
 cacert.pem
 pg_hba.conf.lock
 global
 gaussdb.state
(32 rows)
```

- pg_read_file(filename text, offset bigint, length bigint)

  Description: Returns the content of a text file.

  Return type: text

  Note: **pg_read_file** returns part of a text file. It can return a maximum of *length* bytes from *offset*. The actual size of fetched data is less than *length* if the end of the file is reached first. If *offset* is negative, it is the length rolled

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

back from the file end. If *offset* and *length* are omitted, the entire file is returned. Only the database initialization user can use this function.

Example:

```
openGauss=# SELECT pg_read_file('postmaster.pid',0,100);
            pg_read_file
---------------------------------------
 53078                                 +
 /srv/BigData/testdir/data1/coordinator+
 1500022474                            +
 8000                                  +
 /var/run/FusionInsight                +
 localhost                             +
  2
(1 row)
```

- pg_read_binary_file(filename text [, offset bigint, length bigint,missing_ok boolean])

  Description: Returns the contents of a binary file that can be called only by the initial user.

  Return type: bytea

  Note: **pg_read_binary_file** is similar to **pg_read_file**, except that the result is a **bytea** value; accordingly, no encoding checks are performed. In combination with the **convert_from** function, this function can be used to read a file in a specified encoding.

  ```
  openGauss=# SELECT convert_from(pg_read_binary_file('filename'), 'UTF8');
  ```

- pg_stat_file(filename text)

  Description: Returns status information about a file.

  Return type: record

  Note: **pg_stat_file** returns a record containing the file size, last access timestamp, last modification timestamp, last file status change timestamp, and a **Boolean** value indicating if it is a directory. Typical use cases are as follows:

  ```
  openGauss=# SELECT * FROM pg_stat_file('filename');
  openGauss=# SELECT (pg_stat_file('filename')).modification;
  ```

  Example:

  ```
  openGauss=# SELECT convert_from(pg_read_binary_file('postmaster.pid'), 'UTF8');
              convert_from
  ---------------------------------------
   4881                                 +
   /srv/BigData/gaussdb/data1/coordinator+
   1496308688                           +
   25108                                +
   /opt/huawei/Bigdata/gaussdb/gaussdb_tmp +
   *                                    +
    25108001  43352069                  +

  (1 row)
  openGauss=# SELECT * FROM pg_stat_file('postmaster.pid');

   size |         access         |      modification      |         change
  | creation | isdir
  ------+------------------------+------------------------+------------------------
  +----------+-------
    117 | 2017-06-05 11:06:34+08 | 2017-06-01 17:18:08+08 | 2017-06-01 17:18:08+08
  |          | f
  (1 row)
  openGauss=# SELECT (pg_stat_file('postmaster.pid')).modification;
       modification
  ------------------------
  ```

```
 2017-06-01 17:18:08+08
(1 row)
```

## 12.5.26.3 Server Signal Functions

Server signal functions send control signals to other server processes. Only the system administrator has the permission to execute the following functions:

- pg_cancel_backend(pid int)

  Description: Cancels the current query of a backend.

  Return type: Boolean

  Note: **pg_cancel_backend** sends a query cancellation (SIGINT) signal to the backend process identified by **pid**. The PID of an active backend process can be found in the **pid** column of the **pg_stat_activity** view, or can be found by listing the database process using **ps** on the server. A user with the **SYSADMIN** permission, the owner of the database connected to the backend process, the owner of the backend process, or a user who inherits the **gs_role_signal_backend** permission of the built-in role has the permission to use this function.

- pg_cancel_session(pid bigint, sessionid bigint)

  Description: Cancels a backend session.

  Return type: Boolean

  Note: The input parameters of **pg_cancel_session** can be queried using the **pid** and **sessionid** fields in **pg_stat_activity**. It can be used to clear inactive sessions in thread pool mode.

- pg_cancel_invalid_query()

  Description: Cancels the invalid query of a backend.

  Return type: Boolean

  Note: Only the system administrator has the permission to cancel queries that are running in the backend of a degraded GTM.

- pg_reload_conf()

  Description: Causes all server processes to reload their configuration files.

  Return type: Boolean

  Note: **pg_reload_conf** sends a SIGHUP signal to the server. As a result, all server processes reload their configuration files.

- pg_rotate_logfile()

  Description: Rotates the log files of the server.

  Return type: Boolean

  Note: **pg_rotate_logfile** sends a signal to the log file manager, instructing the manager to immediately switch to a new output file. This function works only when **redirect_stderr** is used for log output. Otherwise, no log file manager subprocess exists.

- pg_terminate_session(pid bigint, sessionid bigint)

  Description: Terminates a backend session.

  Return type: Boolean

  Note: The input parameters of this function can be queried using the **pid** and **sessionid** fields in **pg_stat_activity**. It can be used to clear inactive sessions in

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

thread pool mode. A user with the **SYSADMIN** permission, the owner of the database connected to the session, the owner of the session, or a user who inherits the **gs_role_signal_backend** permission of the built-in role has the permission to use this function.

- pg_terminate_backend(pid int)

  Description: Terminates a backend thread. Only the system administrator and thread owner can use this function.

  Return type: Boolean

  Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the **SYSADMIN** permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits the **gs_role_signal_backend** permission of the built-in role can use this function.

  Example:

```
openGauss=# SELECT pid from pg_stat_activity;
       pid
-----------------
 140657876268816
(1 rows)

openGauss=# SELECT pg_terminate_backend(140657876268816);
 pg_terminate_backend
----------------------
 t
(1 row)
```

## 12.5.26.4 Backup and Restoration Control Functions

## Backup Control Functions

Backup control functions help with online backup.

- pg_create_restore_point(name text)

  Description: Creates a named point for performing the restoration operation (restricted to the system administrator).

  Return type: text

  Note: **pg_create_restore_point** creates a named transaction log record that can be used as a restoration target, and returns the corresponding transaction log location. The given name can then be used with **recovery_target_name** to specify the point up to which restoration will proceed. Avoid creating multiple restoration points with the same name, since restoration will stop at the first one whose name matches the restoration target.

- pg_current_xlog_location()

  Description: Obtains the write position of the current transaction log.

  Return type: text

  Note: **pg_current_xlog_location** displays the write position of the current transaction log in the same format as those of the previous functions. Read-only operations do not require permissions of the system administrator.

- pg_current_xlog_insert_location()

  Description: Obtains the insert position of the current transaction log.

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Note: **pg_current_xlog_insert_location** displays the insert position of the current transaction log. The insertion point is the logical end of the transaction log at any instant, while the write location is the end of what has been written out from the server's internal buffers. The write position is the end that can be detected externally from the server. This operation can be performed to archive only some of completed transaction log files. The insert position is mainly used for commissioning the server. Read-only operations do not require permissions of the system administrator.

- gs_current_xlog_insert_end_location()

  Description: Obtains the insert position of the current transaction log.

  Return type: text

  Note: **gs_current_xlog_insert_end_location** displays the insert position of the current transaction log.

- pg_start_backup(label text, is_full_backup boolean)

  Description: Starts to perform online backup. (You need to enable **operate_mode** as an administrator, replication role, or O&M administrator.) Label strings starting with **gs_roach** are reserved and can be used only by the internal backup tool GaussRoach.

  Return type: text

  Note: **pg_start_backup** receives a user-defined backup label (usually the name of the position where the backup dump file is stored). This function writes a backup label file to the data directory of the database cluster and then returns the starting position of backed up transaction logs in text mode.

  ```
  openGauss=# SELECT pg_start_backup('label_goes_here',true);
   pg_start_backup
  -----------------
   0/3000020
  (1 row)
  ```

- pg_stop_backup()

  Description: Completes online backup You need to execute this function as the system administrator or a replication role.

  Return type: text

  Note: **pg_stop_backup** deletes the label file created by **pg_start_backup** and creates a backup history file in the transaction log archive area. The history file includes the label given to **pg_start_backup**, the start and end transaction log locations for the backup, and the start and end time of the backup. The return value is the backup's ending transaction log location. After the end position is calculated, the insert position of the current transaction log automatically goes ahead to the next transaction log file. In this way, the ended transaction log file can be immediately archived so that backup is complete.

- pg_switch_xlog()

  Description: Switches to a new transaction log file You need to enable **operation_mode** as the administrator or O&M administrator.

  Return type: text

  Note: **pg_switch_xlog** moves to the next transaction log file so that the current log file can be archived (if continuous archive is used). The return value is the ending transaction log location + 1 within the just-completed transaction log file. If there has been no transaction log activity since the last

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

transaction log switchover, **pg_switch_xlog** will do nothing but return the start location of the transaction log file currently in use.

- pg_xlogfile_name(location text)

  Description: Converts the position string in a transaction log to a file name.

  Return type: text

  Note: **pg_xlogfile_name** extracts only the transaction log file name. If the given transaction log position is the transaction log file border, a transaction log file name will be returned for both the two functions. This is usually the desired behavior for managing transaction log archiving, since the preceding file is the last one that currently needs to be archived.

- pg_xlogfile_name_offset(location text)

  Description: Converts the position string in a transaction log to a file name and returns the byte offset in the file.

  Return type: text, integer

  Note: **pg_xlogfile_name_offset** can extract transaction log file names and byte offsets from the returned results of the preceding functions. Example:

  ```
  openGauss=# SELECT * FROM pg_xlogfile_name_offset(pg_stop_backup());
  NOTICE:  pg_stop_backup cleanup done, waiting for required WAL segments to be archived
  NOTICE:  pg_stop_backup complete, all required WAL segments have been archived
         file_name         | file_offset
  --------------------------+-------------
  000000010000000000000003 |         272
  (1 row)
  ```

- pg_xlog_location_diff(location text, location text)

  Description: Calculates the difference in bytes between two transaction log locations.

  Return type: numeric

- pg_cbm_tracked_location()

  Description: Queries the LSN location parsed by CBM.

  Return type: text

- pg_cbm_get_merged_file(startLSNArg text, endLSNArg text)

  Description: Combines CBM files within the specified LSN range into one and returns the name of the combined file.

  Return type: text

  Note: Only the system administrator or O&M administrator can obtain the CBM combination file.

- pg_cbm_get_changed_block(startLSNArg text, endLSNArg text)

  Description: Combines CBM files within the specified LSN range into a table and return records of this table.

  Return type: record

  Note: The table columns include the start LSN, end LSN, tablespace OID, database OID, table relfilenode, table fork number, whether the table is deleted, whether the table is created, whether the table is truncated, number of pages in the truncated table, number of modified pages, and list of modified page numbers.

- pg_cbm_recycle_file(targetLSNArg text)

  Description: Deletes the CBM files that are no longer used and returns the first LSN after the deletion.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: text

- pg_cbm_force_track(targetLSNArg text,timeOut int)

  Description: Forcibly executes the CBM trace to the specified Xlog position and returns the Xlog position of the actual trace end point.

  Return type: text

- pg_enable_delay_ddl_recycle()

  Description: Enables DDL delay and returns the Xlog position of the enabling point. You need to enable **operation_mode** as the administrator or O&M administrator.

  Return type: text

- pg_disable_delay_ddl_recycle(barrierLSNArg text, isForce bool)

  Description: Disables DDL delay and returns the Xlog range where DDL delay takes effect. You need to enable **operation_mode** as the administrator or O&M administrator.

  Return type: record

- pg_enable_delay_xlog_recycle()

  Description: Enables the Xlog recycling delay function for CN recovery. You need to enable **operation_mode** as the administrator or O&M administrator.

  Return type: void

- pg_disable_delay_xlog_recycle()

  Description: Disables the Xlog recycling delay function for CN recovery. You need to enable **operation_mode** as the administrator or O&M administrator.

  Return type: void

- pg_cbm_rotate_file(rotate_lsn text)

  Description: Forcibly switches the file after the CBM parses **rotate_lsn**. This function is called during the build process.

  Return type: void

- gs_roach_stop_backup(backupid text)

  Description: Stops a backup started by the internal backup tool GaussRoach. It is similar to the **pg_stop_backup system** function but is more lightweight.

  Return type: text. The content is the insertion position of the current log.

- gs_roach_enable_delay_ddl_recycle(backupid name)

  Description: Enables DDL delay and returns the log location of the enabling point. It is similar to the **pg_enable_delay_ddl_recycle** system function but is more lightweight. In addition, different **backupid** values can be used to concurrently open DDL statements with delay.

  Return type: text. The content is the log location of the start point.

- gs_roach_disable_delay_ddl_recycle(backupid text)

  Description: Disables DDL delay, returns the range of logs on which DDL delay takes effect, and deletes the physical files of column-store tables that are deleted by users within this range. It is similar to the **pg_enable_delay_ddl_recycle** system function but is more lightweight. In addition, the DDL delay function can be disabled concurrently by specifying different backupid values.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: record. The content is the range of logs for which DDL is delayed to take effect.

- gs_roach_switch_xlog(request_ckpt bool)

  Description: Switches the currently used log segment file and triggers a full checkpoint if **request_ckpt** is **true**.

  Return type: text. The content is the location of the segment log.

- gs_block_dw_io(timeout int, identifier text)

  Description: Blocks dual-write page flushing.

  Parameter description:

  – timeout

    Block duration.

    Value range: [0,3600] (s). The value **0** indicates that the block duration is 0s.

  – identifier

    ID of the operation.

    Value range: a string, supporting only uppercase letters, lowercase letters, digits, and underscores (_).

  Return type: Boolean

  Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission, and **operate_mode** must be enabled for the O&M administrator role.

- gs_is_dw_io_blocked()

  Description: Checks whether disk flushing on the current dual-write page is blocked. If disk flushing is blocked, **true** is returned.

  Return type: Boolean

  Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission, and **operate_mode** must be enabled for the O&M administrator role.

## Restoration Control Functions

Restoration control functions provide information about the status of standby nodes. These functions may be executed both during restoration and in normal running.

- pg_is_in_recovery()

  Description: Returns **true** if restoration is still in progress.

  Return type: Boolean

- pg_last_xlog_receive_location()

  Description: Obtains the last transaction log location received and synchronized to disk by streaming replication. While streaming replication is in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received and synchronized to disk during restoration. If streaming replication is disabled or if it has not yet started, the function returns a null value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: text

- pg_last_xlog_replay_location()

  Description: Obtains last transaction log location replayed during restoration. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. When the server has been started normally without restoration, the function returns a null value.

  Return type: text

- pg_last_xact_replay_timestamp()

  Description: Obtains the timestamp of last transaction replayed during restoration. This is the time to commit a transaction or abort a WAL record on the primary node. If no transactions have been replayed during restoration, this function will return a null value. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. If the server normally starts without manual intervention, this function will return a null value.

  Return type: timestamp with time zone

Restoration control functions control restoration processes. These functions may be executed only during restoration.

- pg_is_xlog_replay_paused()

  Description: Returns **true** if restoration is paused.

  Return type: Boolean

- pg_xlog_replay_pause()

  Description: Pauses restoration immediately.

  Return type: void

- pg_xlog_replay_resume()

  Description: Restarts restoration if it was paused.

  Return type: void

- gs_get_active_archiving_standby()

  Description: Queries information about archive standby nodes in the same shard. The standby node name, archive location, and number of archived logs are returned.

  Return type: text, text, int

- gs_pitr_get_warning_for_xlog_force_recycle()

  Description: Checks whether logs are recycled because a large number of logs are stacked in the archive slot after archiving is enabled.

  Return type: Boolean

- gs_pitr_clean_history_global_barriers(stop_barrier_timestamp cstring)

  Description: Clears all barrier records generated before the specified time. The earliest barrier record is returned. The input parameter is of the cstring type and is a Linux timestamp. You need to perform this operation as the administrator or O&M administrator.

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- gs_pitr_archive_slot_force_advance(stop_barrier_timestamp cstring)

  Description: Forcibly pushes the archive slot and clears unnecessary barrier records. The new archive slot location is returned. The input parameter is of the cstring type and is a Linux timestamp. You need to perform this operation as the administrator or O&M administrator.

  Return type: text

While restoration is paused, no further database changes are applied. In hot standby mode, all new queries will see the same consistent snapshot of the database, and no further query conflicts will be generated until restoration is resumed.

If streaming replication is disabled, the paused state may continue indefinitely without problem. While streaming replication is in progress, WAL records will continue to be received, which will eventually fill available disk space. This progress depends on the duration of the pause, the rate of WAL generation, and available disk space.

## 12.5.26.5 Dual-Cluster DR Control Functions

Dual-cluster DR control functions can be used to create an archive slot, which specifies the OBS information for storing physical logs.

- pg_create_physical_replication_slot_extern(slotname text, dummy_standby bool, extra_content text, need_recycle_xlog bool)

  Description: Creates an OBS or a NAS archive slot. **slotname** indicates the slot name of the DR standby. The primary and standby nodes must use the same slot name. **dummy_standby** specifies whether the database is deployed in primary/standby/secondary mode or one-primary and multi-standby mode. The value **false** indicates that the database is deployed in one-primary and multi-standby mode, and the value **true** indicates that the database is deployed in primary/standby/secondary mode. **extra_content** contains some information about the archive slot. For an OBS archive slot, the format is **OBS;obs_server_ip;obs_bucket_name;obs_ak;obs_sk;archive_path;is_recovery;is_vote_replicate**, where **OBS** indicates the archive media of the archive slot, **obs_server_ip** indicates the IP address of OBS, **obs_bucket_name** indicates the bucket name, **obs_ak** indicates the AK of OBS, **obs_sk** indicates the SK of OBS, **archive_path** indicates the archive path **i**, and **is_recovery** indicates whether the slot is an archive slot or a recovery slot. The value **0** indicates that the slot is an archive slot and is used by the primary database instance. The value **1** indicates that the slot is a recovery slot and is used by the DR database instance. **is_vote_replicate** indicates whether the voting copy is archived first. The value **0** indicates that the synchronous standby server is archived first, and the value **1** indicates that the voting copy is archived first. This field is reserved in the current version and is not adapted yet. For a NAS archive slot, the format is **NAS;archive_path;is_recovery;is_vote_replicate**. Compared with the OBS archive slot, the NAS archive slot does not have the OBS configuration information, while the meanings of other fields are the same.

  If the media is not specified, the OBS archive slot is used by default. The **extra_content** format is **obs_server_ip;obs_bucket_name;obs_ak;obs_sk;archive_path;is_recovery;is_vote_replicate**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**need_recycle_xlog** specifies whether to recycle old archived logs when creating an archive slot. The value **true** indicates that old archived logs are recycled, and the value **false** indicates that old archive logs are not recycled.

Return type: records, including **slotname** and **xlog_position** of the current DR standby.

Note: Users who invoke this function must have the **SYSADMIN** permission or the **REPLICATION** permission, or inherit the **gs_role_replication** permission of the built-in role.

Example:

Create an OBS archive slot.

```
openGauss=# select * from pg_create_physical_replication_slot_extern('uuid', false, 'OBS;obs.cn-north-7.ulanqab.huawei.com;dyk;19D772JBCACXX3KWS51D;********;openGauss_uuid/dn1;0;0', false);
 slotname | xlog_position
----------+---------------
 uuid     |
(1 row)
```

Create a NAS archive slot.

```
openGauss=# select * from pg_create_physical_replication_slot_extern('uuid', false, 'NAS;/data/nas/media/openGauss_uuid/dn1;0;0', false);
 slotname | xlog_position
----------+---------------
 uuid     |
```

- gs_set_obs_delete_location(delete_location text)

  Description: Sets the location where OBS archive logs can be deleted. The value of **delete_location** is a LSN. The logs before this location have been replayed and flushed to disks in the DR cluster and can be deleted on OBS.

  Return type: xlog_file_name text, indicating the file name of the logs that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

  ```
  openGauss=# select gs_set_obs_delete_location('0/54000000');
   gs_set_obs_delete_location
  ----------------------------
   000000010000000000000054_00
  (1 row)
  ```

- gs_hadr_do_switchover()

  Description: Triggers a planned switchover in the primary cluster in the geo-redundancy scenario.

  Return type: Boolean, indicating whether the switchover process is performed normally and whether services are taken over successfully.

- gs_set_obs_delete_location_with_slotname(cstring, cstring )

  Description: Sets the location where OBS archive logs can be deleted in a DR relationship. The first parameter indicates the LSN. The logs before this location have been replayed and flushed to disks in the DR database instance and can be deleted on OBS. The second parameter indicates the name of the archive slot.

  Return type: xlog_file_name text, indicating the file name of the logs that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

- gs_streaming_dr_in_switchover()

  Description: Triggers a planned switchover in the primary cluster in remote DR solutions based on streaming replication.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: Boolean, indicating whether the switchover process is performed normally and whether services are taken over successfully.

## 12.5.26.6 Dual-Cluster DR Query Functions

- gs_get_global_barrier_status()

  Description: If two-city 3DC DR is enabled, the primary cluster and DR cluster synchronize logs through OBS. The barrier log is flushed to disks in the primary cluster, and replayed in the DR cluster to determine the archive log progress of the primary cluster and the log replay progress of the DR cluster. **gs_get_global_barrier_status** is used to query the latest global barrier archived in OBS by the primary cluster.

  Return type: text

  global_barrier_id: indicates the globally latest barrier ID.

  global_achive_barrier_id: indicates the globally latest archived barrier ID.

- gs_get_local_barrier_status()

  Description: If two-city 3DC DR is enabled, the primary cluster and DR cluster synchronize logs through OBS. The barrier log is flushed to disks in the primary cluster, and replayed in the DR cluster to determine the archive log progress of the primary cluster and the log replay progress of the DR cluster. **gs_get_local_barrier_status** is used to query the current log replay status of each node in the DR cluster.

  Return type: text

  **barrier_id**: latest barrier ID of a node in the DR cluster.

  **barrier_lsn**: LSN of the latest barrier ID returned by a node in the DR cluster.

  **archive_lsn**: location of archived logs obtained by a node in the DR cluster. This parameter does not take effect currently.

  **flush_lsn**: location of logs that have been flushed to disks on a node in the DR cluster.

- gs_get_global_barriers_status()

  Description: If two-city 3DC DR solutions based on OBS are enabled, logs of the primary database instance and multiple DR database instances are synchronized through OBS. The barrier logs are flushed to the disk of the primary database instance. The progress of archiving logs of the primary database instance and the progress of replaying logs of the DR database instances are determined by replaying the DR database instances. **gs_get_global_barriers_status** is used to query the latest global barrier that has been archived in OBS for the primary database instance.

  Return type: text

  **slot_name**: name of the slot used for DR.

  **global_barrier_id**: globally latest barrier ID.

  **global_achive_barrier_id**: globally latest archived barrier ID.

- gs_upload_obs_file('slot_name', 'src_file', 'dest_file')

  Description: Function used by the primary cluster to upload data to OBS if two-city 3DC DR is enabled.

  Return type: void

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**slot_name**: name of the replication slot created by the CN in the primary cluster.

**src_file**: location of files to be uploaded in the CN data directory of the primary cluster.

**dest_file**: location of files uploaded to OBS.

- gs_download_obs_file('slot_name', 'src_file', 'dest_file')

  Description: Function used by the DR cluster to download data from OBS to the local host if two-city 3DC DR is enabled.

  Return type: void

  **slot_name**: name of the replication slot created by the CN in the DR cluster.

  **src_file**: location of files to be downloaded from OBS.

  **dest_file**: location of downloaded files in the CN data directory of the DR cluster.

- gs_get_obs_file_context('file_name', 'slot_name')

  Description: Queries file content on OBS if two-city 3DC DR is enabled.

  Return type: text

  **file_name**: name of the file on OBS.

  **slot_name**: name of the replication slot created by the CN in the primary or DR cluster.

- gs_set_obs_file_context('file_name', 'file_context','slot_name')

  Description: Creates a file on OBS and writes content into the file if two-city 3DC DR is enabled.

  Return type: text

  **file_name**: name of the file on OBS.

  **file_context**: content to be written into the file.

  **slot_name**: name of the replication slot created by the CN in the primary or DR cluster.

- gs_get_hadr_key_cn()

  Description: Creates a file on OBS and writes content into the file if two-city 3DC DR is enabled.

  Return type: text

  **file_name**: name of the file on OBS.

  **file_context**: content to be written into the file.

  **slot_name**: name of the replication slot created by the CN in the primary or DR cluster.

- gs_hadr_has_barrier_creator()

  Description: Checks whether the **barrier_creator** thread exists on the current CN if two-city 3DC DR is enabled. If yes, **true** is returned (restricted to the system administrator).

  Return type: Boolean

  Note: This function is used only when a planned switchover is performed in the DR cluster.

- gs_hadr_in_recovery()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Checks whether the current node is in barrier-based log restoration if two-city 3DC DR is enabled. If yes, **true** is returned. Only after the log restoration is complete, can the DR cluster be promoted to the production cluster during the switchover process. This operation must be performed by the system administrator.

Return type: Boolean

NOTE

This function is used only when a planned switchover is performed in the DR cluster.

- gs_streaming_dr_get_switchover_barrier()

  Description: Checks whether the CN and first standby DN in the DR cluster have received the switchover barrier logs and replayed the logs in the streaming replication-based two-city 3DC DR solution. If it has, **true** is returned. In the DR cluster, the procedure for promoting the DR database instance to the production database instance in the switchover process can be started only after the switchover barrier logs of all DNs are replayed (restricted to the system administrator).

  Return type: Boolean

  Note: This function is used only when a planned switchover is performed in the DR database instance in streaming DR solutions.

- gs_streaming_dr_service_truncation_check()

  Description: Checks whether the CN and primary DN in the primary cluster has sent the switchover barrier logs in the streaming replication-based two-city 3DC DR solution. If it has, **true** is returned. The procedure for demoting the production database instance to the DR database instance in the switchover process can be started only after the logs are sent (restricted to the system administrator).

  Return type: Boolean

  Note: This function is used only when a planned switchover is performed in the DR database instance.

- gs_hadr_local_rto_and_rpo_stat()

  Description: Displays the log flow control information of the local database instance and DR database instance for streaming DR. (If this command is executed on a node that does not participate in streaming DR, for example, a standby DN or a CN, no information may be returned.)

  The return value type is record. The types and meanings of the fields are as follows:

| Parameter | Type | Description |
| --- | --- | --- |
| hadr_sender_node_name | text | Node name, including the primary database instance and the first standby node of the standby database instance. |
| hadr_receiver_node_name | text | Name of the first standby node of the standby database instance. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description |
| --- | --- | --- |
| source_ip | text | IP address of the primary DN of the primary database instance. |
| source_port | int | Communication port of the primary DN of the primary database instance. |
| dest_ip | text | IP address of the first standby DN of the standby database instance. |
| dest_port | int | Communication port of the first standby DN of the standby database instance. |
| current_rto | int | Flow control information, that is, log RTO time of the current primary and standby database instances (unit: second). |
| target_rto | int | Flow control information, that is, RTO time between the target primary and standby database instances (unit: second). |
| current_rpo | int | Flow control information, that is, log RPO time of the current primary and standby database instances (unit: second). |
| target_rpo | int | Flow control information, that is, RPO time between the target primary and standby database instances (unit: second). |
| rto_sleep_time | int | RTO flow control information, that is, expected sleep time (unit: μs) required by walsender on the host to reach the specified RTO. |
| rpo_sleep_time | int | RPO flow control information, that is, the expected sleep time (unit: μs) required by xlogInsert on the host to reach the specified RPO. |

- gs_hadr_remote_rto_and_rpo_stat()

  Description: Displays the log flow control information of all other shards or CN database instances and DR database instances for streaming DR. (Generally, this command is executed on CNs. If this command is executed on DNs, no information may be returned.)

  The return value type is record. The types and meanings of the fields are as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description |
| --- | --- | --- |
| hadr_sender_node_name | text | Node name, including the primary database instance and the first standby node of the standby database instance. |
| hadr_receiver_node_name | text | Name of the first standby node of the standby database instance. |
| source_ip | text | IP address of the primary DN of the primary database instance. |
| source_port | int | Communication port of the primary DN of the primary database instance. |
| dest_ip | text | IP address of the first standby DN of the standby database instance. |
| dest_port | int | Communication port of the first standby DN of the standby database instance. |
| current_rto | int | Flow control information, that is, log RTO time of the current primary and standby database instances (unit: second). |
| target_rto | int | Flow control information, that is, RTO time between the target primary and standby database instances (unit: second). |
| current_rpo | int | Flow control information, that is, log RPO time of the current primary and standby database instances (unit: second). |
| target_rpo | int | Flow control information, that is, RPO time between the target primary and standby database instances (unit: second). |
| rto_sleep_time | int | RTO flow control information, that is, expected sleep time (unit: μs) required by walsender on the host to reach the specified RTO. |
| rpo_sleep_time | int | RPO flow control information, that is, the expected sleep time (unit: μs) required by xlogInsert on the host to reach the specified RPO. |

## 12.5.26.7 Snapshot Synchronization Functions

Snapshot synchronization functions save the current snapshot and return its identifier.

- pg_export_snapshot()
  Description: Saves the current snapshot and returns its identifier.
  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Note: **pg_export_snapshot** saves the current snapshot and returns a text string identifying the snapshot. This string must be passed to clients that want to import the snapshot. A snapshot can be imported when the **set transaction snapshot snapshot_id;** command is executed. Doing so is possible only when the transaction is set to the **SERIALIZABLE** or **REPEATABLE READ** isolation level. GaussDB does not support these two isolation levels currently. The output of the function cannot be used as the input of **set transaction snapshot**.

- pg_export_snapshot_and_csn()

  Description: Saves the current snapshot and returns its identifier. Compared with **pg_export_snapshot()**, **pg_export_snapshot()** returns a CSN, indicating the CSN of the current snapshot.

  Return type: text

## 12.5.26.8 Database Object Functions

## Database Object Size Functions

Database object size functions calculate the actual disk space used by database objects.

- pg_column_size(any)

  Description: Specifies the number of bytes used to store a particular value (possibly compressed)

  Return type: int

  Note: **pg_column_size** displays the space for storing an independent data value.

  ```
  openGauss=# SELECT pg_column_size(1);
   pg_column_size
  ----------------
               4
  (1 row)
  ```

- pg_database_size(oid)

  Description: Specifies the disk space used by the database with the specified OID.

  Return type: bigint

- pg_database_size(name)

  Description: Specifies the disk space used by the database with the specified name.

  Return type: bigint

  Note: **pg_database_size** receives the OID or name of a database and returns the disk space used by the corresponding object.

  Example:

  ```
  openGauss=# SELECT pg_database_size('postgres');
   pg_database_size
  ------------------
          51590112
  (1 row)
  ```

- pg_relation_size(oid)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Specifies the disk space used by the table with a specified OID or index.

Return type: bigint

- get_db_source_datasize()

  Description: Estimates the total size of non-compressed data in the current database.

  Return type: bigint

  Remarks: (1) Perform an analysis before this function is called. (2) Calculate the total data capacity in the non-compressed state by estimating the compression rate of the column-store tables.

  Example:

```
openGauss=# analyze;
ANALYZE
openGauss=# select get_db_source_datasize();
 get_db_source_datasize
------------------------
            35384925667
(1 row)
```

- pg_relation_size(text)

  Description: Specifies the disk space used by the table with a specified name or index. The table name can be schema-qualified.

  Return type: bigint

- pg_relation_size(relation regclass, fork text)

  Description: Specifies the disk space used by the specified bifurcating tree ('main', 'fsm', or 'vm') of a certain table or index.

  Return type: bigint

- pg_relation_size(relation regclass)

  Description: Is an abbreviation of **pg_relation_size(..., 'main')**.

  Return type: bigint

  Note: **pg_relation_size** receives the OID or name of a table, an index, or a compressed table, and returns the size.

- pg_partition_size(oid,oid)

  Description: Specifies the disk space used by the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.

  Return type: bigint

- pg_partition_size(text, text)

  Description: Specifies the disk space used by the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.

  Return type: bigint

- pg_partition_indexes_size(oid,oid)

  Description: Specifies the disk space used by the index of the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.

  Return type: bigint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_partition_indexes_size(text,text)

  Description: Specifies the disk space used by the index of the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.

  Return type: bigint

- pg_indexes_size(regclass)

  Description: Specifies the total disk space used by the index appended to the specified table.

  Return type: bigint

- pg_size_pretty(bigint)

  Description: Converts a size in bytes expressed as a 64-bit integer into a human-readable format with size units.

  Return type: text

- pg_size_pretty(numeric)

  Description: Converts a size in bytes expressed as a numeric value into a human-readable format with size units.

  Return type: text

  Note: **pg_size_pretty** formats the results of other functions into a human-readable format. KB, MB, GB, and TB can be used.

- pg_table_size(regclass)

  Description: Specifies the disk space used by the specified table, excluding indexes (but including TOAST, free space mapping, and visibility mapping).

  Return type: bigint

- pg_tablespace_size(oid)

  Description: Specifies the disk space used by the tablespace with a specified OID.

  Return type: bigint

- pg_tablespace_size(name)

  Description: Specifies the disk space used by the tablespace with a specified name.

  Return type: bigint

  Note:

  **pg_tablespace_size** receives the OID or name of a database and returns the disk space used by the corresponding object.

- pg_total_relation_size(oid)

  Description: Specifies the disk space used by the table with a specified OID, including the index and the compressed data.

  Return type: bigint

- pg_total_relation_size(regclass)

  Description: Specifies the total disk space used by the specified table, including all indexes and TOAST data.

  Return type: bigint

- pg_total_relation_size(text)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Specifies the disk space used by the table with a specified name, including the index and the compressed data. The table name can be schema-qualified.

Return type: bigint

Note: **pg_total_relation_size** receives the OID or name of a table or a compressed table, and returns the sizes of the data, related indexes, and the compressed table in bytes.

- datalength(any)

  Description: Specifies the number of bytes used by an expression of a specified data type (data management space, data compression, or data type conversion is not considered).

  Return type: int

  Note: **datalength** is used to calculate the space of an independent data value.

  Example:

```
openGauss=# SELECT datalength(1);
datalength
------------
4
(1 row)
```

The following table lists the supported data types and calculation methods.

| Data Type | | | Storage Space |
| --- | --- | --- | --- |
| Numeric data types | Integer types | TINYINT | 1 |
| | | SMALLINT | 2 |
| | | INTEGER | 4 |
| | | BINARY_INTEGER | 4 |
| | | BIGINT | 8 |
| | Arbitrary precision types | DECIMAL | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
| | | NUMERIC | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
| | | NUMBER | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| | | | |
|---|---|---|---|
| | Sequence integer | SMALLSERIAL | 2 |
| | | SERIAL | 4 |
| | | BIGSERIAL | 8 |
| | Floating point types | FLOAT4 | 4 |
| | | DOUBLE PRECISION | 8 |
| | | FLOAT8 | 8 |
| | | BINARY_DOUBLE | 8 |
| | | FLOAT[(p)] | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
| | | DEC[(p[,s])] | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
| | | INTEGER[(p[,s])] | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
| Boolean data types | Boolean type | BOOLEAN | 1 |
| Character data types | Character types | CHAR | n |
| | | CHAR(n) | n |
| | | CHARACTER(n) | n |
| | | NCHAR(n) | n |
| | | VARCHAR(n) | n |
| | | CHARACTER | Actual number of bytes of a character |
| | | VARYING(n) | Actual number of bytes of a character |
| | | VARCHAR2(n) | Actual number of bytes of a character |
| | | NVARCHAR2(n) | Actual number of bytes of a character |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| | | | |
|---|---|---|---|
| | | TEXT | Actual number of bytes of a character |
| | | CLOB | Actual number of bytes of a character |
| Time data types | Time types | DATE | 8 |
| | | TIME | 8 |
| | | TIMEZ | 12 |
| | | TIMESTAMP | 8 |
| | | TIMESTAMPZ | 8 |
| | | SMALLDATETIME | 8 |
| | | INTERVAL DAY TO SECOND | 16 |
| | | INTERVAL | 16 |
| | | RELTIME | 4 |
| | | ABSTIME | 4 |
| | | TINTERVAL | 12 |

## Database Object Position Functions

- pg_relation_filenode(relation regclass)

  Description: Specifies the ID of a filenode with the specified relationship.

  Return type: oid

  Description: **pg_relation_filenode** receives the OID or name of a table, index, sequence, or compressed table, and returns the **filenode** number allocated to it. **filenode** is the basic component of the file name used by the relationship. For most tables, the result is the same as that of **pg_class.relfilenode**. For the specified system directory, **relfilenode** is **0** and this function must be used to obtain the correct value. If a relationship that is not stored is transmitted, such as a view, this function returns a null value.

- pg_relation_filepath(relation regclass)

  Description: Specifies the name of a file path with the specified relationship.

  Return type: text

  Description: **pg_relation_filepath** is similar to **pg_relation_filenode**, except that **pg_relation_filepath** returns the whole file path name for the relationship (relative to the data directory **PGDATA** of the database cluster).

- get_large_table_name(relfile_node text, threshold_size_gb int8)

  Description: Queries whether the table size (in GB) exceeds the threshold (**threshold_size_gb**) based on the table file code (**relfile_node**). If yes, the schema name and table name (in schemaname.tablename format) are returned, otherwise, null is returned.

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_filenode_relation(tablespacename, relname)

  Description: Obtains the table names corresponding to the tablespace and relfilenode.

  Return type: regclass

- pg_partition_filenode(partition_oid)

  Description: Obtains **filenode** corresponding to the OID lock of a specified partitioned table.

  Return type: oid

- pg_partition_filepath(partition_oid)

  Description: Specifies the file path name of a partition.

  Return type: text

## Recycle Bin Object Functions

- gs_is_recycle_object(classid, objid, objname)

  Description: Determines whether an object is in the recycle bin. This function is not supported in distributed mode.

  Return type: Boolean

## 12.5.26.9 Advisory Lock Functions

Advisory lock functions manage advisory locks.

- pg_advisory_lock(key bigint)

  Description: Obtains an exclusive session-level advisory lock.

  Return type: void

  Note: **pg_advisory_lock** locks resources defined by an application. The resources can be identified using a 64-bit or two nonoverlapped 32-bit key values. If another session locks the resources, the function blocks the resources until they can be used. The lock is exclusive. Multiple locking requests are pushed into the stack. Therefore, if the same resource is locked three times, it must be unlocked three times so that it is released to another session.

- pg_advisory_lock(key1 int, key2 int)

  Description: Obtains an exclusive session-level advisory lock.

  Return type: void

  Note: Only users with the **sysadmin** permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).

- pg_advisory_lock(int4, int4, Name)

  Description: Obtains the exclusive advisory lock of a specified database.

  Return type: void

- pg_advisory_lock_shared(key bigint)

  Description: Obtains a shared session-level advisory lock.

  Return type: void

- pg_advisory_lock_shared(key1 int, key2 int)

  Description: Obtains a shared session-level advisory lock.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: void

Note: **pg_advisory_lock_shared** works in the same way as **pg_advisory_lock**, except the lock can be shared with other sessions requesting shared locks. Only would-be exclusive lockers are locked out.

- pg_advisory_unlock(key bigint)

  Description: Releases an exclusive session-level advisory lock.

  Return type: Boolean

- pg_advisory_unlock(key1 int, key2 int)

  Description: Releases an exclusive session-level advisory lock.

  Return type: Boolean

  Note: **pg_advisory_unlock** releases the obtained exclusive advisory lock. If the release is successful, the function returns **true**. If the lock was not held, it will return **false**. In addition, a SQL warning will be reported by the server.

- pg_advisory_unlock(int4, int4, Name)

  Description: Releases the exclusive advisory lock of a specified database.

  Return type: Boolean

  Note: If the release is successful, **true** is returned. If no lock is held, **false** is returned.

- pg_advisory_unlock_shared(key bigint)

  Description: Releases a shared session-level advisory lock.

  Return type: Boolean

- pg_advisory_unlock_shared(key1 int, key2 int)

  Description: Releases a shared session-level advisory lock.

  Return type: Boolean

  Note: **pg_advisory_unlock_shared** works in the same way as **pg_advisory_unlock**, except it releases a shared session-level advisory lock.

- pg_advisory_unlock_all()

  Description: Releases all advisory locks owned by the current session.

  Return type: void

  Note: **pg_advisory_unlock_all** releases all advisory locks owned by the current session. The function is implicitly invoked when the session ends even if the client is abnormally disconnected.

- pg_advisory_xact_lock(key bigint)

  Description: Obtains an exclusive transaction-level advisory lock.

  Return type: void

- pg_advisory_xact_lock(key1 int, key2 int)

  Description: Obtains an exclusive transaction-level advisory lock.

  Return type: void

  Note: **pg_advisory_xact_lock** works in the same way as **pg_advisory_lock**, except the lock is automatically released at the end of the current transaction and cannot be released explicitly. Only users with the **sysadmin** permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_advisory_xact_lock_shared(key bigint)

  Description: Obtains a shared transaction-level advisory lock.

  Return type: void

- pg_advisory_xact_lock_shared(key1 int, key2 int)

  Description: Obtains a shared transaction-level advisory lock.

  Return type: void

  Note: **pg_advisory_xact_lock_shared** works in the same way as **pg_advisory_lock_shared**, except the lock is automatically released at the end of the current transaction and cannot be released explicitly.

- pg_try_advisory_lock(key bigint)

  Description: Obtains an exclusive session-level advisory lock if available.

  Return type: Boolean

  Note: **pg_try_advisory_lock** is similar to **pg_advisory_lock**, except **pg_try_advisory_lock** does not block the resource until the resource is released. **pg_try_advisory_lock** either immediately obtains the lock and returns **true** or returns **false**, which indicates the lock cannot be performed currently.

- pg_try_advisory_lock(key1 int, key2 int)

  Description: Obtains an exclusive session-level advisory lock if available.

  Return type: Boolean

  Note: Only users with the **sysadmin** permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).

- pg_try_advisory_lock_shared(key bigint)

  Description: Obtains a shared session-level advisory lock if available.

  Return type: Boolean

- pg_try_advisory_lock_shared(key1 int, key2 int)

  Description: Obtains a shared session-level advisory lock if available.

  Return type: Boolean

  Note: **pg_try_advisory_lock_shared** is similar to **pg_try_advisory_lock**, except **pg_try_advisory_lock_shared** attempts to obtain a shared lock instead of an exclusive lock.

- pg_try_advisory_xact_lock(key bigint)

  Description: Obtains an exclusive transaction-level advisory lock if available.

  Return type: Boolean

- pg_try_advisory_xact_lock(key1 int, key2 int)

  Description: Obtains an exclusive transaction-level advisory lock if available.

  Return type: Boolean

  Note: **pg_try_advisory_xact_lock** works in the same way as **pg_try_advisory_lock**, except the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly. Note: Only users with the **sysadmin** permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).

- pg_try_advisory_xact_lock_shared(key bigint)

  Description: Obtains a shared transaction-level advisory lock if available.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: Boolean

- pg_try_advisory_xact_lock_shared(key1 int, key2 int)

  Description: Obtains a shared transaction-level advisory lock if available.

  Return type: Boolean

  Note: **pg_try_advisory_xact_lock_shared** works in the same way as **pg_try_advisory_lock_shared**, except the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly.

- lock_cluster_ddl()

  Description: Attempts to obtain a session-level exclusive advisory lock for all active CNs in the cluster.

  Return type: Boolean

  Note: Only users with the **sysadmin** permission can call this function.

- unlock_cluster_ddl()

  Description: Attempts to add a session-level exclusive advisory lock on a CN.

  Return type: Boolean

## 12.5.26.10 Logical Replication Functions

- pg_create_logical_replication_slot('slot_name', 'plugin_name')

  Description: Creates a logical replication slot.

  Parameter description:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One period or two periods cannot be used as the replication slot name.

  – plugin_name

    Indicates the name of the plugin.

    Value range: a string, supporting only **mppdb_decoding**

  Return type: name, text

  Note: The first return value is the slot name, and the second one is the start LSN for decoding in the logical replication slot. Users who call this function must have the **SYSADMIN** permission or the **REPLICATION** permission, or inherit the **gs_role_replication** permission of the built-in role.

- pg_create_physical_replication_slot('slot_name', 'isDummyStandby')

  Description: Creates a physical replication slot.

  Parameter description:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One period or two periods cannot be used as the replication slot name.

  – isDummyStandby

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Specifies whether the replication slot is created by connecting the standby node to the primary node.

Type: Boolean

Return type: name, text

Note: Users who call this function must have the **SYSADMIN** permission or the **REPLICATION** permission, or inherit the **gs_role_replication** permission of the built-in role.

- pg_drop_replication_slot('slot_name')

  Description: Deletes a streaming replication slot.

  Parameter description:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One period or two periods cannot be used as the replication slot name.

  Return type: void

  Note: Users who call this function must have the **SYSADMIN** permission or the **REPLICATION** permission, or inherit the **gs_role_replication** permission of the built-in role.

- pg_logical_slot_peek_changes('slot_name', 'LSN', upto_nchanges, 'options_name', 'options_value')

  Description: Performs decoding but does not go to the next streaming replication slot. (The decoding result will be returned again during the next decoding.)

  Parameter description:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One period or two periods cannot be used as the replication slot name.

  – LSN

    Indicates a target LSN. Decoding is performed only when an LSN is less than or equal to this value.

    Value range: a string, in the format of *xlogid*/*xrecoff*, for example, 1/2AAFC60 (If this parameter is set to a null value, the target LSN indicating the end position of decoding is not specified.)

  – upto_nchanges

    Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto_nchanges** after decoding in the first two transactions is complete.

    Value range: a non-negative integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

If any of the **LSN** and **upto_nchanges** values are reached, decoding ends.

- **options**: Specifies optional parameters, consisting of **options_name** and **options_value**.
  - include-xids

    Specifies whether the decoded **data** column contains XID information.

    Valid value: **0** and **1**. The default value is **1**.
    - **0**: The decoded **data** column does not contain XID information.
    - **1**: The decoded **data** column contains XID information.
  - skip-empty-xacts

    Specifies whether to ignore empty transaction information during decoding.

    Valid value: **0** and **1**. The default value is **0**.
    - **0**: The empty transaction information is not ignored during decoding.
    - **1**: The empty transaction information is ignored during decoding.
  - include-timestamp

    Specifies whether decoded information contains the **commit** timestamp.

    Valid value: **0** and **1**. The default value is **0**.
    - **0**: The decoded information does not contain the **commit** timestamp.
    - **1**: The decoded information contains the **commit** timestamp.
  - only-local

    Specifies whether to decode only local logs.

    Valid value: **0** and **1**. The default value is **1**.
    - **0**: Non-local logs and local logs are decoded.
    - **1**: Only local logs are decoded.
  - force-binary

    Specifies whether to output the decoding result in binary format.

    Value range: **0**
    - **0**: The decoding result is output in text format.
  - white-table-list

    Whitelist parameter, including the schema and table name to be decoded.

    Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed. Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**select * from pg_logical_slot_peek_changes('slot1', NULL, 4096, 'white-table-list', 'public.t1,public.t2');**

- max-txn-in-memory

  Memory control parameter. The unit is MB. If the memory occupied by a single transaction is greater than the value of this parameter, data is flushed to disks.

  Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.

- max-reorderbuffer-in-memory

  Memory control parameter. The unit is GB. If the total memory (including the cache) of transactions being concatenated in the sender thread is greater than the value of this parameter, the current decoding transaction is flushed to disks.

  Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.

Return type: text, xid, text

Note: The function returns the decoding results. Each decoding result contains three columns, corresponding to the above return types and indicating the LSN, XID, and decoded content, respectively. Users who call this function must have the **SYSADMIN** permission or the **REPLICATION** permission, or inherit the **gs_role_replication** permission of the built-in role.

- pg_logical_slot_get_changes('slot_name', 'LSN', upto_nchanges, 'options_name', 'options_value')

  Description: Performs decoding and goes to the next streaming replication slot.

  Parameter: This function has the same parameters as **pg_logical_slot_peek_changes**. For details, see **•pg_logical_slot_peek_ch...**.

  Note: Users who call this function must have the **SYSADMIN** permission or the **REPLICATION** permission, or inherit the **gs_role_replication** permission of the built-in role.

- pg_logical_slot_peek_binary_changes('slot_name', 'LSN', upto_nchanges, 'options_name', 'options_value')

  Description: Performs decoding in binary mode and does not go to the next streaming replication slot. (The decoded data can be obtained again during the next decoding.)

  Parameter description:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One period or two periods cannot be used as the replication slot name.

  – LSN

    Indicates a target LSN. Decoding is performed only when an LSN is less than or equal to this value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Value range: a string, in the format of *xlogid*/*xrecoff*, for example, 1/2AAFC60 (If this parameter is set to a null value, the target LSN indicating the end position of decoding is not specified.)

– upto_nchanges

Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto_nchanges** after decoding in the first two transactions is complete.

Value range: a non-negative integer

NOTE

If any of the **LSN** and **upto_nchanges** values are reached, decoding ends.

– **options**: Specifies optional parameters, consisting of **options_name** and **options_value**.

- include-xids

  Specifies whether the decoded **data** column contains XID information.

  Valid value: **0** and **1**. The default value is **1**.

  - **0**: The decoded **data** column does not contain XID information.
  - **1**: The decoded **data** column contains XID information.

- skip-empty-xacts

  Specifies whether to ignore empty transaction information during decoding.

  Valid value: **0** and **1**. The default value is **0**.

  - **0**: The empty transaction information is not ignored during decoding.
  - **1**: The empty transaction information is ignored during decoding.

- include-timestamp

  Specifies whether decoded information contains the **commit** timestamp.

  Valid value: **0** and **1**. The default value is **0**.

  - **0**: The decoded information does not contain the **commit** timestamp.
  - **1**: The decoded information contains the **commit** timestamp.

- only-local

  Specifies whether to decode only local logs.

  Valid value: **0** and **1**. The default value is **1**.

  - **0**: Non-local logs and local logs are decoded.
  - **1**: Only local logs are decoded.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

  - force-binary

    Specifies whether to output the decoding result in binary format.

    Value range: **0** and **1**. The default value is **0**. The result is output in binary format.

  - white-table-list

    Whitelist parameter, including the schema and table name to be decoded.

    Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed. Example: **select * from pg_logical_slot_peek_binary_changes('slot1', NULL, 4096, 'white-table-list', 'public.t1,public.t2');**

  Return type: text, xid, bytea

  Note: The function returns the decoding results. Each decoding result contains three columns, corresponding to the above return types and indicating the LSN, XID, and decoded content in binary format, respectively. Users who call this function must have the **SYSADMIN** permission or the **REPLICATION** permission, or inherit the **gs_role_replication** permission of the built-in role.

- pg_logical_slot_get_binary_changes('slot_name', 'LSN', upto_nchanges, 'options_name', 'options_value')

  Description: Performs decoding in binary mode and does not go to the next streaming replication slot.

  Parameter: This function has the same parameters as **pg_logical_slot_peek_binary_changes**. For details, see **•pg_logical_slot_peek_bi...**

  Note: Users who call this function must have the **SYSADMIN** permission or the **REPLICATION** permission, or inherit the **gs_role_replication** permission of the built-in role.

- pg_replication_slot_advance ('slot_name', 'LSN')

  Description: Directly goes to the streaming replication slot for a specified LSN, without outputting any decoding result.

  Parameter description:

  – slot_name

    Indicates the name of the streaming replication slot.

    Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One period or two periods cannot be used as the replication slot name.

  – LSN

    Indicates a target LSN. Next decoding will be performed only in transactions whose commit position is greater than this value. If an input LSN is smaller than the position recorded in the current streaming replication slot, the function is directly returned. If the input LSN is greater than the LSN of the current physical log, the latter LSN will be directly used for decoding.

    Value range: a string, in the format of *xlogid*/*xrecoff*

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: name, text

Note: A return result contains the slot name and LSN that is actually used for decoding. Users who call this function must have the **SYSADMIN** permission or the **REPLICATION** permission, or inherit the **gs_role_replication** permission of the built-in role.

- pg_get_replication_slots()

  Description: Obtains the replication slot list.

  Example:

```
openGauss=# select * from pg_get_replication_slots();
 slot_name |     plugin     | slot_type | datoid | active | xmin | catalog_xmin | restart_lsn |
dummy_standby | confirmed_flush
-----------+----------------+-----------+--------+--------+------+--------------+-------------+---------------
+-----------------
 dn_s1     |                | physical  |      0 | t      |      |              | 0/23DB14E0  | f             |
 slot1     | mppdb_decoding | logical   |  16304 | f      |      |        60966 | 0/1AFA1BB0  | f             |
0/23DA5700
(2 rows)
```

  Return value: text, text, text, oid, boolean, xid, xid, text, boolean, text

- pg_logical_get_area_changes('LSN_start', 'LSN_end', upto_nchanges, 'decoding_plugin', 'xlog_path', 'options_name', 'options_value')

  Description: Specifies an LSN range or an Xlog file for decoding when no DDL operation is performed.

  The constraints are as follows:

  1. When the API is called, only when **wal_level** is set to **logical**, the generated log files can be parsed. If the used Xlog file is not of the logical level, the decoded content does not have the corresponding value and type, and there is no other impact.

  2. The Xlog file can be parsed only by a copy of a fully homogeneous DN to ensure that the metadata corresponding to the data can be found and no DDL or VACUUM FULL operation is performed.

  3. You can find the Xlog to be parsed.

  4. Do not read too many Xlog files at a time. You are advised to read one Xlog file at a time. It is estimated that the memory occupied by one Xlog file is two to three times the size of the Xlog file.

  5. The Xlog file before scale-out cannot be decoded.

  Note: Users who call this function must have the **SYSADMIN** permission or the O&M administrator permission in O&M mode.

  Parameter description:

  – LSN_start

    Specifies the LSN at the start of decoding.

    Value range: a string, in the format of *xlogid*/*xrecoff*, for example, 1/2AAFC60 (If this parameter is set to a null value, the target LSN indicating the end position of decoding is not specified.)

  – LSN_end

    Specifies the LSN at the end of decoding.

    Value range: a string, in the format of *xlogid*/*xrecoff*, for example, 1/2AAFC60 (If this parameter is set to a null value, the target LSN indicating the end position of decoding is not specified.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

  - upto_nchanges

    Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto_nchanges** after decoding in the first two transactions is complete.

    Value range: a non-negative integer

    NOTE

    If any of the **LSN** and **upto_nchanges** values are reached, decoding ends.

  - decoding_plugin

  Decoding plug-in, which is a .so plug-in that specifies the output format of the decoded content.

  Value range: **mppdb_decoding** and **sql_decoding**.

  - xlog_path

  Decoding plug-in, which specifies the Xlog absolute path and file level of the decoding file.

  Value range: **NULL** or a character string of the absolute path of the Xlog file.

  - **options**: This parameter is optional and consists of a series of **options_name** and **options_value**. You can retain the default value. For details, see **pg_logical_slot_peek_changes**.

  Example:

```
openGauss=# SELECT pg_current_xlog_location();
 pg_current_xlog_location
--------------------------
 0/E62E238
(1 row)

openGauss=# create table t1 (a int primary key,b int,c int);
NOTICE:  CREATE TABLE / PRIMARY KEY will create implicit index "t1_pkey" for table "t1"
CREATE TABLE
openGauss=# insert into t1 values(1,1,1);
INSERT 0 1
openGauss=# insert into t1 values(2,2,2);
INSERT 0 1

openGauss=# select data from pg_logical_get_area_changes('0/
E62E238',NULL,NULL,'sql_decoding',NULL);
 location  |  xid  |                      data
-----------+-------+-------------------------------------------------
 0/E62E8D0 | 27213 | COMMIT (at 2022-01-26 15:08:03.349057+08) 3020226
 0/E6325F0 | 27214 | COMMIT (at 2022-01-26 15:08:07.309869+08) 3020234
...
```

- gs_get_parallel_decode_status()

  Description: Monitors the length of the read log queue and decoding result queue of each decoding thread to locate the concurrent decoding performance bottleneck.

  Return type: text, int, text, text, text, int64, int64

  Example:

```
openGauss=# select * from gs_get_parallel_decode_status();
 slot_name | parallel_decode_num | read_change_queue_length  | decode_change_queue_length |
reader_lsn | working_txn_cnt | working_txn_memory
```

```
-----------+---------------------+--------------------------+--------------------------+-----------
+-----------------+--------------------
 slot1     |                   2 | queue0: 1005, queue1: 320 | queue0: 63, queue1: 748    | 0/1DCE2578
|              42 |          192927504
(1 row)
```

Note: In the return values, **slot_name** indicates the replication slot name, **parallel_decode_num** indicates the number of parallel decoder threads in the replication slot, **read_change_queue_length** indicates the current length of the log queue read by each decoder thread, **decode_change_queue_length** indicates the current length of the decoding result queue of each decoder thread, **reader_lsn** indicates the log location read by the reader thread, **working_txn_cnt** indicates the number of transactions being concatenated in the current sender thread, and **working_txn_memory** indicates the total memory (in bytes) occupied by the concatenation transactions in the sender thread.

- pg_replication_origin_create (node_name)

  Description: Creates a replication source with a given external name and returns the internal ID assigned to it.

  Note: Users who call this function must have the **SYSADMIN** permission.

  Parameter description:

  – node_name

    Specifies the name of the replication source to be created.

    Value range: a string, supporting only letters, digits, and the following special characters: _?-.

  Return type: oid

- pg_replication_origin_drop (node_name)

  Description: Deletes a previously created replication source, including any associated replay progress.

  Note: Users who call this function must have the **SYSADMIN** permission.

  Parameter description:

  – node_name

    Specifies the name of the replication source to be deleted.

    Value range: a string, supporting only letters, digits, and the following special characters: _?-.

- pg_replication_origin_oid (node_name)

  Description: Searches for a replication source by name and returns the internal ID. If no such replication source is found, an error is thrown.

  Note: Users who call this function must have the **SYSADMIN** permission.

  Parameter description:

  – node_name

    Specifies the name of the replication source to be queried.

    Value range: a string, supporting only letters, digits, and the following special characters: _?-.

  Return type: oid

- pg_replication_origin_session_setup (node_name)

  Description: Marks the current session for replaying from a given origin, allowing you to trace replay progress. This function can be used only when no

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

origin is selected. Run the **pg_replication_origin_session_reset** command to cancel the configuration.

Note: Users who call this function must have the **SYSADMIN** permission.

Parameter description:

– node_name

Specifies the name of the replication source.

Value range: a string, supporting only letters, digits, and the following special characters: _?-.

- pg_replication_origin_session_reset ()

  Description: Cancels the **pg_replication_origin_session_setup()** effect.

  Note: Users who call this function must have the **SYSADMIN** permission.

- pg_replication_origin_session_is_setup ()

  Description: Returns a true value if a replication source is selected in the current session.

  Note: Users who call this function must have the **SYSADMIN** permission.

  Return type: Boolean

- pg_replication_origin_session_progress (flush)

  Description: Returns the replay position of the replication source selected in the current session.

  Note: Users who call this function must have the **SYSADMIN** permission.

  Parameter description:

  – flush

  Specifies whether the corresponding local transaction has been flushed to disks.

  Value range: Boolean

  Return type: LSN

- pg_replication_origin_xact_setup (origin_lsn, origin_timestamp)

  Description: Marks the current transaction as recommitted at a given LSN and timestamp. This function can be called only when **pg_replication_origin_session_setup** is used to select a replication source.

  Note: Users who call this function must have the **SYSADMIN** permission.

  Parameter description:

  – origin_lsn

  Specifies the position for replaying the replication source.

  Value range: LSN

  – origin_timestamp

  Specifies the time when a transaction is committed.

  Value range: timestamp with time zone

- pg_replication_origin_xact_reset ()

  Description: Cancels the **pg_replication_origin_xact_setup()** effect.

  Note: Users who call this function must have the **SYSADMIN** permission.

- pg_replication_origin_advance (node_name, lsn)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description:

Sets the replication progress of a given node to a given position. This is primarily used to set the initial position, or to set a new position after a configuration change or similar change.

Note: Improper use of this function may cause inconsistent replication data.

Note: Users who call this function must have the **SYSADMIN** permission.

Parameter description:

- node_name

  Specifies the name of an existing replication source.

  Value range: a string, supporting only letters, digits, and the following special characters: _?-.

- lsn

  Specifies the position for replaying the replication source.

  Value range: LSN

- pg_replication_origin_progress (node_name, flush)

  Description: Returns the position for replaying the given replication source.

  Note: Users who call this function must have the **SYSADMIN** permission.

  Parameter description:

  - node_name

    Specifies the name of the replication source.

    Value range: a string, supporting only letters, digits, and the following special characters: _?-.

  - flush

    Specifies whether the corresponding local transaction has been flushed to disks.

    Value range: Boolean

- pg_show_replication_origin_status()

  Description: Displays the replication status of the replication source.

  Note: Users who call this function must have the **SYSADMIN** permission.

  Return type:

  - **local_id**: OID, which specifies the ID of the replication source.
  - **external_id**: text, which specifies the name of the replication source.
  - **remote_lsn**: LSN of the replication source.
  - **local_lsn**: local LSN.

- pg_get_publication_tables(pub_name)

  Description: Returns the relid list of tables to be published based on the publication name.

  Parameter description:

  - pub_name

    Specifies the name of an existing publication.

    Value range: a string, supporting only letters, digits, and the following special characters: _?-.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: relid list

- pg_stat_get_subscription(sub_oid oid) → record

  Description:

  Returns the subscription status information after a subscription OID is entered.

  Parameter description:

- subid

  Specifies the OID of a subscription.

  Value range: oid

  Return type:

  - **relid**: OID of the table.
  - **pid**: thread_id, which indicates the thread ID of the background apply/sync thread.
  - **received_lsn**: pg_lsn, which indicates the latest LSN received from the publisher.
  - **last_msg_send_time**: timestamp, which indicates the time when the last message is sent from the publisher.
  - **last_msg_receipt_time**: timestamp, which indicates the time when the last message is received by the subscriber.
  - **latest_end_lsn**: pg_lsn, which indicates the LSN of the publisher when the last keepalive message is received.
  - **latest_end_time**: timstamp, which indicates the time when the last keepalive message is received.

## 12.5.26.11 Segment-Page Storage Functions

- local_segment_space_info(tablespacename TEXT, databasename TEXT)

  Description: Generates usage information about all extent groups in the tablespace of the current node.

  Return type:

| | |
|---|---|
| node_name | Node name |
| extent_size | Extent specifications of an extent group. The unit is the number of blocks. |
| forknum | Fork number |
| total_blocks | Total number of extents in a physical file |
| meta_data_blocks | Number of blocks occupied by the metadata managed in a tablespace, including the space header and map page but excluding the segment head |
| used_data_blocks | Number of extents used for storing data, including the segment head |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| | |
|---|---|
| utilization | Percentage of the number of used blocks to the total number of blocks, that is, (the value of **used_data_blocks** + the value of **meta_data_block**)/the value of **total_blocks** |
| high_water_mark | High-water mark, indicating the number of allocated extents and maximum physical page number. Blocks that exceed the high-water mark are not used and can be directly recycled. |

Example:

```
select * from local_segment_space_info('pg_default', 'postgres');
     node_name      | extent_size | forknum | total_blocks | meta_data_blocks | used_data_blocks |
utilization | high_water_mark
--------------------+-------------+---------+--------------+------------------+------------------+-------------
+-----------------
 dn_6001_6002_6003 |           1 |       0 |        16384 |             4157 |                1 |     .253784 |
4158
 dn_6001_6002_6003 |           8 |       0 |        16384 |             4157 |                8 |     .254211 |
4165
(2 rows)
```

- global_segment_space_info(tablespacename TEXT, databasename TEXT)

  Description: Returns the usage information of all nodes in the cluster. The effect is similar to that of **local_segment_space_info**.

- pg_stat_segment_extent_usage(int4 tablespace oid, int4 database oid, int4 extent_type, int4 forknum)

  Description: Specifies the usage information of each allocated extent in an extent group returned each time. **extent_type** indicates the type of the extent group. The value is an integer ranging from 1 to 5. If the value is not within the range, an error is reported. **forknum** indicates the fork number. The value is an integer ranging from 0 to 4. Currently, only the following values are valid: **0** for data files, **1** for FSM files, and **2** for visibility map files.

  Return type:

| Name | Description |
|---|---|
| start_block | Start physical page number of an extent |
| extent_size | Size of an extent |
| usage_type | Usage type of an extent, for example, **segment head** and **data extent** |
| ower_location | Object location of an extent to which a pointer points. For example, the owner of a data extent is the head of the segment to which the data extent belongs. |
| special_data | Position of an extent in its owner. The value of this field is related to the usage type. For example, special data of a data extent is the extent ID in the segment to which the data extent belongs. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The value of **usage_type** is enumerated. The meaning of each value is as follows:

- **Non-bucket table segment head**: data segment head of a non-hash bucket table
- **Non-bucket table fork head**: Fork segment header of a non-segment-page table
- **Bucket table main head**: primary table segment header of a hash bucket table
- **Bucket table map block**: Map block of a hash bucket table
- **Bucket segment head**: segment head of each bucket in a hash bucket table
- **Data extent**: data block

Example:

```
select * from pg_stat_segment_extent_usage((select oid::int4 from pg_tablespace where
spcname='pg_default'), (select oid::int4 from pg_database where datname='postgres'), 1, 0);
start_block | extent_size |       usage_type       | ower_location | special_data
-------------+-------------+------------------------+---------------+--------------
4157 |           1 | Bucket table main head |    4294967295 |            0
4158 |           1 | Bucket table map block |          4157 |            0
4159 |           1 | Bucket table map block |          4157 |            1
4160 |           1 | Bucket table map block |          4157 |            2
4161 |           1 | Bucket table map block |          4157 |            3
4162 |           1 | Bucket table map block |          4157 |            4
4163 |           1 | Bucket table map block |          4157 |            5
4164 |           1 | Bucket table map block |          4157 |            6
4165 |           1 | Bucket table map block |          4157 |            7
4166 |           1 | Bucket table map block |          4157 |            8
```

- local_space_shrink(tablespacename TEXT, databasename TEXT)

  Description: Shrinks specified physical segment-page space on the current node. Only the currently connected database can be shrank.

  Return value: empty

- gs_space_shrink(int4 tablespace, int4 database, int4 extent_type, int4 forknum)

  Description: Works similar to **local_space_shrink**. That is, shrinks specified physical segment-page space. However, the parameters are different. The input parameters are the OIDs of the tablespace and database, and the value of **extent_type** is an integer ranging from 2 to 5. Note: The value **1** of **extent_type** indicates segment-page metadata. Currently, the physical file that contains the metadata cannot be shrunk. This function is used only by tools. You are not advised to use it directly.

  Return value: empty

- global_space_shrink(tablespacename TEXT, databasename TEXT)

  Description: Compresses segment-page storage space on all DNs in a cluster. This is performed on a CN.

  Note: If **global_space_shrink** locks the cluster. DDL operations cannot be performed. **local_space_shrink** does not lock the cluster.

- pg_stat_remain_segment_info()

  Description: Displays residual extents on the current node due to faults. Residual extents are classified into two types: segments that are allocated but not used and extents that are allocated but not used. The main difference is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

that a segment contains multiple extents. During reclamation, all extents in the segment need to be recycled.

Return type:

| Name | Description |
| --- | --- |
| space_id | Tablespace ID |
| db_id | Database ID |
| block_id | Extent ID |
| type | Extent type. The options are as follows: **ALLOC_SEGMENT**, **DROP_SEGMENT**, and **SHRINK_EXTENT**. |

The values of **type** are described as follows:

- **ALLOC_SEGMENT**: When a user creates a segment-page table and the segment is just allocated but the transaction of creating a table is not committed, the node is faulty. As a result, the segment is not used after being allocated.
- **DROP_SEGMENT**: When a user deletes a segment-page table and the transaction is successfully committed, the bit corresponding to the segment page of the table is not reset and a fault, such as power failure, occurs. As a result, the segment is not used or released.
- **SHRINK_EXTENT**: When a user shrinks a segment-page table and does not release the idle extent, a fault, such as power failure, occurs. As a result, the extent remains and cannot be reused.

Example:

```
select * from pg_stat_remain_segment_info();
space_id | db_id | block_id | type
----------+-------+----------+------
1663     |   16385|       4156| ALLOC_SEGMENT
```

- pg_free_remain_segment(int4 spaceId, int4 dbId, int4 segmentId)

  Description: Releases a specified residual extent. The value must be obtained from the **pg_stat_remain_segment_info** function. The function verifies input values. If the specified extent is not among the recorded residual extents, an error message is returned. If the specified extent is a single extent, the extent is released independently. If it is a segment, the segment and all extents in the segment are released.

  Return value: empty

## 12.5.26.12 Other Functions

- pgxc_pool_check()

  Description: Checks whether the connection data buffered in the pool is consistent with **pgxc_node**.

  Return type: Boolean

- pgxc_pool_reload()

  Description: Updates the connection information buffered in the pool.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: Boolean

- reload_active_coordinator()

  Description: Updates the connection information buffered in the pool for all active CNs.

  Return type: void

- pgxc_lock_for_backup()

  Description: Locks a cluster for taking backup that would be restored on the new node to be added.

  Return type: Boolean

  NOTE

  **pgxc_lock_for_backup** locks a cluster before **gs_dump** or **gs_dumpall** is used to back up the cluster. After a cluster is locked, operations changing the system structure are not allowed. This function does not affect DML statements.

- pg_pool_validate(clear bool, node_name text)

  Description: Displays invalid connections in the pooler between the CN and node_name. When the value of **clear** is **true**, invalid connections are cleared.

  Return type: record

- pgxc_pool_connection_status()

  Description: Checks whether the pooler connection status is **normal**.

  Return type: Boolean

- pg_nodes_memory()

  Description: Queries the memory usage of all nodes.

  Return type: record

- table_skewness(text)

  Description: Queries the percentage of table data among all nodes.

  Parameter: Indicates that the type of the name of the to-be-queried table is text.

  Return type: record

- table_skewness(text, text, text)

  Description: Queries the percentage of a specified column in the table data among all nodes.

  Parameters: name of the table to be queried, specified column name, and number of records in the specified table. The default value is **0**, indicating that all records are queried. All parameters are of the text type.

  Return type: record

  Return value description: Node ID, number of data rows in a specified column, and percentage of the data volume of the current node to the total data volume

  Example:

  ```
  Return the distribution of the first five rows of data in the a column of the t table on a node.
  openGauss=# select table_skewness('t', 'a',5);
   table_skewness
  ----------------
   (1,3,60.000%)
   (2,2,40.000%)
  (2 rows)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
Return the distribution of all data in the a column of the t table on a node.
openGauss=# select table_skewness('t', 'a');
 table_skewness
----------------
 (1,7,70.000%)
 (2,2,20.000%)
 (0,1,10.000%)
(3 rows)
```

- table_skewness_with_schema(text, text)

  Description: Checks the proportion of table data on all nodes. The function is the same as that of **table_skewness(text)**.

  **text** indicates that the types of the schema name and table name for the table to be queried are both text.

  Return type: record

- table_data_skewness(colrecord, type)

  Description: Queries the node where the table data is located.

  Parameter description:

  **colrecord**: column name record of the table to be queried. The value is of the record type.

  **type**: hash distribution type

  Return type: smallint

  Example:

  ```
  openGauss=# select table_data_skewness(row(index), 'R') from test1;
   table_data_skewness
  ---------------------
                     4
                     3
                     1
                     2
  (4 rows)
  ```

- table_distribution(schemaname text, tablename text)

  Description: Queries the storage space occupied by a specified table on each node.

  **text** indicates that the types of the schema name and table name for the table to be queried are both text.

  Return type: record

  NOTE

  - To query the storage distribution of a specified table by using this function, you must have the SELECT permission for the table.
  - The performance of **table_distribution** is better than that of **table_skewness**. Especially, in a large cluster with a large amount of data, **table_distribution** is recommended. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)
  - When you use **table_distribution** and want to view the space usage, you can use **dnsize** or **(sum(dnsize) over ())** to view the percentage.

- table_distribution()

  Description: Queries the storage distribution of all tables in the current database.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- This function involves the query for information about all tables in the database. To execute this function, you must have the administrator rights.
- Based on the **table_distribution()** function, GaussDB provides the **15.3.192 PGXC_GET_TABLE_SKEWNESS** view as an alternative way to query data skew. You are advised to use this view when the number of tables in the database is less than 10000.

- plan_seed

  Description: Obtains the seed value of the previous query statement (internal use).

  Return type: int

- pg_stat_get_env

  Description: Obtains the environment variable information of the current node. Only users with the sysadmin or monitor admin permission can access the environment variable information.

  Return type: record

  Example:

```
openGauss=# select pg_stat_get_env();
                                                
```

- pgxc_get_node_env

  Description: Provides the environment variable information about all nodes in a cluster.

  Return type: record

- pgxc_disaster_read_set(text)

  Description: Configures node information about the DR cluster on ETCD. Only the DR cluster is available and can be called only by initial users.

  Return type: Boolean

- pgxc_disaster_read_init

  Description: Initializes readable DR resources and status information. Only the DR cluster is available and can be called only by initial users.

  Return type: Boolean

- pgxc_disaster_read_clear

  Description: Clears readable DR resources and status information. Only the DR cluster is available and can be called only by initial users.

  Return type: Boolean

- pgxc_disaster_read_status

  Description: Provides node information about the DR cluster. This function is available only for the DR cluster.

  Return type: record

- gs_switch_relfilenode

  Description: Exchanges metadata of two tables or partitions. (This is only used for the redistribution tool. An error message is displayed when the function is directly used by users).

  Return type: int

- pg_catalog.plancache_clean()

  Description: Clears the global plan cache that is not used on the current node.

  Return type: Boolean

- DBE_PERF.global_plancache_clean()

  Description: Clears the global plan cache that is not used on all nodes.

  Return type: Boolean

- copy_error_log_create()

  Description: Creates the error table (**public.pgxc_copy_error_log**) required by the COPY FROM error tolerance mechanism.

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- This function attempts to create the **public.pgxc_copy_error_log** table. For details about the table, see **Table 12-56**.
- In addition, it creates a B-tree index on the **relname** column and executes **REVOKE ALL on public.pgxc_copy_error_log FROM public** to manage permissions on the error table (the permissions are the same as those of the COPY statement).
- **public.pgxc_copy_error_log** is a row-store table. Therefore, this function can be executed and COPY error tolerance is available only when row-store tables can be created in the cluster. Row-store tables cannot be created in the cluster if **enable_hadoop_env** is set to **on** (by default, this parameter set to **off** for GaussDB).
- Same as the error table and the COPY statement, the function requires sysadmin or higher permissions.
- If the **public.pgxc_copy_error_log** table or the **copy_error_log_relname_idx** index exists before the function creates it, the function will report an error and roll back.

**Table 12-56** Error table public.pgxc_copy_error_log

| Column | Type | Description |
| --- | --- | --- |
| relname | character varying | Table name in the form of *Schema name*.*Table name* |
| begintime | timestamp with time zone | Time when a data format error was reported |
| filename | character varying | Name of the source data file where a data format error occurs |
| lineno | bigint | Number of the row where a data format error occurs in a source data file |
| rawrecord | text | Raw record of a data format error in the source data file |
| detail | text | Error details |

- pg_stat_get_data_senders()

  Description: Provides detailed information about the data-copy sending thread active at the moment.

  Return type: record
- textlen()

  Description: Provides the method of querying the logical length of text.

  Return type: int
- threadpool_status()

  Description: Displays the status of worker threads and sessions in the thread pool.

  Return type: record
- get_local_active_session()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Provides sampling records of historical active sessions stored in the memory by current node. Users with the sysadmin or monitor admin permission can view all historical active session records of the current node. Common users can view the historical active session records of the current session.

Return type: record

- dbe_perf.get_global_active_session()

  Description: Provides sampling records of the historical active sessions stored in the memory of all nodes.

  Return type: record

- dbe_perf.get_global_gs_asp(timestamp,timestamp)

  Description: Provides sampling records of the historical active sessions stored in the **gs_asp** system catalog of all nodes.

  Return type: record

- get_wait_event_info()

  Description: Provides detailed information about the wait event.

  Return type: record

- dbe_perf.get_datanode_active_session(text)

  Description: Provides sampling records of historical active sessions stored in the memory of DN, which is queried from CN.

  Return type: record

  Note: This function queries the records in the **local_active_session** view on the target DN and matches the records with those in the **local_active_session** view on all CNs to obtain the query string. Therefore, a large amount of memory is occupied.

- dbe_perf.get_datanode_active_session_hist(text,timestamp,timestamp)

  Description: Provides sampling records of historical active sessions stored in the **gs_asp** system catalog of DN, which is queried from CN.

  Return type: record

  Note: This function queries the **gs_asp** records of a specified period on the target DN. If the period is specified too long, too many records will be queried, which takes a long time.

- generate_wdr_report(bigint, bigint, cstring, cstring,cstring)

  Description: Generates a system diagnosis report based on two snapshots. By default, the initial user or monitor administrator can access the report. The result can be queried only in the system database but cannot be queried in the user database.

  Return type: text

  **Table 12-57** generate_wdr_report parameter description

| Parameter | Description | Range |
| --- | --- | --- |
| begin_snap_id | Snapshot ID that starts the diagnosis report period. | N/A |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| | | |
|---|---|---|
| end_snap_id | Snapshot ID that ends the diagnosis report period. By default, the value of **end_snap_id** is greater than that of **begin_snap_id**. | N/A |
| report_type | Specifies the type of the generated report. | • **summary**<br>• **detail**<br>• **all**: Both **summary** and **detail** types are included. |
| report_scope | Specifies the scope for a report to be generated. | • **cluster**: database-level information<br>• **node**: node-level information. |
| node_name | • When **report_scope** is set to **node**, set this parameter to the name of the corresponding node.<br>• If **report_scope** is set to **cluster**, this parameter can be omitted or set to **NULL**. | • **node**: node name in GaussDB.<br>• **cluster**: This value is omitted, left blank or set to **NULL**. |

- create_wdr_snapshot()

  Description: Manually generates system diagnosis snapshots. This function requires the sysadmin permission and can be executed only on the CCN.

  Return type: text

- kill_snapshot()

  Description: Kills the WDR snapshot background thread. Users who invoke this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the **gs_role_replication** permission of the built-in role.

  Return type: void

- capture_view_to_json(text,integer)

  Description: Saves the view result to the directory specified by GUC: **perf_directory**. If **is_crossdb** is set to **1**, the view is accessed once for all databases. If the value of **is_crossdb** is **0**, the current database is accessed only once. Only users with the sysadmin or monitor admin permission can execute this function.

  Return type: int

- reset_unique_sql(text,text,bigint)

  Description: Clears the unique SQL statements in the memory of CN/DN. (The sysadmin or monitor admin permission is required.)

  Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-58** reset_unique_sql parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| scope | text | Clearance scope type. The options are as follows:<br>**'GLOBAL'**: Clears all CNs/DNs. If the value is **'GLOBAL'**, this function can be executed only on the CN.<br>**'LOCAL'**: Clears the current node. |
| clean_type | text | **'BY_USERID'**: Unique SQL statements are cleared based on user IDs.<br>**'BY_CNID'**: Unique SQL statements are cleared based on CN IDs.<br>**'ALL'**: All data is cleared. |
| clean_value | int8 | Clearance value corresponding to the clearance type. If the second parameter is set to **ALL**, the third parameter does not take effect and can be set to any value. |

- wdr_xdb_query(db_name_str text, query text)

  Description: Provides the capability of executing local cross-database queries. For example, when connecting to the Postgres database, access tables in the **test** database. Only the system administrator has the permission to execute this function.

  ```
  select col1 from wdr_xdb_query('dbname=test','select col1 from t1') as dd(col1 int);
  ```

  Return type: record

- pg_wlm_jump_queue(pid int)

  Description: Moves a task to the top of the queue of CN.

  Return type: Boolean

  - **true**: success
  - **false**: failure

- gs_wlm_switch_cgroup(pid int, cgroup text)

  Description: Moves a job to another Cgroup to change the job priority.

  Return type: Boolean

  - **true**: success
  - **false**: failure

- pv_session_memctx_detail(threadid tid, MemoryContextName text)

  Description: Records information about the memory context **MemoryContextName** of the thread **tid** into the *threadid*_**timestamp.log** file in the *$GAUSSLOG*/**pg_log/***${node_name}*/**dumpmem** directory. *threadid* can be obtained from *sessid* in the **PV_SESSION_MEMORY_DETAIL** table. In the officially released version, only the **MemoryContextName** that is an empty string (two single quotation marks indicate that the input is an empty string) is accepted. In this case, all memory context information is recorded.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Otherwise, no operation is performed. This function can be executed only by the administrator.

Return type: Boolean

- **true**: success
- **false**: failure

- pg_shared_memctx_detail(MemoryContextName text)

  Description: Records information about the memory context **MemoryContextName** into the *threadid*_**timestamp.log** file in the *$GAUSSLOG*/**pg_log**/*${node_name}*/**dumpmem** directory. Calling this function in the officially released version does not involve any operation. Only the administrator can execute this function.

  Return type: Boolean

  - **true**: success
  - **false**: failure

- pv_compute_pool_workload()

  Description: Provides the current load information about computing cluster on cloud. (Due to specification changes, the current version no longer supports the current feature. Do not use this feature.)

  Return type: record

- local_bgwriter_stat()

  Description: Displays the information about pages flushed by the bgwriter thread of this instance, number of pages in the candidate buffer chain, and buffer eviction information.

  Return type: record

- local_candidate_stat()

  Description: Displays the number of pages in the candidate buffer chain of this instance and buffer eviction information, including the normal buffer pool and segment buffer pool.

  Return type: record

- local_ckpt_stat()

  Description: Displays the information about checkpoints and flushing pages of the current instance.

  Return type: record

- local_double_write_stat()

  Description: Displays the doublewrite file status of the current instance.

  Return type: record

**Table 12-59** local_double_write_stat parameters

| Parameter | Type | Description |
| --- | --- | --- |
| node_name | text | Instance name |
| curr_dwn | int8 | Sequence number of the doublewrite file |
| curr_start_page | int8 | Start page for restoring the doublewrite file |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description |
| --- | --- | --- |
| file_trunc_num | int8 | Number of times that the doublewrite file is reused |
| file_reset_num | int8 | Number of reset times after the doublewrite file is full |
| total_writes | int8 | Total number of I/Os of the doublewrite file |
| low_threshold_writes | int8 | Number of I/Os for writing the doublewrite files with low efficiency (the number of I/O flushing pages at a time is less than 16.) |
| high_threshold_writes | int8 | Number of I/Os for writing the doublewrite file with high efficiency (the number of I/O flushing pages at a time is more than 421.) |
| total_pages | int8 | Total number of pages that are flushed to the doublewrite file area |
| low_threshold_pages | int8 | Number of pages that are flushed with low efficiency |
| high_threshold_pages | int8 | Number of pages that are flushed with high efficiency |
| file_id | int8 | ID of the current doublewrite file |

- local_single_flush_dw_stat()

  Description: Displays the eviction of dual-write files on a single page in the instance.

  Return type: record
- local_pagewriter_stat()

  Description: Displays the page flushing information and checkpoint information of the current instance.

  Return type: record
- local_redo_stat()

  Description: Displays the replay status of the current standby instance.

  Return type: record

  Note: The returned replay status includes the current replay position and the replay position of the minimum restoration point.
- local_recovery_status()

  Description: Displays log flow control information about the primary and standby nodes.

  Return type: record
- local_rto_status()

  Description: Displays log flow control information about the primary and standby nodes.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- gs_wlm_node_recover(boolean isForce)

  Description: Recovers nodes after the dynamic load management node is faulty. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) Only administrators can execute this function. This function is called by the cluster management module. You are not advised to directly call this function.

  Return type: Boolean

- gs_wlm_node_clean(cstring nodename)

  Description: Clears data after the dynamic load management node is faulty. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) Only administrators can execute this function. This function is called by the cluster management module. You are not advised to directly call this function.

  Return type: Boolean

- gs_cgroup_map_ng_conf(group name)

  Description: Reads the Cgroup configuration file of a specified logical cluster. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) Only users with the sysadmin permission can execute this function.

  Return type: record

- pgxc_cgroup_map_ng_conf(group name)

  Description: Reads the Cgroup configuration file of a specified logical cluster on all nodes. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) Only users with the sysadmin permission can execute this function.

  Return type: Boolean

- gs_wlm_switch_cgroup(sess_id int8, cgroup name)

  Description: Switches the Cgroup of a specified session.

  Return type: record

- comm_client_info()

  Description: Queries active client connections of a single node. For details about the returned result, see **15.3.29 COMM_CLIENT_INFO**.

  Return type: setof record

- pg_sync_cstore_delta(text)

  Description: Synchronizes the delta table structure of a specified column-store table with that of the column-store primary table.

  Return type: bigint

- pg_sync_cstore_delta()

  Description: Synchronizes the delta table structure of all column-store tables with that of the column-store primary table.

  Return type: bigint

- pg_get_flush_lsn()

  Description: Returns the location of the Xlog flushed from the current node.

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_get_sync_flush_lsn()

  Description: Returns the location of the Xlog flushed by the majority on the current node.

  Return type: text

- gs_create_log_tables()

  Description: Creates foreign tables and views for run logs and performance logs. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)

  Example:

  ```
  openGauss=# select gs_create_log_tables();
   gs_create_log_tables
  ----------------------

  (1 row)
  ```

  Return type: void

- pgxc_wlm_rebuild_user_resource_pool()

  Description: Rebuilds user and resource pool cache information. Only the system administrator can execute this function.

  Return type: Boolean

- locktag_decode(locktag text)

  Description: Parses lock details from **locktag**.

  Example:

  ```
  openGauss=# select locktag_decode('271b:0:0:0:0:6');
                locktag_decode
  ---------------------------------------------
   locktype:transactionid, transactionid:10011
  (1 row)
  ```

  Return type: text

- disable_conn(disconn_mode text, host text, port integer)

  Description: Specifies that the CM Agent processes commands delivered by the CM Server. When a DN is selected as the primary DN, it is configured to reject connections to all DNs, forcibly connect to a DN, or connect to all DNs in polling mode. Only the initial user and system administrator can call this function.

  Return type: void

  **Table 12-60** disable_conn parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| disconn_mode | text | DN connection mode:<br>• **'prohibit_connection'**: rejects to connect to all DNs.<br>• **'specify_connection'**: forcibly connects to a DN.<br>• **'polling_connection'**: connects to all DNs in polling mode. |
| host | text | IP address of the DN |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description |
| --- | --- | --- |
| port | integer | Port number of the DN |

- dbe_perf.get_global_full_sql_by_timestamp(start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)

  Description: Obtains full SQL information about a cluster. The result can be queried only in the system database but cannot be queried in the user database.

  Return type: record

  **Table 12-61** dbe_perf.get_global_full_sql_by_timestamp parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| start_timestamp | timestamp with time zone | Start point of the SQL start time range. |
| end_timestamp | timestamp with time zone | End point of the SQL start time range. |

- dbe_perf.get_global_slow_sql_by_timestamp(start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)

  Description: Obtains cluster-level slow SQL information. The result can be queried only in the system database but cannot be queried in the user database.

  Return type: record

  **Table 12-62** dbe_perf.get_global_slow_sql_by_timestamp parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| start_timestamp | timestamp with time zone | Start point of the SQL start time range. |
| end_timestamp | timestamp with time zone | End point of the SQL start time range. |

- statement_detail_decode(detail text, format text, pretty boolean)

  Description: Parses the **details** column in a full or slow SQL statement. The result can be queried only in the system database but cannot be queried in the user database.

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-63** statement_detail_decode parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| **detail** | text | Set of events generated by the SQL statement (unreadable). |
| format | text | Parsing output format. The value is **plaintext**. |
| pretty | boolean | Whether to display the text in pretty format when **format** is set to **plaintext**. The options are as follows:<br>• The value **true** indicates that **\n** is used to separate events.<br>• The value **false** indicates that events are separated by commas (,). |

- pgxc_get_csn(tid)

  Description: Returns the transaction submission sequence number (CSN) corresponding to a given transaction ID.

  Return type: int8

- pgxc_get_searchlet_info()

  Description: Returns information about Searchlets on all nodes.

  Return type: setof record

  NOTE

  This function is no longer supported in the current version due to specification changes. Do not use this function.

- pgxc_get_searchlet_table_attr_info()

  Description: Returns the attribute information of tables in searchlet on all nodes.

  Return type: setof record

  NOTE

  This function is no longer supported in the current version due to specification changes. Do not use this function.

- get_global_user_transaction()

  Description: Returns transaction information about each user on all nodes.

  Return type: node_name name, usename name, commit_counter bigint, rollback_counter bigint, resp_min bigint, resp_max bigint, resp_avg bigint, resp_total bigint, bg_commit_counter bigint, bg_rollback_counter bigint, bg_resp_min bigint, bg_resp_max bigint, bg_resp_avg bigint, and bg_resp_total bigint

- pg_collation_for

  Description: Returns the sorting rule corresponding to the input parameter string.

  Parameter: any (Explicit type conversion is required for constants.)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: text

- pgxc_unlock_for_sp_database(name Name)

  Description: Releases a specified database lock.

  Parameter: database name

  Return type: Boolean

- pgxc_lock_for_sp_database(name Name)

  Description: Locks a specified database.

  Parameter: database name

  Return type: Boolean

- pgxc_unlock_for_transfer(name Name)

  Description: Releases the lock used for data transmission (data redistribution).

  Parameter: database name

  Return type: Boolean

- pgxc_lock_for_transfer(name Name)

  Description: Locks the database for data transmission (data redistribution).

  Parameter: database name

  Return type: Boolean

- gs_catalog_attribute_records()

  Description: Returns the definition of each field in a specified system catalog. Only common system catalogs whose OIDs are less than 10000 are supported. Indexes and TOAST tables are not supported.

  Parameter: OID of the system catalog

  Return type: record

- gs_comm_proxy_thread_status()

  Description: Collects statistics on data packets sent and received by the proxy communication library **comm_proxy** when a user-mode network is configured for the cluster. This function is not supported in the current version.

  Parameter: nan

  Return type: record

- dynamic_func_control(scope text, function_name text, action text, "{params}" text[])

  Description: Dynamically enables built-in functions. Currently, only full SQL statements can be dynamically enabled.

  Return type: record

**Table 12-64** Parameter description of dynamic_func_control

| Parameter | Type | Description |
| --- | --- | --- |
| scope | text | Scope where the function is to be dynamically enabled. Currently, only **'GLOBAL'** and **'LOCAL'** are supported. |
| function_name | text | Function name. Currently, only **'STMT'** is supported. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description |
| --- | --- | --- |
| action | text | When **function_name** is set to **'STMT'**, the value of **action** can only be **TRACK**, **UNTRACK**, **LIST**, or **CLEAN**.<br>● **TRACK**: records the full SQL information of normalized SQL statements.<br>● **UNTRACK**: cancels the recording of full SQL information of normalized SQL statements.<br>● **LIST**: lists normalized SQL information that is recorded in the current track.<br>● **CLEAN**: cleans normalized SQL information that is recorded in the current track. |
| params | text[] | When **function_name** is set to **'STMT'**, the parameters corresponding to different actions are set as follows:<br>● TRACK: '{"Normalized SQLID", "L0/L1/L2"}'<br>● UNTRACK: '{"Normalized SQLID"}'<br>● LIST - '{}'<br>● CLEAN - '{}' |

- gs_parse_page_bypath(path text, blocknum bigint, relation_type text, read_memory boolean)

  Description: Parses a specified table page and returns the path for storing the parsed content.

  Return type: text

  Note: Only the system administrator or O&M administrator can execute this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-65** gs_parse_page_bypath parameters

| Parameter | Type | Description |
| --- | --- | --- |
| path | text | • For an ordinary table or a segment-page ordinary table, the relative path is *Tablespace name*/*Database OID*/*Relfilenode of the table (physical file name)*. For example, **base/16603/16394**.<br>• For a segment-page hash bucket table, the relative path is *Tablespace name*/*Database OID*/*Logical page number of the segment head*_**b(bucketid)**. For example, **base/16603/16394_b1437**.<br>• You can run the **pg_relation_filepath(table_name text)** command to query the relative path of the table file. To obtain the path of the partitioned table, view the **pg_partition** system catalog and call **pg_partition_filepath(partition_oid)**.<br>• Valid path formats are as follows:<br>– global/relNode<br>– base/dbNode/relNode<br>– pg_tblspc/spcNode/version_dir/dbNode/relNode<br>For hash bucket tables, add **_b(bucketid)** to the end of the path. |
| blocknum | bigint | • **–1**: Information about all blocks (forcibly parsed from disks)<br>• **0-***MaxBlockNumber*: Information about the corresponding block |
| relation_type | text | • **heap**: Astore table<br>• **btree**: B-tree index<br>• **segment**: Segment-page table |
| read_memory | boolean | • **false**: The system parses the page from the disk file.<br>• **true**: The system attempts to parse the page from the shared buffer. If the page does not exist in the shared buffer, the system parses the page from the disk file. |

- gs_xlogdump_lsn(start_lsn text, end_lsn text)

  Description: Parses Xlogs within the specified LSN range and returns the path for storing the parsed content. You can use **pg_current_xlog_location()** to obtain the current Xlog position.

  Parameters: LSN start position and LSN end position

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.

- gs_xlogdump_xid(c_xid xid)

  Description: Parses Xlogs of a specified XID and returns the path for storing the parsed content. You can use **txid_current()** to obtain the current XID.

  Parameter: XID

  Return type: text

  Note: Only the system administrator or O&M administrator can execute this function.

- gs_xlogdump_tablepath(path text, blocknum bigint, relation_type text)

  Description: Parses logs corresponding to a specified table page and returns the path for storing the parsed content.

  Return type: text

  Note: Only the system administrator or O&M administrator can execute this function.

**Table 12-66** gs_xlogdump_tablepath parameters

| Parameter | Type | Description |
| --- | --- | --- |
| path | text | • For an ordinary table or a segment-page ordinary table, the relative path is *Tablespace name*/*Database OID*/*Relfilenode of the table (physical file name)*. For example, **base/16603/16394**.<br>• For a segment-page hash bucket table, the relative path is *Tablespace name*/*Database OID*/*Logical page number of the segment head*_**b(bucketid)**. For example, **base/16603/16394_b1437**.<br>• You can run the **pg_relation_filepath(table_name text)** command to query the relative path of the table file. To obtain the path of the partitioned table, view the **pg_partition** system catalog and call **pg_partition_filepath(partition_oid)**.<br>• Valid path formats are as follows:<br>– global/relNode<br>– base/dbNode/relNode<br>– pg_tblspc/spcNode/version_dir/dbNode/relNode<br>For hash bucket tables, add **_b(bucketid)** to the end of the path. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description |
| --- | --- | --- |
| blocknum | bigint | • **–1**: Information about all blocks (forcibly parsed from disks)<br>• **0-***MaxBlockNumber*: Information about the corresponding block |
| relation_type | text | • **heap**: Astore table<br>• **btree**: B-tree index<br>• **segment**: Segment-page table |

- gs_xlogdump_parsepage_tablepath(path text, blocknum bigint, relation_type text, read_memory boolean)

  Description: Parses the specified table page and logs corresponding to the table page and returns the path for storing the parsed content. It can be regarded as one execution of **gs_parse_page_bypath** and **gs_xlogdump_tablepath**. The prerequisite for executing this function is that the table file exists. To view logs of deleted tables, call **gs_xlogdump_tablepath**.

  Return type: text

  Note: Only the system administrator or O&M administrator can execute this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-67** gs_xlogdump_parsepage_tablepath parameters

| Parameter | Type | Description |
| --- | --- | --- |
| path | text | • For an ordinary table or a segment-page ordinary table, the relative path is *Tablespace name*/*Database OID*/*Relfilenode of the table (physical file name)*. For example, **base/16603/16394**.<br>• For a segment-page hash bucket table, the relative path is *Tablespace name*/*Database OID*/*Logical page number of the segment head*_**b(bucketid)**. For example, **base/16603/16394_b1437**.<br>• You can run the **pg_relation_filepath(table_name text)** command to query the relative path of the table file. To obtain the path of the partitioned table, view the **pg_partition** system catalog and call **pg_partition_filepath(partition_oid)**.<br>• Valid path formats are as follows:<br>– global/relNode<br>– base/dbNode/relNode<br>– pg_tblspc/spcNode/version_dir/dbNode/relNode<br>For hash bucket tables, add **_b(bucketid)** to the end of the path. |
| blocknum | bigint | • **–1**: Information about all blocks (forcibly parsed from disks)<br>• **0-***MaxBlockNumber*: Information about the corresponding block |
| relation_type | text | • **heap**: Astore table<br>• **btree**: B-tree index<br>• **segment**: Segment-page table |
| read_memory | boolean | • **false**: The system parses the page from the disk file.<br>• **true**: The system attempts to parse the page from the shared buffer. If the page does not exist in the shared buffer, the system parses the page from the disk file. |

- gs_index_recycle_queue(Oid oid, int type, uint32 blkno)
  Description: Parses the UB-tree index recycling queue information.
  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-68** gs_index_recycle_queue parameters

| Parameter | Type | Description |
| --- | --- | --- |
| oid | Oid | • Index file **relfilenode**, which can be queried using **select relfilenode from pg_class where relname='***name***'**, where *name* indicates the name of the index file. |
| type | int | • **0** indicates that the entire queue to be recycled is parsed.<br>• **1** indicates that the entire empty page queue is parsed.<br>• **2** indicates that a single page is parsed. |
| blkno | uint32 | ID of the recycling queue page. This parameter is valid only when **type** is set to **2**. The value of **blkno** ranges from 1 to 4294967294. |

NOTE

This function is not supported in the distributed version. An error message will be displayed if it is used in the distributed version.

- gs_stat_wal_entrytable(int64 idx)

  Description: Exports the content of the WAL insertion status table in the Xlog.

  Return type: record

**Table 12-69** gs_stat_wal_entrytable parameters

| Category | Parameter | Type | Description |
| --- | --- | --- | --- |
| Input parameter | idx | int64 | • **–1**: queries all elements in an array.<br>• **0-***Maximum value*: content of a specific array element. |
| Output parameter | idx | uint64 | Records the subscripts in the corresponding array. |
| Output parameter | endlsn | uint64 | Records the LSN label. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Category | Parameter | Type | Description |
| --- | --- | --- | --- |
| Output parameter | lrc | int32 | Records the corresponding LRC. |
| Output parameter | status | uint32 | Specifies whether the Xlog corresponding to the current entry has been completely copied to the WAL buffer.<br>• **0**: Not copied.<br>• **1**: Copied |

- gs_walwriter_flush_position()

  Description: Outputs the refresh position of WALs.

  Return type: record

  **Table 12-70** gs_walwriter_flush_position parameters

| Category | Parameter | Type | Description |
| --- | --- | --- | --- |
| Output parameter | last_flush_status_entry | int32 | Subscript index obtained after the Xlog flushes the tblEntry of the last flushed disk. |
| Output parameter | last_scanned_lrc | int32 | LRC obtained after the Xlog flushes the last tblEntry scanned last time. |
| Output parameter | curr_lrc | int32 | Latest LRC usage in the WALInsertStatusEntry status table. The LRC indicates the LRC value corresponding to the WALInsertStatusEntry when the next Xlog record is written. |
| Output parameter | curr_byte_pos | uint64 | The latest Xlog position after the Xlog is written to the WAL file, which is also the next Xlog insertion point. |
| Output parameter | prev_byte_size | uint32 | Length of the previous Xlog record. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Category | Parameter | Type | Description |
| --- | --- | --- | --- |
| Output parameter | flush_result | uint64 | Position of the current global Xlog flush. |
| Output parameter | send_result | uint64 | Xlog sending position on the current host. |
| Output parameter | shm_rqst_write_pos | uint64 | Write position of the LogwrtRqst request in the XLogCtl recorded in the shared memory. |
| Output parameter | shm_rqst_flush_pos | uint64 | Flush position of the LogwrtRqst request in the XLogCtl recorded in the shared memory. |
| Output parameter | shm_result_write_pos | uint64 | Write position of the LogwrtResult request in the XLogCtl recorded in the shared memory. |
| Output parameter | shm_result_flush_pos | uint64 | Flush position of the LogwrtResult request in the XLogCtl recorded in the shared memory. |
| Output parameter | curr_time | text | Current time. |

- gs_walwriter_flush_stat(int operation)

  Description: Collects statistics on the frequency of writing and synchronizing WALs, data volume, and Xlog file information.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-71** gs_walwriter_flush_stat parameters

| Category | Parameter | Type | Description |
| --- | --- | --- | --- |
| Input parameter | operation | int | • **–1**: Disables the statistics function. (Default value)<br>• **0**: Enables the statistics function.<br>• **1**: Queries statistics.<br>• **2**: Resets statistics. |
| Output parameter | write_times | uint64 | Number of times that the Xlog calls the **write** API. |
| Output parameter | sync_times | uint64 | Number of times that the Xlog calls the **sync** API. |
| Output parameter | total_xlog_sync_bytes | uint64 | Total number of backend thread requests for writing data to Xlogs. |
| Output parameter | total_actual_xlog_sync_bytes | uint64 | Total number of Xlogs that call the **sync** API for disk flushing. |
| Output parameter | avg_write_bytes | uint32 | Number of Xlogs written each time the **XLogWrite** API is called. |
| Output parameter | avg_actual_write_bytes | uint32 | Number of Xlogs written each time the **write** API is called. |
| Output parameter | avg_sync_bytes | uint32 | Average number of Xlogs for requesting the **sync** API each time. |
| Output parameter | avg_actual_sync_bytes | uint32 | Actual number of Xlogs for disk flushing by calling the **sync** API each time. |
| Output parameter | total_write_time | uint64 | Total time for calling the **write** API (unit: μs). |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Category | Parameter | Type | Description |
| --- | --- | --- | --- |
| Output parameter | total_sync_time | uint64 | Total time for calling the **sync** API (unit: μs). |
| Output parameter | avg_write_time | uint32 | Average time for calling the **write** API each time (unit: μs). |
| Output parameter | avg_sync_time | uint32 | Average time for calling the **sync** API each time (unit: μs). |
| Output parameter | curr_init_xlog_segno | uint64 | ID of the latest Xlog segment file. |
| Output parameter | curr_open_xlog_segno | uint64 | ID of the Xlog segment file that is being written. |
| Output parameter | last_reset_time | text | Time when statistics were last collected. |
| Output parameter | curr_time | text | Current time. |

- pg_ls_tmpdir()

  Description: Returns the name, size, and last modification time of each file in the temporary directory (**pgsql_tmp**) of the default tablespace.

  Parameter: nan

  Return type: record

  Note: Only the system administrator or monitoring administrator can execute this function.

| Category | Parameter | Type | Description |
| --- | --- | --- | --- |
| Output parameter | name | text | File name |
| Output parameter | size | int8 | File size (unit: byte) |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| | | | |
|---|---|---|---|
| Output parameter | modification | timestamptz | Last file modification time |

- pg_ls_tmpdir(oid)

  Description: Returns the name, size, and last modification time of each file in the temporary directory (**pgsql_tmp**) of the specified tablespace.

  Parameter: oid

  Return type: record

  Note: Only the system administrator or monitoring administrator can execute this function.

| Category | Parameter | Type | Description |
|---|---|---|---|
| Input parameter | oid | oid | Tablespace ID |
| Output parameter | name | text | File name |
| Output parameter | size | int8 | File size (unit: byte) |
| Output parameter | modification | timestamptz | Last file modification time |

- pg_ls_waldir()

  Description: Returns the name, size, and last modification time of each file in the WAL directory.

  Parameter: nan

  Return type: record

  Note: Only the system administrator or monitoring administrator can execute this function.

| Category | Parameter | Type | Description |
|---|---|---|---|
| Output parameter | name | text | File name |
| Output parameter | size | int8 | File size (unit: byte) |
| Output parameter | modification | timestamptz | Last file modification time |

- gs_undo_dump_xid(undo_xid xid)

  Description: Parses undo records based on the XID.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-72** gs_undo_dump_xid parameter description

| Category | Parameter | Type | Description |
| --- | --- | --- | --- |
| Input parameter | undo_xid | xid | XID |
| Output parameter | undoptr | xid | Start position of the undo record to be parsed |
| Output parameter | xactid | text | XID |
| Output parameter | cid | text | Command ID |
| Output parameter | reloid | text | Relation OID |
| Output parameter | relfilenode | text | Relfinode of the file |
| Output parameter | utype | text | Undo record type |
| Output parameter | blkprev | text | Position of the previous undo record in the same block |
| Output parameter | blockno | text | Block number |
| Output parameter | uoffset | text | Undo record offset |
| Output parameter | prevurp | text | Position of the previous undo record |
| Output parameter | payloadlen | text | Length of the undo record data |
| Output parameter | oldxactid | text | Previous XID |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Category | Parameter | Type | Description |
| --- | --- | --- | --- |
| Output parameter | partitionoid | text | Partition OID |
| Output parameter | tablespace | text | Tablespace |
| Output parameter | alreadyread_bytes | text | Length of the read undo record |
| Output parameter | prev_undorec_len | text | Length of the previous undo record |
| Output parameter | td_id | text | ID of the transaction directory |
| Output parameter | reserved | text | Whether to save the information |
| Output parameter | flag | text | Flag 1 |
| Output parameter | flag2 | text | Flag 2 |
| Output parameter | t_hoff | text | Length of the undo record data header |

- gs_write_term_log(void)

  Description: Writes a log to record the current **term** value of a DN. The standby DN returns **false**. After the data is successfully written to the primary DN, **true** is returned.

  Return type: Boolean

## 12.5.27 Statistics Information Functions

Statistics information functions are divided into the following two categories: functions that access a database by using the OID of each table or index in the database to mark the database for which statistics are generated; functions that access a server identified by the server process ID whose value ranges from 1 to the number of currently active servers.

- pg_stat_get_db_conflict_tablespace(oid)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Specifies the number of queries canceled due to a conflict between the restored tablespace and the deleted tablespace in the database.

Return type: bigint

- pg_control_group_config()

  Description: Prints Cgroup configurations on the current node. Only users with the **sysadmin** permission can execute this function.

  Return type: record

- pg_stat_get_db_stat_reset_time(oid)

  Description: Specifies the most recent time when database statistics were reset. It is initialized to the system time during the first connection to each database. The reset time is updated when you call **pg_stat_reset** in the database and execute **pg_stat_reset_single_table_counters** on any table or index in the database.

  Return type: timestamptz

- pg_stat_get_function_total_time(oid)

  Description: Specifies the total wall clock time spent on the function, in microseconds. The time spent on this function call is included.

  Return type: bigint

- pg_stat_get_xact_tuples_returned(oid)

  Description: Specifies the number of rows read through sequential scans when parameters are in a table in the current transaction or the number of index entries returned when parameters are in an index.

  Return type: bigint

- pg_stat_get_xact_numscans(oid)

  Description: Specifies the number of sequential scans performed when parameters are in a table in the current transaction or the number of index scans performed when parameters are in an index.

  Return type: bigint

- pg_stat_get_xact_blocks_fetched(oid)

  Description: Specifies the number of disk block fetch requests for a table or an index in the current transaction.

  Return type: bigint

- pg_stat_get_xact_blocks_hit(oid)

  Description: Specifies the number of disk block fetch requests for a table or an index found in cache in the current transaction.

  Return type: bigint

- pg_stat_get_xact_function_calls(oid)

  Description: Specifies the number of times the function is called in the current transaction.

  Return type: bigint

- pg_stat_get_xact_function_self_time(oid)

  Description: Specifies the time spent only on this function in the current transaction. The time spent on this function call is not included.

  Return type: bigint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_stat_get_xact_function_total_time(oid)

  Description: Specifies the total wall clock time spent on this function in the current transaction, in microseconds. The time spent on this function call is included.

  Return type:

- pg_lock_status()

  Description: Queries information about locks held by open transactions. All users can execute this function.

  Return type: For details, see the return result of **15.3.126 PG_LOCKS**, which is obtained by querying this function.

- pg_stat_get_wal_senders()

  Description: Queries WAL sender information on the primary node.

  Return type: setofrecord

- pgxc_get_senders_catchup_time()

  Description: Queries whether a standby DN in the log catchup state exists in the CN instance query cluster and details about the log catchup state.

  Return type: setofrecord

- pg_stat_get_stream_replications()

  Description: Queries the primary-standby replication status.

  Return type: setofrecord

- pg_stat_get_db_numbackends(oid)

  Description: Specifies the number of active server processes in a database.

  Return type: integer

- pg_stat_get_db_xact_commit(oid)

  Description: Specifies the number of transactions committed in a database.

  Return type: bigint

- pg_stat_get_db_xact_rollback(oid)

  Description: Specifies the number of transactions rolled back in a database.

  Return type: bigint

- pg_stat_get_db_blocks_fetched(oid)

  Description: Specifies the number of disk block fetch requests in a database.

  Return type: bigint

- pg_stat_get_db_blocks_hit(oid)

  Description: Specifies the number of disk block fetch requests found in cache in a database.

  Return type: bigint

- pg_stat_get_db_tuples_returned(oid)

  Description: Specifies the number of tuples returned for a database.

  Return type: bigint

- pg_stat_get_db_tuples_fetched(oid)

  Description: Specifies the number of tuples fetched for a database.

  Return type: bigint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_stat_get_db_tuples_inserted(oid)

  Description: Specifies the number of tuples inserted into a database.

  Return type: bigint

- pg_stat_get_db_tuples_updated(oid)

  Description: Specifies the number of tuples updated in a database.

  Return type: bigint

- pg_stat_get_db_tuples_deleted(oid)

  Description: Specifies the number of tuples deleted from a database.

  Return type: bigint

- pg_stat_get_db_conflict_lock(oid)

  Description: Specifies the number of lock conflicts in a database.

  Return type: bigint

- pg_stat_get_db_deadlocks(oid)

  Description: Specifies the number of deadlocks in a database.

  Return type: bigint

- pg_stat_get_numscans(oid)

  Description: Specifies the number of rows read by sequential scans if parameters are in a table, or the number of index rows if parameters are in an index.

  Return type: bigint

- pg_stat_get_role_name(oid)

  Description: Obtains the username based on the user OID. Only users with the **sysadmin** or **monitor admin** permission can access the information.

  Return type: text

  Example:

  ```
  openGauss=# select pg_stat_get_role_name(10);
   pg_stat_get_role_name
  -----------------------
   aabbcc
  (1 row)
  ```

- pg_stat_get_tuples_returned(oid)

  Description: Specifies the number of rows read by sequential scans if parameters are in a table, or the number of index rows if parameters are in an index.

  Return type: bigint

- pg_stat_get_tuples_fetched(oid)

  Description: Specifies the number of table rows fetched by bitmap scans if parameters are in a table, or the number of table rows fetched by simple index scans if parameters are in an index.

  Return type: bigint

- pg_stat_get_tuples_inserted(oid)

  Description: Specifies the number of rows inserted into a table.

  Return type: bigint

- pg_stat_get_tuples_updated(oid)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Specifies the number of rows updated in a table.

Return type: bigint

- pg_stat_get_tuples_deleted(oid)

  Description: Specifies the number of rows deleted from a table.

  Return type: bigint

- pg_stat_get_tuples_changed(oid)

  Description: Specifies the total number of inserted, updated, and deleted rows after a table was last analyzed or autoanalyzed.

  Return type: bigint

- pg_stat_get_tuples_hot_updated(oid)

  Description: Specifies the number of rows hot updated in a table.

  Return type: bigint

- pg_stat_get_live_tuples(oid)

  Description: Specifies the number of live rows in a table.

  Return type: bigint

- pg_stat_get_dead_tuples(oid)

  Description: Specifies the number of dead rows in a table.

  Return type: bigint

- pg_stat_get_blocks_fetched(oid)

  Description: Specifies the number of disk block fetch requests for a table or an index.

  Return type: bigint

- pg_stat_get_blocks_hit(oid)

  Description: Specifies the number of disk block requests found in cache for a table or an index.

  Return type: bigint

- pg_stat_get_partition_tuples_inserted(oid)

  Description: Specifies the number of rows inserted into the corresponding table partition.

  Return type: bigint

- pg_stat_get_partition_tuples_updated(oid)

  Description: Specifies the number of rows updated in the corresponding table partition.

  Return type: bigint

- pg_stat_get_partition_tuples_deleted(oid)

  Description: Specifies the number of rows deleted from the corresponding table partition.

  Return type: bigint

- pg_stat_get_partition_tuples_changed(oid)

  Description: Specifies the total number of inserted, updated, and deleted rows after a table partition was last analyzed or autoanalyzed.

  Return type: bigint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_stat_get_partition_live_tuples(oid)

  Description: Specifies the number of live rows in a table partition.

  Return type: bigint
- pg_stat_get_partition_dead_tuples(oid)

  Description: Specifies the number of dead rows in a table partition.

  Return type: bigint
- pg_stat_get_xact_tuples_fetched(oid)

  Description: Specifies the number of tuple rows scanned in a transaction.

  Return type: bigint
- pg_stat_get_xact_tuples_inserted(oid)

  Description: Specifies the number of tuples inserted into the active subtransactions related to a table.

  Return type: bigint
- pg_stat_get_xact_tuples_deleted(oid)

  Description: Specifies the number of tuples deleted from the active subtransactions related to a table.

  Return type: bigint
- pg_stat_get_xact_tuples_hot_updated(oid)

  Description: Specifies the number of tuples hot updated in the active subtransactions related to a table.

  Return type: bigint
- pg_stat_get_xact_tuples_updated(oid)

  Description: Specifies the number of tuples updated in the active subtransactions related to a table.

  Return type: bigint
- pg_stat_get_xact_partition_tuples_inserted(oid)

  Description: Specifies the number of tuples inserted into the active subtransactions related to a table partition.

  Return type: bigint
- pg_stat_get_xact_partition_tuples_deleted(oid)

  Description: Specifies the number of tuples deleted from the active subtransactions related to a table partition.

  Return type: bigint
- pg_stat_get_xact_partition_tuples_hot_updated(oid)

  Description: Specifies the number of tuples hot updated in the active subtransactions related to a table partition.

  Return type: bigint
- pg_stat_get_xact_partition_tuples_updated(oid)

  Description: Specifies the number of tuples updated in the active subtransactions related to a table partition.

  Return type: bigint
- pg_stat_get_last_vacuum_time(oid)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Specifies the most recent time when the user manually cleared a table or when the autovacuum thread was started to clear a table.

Return type: timestamptz

- pg_stat_get_last_autovacuum_time(oid)

  Description: Specifies the most recent time when the autovacuum daemon was started to clear a table.

  Return type: timestamptz

- pg_stat_get_vacuum_count(oid)

  Description: Specifies the number of times a table is manually cleared by the user.

  Return type: bigint

- pg_stat_get_autovacuum_count(oid)

  Description: Specifies the number of times the autovacuum daemon is started to clear a table.

  Return type: bigint

- pg_stat_get_last_analyze_time(oid)

  Description: Specifies the most recent time when the user manually analyzed a table or when the autovacuum thread was started to analyze a table.

  Return type: timestamptz

- pg_stat_get_last_autoanalyze_time(oid)

  Description: Specifies the most recent time when the autovacuum daemon was started to analyze a table.

  Return type: timestamptz

- pg_stat_get_analyze_count(oid)

  Description: Specifies the number of times a table is manually analyzed by the user.

  Return type: bigint

- pg_stat_get_autoanalyze_count(oid)

  Description: Specifies the number of times a table is analyzed by the autovacuum daemon.

  Return type: bigint

- pg_total_autovac_tuples(bool)

  Description: Returns tuple records related to the total autovac, such as **nodename**, **nspname**, **relname**, and tuple IUDs. The input parameters specify whether to query **relation** and **local** information, respectively.

  Return type: setofrecord

- pg_autovac_status(oid)

  Description: Returns autovac information, such as **nodename**, **nspname**, **relname**, **analyze**, **vacuum**, thresholds for the ANALYZE and VACUUM operations, and the number of analyzed or vacuumed tuples. Only users with the **sysadmin** permission can use this function.

  Return type: setofrecord

- pg_autovac_timeout(oid)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Returns the number of consecutive timeouts during the autovac operation on a table. If the table information is invalid or the node information is abnormal, **NULL** is returned.

Return type: bigint

- pg_autovac_coordinator(oid)

  Description: Returns the name of the CN performing the autovac operation on a table. If the table information is invalid or the node information is abnormal, **NULL** is returned.

  Return type: text

- pg_stat_get_last_data_changed_time(oid)

  Description: Returns the time when INSERT, UPDATE, DELETE, or EXCHANGE/TRUNCATE/DROP PARTITION was performed last time on a table. The data in the **last_data_changed** column of the **15.3.149 PG_STAT_ALL_TABLES** view is calculated by using this function. The performance of obtaining the last modification time by using the view is poor when the table has a large amount of data. In this case, you are advised to use this function.

  Return type: timestamptz

- pg_stat_set_last_data_changed_time(oid)

  Description: Manually changes the time when INSERT, UPDATE, DELETE, or EXCHANGE/TRUNCATE/DROP PARTITION was performed last time on a table.

  Return type: void

- pg_backend_pid()

  Description: Specifies the thread ID of the server thread attached to the current session.

  Return type: integer

- pg_stat_get_activity(integer)

  Description: Returns a record about the background process with the specified PID. A record for each active background process in the system is returned if **NULL** is specified. The returned result does not contain the **connection_info** column. The initial user, system administrators, and users with the **monadmin** permission can view all data. Common users can query only their own data.

  Example:

```
openGauss=# select * from pg_stat_get_activity(139881386280704);
 datid |       pid       | sessionid | usesysid | application_name | state  |
query                      | waiting |          xact_start           |          query_start          |
    backend_start         |         state_change          | client_addr | client_hostname | client_port | enqueue
|     query_id      |   srespool   | global_sessionid | unique_sql_id | trace_id
-------+-----------------+-----------+----------+------------------+--------
+-----------------------------------------------------+---------+-------------------------------
+---------------------------------+-----
-------------------------+-----------------------------+-------------+-----------------+-------------+---------
+------------------+--------------+-----------------+---------------+----------
 16545 | 139881386280704 |        69 |       10 | gsql             | active | select * from

(1 row)
```

  Return type: setofrecord

- pg_stat_get_activity_with_conninfo(integer)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Returns a record about the background process with the specified PID. A record for each active background process in the system is returned if **NULL** is specified. The initial user, system administrators, and users with the **monadmin** permission can view all data. Common users can query only their own data.

```
openGauss=# select * from pg_stat_get_activity_with_conninfo(139881386280704);
 datid |       pid       | sessionid | usesysid | application_name | state  |
query                              | waiting |          xact_start           |          query_start
       |         backend_start         |         state_change          | client_addr | client_hostname | client_port
| enqueue |     query_id      |
      connection_info                                                       |   srespool   | global_sessionid |
unique_sql_id | trace_id

(1 row)
```

Return type: setofrecord

- pg_stat_get_activity_ng(integer)

  Description: Returns a record about the active backend thread with the specified PID. A record for each active backend thread is returned if **NULL** is specified. System administrators and users with the **monadmin** permission can view all data. Common users can query only their own data.

  Return type: setofrecord

  The following table describes return fields.

| Name | Type | Description |
| --- | --- | --- |
| datid | oid | Database OID |
| pid | bigin it | Background thread ID |
| sessioni d | bigin it | Session ID |
| node_gr oup | text | Logical cluster of the user to which the data belongs (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) |

- pg_user_iostat(text)

  Description: Displays the I/O load management information about the job currently executed by the user. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)

  Return type: record

  The following table describes return fields.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Type | Description |
| --- | --- | --- |
| userid | oid | User ID |
| min_curr_iops | int4 | Minimum I/O of the current user across each DN. The IOPS is counted by ones for column storage and by ten thousands for row storage. |
| max_curr_iops | int4 | Maximum I/O of the current user across each DN. The IOPS is counted by ones for column storage and by ten thousands for row storage. |
| min_peak_iops | int4 | Minimum peak I/O of the current user across each DN. The IOPS is counted by ones for column storage and by ten thousands for row storage. |
| max_peak_iops | int4 | Maximum peak I/O of the current user across each DN. The IOPS is counted by ones for column storage and by ten thousands for row storage. |
| io_limits | int4 | I/O limit set for the resource pool specified by the user. The IOPS is counted by ones for column storage and by ten thousands for row storage. |
| io_priority | text | I/O priority set by the user. The IOPS is counted by ones for column storage and by ten thousands for row storage. |
| curr_io_limits | int4 | Real-time value of **io_limits** when **io_priority** is used to control I/Os |

- pg_stat_get_function_calls(oid)

  Description: Specifies the number of times the function has been called.

  Return type: bigint

- pg_stat_get_function_self_time(oid)

  Description: Specifies the time spent on only this function. The time spent on nested functions to call other functions is excluded.

  Return type: bigint

- pg_stat_get_backend_idset()

  Description: Sets the number of currently active server processes (from 1 to the number of active server processes).

  Return type: setofinteger

- pg_stat_get_backend_pid(integer)

  Description: Specifies the ID of the given server thread.

  Return type: bigint

- pg_stat_get_backend_dbid(integer)

  Description: Specifies the ID of the database connected to the given server process.

  Return type: oid

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_stat_get_backend_userid(integer)

  Description: Specifies the user ID of the given server process. This function can be called only by the system administrator.

  Return type: oid

- pg_stat_get_backend_activity(integer)

  Description: Queries the current activity of the given server process. The query result can be obtained only when the user who calls this function is a system administrator or the same user as that of the session being queried and **track_activities** is enabled.

  Return type: text

- pg_stat_get_backend_waiting(integer)

  Description: Returns a true value if the given server process is waiting for a lock, but only when the user who calls this function is a system administrator or the same user as that of the session being queried and **track_activities** is enabled.

  Return type: Boolean

- pg_stat_get_backend_activity_start(integer)

  Description: Specifies the time when the given server process's currently executing query is started only when the user who calls this function is a system administrator or the same user as that of the session being queried and **track_activities** is enabled.

  Return type: timestamp with time zone

- pg_stat_get_backend_xact_start(integer)

  Description: Specifies the time when the given server process's currently executing transaction is started only when the user who calls this function is a system administrator or the same user as that of the session being queried and **track_activities** is enabled.

  Return type: timestamp with time zone

- pg_stat_get_backend_start(integer)

  Description: Specifies the time when the given server process is started. If the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** is returned.

  Return type: timestamp with time zone

- pg_stat_get_backend_client_addr(integer)

  Description: Specifies the IP address of the client connected to the given server process. If the connection is over a Unix domain socket, or if the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** is returned.

  Return type: inet

- pg_stat_get_backend_client_port(integer)

  Description: Specifies the TCP port number of the client connected to the given server process. If the connection is over a Unix domain socket, **–1** is returned. If the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** is returned.

  Return type: integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- pg_stat_get_bgwriter_timed_checkpoints()

  Description: Specifies the time when the background writer starts scheduled checkpoints (because the time specified by **checkpoint_timeout** has expired).

  Return type: bigint

- pg_stat_get_bgwriter_requested_checkpoints()

  Description: Specifies the time when the background writer starts checkpoints based on requests from the backend because the value specified by **checkpoint_segments** has been exceeded or the **CHECKPOINT** command has been executed.

  Return type: bigint

- pg_stat_get_bgwriter_buf_written_checkpoints()

  Description: Specifies the number of buffers written by the background writer during checkpoints.

  Return type: bigint

- pg_stat_get_bgwriter_buf_written_clean()

  Description: Specifies the number of buffers written by the background writer for routine cleaning of dirty pages.

  Return type: bigint

- pg_stat_get_bgwriter_maxwritten_clean()

  Description: Specifies the time when the background writer stops its cleaning scan because it has written more buffers than those specified by the **bgwriter_lru_maxpages** parameter.

  Return type: bigint

- pg_stat_get_buf_written_backend()

  Description: Specifies the number of buffers written by the backend process because a new buffer needs to be allocated.

  Return type: bigint

- pg_stat_get_buf_alloc()

  Description: Specifies the total number of the allocated buffers.

  Return type: bigint

- pg_stat_clear_snapshot()

  Description: Discards the current statistics snapshot. Only users with the **sysadmin** or **monitoradmin** permission can execute this function.

  Return type: void

- pg_stat_reset()

  Description: Resets all statistics counters for the current database to zero (requiring system administrator permissions).

  Return type: void

- gs_stat_reset()

  Description: Resets all statistics counters for the current database on each node to zero (requiring system administrator permissions).

  Return type: void

- pg_stat_reset_shared(text)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Resets all statistics counters for the current database on each node in a shared cluster to zero (requiring system administrator permissions).

Return type: void

- pg_stat_reset_single_table_counters(oid)

  Description: Resets statistics on a single table or index in the current database to zero (requiring system administrator permissions).

  Return type: void

- pg_stat_reset_single_function_counters(oid)

  Description: Resets statistics on a single function in the current database to zero (requiring system administrator permissions).

  Return type: void

- pg_stat_session_cu(int, int, int)

  Description: Obtains the compression unit (CU) hit statistics on sessions running on the current node.

  Return type: record

- gs_get_stat_session_cu(text, int, int, int)

  Description: Obtains the CU hit statistics on all sessions running in a cluster.

  Return type: record

- gs_get_stat_db_cu(text, text, bigint, bigint, bigint)

  Description: Obtains the CU hit statistics on a database in a cluster.

  Return type: record

- pg_stat_get_cu_mem_hit(oid)

  Description: Obtains the number of memory CU hits of a column-store table in the current database on the current node.

  Return type: bigint

- pg_stat_get_cu_hdd_sync(oid)

  Description: Obtains the times CU is synchronously read from a disk by a column-store table in the current database on the current node.

  Return type: bigint

- pg_stat_get_cu_hdd_asyn(oid)

  Description: Obtains the times CU is asynchronously read from a disk by a column-store table in the current database on the current node.

  Return type: bigint

- pg_stat_get_db_cu_mem_hit(oid)

  Description: Obtains the number of memory CU hits in a database on the current node.

  Return type: bigint

- pg_stat_get_db_cu_hdd_sync(oid)

  Description: Obtains the times CU is synchronously read from a disk in a database on the current node.

  Return type: bigint

- pgxc_get_wlm_current_instance_info(text, int default null)

  Description: Queries the current resource usage of each node in a cluster on a CN and reads the data that is not stored in the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**GS_WLM_INSTANCE_HISTORY** system catalog in the memory. The input parameters are the node name (**ALL**, **C**, **D**, or *Instance name*) and the maximum number of records returned by each node. The return value is **GS_WLM_INSTANCE_HISTORY**.

Return type: setofrecord

- pgxc_get_wlm_history_instance_info(text, TIMESTAMP, TIMESTAMP, int default null)

  Description: Queries the historical resource usage in a cluster on a CN and reads data from the **GS_WLM_INSTANCE_HISTORY** system catalog. The input parameters are the node name (**ALL**, **C**, **D**, or *Instance name*), start time, end time, and maximum number of records returned by each instance. The return value is **GS_WLM_INSTANCE_HISTORY**.

  Return type: setofrecord

- pg_stat_get_db_cu_hdd_asyn(oid)

  Description: Obtains the times CU is asynchronously read from a disk in a database on the current node.

  Return type: bigint

- pgxc_fenced_udf_process(integer)

  Description: Displays the number of UDF master and worker processes. Only users with the **sysadmin** or **monadmin** permission can execute this function. If the input parameter is set to **1**, the number of master processes is queried. If the input parameter is set to **2**, the number of worker processes is queried. If the input parameter is set to **3**, all worker processes are killed.

  Return type: text

- fenced_udf_process()

  Description: Displays the number of local UDF master and worker processes.

  Return type: record

- total_cpu()

  Description: Obtains the CPU time used by the current node, in jiffies.

  Return type: bigint

- total_memory()

  Description: Obtains the size of the virtual memory used by the current node, in KB.

  Return type: bigint

- pgxc_terminate_all_fenced_udf_process()

  Description: Kills all UDF worker processes. Only users with the **sysadmin** or **monadmin** permission can execute this function.

  Return type: Boolean

- GS_ALL_NODEGROUP_CONTROL_GROUP_INFO(text)

  Description: Provides Cgroup information for all logical clusters. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) Before calling this function, you need to specify the name of the logical cluster to be queried. For example, to query the Cgroup information for the **'installation'** logical cluster, run the following command:

  ```
  SELECT * FROM GS_ALL_NODEGROUP_CONTROL_GROUP_INFO('installation')
  ```

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

The following table describes return fields.

| Name | Type | Description |
| --- | --- | --- |
| name | text | Cgroup name |
| type | text | Cgroup type |
| gid | bigint | Cgroup ID |
| classgid | bigint | ID of the class Cgroup to which a workload Cgroup belongs |
| class | text | Class Cgroup |
| workload | text | Workload Cgroup |
| shares | bigint | CPU quota allocated to a Cgroup |
| limits | bigint | Limit of CPUs allocated to a Cgroup |
| wdlevel | bigint | Workload Cgroup level |
| cpucores | text | Usage of CPU cores in a Cgroup |

- gs_get_nodegroup_tablecount(name)

  Description: Obtains the total number of user tables in all databases in a logical cluster. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)

  Return type: integer

- pgxc_max_datanode_size(name)

  Description: Obtains the maximum disk space occupied by database files on all DNs in a logical cluster. The unit is byte. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)

  Return type: bigint

- gs_check_logic_cluster_consistency()

  Description: Checks whether the system information of all logical clusters in the system is consistent. If no record is returned, the information is consistent. Otherwise, the node group information on CNs and DNs in the logical cluster is inconsistent. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) This function cannot be called during redistribution in scale-in or scale-out.

  Return type: record

- gs_check_tables_distribution()

  Description: Checks whether the user table distribution in the system is consistent. If no record is returned, table distribution is consistent. This function cannot be called during redistribution in scale-in or scale-out.

  Return type: record

- pg_stat_bad_block(text, int, int, int, int, int, timestamp with time zone, timestamp with time zone)

  Description: Obtains damage information about pages or CUs after the current node is started.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: record

- pgxc_stat_bad_block(text, int, int, int, int, int, timestamp with time zone, timestamp with time zone)

  Description: Obtains damage information about pages or CUs after all nodes in the cluster are started.

  Return type: record

- pg_stat_bad_block_clear()

  Description: Deletes the page or CU damage information that is read and recorded on the node (requiring system administrator permissions).

  Return type: void

- pgxc_stat_bad_block_clear

  Description: Deletes the page or CU damage information that is read and recorded on all nodes in the cluster (requiring system administrator permissions).

  Return type: void

- pgxc_log_comm_status(void)

  Description: When the TCP proxy communication is used, the PGXC system view exports the communication layer status of DNs to each log file.

  Return type: void

- gs_respool_exception_info(pool text)

  Description: Queries the query rule of a specified resource pool.

  Return type: record

- gs_control_group_info(pool text)

  Description: Queries information about Cgroups associated with a resource pool. Only users with the **sysadmin** permission can execute this function.

  Return type: record

  The following information is displayed:

| Attribute | Value | Description |
| --- | --- | --- |
| name | class_a:workload_a1 | Class name and workload name |
| class | class_a | Class Cgroup name |
| workload | workload_a1 | Workload Cgroup name |
| type | DEFWD | Cgroup type (**Top**, **CLASS**, **BAKWD**, **DEFWD**, or **TSWD**) |
| gid | 87 | Cgroup ID |
| shares | 30 | Percentage of CPU resources to those on the parent node |
| limits | 0 | Percentage of CPU cores to those on the parent node |
| rate | 0 | Allocation ratio in Timeshare |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Attribute | Value | Description |
| --- | --- | --- |
| cpucores | 0-3 | Number of CPU cores |

- gs_all_control_group_info()

  Description: Collects information about all Cgroups in the database. For details about the columns returned by the function, see **16.3.48 GS_ALL_CONTROL_GROUP_INFO**.

  Return type: record

- gs_get_control_group_info()

  Description: Collects information about all Cgroups. For details about the columns returned by the function, see **16.3.53 GS_GET_CONTROL_GROUP_INFO**. Only users with the **sysadmin** permission can execute this function.

  Return type: record

- get_instr_workload_info(integer)

  Description: Obtains the transaction volume and time information on the current CN.

  Return type: record

| Attribute | Value | Description |
| --- | --- | --- |
| user_oid | 10 | User ID |
| commit_counter | 4 | Number of frontend transactions that were committed |
| rollback_counter | 1 | Number of frontend transactions that were rolled back |
| resp_min | 949 | Minimum response time of frontend transactions (unit: μs) |
| resp_max | 201891 | Maximum response time of frontend transactions (unit: μs) |
| resp_avg | 43564 | Average response time of frontend transactions (unit: μs) |
| resp_total | 217822 | Total response time of frontend transactions (unit: μs) |
| bg_commit_counter | 910 | Number of background transactions that were committed |
| bg_rollback_counter | 0 | Number of background transactions that were rolled back |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Attribute | Value | Description |
| --- | --- | --- |
| bg_resp_min | 97 | Minimum response time of background transactions (unit: μs) |
| bg_resp_max | 678080687 | Maximum response time of background transactions (unit: μs) |
| bg_resp_avg | 327847884 | Average response time of background transactions (unit: μs) |
| bg_resp_total | 298341575300 | Total response time of background transactions (unit: μs) |

- pv_instance_time()

  Description: Obtains the time consumed in each key phase on the current node.

  Return type: record

| Stat_name Attribute | Value | Description |
| --- | --- | --- |
| DB_TIME | 1062385 | Total end-to-end wall time consumed by all threads (unit: μs) |
| CPU_TIME | 311777 | Total CPU time consumed by all threads (unit: μs) |
| EXECUTION_TIME | 380037 | Total time consumed on the executor (unit: μs) |
| PARSE_TIME | 6033 | Total time consumed for parsing SQL statements (unit: μs) |
| PLAN_TIME | 173356 | Total time consumed for generating an execution plan (unit: μs) |
| REWRITE_TIME | 2274 | Total time consumed for rewriting queries (unit: μs) |
| PL_EXECUTION_TIME | 0 | Total time consumed for executing PL/SQL statements (unit: μs) |
| PL_COMPILATION_TIME | 557 | Total time consumed for compiling SQL statements (unit: μs) |
| NET_SEND_TIME | 1673 | Total time consumed for sending data over the network (unit: μs) |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Stat_name Attribute | Value | Description |
| --- | --- | --- |
| DATA_IO_TIME | 426622 | Total time consumed for reading and writing data (unit: μs) |

- DBE_PERF.get_global_instance_time()

  Description: Provides the time consumed in each key phase in the entire cluster. The time consumed can be queried only on the CN.

  Return type: record

- get_instr_unique_sql()

  Description: Obtains information about execution statements (normalized SQL statements) on the current node. Only users with the **sysadmin** or **monitor admin** permission can query this function.

  Return type: record

- get_instr_wait_event(integer)

  Description: Obtains the statistics on wait events on the current node.

  Return type: record

- get_instr_user_login()

  Description: Obtains the number of user login and logout times on the current node. Only users with the **sysadmin** or **monitor admin** permission can query this function.

  Return type: record

- get_instr_rt_percentile(integer)

  Description: Obtains the response time distribution for 80% and 95% SQL statements in the CCN. The unified cluster information is stored on the CCN. The query result from other nodes is **0**.

  Return type: record

- get_node_stat_reset_time()

  Description: Obtains statistics on reset (restart, primary-standby switchover, and database deletion) time of the current node.

  Return type: record

- gs_session_memory_detail_tp()

  Description: Collects statistics on thread memory usage by the MemoryContext node. When **enable_thread_pool** is set to **on**, this view contains memory usage of all threads and sessions.

  Return type: record

- create_wlm_operator_info(int flag)

  Description: Clears top SQL operator-level statistics recorded in the current memory. If the input parameter is greater than 0, the information is archived to **gs_wlm_operator_info** and **gs_wlm_ec_operator_info**. Otherwise, the information is not archived. Only users with the **sysadmin** permission can execute this function.

  Return type: int

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- create_wlm_session_info(int flag)

  Description: Clears top SQL query statement-level statistics recorded in the current memory. If the input parameter is greater than 0, the information is archived to **gs_wlm_session_query_info_all**. Otherwise, the information is not archived. Only users with the **sysadmin** permission can execute this function.

  Return type: int

- pg_stat_get_wlm_session_info(int flag)

  Description: Obtains top SQL query statement-level statistics recorded in the current memory. If the input parameter is not 0, the information is cleared from the memory. Only users with the **system admin** or **monitor admin** permission can execute this function.

  Return type: record

- gs_paxos_stat_replication()

  Description: Queries the standby node information on the primary node. Currently, the distributed mode is not supported.

- get_paxos_replication_info()

  Description: Queries the primary-standby replication information. Currently, the distributed mode is not supported.

- gs_wlm_get_resource_pool_info(int)

  Description: Obtains the resource usage statistics of all users. The input parameter is of the int type and can be any int value or **NULL**.

  Return type: record

- gs_wlm_get_all_user_resource_info()

  Description: Obtains the resource usage statistics of all users. Only users with the **sysadmin** permission can execute this function.

  Return type: record

- gs_wlm_get_user_info(int)

  Description: Obtains information about all users. The input parameter is of the int type and can be any int value or **NULL**. Only users with the **sysadmin** permission can execute this function.

  Return type: record

- gs_wlm_get_workload_records()

  Description: Obtains all job information in dynamic load management. This function is valid only when dynamic load management is enabled. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)

  Return type: record

- gs_wlm_persistent_user_resource_info()

  Description: Archives all user resource usage statistics to the **gs_wlm_user_resource_history** system catalog. Only users with the **sysadmin** permission can execute this function.

  Return type: record

- gs_wlm_readjust_user_space(oid)

  Description: Corrects the storage space usage of all users. Only the administrator can execute this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: record

- gs_wlm_readjust_user_space_through_username(text name)

  Description: Corrects the storage space usage of a specified user. Common users can use this function to correct only their own storage space usage. Only the administrator can correct the storage space usage of all users. If the value of **name** is **0000**, the storage space usage of all users needs to be corrected.

  Return type: record

- gs_wlm_readjust_user_space_with_reset_flag(text name, boolean isfirst)

  Description: Corrects the storage space usage of a specified user. If the input parameter **isfirst** is set to **true**, statistics are collected from 0. Otherwise, statistics are collected from the previous result. Common users can use this function to correct only their own storage space usage. Only the administrator can correct the storage space usage of all users. If the value of **name** is **0000**, the storage space usage of all users needs to be corrected.

  Return type: record

- gs_wlm_session_respool(bigint)

  Description: Obtains the session resource pool information about all backend threads. The input parameter is of the bigint type and can be set to any bigint value or **NULL**.

  Return type: record

- gs_total_nodegroup_memory_detail

  Description: Returns statistics on memory usage of the logical cluster in the current database, in the unit of MB. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.)

  NOTE

  If **enable_memory_limit** is set to **off**, this function cannot be used.

  Return type: setof record

**Table 12-73** Return value description

| Name | Type | Description |
| --- | --- | --- |
| ngname | text | Name of the logical cluster |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Type | Description |
| --- | --- | --- |
| memorytype | text | Memory type. The value must be one of the following:<br>• **ng_total_memory**: total memory of the logical cluster<br>• **ng_used_memory**: memory usage of the logical cluster<br>• **ng_estimate_memory**: estimated memory usage of the logical cluster<br>• **ng_foreignrp_memsize**: total memory of the external resource pool of the logical cluster<br>• **ng_foreignrp_usedsize**: memory usage of the external resource pool of the logical cluster<br>• **ng_foreignrp_peaksize**: peak memory usage of the external resource pool of the logical cluster<br>• **ng_foreignrp_mempct**: percentage of the external resource pool of the logical cluster to the total memory of the logical cluster<br>• **ng_foreignrp_estmsize**: estimated memory usage of the external resource pool of the logical cluster |
| memorymbytes | integer | Size of allocated memory |

- gs_io_wait_status()

  Description: Returns the real-time statistics on I/O control on the current node.

  Return type: setof record

| Name | Type | Description |
| --- | --- | --- |
| node_name | text | Node name |
| device_name | text | Name of the data disk mounted to the node |
| read_per_second | float | Number of read operations completed per second |
| write_per_second | float | Number of write operations completed per second |
| write_ratio | float | Ratio of the disk write I/Os to the total I/Os |
| io_util | float | Percentage of the I/O time to the total CPU time per second |
| total_io_util | integer | Level of the CPU time occupied by the last three I/Os. The value ranges from 0 to 6. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Type | Description |
| --- | --- | --- |
| tick_count | integer | Interval for updating disk I/O information. The value is fixed to 1 second. The value is cleared each time before data is read. |
| io_wait_list_len | integer | Size of the I/O request thread wait queue. If the value is **0**, no I/O is under control. |

- gs_get_shared_memctx_detail(text)

  Description: Returns the memory allocation details of the specified memory context, including the file, line number, and size of each memory allocation (the size of the same line in the same file is accumulated). Only the memory context queried through the **pg_shared_memory_detail** view can be queried. The input parameter is the memory context name (that is, the **contextname** column in the result returned by the **pg_shared_memory_detail** view). Only users with the sysadmin or monitor admin permission can query this function.

  Return type: setof record

| Name | Type | Description |
| --- | --- | --- |
| file | text | Name of the file where the memory is allocated to |
| line | int8 | Line number of the code in the file where the memory is allocated to |
| size | int8 | Size of the allocated memory. The value is accumulated if the memory is allocated for multiple times to the same line in the same file. |

  NOTE

  This view is not supported in the Lite release version.

- gs_get_session_memctx_detail(text)

  Description: Returns the memory allocation details of the specified memory context, including the file, line number, and size of each memory allocation (the size of the same line in the same file is accumulated). This function is valid only in thread pool mode. Only the memory context queried through the **pv_session_memory_context** view can be queried. The input parameter is the memory context name (that is, the **contextname** column in the result returned by the **pv_session_memory_context** view). Only users with the sysadmin or monitor admin permission can query this function.

  Return type: setof record

| Name | Type | Description |
| --- | --- | --- |
| file | text | Name of the file where the memory is allocated to |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Type | Description |
| --- | --- | --- |
| line | int8 | Line number of the code in the file where the memory is allocated to |
| size | int8 | Size of the allocated memory, in bytes. The value is accumulated if the memory is allocated for multiple times to the same line of the same file. |

NOTE

This view takes effect only in thread pool mode and is not supported in the Lite release version.

- gs_get_thread_memctx_detail(tid,text)

  Description: Returns the memory allocation details of the specified memory context, including the file, line number, and size of each memory allocation (the size of the same line in the same file is accumulated). Only the memory context queried through the **pv_thread_memory_context** view can be queried. The first input parameter is the thread ID (the **tid** column of the data returned by **pv_thread_memory_context**), and the second parameter is the memory context name (the **contextname** column of the data returned by **pv_thread_memory_context**). Only users with the sysadmin or monitor admin permission can query this function.

  Return type: setof record

| Name | Type | Description |
| --- | --- | --- |
| file | text | Name of the file where the memory is allocated to |
| line | int8 | Line number of the code in the file where the memory is allocated to |
| size | int8 | Size of the allocated memory, in bytes. The value is accumulated if the memory is allocated for multiple times to the same line of the same file. |

NOTE

This view is not supported in the Lite release version.

- gs_get_history_memory_detail(cstring)

  Description: Queries historical memory snapshot information. The input parameter type is cstring. The value can be **NULL** or the name of the memory snapshot log file.

  a. If the value of the input parameter is **NULL**, the list of all memory snapshot log files on the current node is displayed.

  b. If the value of the input parameter is the name of the memory snapshot log file in the list queried in **a**, the detailed information about the memory snapshot recorded in the log file is displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

c. If you enter any other input parameter, the system displays a message indicating that the input parameter is incorrect or the file fails to be opened.

Only users with the sysadmin or monitor admin permission can query this function.

Return type: text

| Name | Type | Description |
| --- | --- | --- |
| memory_info | text | Memory information. If the input parameter of the function is set to **NULL**, the memory snapshot file list is displayed. If the input parameter is set to the name of the memory snapshot file, the content of the file is displayed. |

- gs_stat_get_hotkeys_info()

  NOTE

  If the GUC parameter **enable_hotkeys_collection** is set to **off**, the **gs_stat_get_hotkeys_info** and **global_stat_get_hotkeys_info** functions as well as the **global_stat_hotkeys_info** view cannot be queried. The use of the **gs_stat_clean_hotkeys** and **global_stat_clean_hotkeys** interfaces is not affected.

  Description: Obtains the hotspot key statistics on the current node.

  Return type: record

```
openGauss=# select * from gs_stat_get_hotkeys_info() order by count, hash_value;
 database_name | schema_name |     table_name     | key_value | hash_value | count
---------------+-------------+--------------------+-----------+------------+-------
 regression    | public      | hotkey_single_col | {22}      | 1858004829 |     2
 regression    | public      | hotkey_single_col | {11}      | 2011968649 |     2
(2 rows)
```

  Table 1 Return value description

| Name | Type | Description |
| --- | --- | --- |
| database_name | text | Name of the database where the hotspot key is located |
| schema_name | text | Name of the schema where the hotspot key is located |
| table_name | text | Name of the table where the hotspot key is located |
| key_value | text | Value of the hotspot key |
| hash_value | bigint | Hash value of the hotspot key in the database. If the table is a list or range distribution table, the value of this field is **0**. |
| count | bigint | Frequency of accessing the hotspot key |

- gs_stat_clean_hotkeys()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- Hotspot key detection is designed for high-concurrency and heavy-traffic scenarios. In the scenario where the access is performed for several times, the clearing query result may be inaccurate.
- The clearing interface is designed to clear only the statistics in the LRU queue but not the historical data in the FIFO. Therefore, if the historical key value in the FIFO is accessed again after the clearing, the historical key value is still processed as a hotspot key. This rule also applies to **global_stat_clean_hotkeys**.

Description: Clears statistics on hotspot keys on the current node.

Return type: Boolean

```
openGauss=# select * from gs_stat_clean_hotkeys();
 gs_stat_clean_hotkeys
-----------------------
 t
(1 row)
```

- global_stat_get_hotkeys_info()

  NOTE

  Run the **select * from global_stat_hotkeys_info minus select * from global_stat_get_hotkeys_info()** command during service execution. The value may not be **0** due to time difference.

  Description: Obtains statistics on hotspot keys in the entire cluster.

  Return type: record

```
openGauss=# select * from global_stat_get_hotkeys_info() order by count, hash_value;
 database_name | schema_name |    table_name     | key_value | hash_value | count
---------------+-------------+-------------------+-----------+------------+-------
 regression    | public      | hotkey_single_col | {22}      | 1858004829 |     2
 regression    | public      | hotkey_single_col | {11}      | 2011968649 |     2
(2 rows)
```

- global_stat_clean_hotkeys()

  Description: Clears statistics on hotspot keys in the entire cluster.

  Return type: Boolean

```
openGauss=# select * from global_stat_clean_hotkeys();
 global_stat_clean_hotkeys
-----------------------
 t
(1 row)
```

- global_comm_get_recv_stream()

  Description: Obtains the status of the stream received by all communication libraries on all DNs. For details about the columns returned by the function, see **15.3.116 PG_COMM_RECV_STREAM**.

  Return type: record

- global_comm_get_send_stream()

  Description: Obtains the status of the stream sent by all communication libraries on all DNs. For details about the columns returned by the function, see **15.3.117 PG_COMM_SEND_STREAM**.

  Return type: record

- global_comm_get_status()

  Description: Obtains the communication library status on all DNs. For details about the columns returned by the function, see **15.3.118 PG_COMM_STATUS**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: record

- global_comm_client_info()

  Description: Obtains information about active client connections of global nodes. For details about the columns returned by the function, see **15.3.29 COMM_CLIENT_INFO**.

  Return type: record

- global_comm_get_client_info()

  Description: Obtains information about client connections of global nodes. For details about the columns returned by the function, see **15.3.29 COMM_CLIENT_INFO**.

  Return type: record

- pgxc_get_wlm_ec_operator_history()

  Description: Displays the operator information when the execution of ExtensionConnector (EC) jobs cached on all CNs is complete. The information is cleared every 3 minutes. Only users with the **sysadmin** permission can execute this function.

  Return type: record

- pgxc_get_wlm_ec_operator_info()

  Description: Displays the operator information when the execution of EC jobs on all CNs is complete. Only users with the **sysadmin** permission can execute this function.

  Return type: record

- pgxc_get_wlm_ec_operator_statistics()

  Description: Displays the operator information when EC jobs on all CNs are being executed. Only users with the **sysadmin** permission can execute this function.

  Return type: record

- pgxc_get_wlm_operator_history()

  Description: Displays the operator information when the execution of jobs cached on all CNs is complete. The information is cleared every 3 minutes. Only users with the **sysadmin** permission can execute this function.

  Return type: record

- pgxc_get_wlm_operator_info()

  Description: Displays the operator information when the execution of jobs on all CNs is complete. Only users with the **sysadmin** permission can execute this function.

  Return type: record

- pgxc_get_wlm_operator_statistics()

  Description: Displays the operator information when jobs on all CNs are being executed. Only users with the **sysadmin** permission can execute this function.

  Return type: record

- pgxc_get_wlm_session_history()

  Description: Displays the load management information when the execution of jobs cached on all CNs is complete. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) The

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

information is cleared every 3 minutes. Only users with the **sysadmin** permission can execute this function.

Return type: record

- pgxc_get_wlm_session_info()

  Description: Displays the load management information when the execution of jobs cached on all CNs is complete. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) Only users with the **sysadmin** permission can execute this function.

  Return type: record

- pgxc_get_wlm_session_info_bytime(tag text, begin timestamp, end timestamp, limit int)

  Description: Displays load management information of jobs whose start or end time is within a time range on all CNs. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) Only users with the **sysadmin** permission can execute this function.

  Parameter description:

  **tag**: The value can only be **'start_time'** or **'finish_time'**, indicating that the query is restricted by the start time or end time of the job.

  **begin**: start time of a time range

  **end**: end time of a time range

  **limit**: number of returned records

  Return type: record

- pgxc_get_wlm_session_statistics()

  Description: Displays load management information when jobs on all CNs are being executed. (The current feature is a lab feature. Contact Huawei engineers for technical support before using it.) Only users with the **sysadmin** permission can execute this function.

  Return type: record

- pgxc_stat_activity()

  Description: Displays information about all CNs in the current cluster queried by the current user. Only users with the **sysadmin** or **monitor admin** permission can execute this function, and common users can view only their own information.

  Return type: record

| Name | Type | Description |
| --- | --- | --- |
| coorname | text | Name of a CN in the current cluster |
| datid | oid | OID of the database that the user session connects to in the background |
| datname | text | Name of the database that the user session connects to in the background |
| pid | bigint | Backend thread ID |
| sessionid | bigint | Session ID |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Type | Description |
| --- | --- | --- |
| usesysid | oid | OID of the user logged in to the background |
| usename | text | Name of the user logged in to the background |
| application_name | text | Name of the application connected to the background |
| client_addr | inet | IP address of the client connected to the background. If this column is null, it indicates either that the client is connected via a Unix socket on the server machine or that this is an internal process, such as autovacuum. |
| client_hostname | text | Host name of the connected client, as reported by a reverse DNS lookup of **client_addr**. This column is not null only for IP connections and only when **log_hostname** is enabled. |
| client_port | integer | TCP port number that the client uses for communication with the background (**–1** if a Unix socket is used) |
| backend_start | timestamp with time zone | Time when this process was started, that is, when the client connected to the server |
| xact_start | timestamp with time zone | Time when the current transaction was started (null if no transactions are active) If the current query is the first of its transaction, the value of this column is the same as that of the **query_start** column. |
| query_start | timestamp with time zone | Time when the currently active query was started, or time when the last query was started if the value of **state** is not **active** |
| state_change | timestamp with time zone | Time when **state** was last modified |
| waiting | boolean | Whether the background is currently waiting for a lock. If it is, the value is **true**. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Type | Description |
| --- | --- | --- |
| enqueue | text | Queuing state of a statement.<br>Possible values are:<br>• **waiting in queue**: The statement is in the queue.<br>• **Empty**: The statement is being executed. |
| state | text | Overall state of the background.<br>Possible values are:<br>• **active**: The background is executing a query.<br>• **idle**: The background is waiting for a new client command.<br>• **idle in transaction**: The background is in a transaction, but there is no statement being executed in the transaction.<br>• **idle in transaction** (aborted): The background is in a transaction, but there are statements failed in the transaction.<br>• **fastpath function call**: The background is executing a fast-path function.<br>• **disabled**: This state is reported if **track_activities** is disabled in the background.<br>**NOTE**<br>Only system administrators can view the session state of their accounts. The state information of other accounts is empty. For example, after user **judy** is connected to the database, the state information of user **joe** and the initial user **omm** in **pgxc_stat_activity** is empty.<br>SELECT datname, usename, usesysid, state,pid FROM pgxc_stat_activity;<br>datname \| usename \| usesysid \| state \| pid<br>----------+---------+----------+--------+-----------------<br>postgres \| omm \| 10 \| \| 139968752121616<br>postgres \| omm \| 10 \| \| 139968903116560<br>db_tpcds \| judy \| 16398 \| active \| 139968391403280<br>postgres \| omm \| 10 \| \| 139968643069712<br>postgres \| omm \| 10 \| \| 139968680818448<br>postgres \| joe \| 16390 \| \| 139968563377936<br>(6 rows) |

| Name | Type | Description |
| --- | --- | --- |
| resource_pool | name | Resource pool used by the user |
| query_id | bigint | ID of a query |
| query | text | Latest query in the background If the value of **state** is **active**, this column shows the ongoing query. In all other states, it shows the last query that was executed. |
| global_sessionid | text | Global session ID |
| unique_sql_id | bigint | Unique SQL statement ID |
| trace_id | text | Driver-specific trace ID, which is associated with an application request |

- pgxc_stat_activity_with_conninfo()

  Description: Displays query information about the current user on all CNs in the current cluster. For details, see the **pgxc_stat_activity** view. Only users with the **sysadmin** or **monitor admin** permission can execute this function, and common users can view only their own information.

  Return type: record

- pgxc_stat_all_tables()

  Description: Displays statistics on a row in each table (including TOAST tables) on each node. Only users with the **sysadmin** or **monitor admin** permission can execute this function.

  Return type: record

- pgxc_get_thread_wait_status()

  Description: Queries the call hierarchy between threads generated by all SQL statements on each node in a cluster and the block waiting status of each thread.

  Return type: record

- pgxc_wlm_get_workload_records()

  Description: Displays the status information when jobs on all CNs are being executed. Only system administrators can execute this function.

  Return type: record

- pv_session_memory

  Description: Collects statistics on memory usage at the session level, including all the memory allocated to Postgres and stream threads on DNs for jobs currently executed by users.

  NOTE

  If **enable_memory_limit** is set to **off**, this function cannot be used.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-74** Return value description

| Name | Type | Description |
| --- | --- | --- |
| sessid | text | Thread start time and ID |
| init_mem | integer | Memory allocated to the currently executed jobs before they enter the executor, in MB |
| used_mem | integer | Memory allocated to the currently executed jobs, in MB |
| peak_mem | integer | Peak memory allocated to the currently executed jobs, in MB |

- dbe_perf.gs_stat_activity_timeout(int)

  Description: Obtains information about query jobs whose execution time exceeds the timeout threshold on the current node. The correct result can be returned only when the GUC parameter **track_activities** is set to **on**. The timeout threshold ranges from 0 to 2147483.

  Return type: setof record

| Name | Type | Description |
| --- | --- | --- |
| database | name | Name of the database connected to the user session |
| pid | bigint | Backend thread ID |
| sessionid | bigint | Session ID |
| usesysid | oid | OID of the user logged in to the background |
| application_name | text | Name of the application connected to the background |
| query | text | Query that is being executed in the background |
| xact_start | timestamptz | Time when the current transaction is started |
| query_start | timestamptz | Time when the current query starts |
| query_id | bigint | Query statement ID |

- dbe_perf.global_stat_activity_timeout(int)

  Description: Obtains information about query jobs whose execution time exceeds the timeout threshold in the current system (all CNs). The correct result can be returned only when the GUC parameter **track_activities** is set to **on**. The timeout threshold ranges from 0 to 2147483.

  Return type: setof record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Type | Description |
| --- | --- | --- |
| nodename | text | Name of the CN connected to the user session |
| database | name | Name of the database connected to the user session |
| pid | bigint | Backend thread ID |
| sessionid | bigint | Session ID |
| usesysid | oid | OID of the user logged in to the background |
| application_name | text | Name of the application connected to the background |
| query | text | Query that is being executed in the background |
| xact_start | timestamptz | Time when the current transaction is started |
| query_start | timestamptz | Time when the current query starts |
| query_id | bigint | Query statement ID |

- dbe_perf.get_average_value()

  Description: Obtains statistics on reset (restart, primary-standby switchover, and database deletion) time of the current node.

  Return type: record

- DBE_PERF.get_global_active_session()

  Description: Displays a summary of samples in the **ACTIVE SESSION PROFILE** memory on all nodes.

  Return type: record

- DBE_PERF.get_global_os_runtime()

  Description: Displays the running status of the current OS. This function can be queried only on CNs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_os_threads()

  Description: Provides thread status information on all normal nodes in the entire cluster. The information can be queried only on CNs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_os_threads()

  Description: Provides thread status information on all normal nodes in the entire cluster. The information can be queried only on CNs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: record

- DBE_PERF.get_summary_workload_sql_count()

  Description: Provides the count information of SELECT, UPDATE, INSERT, DELETE, DDL, DML, and DCL in different loads in the entire cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_workload_sql_elapse_time()

  Description: Provides SELECT, UPDATE, INSERT, DELETE, and response time information (TOTAL, AVG, MIN, and MAX) in different loads in the entire cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_workload_transaction()

  Description: Obtains the transaction volume and time information on all nodes in the cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_session_stat()

  Description: Obtains the session status information on all nodes in the cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

  NOTE

  The status information contains the following items: commit, rollback, sql, table_scan, blocks_fetched, physical_read_operation, shared_blocks_dirtied, local_blocks_dirtied, shared_blocks_read, local_blocks_read, blocks_read_time, blocks_write_time, sort_imemory, sort_idisk, cu_mem_hit, cu_hdd_sync_read, and cu_hdd_asyread

- DBE_PERF.get_global_session_time()

  Description: Provides the time consumed in each key phase on each node in the entire cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_session_memory()

  Description: Aggregates statistics on memory usage at the session level on each node in the unit of MB, including all the memory allocated to Postgres and stream threads on DNs for jobs currently executed by users. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_session_memory_detail()

  Description: Aggregates statistics on thread memory usage on each node by the MemoryContext node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- DBE_PERF.get_global_session_stat_activity()

  Description: Aggregates information about running threads on each node in the cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_thread_wait_status()

  Description: Aggregates the blocking waiting status of the backend thread and auxiliary thread on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_wlm_controlgroup_ng_config()

  Description: Collects information about all Cgroups in the database. After a cluster is created, by default, you must have the **sysadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_wlm_workload_runtime()

  Description: Aggregates the status information about jobs executed by the current user on each CN. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_operator_ec_history()

  Description: Aggregates the historical status information about the current user's EC operators on each CN. After a cluster is created, by default, you must have the **monadmin** or **sysadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_operator_ec_history_table()

  Description: Aggregates the historical status information (persistent) of the current user's EC operators on each CN. After a cluster is created, by default, you must have the **monadmin** or **sysadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_operator_ec_runtime()

  Description: Aggregates the real-time status information about the current user's EC operators on each CN. After a cluster is created, by default, you must have the **monadmin** or **sysadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_operator_history_table()

  Description: Aggregates the operator records (persistent) after jobs are executed by the current user on all CNs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_operator_history()

  Description: Aggregates the operator records after jobs are executed by the current user on all CNs. After a cluster is created, by default, you must have the **monadmin** or **sysadmin** permission to query this function.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- DBE_PERF.get_global_operator_runtime()

  Description: Aggregates real-time operator records of jobs executed by the current user on all CNs. After a cluster is created, by default, you must have the **monadmin** or **sysadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_statement_complex_history()

  Description: Aggregates the historical records of complex queries executed by the current user on all CNs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_statement_complex_history_table()

  Description: Aggregates the historical records of complex queries (persistent) executed by the current user on all CNs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_statement_complex_runtime()

  Description: Aggregates real-time information about complex queries executed by the current user on all CNs. After a cluster is created, by default, you must have the **monadmin** or **sysadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_memory_node_detail()

  Description: Aggregates the memory usage of a database on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_shared_memory_detail()

  Description: Aggregates the usage information about the shared memory contexts on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_comm_delay()

  Description: Aggregates the communication library delay status on all DNs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_comm_recv_stream()

  Description: Aggregates the status of the stream received by the communication library on all DNs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_comm_send_stream()

  Description: Aggregates the status of the stream sent by the communication library on all DNs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- DBE_PERF.get_global_comm_status()

  Description: Aggregates the status of the communication library on all DNs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_statio_all_indexes

  Description: Aggregates index information and I/O statistics in the current database on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_local_toastname_and_toastindexname()

  Description: Provides the mapping between the name and index of the local TOAST table and its associated tables.

  Return type: record

- DBE_PERF.get_summary_statio_all_indexes

  Description: Collects I/O statistics on specific indexes, covering all index lines in the current database on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_statio_all_sequences

  Description: Provides I/O status information about all sequences in the namespace. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_statio_all_tables

  Description: Aggregates I/O statistics on each table in the database on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_statio_all_tables

  Description: Collects statistics on I/Os of each table in the cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_local_toast_relation()

  Description: Provides the mapping between the name of the local TOAST table and its associated tables.

  Return type: record

- DBE_PERF.get_global_statio_sys_indexes()

  Description: Aggregates I/O status information about all system catalog indexes in namespaces on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_statio_sys_indexes()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Collects statistics on I/O status information about all system catalog indexes in namespaces on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

Return type: record

- DBE_PERF.get_global_statio_sys_sequences()

  Description: Provides I/O status information about all system catalog sequences in namespaces. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_statio_sys_tables()

  Description: Provides I/O status information about all system catalogs in the namespaces on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_statio_sys_tables()

  Description: Aggregates I/O status information about all system catalogs in the namespaces of the cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_statio_user_indexes()

  Description: Provides I/O status information about all user relationship table indexes in the namespaces on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_statio_user_indexes()

  Description: Aggregates I/O status information about all user relationship table indexes in the namespaces of the cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_statio_user_sequences()

  Description: Provides I/O status information about all user sequences in the namespaces on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_statio_user_tables()

  Description: Provides I/O status information about all user relationship tables in the namespaces on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_statio_user_tables()

  Description: Aggregates I/O status information about all user relationship tables in the namespaces of the cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_stat_db_cu()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Collects statistics on the CU hit ratio of all databases on each cluster node in a view. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

Return type: record

- DBE_PERF.get_global_dn_stat_all_tables()

  Description: Aggregates statistics on all tables in the database on each DN. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_cn_stat_all_tables()

  Description: Aggregates statistics on all tables in the database on each CN. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_dn_stat_all_tables()

  Description: Collects statistics on all tables in the database on each DN. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_cn_stat_all_tables()

  Description: Collects statistics on all tables in the database on each CN. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_all_indexes()

  Description: Aggregates statistics on all indexes in the database on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_stat_all_indexes()

  Description: Collects statistics on all indexes in the database on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_sys_tables()

  Description: Aggregates statistics on the system catalogs of all the namespaces in the **pg_catalog** or **information_schema** schema on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_stat_sys_tables()

  Description: Collects statistics on the system catalogs of all the namespaces in the **pg_catalog** or **information_schema** schema on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- DBE_PERF.get_global_stat_sys_indexes()

  Description: Aggregates index status information about all system catalogs in the **pg_catalog** or **information_schema** schema on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_stat_sys_indexes()

  Description: Collects index status information about all system catalogs in the **pg_catalog** or **information_schema** schema on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_user_tables()

  Description: Aggregates status information about user-defined ordinary tables in all namespaces. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_stat_user_tables()

  Description: Collects status information about user-defined ordinary tables in all namespaces. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_user_indexes()

  Description: Aggregates status information about the indexes of user-defined ordinary tables in all databases. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_stat_user_indexes()

  Description: Collects status information about the indexes of user-defined ordinary tables in all databases. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_database()

  Description: Aggregates statistics on databases on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_database_conflicts()

  Description: Collects statistics on databases on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_xact_all_tables()

  Description: Aggregates transaction status information about all ordinary tables and TOAST tables in namespaces. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: record

- DBE_PERF.get_summary_stat_xact_all_tables()

  Description: Collects transaction status information about all ordinary tables and TOAST tables in the namespace. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_xact_sys_tables()

  Description: Aggregates transaction status information about system catalogs in namespaces on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_stat_xact_sys_tables()

  Description: Collects transaction status information about system catalogs in namespaces on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_xact_user_tables()

  Description: Aggregates transaction status information about user tables in namespaces on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_stat_xact_user_tables()

  Description: Collects transaction status information about user tables in namespaces on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_user_functions()

  Description: Aggregates transaction status information about user-defined functions in namespaces on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_xact_user_functions()

  Description: Collects transaction status information about user-defined functions in namespaces on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_stat_bad_block()

  Description: Aggregates information about the failure to read files such as tables and indexes on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_file_redo_iostat()

  Description: Collects information about the failure to read files such as tables and indexes on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: record

- DBE_PERF.get_global_file_iostat()

  Description: Aggregates I/O statistics on data files on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_locks()

  Description: Aggregates lock information on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_replication_slots()

  Description: Aggregates logical replication information on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_bgwriter_stat()

  Description: Aggregates statistics on the backend write process activities on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_replication_stat()

  Description: Aggregates status information about log synchronization on all nodes, such as the location where the sender sends logs and the location where the receiver receives logs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_pooler_status()

  Description: Aggregates cache connection status in the pooler on all CNs. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_transactions_running_xacts()

  Description: Aggregates information about running transactions on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_transactions_running_xacts()

  Description: Collects information about running transactions on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_transactions_prepared_xacts()

  Description: Aggregates information about transactions that are currently prepared for two-phase commit on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: record

- DBE_PERF.get_summary_transactions_prepared_xacts()

  Description: Collects information about transactions that are currently prepared for two-phase commit on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_statement()

  Description: Aggregates the status of historical statements executed on each node. After a cluster is created, by default, you must have the **monadmin** or **sysadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_statement_count()

  Description: Aggregates SELECT, UPDATE, INSERT, DELETE, and response time information (TOTAL, AVG, MIN, and MAX) on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_config_settings()

  Description: Aggregates GUC parameter settings on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_wait_events()

  Description: Aggregates status information about the wait events on each node. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_statement_responsetime_percentile()

  Description: Obtains the response time distribution for 80% and 95% SQL statements in the cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_summary_user_login()

  Description: Collects statistics on the number of user login and logout times on each node in the cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.get_global_record_reset_time()

  Description: Aggregates statistics on reset (restart, primary-standby switchover, and database deletion) time in the cluster. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- DBE_PERF.track_memory_context(context_list text)

  Description: Sets the memory context whose memory application details need to be collected. The input parameter contains the memory context names,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

which are separated by commas (,), for example, **ThreadTopMemoryContext, SessionCacheMemoryContext**. Note that the memory context names are context-sensitive. In addition, the length of a single memory context is 63, and the exceeded part is truncated. The maximum number of memory contexts for collection at a time is 16. If the number of memory contexts exceeds 16, the setting fails. Each time this function is called, the previous collection result is cleared. When the input parameter is set to **""**, the collection function is disabled. Only the initial user or a user with the **monadmin** permission can execute this function.

Return type: Boolean

- DBE_PERF.track_memory_context_detail()

  Description: Obtains the memory application details of the memory context specified by the **DBE_PERF.track_memory_context** function. For details, see the **DBE_PERF.track_memory_context_detail** view. Only the initial user or a user with the **monadmin** permission can execute this function.

  Return type: record

- DBE_PERF.global_io_wait_info()

  Description: Queries real-time I/O control statistics on all CNs and DNs.

  Return type: record

- pg_stat_get_mem_mbytes_reserved(tid)

  Description: Collects statistics on variables related to resource management, which is used only for fault locating.

  Parameter: thread ID

  Return type: text

- gs_wlm_user_resource_info(name text)

  Description: Queries a user's resource quota and resource usage. Common users can query only their own information. Administrators can query information about all users.

  Return type: record

- pg_stat_get_file_stat()

  Description: Collects statistics on data file I/Os to indicate I/O performance and detect performance problems such as abnormal I/O operations.

  Return type: record

- pg_stat_get_redo_stat()

  Description: Displays statistics on the replay of session thread logs.

  Return type: record

- pg_stat_get_status(int8)

  Description: Tests the block waiting status about the backend thread and auxiliary thread of the current instance.

  Return type: record

- get_local_rel_iostat()

  Description: Queries the accumulated I/O status of data files on the current node.

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- DBE_PERF.get_global_rel_iostat()

  Description: Aggregates I/O statistics on data files on all nodes. After a cluster is created, by default, you must have the **monadmin** permission to query this function.

  Return type: record

- pg_catalog.plancache_status()

  Description: Displays status information about the global plan cache on the current node. The information returned by the function is the same as that in **16.2.18.2 GLOBAL_PLANCACHE_STATUS**.

  Return type: record

- DBE_PERF.global_plancache_status()

  Description: Displays status information about the global plan cache on all nodes. For details about the information returned by the function, see **16.2.18.2 GLOBAL_PLANCACHE_STATUS**.

  Return type: record

- pg_catalog.prepare_statement_status() (Discarded)

  Description: Displays status information about the PREPARE statement on the current node. The information returned by the function is the same as that in **16.2.18.4 GLOBAL_PREPARE_STATEMENT_STATUS (Discarded)**.

  Return type: record

- DBE_PERF.global_prepare_statement_status() (Discarded)

  Description: Displays status information about the **PREPARE** statement on all nodes. For details about the information returned by the function, see **16.2.18.4 GLOBAL_PREPARE_STATEMENT_STATUS (Discarded)**.

  Return type: record

- DBE_PERF.global_threadpool_status()

  Description: Displays status information about worker threads and sessions in thread pools on all nodes. For details about the information returned by the function, see **16.2.7.14 GLOBAL_THREADPOOL_STATUS**.

  Return type: record

- comm_check_connection_status

  Description: Returns the connection status between the CN and all active nodes (CNs and primary DNs). This function can be queried only on CNs and can be used by common users.

  Parameter: nan

  Return type: node_name text, remote_name text, remote_host text, remote_port integer, is_connected boolean, and no_error_occur boolean

- DBE_PERF.global_comm_check_connection_status

  Description: Returns the connection status between all CNs and all active nodes (CNs and primary DNs). This function can be queried only on CNs. Permission control is inherited from the **DBE_PERF** schema.

  Parameter: nan

  Return type: node_name text, remote_name text, remote_host text, remote_port integer, is_connected boolean, and no_error_occur boolean

- create_wlm_instance_statistics_info

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Saves the historical monitoring data of the current instance persistently.

Parameter: nan

Return type: integer

- remote_candidate_stat()

  Description: Displays the number of pages in the candidate buffer chain of the instance and buffer eviction information, including the normal buffer pool and segment buffer pool.

  Return type: record

  **Table 12-75** remote_candidate_stat parameter description

| Name | Type | Description |
| --- | --- | --- |
| node_name | text | Node name |
| candidate_slots | integer | Number of pages in the candidate buffer chain of the current normal buffer pool |
| get_buf_from_list | bigint | Number of times that pages are obtained from the candidate buffer chain during buffer eviction in the current normal buffer pool |
| get_buf_clock_sweep | bigint | Number of times that pages are obtained from the original eviction solution during buffer eviction in the current normal buffer pool |
| seg_candidate_slots | integer | Number of pages in the candidate buffer chain of the current segment buffer pool |
| seg_get_buf_from_list | bigint | Number of times that pages are obtained from the candidate buffer chain during buffer eviction in the current segment buffer pool |
| seg_get_buf_clock_sweep | bigint | Number of times that pages are obtained from the original eviction solution during buffer eviction in the current segment buffer pool |

- remote_ckpt_stat()

  Description: Displays the checkpoint information and log flushing information about all instances in the cluster (unavailable on DNs, except for the current node).

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-76** remote_ckpt_stat parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| node_name | text | Instance name |
| ckpt_redo_point | text | Checkpoint in the current instance |
| ckpt_clog_flush_num | int8 | Number of Clog flushing pages from the startup time to the current time |
| ckpt_csnlog_flush_num | int8 | Number of CSN log flushing pages from the startup time to the current time |
| ckpt_multixact_flush_num | int8 | Number of MultiXact flushing pages from the startup time to the current time |
| ckpt_predicate_flush_num | int8 | Number of predicate flushing pages from the startup time to the current time |
| ckpt_twophase_flush_num | int8 | Number of two-phase flushing pages from the startup time to the current time |

- remote_double_write_stat()

  Description: Displays doublewrite file status of all instances in the cluster (unavailable on DNs, except for the current node).

  Return type: record

  **Table 12-77** remote_double_write_stat parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| node_name | text | Instance name |
| curr_dwn | int8 | Sequence number of the doublewrite file |
| curr_start_page | int8 | Start page for restoring the doublewrite file |
| file_trunc_num | int8 | Number of times that the doublewrite file is reused |
| file_reset_num | int8 | Number of reset times after the doublewrite file is full |
| total_writes | int8 | Total number of I/Os of the doublewrite file |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description |
| --- | --- | --- |
| low_threshold_writes | int8 | Number of I/Os for writing the doublewrite file with low efficiency (the number of I/O flushing pages at a time is less than 16.) |
| high_threshold_writes | int8 | Number of I/Os for writing the doublewrite file with high efficiency (the number of I/O flushing pages at a time is more than 421.) |
| total_pages | int8 | Total number of pages that are flushed to the doublewrite file area |
| low_threshold_pages | int8 | Number of pages that are flushed with low efficiency |
| high_threshold_pages | int8 | Number of pages that are flushed with high efficiency |
| file_id | int8 | ID of the doublewrite file |

- remote_single_flush_dw_stat()

  Description: Displays the single-page doublewrite file eviction status of all instances in the cluster (unavailable on DNs, except for the current node).

  Return type: record

  **Table 12-78** remote_single_flush_dw_stat parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| node_name | text | Instance name |
| curr_dwn | integer | Sequence number of the doublewrite file |
| curr_start_page | integer | Start position of the doublewrite file |
| total_writes | bigint | Total number of data write pages in the doublewrite file |
| file_trunc_num | bigint | Number of times that the doublewrite file is reused |
| file_reset_num | bigint | Number of reset times after the doublewrite file is full |

- remote_pagewriter_stat()

  Description: Displays the page flushing information and checkpoint information about all instances in the cluster (unavailable on DNs, except for the current node).

  Return type: record

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-79** remote_pagewriter_stat parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| node_name | text | Instance name |
| pgwr_actual_flush_total_num | int8 | Total number of dirty pages flushed from the startup time to the current time |
| pgwr_last_flush_num | int4 | Number of dirty pages flushed in the previous batch |
| remain_dirty_page_num | int8 | Estimated number of dirty pages that are not flushed |
| queue_head_page_rec_lsn | text | **recovery_lsn** of the first dirty page in the dirty page queue in the current instance |
| queue_rec_lsn | text | **recovery_lsn** of the dirty page queue in the current instance |
| current_xlog_insert_lsn | text | Write position of Xlogs in the current instance |
| ckpt_redo_point | text | Checkpoint in the current instance |

- remote_recovery_status()

  Description: Displays log flow control information about the primary and standby nodes (unavailable on DNs, except for the current node).

  Return type: record

**Table 12-80** remote_recovery_status parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| node_name | text | Node name (including the primary and standby nodes) |
| standby_node_name | text | Name of the standby node |
| source_ip | text | IP address of the primary node |
| source_port | int4 | Port number of the primary node |
| dest_ip | text | IP address of the standby node |
| dest_port | int4 | Port number of the standby node |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description |
| --- | --- | --- |
| current_rto | int8 | Current log flow control time of the standby node (unit: s) |
| target_rto | int8 | Expected flow control time of the standby node specified by the corresponding GUC parameter (unit: s) |
| current_sleep_time | int8 | Sleep time required by the primary node to achieve the expected flow control time (unit: μs) |

- remote_rto_status()

  Description: Displays log flow control information about the primary and standby nodes (unavailable on DNs, except for the current node).

  Return type: record

  **Table 12-81** remote_rto_status parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| node_name | text | Node name (including the primary and standby nodes) |
| rto_info | text | Flow control information, including the current log flow control time (unit: second) of the standby node, the expected flow control time (unit: second) specified by the GUC parameter, and the sleep time required by the primary node to achieve the expected flow control time (unit: μs) |

- remote_redo_stat()

  Description: Displays the log replay status of all instances in the cluster (unavailable on DNs, except for the current node).

  Return type: record

  **Table 12-82** remote_redo_stat parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| node_name | text | Instance name |
| redo_start_ptr | int8 | Start point for replaying the current instance logs |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description |
| --- | --- | --- |
| redo_start_time | int8 | Start time (UTC) when the current instance logs are replayed |
| redo_done_time | int8 | End time (UTC) when the current instance logs are replayed |
| curr_time | int8 | Current time (UTC) of the current instance |
| min_recovery_point | int8 | Position of the minimum consistency point of the current instance logs |
| read_ptr | int8 | Position for reading the current instance logs |
| last_replayed_read_ptr | int8 | Position for replaying the current instance logs |
| recovery_done_ptr | int8 | Replay position after the current instance is started |
| read_xlog_io_counter | int8 | Number of I/Os when the current instance reads and replays logs |
| read_xlog_io_total_dur | int8 | Total I/O latency when the current instance reads and replays logs |
| read_data_io_counter | int8 | Number of data page I/O reads during replay in the current instance |
| read_data_io_total_dur | int8 | Total I/O latency of data page reads during replay in the current instance |
| write_data_io_counter | int8 | Number of data page I/O writes during replay in the current instance |
| write_data_io_total_dur | int8 | Total I/O latency of data page writes during replay in the current instance |
| process_pending_counter | int8 | Number of synchronization times of log distribution threads during replay in the current instance |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description |
| --- | --- | --- |
| process_pending_total_dur | int8 | Total synchronization latency of log distribution threads during replay in the current instance |
| apply_counter | int8 | Number of synchronization times of replay threads during replay in the current instance |
| apply_total_dur | int8 | Total synchronization latency of replay threads during replay in the current instance |
| speed | int8 | Log replay rate of the current instance |
| local_max_ptr | int8 | Maximum number of replay logs received by the local host after the current instance is started |
| primary_flush_ptr | int8 | Position where the host flushes logs to a disk |
| worker_info | text | Replay thread information of the current instance. If concurrent replay is disabled, this parameter is left empty. |

- PGXC_GTM_SNAPSHOT_STATUS()

  Description: Queries transaction information on the current GTM. This function is supported only in GTM mode.

  Return type: record

  The following table describes return parameters.

  **Table 12-83** PGXC_GTM_SNAPSHOT_STATUS return parameters

| Name | Type | Description |
| --- | --- | --- |
| xmin | xid | Minimum XID of the running transactions |
| xmax | xid | XID of the transaction next to the executed transaction with the maximum XID |
| csn | integer | Sequence number of the transaction to be committed |
| oldestxmin | xid | Minimum XID of the executed transactions |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Name | Type | Description |
| --- | --- | --- |
| xcnt | integer | Number of the running transactions |
| running_xids | text | XID of the running transaction |

- pg_stat_get_partition_tuples_hot_updated

  Description: Returns statistics on the number of hot updated tuples in a partition with a specified partition ID.

  Parameter: oid

  Return type: bigint

- pv_os_run_info

  Description: Displays the running status of the current OS. For details about the fields, see **15.3.217 PV_OS_RUN_INFO**.

  Parameter: nan

  Return type: setof record

- pv_session_stat

  Description: Collects session status information by session thread or AutoVacuum thread. For details about the fields, see **15.3.222 PV_SESSION_STAT**.

  Parameter: nan

  Return type: setof record

- pv_session_time

  Description: Collects statistics on the running time of session threads and the time consumed in each execution phase. For details about the fields, see **15.3.223 PV_SESSION_TIME**.

  Parameter: nan

  Return type: setof record

- pg_stat_get_db_temp_bytes

  Description: Collects statistics on the total amount of data written to temporary files through database query. All temporary files are counted, regardless of why the temporary files were created and regardless of the **log_temp_files** setting.

  Parameter: oid

  Return type: bigint

- pg_stat_get_db_temp_files

  Description: Queries the number of temporary files created in the database. All temporary files are counted, regardless of why the temporary files were created (for example, sorting or hashing) and regardless of the **log_temp_files** setting.

  Parameter: oid

  Return type: bigint

- local_redo_time_count()

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Returns statistics on time consumed in each process of each replay thread on the current node (valid data exists only on the standby node).

The return values are as follows:

**Table 12-84** local_redo_time_count return parameters

| Field | Description |
| --- | --- |
| thread_name | Thread name |
| step1_total | Total duration of step 1. The process of each thread is as follows:<br>Ultimate RTO:<br>● **batch redo**: obtains a log from a queue.<br>● **redo manager**: obtains a log from a queue.<br>● **redo worker**: obtains a log from a queue.<br>● **trxn manager**: reads a log from a queue.<br>● **trxn worker**: reads a log from a queue.<br>● **read worker**: reads an Xlog page (overall) from a file.<br>● **read page worker**: obtains a log from a queue.<br>● **startup**: obtains a log from a queue.<br>Parallel replay:<br>● **page redo**: obtains a log from a queue.<br>● **startup**: reads a log. |
| step1_count | Number of accumulated execution times of step 1 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Field | Description |
| --- | --- |
| step2_total | Total duration of step 2. The process of each thread is as follows:<br>Ultimate RTO:<br>• **batch redo**: processes logs (overall).<br>• **redo manager**: processes logs (overall).<br>• **redo worker**: processes logs (overall).<br>• **trxn manager**: processes logs (overall).<br>• **trxn worker**: processes logs (overall).<br>• **redo worker**: specifies the time required for reading the Xlog page.<br>• **read page worker**: generates and sends LSN forwarders.<br>• **startup**: checks whether to replay to the specified position.<br>Parallel replay:<br>**page redo**: processes logs (overall).<br>**startup**: checks whether to replay to the specified position. |
| step2_count | Number of accumulated execution times of step 2 |
| step3_total | Total duration of step 3. The process of each thread is as follows:<br>Ultimate RTO:<br>• **batch redo**: updates the standby state.<br>• **redo manager**: processes data logs.<br>• **redo worker**: replays page logs (overall).<br>• **trxn manager**: updates the flush LSN.<br>• **trxn worker**: replays logs.<br>• **redo worker**: pushes the Xlog segment.<br>• **read page worker**: obtains a new item.<br>• **startup**: collects statistics on the wait time of the delayed replay feature.<br>Parallel replay:<br>• **page redo**: updates the standby state.<br>• **startup**: collects statistics on the wait time of the delayed replay feature. |
| step3_count | Number of accumulated execution times of step 3 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Field | Description |
| --- | --- |
| step4_total | Total duration of step 4. The process of each thread is as follows:<br>Ultimate RTO:<br>• **batch redo**: parses Xlogs.<br>• **redo manager**: processes DDL.<br>• **redo worker**: reads data pages.<br>• **trxn manager**: synchronizes the wait time.<br>• **trxn worker**: updates the LSN of the current thread.<br>• **read page worker**: stores logs in the distribution thread.<br>• **startup**: distributes logs (overall).<br>Parallel replay:<br>• **page redo**: replays undo logs.<br>• **startup**: distributes logs (overall). |
| step4_count | Number of accumulated execution times of step 4 |
| step5_total | Total duration of step 5. The process of each thread is as follows:<br>Ultimate RTO:<br>• **batch redo**: distributes logs to the redo manager.<br>• **redo manager**: distributes logs to redo workers.<br>• **redo worker**: replays data page logs.<br>• **trxn manager**: distributes data to the trxn worker.<br>• **trxn worker**: forcibly synchronizes the wait time.<br>• **read page worker**: updates the LSN of the current thread.<br>• **startup**: decodes logs.<br>Parallel replay:<br>• **page redo**: replays sharetrxn logs.<br>• **startup**: replays logs. |
| step5_count | Number of accumulated execution times of step 5. |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Field | Description |
| --- | --- |
| step6_total | Total duration of step 6. The process of each thread is as follows:<br>Ultimate RTO:<br>• **redo worker**: replays non-data page logs.<br>• **trxn manager**: updates global LSNs.<br>• **read page worker**: performs CRC on logs.<br>Parallel replay:<br>• **page redo**: replays synctrxn logs.<br>• **startup**: forcibly synchronizes the wait time. |
| step6_count | Number of accumulated execution times of step 6 |
| step7_total | Total duration of step 7. The process of each thread is as follows:<br>Ultimate RTO:<br>• **redo manager**: creates tablespaces.<br>• **redo worker**: updates FSM.<br>Parallel replay:<br>**page redo**: replays a single log. |
| step7_count | Number of accumulated execution times of step 7 |
| step8_total | Total duration of step 8. The process of each thread is as follows:<br>Ultimate RTO:<br>**redo worker**: forcibly synchronizes the wait time.<br>Parallel replay:<br>**page redo**: All workers replay redo logs. |
| step8_count | Number of accumulated execution times of step 8 |
| step9_total | Total duration of step 9. The process of each thread is as follows:<br>Ultimate RTO:<br>None<br>Parallel replay:<br>**page redo**: Multiple workers replay redo logs. |
| step9_count | Number of accumulated execution times of step 9 |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- local_xlog_redo_statics()

  Description: Returns the statistics on each type of logs that have been replayed on the current node (valid data exists only on the standby node).

  The return values are as follows:

  **Table 12-85** local_xlog_redo_statics parameter description

| Field | Description |
| --- | --- |
| xlog_type | Log type |
| rmid | Resource manager ID |
| info | xlog operation |
| num | Number of logs |
| extra | Valid values are available for page replay logs and xact logs. The page replay logs indicate the number of pages read from the disk. The xact logs indicate the number of deleted files. |

- remote_bgwriter_stat()

  Description: Displays information about pages flushed by the bgwriter threads of all instances in the cluster, number of pages in the candidate buffer chain, and buffer eviction information (not available on the DN, except for the current node).

  Return type: record

  **Table 12-86** remote_bgwriter_stat parameter description

| Parameter | Type | Description |
| --- | --- | --- |
| node_name | text | Instance name |
| bgwr_actual_flush_total_num | bigint | Total number of dirty pages flushed by the bgwriter thread from the startup time to the current time |
| bgwr_last_flush_num | integer | Number of dirty pages flushed by the bgwriter thread in the previous batch |
| candidate_slots | integer | Number of pages in the current candidate buffer chain |
| get_buffer_from_list | bigint | Number of times that pages are obtained from the candidate buffer chain during buffer eviction |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description |
| --- | --- | --- |
| get_buf_clock_sweep | bigint | Number of times that pages are obtained from the original eviction solution during buffer eviction |

Example:

The **pg_backend_pid** function shows the ID of the current background service thread.

```
openGauss=# SELECT pg_backend_pid();
 pg_backend_pid
-----------------
 139706243217168
(1 row)
```

The **pg_stat_get_backend_pid** function shows the ID of a given backend thread.

```
openGauss=# SELECT pg_stat_get_backend_pid(1);
 pg_stat_get_backend_pid
-------------------------
        139706243217168
(1 row)
```

- gs_stack()

  Description: Displays the call stack of a thread. To query this function, you must have the **sysadmin** or **monadmin** permission.

  Parameter: tid, which indicates the thread ID. **tid** is an optional parameter. If it is specified, the function returns the call stack of the thread corresponding to **tid**. If it is not specified, the function returns the call stacks of all threads.

  Return value: If **tid** is specified, the return value is **text**. If **tid** is not specified, the return value is **setof record**.

  Example:

```
openGauss=# SELECT gs_stack(139663481165568);
                           gs_stack
-----------------------------------------------------------------------
 __poll + 0x2d                                                        +
 WaitLatchOrSocket(Latch volatile*, int, int, long) + 0x29f        +
 WaitLatch(Latch volatile*, int, long) + 0x2e                    +
 JobScheduleMain() + 0x90f                                      +
 int GaussDbThreadMain<(knl_thread_role)9>(knl_thread_arg*) + 0x456+
 InternalThreadFunc(void*) + 0x2d                                +
 ThreadStarterFunc(void*) + 0xa4                                 +
 start_thread + 0xc5                                           +
 clone + 0x6d                                                 +
(1 row)
```

# 12.5.28 Trigger Functions

- pg_get_triggerdef(oid)

  Description: Obtains the definition information of a trigger.

  Parameter: OID of the trigger to be queried

  Return type: text

- pg_get_triggerdef(oid, boolean)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Obtains the definition information of a trigger.

Parameter: OID of the trigger to be queried and whether it is displayed in pretty mode

Return type: text

## 12.5.29 Hash Function

- bucketabstime (value, flag)

  Description: Hashes the value in the abstime format and finds the corresponding hash bucket.

  Parameter: **value** indicates the value to be converted, which is of the abstime type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

  Return type: int32

  Example:

```
openGauss=# select bucketabstime('2011-10-01 10:10:10.112',1);
 bucketabstime
---------------
         13954
(1 row)
```

- bucketbool (value, flag)

  Description: Hashes the value in the bool format and finds the corresponding hash bucket.

  Parameter: **value** indicates the value to be converted, which is of the bool type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

  Return type: int32

  Example:

```
openGauss=# select bucketbool(true,1);
 bucketbool
------------
          1
(1 row)
openGauss=# select bucketbool(false,1);
 bucketbool
------------
          0
(1 row)
```

- bucketbpchar(value, flag)

  Description: Hashes the value in the bpchar format and finds the corresponding hash bucket.

  Parameter: **value** indicates the value to be converted, which is of the bpchar type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

  Return type: int32

  Example:

```
openGauss=# select bucketbpchar('test',1);
 bucketbpchar
--------------
         9761
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- bucketbytea (value, flag)

  Description: Hashes the value in the bytea format and finds the corresponding hash bucket.

  Parameter: **value** indicates the value to be converted, which is of the bytea type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

  Return type: int32

  Example:

  ```
  openGauss=# select bucketbytea('test',1);
   bucketbytea
  -------------
         9761
  (1 row)
  ```

- bucketcash (value, flag)

  Description: Hashes the value in the money format and finds the corresponding hash bucket.

  Parameter: **value** indicates the value to be converted, which is of the money type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

  Return type: int32

  Example:

  ```
  openGauss=# select bucketcash(10::money,1);
   bucketcash
  ------------
        8468
  (1 row)
  ```

- getbucket (value, flag)

  Description: Obtains the hash bucket from the distribution column.

  **value** indicates the value to be entered, which can be of the following types:

  "char", abstime, bigint, boolean,bytea, character varying, character, date, double precision, int2vector, integer, interval, money, name, numeric, nvarchar2, oid, oidvector, raw, real, record, reltime, smalldatetime, smallint,text, time with time zone, time without time zone, timestamp with time zone, timestamp without time zone, tinyint, uuid

  **flag** is of the int type, indicating the data distribution mode.

  Return type: integer

  Example:

  ```
  openGauss=# select getbucket(10,'H');
   getbucket
  -----------
      14535
  (1 row)

  openGauss=# select getbucket(11,'H');
   getbucket
  -----------
      13449
  (1 row)

  openGauss=# select getbucket(11,'R');
   getbucket
  -----------
      13449
  (1 row)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# select getbucket(12,'R');
 getbucket
-----------
      9412
(1 row)
```

- hash_array(anyarray)

  Description: Hashes an array, obtains the result of an array element using the hash function, and returns the combination result.

  Parameter: data of the anyrange type.

  Return type: integer

  Example:

```
openGauss=# select hash_array(ARRAY[[1,2,3],[1,2,3]]);
 hash_array
------------
 -382888479
(1 row)
```

- hash_group(key)

  Description: Calculates the hash value of each column in the Group Clause in the streaming engine. (Due to specification changes, the current version no longer supports the current feature. Do not use this feature.)

  Parameter: **key** indicates the value of each column in the Group Clause.

  Return type: 32-bit hash value

  Example:

```
Perform the following steps in sequence.
openGauss=# CREATE TABLE tt(a int, b int,c int,d int);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
openGauss=# select * from tt;
 a | b | c | d
---+---+---+---
(0 rows)

openGauss=# insert into tt values(1,2,3,4);
INSERT 0 1
openGauss=# select * from tt;
 a | b | c | d
---+---+---+---
 1 | 2 | 3 | 4
(1 row)

openGauss=# insert into tt values(5,6,7,8);
INSERT 0 1
openGauss=# select * from tt;
 a | b | c | d
---+---+---+---
 1 | 2 | 3 | 4
 5 | 6 | 7 | 8
(2 rows)

openGauss=# select hash_group(a,b) from tt where a=1 and b=2;
 hash_group
------------
  990882385
(1 row)
```

- hash_numeric(numeric)

  Description: Calculates the hash value of numeric data.

  Parameter: data of the numeric type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: integer

Example:

```
openGauss=# select hash_numeric(30);
 hash_numeric
--------------
   -282860963
(1 row)
```

- hash_range(anyrange)

  Description: Calculates the hash value of a range.

  Parameter: data of the anyrange type.

  Return type: integer

  Example:

```
openGauss=# select hash_range(numrange(1.1,2.2));
 hash_range
------------
  683508754
(1 row)
```

- hashbpchar(character)

  Description: Calculates the hash value of bpchar.

  Parameter: data of the character type.

  Return type: integer

  Example:

```
openGauss=# select hashbpchar('hello');
 hashbpchar
-------------
 -1870292951
(1 row)
```

- hashchar(char)

  Description: Converts char and Boolean data into hash values.

  Parameter: data of the char or bool type.

  Return type: integer

  Example:

```
openGauss=# select hashbpchar('hello');
 hashbpchar
-------------
 -1870292951
(1 row)

openGauss=# select hashchar('true');
  hashchar
------------
 1686226652
(1 row)
```

- hashenum(anyenum)

  Description: Converts enumerated values to hash values.

  Parameter: data of the anyenum type.

  Return type: integer

  Example:

```
openGauss=# CREATE TYPE b1 AS ENUM('good', 'bad', 'ugly');
CREATE TYPE
openGauss=# call hashenum('good'::b1);
  hashenum
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
------------
 1821213359
(1 row)
```

- hashfloat4(real)

  Description: Converts float4 values to hash values.

  Parameter: data of the real type.

  Return type: integer

  Example:

```
openGauss=# select hashfloat4(12.1234);
 hashfloat4
------------
 1398514061
(1 row)
```

- hashfloat8(double precision)

  Description: Converts float8 values to hash values.

  Parameter: data of the double precision type.

  Return type: integer

  Example:

```
openGauss=# select hashfloat8(123456.1234);
 hashfloat8
------------
 1673665593
(1 row)
```

- hashinet(inet)

  Description: Supports hash indexing on inet/cidr and returns the hash value of inet.

  Parameter: data of the inet type.

  Return type: integer

  Example:

```
openGauss=# select hashinet('127.0.0.1'::inet);
  hashinet
-------------
 -1435793109
(1 row)
```

- hashint1(tinyint)

  Description: Converts INT1 values to hash values.

  Parameter: data of the tinyint type.

  Return type: uint32

  Example:

```
openGauss=# select hashint1(20);
  hashint1
-------------
 -2014641093
(1 row)
```

- hashint2(smallint)

  Description: Converts INT2 values to hash values.

  Parameter: data of the smallint type.

  Return type: uint32

  Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

```
openGauss=# select hashint2(20000);
 hashint2
------------
 -863179081
(1 row)
```

- bucketchar
  Description: Calculates the hash value of the input parameter.
  Parameter: char, integer
  Return type: integer
- bucketdate
  Description: Calculates the hash value of the input parameter.
  Parameter: date, integer
  Return type: integer
- bucketfloat4
  Description: Calculates the hash value of the input parameter.
  Parameter: real, integer
  Return type: integer
- bucketfloat8
  Description: Calculates the hash value of the input parameter.
  Parameters: double precision, integer
  Return type: integer
- bucketint1
  Description: Calculates the hash value of the input parameter.
  Parameter: tinyint, integer
  Return type: integer
- bucketint2
  Description: Calculates the hash value of the input parameter.
  Parameter: smallint, integer
  Return type: integer
- bucketint2vector
  Description: Calculates the hash value of the input parameter.
  Parameter: int2vector, integer
  Return type: integer
- bucketint4
  Description: Calculates the hash value of the input parameter.
  Parameter: integer, integer
  Return type: integer
- bucketint8
  Description: Calculates the hash value of the input parameter.
  Parameter: bigint, integer
  Return type: integer
- bucketinterval
  Description: Calculates the hash value of the input parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Parameter: interval, integer
Return type: integer

- bucketname
  Description: Calculates the hash value of the input parameter.
  Parameter: name, integer
  Return type: integer
- bucketnumeric
  Description: Calculates the hash value of the input parameter.
  Parameter: numeric, integer
  Return type: integer
- bucketnvarchar2
  Description: Calculates the hash value of the input parameter.
  Parameter: nvarchar2, integer
  Return type: integer
- bucketoid
  Description: Calculates the hash value of the input parameter.
  Parameters: oid, integer
  Return type: integer
- bucketoidvector
  Description: Calculates the hash value of the input parameter.
  Parameter: oidvector, integer
  Return type: integer
- bucketraw
  Description: Calculates the hash value of the input parameter.
  Parameter: raw, integer
  Return type: integer
- bucketreltime
  Description: Calculates the hash value of the input parameter.
  Parameter: reltime, integer
  Return type: integer
- bucketsmalldatetime
  Description: Calculates the hash value of the input parameter.
  Parameter: smalldatetime, integer
  Return type: integer
- buckettext
  Description: Calculates the hash value of the input parameter.
  Parameter: text, integer
  Return type: integer
- buckettime
  Description: Calculates the hash value of the input parameter.
  Parameter: time without time zone, integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: integer

- buckettimestamp
  Description: Calculates the hash value of the input parameter.
  Parameter: timestamp without time zone, integer
  Return type: integer
- buckettimestamptz
  Description: Calculates the hash value of the input parameter.
  Parameter: timestamp with time zone, integer
  Return type: integer
- buckettimetz
  Description: Calculates the hash value of the input parameter.
  Parameter: time with time zone, integer
  Return type: integer
- bucketuuid
  Description: Calculates the hash value of the input parameter.
  Parameter: uuid, integer
  Return type: integer
- bucketvarchar
  Description: Calculates the hash value of the input parameter.
  Parameter: character varying, integer
  Return type: integer

## 12.5.30 Prompt Message Function

- report_application_error
  Description: This function can be used to throw errors during PL execution.
  Return type: void

  **Table 12-87** report_application_error parameter description

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| log | text | Content of an error message. | Yes |
| code | int4 | Error code corresponding to an error message. The value ranges from –20999 to –20000. | No |

## 12.5.31 Fault Injection System Function

gs_fault_inject(int64, text, text, text, text, text)

Description: This function cannot be called. WARNING information "unsupported fault injection" is reported when this function is called, which does not affect or change the database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Parameter: fault injection of the int64 type (**0**: CLOG extended page; **1**: CLOG page reading; **2**: forcible deadlock)

- If the first input parameter of text is set to **2** and the second input parameter of text is set to **1**, the second input parameter deadlock occurs. Other input parameters are not deadlocked. When the first input parameter is **0** or **1**, the second input parameter indicates the number of the start page from which the CLOG starts to be extended or read.
- The third input parameter of text indicates the number of extended or read pages when the first input parameter is **0** or **1**.
- The fourth to sixth input parameters of text are reserved.

Return type: int64

## 12.5.32 Redistribution Parameters

The following functions are system functions used by **gs_redis** during redistribution. Do not call them unless absolutely necessary.

- pg_get_redis_rel_end_ctid(text, name, int, int)
- pg_get_redis_rel_start_ctid(text, name, int, int)
- pg_enable_redis_proc_cancelable()
- pg_disable_redis_proc_cancelable()
- pg_tupleid_get_blocknum(tid)
- pg_tupleid_get_offset(tid)
- pg_tupleid_get_ctid_to_bigint (ctid)

The following functions and OIDs are all for time series tables.

- redis_ts_table(oid)

Description: Moves data from the old table (for example, **redis_old_cpu**) to the new table (**redis_new_cpu**) from the last partition of the timeline, deletes the partition if the partition of **redis_old_cpu** is empty, deletes the old table when only one partition is left, and restores the table to the original CPU table. This function is called by the following job and does not need to be manually called.

Return type: void

**Table 12-88** redis_ts_table parameter description

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| old_oid | oid | ID of **redis_old_cpu**. | Yes |

- cancel_unuse_redis()

Description: Cancels redistribution of a time series table.

Return value: void

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- submit_redis_task(oid, interval)

Description: Calls the **redis_ts_table** function. Only one job can be called for a table. For modification, stop the job and call it again.

Parameter: The CPU table is used as an example. For details, see **Table 12-89**.

Return type: void

**Table 12-89** submit_redis_task parameter description

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| old_oid | oid | ID of **redis_old_cpu**. | Yes |
| schedule_interval | interval | This parameter is used to calculate the input value of **interval_time** in **dbe_task.submit**, indicating the interval for executing the job. | No |

- submit_all_redis_task(interval)

Description: Calls the **submit_redis_task** function for all tables that are not redistributed in the currently connected database.

Return type: void

**Table 12-90** Parameter description

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| schedule_interval | interval | This parameter has the same meaning as the input parameter **schedule_interval** of **submit_redis_task**. | No |

- cancel_redis_task(oid)

Description: Stops the job for transferring a table after the table has been transferred.

Parameter: OID of **redis_old_cpu** (using the cpu table as an example).

Return type: void

- cancel_all_redis_task()

Description: Stops all the jobs that are being transferred for all the time series tables connected to the database.

Return type: void

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- submit_cancel_redis_task(interval)

Description: Creates jobs for all time series tables connected to the database and calls the **cancel_redis_task** function.

Parameter: interval for calling the job. The default value is **1h**.

Return type: void

- flush_depend_rule(oid)

Description: Take the CPU table as an example. If a user directly executes some SQL statements on the **redis_old_cpu** and **redis_new_cpu** tables, the original rules cannot work properly. In this case, you can use this function to recreate related rules. The statements for creating rules are in the **pg_rules** system catalog, and you are advised to perform only allowed operations. If you directly run SQL statements on **redis_new_cpu** and **redis_old_cpu**, unknown errors may occur.

Parameter: OID of the CPU table.

Return type: void

## 12.5.33 Distribution Column Recommendation Functions

Distribution column recommendation is used to recommend distribution columns and distribution modes in a distributed database. The purpose is to reduce the labor cost of selecting distribution columns during service migration or rollout.

- sqladvisor.init(char, boolean, boolean, boolean, int, int)

Description: Initializes parameters.

Return type: Boolean

**Table 12-91** Parameter description of init

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| kind | char | Recommendation type. Currently, this parameter can only be set to **D**. | Yes |
| isUseCost | boolean | Indicates whether optimizers are used. If data is available, optimizers are used. | Yes |
| isUseCollect | boolean | Indicates whether the analysis is started from the collected load. The default value is **false**. | No |
| isConstraintPrimaryKey | boolean | Indicates whether primary key constraints are retained. The default value is **true**. | No |
| sqlCount | int | Number of collected SQL statements. The default value is **10000**. The value ranges from 1 to 100000. | No |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| maxMemory | int | Maximum memory occupied by distribution column recommendation. The default value is **1024**. The value ranges from 1 to 10240, in MB. | No |

- sqladvisor.set_weight_params(real, real, real)

Description: Sets the weight of different components in heuristic rules. A default parameter is set when the init function is invoked. This function does not need to be invoked during analysis.

Return type: Boolean

**Table 12-92** Parameter description of set_weight_params

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| joinWeight | real | Weight of JOIN. The value ranges from 0 to 1000. | Yes |
| goupbyWeight | real | Weight of GROUP BY. The value ranges from 0 to 1000. | Yes |
| qualWeight | real | Weight of predicate. The value ranges from 0 to 1000. | Yes |

NOTE

This function is optional. When the init function is executed, the default weights of JOIN, GROUP BY, and predicate are preset to 1.0, 0.1, and 0.05, respectively.

- sqladvisor.set_cost_params(bigint, boolean, text)

Description: Parameter that can be set in the Whtif cost model.

Return type: Boolean

**Table 12-93** Parameter description of set_cost_params

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| maxTime | bigint | Maximum recommendation duration, in minutes. If the value is less than or equal to **0**, the duration is not limited by default. | Yes |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| isTotalSQL | boolean | Indicates whether all SQL statements are used for calculation. The value **true** indicates that all SQL statements are used for calculation. The value **false** indicates that SQL statements whose cost is too high or too low are filtered out based on the percentile. | Yes |
| compressLevel | text | Search space size of the recommendation algorithm. The options are **low**, **med**, and **high**. | Yes |

NOTE

- This function is optional. When the init function is executed, **maxTime** is preset to **–1**, **isTotalSQL** is preset to **true**, and **compressLevel** is preset to **high**.
- A lower compression level indicates longer time, and it is more likely that a better result can be achieved.

- sqladvisor.assign_table_type(text)

Description: Specifies a table as a replication table.

Parameter: table name

Return type: Boolean

NOTE

The specified replication table must be used before **analyze_query** and **analyze_workload** are invoked.

- sqladvisor.analyze_query(text, int)

Description: Imports SQL statements to be recommended and analyzes the components of the statements.

Return type: Boolean

**Table 12-94** Parameter description of analyze_query

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| query | text | SQL statement | Yes |
| frequency | int | Frequency of a statement in the load. The default value is **1**. The value ranges from 1 to 2147483647. | No |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

NOTE

- If the value of the **query** parameter contains special characters, such as single quotation marks ('), you can use single quotation marks (') to escape the special characters.
- This function is not supported in semi-online mode.

- sqladvisor.analyze_workload()

Description: Analyzes the load information collected online.

Return type: Boolean

- sqladvisor.get_analyzed_result(text)

Description: Obtains beneficial components extracted from the current table.

Parameter: text

Return type: record

The following table describes return fields.

| Name | Type | Description |
| --- | --- | --- |
| schema_name | text | Schema name |
| table_name | text | Table name |
| col_name | text | Column name |
| operator | text | Operator type |
| count | int | Number of times that an operator is used |

- sqladvisor.run()

Description: Performs calculation and analysis based on the specified schema and input SQL statements.

Return type: Boolean

- sqladvisor.get_distribution_key()

Description: Obtains the recommendation result.

NOTE

The analysis result is saved in a session. If the session disconnects, the result will be lost.

Return type: record

The following table describes return fields.

| Name | Type | Description |
| --- | --- | --- |
| db_name | text | Database name |
| schema_name | text | Schema name |
| table_name | text | Table name |
| distribution_type | text | Recommended distribution type |
| distribution_key | text | Recommended distribution column |
| start_time | timestamp | Recommended start time |
| end_time | timestamp | Recommended end time |
| cost_improve | text | Cost increase brought by the recommendation result |
| comment | text | Comment |

- sqladvisor.clean()

Description: Clears all the memory in the recommendation process of a session.

Return type: Boolean

- sqladvisor.start_collect_workload(int, int)

Description: Starts online load collection.

Return type: Boolean

**Table 12-95** Parameter description of start_collect_workload

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| sqlCount | int | Maximum number of SQL statements for online load collection. The value ranges from 1 to 100000 and the default value is **10000**. | Yes |

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

| Parameter | Type | Description | Mandatory or Not |
| --- | --- | --- | --- |
| maxMemory | int | Maximum memory occupied by online load collection. The default value is **1024**. The value ranges from 1 to 10240, in MB. | Yes |

**NOTICE**

- The online collection function can be invoked only by the system administrator.
- The load of only one database can be collected at a time.
- Currently, only common SQL statements as well as DML and DQL statements in stored procedures are supported.

- sqladvisor.end_collect_workload()

Description: Disables online load collection.

Return type: Boolean

**NOTICE**

- The online collection function can be disabled only by the system administrator.

- sqladvisor.clean_workload()

Description: Clears the memory in the load.

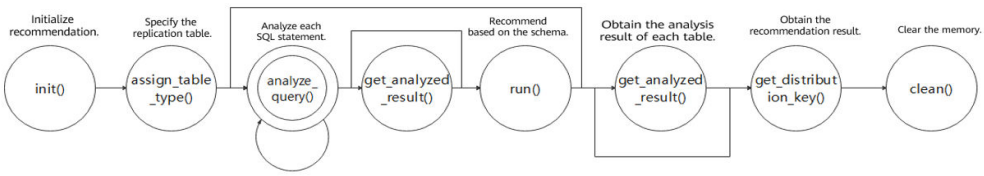
Return type: Boolean

**NOTICE**

- The function of clearing memory in the load can be invoked only by the system administrator.
- You must manually execute the cleanup function.

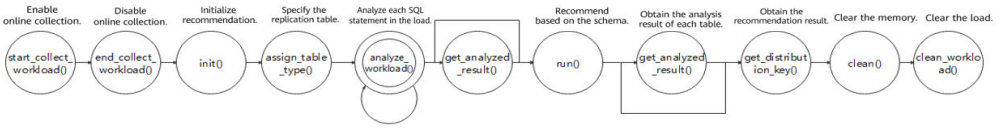
## Suggestions

- Invoke state machines in the heuristic or WhatIf cost recommendation mode.



- Invoke state machines in semi-online recommendation mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 



# 12.5.34 Other System Functions

- The GaussDB built-in functions and operators are inherited from the open-source PGXC/PG. For details about the functions listed in this section, see the official documents of PGXC/PG at the following URL:

  http://postgres-xc.sourceforge.net/docs/1_1/functions.html

The following table lists the functions used by GaussDB to implement internal system functions. You are not advised to use these functions. If you need to use them, contact Huawei technical support.

- smgreq(a smgr, b smgr)

  Description: Compares two smgrs to check whether they are the same.

  Parameters: smgr, smgr

  Return type: Boolean

- smgrne(a smgr, b smgr)

  Description: Checks whether the two smgrs are different.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Parameters: smgr, smgr

Return type: Boolean

- spread_collect

  Description: Calculates the difference between the maximum and minimum values in a certain period of time. This function is used for data collection of aggregate functions.

  Parameters: s real[], v real[]

  Return type: real[]

- spread_final

  Description: Calculates the difference between the maximum and minimum values in a certain period of time. This function is used for the final data processing of the aggregate function.

  Parameter: s real[]

  Return type: real

- spread_internal

  Description: Calculates the difference between the maximum and minimum values in a certain period of time. This function is used for the process of aggregate functions.

  Parameters: s real[], v real

  Return type: real[]

- xidin4

  Description: Inputs a 4-byte xid.

  Parameter: cstring

  Return type: xid32

- set_hashbucket_info

  Description: Sets hash bucket information.

  Parameter: text

  Return type: Boolean

- gap_fill_internal

  Description: Returns the first non-NULL value in the parameter list.

  Parameter: s anyelement, v anyelement

  Return type: anyelement

- hs_concat

  Description: Concatenates two pieces of hstore data.

  Parameters: hstore, hstore

  Return type: hstore

- hs_contained

  Description: Determines whether two hstore data records are included. The return value is of the Boolean type.

  Parameters: hstore, hstore

  Return type: Boolean

- hs_contains

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Determines whether two hstore data records are included. The return value is of the Boolean type.

Parameters: hstore, hstore

Return type: Boolean

- hstore

  Description: Converts parameters to the hstore type.

  Parameters: text, text

  Return type: hstore

- hstore_in

  Description: Receives hstore data in string format.

  Parameter: cstring

  Return type: hstore

- hstore_out

  Description: Sends hstore data in string format.

  Parameter: hstore

  Return type: cstring

- hstore_send

  Description: Sends hstore data in bytea format.

  Parameter: hstore

  Return type: bytea

- hstore_to_array

  Description: Sends hstore data in text array format.

  Parameter: hstore

  Return type: text[]

- hstore_to_matrix

  Description: Sends hstore data in text array format.

  Parameter: hstore

  Return type: text[]

- hstore_version_diag

  Description: Sends hstore data in integer array format.

  Parameter: hstore

  Return type: integer

- int1send

  Description: Packs unsigned 1-byte integers into the internal data buffer stream.

  Parameter: tinyint

  Return type: bytea

- is_contain_namespace

  Description: Searches for the table name and namespace split location. If no namespace exists, 0 is returned.

  Parameter: relationname name

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: integer

- is_oid_in_group_members

  Description: Not supported

  Parameter: node_oid oid, group_members oidvector_extend

  Return type: Boolean

- isdefined

  Description: Checks whether a specified key exists.

  Parameters: hstore, text

  Return type: Boolean

- isubmit_on_nodes_internal

  Description: Not supported

  Parameter: job bigint, node_name name, database name, what text, next_date timestamp without time zone, job_interval text

  Return type: integer

- listagg

  Description: aggregate function of the list type

  Parameters: smallint, text

  Return type: text

- log_fdw_validator

  Description: validate function

  Parameter: text[], oid

  Return type: void

- nvarchar2typmodin

  Description: Obtains the typmod information of varchar.

  Parameter: cstring[]

  Return type: integer

- nvarchar2typmodout

  Description: Obtains the typmod information of varchar, constructs a character string, and returns the character string.

  Parameter: integer

  Return type: cstring

- pg_nodes_memmon

  Description: Not supported

  Parameter: nan

  Return type: innernname text, innerusedmem bigint, innertopctxt bigint, nname text, usedmem text, sharedbuffercache text, topcontext text

- read_disable_conn_file

  Description: Reads forbidden connection files.

  Parameter: nan

  Return type: disconn_mode text, disconn_host text, disconn_port text, local_host text, local_port text, redo_finished text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- regex_like_m

  Description: Regular expression match, which is used to determine whether a character string complies with a specified regular expression.

  Parameters: text, text

  Return type: Boolean

- update_pgjob

  Description: Updates a job.

  Parameter: bigint, "char", bigint, timestamp without time zone, timestamp without time zone, timestamp without time zone, timestamp without time zone, timestamp without time zone, smallint, text

  Return type: void

- enum_cmp

  Description: Enumeration comparison function, which is used to determine whether two enumeration classes are equal and determine their relative sizes.

  Parameter: anyenum, anyenum

  Return type: integer

- enum_eq

  Description: Enumeration comparison function, which is used to implement the = symbol.

  Parameter: anyenum, anyenum

  Return type: Boolean

- enum_first

  Description: Returns the first element in the enumeration class.

  Parameter: anyenum

  Return type: anyenum

- enum_ge

  Description: Enumeration comparison function, which is used to implement the >= symbol.

  Parameter: anyenum, anyenum

  Return type: Boolean

- enum_gt

  Description: Enumeration comparison function, which is used to implement the > sign.

  Parameter: anyenum, anyenum

  Return type: Boolean

- enum_in

  Description: Enumeration comparison function, which is used to determine whether an element is in an enumeration class.

  Parameter: cstring, oid

  Return type: anyenum

- enum_larger

  Description: Enumeration comparison function, which is used to implement the > sign.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Parameter: anyenum, anyenum

Return type: anyenum

- enum_last

  Description: Returns the last element in the enumeration class.

  Parameter: anyenum

  Return type: anyenum

- enum_le

  Description: Enumeration comparison function, which is used to implement the <= symbol.

  Parameter: anyenum, anyenum

  Return type: Boolean

- enum_lt

  Description: Enumeration comparison function, which is used to implement the < symbol.

  Parameter: anyenum, anyenum

  Return type: Boolean

- enum_smaller

  Description: Enumeration comparison function, which is used to implement the < symbol.

  Parameter: anyenum, anyenum

  Return type: Boolean

- node_oid_name

  Description: Not supported

  Parameter: oid

  Return type: cstring

- pg_buffercache_pages

  Description: Reads data from the shared buffer.

  Parameter: nan

  Return type: bufferid integer, relfilenode oid, bucketid smallint, storage_type oid, reltablespace oid, reldatabase oid, relforknumber smallint, relblocknumber bigint, isdirty boolean, and usage_count smallint

- pg_check_xidlimit

  Description: Checks whether nextxid is greater than or equal to xidwarnlimit.

  Parameter: nan

  Return type: Boolean

- pg_comm_delay

  Description: Displays the delay status of the communication library of a single DN.

  Parameter: nan

  Return type: text, text, integer, integer, integer, integer

- pg_comm_recv_stream

  Description: Displays the receiving stream status of all communication libraries on a single DN.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Parameter: nan

Return type: text, bigint, text, bigint, integer, integer, integer, text, bigint, integer, integer, integer, bigint, bigint, bigint, bigint, bigint

- pg_comm_send_stream

  Description: Displays the sending stream status of all communication libraries on a single DN.

  Parameter: nan

  Return type: text, bigint, text, bigint, integer, integer, integer, text, bigint, integer, integer, integer, bigint, bigint, bigint, bigint, bigint

- pg_comm_status

  Description: Displays the communication status of a single DN.

  Parameter: nan

  Return type: text, integer, integer, bigint, bigint, bigint, bigint, bigint, integer, integer, integer, integer, integer

- pg_log_comm_status

  Description: Prints some logs on the DN.

  Parameter: nan

  Return type: Boolean

- pg_parse_clog

  Description: Parses clog to obtain the status of xid.

  Parameter: nan

  Return type: xid xid, status text

- pg_pool_ping

  Description: Sets PoolerPing.

  Parameter: Boolean

  Return type: SETOF boolean

- pg_pool_validate

  Description: Compares fields in the **pgxc_node** system catalog to check whether a connection is available.

  Parameter: clear boolean, co_node_name cstring

  Return type: pid bigint, node_name text

- pg_resume_bkp_flag

  Description: Obtains the delay xlong flag for backup and restoration.

  Parameter: slot_name name

  Return type: start_backup_flag boolean, to_delay boolean, ddl_delay_recycle_ptr text, rewind_time text

- pg_stat_get_pooler_status

  Description: Queries the cache connection status in the pooler.

  Parameter: nan

  Return type: text, text, bigint, text, bigint, boolean, text, bigint, bigint, bigint, bigint, bigint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

**Table 12-96** PG_STAT_GET_POOLER_STATUS columns

| Name | Type | Description |
| --- | --- | --- |
| database_name | text | Database name |
| user_name | text | Username |
| tid | bigint | In non-thread pool logic, this parameter indicates the ID of the thread connected to the CN. In thread pool logic, this parameter indicates the ID of the session connected to the CN. |
| pgoptions | text | Database connection option. For details, see the **options** columns in **6.5.5 Link Parameters**. |
| node_oid | bigint | OID of the node connected |
| in_use | boolean | Whether the connection is currently used.<br>• **t** (true): The connection is in use.<br>• **f** (false): The connection is not in use. |
| session_params | text | GUC session parameter delivered by the connection |
| fdsock | bigint | Local socket |
| remote_pid | bigint | Peer thread ID |
| used_count | bigint | Number of reuse times of a connection |
| idx | bigint | Peer DN ID in the local CN |
| streamid | bigint | Stream ID in the physical connection |

- psortoptions

  Description: Returns the psort attribute.

  Parameter: text[], boolean

  Return type: bytea
- remove_job_class_depend

  Description: Removes the job dependency.

  Parameter: oid

  Return type: void
- sweep_series

  Description: Clears useless timelines outside the time window on a specified table. This function applies only to time series tables with the TTL and period specified. You need to use **search_path** to specify the schema in advance. The default value is **public**. The upper bound of the time window is the invocation time plus a period, and the lower bound is the invocation time minus a TTL.

  Parameter: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: void

- sweep_series_preview

  Description: Prints the tag IDs of the useless timelines outside the time window to logs. This function applies only to time series tables with the TTL and period specified. You need to use **search_path** to specify the schema in advance. The default value is **public**. The upper bound of the time window is the invocation time plus a period, and the lower bound is the invocation time minus a TTL. **log_min_message** needs to be set to **DEBUG2**.

  Parameter: text

  Return type: void

- xideq4

  Description: Compares two xids to check whether they are the same.

  Parameter: xid32, xid32

  Return type: Boolean

- xideqint8

  Description: Compares two xids to check whether they are the same.

  Parameter: xid, bigint

  Return type: Boolean

- xidlt

  Description: Returns whether xid1 < xid2 is true.

  Parameter: xid, xid

  Return type: Boolean

- xidlt4

  Description: Returns whether xid1 < xid2 is true.

  Parameter: xid32, xid32

  Return type: Boolean

- get_local_cont_query_stat

  Description: Obtains the statistics of a specified continuous computing view on the local node.

  Parameter: cq_id oid

  Return type: cq oid, w_in_rows int8, w_in_bytes int8, w_out_rows int8, w_out_bytes int8, w_pendings int8, w_errors int8, r_in_rows int8, r_in_bytes int8, r_out_rows int8, r_out_bytes int8, r_errors int8, c_in_rows int8, c_in_bytes int8, c_out_rows int8, c_out_bytes int8, c_pendings int8, c_errors int8

- get_local_cont_query_stats

  Description: Obtains all continuous computing view statistics of the local node.

  Parameter: nan

  Return type: cq oid, w_in_rows int8, w_in_bytes int8, w_out_rows int8, w_out_bytes int8, w_pendings int8, w_errors int8, r_in_rows int8, r_in_bytes int8, r_out_rows int8, r_out_bytes int8, r_errors int8, c_in_rows int8, c_in_bytes int8, c_out_rows int8, c_out_bytes int8, c_pendings int8, c_errors int8

- get_cont_query_stats

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Description: Obtains statistics about all continuous computing views on each DN.

Parameter: nan

Return type: node name, cq oid, w_in_rows int8, w_in_bytes int8, w_out_rows int8, w_out_bytes int8, w_pendings int8, w_errors int8, r_in_rows int8, r_in_bytes int8, r_out_rows int8, r_out_bytes int8, r_errors int8, c_in_rows int8, c_in_bytes int8, c_out_rows int8, c_out_bytes int8, c_pendings int8, c_errors int8

- reset_local_cont_query_stat

  Description: Resets the statistics of a specified continuous computation view on the local node.

  Parameter: cq_id oid

  Return type: Boolean

- reset_local_cont_query_stats

  Description: Resets association statistics on the specified continuous computation view of the local node.

  Parameter: cq_id oid

  Return type: Boolean

- reset_cont_query_stats

  Description: Resets the continuous computation view statistics corresponding to the STREAM object on each DN.

  Parameter: stream_id oid

  Return type: Boolean

- check_cont_query_schema_changed

  Description: Determines the schema change status of a specified continuous computation view.

  Parameter: cq_id oid

  Return type: Boolean

- gs_get_standby_cluster_barrier_status

  Description: Queries the barrier log playback information of the standby CN or DN, including the latest received barrier, LSN of the latest received barrier, barrier played back last time, and target barrier to be played back.

  Parameter: nan

  Return type: barrier_id text, barrier_lsn text, recovery_id text, target_id text

  Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission, and **operate_mode** must be enabled for the O&M administrator role.

- gs_set_standby_cluster_target_barrier_id

  Description: Set the target barrier to be played back.

  Parameter: barrier_id

  Return type: target_id text

  Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission, and **operate_mode** must be enabled for the O&M administrator role.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- gs_query_standby_cluster_barrier_id_exist

  Description: Queries whether the specified barrier is received by the standby node.

  Parameter: barrier_id

  Return type: Boolean

  Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission, and **operate_mode** must be enabled for the O&M administrator role.

  The following stream functions exist but are not supported. You are not advised to use them.

  streaming_int8_avg_gather, streaming_numeric_avg_gather, streaming_float8_avg_gather, streaming_interval_avg_gather, streaming_int8_sum_gather, and streaming_int2_int4_sum_gather

## 12.5.35 Internal Functions

The following functions of GaussDB use internal data types, which cannot be directly called by users.

- Selection rate calculation functions

| areajoinsel | areasel | arraycontjoinsel | arraycontsel | contjoinsel | contsel | eqjoinsel |
|---|---|---|---|---|---|---|
| eqsel | iclikejoinsel | iclikesel | icnlikejoinsel | icnlikesel | icregexeqjoinsel | icregexeqsel |

- Function for reading data remotely

  **gs_read_block_from_remote** is used to read the pages of a non-segment-page table file. By default, only the initial user can view the data. Other users can view the data only after being granted with permissions.

  **gs_read_segment_block_from_remote** is used to read the pages of a segment-page table file. By default, only the initial user can view the data. Other users can view the data only after being granted with permissions.

- Function for reading files remotely

  **gs_read_file_size_from_remote** is used to read the size of a specified file. Before using the **gs_repair_file** function to repair a file, you need to obtain the size of the file from the remote end to verify the missing file information and repair the missing files one by one. By default, only the initial user can view the data. Other users can view the data only after being granted with permissions.

  **gs_read_file_from_remote** is used to read a specified file. After obtaining the file size by using the **gs_read_file_size_from_remote** function, **gs_repair_file** reads the remote file segment by segment using this function. By default, only the initial user can view the data. Other users can view the data only after being granted with permissions.

# 12.5.36 AI Feature Functions

- db4ai_predict_by_bool (text, VARIADIC "any")

  Description: Obtains a model whose return value is of the Boolean type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

  Parameter: model name and input column name of the inference task

  Return type: Boolean

- db4ai_predict_by_float4(text, VARIADIC "any")

  Description: Obtains a model whose return value is of the float4 type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

  Parameter: model name and input column name of the inference task

  Return type: float

- db4ai_predict_by_float8(text, VARIADIC "any")

  Description: Obtains a model whose return value is of the float8 type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

  Parameter: model name and input column name of the inference task

  Return type: float

- db4ai_predict_by_int32(text, VARIADIC "any")

  Description: Obtains a model whose return value is of the int32 type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

  Parameter: model name and input column name of the inference task

  Return type: int

- db4ai_predict_by_int64(text, VARIADIC "any")

  Description: Obtains a model whose return value is of the int64 type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

  Parameter: model name and input column name of the inference task

  Return type: int

- db4ai_predict_by_numeric(text, VARIADIC "any")

  Description: Obtains a model whose return value is of the numeric type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

  Parameter: model name and input column name of the inference task

  Return type: numeric

- db4ai_predict_by_text(text, VARIADIC "any")

  Description: Obtains a model whose return value is of the character type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

  Parameter: model name and input column name of the inference task

  Return type: text

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

- db4ai_predict_by_float8_array(text, VARIADIC "any")

  Description: Obtains a model whose return value is of the character type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

  Parameter: model name and input column name of the inference task

  Return type: text

- gs_explain_model(text)

  Description: Obtains the model whose return value is of the character type for text-based model parsing.

  Parameter: model name

  Return type: text

## 12.5.37 Dynamic Data Masking Functions

NOTE

This function is an internal function. For details, see "Database Security > Dynamic Data Anonymization" in *Feature Description*.

- creditcardmasking(col text, letter char default 'x')

  Description: Replaces the digits before the last four bits following the col string with letters.

  Parameter: Character string to be replaced or character string used for replacement

  Return type: text

- basicmailmasking(col text, letter char default 'x')

  Description: Replaces the characters before the first at sign (@) in the col string with letters.

  Parameter: Character string to be replaced or character string used for replacement

  Return type: text

- fullmailmasking(col text, letter char default 'x')

  Description: Replaces the characters (except **@**) before the last period (.) in the col string with letters.

  Parameter: Character string to be replaced or character string used for replacement

  Return type: text

- alldigitsmasking(col text, letter char default '0')

  Description: Replaces the digits in the col string with letters.

  Parameter: Character string to be replaced or character string used for replacement

  Return type: text

- shufflemasking(col text)

  Description: Sorts the characters in the col string out of order.

  Parameter: Character string to be replaced or character string used for replacement

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

Return type: text

- randommasking(col text)

  Description: Randomizes the characters in the col string.

  Parameter: Character string to be replaced or character string used for replacement

  Return type: text

- regexpmasking(col text, reg text, replace_text text, pos INTEGER default 0, reg_len INTEGER default -1)

  Description: Replaces the col string with a regular expression.

  Parameters: Character string to be replaced, regular expression, replacement start position, and replacement length.

  Return type: text

## 12.5.38 Hotkey Feature Functions

- gs_stat_get_hotkeys_info()

  Description: Obtains hotkey information queried on the local node.

  Return type: Tuple

  Example:

```
openGauss=# select * from gs_stat_get_hotkeys_info() order by count, hash_value;
 database_name | schema_name |     table_name      | key_value | hash_value | count
---------------+-------------+---------------------+-----------+------------+-------
 regression    | public      | hotkey_single_col | {22}      | 1858004829 |     2
 regression    | public      | hotkey_single_col | {11}      | 2011968649 |     2
(2 rows)
```

- gs_stat_clean_hotkeys()

  Description: Clears hotkey cache and resets hotkey status information.

  Return type: bool, and the return value is always **true**.

  Example:

```
openGauss=# select * from gs_stat_clean_hotkeys();
 gs_stat_clean_hotkeys
-----------------------
 t
(1 row)
```

## 12.5.39 Global SysCache Functions

The current feature is a lab feature. Contact Huawei technical support before using it.

- gs_gsc_table_detail(database_id default NULL, rel_id default NULL)

  Description: Queries the table metadata in the global system cache in a database. The user who calls this function must have the **SYSADMIN** permission.

  Parameter: Specifies the database and table to be queried in the global system cache. The default value **NULL** or value **–1** of **database_id** indicates all databases. The value **0** indicates a shared table. Other values indicate a specified database and a shared table. **rel_id** indicates the OID of a specified table. The default value **NULL** or value **–1** indicates all tables. Other values

 Copyright © Huawei Cloud Computing Technologies Co., Ltd. 

indicate a specified table. If **database_id** does not exist, an error is reported. If **rel_id** does not exist, the query result is empty.

Return type: Tuple

```
select * from gs_gsc_table_detail(-1) limit 1;
database_oid | database_name | reloid |         relname          | relnamespace | reltype | reloftype |
relowner | relam | relfilenode | reltablespace | relhasindex | relisshared | relkind | relnatts | relhasoids |
relhaspkey | parttype | tdhasuids | attnames  | extinfo
--------------+---------------+---------+--------------------------+--------------+---------+-----------+----------
+-------+-------------+---------------+-------------+-------------+---------+----------+------------+------------
