Contents

1 Database System Overview	1
1.1 Database Logical Architecture	1
1.2 Query Request Handling Process	2
1.3 Managing Transactions	2
1.4 Concepts	6
2 Database Security	8
2.1 Users and Permissions	8
2.1.1 Default Permission Mechanism	8
2.1.2 Administrators	9
2.1.3 Separation of Duties	11
2.1.4 Users	13
2.1.5 Roles	14
2.1.6 Schemas	16
2.1.7 User Permissions	17
2.1.8 Row-Level Security Policy	18
2.2 Database Audit	20
3 Database Quick Start	22
3.1 Connecting to a Database	22
3.1.1 Using gsql to Connect to a Database	22
3.1.2 APIs	22
3.2 Operating a Database	23
3.2.1 Creating a Database Account	23
3.2.2 Creating and Managing Databases	24
3.2.3 Creating and Managing Tablespaces	26
3.2.4 Creating and Managing Tables	28
3.2.4.1 Creating a Table	29
3.2.4.2 Inserting Data to a Table	29
3.2.4.3 Updating Data in a Table	33
3.2.4.4 Viewing Data	34
3.2.4.5 Deleting Data from a Table	34
3.2.5 Querying System Catalogs	35
3.2.6 Other Operations	37

3.2.6.1 Creating and Managing Schemas.....	37
3.2.6.2 Creating and Managing Partitioned Tables.....	40
3.2.6.3 Creating and Managing Indexes.....	44
3.2.6.4 Creating and Managing Views.....	48
3.2.6.5 Creating and Managing Sequences.....	49
3.2.6.6 Creating and Managing Scheduled Jobs.....	51
4 Development and Design Proposal.....	55
4.1 Overview.....	55
4.2 Database Object Naming Conventions.....	55
4.3 Database Object Design.....	56
4.3.1 Database and Schema Design.....	56
4.3.2 Table Design.....	57
4.3.3 Column Design.....	61
4.3.4 Constraint Design.....	62
4.3.5 View and Joined Table Design.....	62
4.4 Tool Interconnection.....	62
4.4.1 JDBC Configuration.....	62
4.5 SQL Compilation.....	64
5 Application Development Guide.....	68
5.1 Development Specifications.....	68
5.2 Obtaining the Driver Package.....	69
5.3 Development Based on JDBC.....	69
5.3.1 JDBC Package, Driver Class, and Environment Class.....	69
5.3.2 Development Process.....	73
5.3.3 Loading a Driver.....	73
5.3.4 Connecting to a Database.....	74
5.3.5 Connecting to a Database (Using SSL).....	88
5.3.6 Connecting to a Database (Using UDS).....	91
5.3.7 Running SQL Statements.....	92
5.3.8 Processing Data in a Result Set.....	97
5.3.9 Closing a Connection.....	99
5.3.10 Log Management.....	100
5.3.11 Examples: Common Operations.....	103
5.3.12 Example: Retrying SQL Queries for Applications.....	108
5.3.13 Example: Logical Replication Code.....	111
5.3.14 Example: Parameters for Connecting to the Database in Different Scenarios.....	119
5.3.15 JDBC Interface Reference.....	120
5.3.15.1 java.sql.Connection.....	120
5.3.15.2 java.sql.CallableStatement.....	123
5.3.15.3 java.sql.DatabaseMetaData.....	125
5.3.15.4 java.sql.Driver.....	133
5.3.15.5 java.sql.PreparedStatement.....	133

5.3.15.6 java.sql.ResultSet.....	137
5.3.15.7 java.sql.ResultSetMetaData.....	144
5.3.15.8 java.sql.Statement.....	145
5.3.15.9 javax.sql.ConnectionPoolDataSource.....	148
5.3.15.10 javax.sql.DataSource.....	148
5.3.15.11 javax.sql.PooledConnection.....	148
5.3.15.12 javax.naming.Context.....	149
5.3.15.13 javax.naming.spi.InitialContextFactory.....	149
5.3.15.14 CopyManager.....	150
5.3.15.15 PGReplicationConnection.....	151
5.3.15.16 PGReplicationStream.....	154
5.3.15.17 ChainedStreamBuilder.....	156
5.3.15.18 ChainedCommonStreamBuilder.....	156
5.3.16 Common JDBC Parameters.....	157
5.3.17 FAQs.....	161
5.3.17.1 Incorrect batchSize Settings.....	161
5.3.17.2 Error Is Reported When Verification Is Enabled for Data Insertion in the Hibernate Framework.....	162
5.3.18 Mapping for JDBC Data Types.....	164
5.4 Development Based on ODBC.....	165
5.4.1 ODBC Packages, Dependent Libraries, and Header Files.....	167
5.4.2 Development Process.....	167
5.4.3 Configuring a Data Source in the Linux OS.....	169
5.4.4 Configuring a Data Source in the Windows OS.....	182
5.4.5 Example: Common Functions and Batch Binding.....	186
5.4.6 Typical Application Scenarios and Configurations.....	193
5.4.7 ODBC Interface Reference.....	201
5.4.7.1 SQLAllocEnv.....	202
5.4.7.2 SQLAllocConnect.....	202
5.4.7.3 SQLAllocHandle.....	202
5.4.7.4 SQLAllocStmt.....	203
5.4.7.5 SQLBindCol.....	203
5.4.7.6 SQLBindParameter.....	205
5.4.7.7 SQLColAttribute.....	206
5.4.7.8 SQLConnect.....	207
5.4.7.9 SQLDisconnect.....	209
5.4.7.10 SQLExecDirect.....	209
5.4.7.11 SQLExecute.....	211
5.4.7.12 SQLFetch.....	212
5.4.7.13 SQLFreeStmt.....	212
5.4.7.14 SQLFreeConnect.....	213
5.4.7.15 SQLFreeHandle.....	213
5.4.7.16 SQLFreeEnv.....	214

5.4.7.17 SQLPrepare.....	214
5.4.7.18 SQLGetData.....	215
5.4.7.19 SQLGetDiagRec.....	216
5.4.7.20 SQLSetConnectAttr.....	219
5.4.7.21 SQLSetEnvAttr.....	220
5.4.7.22 SQLSetStmtAttr.....	221
5.5 Development Based on libpq.....	222
5.5.1 libpq Package, Dependent Library, and Header File.....	222
5.5.2 Development Process.....	222
5.5.3 Examples.....	223
5.5.4 libpq Interface Reference.....	228
5.5.4.1 Database Connection Control Functions.....	228
5.5.4.1.1 PQconnectdbParams.....	229
5.5.4.1.2 PQconnectdb.....	229
5.5.4.1.3 PQbackendPID.....	230
5.5.4.1.4 PQsetdbLogin.....	230
5.5.4.1.5 PQfinish.....	232
5.5.4.1.6 PQreset.....	232
5.5.4.1.7 PQstatus.....	233
5.5.4.2 Database Statement Execution Functions.....	234
5.5.4.2.1 PQexec.....	234
5.5.4.2.2 PQprepare.....	235
5.5.4.2.3 PQresultStatus.....	236
5.5.4.2.4 PQclear.....	237
5.5.4.3 Functions for Asynchronous Command Processing.....	238
5.5.4.3.1 PQsendQuery.....	238
5.5.4.3.2 PQsendQueryParams.....	239
5.5.4.3.3 PQsendPrepare.....	240
5.5.4.3.4 PQsendQueryPrepared.....	241
5.5.4.3.5 PQflush.....	242
5.5.4.4 Functions for Canceling Queries in Progress.....	242
5.5.4.4.1 PQgetCancel.....	242
5.5.4.4.2 PQfreeCancel.....	243
5.5.4.4.3 PQcancel.....	244
5.5.5 Connection Parameters.....	245
5.6 Psycopg-based Development.....	250
5.6.1 Development Process.....	251
5.6.2 Development Procedure.....	252
5.6.3 Examples: Common Operations.....	254
5.6.4 Psycopg API Reference.....	256
5.6.4.1 psycopg2.connect().....	256
5.6.4.2 connection.cursor().....	258

5.6.4.3 cursor.execute(query,vars_list).....	259
5.6.4.4 curosr.executemany(query,vars_list).....	259
5.6.4.5 connection.commit().....	260
5.6.4.6 connection.rollback().....	261
5.6.4.7 cursor.fetchone().....	261
5.6.4.8 cursor.fetchall().....	262
5.6.4.9 cursor.close().....	262
5.6.4.10 connection.close().....	262
5.7 ECPG-based Development.....	263
5.7.1 Development Process.....	264
5.7.2 ecpg Components.....	265
5.7.3 ecpg Preprocessing and Compiling.....	266
5.7.4 Managing Database Connections.....	267
5.7.4.1 Connecting to a Database.....	267
5.7.4.2 Managing Connections.....	268
5.7.5 Running SQL Commands.....	269
5.7.5.1 Running SQL Statements.....	269
5.7.5.2 Using Cursors.....	270
5.7.5.3 Transaction.....	271
5.7.5.4 Prepared Statements.....	271
5.7.5.5 Embedded SQL Commands.....	272
5.7.5.5.1 ALLOCATE DESCRIPTOR.....	272
5.7.5.5.2 CONNECT.....	272
5.7.5.5.3 DEALLOCATE DESCRIPTOR.....	275
5.7.5.5.4 DECLARE.....	275
5.7.5.5.5 DESCRIBE.....	276
5.7.5.5.6 DISCONNECT.....	277
5.7.5.5.7 EXECUTE IMMEDIATE.....	277
5.7.5.5.8 GET DESCRIPTOR.....	278
5.7.5.5.9 OPEN.....	280
5.7.5.5.10 PREPARE.....	280
5.7.5.5.11 SET AUTOCOMMIT.....	281
5.7.5.5.12 SET CONNECTION.....	281
5.7.5.5.13 SET DESCRIPTOR.....	282
5.7.5.5.14 TYPE.....	283
5.7.5.5.15 VAR.....	284
5.7.5.5.16 WHENEVER.....	285
5.7.6 Querying the Result Set.....	285
5.7.7 Closing a Database Connection.....	286
5.7.8 Host Variables.....	286
5.7.8.1 Overview.....	287
5.7.8.2 DECLARE Section.....	287

5.7.8.3 Retrieving Query Results.....	287
5.7.8.4 Type Mapping.....	288
5.7.8.5 Handling Character Strings.....	289
5.7.8.6 Host Variables with Non-Primitive Types.....	290
5.7.8.7 Accessing Special Data Types.....	292
5.7.8.8 Handling Non-Primitive SQL Data Types.....	294
5.7.9 Executing Dynamic SQL Statements.....	296
5.7.9.1 Executing a Statement Without a Result Set.....	297
5.7.9.2 Executing a Statement with Input Parameters.....	297
5.7.9.3 Executing a Statement with a Result Set.....	297
5.7.10 Error Handling.....	298
5.7.10.1 Setting Callbacks.....	298
5.7.10.2 sqlca.....	299
5.7.10.3 SQLSTATE and SQLCODE.....	300
5.7.11 Preprocessor Directives.....	304
5.7.11.1 Including Files.....	304
5.7.11.2 Directives: ifdef, ifndef, else, elif, and endif.....	305
5.7.11.3 Directives: define and undef.....	305
5.7.12 Using Library Functions.....	306
5.7.13 SQL Descriptor Area.....	308
5.7.13.1 Named SQLDA.....	308
5.7.13.2 SQLDA.....	309
5.7.14 Examples.....	313
5.7.15 ecpg and Pro*C Compatibility Comparison.....	320
5.7.16 ECPG API Reference.....	321
5.7.16.1 Interval Type.....	321
5.7.16.2 Numeric Type.....	322
5.7.16.3 Date Type.....	326
5.7.16.4 Timestamp Type.....	330
5.8 Development Based on the Go Driver.....	333
5.8.1 Setting Up the Go Driver Environment.....	333
5.8.2 Development Process.....	335
5.8.3 Connecting to a Database.....	336
5.8.4 Connecting to a Database (Using SSL).....	344
5.8.5 Go APIs.....	346
5.8.5.1 sql.Open.....	346
5.8.5.2 type DB.....	346
5.8.5.3 type Stmt.....	349
5.8.5.4 type Tx.....	353
5.8.5.5 type Rows.....	355
5.8.5.6 type Row.....	355
5.8.5.7 type ColumnType.....	356

5.8.5.8 type Result.....	356
5.9 Debugging.....	357
6 SQL Optimization.....	361
6.1 Query Execution Process.....	361
6.2 Introduction to the SQL Execution Plan.....	364
6.2.1 Overview.....	364
6.2.2 Description.....	366
6.3 Optimization Process.....	374
6.4 Updating Statistics.....	375
6.5 Reviewing and Modifying a Table Definition.....	376
6.5.1 Overview.....	376
6.5.2 Selecting a Distribution Mode.....	377
6.5.3 Selecting Distribution Keys.....	378
6.5.4 Using Partitioned Tables.....	379
6.5.5 Selecting a Data Type.....	379
6.6 Typical SQL Optimization Methods.....	380
6.6.1 Optimizing SQL Self-Diagnosis.....	380
6.6.2 Optimizing Statement Pushdown.....	382
6.6.3 Optimizing Subqueries.....	391
6.6.4 Optimizing Statistics.....	399
6.6.5 Optimizing Operators.....	404
6.7 Experience in Rewriting SQL Statements.....	407
6.8 Configuring Key Parameters for SQL Tuning.....	409
6.9 Hint-based Tuning.....	411
6.9.1 Plan Hint Optimization.....	411
6.9.2 Hint Specifying the Query Block Where the Hint Is Located.....	417
6.9.3 Hint Specifying the Query Block and Schema of a Table.....	420
6.9.4 Join Order Hints.....	421
6.9.5 Join Operation Hints.....	423
6.9.6 Rows Hints.....	424
6.9.7 Stream Operation Hints.....	425
6.9.8 Scan Hints.....	427
6.9.9 Sublink Name Hints.....	429
6.9.10 Skew Hints.....	430
6.9.11 Parameterized Path Hint.....	432
6.9.12 Hint Errors, Conflicts, and Other Warnings.....	433
6.9.13 GUC Parameter Hints.....	435
6.9.14 Hints for Selecting the Custom Plan or Generic Plan.....	437
6.9.15 Hints Specifying Not to Expand Subqueries.....	438
6.9.16 Hints Specifying Not to Use Global Plan Cache.....	439
6.9.17 Hint of Parameterized Paths at the Same Level.....	440
6.9.18 Hint for Setting Slow SQL Control Rules.....	442

6.9.19 Bitmap Scan Hints.....	442
6.9.20 Hint for Inner Table Materialization During Join.....	443
6.9.21 AGG Hint.....	444
6.10 Checking the Implicit Conversion Performance.....	445
6.11 Tuning with SQL PATCH.....	446
6.12 Optimization Cases.....	452
6.12.1 Case: Selecting an Appropriate Distribution Key.....	452
6.12.2 Case: Creating an Appropriate Index.....	453
6.12.3 Case: Adjusting Distribution Keys.....	455
6.12.4 Case: Adjusting the GUC Parameter best_agg_plan.....	455
6.12.5 Case: Rewriting SQL and Deleting Subqueries (1).....	457
6.12.6 Case: Rewriting SQL Statements to Eliminate Pruning Interference.....	458
6.12.7 Case: Rewriting SQL Statements and Deleting in-clause.....	459
6.12.8 Case: Modifying the GUC Parameter rewrite_rule.....	460
6.12.9 Using DN Gather to Reduce Stream Nodes in the Plan.....	467
7 SQL Reference.....	476
7.1 SQL.....	476
7.2 Keywords.....	477
7.3 Data Type.....	514
7.3.1 Numeric Types.....	514
7.3.2 Monetary Types.....	520
7.3.3 Boolean Types.....	521
7.3.4 Character Types.....	522
7.3.5 Binary Types.....	526
7.3.6 Date/Time Types.....	529
7.3.7 Geometric Types.....	539
7.3.8 Network Address Types.....	542
7.3.9 Bit String Types.....	543
7.3.10 UUID Type.....	544
7.3.11 JSON/JSONB Types.....	545
7.3.12 HLL.....	549
7.3.13 Range.....	553
7.3.14 Object Identifier Types.....	557
7.3.15 Pseudo-Types.....	559
7.3.16 XML Type.....	561
7.3.17 XMLType.....	563
7.3.18 ACLItem.....	564
7.3.19 Array Types.....	565
7.4 Constant and Macro.....	570
7.5 Functions and Operators.....	571
7.5.1 Logical Operators.....	572
7.5.2 Comparison Operators.....	572

7.5.3 Character Processing Functions and Operators.....	573
7.5.4 Binary String Functions and Operators.....	609
7.5.5 Bit String Functions and Operators.....	613
7.5.6 Pattern Matching Operators.....	615
7.5.7 Arithmetic Functions and Operators.....	620
7.5.8 Date and Time Processing Functions and Operators.....	637
7.5.9 Type Conversion Functions.....	668
7.5.10 Geometric Functions and Operators.....	698
7.5.11 Network Address Functions and Operators.....	709
7.5.12 Text Search Functions and Operators.....	714
7.5.13 JSON/JSONB Functions and Operators.....	720
7.5.14 HLL Functions and Operators.....	731
7.5.15 SEQUENCE Functions.....	744
7.5.16 Array Functions and Operators.....	746
7.5.17 Range Functions and Operators.....	754
7.5.18 Aggregate Functions.....	759
7.5.19 Window Functions.....	772
7.5.20 Security Functions.....	778
7.5.21 Encrypted Functions and Operators.....	786
7.5.22 Set Returning Functions.....	789
7.5.23 Conditional Expression Functions.....	791
7.5.24 System Information Functions.....	795
7.5.25 System Administration Functions.....	837
7.5.25.1 Configuration Settings Functions.....	837
7.5.25.2 Universal File Access Functions.....	838
7.5.25.3 Server Signal Functions.....	840
7.5.25.4 Backup and Restoration Control Functions.....	842
7.5.25.5 Dual-Cluster DR Control Functions.....	851
7.5.25.6 Dual-Cluster DR Query Functions.....	852
7.5.25.7 Snapshot Synchronization Functions.....	855
7.5.25.8 Database Object Functions.....	855
7.5.25.9 Advisory Lock Functions.....	861
7.5.25.10 Logical Replication Functions.....	864
7.5.25.11 Undo System Functions.....	885
7.5.25.12 Other Functions.....	906
7.5.25.13 SQL Statement Concurrency Control Function.....	939
7.5.26 Statistics Information Functions.....	944
7.5.27 Trigger Functions.....	1025
7.5.28 Hash Function.....	1026
7.5.29 Prompt Message Function.....	1034
7.5.30 Fault Injection System Function.....	1034
7.5.31 Redistribution Parameters.....	1034

7.5.32 Distribution Key Recommendation Functions.....	1035
7.5.33 Other System Functions.....	1040
7.5.34 Internal Functions.....	1069
7.5.35 AI Feature Functions.....	1076
7.5.36 Dynamic Data Masking Functions.....	1078
7.5.37 Hotkey Feature Functions.....	1079
7.5.38 Global SysCache Functions.....	1080
7.5.39 Data Damage Detection and Repair Functions.....	1082
7.5.40 Functions of the XML Type.....	1096
7.5.41 Functions of the XMLType Type.....	1112
7.5.42 Obsolete Functions.....	1120
7.6 Expressions.....	1120
7.6.1 Simple Expressions.....	1120
7.6.2 Condition Expressions.....	1123
7.6.3 Subquery Expressions.....	1127
7.6.4 Array Expressions.....	1129
7.6.5 Row Expressions.....	1131
7.7 Pseudocolumn.....	1133
7.8 Type Conversion.....	1136
7.8.1 Overview.....	1136
7.8.2 Operators.....	1138
7.8.3 Functions.....	1140
7.8.4 Value Storage.....	1142
7.8.5 UNION, CASE, and Related Constructs.....	1143
7.9 System Operation.....	1147
7.10 Controlling Transactions.....	1148
7.11 DDL Syntax Overview.....	1149
7.12 DML Syntax Overview.....	1153
7.13 DCL Syntax Overview.....	1155
7.14 SQL Syntax.....	1156
7.14.1 SQL Syntax.....	1156
7.14.2 ABORT.....	1156
7.14.3 ALTER AUDIT POLICY.....	1157
7.14.4 ALTER COLUMN ENCRYPTION KEY.....	1159
7.14.5 ALTER COORDINATOR.....	1160
7.14.6 ALTER DATABASE.....	1161
7.14.7 ALTER DATABASE LINK.....	1164
7.14.8 ALTER DEFAULT PRIVILEGES.....	1165
7.14.9 ALTER DIRECTORY.....	1167
7.14.10 ALTER FOREIGN DATA WRAPPER.....	1168
7.14.11 ALTER FUNCTION.....	1169
7.14.12 ALTER GLOBAL CONFIGURATION.....	1173

7.14.13 ALTER GROUP.....	1174
7.14.14 ALTER INDEX.....	1175
7.14.15 ALTER LANGUAGE.....	1177
7.14.16 ALTER MASKING POLICY.....	1177
7.14.17 ALTER MATERIALIZED VIEW.....	1179
7.14.18 ALTER NODE.....	1180
7.14.19 ALTER NODE GROUP.....	1181
7.14.20 ALTER RESOURCE LABEL.....	1182
7.14.21 ALTER ROLE.....	1183
7.14.22 ALTER ROW LEVEL SECURITY POLICY.....	1185
7.14.23 ALTER SCHEMA.....	1187
7.14.24 ALTER SEQUENCE.....	1189
7.14.25 ALTER SERVER.....	1190
7.14.26 ALTER SESSION.....	1192
7.14.27 ALTER SYNONYM.....	1193
7.14.28 ALTER SYSTEM KILL SESSION.....	1194
7.14.29 ALTER TABLE.....	1195
7.14.30 ALTER TABLE PARTITION.....	1213
7.14.31 ALTER TABLESPACE.....	1220
7.14.32 ALTER TRIGGER.....	1222
7.14.33 ALTER TYPE.....	1223
7.14.34 ALTER USER.....	1225
7.14.35 ALTER VIEW.....	1227

1 Database System Overview

1.1 Database Logical Architecture

Each DN in a cluster stores data on disks. This section describes the objects on each DN from the logical view, the relationship between these objects, and how data is distributed on different nodes. [Figure 1-1](#) shows the database logical structure.

Figure 1-1 Database logical architecture

NOTE

- A tablespace is a directory. A database contains one or more tablespaces to store physical files of the database. Each tablespace can contain files belonging to different databases.
- A database manages various data objects and is isolated from each other. Objects managed by a database can be distributed to multiple tablespaces.
- A datafile segment stores data of only one table. A table containing more than 1 GB of data is stored in multiple datafile segments.
- One table belongs to only one database and one tablespace. The datafile segments storing the data of the same table must be in the same tablespace.
- A block is a basic unit for database management. Its default size is 8 KB.
- Data can be distributed on DN in replication, hash, range, or list mode. You can specify a mode when creating a table.

1.2 Query Request Handling Process

Figure 1-2 GaussDB service response process

1.3 Managing Transactions

A transaction is a customized sequence of database operations, which form an integral unit of work. In GaussDB, you can start, set, commit, and roll back transactions. GaussDB supports the following transaction isolation levels: READ

COMMITTED, REPEATABLE READ, and SERIALIZABLE. SERIALIZABLE is equivalent to REPEATABLE READ.

Controlling Transactions

Transaction operations supported by a database are as follows:

- Starting transactions
You can use the `START TRANSACTION` or `BEGIN` syntax to start a transaction. For details, see [START TRANSACTION](#) and [BEGIN](#).
- Setting transactions
You can use the `SET TRANSACTION` or `SET LOCAL TRANSACTION` syntax to set transactions. For details, see [SET TRANSACTION](#).
- Committing transactions
You can commit all operations of a transaction using `COMMIT` or `END`. For details, see [COMMIT | END](#).
- Rolling back transactions
Rollback indicates that the system cancels all changes that a transaction has made to a database if the transaction fails to be executed due to a fault. For details, see [ROLLBACK](#).

Transaction Isolation Levels

A transaction isolation level specifies how concurrent transactions process the same object.

NOTE

The isolation level cannot be changed after the first data manipulation statement (`SELECT`, `INSERT`, `DELETE`, `UPDATE`, `FETCH`, or `COPY`) in a transaction is executed.

- **READ COMMITTED:** At this level, a transaction can access only committed data. This is the default level.
The `SELECT` statement accesses the snapshot of the database taken when the query begins. The `SELECT` statement can also access the data modifications in its transaction, regardless of whether they have been committed. Note that different database snapshots may be available to two consecutive `SELECT` statements for the same transaction, because data may be committed for other transactions while the first `SELECT` statement is executed.
At the **READ COMMITTED** level, the execution of each statement begins with a new snapshot, which contains all the transactions that have been committed by the execution time. Therefore, during a transaction, a statement can access the result of other committed transactions. Check whether a single statement always accesses absolutely consistent data in a database.
Transaction isolation at this level meets the requirements of many applications, and is fast and easy to use. However, applications performing complicated queries and updates may require data that is more consistent than this level can provide.
- **REPEATABLE READ:** At this level, a transaction can only read data committed before it starts. Uncommitted data or data committed in other concurrent transactions cannot be read. However, a query can read earlier data

modifications in its transaction, regardless of whether they have been committed. **READ COMMITTED** differs from this level in that a transaction reads the snapshot taken at the start of the transaction, not at the beginning of the current query within the transaction. Therefore, the **SELECT** statement within a transaction always reads the same data, and cannot read data committed by other concurrent transactions after the transaction starts. Applications at this level must be able to retry transactions, because serialization failures may occur.

- **SERIALIZABLE**: Currently, GaussDB does not support this isolation level. Setting this isolation level is equivalent to **REPEATABLE READ**.

 NOTE

REPEATABLE READ is implemented based on multi-version snapshots and write skew may occur. To avoid this scenario, perform the SELECT FOR UPDATE operation on the rows involved in the transaction. An example of write skew is as follows:

Scenario 1: Table **a** has the **id** and **value** columns of the int type. Two data records are inserted. Assume that the sum of the values of the two data records must be less than or equal to 10 in the service logic of table **a**. Two transactions are concurrently started. The values are updated and modified based on the read values. After the modification, the sum of values is less than or equal to 10 in the transactions. After the modification is committed, the sum of values is 12, which violates the assumed service logic of table **a**.

```
gaussdb=# create table a(id int, value int);
CREATE TABLE
gaussdb=# insert into a values(1,4);
INSERT 0 1
gaussdb=# insert into a values(2,4);
INSERT 0 1
session1 :
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# select * from a;
id | value
----+-----
 1 |  4
 2 |  4
(2 rows)
gaussdb=# update a set value = 6 where id = 1;
UPDATE 1
gaussdb=# select * from a;
id | value
----+-----
 1 |  6
 2 |  4
(2 rows)
session2:
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# select * from a;
id | value
----+-----
 1 |  4
 2 |  4
(2 rows)
gaussdb=# update a set value = 6 where id = 2;
UPDATE 1
gaussdb=# select * from a;
id | value
----+-----
 1 |  4
 2 |  6
(2 rows)
session1:
gaussdb=# commit;
COMMIT
session2:
gaussdb=# commit;
COMMIT
gaussdb=# select * from a;
id | value
----+-----
 1 |  6
 2 |  6
(2 rows)
```

Scenario 2: Table **a** has the **id** and **value** columns of the int type. The **id** is the primary key. When the primary key is deleted and inserted concurrently, the values of two primary keys may be read in the transaction, violating the primary key constraint.

```
gaussdb=# create table a(id int primary key, value int);
NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "a_pkey" for table "a"
CREATE TABLE
gaussdb=# insert into a values(1,10);
INSERT 0 1
session1:
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# delete a where id = 1;
DELETE 1
session2:
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# select * from a;
id | value
----+-----
 1 |   10
(1 row)
session1:
gaussdb=# commit;
COMMIT
session2:
gaussdb=# insert into a values(1, 100);
INSERT 0 1
gaussdb=# select * from a;
id | value
----+-----
 1 |   10
 1 |  100
(2 rows)
```

1.4 Concepts

Databases

Databases manage various data objects and are isolated from each other. While creating a database, you can specify a tablespace. If you do not specify it, the object will be saved to the PG_DEFAULT tablespace by default. Objects managed by a database can be distributed to multiple tablespaces.

Tablespaces

In GaussDB, a tablespace is a directory storing physical files of the databases. Multiple tablespaces can coexist. Files are physically isolated using tablespaces and managed by a file system.

Schemas

GaussDB schemas logically separate databases. All database objects are created under certain schemas. In GaussDB, schemas and users are loosely bound. When you create a user, a schema with the same name as the user will be created automatically. You can also create a schema or specify another schema.

Users and Roles

GaussDB uses users and roles to control the access to databases. A role can be a database user or a group of database users, depending on role settings. Each user

can have only one role. In GaussDB, the difference between roles and users is that a role does not have the LOGIN permission by default. In GaussDB, you can put a user's role under a parent role for flexible management.

Transactions

In GaussDB, transactions are managed by multi-version concurrency control (MVCC) and two-phase locking (2PL). It enables smooth data reads and writes. In GaussDB, an Astore storage engine saves historical version data together with the current tuple version. The GaussDB Astore engine uses a VACUUM thread instead of rollback segments to periodically delete historical version data. Generally, you do not need to pay special attention to the VACUUM thread unless you need to optimize the performance. The GaussDB Ustore engine stores historical version data to the undo rollback segments. The thread for purging undo deletes historical version data in a unified manner. In addition, GaussDB automatically commits transactions for single-statement queries (without using statements such as BEGIN to explicitly start a transaction block).

2 Database Security

2.1 Users and Permissions

2.1.1 Default Permission Mechanism

A user who creates an object is the owner of this object. By default, [separation of duties](#) is disabled after cluster installation. A database system administrator has the same permissions as object owners. After an object is created, only the object owner or system administrator can query, modify, and delete the object, and grant permissions for the object to other users through [GRANT](#) by default.

To enable another user to use the object, grant required permissions to the user or the role that contains the user.

GaussDB supports the following permissions: SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, CREATE, CONNECT, EXECUTE, USAGE, ALTER, DROP, COMMENT, INDEX, and VACUUM. Permission types are associated with object types. For permission details, see [GRANT](#).

To revoke permissions, use [REVOKE](#). Object owners have implicit permissions (such as ALTER, DROP, COMMENT, INDEX, VACUUM, GRANT, and REVOKE) on objects. That is, once becoming the owner of an object, the owner is immediately granted the implicit permissions on the object. Object owners can remove their own common permissions (SELECT, INSERT, UPDATE, and DELETE), for example, making tables read-only to themselves or others, except the system administrator.

System catalogs and views are visible to either system administrators or all users. System catalogs and views that require system administrator permissions can be queried only by system administrators. For details, see [System Catalogs and System Views](#).

The database provides the object isolation feature. If this feature is enabled, users can view only the objects (tables, views, columns, and functions) that they have the permission to access. System administrators are not affected by this feature. For details, see [ALTER DATABASE](#).

It is not recommended to modify the permissions on system catalogs and system views.

2.1.2 Administrators

Initial User

The account automatically generated during the cluster installation is called the initial user. The initial user is also the system administrator, security administrator, audit administrator, monitor administrator, O&M administrator, and security policy administrator. It has the highest permissions in the system and can perform all operations. If the initial username is not set during the installation, the username is the same as the name of the OS user who installs the cluster. If the password of the initial user is not set during the cluster installation, the password is empty after the installation. In this case, you need to set the password of the initial user on the `gsql` client before performing other operations. If the initial user password is empty, you cannot perform other SQL operations, such as upgrade, capacity expansion, and node replacement, except changing the password.

An initial user bypasses all permission checks. You are advised to use an initial user as a database administrator only for database management other than service running.

System Administrator

A system administrator is an account with the **SYSADMIN** attribute. By default, a system administrator has the same permissions as the object owner but does not have the object permissions in the `db_perf` schema or the permission to use Roach to perform backup and restoration.

To create a database administrator, connect to the database as the initial user or a system administrator and use the **CREATE USER** or **ALTER USER** statement with the **SYSADMIN** option.

```
gaussdb=# CREATE USER sysadmin WITH SYSADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe SYSADMIN;
```

When **ALTER USER** is executed, the user must exist.

Security Administrator

A security administrator is an account with the **CREATEROLE** attribute, which has the permission to create, modify, and delete users or roles.

If you want to create a security administrator and separation of duties is disabled, connect to the database as a system administrator or security administrator. If separation of duties is enabled, connect to the database as a security administrator and use the **CREATE USER** or **ALTER USER** statement with the **CREATEROLE** option.

```
gaussdb=# CREATE USER createrole WITH CREATEROLE password '*****';
```

Or

```
gaussdb=# ALTER USER joe CREATEROLE;
```

When **ALTER USER** is executed, the user must exist.

Audit Administrator

An audit administrator is an account with the **AUDITADMIN** attribute, which has the permission to view and delete audit logs.

If you want to create an audit administrator and separation of duties is disabled, connect to the database as a system administrator or security administrator. If separation of duties is enabled, connect to the database only as the initial user and use the **CREATE USER** or **ALTER USER** statement with the **AUDITADMIN** option.

```
gaussdb=# CREATE USER auditadmin WITH AUDITADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe AUDITADMIN;
```

When ALTER USER is executed, the user must exist.

Monitor Administrator

A monitor administrator is an account with the **MONADMIN** attribute and has the permission to view views and functions in the `dbe_perf` schema. The monitor administrator can also grant or revoke object permissions in the `dbe_perf` schema.

To create a monitor administrator, connect to the database as a system administrator and use the **CREATE USER** or **ALTER USER** statement with the **MONADMIN** option.

```
gaussdb=# CREATE USER monadmin WITH MONADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe MONADMIN;
```

When ALTER USER is executed, the user must exist.

O&M Administrator

An O&M administrator is an account with the **OPRADMIN** attribute and has the permission to use Roach to perform backup and restoration.

To create an O&M administrator, connect to the database as an initial user and use the **CREATE USER** or **ALTER USER** statement with the **OPRADMIN** option.

```
gaussdb=# CREATE USER opradmin WITH OPRADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe OPRADMIN;
```

When ALTER USER is executed, the user must exist.

Security Policy Administrator

A security policy administrator is an account with the **POLADMIN** attribute and has the permission to create resource tags, masking policies, and unified audit policies.

To create a security policy administrator, connect to the database as an administrator and use the **CREATE USER** or **ALTER USER** statement with the **POLADMIN** option.

```
gaussdb=# CREATE USER poladmin WITH POLADMIN password "*****";
```

Or

```
gaussdb=# ALTER USER joe POLADMIN;
```

When ALTER USER is executed, the user must exist.

2.1.3 Separation of Duties

Descriptions in **Default Permission Mechanism** and **Administrators** are about the initial situation after a cluster is created. By default, the system administrator with the **SYSADMIN** attribute has the highest permission in the system.

To avoid risks caused by centralized permissions, you can enable separation of duties to assign the system administrator's user management permission to security administrators and audit management permission to audit administrators.

After separation of duties, the system administrator does not have the **CREATEROLE** attribute (security administrator) or the **AUDITADMIN** attribute (audit administrator). That is, the system administrator can neither create roles or users, nor view or maintain database audit logs. For details about the **CREATEROLE** and **AUDITADMIN** attributes, see **CREATE ROLE**.

Separation of duties does not take effect for an initial user. Therefore, you are advised to use an initial user as a database administrator only for database management other than service running.

Contact Huawei technical support.

WARNING

If you need to use the separation of duties model, specify it during database initialization. You are advised not to switch the permission management model back and forth. In particular, if you want to switch from a non-separation-of-duties permission management model to the separation-of-duties permission management model, you need to review the permission set of existing users. If a user has the system administrator permission and audit administrator permission, the permissions need to be tailored.

After separation of duties, the system administrator does not have permissions for non-system schemas of other users. Therefore, the system administrator cannot access the objects in other users' schemas before being granted the permissions. For details about permission changes before and after enabling separation of duties, see **Table 2-1** and **Table 2-2**.

Table 2-1 Default user permissions

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
Tablespaces	Has all permissions.	Can create, modify, delete, access, or grant permissions for tablespaces.	Cannot create, modify, delete, or grant permissions for tablespaces and can access tablespaces if the access permission is granted.		
Schemas		Has all permissions for all schemas except db_perf.	Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users.		
User-defined functions		Has all permissions for all user-defined functions.	Has all permissions for their own functions, and has only the call permission for other users' functions.		
User-defined tables or views		Has all permissions for all user-defined tables or views.	Has all permissions for their own tables or views, but does not have permissions for other users' tables or views.		

Table 2-2 Changes in permissions after separation of duties

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
Tablespaces	No change. Has all permissions.	No change.	No change.		
Schemas		Permissions reduced Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users.	No change.		
User-defined functions		Cannot access functions in non-system schemas of other users before being granted the permissions.	No change.		

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
User-defined tables or views		Cannot access tables or views in non-system schemas of other users before being granted the permissions.	No change.		

NOTICE

PG_STATISTIC and PG_STATISTIC_EXT store sensitive information about statistical objects, such as high-frequency MCVs. After separation of duties is enabled, the system administrator can still access the two system catalogs to obtain sensitive information in the statistics.

2.1.4 Users

You can use CREATE USER and ALTER USER to create and manage database users, respectively. A database cluster can have one or more databases. Users and roles are shared within the entire cluster, but their data is not shared. That is, a user can connect to any database, but after the connection is successful, any user can access only the database declared in the connection request.

In modes other than **separation of duties**, GaussDB user accounts can be created and deleted only by a system administrator or a security administrator with the **CREATEROLE** attribute. In separation-of-duties mode, a user account can be created only by an initial user or a security administrator.

When a user logs in, GaussDB authenticates the user. A user can own databases and database objects (such as tables), and grant permissions of these objects to other users and roles. In addition to system administrators, users with the **CREATEDB** attribute can create databases and grant permissions on these databases.

Adding, Modifying, and Deleting Users

- To create a user, use the SQL statement **CREATE USER**.
For example, create user **joe** and set the **CREATEDB** attribute for the user.
gaussdb=# CREATE USER joe WITH CREATEDB PASSWORD '*****';
CREATE ROLE
- To create a system administrator, use the **CREATE USER** statement with the **SYSADMIN** option.
- To delete an existing user, use **DROP USER**.
- To change a user account (for example, rename the user or change the password), use **ALTER USER**.

- To view a user list, query the **PG_USER** view.
`gaussdb=# SELECT * FROM pg_user;`
- To view user attributes, query the **PG_AUTHID** system catalog.
`gaussdb=# SELECT * FROM pg_authid;`

Permanent User

GaussDB provides a permanent user solution. You can create a permanent user with the **PERSISTENCE** attribute, which can use the `service_reserved_connections` channel to connect to the database.

NOTE

service_reserved_connections indicates the minimum number of connections reserved with the **PERSISTENCE** attribute. You are advised not to set this parameter to a large value.

```
gaussdb=# CREATE USER user_persistence WITH PERSISTENCE IDENTIFIED BY "*****";
```

Only the initial user is allowed to create, modify, and delete permanent users with the **PERSISTENCE** attribute.

2.1.5 Roles

After a role is granted to a user through **GRANT**, the user will have all the permissions of the role. It is recommended that roles be used to efficiently grant permissions. For example, you can create different roles of design, development, and maintenance personnel, grant the roles to users, and then grant specific data permissions required by different users. When permissions are granted or revoked at the role level, these changes take effect on all members of the role.

GaussDB provides an implicitly defined group **PUBLIC** that contains all roles. By default, all new users and roles have the permissions of **PUBLIC**. For details about the default permissions of **PUBLIC**, see **GRANT**. To revoke permissions of **PUBLIC** from a user or role, or re-grant these permissions to them, add the **PUBLIC** keyword in the **REVOKE** or **GRANT** statement.

To view all roles, query the system catalog **PG_ROLES**.

```
SELECT * FROM PG_ROLES;
```

Adding, Modifying, and Deleting Roles

In scenarios other than separation of duties, a role can be created, modified, and deleted only by a system administrator or a user with the **CREATEROLE** attribute. In **separation-of-duties** scenarios, a role can be created, modified, and deleted only by an initial user or a user with the **CREATEROLE** attribute.

- To create a role, use **CREATE ROLE**.
- To add or delete users in an existing role, use **ALTER ROLE**.
- To delete a role, use **DROP ROLE**. **DROP ROLE** deletes only a role, rather than member users in the role.

Built-in Roles

GaussDB provides a group of default roles whose names start with **gs_role_**. These roles are provided to access to specific, typically high-privileged operations. You

can grant these roles to other users or roles within the database so that they can use specific functions. These roles should be given with great care to ensure that they are used where they are needed. [Table 2-3](#) describes the permissions of built-in roles.

Table 2-3 Built-in roles and their permissions

Roles	Permission
gs_role_signal_backend	Permission to call the <code>pg_cancel_backend</code> , <code>pg_terminate_backend</code> , and <code>pg_terminate_session</code> functions to cancel or terminate other sessions, or to call the <code>pg_terminate_active_session_socket</code> function to close active sessions and the socket connection of the client. However, this role cannot perform operations on sessions of the initial user or PERSISTENCE user.
gs_role_tablespace	Permission to create a tablespace.
gs_role_replication	Permission to call logical replication functions, such as <code>kill_snapshot</code> , <code>pg_create_logical_replication_slot</code> , <code>pg_create_physical_replication_slot</code> , <code>pg_drop_replication_slot</code> , <code>pg_replication_slot_advance</code> , <code>pg_create_physical_replication_slot_extern</code> , <code>pg_logical_slot_get_changes</code> , <code>pg_logical_slot_peek_changes</code> , <code>pg_logical_slot_get_binary_changes</code> , and <code>pg_logical_slot_peek_binary_changes</code> .
gs_role_account_lock	Permission to lock and unlock users. However, this role cannot lock or unlock the initial user or users with the PERSISTENCE attribute.
gs_role_pldebugger	Permission to debug functions in <code>db_epldebugger</code> .
gs_role_public_dblink_drop	Permission to delete public database links.
gs_role_public_dblink_alter	Permission to modify public database links.

The restrictions on built-in roles are as follows:

- The role names starting with **gs_role_** are reserved for built-in roles in the database. Do not create users, roles, or schemas starting with **gs_role_** or rename existing users, roles, or schemas to names starting with **gs_role_**.
- Do not perform ALTER or DROP operations on built-in roles.
- By default, built-in roles do not have the LOGIN permission and do not have preset passwords.
- The `gsql` meta-commands `\du` and `\dg` do not display information about built-in roles. However, if **pattern** is set to a specific built-in role, the information is displayed.

- When separation of duties is disabled, the initial user, users with the SYSADMIN permission, and users with the ADMIN OPTION built-in role permission have the permission to perform GRANT and REVOKE operations on built-in roles. When separation-of-duties is enabled, the initial user and users with the ADMIN OPTION built-in role permission have the permission to perform GRANT and REVOKE operations on built-in roles. Example:

```
GRANT gs_role_signal_backend TO user1;  
REVOKE gs_role_signal_backend FROM user1;
```

2.1.6 Schemas

Schemas allow multiple users to use the same database without interference. In this way, database objects can be organized into logical groups that are easy to manage, and third-party applications can be added to corresponding schemas without causing conflicts.

Each database has one or more schemas. Each schema contains tables and other types of objects. When a database is created, a public schema named **public** is created by default, and all users have the USAGE permission on this schema. In addition, each database has a pg_catalog schema, which contains system catalogs and all built-in data types, functions, and operators. Only the system administrator and initial user can create functions, stored procedures, and synonyms under the public and pg_catalog schemas. Other users cannot create these objects even if they are granted with the CREATE permission on the public and pg_catalog schemas. You can group database objects by schema. A schema is similar to an OS directory but cannot be nested. By default, only the initial user can create objects in pg_catalog.

The same database object name can be used in different schemas of the same database without causing conflicts. For example, both a_schema and b_schema can contain a table named **mytable**. Users with required permissions can access objects across multiple schemas of the same database.

When you run the **CREATE USER** command to create a user, the system creates a schema with the same name as the user in the database where the command is executed.

Database objects are generally created in the first schema in a database search path. For details about the first schema and how to change the schema order, see [Search Path](#).

Creating, Modifying, and Deleting Schemas

- To create a schema, use **CREATE SCHEMA**. By default, the initial user and system administrator can create schemas. Other users can create schemas in the database only when they have the CREATE permission on the database. For details about how to grant the permission, see the syntax in [GRANT](#).
- To change the name or owner of a schema, use **ALTER SCHEMA**. The schema owner can change a schema.
- To delete a schema and its objects, use **DROP SCHEMA**. The schema owner can delete a schema.
- To create a table in a schema, use the *schema_name.table_name* format to specify the table. If *schema_name* is not specified, the table will be created in the first schema in [search path](#).

- To view the owner of a schema, perform the join query on the system catalogs PG_NAMESPACE and PG_USER. Replace *schema_name* in the statement with the name of the schema to be queried.

```
gaussdb=# SELECT s.nspname,u.username AS nspowner FROM pg_namespace s, pg_user u WHERE nspname='schema_name' AND s.nspowner = u.usesysid;
```
- To view a list of all schemas, query the system catalog PG_NAMESPACE.

```
gaussdb=# SELECT * FROM pg_namespace;
```
- To view a list of tables in a schema, query the system catalog PG_TABLES. For example, the following query will return a table list from PG_CATALOG in the schema:

```
gaussdb=# SELECT distinct(tablename),schemaname from pg_tables where schemaname = 'pg_catalog';
```

Search Path

A search path is defined in the GUC parameter **search_path**. The parameter value is a list of schema names separated by commas (,). If no target schema is specified during object creation, the object will be added to the first schema listed in the search path. If there are objects with the same name across different schemas and no schema is specified for an object query, the object will be returned from the first schema containing the object in the search path.

- To view the current search path, use **SHOW**.

```
gaussdb=# SHOW SEARCH_PATH;
search_path
-----
"$user",public
(1 row)
```

The default value of **search_path** is **"\$user",public**. *\$user* indicates the name of the schema with the same name as the current session user. If the schema does not exist, *\$user* will be ignored. By default, after a user connects to a database that has schemas with the same name, objects will be added to all the schemas. If there are no such schemas, objects will be added only to the public schema.

- To change the default schema of the current session, run the SET statement.

Set the search path to **myschema, public** (**myschema** will be searched first).

```
gaussdb=# SET SEARCH_PATH TO myschema, public;
SET
```

2.1.7 User Permissions

- To grant permissions for an object to a user, use **GRANT**.

When permissions for a table or view in a schema are granted to a user or role, the USAGE permission of the schema must be granted together. Otherwise, the user or role can only see these objects but cannot access them.

In the following example, permissions for the schema **tpcds** are first granted to user **joe**, and then the SELECT permission for the **tpcds.web_returns** table is also granted:

```
gaussdb=# GRANT USAGE ON SCHEMA tpcds TO joe;
gaussdb=# GRANT SELECT ON TABLE tpcds.web_returns to joe;
```

- Grant a role to a user to allow the user to inherit the object permissions of the role.
 - a. Create a role.
Create a role **lily** and grant the system permission CREATEDB to the role.

```
gaussdb=# CREATE ROLE lily WITH CREATEDB PASSWORD '*****';
```

- b. To grant object permissions to a role, use **GRANT**.

For example, first grant permissions for the schema `tpcds` to the role `lily`, and then grant the `SELECT` permission of the `tpcds.web_returns` table to `lily`.

```
gaussdb=# GRANT USAGE ON SCHEMA tpcds TO lily;
gaussdb=# GRANT SELECT ON TABLE tpcds.web_returns TO lily;
```

- c. Grant the role permissions to a user.

```
gaussdb=# GRANT lily TO joe;
```

NOTE

When the permissions of a role are granted to a user, the attributes of the role are not transferred together.

- To revoke user permissions, use **REVOKE**.

2.1.8 Row-Level Security Policy

The row-level security feature enables database access control to be accurate to each row of data tables. In this way, the same SQL query may return different results for different users.

You can create a row-level security policy for a data table. The policy defines an expression that takes effect only for specific database users and SQL operations. When a database user accesses the data table, if an SQL statement meets the specified row-level security policies of the data table, the expressions that meet the specified condition will be combined by using `AND` or `OR` based on the attribute type (`PERMISSIVE` | `RESTRICTIVE`) and applied to the execution plan in the query optimization phase.

Row-level security policy is used to control the visibility of row-level data in tables. By predefining filters for data tables, the expressions that meet the specified condition can be applied to execution plans in the query optimization phase, which will affect the final execution result. Currently, the SQL statements that can be affected include `SELECT`, `UPDATE`, and `DELETE`.

Scenario 1: A table summarizes the data of different users. Users can view only their own data.

```
-- Create users alice, bob, and peter.
gaussdb=# CREATE USER alice PASSWORD '*****';
gaussdb=# CREATE USER bob PASSWORD '*****';
gaussdb=# CREATE USER peter PASSWORD '*****';

-- Create the all_data table that contains user information.
gaussdb=# CREATE TABLE all_data(id int, role varchar(100), data varchar(100));

-- Insert data into the data table.
gaussdb=# INSERT INTO all_data VALUES(1, 'alice', 'alice data');
gaussdb=# INSERT INTO all_data VALUES(2, 'bob', 'bob data');
gaussdb=# INSERT INTO all_data VALUES(3, 'peter', 'peter data');

-- Grant the read permission for the all_data table to users alice, bob, and peter.
gaussdb=# GRANT SELECT ON all_data TO alice, bob, peter;

-- Enable row-level security policy.
gaussdb=# ALTER TABLE all_data ENABLE ROW LEVEL SECURITY;

-- Create a row-level security policy to specify that the current user can view only their own data.
gaussdb=# CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role = CURRENT_USER);
```

```

-- View table details.
gaussdb=# \d+ all_data
          Table "public.all_data"
Column |      Type      | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
id     | integer        |           |         |              |
role   | character varying(100) |           | extended |              |
data   | character varying(100) |           | extended |              |
Row Level Security Policies:
  POLICY "all_data_rls" FOR ALL
  TO public
  USING (((role)::name = "current_user"()))
Has OIDs: no
Distribute By: HASH(id)
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no, enable_rowsecurity=true

-- Switch to user alice and run SELECT * FROM public.all_data.
gaussdb=# SELECT * FROM public.all_data;
id | role | data
---+---+---
 1 | alice | alice data
(1 row)

gaussdb=# EXPLAIN(COSTS OFF) SELECT * FROM public.all_data;
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on all_data
   Filter: ((role)::name = 'alice'::name)
Notice: This query is influenced by row level security feature
(5 rows)

-- Switch to user peter and run SELECT * FROM public.all_data.
gaussdb=# SELECT * FROM public.all_data;
id | role | data
---+---+---
 3 | peter | peter data
(1 row)

gaussdb=# EXPLAIN(COSTS OFF) SELECT * FROM public.all_data;
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on all_data
   Filter: ((role)::name = 'peter'::name)
Notice: This query is influenced by row level security feature
(5 rows)

```

NOTICE

PG_STATISTIC and PG_STATISTIC_EXT store sensitive information about statistical objects, such as high-frequency MCVs. If the permission to query the two system catalogs is granted to a common user after the row-level security policy is created, the common user can still access the two system catalogs to obtain sensitive information in the statistical objects.

2.2 Database Audit

Context

Database audit is critical to the security of the database system. Database audit administrators can use the audit logs to reproduce a series of events that cause faults in the database and identify unauthorized users, unauthorized operations, and the time when these operations are performed.

You need to understand the following information about the audit function:

- The GUC parameter **audit_enabled** is used to enable or disable the audit function. Its value can be dynamically loaded. After you change the switch status when the database is running, the change takes effect immediately and you do not need to restart the database. Its default value is **on**, indicating that the audit function is enabled.
- In addition to the overall audit switch, each audit item has an independent switch. An audit item is available only after its own switch is turned on.
- The switch of each audit supports dynamic loading. After changing the audit switch status when the database is running, the modification takes effect immediately without restarting the database.

Table 2-4 describes the audit items supported by GaussDB. If you need to modify a specific audit configuration item, contact the administrator.

Table 2-4 Audit items

Configuration Item	Description
User login and logout audit	Parameter: audit_login_logout Its default value is 7 , which indicates that the function of user login and logout audit is enabled. 0 indicates that the function of user login and logout audit is disabled. Other values are not recommended.
Database startup, stop, recovery, and switchover audit	Parameter: audit_database_process Its default value is 1 , which indicates that the audit of database startup, stop, recovery, and switchover is enabled.
User locking and unlocking audit	Parameter: audit_user_locked Its default value is 1 , which indicates that the audit of user locking and unlocking is enabled.
Unauthorized access audit	Parameter: audit_user_violation Its default value is 0 , which indicates that the audit of unauthorized access is disabled.

Configuration Item	Description
Permission granting and revoking audit	Parameter: audit_grant_revoke Its default value is 1 , which indicates that the audit of permission granting and revoking is enabled.
Full audit of user operations	Parameter: full_audit_users Its default value is an empty string, indicating that the default configuration is used and no full audit of user operations is configured.
Names and IP addresses of clients that do not need to be audited	Parameter: no_audit_client Its default value is an empty string, indicating that the default configuration is used and no clients and IP addresses are added to the audit blacklist.
Audit of CREATE, ALTER, and DROP operations on database objects	Parameter: audit_system_object Its default value is 67121159 , which indicates that the CREATE, ALTER, and DROP operations only on databases, schemas, users, and node groups are audited.
Audit of INSERT, UPDATE, and DELETE operations on a specific table	Parameter: audit_dml_state Its default value is 0 , which indicates that the audit of DML operations (except SELECT) on a specific table is disabled.
SELECT operation audit	Parameter: audit_dml_state_select Its default value is 0 , which indicates that the audit of the SELECT operation is disabled.
COPY operation audit	Parameter: audit_copy_exec Its default value is 1 , which indicates that the audit of COPY operations is enabled.
Audit of execution of stored procedures and customized functions	Parameter: audit_function_exec Its default value is 0 , which indicates that no execution audit logs of stored procedures and customized functions are recorded.
Audit of system functions in the whitelist	Parameter: audit_system_function_exec Its default value is 0 , which indicates that audit logs of system function execution are not recorded.
SET operation audit	Parameter: audit_set_parameter Its default value is 0 , which indicates that the audit of the SET operation is disabled.
Transaction ID record	Parameter: audit_xid_info Its default value is 0 , which indicates that the function of recording transaction IDs in audit logs is disabled.

3 Database Quick Start

3.1 Connecting to a Database

Client tools used for connecting to a database include **gsql** and APIs (such as **ODBC** and **JDBC**).

- **gsql** is a client tool provided by GaussDB. As described in [Using gsql to Connect to a Database](#), **gsql** is used to enter, edit, and run SQL statements in an interactive manner.
- As described in [APIs](#), you can use standard database APIs, such as **ODBC** and **JDBC**, to develop GaussDB-based applications.

3.1.1 Using gsql to Connect to a Database

gsql is a client tool provided by GaussDB. You can use **gsql** to connect to a database and then enter, edit, and execute SQL statements in an interactive manner. For details about the connection mode, see [Connecting to a DB Instance](#).

NOTICE

For distributed instances, you can use a client tool to connect to a database through any CN. Before connection, you must obtain the IP address and port number of the server where the CN is deployed. The client tool can access the database by connecting to any CN. Do not connect to a database through a DN when services are running properly.

3.1.2 APIs

You can use standard database APIs, such as **ODBC** and **JDBC**, to develop GaussDB-based applications.

Supported APIs

Each application is an independent GaussDB development project. APIs alleviate applications from directly operating in databases, and enhance the database

portability, extensibility, and maintainability. [Table 3-1](#) lists the APIs supported by GaussDB and the download addresses.

Table 3-1 Database APIs

API	How to Obtain
ODBC	<ul style="list-style-type: none">Linux: Driver: GaussDB-Kernel_Database version number_OS version number_64bit_Odbc.tar.gz unixODBC source code package: https://gitee.com/src-openeuler/unixODBC/blob/openEuler-22.03-LTS-SP1/unixODBC-2.3.7.tar.gzWindows: Driver: GaussDB-Kernel_Database version number_Windows_Odbc.tar.gz
JDBC	<ul style="list-style-type: none">Driver: GaussDB-Kernel_Database version number_OS version number_64bit-Jdbc.tar.gzDriver: org.postgresql.Driver

The JDBC and ODBC APIs are used to connect to the database remotely. Therefore, you need to configure a remote connection in GaussDB. Contact the administrator for related operations.

For details about more APIs, see [Application Development Guide](#).

3.2 Operating a Database

This section explains how to use databases, including creating database accounts, databases, and tables, inserting data to tables, and querying data in tables.

3.2.1 Creating a Database Account

Only administrators that are created during the cluster installation can access the initial database by default. You can also create other database users.

```
gaussdb=# CREATE USER joe WITH PASSWORD '*****';
```

If the following information is displayed, the creation is successful:

```
CREATE ROLE
```

In this case, you have created a user account named **joe**, and the user password is *********. Set user **joe** as a system administrator.

```
gaussdb=# GRANT ALL PRIVILEGES TO joe;
```

Run the **GRANT** command to set related permissions. For details, see [GRANT](#).

NOTE

For more information about database users, see [Users and Permissions](#).

3.2.2 Creating and Managing Databases

Prerequisites

Only the database system administrator or users granted with database creation permissions can create a database. For details about how to grant database creation permissions to a user, see [Users and Permissions](#).

Context

- GaussDB has two default template databases **template0** and **template1** and a default user database **postgres**.
- CREATE DATABASE creates a database by copying a template database. Only **template0** can be copied. Do not use a client or other methods to connect to or operate the two template databases.

NOTE

- The template database does not contain any user table. You can view the attributes of the template database in the PG_DATABASE system catalog.
- The **template0** template does not allow user connections. Only the initial user of the database and the system administrator can connect to **template1**.
- A database system consists of multiple databases. A client can connect to only one database at a time. Currently, cross-database query or cross-database transaction is not supported.
- If multiple databases exist in the database cluster, you can use the **-d** parameter of the client tool to specify the target database for login. Alternatively, you can run the **\c** command to switch the database after the client program logs in to the database.

Precautions

Assume that the database encoding is SQL_ASCII. (You can run the **show server_encoding** command to query the encoding used for storing data in the current database.) If the database object name contains multi-byte characters (such as Chinese) or if the object name length exceeds the allowed maximum (63 bytes), the database truncates the last byte (not the last character) of the object name. In this case, half characters may appear.

To resolve this problem, you need to:

- Ensure that the name of the data object does not exceed the maximum length.
- Use a proper coded character set, such as UTF-8, as the default database storage code set (server_encoding).
- Exclude multi-byte characters from object names.
- If you fail to delete an object whose name is truncated mistakenly, specify its original name to delete it, or manually delete it from the corresponding system catalog on each node.

Procedure

Step 1 Create a database named **db_tpcds**.

```
gaussdb=# CREATE DATABASE db_tpcds;  
CREATE DATABASE
```

NOTE

- Database names must comply with the general naming convention rules of SQL identifiers. The current role automatically becomes the owner of this new database.
- If a database system is used to support independent users and projects, store them in different databases.
- If the projects or users are associated with each other and share resources, store them in one database. However, you can divide them into different schemas. A schema is a logical structure, and the access permission for a schema is controlled by the permission system module.
- A database name contains a maximum of 63 bytes and the excessive bytes at the end of the name will be truncated by the server. You are advised to specify a database name no longer than 63 bytes when you create a database.

- New databases are created in the `pg_default` tablespace by default. Specify another tablespace.

```
gaussdb=# CREATE DATABASE db_tpcds WITH TABLESPACE = hr_local;  
CREATE DATABASE
```

hr_local indicates the tablespace name. For details about how to create a tablespace, see [Creating and Managing Tablespaces](#).

- After creating the **db_tpcds** database, you can perform other operations in the default **postgres** database. Alternatively, you can perform the following operations to exit the **postgres** database, connect to the **db_tpcds** database as a new user, and perform operations such as creating tables.

```
gaussdb=# \q  
gsq! -d db_tpcds -p 8000 -U joe  
Password for user joe:  
gsq!((GaussDB Kernel 503.0.XXX build f521c606) compiled at 2021-09-16 14:55:22 commit 2935  
last mr 6385 release)  
Non-SSL connection (SSL connection is recommended when requiring high-security)  
Type "help" for help.  
db_tpcds=>
```

Step 2 View databases.

- Run the `\l` meta-command to view the database list of the database system.

```
gaussdb=# \l
```

- Query the database list in the `pg_database` system catalog.

```
gaussdb=# SELECT datname FROM pg_database;
```

Step 3 Modify the database.

You can modify database configuration such as the database owner, name, and default settings.

- Rename the database.

```
gaussdb=# ALTER DATABASE db_tpcds RENAME TO human_tpcds;  
ALTER DATABASE
```

NOTE

After setting the parameters, you need to manually run the **CLEAN CONNECTION** command to clear the old connections. Otherwise, the parameter values between nodes may be inconsistent.

Step 4 Delete the database.

You can run the **DROP DATABASE** command to delete a database. This command deletes the system directory in the database, as well as the database directory on the disk that stores data. Only the database owner or system administrator can delete a database. A database accessed by users cannot be deleted. You need to connect to another database before deleting this database.

Delete the database.

```
gaussdb=# DROP DATABASE human_tpcds;  
DROP DATABASE
```

----End

3.2.3 Creating and Managing Tablespaces

Context

The administrator can use tablespaces to control the layout of disks where a database is installed. The advantages are as follows:

- If the disk partition or tablespace initially allocated to the database is full and the space cannot be logically extended, you can create and use tablespaces in other partitions until the system space is reconfigured.
- Tablespaces allow the administrator to distribute data based on the schema of database objects, improving system performance.
 - A frequently used index can be stored in a disk having stable performance and high computing speed, such as a solid-state device.
 - A table that stores archived data and is rarely used or has low performance requirements can be placed in a disk with a slow computing speed.
- You can use tablespaces to limit the disk space of databases. If a tablespace shares a partition with other tablespaces, the tablespace will never occupy the space allocated to other tablespaces.
- You can use tablespaces to manage the disk space used to store database data. The database will switch to the read-only mode when the disk usage of the tablespace reaches 90%. Once the disk usage drops below 90%, the database will be restored to the read-write mode. The automatic disk check of the CM is enabled by default. If the function is disabled, contact the administrator to enable it.
- Each tablespace corresponds to a file system directory. Create a tablespace corresponding to **/pg_location/mount1/path1** and specify the maximum available space to 500 GB.

-- Create a tablespace.

```
gaussdb=# CREATE TABLESPACE ds_location1 LOCATION '/pg_location/mount1/path1' MAXSIZE  
'500G';
```

If **MAXSIZE** is used to manage tablespace quotas, the concurrent insertion performance may deteriorate by about 30%. **MAXSIZE** specifies the maximum quota for each DN. The difference between the actual tablespace capacity of each DN and the specified quota should be within 500 MB. Determine whether to set a tablespace to its maximum size as required.

GaussDB provides two tablespaces: `pg_default` and `pg_global`.

- Default tablespace `pg_default`: stores non-shared system catalogs, user tables, user table indexes, temporary tables, temporary table indexes, and internal temporary tables. The corresponding storage directory is the base directory in the instance data directory.
- Shared tablespace `pg_global`: stores shared system catalogs. The corresponding storage directory is the base directory in the global data directory.

Precautions:

- You are advised not to use user-defined tablespaces in scenarios such as HCS and Huawei Cloud.
This is because user-defined tablespaces are usually used with storage media other than the main storage (storage device where the default tablespace is located, such as a disk) to isolate I/O resources that can be used by different services. Storage devices use standard configurations and do not have other available storage media in scenarios such as HCS and Huawei Cloud. If the user-defined tablespace is not properly used, the system cannot run stably for a long time and the overall performance is affected. Therefore, you are advised to use the default tablespace.

Procedure

- Create a tablespace.
 - a. Create user **jack**.

```
gaussdb=# CREATE USER jack IDENTIFIED BY '*****';
```

If the following information is displayed, the creation is successful:

```
CREATE ROLE
```
 - b. Create a tablespace.

```
gaussdb=# CREATE TABLESPACE fastspace RELATIVE LOCATION 'my_tablespace/tablesace1';
```

If the following information is displayed, the creation is successful:

```
CREATE TABLESPACE
```

fastspace is the new tablespace, and *CN/DN data directory/pg_location/my_tablespace/tablesace1* is an empty directory on which users have read and write permissions.
 - c. Grant the permission of accessing the **fastspace** tablespace to user **jack** as a database system administrator.

```
gaussdb=# GRANT CREATE ON TABLESPACE fastspace TO jack;
```

If the following information is displayed, the grant operation is successful:

```
GRANT
```
- Create an object in a tablespace.

If you have the CREATE permission on the tablespace, you can create database objects in the tablespace, such as tables and indexes.

Take creating a table as an example:

 - Method 1: Create a table in a specified tablespace.

```
gaussdb=# CREATE TABLE foo(i int) TABLESPACE fastspace;
```

If the following information is displayed, the creation is successful:

```
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'i' as the distribution column by default.  
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.  
CREATE TABLE
```

- Method 2: Run **SET default_tablespace** to set the default tablespace and then create a table.

```
gaussdb=# SET default_tablespace = 'fastspace';
SET
gaussdb=# CREATE TABLE foo2(i int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'i' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
```

In this example, **fastspace** is the default tablespace, and **foo2** is the created table.

- Query a tablespace.
 - Method 1: Check the pg_tablespace system catalog. View all the tablespaces defined by the system and users.

```
gaussdb=# SELECT spcname FROM pg_tablespace;
```
 - Method 2: Run the meta-command of the gsql program to query the tablespaces.

```
gaussdb=# \db
```
- Query the tablespace usage.
 - a. Query the current usage of the tablespace.

```
gaussdb=# SELECT PG_TABLESPACE_SIZE('fastspace');
```

Information similar to the following is displayed:

```
pg_tablespace_size
-----
                2146304
(1 row)
```

2146304 is the size of the tablespace, and its unit is byte.
 - b. Calculate the tablespace usage.

Tablespace usage = Value of **PG_TABLESPACE_SIZE**/Size of the disk where the tablespace resides
- Modify a tablespace.

Rename tablespace **fastspace** to **fspace**.

```
gaussdb=# ALTER TABLESPACE fastspace RENAME TO fspace;
ALTER TABLESPACE
```
- Delete a tablespace and related data.
 - Delete user **jack**.

```
gaussdb=# DROP USER jack CASCADE;
DROP ROLE
```
 - Delete tables **foo** and **foo2**.

```
gaussdb=# DROP TABLE foo;
gaussdb=# DROP TABLE foo2;
```

If the following information is displayed, the operation is successful:

```
DROP TABLE
```
 - Delete tablespace **fspace**.

```
gaussdb=# DROP TABLESPACE fspace;
DROP TABLESPACE
```

 **NOTE**

Only the tablespace owner or system administrator can delete a tablespace.

3.2.4 Creating and Managing Tables

3.2.4.1 Creating a Table

Context

A table is created in a database and can be saved in different databases. Tables under different schemas in a database can have the same name.

For details about how to design a table suitable for services, see [Best Practices of Table Design](#).

Creating a Table

Create a table.

```
gaussdb=# CREATE TABLE customer_t1  
(  
  c_customer_sk      integer,  
  c_customer_id      char(5),  
  c_first_name       char(6),  
  c_last_name        char(8)  
)  
distribute by hash (c_last_name);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

c_customer_sk, **c_customer_id**, **c_first_name**, and **c_last_name** are the column names of the table. **integer**, **char(5)**, **char(6)**, and **char(8)** are column name types.

NOTE

- By default, new database objects are created in the \$user schema. For more details about schemas, see [Creating and Managing Schemas](#).
- In addition to the created tables, a database contains many system catalogs. These system catalogs contain cluster installation information and information about various queries and processes in GaussDB. You can collect information about the database by querying system catalogs. For details, see [Querying System Catalogs](#).
- For more details about how to create a table, see [CREATE TABLE](#).

3.2.4.2 Inserting Data to a Table

A new table contains no data. You need to insert data to the table before using it. This section describes how to insert a row or multiple rows of data using the **INSERT** command and to insert data from a specified table. Contact the administrator if a large amount of data needs to be imported.

Context

The length of a character on the server and client may vary by the character sets they use. A string entered on the client will be processed based on the server's character set, so the result may differ from expected.

Table 3-2 Comparison of character set output between the client and server

Procedure	Server and Client Use Same Encoding	Server and Client Use Different Encoding
No operations are performed on the string while it is saved and read.	Your expected result is returned.	If the encoding for input and output on the client is the same, your expected result is returned.
Operations (such as executing string functions) are performed to the string while it is saved and read.	Your expected result is returned.	The result may not be as expected, depending on the operations performed on the string.
A long string is truncated while it is saved.	Your expected result is returned.	If the character sets used on the client and server have different character length, the result may not be as expected.

More than one of the preceding operations can be performed to a string. For example, if the character sets of the client and server are different, a string may be processed and then truncated. In this case, the result will also be unexpected. For details, see [Table 3-3](#).

 **NOTE**

Long strings are truncated only if **DBCOMPATIBILITY** is set to **TD** (compatible with Teradata) and the GUC parameter **td_compatible_truncation** is set to **on**.

Create **table1** and **table2** to be used in the example.

```
gaussdb=# CREATE TABLE table1(id int, a char(6), b varchar(6),c varchar(6));
gaussdb=# CREATE TABLE table2(id int, a char(20), b varchar(20),c varchar(20));
```

Table 3-3 Example

No.	Server Character Set	Client Character Set	Automatic Truncation Enabled	Example	Result	Description
1	SQL_ASCII	UTF8	Yes	gaussdb=# INSERT INTO table1 VALUES(1,reverse('123AA78'),reverse('123AA78'),reverse('123AA78'));	id a b c ----+----- +-----+----- 1 87 87 87	A string is reversed on the server and then truncated. Because character sets used by the server and client are different, character A is displayed in multiple bytes on the server and the result is incorrect.
2	SQL_ASCII	UTF8	Yes	gaussdb=# INSERT INTO table1 VALUES(2,reverse('123A78'),reverse('123A78'),reverse('123A78'));	id a b c ----+----- +-----+----- 2 873 873 873	A string is reversed and then automatically truncated. Therefore, the result is unexpected.
3	SQL_ASCII	UTF8	Yes	gaussdb=# INSERT INTO table1 VALUES(3,'87A123','87A123','87A123');	id a b c ----+----- +-----+----- 3 87A1 87A1 87A1	The column length in the string type is an integer multiple of the length in client character encoding. Therefore, the result is correct after truncation.

No.	Server Character Set	Client Character Set	Automatic Truncation Enabled	Example	Result	Description
4	SQL_ASCII	UTF8	No	<pre>gaussdb=# INSERT INTO table2 VALUES(1,reverse('123AA78'),reverse('123AA78'),reverse('123AA78')); gaussdb=# INSERT INTO table2 VALUES(2,reverse('123A78'),reverse('123A78'),reverse('123A78'));</pre>	<pre>id a b c ---- +-----+ --+----- +----- 1 87 321 87 321 87 321 2 87321 87321 87321</pre>	Similar to the first example, multi-byte characters no longer indicate the original characters after being reversed.

Procedure

You need to create a table before inserting data to it. For details about how to create a table, see [Creating and Managing Tables](#).

- Insert a row to table **customer_t1**.

Data values are arranged in the same order as the columns in the table and are separated by commas (,). Generally, column values are text values (constants). But column values can also be scalar expressions.

```
gaussdb=# INSERT INTO customer_t1(c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', 'Grace');
```

If you know the sequence of the columns in the table, you can obtain the same result without listing these columns. For example, the following command generates the same result as the preceding command:

```
gaussdb=# INSERT INTO customer_t1 VALUES (3769, 'hello', 'Grace');
```

If you do not know some of the column values, you can omit them. If no value is specified for a column, the column is set to the default value.

Example:

```
gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_first_name) VALUES (3769, 'Grace');
```

```
gaussdb=# INSERT INTO customer_t1 VALUES (3769, 'hello');
```

You can also specify the default value of a column or row:

```
gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', DEFAULT);
```

```
gaussdb=# INSERT INTO customer_t1 DEFAULT VALUES;
```

- Insert multiple rows to a table.

```
gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES
(6885, 'maps', 'Joes'),
(4321, 'tpcds', 'Lily'),
(9527, 'world', 'James');
```

You can also insert multiple rows by running the command for inserting one row for multiple times. However, you are advised to run this command to improve efficiency.

- Assume that you have created a backup table **customer_t2** for table **customer_t1**. To insert data from **customer_t1** to **customer_t2**, run the following commands:

```
gaussdb=# CREATE TABLE customer_t2
(
  c_customer_sk      integer,
  c_customer_id      char(5),
  c_first_name       char(6),
  c_last_name        char(8)
);

gaussdb=# INSERT INTO customer_t2 SELECT * FROM customer_t1;
```

NOTE

If implicit conversion is not implemented between the column data types of the specified table and those of the current table, the two tables must have the same column data types when data is inserted from the specified table to the current table.

- Delete a backup table.

```
gaussdb=# DROP TABLE customer_t2 CASCADE;
```

NOTE

If the table to be deleted is dependent on other tables, you need to delete its dependent tables first.

3.2.4.3 Updating Data in a Table

Existing data in a database can be updated. You can update one row, all rows, or specified rows of data, or update data in a single column without affecting the data in the other columns.

The following information is required when the UPDATE statement is used to update rows:

- Table name and column name of the data to be updated
- New column value
- Rows to be updated

Generally, the SQL language does not provide a unique ID for a row of data. Therefore, it is impossible to directly specify the rows of the data to be updated. However, you can specify the rows by declaring the conditions that must be met by the updated row. If a table contains primary keys, you can specify a row using the primary keys.

For details about how to create a table and insert data to it, see [Creating a Table](#) and [Inserting Data to a Table](#).

c_customer_sk in the table **customer_t1** must be changed from **9527** to **9876**:

```
gaussdb=# UPDATE customer_t1 SET c_customer_sk = 9876 WHERE c_customer_sk = 9527;
```

You can use a schema to modify the table name. If no such modifier is specified, the table is located based on the default schema path. SET is followed by the column and the new column value. The new value can be a constant or an expression.

For example, increase all the values in the **c_customer_sk** column by 100.

```
gaussdb=# UPDATE customer_t1 SET c_customer_sk = c_customer_sk + 100;
```

This statement does not contain the WHERE clause, so all rows are updated. If the statement contains the WHERE clause, only the rows matching the clause are updated.

In the SET clause, the equal sign (=) indicates value setting. In the WHERE clause, the equal sign indicates comparison. A WHERE condition does not have to be an equality comparison, but can be another operator.

You can run an UPDATE statement to update multiple columns by specifying multiple values in the SET clause. Example:

```
gaussdb=# UPDATE customer_t1 SET c_customer_id = 'Admin', c_first_name = 'Local' WHERE  
c_customer_sk = 4421;
```

After data has been updated or deleted in batches, a large number of deletion markers are generated in the data file. During query, data with these deletion markers needs to be scanned as well. In this case, a large amount of data with deletion marks can greatly affect the query performance after batch updates or deletions. If data needs to be updated or deleted in batches frequently, you are advised to periodically execute the VACUUM FULL statement to maintain the query performance.

3.2.4.4 Viewing Data

- Run the following command to query information about all tables in a database in the system catalog **pg_tables**:
gaussdb=# SELECT * FROM pg_tables;
- Run the **\d+** command of the **gsql** tool to query table attributes:
gaussdb=# \d+ customer_t1;
- Run the following command to query the data volume of table **customer_t1**:
gaussdb=# SELECT count(*) FROM customer_t1;
- Run the following command to query all data in the table **customer_t1**:
gaussdb=# SELECT * FROM customer_t1;
- Run the following command to query only the data in the column **c_customer_sk**:
gaussdb=# SELECT c_customer_sk FROM customer_t1;
- Run the following command to filter repeated data in the column **c_customer_sk**:
gaussdb=# SELECT DISTINCT(c_customer_sk) FROM customer_t1;
- Run the following command to query all data whose column **c_customer_sk** is **3869**:
gaussdb=# SELECT * FROM customer_t1 WHERE c_customer_sk = 3869;
- Run the following command to collate data based on the column **c_customer_sk**:
gaussdb=# SELECT * FROM customer_t1 ORDER BY c_customer_sk;

3.2.4.5 Deleting Data from a Table

Outdated data may need to be deleted when tables are used. Data can be deleted from tables only by row.

SQL statements can only access and delete an independent row by declaring conditions that match the row. If a table has a primary key, you can use it to specify a row. You can delete several rows that match the specified condition or delete all the rows from a table.

For example, delete all the rows whose `c_customer_sk` column is **3869** from the table `customer_t1`.

```
gaussdb=# DELETE FROM customer_t1 WHERE c_customer_sk = 3869;
```

To delete all rows from the table, run either of the following commands:

```
gaussdb=# DELETE FROM customer_t1;
```

Or

```
gaussdb=# TRUNCATE TABLE customer_t1;
```

NOTE

If you need to delete an entire table, you are advised to use the TRUNCATE statement rather than DELETE.

Delete the created table.

```
gaussdb=# DROP TABLE customer_t1;
```

3.2.5 Querying System Catalogs

In addition to the created tables, a database contains many system catalogs. These system catalogs contain cluster installation information and information about various queries and processes in GaussDB. You can obtain information about the database by querying system catalogs.

In [System Catalogs and System Views](#), the description about each table specifies whether the table is visible to all users or only the initial user. To query tables that are visible only to the initial user, log in as the initial user.

GaussDB provides the following types of system catalogs and views:

- PostgreSQL-compatible system catalogs and views
These system catalogs and views have the prefix **PG**.
- New system catalogs and views of GaussDB
These system catalogs and views have the prefix **GS**.
- Oracle-compatible system catalogs and views
These system catalogs and views have the prefix **ALL**, **DBA**, **USER**, or **PV**.

Querying Database Tables

Create the following tables in the public schema:

```
gaussdb=# CREATE TABLE public.search_table_t1(a int) distribute by hash(a);  
CREATE TABLE  
gaussdb=# CREATE TABLE public.search_table_t2(b int) distribute by hash(b);  
CREATE TABLE  
gaussdb=# CREATE TABLE public.search_table_t3(c int) distribute by hash(c);  
CREATE TABLE  
gaussdb=# CREATE TABLE public.search_table_t4(d int) distribute by hash(d);  
CREATE TABLE  
gaussdb=# CREATE TABLE public.search_table_t5(e int) distribute by hash(e);  
CREATE TABLE
```

In the PG_TABLES system catalog, view the tables prefixed with search_table in the public schema.

```
gaussdb=# SELECT distinct(tablename) FROM pg_tables WHERE SCHEMANAME = 'public' AND  
TABLENAME LIKE 'search_table%';
```

The result is as follows:

```

tablename
-----
search_table_t1
search_table_t2
search_table_t3
search_table_t4
search_table_t5
(5 rows)

```

Viewing Database Users

You can use PG_USER to view the list of all users in the database, and view the user ID (USESYSID) and permissions.

```

SELECT * FROM pg_user;
username | usesysid | usecreatedb | usesuper | usecatupd | userepl | passwd | valbegin | valuntil |
respool  | parent  | spacelimit | useconfig | nodegroup | tempspacelimit | spillspacelimit
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+
roach | 10 | t | t | t | t | ***** | | | default_pool |
0 | | | | | | | | |
(1 row)

```

Viewing and Stopping the Running Query Statements

You can view the running query statements in the [PG_STAT_ACTIVITY](#) view. You can use the following methods:

Step 1 Set the parameter **track_activities** to **on**.

```
SET track_activities = on;
```

The database obtains the running information about active queries only if the parameter is set to **on**.

Step 2 View the running query statements. View the database names, users performing queries, query status, and the corresponding PID which are connected to the running query statements.

```

SELECT datname, username, state, pid FROM pg_stat_activity;
datname | username | state | pid
-----+-----+-----+-----
testdb | Ruby | active | 140298793514752
testdb | Ruby | active | 140298718004992
testdb | Ruby | idle | 140298650908416
testdb | Ruby | idle | 140298625742592
testdb | omm | active | 140298575406848
(5 rows)

```

If the **state** column is **idle**, the connection is idle and requires a user to enter a command.

Identify only active query statements.

```
SELECT datname, username, state, pid FROM pg_stat_activity WHERE state != 'idle';
```

Step 3 To cancel queries that have been running for a long time, use the PG_TERMINATE_BACKEND function to end sessions based on the thread ID (corresponding to the PID in [Step 2](#)).

```
SELECT PG_TERMINATE_BACKEND(140298793514752);
```

If the following information is displayed, the session is successfully terminated:

```
PG_TERMINATE_BACKEND
-----
t
(1 row)
```

If the following information is displayed, a user has terminated the current session:

```
FATAL: terminating connection due to administrator command
FATAL: terminating connection due to administrator command
```

 **NOTE**

1. When an initial user uses the PG_TERMINATE_BACKEND function to terminate the backend threads of active sessions, the gsql client is reconnected automatically rather than be logged out. The message "The connection to the server was lost. Attempting reset: Succeeded." is returned. If non-initial users do this operation, the message "The connection to the server was lost. Attempting reset: Failed." is returned. This is because only initial users can log in to the system in password-free mode.
2. If the PG_TERMINATE_BACKEND function is used to end inactive backend threads, and the thread pool is enabled, idle sessions do not have thread IDs and cannot be terminated. In non-thread pool mode, terminated sessions are not automatically reconnected.

----End

3.2.6 Other Operations

3.2.6.1 Creating and Managing Schemas

Context

Schemas allow multiple users to use the same database without interference. In this way, database objects can be organized into logical groups that are easy to manage, and third-party applications can be added to corresponding schemas without causing conflicts. Schema management involves creating a schema, using a schema, deleting a schema, setting a search path for a schema, and setting schema permissions.

Precautions

- A database cluster can have one or more databases. Users and user groups are shared within entire cluster, but their data is exclusive. Any user who has connected to a server can access only the database specified in the connection request.
- A database can have one or more schemas, and a schema can contain tables and other data objects, such as data types, functions, and operators. One object name can be used in different schemas. For example, both **schema1** and **schema2** can have a table named **mytable**.
- Different from databases, schemas are not isolated. You can access the objects in a schema of the connected database if you have schema permissions. To manage schema permissions, you need to have knowledge about database permissions.
- A schema named with the **PG_** prefix cannot be created because this type of schema is reserved for the database system.

- Each time a new user is created, the system creates a schema with the same name for the new user in the current database. In other databases, such a schema needs to be manually created.
- To reference a table that is not modified with a schema name, the system uses **search_path** to find the schema that the table belongs to. `pg_temp` and `pg_catalog` are always the first two schemas to be searched no matter whether or how they are specified in **search_path**. **search_path** is a schema name list, and the first table detected in it is the target table. If no target table is found, an error will be reported. (If a table exists but the schema it belongs to is not listed in **search_path**, the search fails as well.) The first schema in **search_path** is called "current schema". This schema is the first one to be searched. If no schema name is declared, newly created database objects are saved in this schema by default.
- Each database has a `pg_catalog` schema, which contains system catalogs and all built-in data types, functions, and operators. `pg_catalog` is a part of the search path and has the second highest search priority. It is searched after the schema of temporary tables and before other schemas specified in **search_path**. This search order ensures that database built-in objects can be found. To use a custom object that has the same name as a built-in object, you can specify the schema of the custom object.

Procedure

- Create a schema.
 - Create a schema.

```
gaussdb=# CREATE SCHEMA myschema;
```

If the following information is displayed, the schema named **myschema** is successfully created:

```
CREATE SCHEMA
```

To create or access an object in the schema, specify the complete object name, which consists of the schema name and the object names separated by periods (.). Example: **myschema.table**.
 - Create a schema and specify the owner.

```
gaussdb=# CREATE SCHEMA myschema AUTHORIZATION omm;
```

If the following information is displayed, the **myschema** schema that belongs to **omm** is created successfully:

```
CREATE SCHEMA
```
- Use a schema.

If you want to create or access an object in a specified schema, the object name must contain the schema name. To be specific, the name consists of a schema name and an object name, which are separated by a dot (.).

 - Create the **mytable** table in **myschema**:

```
gaussdb=# CREATE TABLE myschema.mytable(id int, name varchar(20));
```

```
CREATE TABLE
```

To specify the location of an object, the object name must contain the schema name.
 - Query all data of the **mytable** table in **myschema**.

```
gaussdb=# SELECT * FROM myschema.mytable;
```

```
id | name
```

```
----+-----
```

```
(0 rows)
```

- View the search path of a schema.

You can set **search_path** to specify the sequence of schemas in which objects are searched. The first schema listed in the search path will become the default schema. If no schema is specified during object creation, the object will be created in the default schema.

 - View the search path.

```
gaussdb=# SHOW SEARCH_PATH;
search_path
-----
"$user",public
(1 row)
```
 - Set the search path to **myschema, public** (**myschema** will be searched first).

```
gaussdb=# SET SEARCH_PATH TO myschema, public;
SET
```
- Set permissions for a schema.

By default, a user can only access database objects in their own schema. Only after a user is granted with the usage permission for a schema by the schema owner, the user can access the objects in the schema.

By granting the CREATE permission for a schema to a user, the user can create objects in this schema. By default, all roles have the USAGE permission in the public schema, but common users do not have the CREATE permission in the public schema. It is insecure for a common user to connect to a specified database and create objects in its public schema. If the common user has the CREATE permission on the public schema, it is advised to:

 - Revoke **PUBLIC**'s permission to create objects in the public schema. **public** indicates the schema and **PUBLIC** indicates all roles.

```
gaussdb=# REVOKE CREATE ON SCHEMA public FROM PUBLIC;
REVOKE
```
 - View the current schema.

```
gaussdb=# SELECT current_schema();
current_schema
-----
myschema
(1 row)
```
 - Create user **jack** and grant the usage permission for **myschema** to the user.

```
gaussdb=# CREATE USER jack IDENTIFIED BY '*****';
CREATE ROLE
gaussdb=# GRANT USAGE ON schema myschema TO jack;
GRANT
```
 - Revoke the usage permission for **myschema** from **jack**.

```
gaussdb=# REVOKE USAGE ON schema myschema FROM jack;
REVOKE
```
- Delete a schema.
 - If a schema is empty, that is, it contains no database objects, you can run the **DROP SCHEMA** command. For example, delete an empty schema named **nullschema**.

```
gaussdb=# DROP SCHEMA IF EXISTS nullschema;
DROP SCHEMA
```
 - To delete a schema that is not null, use the keyword **CASCADE** to delete it and all its objects. For example, delete **myschema** and all its objects in it.

```
gaussdb=# DROP SCHEMA myschema CASCADE;
DROP SCHEMA
```

- Delete user **jack**.
gaussdb=# **DROP USER jack;**
DROPPING ROLE

3.2.6.2 Creating and Managing Partitioned Tables

Context

GaussDB supports range partitioned tables, list partitioned tables, and hash partitioned tables.

- Range partitioned table: Data within a certain range is mapped to each partition. The range is determined by the partition key specified when the partitioned table is created. This partitioning mode is most commonly used. The partition key is usually a date. For example, sales data is partitioned by month.
- List partitioned table: Key values contained in the data are stored in different partitions, and the data is mapped to each partition in sequence. The key values contained in the partitions are specified when the partitioned table is created.
- Hash partitioned table: Data is mapped to each partition based on the internal hash algorithm. The number of partitions is specified when the partitioned table is created.

A partitioned table has the following advantages over an ordinary table:

- High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
- High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
- Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.
- Balanced I/O: Partitions can be mapped to different disks to balance I/O and improve the overall system performance.

To convert an ordinary table to a partitioned table, you need to create a partitioned table and import data to it from the ordinary table. When you design tables, plan whether to use partitioned tables based on service requirements.

Procedure

Example 1: Use the default tablespace.

- Create a partitioned table (assuming that the **tpcds** schema has been created).

```
gaussdb=# CREATE TABLE tpcds.customer_address
(
  ca_address_sk integer NOT NULL ,
  ca_address_id character(16) NOT NULL ,
  ca_street_number character(10) ,
  ca_street_name character varying(60) ,
  ca_street_type character(15) ,
  ca_suite_number character(10) ,
  ca_city character varying(60) ,
  ca_county character varying(30) ,
  ca_state character(2) ,
  ca_zip character(10) ,
```

```

ca_country      character varying(20)      ,
ca_gmt_offset   numeric(5,2)          ,
ca_location_type character(20)
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
    PARTITION P1 VALUES LESS THAN(5000),
    PARTITION P2 VALUES LESS THAN(10000),
    PARTITION P3 VALUES LESS THAN(15000),
    PARTITION P4 VALUES LESS THAN(20000),
    PARTITION P5 VALUES LESS THAN(25000),
    PARTITION P6 VALUES LESS THAN(30000),
    PARTITION P7 VALUES LESS THAN(40000),
    PARTITION P8 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;

```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Insert data.

Insert data from the **tpcds.customer_address** table to the **tpcds.web_returns_p2** table.

Suppose that the backup table **tpcds.web_returns_p2** of the **tpcds.customer_address** table has been created in the database. You can insert the data of the **tpcds.customer_address** table into the backup table **tpcds.web_returns_p2**.

```

gaussdb=# CREATE TABLE tpcds.web_returns_p2
(
    ca_address_sk      integer          NOT NULL ,
    ca_address_id     character(16)     NOT NULL ,
    ca_street_number   character(10)
    ,
    ca_street_name     character varying(60)
    ,
    ca_street_type     character(15)
    ,
    ca_suite_number    character(10)
    ,
    ca_city            character varying(60)
    ,
    ca_county          character varying(30)
    ,
    ca_state           character(2)
    ,
    ca_zip             character(10)
    ,
    ca_country         character varying(20)
    ,
    ca_gmt_offset      numeric(5,2)
    ,
    ca_location_type   character(20)
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
    PARTITION P1 VALUES LESS THAN(5000),
    PARTITION P2 VALUES LESS THAN(10000),
    PARTITION P3 VALUES LESS THAN(15000),
    PARTITION P4 VALUES LESS THAN(20000),
    PARTITION P5 VALUES LESS THAN(25000),
    PARTITION P6 VALUES LESS THAN(30000),
    PARTITION P7 VALUES LESS THAN(40000),
    PARTITION P8 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;
CREATE TABLE
gaussdb=# INSERT INTO tpcds.web_returns_p2 SELECT * FROM tpcds.customer_address;
INSERT 0 0

```

- Modify the row movement attributes of the partitioned table.

```

gaussdb=# ALTER TABLE tpcds.web_returns_p2 DISABLE ROW MOVEMENT;
ALTER TABLE

```

- Delete a partition.
Delete partition **P8**.

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 DROP PARTITION P8;
ALTER TABLE
```

- Add a partition.

Add partition **P8** and set its range to [40000,MAXVALUE).

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN
(MAXVALUE);
ALTER TABLE
```

- Rename partitions.

- Rename partition **P8** to **P_9**.

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION P8 TO P_9;
ALTER TABLE
```

- Rename partition **P_9** to **P8**.

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;
ALTER TABLE
```

- Query a partition.

Query partition **P6**.

```
gaussdb=# SELECT * FROM tpcds.web_returns_p2 PARTITION (P6);
gaussdb=# SELECT * FROM tpcds.web_returns_p2 PARTITION FOR (35888);
```

- Delete a partitioned table and its tablespaces.

```
gaussdb=# DROP TABLE tpcds.customer_address;
DROP TABLE
gaussdb=# DROP TABLE tpcds.web_returns_p2;
DROP TABLE
```

Example 2: Use a user-defined tablespace (assuming that the **tpcds** schema has been created).

Perform the following operations on the range partitioned table (the **tpcds** namespace in the example must be created in advance):

- Create tablespaces.

```
gaussdb=# CREATE TABLESPACE example1 RELATIVE LOCATION 'tablespace1/tablespace_1';
gaussdb=# CREATE TABLESPACE example2 RELATIVE LOCATION 'tablespace2/tablespace_2';
gaussdb=# CREATE TABLESPACE example3 RELATIVE LOCATION 'tablespace3/tablespace_3';
gaussdb=# CREATE TABLESPACE example4 RELATIVE LOCATION 'tablespace4/tablespace_4';
```

If the following information is displayed, the creation is successful:

```
CREATE TABLESPACE
```

- Create a partitioned table.

```
gaussdb=# CREATE TABLE tpcds.customer_address
(
  ca_address_sk integer NOT NULL ,
  ca_address_id character(16) NOT NULL ,
  ca_street_number character(10) ,
  ca_street_name character varying(60) ,
  ca_street_type character(15) ,
  ca_suite_number character(10) ,
  ca_city character varying(60) ,
  ca_county character varying(30) ,
  ca_state character(2) ,
  ca_zip character(10) ,
  ca_country character varying(20) ,
  ca_gmt_offset numeric(5,2) ,
  ca_location_type character(20)
)
TABLESPACE example1
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
  PARTITION P1 VALUES LESS THAN(5000),
  PARTITION P2 VALUES LESS THAN(10000),
  PARTITION P3 VALUES LESS THAN(15000),
```

```

PARTITION P4 VALUES LESS THAN(20000),
PARTITION P5 VALUES LESS THAN(25000),
PARTITION P6 VALUES LESS THAN(30000),
PARTITION P7 VALUES LESS THAN(40000),
PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
)
ENABLE ROW MOVEMENT;

```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Insert data.

Insert data from the **tpcds.customer_address** table to the **tpcds.web_returns_p2** table.

Suppose that the backup table **tpcds.web_returns_p2** of the **tpcds.customer_address** table has been created in the database. You can insert the data of the **tpcds.customer_address** table into the backup table **tpcds.web_returns_p2**.

```

gaussdb=# CREATE TABLE tpcds.web_returns_p2
(
  ca_address_sk      integer          NOT NULL ,
  ca_address_id     character(16)     NOT NULL ,
  ca_street_number  character(10)     ,
  ca_street_name    character varying(60) ,
  ca_street_type    character(15)     ,
  ca_suite_number   character(10)     ,
  ca_city           character varying(60) ,
  ca_county        character varying(30) ,
  ca_state          character(2)       ,
  ca_zip           character(10)       ,
  ca_country        character varying(20) ,
  ca_gmt_offset     numeric(5,2)      ,
  ca_location_type  character(20)     ,
)
TABLESPACE example1
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
  PARTITION P1 VALUES LESS THAN(5000),
  PARTITION P2 VALUES LESS THAN(10000),
  PARTITION P3 VALUES LESS THAN(15000),
  PARTITION P4 VALUES LESS THAN(20000),
  PARTITION P5 VALUES LESS THAN(25000),
  PARTITION P6 VALUES LESS THAN(30000),
  PARTITION P7 VALUES LESS THAN(40000),
  PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
)
ENABLE ROW MOVEMENT;
CREATE TABLE
gaussdb=# INSERT INTO tpcds.web_returns_p2 SELECT * FROM tpcds.customer_address;
INSERT 0 0

```

- Modify the row movement attributes of the partitioned table.

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 DISABLE ROW MOVEMENT;
ALTER TABLE
```

- Delete a partition.

Delete partition **P8**.

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 DROP PARTITION P8;
ALTER TABLE
```

- Add a partition.

Add partition **P8** and set its range to [40000,MAXVALUE].

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN
(MAXVALUE);
ALTER TABLE
```

- Rename partitions.
 - Rename partition **P8** to **P_9**.
gaussdb=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION P8 TO P_9;
ALTER TABLE
 - Rename partition **P_9** to **P8**.
gaussdb=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;
ALTER TABLE
- Change the tablespaces of partitions.
 - Change the tablespace of partition **P6** to **example3**.
gaussdb=# ALTER TABLE tpcds.web_returns_p2 MOVE PARTITION P6 TABLESPACE example3;
ALTER TABLE
 - Change the tablespace of partition **P4** to **example4**.
gaussdb=# ALTER TABLE tpcds.web_returns_p2 MOVE PARTITION P4 TABLESPACE example4;
ALTER TABLE
- Query a partition.
Query partition **P6**.
gaussdb=# SELECT * FROM tpcds.web_returns_p2 PARTITION (P6);
gaussdb=# SELECT * FROM tpcds.web_returns_p2 PARTITION FOR (35888);
- Delete a partitioned table and its tablespaces.
gaussdb=# DROP TABLE tpcds.customer_address;
DROP TABLE
gaussdb=# DROP TABLE tpcds.web_returns_p2;
DROP TABLE
gaussdb=# DROP TABLESPACE example1;
gaussdb=# DROP TABLESPACE example2;
gaussdb=# DROP TABLESPACE example3;
gaussdb=# DROP TABLESPACE example4;
DROP TABLESPACE

3.2.6.3 Creating and Managing Indexes

Context

Indexes accelerate data access but increase the processing time of insertion, update, and deletion operations. Therefore, before creating an index, consider whether it is necessary and select the columns where indexes are to be created. You can determine whether to create an index for a table by analyzing the service processing and data use of applications, as well as columns that are frequently used as search criteria or need to be collated.

Indexes are created based on columns in database tables. Therefore, you must correctly identify which columns require indexes. You are advised to create indexes for any of the following columns:

- Columns that are often searched and queried. This speeds up searches.
- Columns that function as primary keys. This enforces the uniqueness of the columns and the data collation structures in organized tables.
- Columns that are often joined. This increases the join efficiency.
- Columns that are often searched by range. The index helps collate data, and therefore the specified ranges are contiguous.
- Columns that often need to be collated. The index helps collate data, reducing the time for a collation query.
- Columns where the WHERE clause is executed frequently. This speeds up condition judgment.

- Columns that often appear after the keywords ORDER BY, GROUP BY, and DISTINCT.

 NOTE

- After an index is created, the system automatically determines when to reference it. If the system determines that indexing is faster than sequential scan, the index will be used.
 - After an index is successfully created, it must be synchronized with the associated table to ensure new data can be accurately located, which increases the data operation load. Therefore, delete unnecessary indexes periodically.
 - Partitioned table indexes are classified into local indexes and global indexes. A local index corresponds to a specific partition, and a global index corresponds to the entire partitioned table.
- When logical replication is enabled, if you need to create a primary key index that contains system columns, you must set the **REPLICA IDENTITY** attribute of the table to **FULL** or use **USING INDEX** to specify a unique, non-local, non-deferrable index that does not contain system columns and contains only columns marked **NOT NULL**.

Procedure

To create a partitioned table, see [Creating and Managing Partitioned Tables](#).

- Create an index.
 - Create the partitioned table index **tpcds_web_returns_p2_index1** without specifying the partition name.

```
gaussdb=# CREATE INDEX tpcds_web_returns_p2_index1 ON tpcds.web_returns_p2 (ca_address_id) LOCAL;
```

If the following information is displayed, the creation is successful:

```
CREATE INDEX
```
 - Create the partitioned table index **tpcds_web_returns_p2_index2** with the partition name specified.

```
gaussdb=# CREATE INDEX tpcds_web_returns_p2_index2 ON tpcds.web_returns_p2 (ca_address_sk) LOCAL
(
PARTITION web_returns_p2_P1_index,
PARTITION web_returns_p2_P2_index TABLESPACE example3,
PARTITION web_returns_p2_P3_index TABLESPACE example4,
PARTITION web_returns_p2_P4_index,
PARTITION web_returns_p2_P5_index,
PARTITION web_returns_p2_P6_index,
PARTITION web_returns_p2_P7_index,
PARTITION web_returns_p2_P8_index
) TABLESPACE example2;
```

If the following information is displayed, the creation is successful:

```
CREATE INDEX
```
- Change the tablespace of an index partition.
 - Change the tablespace of index partition **web_returns_p2_P2_index** to **example1**.

```
gaussdb=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 MOVE PARTITION web_returns_p2_P2_index TABLESPACE example1;
```

If the following information is displayed, the modification is successful:

```
ALTER INDEX
```
 - Change the tablespace of index partition **web_returns_p2_P3_index** to **example2**.

```
gaussdb=# ALTER INDEX tpcls.tpcds_web_returns_p2_index2 MOVE PARTITION
web_returns_p2_P3_index TABLESPACE example2;
```

If the following information is displayed, the modification is successful:

```
ALTER INDEX
```

- Rename an index partition.

Rename the index partition **web_returns_p2_P8_index** to **web_returns_p2_P8_index_new**.

```
gaussdb=# ALTER INDEX tpcls.tpcds_web_returns_p2_index2 RENAME PARTITION
web_returns_p2_P8_index TO web_returns_p2_P8_index_new;
```

If the following information is displayed, the rename operation is successful:

```
ALTER INDEX
```

- Query indexes.

- Query all indexes defined by the system and users.

```
gaussdb=# SELECT RELNAME FROM PG_CLASS WHERE RELKIND='i';
```

- Query information about a specified index.

```
gaussdb=# \di+ tpcls.tpcds_web_returns_p2_index2
```

- Delete indexes.

```
gaussdb=# DROP INDEX tpcls.tpcds_web_returns_p2_index1;
gaussdb=# DROP INDEX tpcls.tpcds_web_returns_p2_index2;
```

If the following information is displayed, the deletion is successful:

```
DROP INDEX
```

GaussDB supports four methods for creating indexes. For details, see [Table 3-4](#).

NOTE

- After an index is created, the system automatically determines when to reference it. If the system determines that indexing is faster than sequential scan, the index will be used.
- After an index is successfully created, it must be synchronized with the associated table to ensure new data can be accurately located, which increases the data operation load. Therefore, delete unnecessary indexes periodically.

Table 3-4 Indexing method

Indexing Method	Description
Unique index	An index that requires the uniqueness of an index attribute or an attribute group. If a table declares unique constraints or primary keys, GaussDB automatically creates unique indexes (or composite indexes) for columns that form the primary keys or unique constraints. Currently, unique indexes can be created only for the B-tree and UB-tree in GaussDB.
Composite index	An index that can be defined for multiple attributes of a table. Currently, composite indexes can be created only for B-tree in GaussDB and up to 32 columns can share a composite index.
Partial index	An index that can be created for subsets of a table. This indexing method contains only tuples that meet condition expressions.

Indexing Method	Description
Expression index	An index that is built on a function or expression calculated based on one or more attributes of a table. An expression index works only when the queried expression is the same as the created expression.

- Create an ordinary table.

```
gaussdb=# CREATE TABLE tpcds.customer_address_bak AS TABLE tpcds.customer_address;
INSERT 0 0
```

- Create an ordinary index.

For the **tpcds.customer_address_bak** table, you need to perform the following operations frequently:

```
gaussdb=# SELECT ca_address_sk FROM tpcds.customer_address_bak WHERE ca_address_sk=14888;
```

Generally, the database system needs to scan the

tpcds.customer_address_bak table row by row to find all matched tuples. If the size of the **tpcds.customer_address_bak** table is large but only a few (possibly zero or one) of the WHERE conditions are met, the performance of this sequential scan is low. If the database system uses an index to maintain the **ca_address_sk** attribute, the database system only needs to search a few tree layers for the matched tuples. This greatly improves data query performance. Furthermore, indexes can improve the update and deletion operation performance in the database.

Create an index.

```
gaussdb=# CREATE INDEX index_wr_returned_date_sk ON tpcds.customer_address_bak
(ca_address_sk);
CREATE INDEX
```

- Create a unique index.

Create a unique index on the **SM_SHIP_MODE_SK** column in the **tpcds.ship_mode_t1** table.

```
gaussdb=# CREATE UNIQUE INDEX ds_ship_mode_t1_index1 ON
tpcds.ship_mode_t1(SM_SHIP_MODE_SK);
```

- Create a composite index.

Frequently query records with **ca_address_sk** being **5050** and **ca_street_number** smaller than **1000** in the **tpcds.customer_address_bak** table.

```
gaussdb=# SELECT ca_address_sk,ca_address_id FROM tpcds.customer_address_bak WHERE
ca_address_sk = 5050 AND ca_street_number < 1000;
```

Define a composite index on **ca_address_sk** and **ca_street_number** columns.

```
gaussdb=# CREATE INDEX more_column_index ON
tpcds.customer_address_bak(ca_address_sk ,ca_street_number );
CREATE INDEX
```

- Create a partial index.

If you only want to find records with **ca_address_sk** being **5050**, you can create a partial index to facilitate your query.

```
gaussdb=# CREATE INDEX part_index ON tpcds.customer_address_bak(ca_address_sk) WHERE
ca_address_sk = 5050;
CREATE INDEX
```

- Create an expression index.

Frequently query records with **ca_street_number** smaller than **1000**.
gaussdb=# **SELECT * FROM tpcds.customer_address_bak WHERE trunc(ca_street_number) < 1000,**

The following expression index can be created for this query task:
gaussdb=# **CREATE INDEX para_index ON tpcds.customer_address_bak (trunc(ca_street_number));**
CREATE INDEX

- Delete the **tpcds.customer_address_bak** table.

gaussdb=# **DROP TABLE tpcds.customer_address_bak;**
DROP TABLE

3.2.6.4 Creating and Managing Views

Context

If some columns in one or more tables in a database are frequently searched for, an administrator can define a view for these columns, and then users can directly access these columns in the view without entering search criteria.

Different from a base table, a view is a virtual table. Only view definition is stored in the database and view data is not. The data is stored in a base table. If data in the base table changes, the data in the view changes accordingly. A view is like a window through which users can know their interested data and data changes in the database. A view is triggered every time it is referenced.

Managing Views

- Create a view.

Create the **MyView** view. In the command, **tpcds.web_returns** indicates the created user table that contains the **wr_refunded_cash** integer column.

gaussdb=# **CREATE OR REPLACE VIEW MyView AS SELECT * FROM tpcds.web_returns WHERE trunc(wr_refunded_cash) > 10000;**
CREATE VIEW

NOTE

The **OR REPLACE** parameter in this command is optional. It indicates that if the view exists, the new view will replace the existing view.

- Query a view.

Query **MyView**.

gaussdb=# **SELECT * FROM MyView;**

- Query views of the current user.

gaussdb=# **SELECT * FROM my_views;**

- Query all views.

gaussdb=# **SELECT * FROM adm_views;**

- Query details about a specified view.

View details about **MyView**.

```
gaussdb=# \d+ MyView
View "PG_CATALOG.MyView"
Column |      Type      | Modifiers | Storage | Description
-----+-----+-----+-----+-----
USERNAME | CHARACTER VARYING(64) |          | extended |
View definition:
SELECT PG_AUTHID.ROLNAME::CHARACTER VARYING(64) AS USERNAME
FROM PG_AUTHID;
```

- Delete a view.

Delete **MyView**.

```
gaussdb=# DROP VIEW MyView;  
DROP VIEW
```

3.2.6.5 Creating and Managing Sequences

Context

A sequence is a database object that generates unique integers. Sequence numbers are generated according to a certain rule. Sequences are unique because they increase automatically. This is why they are often used as primary keys.

You can create a sequence for a column in either of the following methods:

- Set the data type of a column to **sequence integer**. A sequence will be automatically created by the database for this column.
- Use the **CREATE SEQUENCE** statement to create a sequence. Set the initial value of the `nextval('sequence_name')` function to the default value of a column.

Procedure

Method 1: Set the data type of a column to a sequence integer. Example:

```
gaussdb=# CREATE TABLE T1  
(  
  id serial,  
  name text  
);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

Method 2: Create a sequence and set the initial value of the `nextval('sequence_name')` function to the default value of a column. You can cache a specific number of sequence values to reduce the requests to the GTM, improving the performance.

1. Create a sequence.

```
gaussdb=# CREATE SEQUENCE seq1 cache 100;
```

If the following information is displayed, the creation is successful:

```
CREATE SEQUENCE
```

2. Set the default value of a column so that the column has a unique identification attribute.

```
gaussdb=# CREATE TABLE T2  
(  
  id int not null default nextval('seq1'),  
  name text  
);
```

If the following information is displayed, the default value has been specified:

```
CREATE TABLE
```

3. Associate a sequence with a column.

Associate a sequence with a specified column included in a table. In this way, the sequence will be deleted when you delete its associated column or the table where the column belongs to.

```
gaussdb=# ALTER SEQUENCE seq1 OWNED BY T2.id;
```

If the following information is displayed, the operation is successful:

ALTER SEQUENCE

 NOTE

The preceding methods are similar, except that the second method specifies cache for the sequence. A sequence having cache defined has inconsecutive values (such as 1, 4, and 5) and cannot maintain the order of its values. After the dependent column of a sequence has been specified, once the sequence is deleted, the sequence of the dependent will be deleted. A sequence shared by multiple columns is not forbidden in a database, but you are advised not to do that.

In the current version, you can specify the auto-increment column or set the default value of a column to **nextval('seqname')** when defining a table. You cannot add an auto-increment column or a column whose default value is **nextval('seqname')** to an existing table.

Precautions

Sequence values are generated by the GTM. By default, each request for a sequence value is sent to the GTM. The GTM calculates the result of the current value plus the step and then returns the result. The GTM is a globally unique node and is the performance bottleneck. Therefore, you are advised not to generate sequence values frequently and numerously, such as to use BulkLoad to import data. For example, the INSERT INTO SELECT FROM statement has poor performance in the following scenario:

```
gaussdb=# CREATE SEQUENCE newSeq1;
gaussdb=# CREATE TABLE newT1
(
  id int not null default nextval('newSeq1'),
  name text
);
gaussdb=# INSERT INTO newT1(name) SELECT name FROM T1;
```

Assume that data imported from table **T1** to table **newT1** has 10,000 rows. The following statements achieve better performance:

```
gaussdb=# INSERT INTO newT1(id, name) SELECT id,name FROM T1;
gaussdb=# SELECT SETVAL('newSeq1', 10000);
```

 NOTE

Rollback is not supported by sequence functions, including nextval() and setval(). The value of the **setval** function immediately takes effect on **nextval** in the current session in any cases and take effect in other sessions only when no cache is specified for them. If cache is specified for a session, it takes effect only after all the cached values have been used. To avoid duplicate values, use **setval** only when necessary. Do not set it to an existing sequence value or a cached sequence value.

To generate the default sequence value using BulkLoad, set sufficient cache for **newSeq1** and do not set **Maxvalue** or **Minvalue**. The database will push down the calling of **nextval('sequence_name')** to DNs to improve performance. Currently, the concurrent connection requests that can be processed by the GTM are limited. If there are too many DNs, a large number of concurrent connection requests will be sent to the GTM. In this case, you need to limit the bulk loading concurrency, so that DNs do not fully occupy GTM connections. If the target table is a duplicate table (DISTRIBUTE BY REPLICATION), pushdown cannot be performed. When the data volume is large, the performance is affected and the space may bloat sharply. After the import is complete, you need to run the **vacuum full** command to restore the data. The best way is not to use BulkLoad to generate the default sequence value.

After a sequence is created, one single-row table is maintained on each node to store the sequence definition and value, which is obtained from the last interaction with the GTM rather than updated in real time. The single-row table on a node does not update when other nodes request a new value from the GTM or when the sequence is modified using **setval**.

3.2.6.6 Creating and Managing Scheduled Jobs

Context

Time-consuming jobs, such as summarizing statistics or synchronizing data from another database, affect service performance if they are performed during the daytime and incur overtime hours if performed at night. To solve this problem, the database is compatible with the scheduled job function in the ORA database. You can create scheduled jobs that are automatically triggered to reduce O&M workload.

This function calls APIs provided by the **DBE_SCHEDULER** and **DBE_TASK** packages to create scheduled jobs, execute jobs automatically, delete jobs, and modify job attributes (including job ID, the enabled/disabled status of a job, job triggering time, triggering interval, and job contents). The DBE_SCHEDULER API is recommended to ensure high availability and reliability and support more flexible job scheduling. For details about the API description and migration guide examples, see [DBE_SCHEDULER](#).

Managing Scheduled Jobs

Step 1 Create a test table.

```
gaussdb=# CREATE TABLE test(id int, time date);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

Step 2 Create a customized stored procedure.

```
gaussdb=# CREATE OR REPLACE PROCEDURE PRC_JOB_1()  
AS  
N_NUM integer :=1;  
BEGIN  
FOR I IN 1..1000 LOOP  
INSERT INTO test VALUES(I,SYSDATE);  
END LOOP;  
END;  
/
```

If the following information is displayed, the creation is successful:

```
CREATE PROCEDURE
```

Step 3 Create a job.

- Create a job with unspecified **job_id** and execute the **PRC_JOB_1** stored procedure every minute.

```
gaussdb=# call db_task.submit('call public.prc_job_1(); ', sysdate, 'interval "1 minute"', :a);  
job  
-----  
1  
(1 row)
```

- Specify **job_id** to create a job. The value of **job_id** ranges from 1 to 32767.

```
gaussdb=# call dbe_task.id_submit(2,'call public.prc_job_1(); ', sysdate, 'interval "1 minute"');
isubmit
-----
(1 row)
```

Step 4 View details of jobs created by the current user.

```
gaussdb=# select job,dbname,start_date,last_date,this_date,next_date,broken,status,interval,failures,what
from my_jobs;
 job | dbname | start_date | last_date | this_date | next_date | broken | status | interval | failures | what
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
 1 | testdb | 2017-07-18 11:38:03 | 2017-07-18 13:53:03.607838 | 2017-07-18 13:53:03.607838 | 2017-07-18 13:54:03 | n | s | interval '1 minute' | 0 | call public.prc_job_1();
(1 row)
```

Step 5 Stop a job.

```
gaussdb=# call dbe_task.finish(1,true);
broken
-----
(1 row)
```

Step 6 Start a job.

```
gaussdb=# call dbe_task.finish(1,false);
broken
-----
(1 row)
```

Step 7 Modify job attributes.

- Modify the **Next_date** parameter information about a job.

```
-- Set Next_date of Job1 to 1 hour so that Job1 will be executed in one hour.
gaussdb=# call dbe_task.next_time(1, sysdate+1.0/24);
next_date
-----
(1 row)
```

- Modify the **Interval** parameter about a job.

```
-- Set Interval of Job1 to 1.
gaussdb=# call dbe_task.interval(1,'sysdate + 1.0/24');
interval
-----
(1 row)
```

- Modify the **What** parameter about a job.

```
-- Set What to the SQL statement insert into public.test values(333, sysdate+5); for Job1.
gaussdb=# call dbe_task.content(1,'insert into public.test values(333, sysdate+5);');
what
-----
(1 row)
```

- Modify **Next_date**, **Interval**, and **What** parameters about a job.

```
gaussdb=# call dbe_task.update(1, 'call public.prc_job_1(); ', sysdate, 'interval "1 minute"');
change
-----
(1 row)
```

Step 8 Delete a job.

```
gaussdb=# call dbe_task.cancel(1);
remove
-----
```

(1 row)

Step 9 View the job execution status.

If a job fails to be automatically executed (that is, the value of **job_status** is 'f'), contact the administrator to view the **pg_log** run log to view the failure information of the job.

From **detail error msg**, you can see the failure causes.

```
LOG: Execute Job Detail:
job_id: 1
what: call public.test();
start_date: 2017-07-19 23:30:47.401818
job_status: failed
detail error msg: relation "test" does not exist
end_date: 2017-07-19 23:30:47.401818
next_run_date: 2017-07-19 23:30:56.855827
```

Step 10 Set job permissions.

- During the creation of a job, the job is bound to the user and database that created the job. Accordingly, the user and database are added to **dbname** and **log_user** columns in the **pg_job** system catalog, respectively.
- If the current user is a database administrator, system administrator, or the user (**log_user** of **pg_job**) who created the job, the user has permissions to delete or modify job parameters using the **remove**, **change**, **next_data**, **what**, or **interval** parameter. Otherwise, the system displays a message indicating that the user has no permissions to perform operations on this job.
- If the current database is the one that created a job, (that is, **dbname** in **pg_job**), you can delete or modify parameter settings of the job using the **cancel**, **update**, **next_data**, **content**, or **interval** parameter.
- When deleting the database that created a job, (that is, **dbname** in **pg_job**), the system automatically deletes the job records of the database.
- When deleting the user who created a job, (that is, **log_user** in **pg_job**), the system automatically deletes the job records of the user.

Step 11 Manage job concurrency.

You can configure the GUC parameter **job_queue_processes** to adjust the number of jobs running at the same time.

- Setting **job_queue_processes** to **0** indicates that the scheduled job function is disabled and all jobs will not be executed.
- Setting **job_queue_processes** to a value that is greater than **0** indicates that the scheduled job function is enabled and this value is the maximum number of jobs that can be concurrently processed.

Too many concurrent jobs consume many system resources, so you need to set the number of concurrent jobs to be processed. If the current number of concurrent jobs reaches the value of **job_queue_processes** and some of them expire, these jobs will be postponed to the next polling period. Therefore, you are advised to set the polling interval (the **Interval** parameter of the **submit** API) based on the execution duration of each job to avoid the problem that jobs in the next polling period cannot be properly processed because of overlong job execution time.

Note: For clusters that do not use jobs, set **job_queue_processes** to **0** to disable job functions to reduce the resource consumption.

----End

4 Development and Design Proposal

4.1 Overview

This section describes the design specifications for database modeling and application development. Modeling based on these specifications fits the distributed processing architecture of GaussDB and outputs efficient SQL code.

The meaning of "Proposal" and "Notice" in this section is as follows:

- **Proposal:** Design rules. Services complying with the rules can run efficiently, and those violating the rules may have low performance or logic errors.
- **Notice:** Details requiring attention during service development. This term identifies SQL behavior that complies with SQL standards but users may have misconceptions about, and default behavior that users may be unaware of in a program.

4.2 Database Object Naming Conventions

Database object names must meet the following requirements:

- The name length of a table or an identifier cannot exceed 63 bytes.
- An identifier starts with a letter or underscore (_) and can contain letters, digits, underscores (_), dollar signs (\$), and number signs (#).
- If an identifier is enclosed in double quotation marks (""), any combination of valid characters can be used, for example, "123gs_column".
- Identifiers are case insensitive unless they are enclosed in double quotation marks.
- Do not use reserved or non-reserved keywords to name database objects.

NOTE

To query the GaussDB keywords, run `select * from pg_get_keywords()` or refer to [Keywords](#).

- Do not use a string enclosed in double quotation marks ("") to define the database object name, unless you need to specify its capitalization. Case sensitivity of database object names makes problem location difficult.

- Use the same naming format for database objects.
 - In a system undergoing incremental development or service migration, you are advised to comply with its historical naming conventions.
 - You are advised to use multiple words separated with underscores (_).
 - You are advised to use intelligible names and common acronyms or abbreviations for database objects. Acronyms or abbreviations that are generally understood are recommended. For example, you can use English words or Chinese pinyin indicating actual business terms. The naming format should be consistent within a cluster.
 - A variable name must be descriptive and meaningful. It must have a prefix indicating its type.
- The name of a table object should indicate its main characteristics, for example, whether it is an ordinary, temporary, or unlogged table.
 - An ordinary table name should indicate the business relevant to a dataset.
 - Temporary tables are named in the format of **tmp_Suffix**.
 - Unlogged tables are named in the format of **ul_Suffix**.
 - Foreign tables are named in the format of **f_Suffix**.
 - Do not create database objects whose names start with **redis_**.
 - Do not create database objects whose names start with **mlog_** or **matviewmap_**.
 - Do not create database objects whose names start with **gs_role_**.
- The name of a table object shall not exceed 63 bytes. If the length of a table name exceeds this value, the kernel truncates the table name. As a result, the actual name is inconsistent with the configured value. In addition, characters may be truncated in different character sets and unexpected characters may appear.

4.3 Database Object Design

4.3.1 Database and Schema Design

In GaussDB, services can be isolated by databases and schemas. Databases share little resources and cannot directly access each other. Connections to and permissions on them are also isolated. Schemas share more resources than databases do. User permissions on schemas and subordinate objects can be controlled using the GRANT and REVOKE syntax.

- You are advised to use schemas to isolate services for convenience and resource sharing.
- It is recommended that system administrators create schemas and databases and then assign required permissions to users.

Database Design

- Create databases as required by your business. Do not use the default **postgres** database of a cluster.

- In a cluster, the recommended number of user-defined databases is 3. It is recommended that the number of user-defined databases be less than or equal to 10. If there are too many user-defined databases, O&M operations, such as upgrade and backup, will be inefficient.
- To make your database compatible with most characters, you are advised to use the UTF-8 encoding when creating a database.
- When you create a database, exercise caution when you set **ENCODING** and **DBCOMPATIBILITY** configuration items. GaussDB supports the TD, ORA, MySQL, and PG compatibility modes which are partially compatible with the Teradata syntax, Oracle syntax, MySQL syntax, and PostgreSQL syntax, respectively. The syntax behavior varies according to the compatibility mode. By default, the MySQL compatibility mode is used.
- By default, a database owner has all permissions for all objects in the database, including the deletion permission. Exercise caution when deleting a permission.

Schema Design

- It is recommended that the number of schemas in the actual user environment be no more than 100. If there are too many schemas in a database, operations that depend on the number of schemas, such as `gs_dump`, becomes slow.
- To let a user access an object in a schema, assign the usage permission and the permissions for the object to the user, unless the user has the `sysadmin` permission or is the schema owner.
- To let a user create an object in the schema, grant the `CREATE` permission for the schema to the user.
- By default, a schema owner has all permissions for all objects in the schema, including the deletion permission. Exercise caution when deleting a permission.

4.3.2 Table Design

GaussDB uses a distributed architecture. Data is distributed on DNs. Generally, well-designed table must comply with the following rules:

- Evenly distribute data on each DN to prevent data skew. If most data is stored on several DNs, the effective capacity of a cluster decreases. Select a proper distribution key to avoid data skew.
- Evenly scan each DN when querying tables. Otherwise, DNs most frequently scanned will become the performance bottleneck. For example, when you use equivalent filter conditions on a fact table, the nodes are not evenly scanned.
- Reduce the amount of data to be scanned. You can use the pruning mechanism of a partitioned table.
- Minimize random I/Os. Through clustering, you can sequentially store hot data, converting random I/O to sequential I/O to reduce the cost of I/O scanning.
- Avoid data shuffle. To shuffle data is to physically transfer it from one node to another. This unnecessarily occupies many network resources. To reduce network pressure, locally process data, and to improve cluster performance

and concurrency, you can minimize data shuffling by using proper association and grouping conditions.

Selecting a Distribution Mode

Table 4-1 shows how to select a table distribution mode.

Table 4-1 Table distribution modes and scenarios

Distribution Mode	Description	Application Scenario
Hash	Table data is distributed on all DNs in a cluster by hash.	Fact tables containing a large amount of data
Replication	Full data in a table is stored on every DN in the cluster.	Dimension tables and fact tables containing a small amount of data
Range	Table data is mapped to specified columns based on the range and distributed to the corresponding DNs.	Users need to customize distribution rules.
List	Table data is mapped to specified columns based on specific values and distributed to corresponding DNs.	Users need to customize distribution rules.

The example of defining a distribution table is as follows:

```
-- Define a table with each row stored in all DNs.
CREATE TABLE warehouse_d1
(
  W_WAREHOUSE_SK      INTEGER      NOT NULL,
  W_WAREHOUSE_ID     CHAR(16)      NOT NULL,
  W_WAREHOUSE_NAME    VARCHAR(20)
  W_WAREHOUSE_SQ_FT   INTEGER
  W_STREET_NUMBER     CHAR(10)
  W_STREET_NAME       VARCHAR(60)
  W_STREET_TYPE       CHAR(15)
  W_SUITE_NUMBER      CHAR(10)
  W_CITY              VARCHAR(60)
  W_COUNTY            VARCHAR(30)
  W_STATE             CHAR(2)
  W_ZIP               CHAR(10)
  W_COUNTRY           VARCHAR(20)
  W_GMT_OFFSET        DECIMAL(5,2)
)DISTRIBUTE BY REPLICATION;

-- Define a table using HASH distribution.
CREATE TABLE warehouse_d2
(
  W_WAREHOUSE_SK      INTEGER      NOT NULL,
  W_WAREHOUSE_ID     CHAR(16)      NOT NULL,
  W_WAREHOUSE_NAME    VARCHAR(20)
  W_WAREHOUSE_SQ_FT   INTEGER
  W_STREET_NUMBER     CHAR(10)
  W_STREET_NAME       VARCHAR(60)
```

```
W_STREET_TYPE      CHAR(15)
W_SUITE_NUMBER     CHAR(10)
W_CITY             VARCHAR(60)
W_COUNTY           VARCHAR(30)
W_STATE            CHAR(2)
W_ZIP              CHAR(10)
W_COUNTRY           VARCHAR(20)
W_GMT_OFFSET       DECIMAL(5,2),
CONSTRAINT W_CONSTR_KEY3 UNIQUE(W_WAREHOUSE_SK)
)DISTRIBUTE BY HASH(W_WAREHOUSE_SK);

-- Define a table using RANGE distribution.
CREATE TABLE warehouse_d3
(
W_WAREHOUSE_SK      INTEGER          NOT NULL,
W_WAREHOUSE_ID      CHAR(16)         NOT NULL,
W_WAREHOUSE_NAME     VARCHAR(20)
W_WAREHOUSE_SQ_FT    INTEGER
W_STREET_NUMBER      CHAR(10)
W_STREET_NAME        VARCHAR(60)
W_STREET_TYPE        CHAR(15)
W_SUITE_NUMBER       CHAR(10)
W_CITY               VARCHAR(60)
W_COUNTY              VARCHAR(30)
W_STATE              CHAR(2)
W_ZIP                 CHAR(10)
W_COUNTRY             VARCHAR(20)
W_GMT_OFFSET          DECIMAL(5,2)
)DISTRIBUTE BY RANGE(W_WAREHOUSE_ID)
(
SLICE s1 VALUES LESS THAN (10) DATANODE dn1,
SLICE s2 VALUES LESS THAN (20) DATANODE dn2,
SLICE s3 VALUES LESS THAN (30) DATANODE dn3,
SLICE s4 VALUES LESS THAN (MAXVALUE) DATANODE dn4
);

-- Define a table using LIST distribution.
CREATE TABLE warehouse_d4
(
W_WAREHOUSE_SK      INTEGER          NOT NULL,
W_WAREHOUSE_ID      CHAR(16)         NOT NULL,
W_WAREHOUSE_NAME     VARCHAR(20)
W_WAREHOUSE_SQ_FT    INTEGER
W_STREET_NUMBER      CHAR(10)
W_STREET_NAME        VARCHAR(60)
W_STREET_TYPE        CHAR(15)
W_SUITE_NUMBER       CHAR(10)
W_CITY               VARCHAR(60)
W_COUNTY              VARCHAR(30)
W_STATE              CHAR(2)
W_ZIP                 CHAR(10)
W_COUNTRY             VARCHAR(20)
W_GMT_OFFSET          DECIMAL(5,2)
)DISTRIBUTE BY LIST(W_COUNTRY)
(
SLICE s1 VALUES ('USA') DATANODE dn1,
SLICE s2 VALUES ('CANADA') DATANODE dn2,
SLICE s3 VALUES ('UK') DATANODE dn3,
SLICE s4 VALUES (DEFAULT) DATANODE dn4
);
```

For details about the table distribution syntax, see [CREATE TABLE](#).

Selecting a Distribution Key

A distribution key is important for a distribution table. An improper distribution key may cause data skew. As a result, the I/O load is heavy on several DNs, affecting the overall query performance. Therefore, after determining the

distribution policy of a distribution table, you need to check the table data skew to ensure that data is evenly distributed. Comply with the following rules to select a distribution key:

- Select a column containing discrete data as the distribution key, so that data can be evenly distributed on each DN. If the data in a single column is not discrete enough, consider using multiple columns as distribution keys. You can select the primary key of a table as the distribution key. For example, in an employee information table, select the certificate number column as the distribution key.
- If the first rule is met, do not select a column having constant filter conditions as the distribution key. For example, in a query on the **dwcj** table, if the **zqdh** column contains the constant filter condition **zqdh='000001'**, avoid selecting the **zqdh** column as the distribution key.
- If the first and second rules are met, select the join conditions in a query as distribution keys. If a join condition is used as a distribution key, the data involved in a join task is locally distributed on DNs, which greatly reduces the data flow cost among DNs.

Selecting a Partitioning Mode

Comply with the following rules to partition a table containing a large amount of data:

- Create partitions on columns that indicate certain ranges, such as dates and regions.
- A partition name should show the data characteristics of a partition. For example, its format can be *Keyword+Range* characteristics.
- Set the upper limit of a partition to **MAXVALUE** to prevent data overflow.

Table 4-2 Table partitioning modes and scenarios

Partitioning Mode	Description
Range	Table data is partitioned by range.
List	Table data is partitioned by a specified column based on a specific value.
Hash	Table data is partitioned by hash.

The example of defining a partitioned table is as follows:

```
-- Create a range partitioned table.
CREATE TABLE staffS_p1
(
  staff_ID    NUMBER(6) not null,
  FIRST_NAME VARCHAR2(20),
  LAST_NAME  VARCHAR2(25),
  EMAIL      VARCHAR2(25),
  PHONE_NUMBER VARCHAR2(20),
  HIRE_DATE  DATE,
  employment_ID VARCHAR2(10),
  SALARY     NUMBER(8,2),
  COMMISSION_PCT NUMBER(4,2),
  MANAGER_ID NUMBER(6),
```

```
section_ID NUMBER(4)
)
PARTITION BY RANGE (HIRE_DATE)
(
  PARTITION HIRE_19950501 VALUES LESS THAN ('1995-05-01 00:00:00'),
  PARTITION HIRE_19950502 VALUES LESS THAN ('1995-05-02 00:00:00'),
  PARTITION HIRE_maxvalue VALUES LESS THAN (MAXVALUE)
);

-- Create a list partitioned table.
CREATE TABLE test_list (col1 int, col2 int)
partition by list(col1)
(
  partition p1 values (2000),
  partition p2 values (3000),
  partition p3 values (4000),
  partition p4 values (5000)
);

-- Create a hash partitioned table.
CREATE TABLE test_hash (col1 int, col2 int)
partition by hash(col1)
(
  partition p1,
  partition p2
);
```

For details about the table partition syntax, see [CREATE TABLE PARTITION](#).

4.3.3 Column Design

Selecting a Data Type

To improve query efficiency, comply with the following rules when designing columns:

- Use the most efficient data types allowed.
If all of the following number types provide the required service precision, they are recommended in descending order of priority: integer, floating point, and numeric.
- In tables that are logically related, columns having the same meaning should use the same data type.
- For string data, you are advised to use variable-length strings and specify the maximum length. Ensure that the specified maximum length is greater than the maximum number of characters to be stored. Otherwise, an error is reported, causing service interruption. You are advised not to use CHAR(n), BPCHAR(n), NCHAR(n), or CHARACTER(n), unless you know that the string length is fixed.

For details about string types, see [Common String Types](#).

Common String Types

Every column requires a data type suitable for its data characteristics. [Character Types](#) lists common string types in GaussDB.

4.3.4 Constraint Design

DEFAULT and NULL Constraints

- If all the column values can be obtained from services, you are advised not to use the DEFAULT constraint. Otherwise, unexpected results will be generated during data loading.
- Add NOT NULL constraints to columns that never have NULL values. The optimizer automatically optimizes the columns in certain scenarios.
- Explicitly name all constraints excluding **NOT NULL** and **DEFAULT**.

Unique Constraints

- The constraint name should indicate that it is a unique constraint, for example, **UNI***Included columns*.

Primary Key Constraints

- The constraint name should indicate that it is a primary key constraint, for example, **PK***Included columns*.

Check Constraints

- The constraint name should indicate that it is a check constraint, for example, **CK***Included columns*.

4.3.5 View and Joined Table Design

View Design

- Do not nest views unless they have strong dependency on each other.
- Try to avoid collation operations in a view definition.

Joined Table Design

- Minimize joined columns across tables.
- Use the same data type for joined columns.
- The names of joined columns should indicate their relationship. For example, they can use the same name.

4.4 Tool Interconnection

4.4.1 JDBC Configuration

Currently, third-party tools are connected to GaussDB through JDBC. This section describes the precautions for configuring the tool.

Connection Parameters

- When a third-party tool connects to GaussDB through JDBC, JDBC sends a connection request to GaussDB. By default, the following configuration

parameters are added. For details, see the implementation of the `ConnectionFactoryImpl` class in the JDBC code.

```
params = {  
    { "user", user },  
    { "database", database },  
    { "client_encoding", "UTF8" },  
    { "DateStyle", "ISO" },  
    { "extra_float_digits", "3" },  
    { "TimeZone", createPostgresTimeZone() },  
};
```

These parameters may cause the JDBC and `gsql` clients to display inconsistent data, for example, date data display mode, floating point precision representation, and timezone.

If the result is not as expected, you are advised to explicitly set these parameters in the Java connection setting.

When the database is connected through JDBC, **extra_float_digits** is set to **3**. When the database is connected using `gsql`, **extra_float_digits** is set to **0**. As a result, the precision of the same data displayed in JDBC clients may be different from that displayed in `gsql` clients.

- In precision-sensitive scenarios, the numeric type is recommended.
- When JDBC connects to the database, ensure that the following three time zones are the same:
 - Time zone of the host where the JDBC client is located
 - Time zone of the host where the GaussDB cluster is located
 - Time zone during GaussDB cluster configuration

NOTE

For details about how to set the time zone, contact the administrator.

fetchsize

To use **fetchsize** in applications, disable **autocommit**. Enabling the **autocommit** switch makes the **fetchsize** configuration invalid.

autocommit

You are advised to enable **autocommit** in the code for connecting to GaussDB by the JDBC. If **autocommit** needs to be disabled to improve performance or for other purposes, applications need to ensure that transactions are committed. For example, explicitly commit transactions after specifying service SQL statements. Particularly, ensure that all transactions are committed before the client exits.

Connection Releasing

- You are advised to use connection pools to limit the number of connections from applications. Do not connect to a database every time you run an SQL statement.
- After an application completes its jobs, disconnect it from GaussDB to release occupied resources. You are advised to set the session timeout interval in the jobs.

- Reset the session environment before releasing connections to the JDBC connection pool. Otherwise, historical session information may cause object conflicts.
 - If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
 - If a temporary table is used, delete the temporary table before you return the connection to the connection pool.

CopyManager

In the scenario where the ETL tool is not used and real-time data import is required, it is recommended that you use the CopyManager API driven by the GaussDB JDBC to import data in batches during application development.

4.5 SQL Compilation

DDL

- In GaussDB, you are advised to perform DDL operations (such as table creation and COMMENT) in a unified manner. Prevent DDL operations in batch processing jobs so that performance is not affected.
- Perform the TRUNCATE operation immediately after the unlogged table is used. GaussDB cannot ensure the security of unlogged tables in abnormal scenarios.
- Suggestions on the storage mode of temporary and unlogged tables are the same as those on base tables.
- The total length of an index column cannot exceed 50 bytes. Otherwise, the index size will increase greatly, resulting in large storage cost and low index performance.
- Do not delete objects using DROP...CASCADE, unless the dependency between objects is specified. Otherwise, the objects may be deleted by mistake.

Data Loading and Unloading

- Explicitly set the inserted column list in the INSERT statement. Example:
`INSERT INTO task(name,id,comment) VALUES ('task1','100','100th task');`
- After data is imported to the database in batches or the data increment reaches the threshold, you are advised to analyze tables to prevent the execution plan from being degraded due to inaccurate statistics.
- To clear all data in a table, you are advised to use TRUNCATE TABLE instead of DELETE TABLE. DELETE TABLE is not efficient and cannot release disk space occupied by the deleted data.

Type Conversion

- Convert data types explicitly. If you perform implicit conversion, the result may differ from expected.
- During data query, explicitly specify the data type for constants, and do not attempt to perform any implicit data type conversion.

- If **sql_compatibility** is set to **ORA**, null strings will be automatically converted to NULL during data import. If null strings need to be reserved, set **sql_compatibility** to **TD**.

Query Operation

- Do not return a large number of result sets to a client except the ETL program. If a large result set is returned, consider modifying your service design.
- Perform DDL and DML operations encapsulated in transactions. For example, operations such as TRUNCATE TABLE, UPDATE TABLE, DELETE TABLE, and DROP TABLE cannot be restored once they are committed. You are advised to encapsulate such operations in transactions so that you can roll back the operations if necessary.
- During query compilation, you are advised to list all columns to be queried and avoid using SELECT *. Doing so reduces output lines, improves query performance, and avoids the impact of adding or deleting columns on front-end service compatibility.
- During table object access, add the schema prefix to the table object to avoid accessing an unexpected table due to schema switchover.
- The cost of joining more than three tables or views, especially full joins, is difficult to be estimated. You are advised to use the WITH TABLE AS statement to create interim tables to improve the readability of SQL statements.
- Avoid using Cartesian products or full joins. Cartesian products and full joins will result in a sharp expansion of result sets and poor performance.
- Only IS NULL and IS NOT NULL can be used to determine NULL value comparison results. If any other method is used, NULL is returned. For example, NULL instead of expected Boolean values is returned for NULL<>NULL, NULL=NULL, and NULL<>1.
- Do not use count(col) instead of count(*) to count the total number of records in a table. count(*) counts the NULL value (actual rows) while count(col) does not.
- While executing count(col), the number of NULL record rows is counted as 0. While executing sum(col), NULL is returned if all records are NULL. If not all the records are NULL, the number of NULL record rows is counted as 0.
- To count multiple columns using count(), column names must be enclosed in parentheses. For example, count ((col1, col2, col3)). Note: When multiple columns are used to count the number of NULL record rows, a row is counted even if all the selected columns are NULL. The result is the same as that when count(*) is executed.
- NULL records are not counted when count(distinct col) is used to calculate the number of non-NULL columns that are not repeated.
- If all statistical columns are NULL when count(distinct (col1,col2,...)) is used to count the number of unique values in multiple columns, Null records are also counted, and the records are considered the same.
- Use the connection operator || to replace the concat function for string connection, because the output of the concat function depends on the data type of the strings to be connected. When the execution plan is generated,

the value cannot be calculated in advance. As a result, the query performance deteriorates severely.

- Use the time-related macros listed in [Table 1](#) to replace the now function and obtain the current time, because the execution plan generated by the now function cannot be pushed down to disks. As a result, the query performance severely deteriorates.

Table 4-3 Time-related macros

Macro Name	Description	Example
CURRENT_DATE	Obtains the current date, excluding the hour, minute, and second details.	gaussdb=# SELECT CURRENT_DATE; date ----- 2018-02-02 (1 row)
CURRENT_TIME	Obtains the current time, excluding the year, month, and day.	gaussdb=# SELECT CURRENT_TIME; timetz ----- 00:39:34.633938+08 (1 row)
CURRENT_TIMESTAMP(n)	Obtains the current date and time, including year, month, day, hour, minute, and second. NOTE <i>n</i> indicates the number of digits after the decimal point in the time string.	gaussdb=# SELECT CURRENT_TIMESTAMP(6); timestampz ----- 2018-02-02 00:39:55.231689+08 (1 row)

- Do not use scalar subquery statements. A scalar subquery is a subquery in the output list of the SELECT statement. In the following example, "SELECT COUNT(*) FROM films f WHERE f.did = s.id" is a scalar subquery statement:
SELECT id, (SELECT COUNT(*) FROM films f WHERE f.did = s.id) FROM staffs_p1 s;

Scalar subqueries often result in query performance deterioration. During application development, scalar subqueries need to be converted into equivalent table associations based on the service logic.

- In WHERE clauses, the filter conditions should be collated. The condition that few records are selected for reading (the number of filtered records is small) is listed at the beginning.
- Filter conditions in WHERE clauses should comply with unilateral rules, that is, to place the column name on one side of a comparison operator. In this way, the optimizer automatically performs pruning optimization in some scenarios. The format is *col op expression*, where *col* indicates a table column, *op* indicates a comparison operator, such as = and >, and *expression* indicates an expression that does not contain a column name. Example:
SELECT id, from_image_id, from_person_id, from_video_id FROM face_data WHERE current_timestamp(6) - time < '1 days'::interval;

The modification is as follows:

```
SELECT id, from_image_id, from_person_id, from_video_id FROM face_data where time >
current_timestamp(6) - '1 days':interval;
```

- Do not perform unnecessary collation operations. Collation requires a large amount of memory and CPU. If service logic permits, ORDER BY and LIMIT can be combined to reduce resource overhead. By default, GaussDB performs collation by ASC & NULL LAST.
- When the ORDER BY clause is used for collation, specify collation modes (**ASC** or **DESC**), and use NULL FIRST or NULL LAST for NULL record sorting.
- Do not rely on only the LIMIT clause to return the result set displayed in a specific sequence. Combine ORDER BY and LIMIT clauses if some specific result sets are returned, and use OFFSET to skip specific results if necessary.
- If the service logic is accurate, you are advised to use UNION ALL instead of UNION.
- If a filter condition contains only an OR expression, convert the OR expression to UNION ALL to improve performance. SQL statements that use OR expressions cannot be optimized, resulting in slow execution. For example, the conversion of the following statements:

```
SELECT * FROM scdc.pub_menu
WHERE (cdp= 300 AND inline=301) OR (cdp= 301 AND inline=302) OR (cdp= 302 AND inline=301);
```

Convert the statement to the following:

```
SELECT * FROM scdc.pub_menu
WHERE (cdp= 300 AND inline=301)
union all
SELECT * FROM scdc.pub_menu
WHERE (cdp= 301 AND inline=302)
union all
SELECT * FROM tablename
WHERE (cdp= 302 AND inline=301)
```

- If an IN(val1, val2, val3...) expression contains a large number of columns, you are advised to replace it with the IN (VALUES (val1), (val2),(val3)...) statement. The optimizer will automatically convert the IN constraint into a non-correlated subquery to improve the query performance.
- Use (NOT) EXIST instead of (NOT) IN when associated columns do not contain null values. For example, in a query statement, if the **T1.C1** column does not contain any **NULL** value, add the **NOT NULL** constraint to the **T1.C1** column, and then rewrite the statements.

```
SELECT * FROM T1 WHERE T1.C1 NOT IN (SELECT T2.C2 FROM T2);
```

Rewrite the statement as follows:

```
SELECT * FROM T1 WHERE NOT EXISTS (SELECT * FROM T2 WHERE T1.C1=T2.C2);
```

NOTE

- If the value of the **T1.C1** column is not **NOT NULL**, the preceding rewriting cannot be performed.
- If the **T1.C1** column is the output of a subquery, check whether the output is **NOT NULL** based on the service logic.
- Use cursors instead of the LIMIT OFFSET syntax to perform pagination queries to avoid resource overheads caused by multiple executions. A cursor must be used in a transaction, and you must disable the cursor and commit the transaction once the query is finished.

5 Application Development Guide

5.1 Development Specifications

If the connection pool mechanism is used during application development, comply with the following specifications:

- If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
- If a temporary table is used, delete the temporary table before you return the connection to the connection pool.

If you do not do so, the connection state in the connection pool will remain, which affects subsequent operations using the connection pool.

Table 5-1 describes the compatibility of application development drivers.

Table 5-1 Compatibility Description

Driver	Compatibility Description
JDBC and Go	The new drivers are forward compatible with the database. To use the new features added to the driver and database, you must upgrade the database.
ODBC, libpq, Psycopg, and ecpg	The driver version must match the database version.

NOTICE

- In principle, you need to set the compatibility parameter after the database creation, instead of switching the parameters when using the database.
- To use the features in the following scenario, you need to upgrade the JDBC driver to 503.1 or later, enable the **s2** compatibility parameter, and set the validity check of **sessiontimezone**:

If the driver is used in a multi-thread environment:

The JDBC driver is non-thread-safe and does not guarantee that the connection methods are synchronized. The caller synchronizes the calls to the driver.

5.2 Obtaining the Driver Package

Obtaining the Driver Package

Download the required packages listed in [Table 5-2](#).

Table 5-2 Driver package download list

Version	Download Address
3.x	Driver package Verification package for the driver package

To prevent a software package from being tampered with during transmission or storage, download the corresponding verification package and perform the following steps to verify the software package:

1. Upload the software package and verification package to the same directory on a Linux VM.
2. Run the following command to verify the integrity of the software package:

```
cat GaussDB_driver.zip.sha256 | sha256sum --check
```

If **OK** is displayed in the command output, the verification is successful.

```
GaussDB_driver.zip: OK
```

5.3 Development Based on JDBC

Java Database Connectivity (JDBC) is a Java API for running SQL statements. It provides unified access APIs for different relational databases, based on which applications process data. The GaussDB library supports JDBC 4.2 and requires JDK 1.8 for code compiling. It does not support JDBC-ODBC bridge.

5.3.1 JDBC Package, Driver Class, and Environment Class

JDBC Package

Obtain the package from the release package `GaussDB-Kernel_Database version number_OS version number_64bit_Jdbc.tar.gz`.

After the decompression, you will obtain the following JDBC packages in .jar format:

- **gsjdbc4.jar**: The main class name is **org.postgresql.Driver**, and the URL prefix of the database connection is **jdbc:postgresql**. This driver package applies to

the scenario where services are migrated from PostgreSQL. The driver class and loading path are the same as those before the migration, but the supported APIs are different. The APIs that are not supported need to be adjusted on the service side.

- **gscejdbc.jar**: The main class name is **com.huawei.gaussdb.jdbc.Driver**. The URL prefix of database connections is **jdbc:gaussdb**. This driver package contains the dependent libraries related to encryption and decryption that need to be loaded to the encrypted database. This driver package is recommended in encrypted scenarios. Currently, only EulerOS is supported. Before using the **gscejdbc.jar** driver package, set the environment variable **LD_LIBRARY_PATH**. For details, see "Setting Encrypted Equality Queries > Using JDBC to Operate an Encrypted Database" in *Feature Guide*.
- **opengaussjdbc.jar**: The main class name is **com.huawei.opengauss.jdbc.Driver**. The URL prefix of the database connection is **jdbc:opengauss**. This driver package is recommended. This driver package is used when both PostgreSQL and GaussDB are accessed in a JVM process.

NOTICE

- The loading paths and URL prefixes of driver classes vary in different driver packages, but the API functions are the same.
- **gsjdbc200.jar**: The main class name is **com.huawei.gauss200.jdbc.Driver**, and the URL prefix of the database connection is **jdbc:gaussdb**. This driver package applies to the scenario where services are migrated from GaussDB 200. The driver class and loading path are the same as those before the migration, but the supported APIs are different. The APIs that are not supported need to be adjusted on the service side.
- The **gsjdbc4** driver package cannot be used to operate the PostgreSQL database. Although the connection can be successfully established in some versions, some API behaviors are different from those of PostgreSQL JDBC, which may cause unknown errors.
- The PostgreSQL driver package cannot be used to operate GaussDB. Although the connection can be successfully established in some versions, some API behaviors are different from those of GaussDB JDBC, which may cause unknown errors.

Driver Class

Before establishing a database connection, load the **org.postgresql.Driver** database driver class (corresponding to the **gsjdbc4.jar** file).

 NOTE

1. GaussDB is compatible with PostgreSQL in the use of JDBC. Therefore, when two JDBC drivers are used in the same process, class names may conflict.
2. JDBC of this version does not support identity & access management suite (IAM) for authentication.
3. Compared with the PostgreSQL driver, the GaussDB JDBC driver has the following enhanced features:
 1. The SHA256 encryption mode is supported for login.
 2. The third-party log framework that implements the sf4j API can be connected.
 3. Distributed load balancing at the connection level is supported.
 4. DR failover is supported.

Environment Class

The JDK1.8 must be configured on the client. JDK supports multiple platforms such as Windows and Linux. The following uses Windows as an example to describe how to configure JDK:

- Step 1** Enter **java -version** in the MS-DOS window (command prompt in Windows) to check the JDK version. Ensure that the JDK version is JDK1.8. If the JDK is not installed, download the installation package and install it.
- Step 2** On the Windows desktop, right-click **This PC** and choose **Properties** from the shortcut menu.
- Step 3** In the **System** window, click **Advanced system settings** in the navigation tree on the left.
- Step 4** In the **System Properties** dialog box, click **Environment Variables** in the lower right corner.
- Step 5** In the **System variables** area of the **Environment Variables** dialog box, set the following variables.

Table 5-3 Variables

Variable	Operation	Variable Value
JAVA_HOME	<ul style="list-style-type: none">• If the variable exists, click Edit.• If the variable does not exist, click New.	Specifies the Java installation directory. Example: C:\Program Files\Java\jdk1.8.0_131 .

Variable	Operation	Variable Value
Path	Click Edit .	<ul style="list-style-type: none">• If <i>JAVA_HOME</i> is configured, add <i>%JAVA_HOME%\bin</i> before the variable value.• If <i>JAVA_HOME</i> is not configured, add the full Java installation path before the variable value: C:\Program Files \Java \jdk1.8.0_131\bin
CLASSPATH	Click New .	%JAVA_HOME% \lib;%JAVA_HOME%\lib \tools.jar

Step 6 Click **OK** and close the windows one by one.

----**End**

5.3.2 Development Process

Figure 5-1 JDBC-based application development process

5.3.3 Loading a Driver

Load the database driver before creating a database connection.

You can load the driver in the following ways:

- Implicitly load the driver at any position before a connection is created in the code: `Class.forName("org.postgresql.Driver")`. For details about the code for creating a connection, see [Examples](#).
- Specify the driver name when a JVM is started. This parameter is used to execute Java code in the DOS window or on Linux. Example: `java -Djdbc.drivers=org.postgresql.Driver jdbctest`.

NOTE

- `jdbctest` is the name of a test application.
- If `opengaussjdbc.jar` is used, change the driver class name to `com.huawei.opengauss.jdbc.Driver`.

5.3.4 Connecting to a Database

After a database is connected, it can be used to run SQL statements to operate data.

Function Prototype

JDBC provides three database connection methods.

- DriverManager.getConnection(String url)
- DriverManager.getConnection(String url, Properties info)
- DriverManager.getConnection(String url, String user, String password)

Parameters

Table 5-4 Database connection parameters

Parameter	Description
url	<p>gsjdbc4.jar database connection descriptor. The format is as follows:</p> <ul style="list-style-type: none"> • jdbc:postgresql: (The default database name is the same as the username.) • jdbc:postgresql:database • jdbc:postgresql://host/database (If the port number is not specified, the default port number is used.) • jdbc:postgresql://host:port/database • jdbc:postgresql://host:port/database?param1=value1&param2=value2 • jdbc:postgresql://host1:port1,host2:port2/database?param1=value1&param2=value2 <p>NOTE If gsjdbc200.jar is used, replace jdbc:postgresql with jdbc:gaussdb.</p> <ul style="list-style-type: none"> • database indicates the name of the database to connect. • host indicates the name or IP address of the database server. For security purposes, the database CN forbids access from other nodes in the cluster without authentication. To access the CN from inside the cluster, deploy the JDBC program on the host where the CN is located and set host to 127.0.0.1. Otherwise, the error message "FATAL: Forbid remote connection with trust method!" may be displayed. It is recommended that the service system be deployed outside the cluster. Otherwise, the database performance may be affected. By default, the local host is used to connect to the server. • port indicates the port number of the database server. By default, the database on port 5431 of the local host is connected. • param indicates a database connection attribute. The parameter can be configured in the URL. The URL starts with a question mark (?), uses an equal sign (=) to assign a value to the parameter, and uses an ampersand (&) to separate parameters. You can also use the attributes of the info object for configuration. For details, see Examples. • value indicates the database connection attribute values.

Parameter	Description
info	<p>Database connection attributes (all attributes are case sensitive). Common attributes are described as follows:</p> <ul style="list-style-type: none"> • PGDBNAME: string type. It specifies the database name. You do not need to set this parameter in the URL because the database name is automatically parsed from the URL. • PGHOST: string type. This parameter specifies the host IP address. Use colons (:) to separate IP addresses and port numbers, and use commas (,) to separate multiple CNs. (This parameter does not need to be set in the URL. The system automatically parses the URL to obtain its value.) For details, see Examples. • PGPORT: integer type. It specifies the host port number. Use colons (:) to separate IP addresses and port numbers, and use commas (,) to separate multiple CNs. (This parameter does not need to be set in the URL. The system automatically parses the URL to obtain its value.) For details, see Examples. • user: string type. It specifies the database user who creates the connection. • password: string type. It specifies the password of the database user. • enable_ce: string type. enable_ce=1 indicates that JDBC supports the basic capability of encrypted equality query. • refreshClientEncryption: string type. If refreshClientEncryption is set to 1 (default value), the encrypted database supports cache update on the client. • loggerLevel: string type. The following log levels are supported: OFF, INFO, DEBUG, and TRACE. OFF indicates that the log function is disabled. The log details vary depending on the log level (INFO, DEBUG, and TRACE). The default value is null, indicating that the function is disabled. • loggerFile: string type. It specifies the log output path (directory and file name). If only the file name is specified and the directory is not specified, logs are generated in the client running program directory. If no path is configured or the configured path does not exist, logs are output through flows by default. This parameter has been discarded and does not take effect. To use this parameter, you can configure it in the java.util.logging attribute file or system attributes. • logger: string type. It indicates the log output framework used by the JDBC driver. The JDBC driver supports the log output framework used for interconnecting with user applications. Currently, only the third-party Slf4j-API-based log framework is supported. For details, see 6.2.9 Log Management. <ol style="list-style-type: none"> 1. If this parameter is not set or is set to JDK LOGGER, JDK LOGGER is used. 2. Otherwise, the slf4j-API-based third-party log framework must be used.

Parameter	Description
	<ul style="list-style-type: none"> ● allowEncodingChanges: Boolean type. If this parameter is set to true, the character set type can be changed. This parameter is used together with characterEncoding=CHARSET to set the character set. The two parameters are separated by ampersands (&). The value of characterEncoding can be UTF8, GBK, LATIN1, or GB18030. The default value is false. NOTE When the database whose character set is GB18030_2022 is connected, setting characterEncoding to GB18030_2022 does not take effect and UTF8 is used by default. You need to set characterEncoding to GB18030 so that the GB18030_2022 characters on the server can be properly parsed. ● currentSchema: string type. You need to specify a schema in search-path. If the schema name contains special characters except letters, digits, and underscores (_), you are advised to enclose the schema name in quotation marks. Note that the schema name is case sensitive after quotation marks are added. If multiple schemas need to be configured, separate them with commas (,). Schemas containing special characters also need to be enclosed in quotation marks. Example: currentSchema=<code>schema_a,"schema-b","schema/c"</code>. ● loadBalanceHosts: Boolean type. In the default mode (disabled), multiple hosts specified in the URL are connected in sequence. If load balancing is enabled, the shuffle algorithm is used to randomly select a host from the candidate hosts to establish a connection. ● autoBalance: string type. <ol style="list-style-type: none"> 1. If this parameter is set to true, balance, or roundrobin, the JDBC load balancing function is enabled to balance multiple connections of an application to each CN available in the database cluster. Example: jdbc:postgresql://host1:port1,host2:port2/database?autoBalance=true. JDBC periodically obtains the list of available CNs in the entire cluster, for example, the obtained list is host1:port1,host2:port2,host3:port3,host4:port4. The refreshCNIPListTime parameter specifies the interval for obtaining the list, and the default value is 10s. Hosts obtained from the CN list are data IP addresses. When autoBalance is enabled on host1 and host2, HA is implemented only for the first connection. The driver will select available CNs from host1, host2, host3, and host4 in sequence to update the available CN list and new connections will be established on host1, host2, host3, and host4 using the RoundRobin algorithm. 2. priorityn indicates that the JDBC-based load balancing function is enabled. Multiple connections of an application are balanced to the first n available CNs configured in the URL. When the first

Parameter	Description
	<p><i>n</i> CNs are unavailable, connections are randomly allocated to other available CNs in the database cluster. <i>n</i> is a number not less than 0 and less than the number of CNs configured in the URL.</p> <p>Example: <code>jdbc:postgresql://host1:port1,host2:port2,host3:port3,host4:port4/database?autoBalance=priority2</code>.</p> <p>JDBC periodically obtains the list of available CNs in the entire cluster (defined by <code>refreshCNIPListTime</code>). For example, the obtained list is <code>host1:port1,host2:port2,host3:port3,host4:port4,host5:port5,host6:port6</code>, where <code>host1</code> and <code>host2</code> are in <code>AZ1</code>, and <code>host3</code> and <code>host4</code> are in <code>AZ2</code>.</p> <p>The driver preferentially selects <code>host1</code> and <code>host2</code> for load balancing. If both <code>host1</code> and <code>host2</code> are unavailable, the driver randomly selects a CN from <code>host3</code>, <code>host4</code>, <code>host5</code>, and <code>host6</code> for connection.</p> <p>3. If this parameter is set to <code>shuffle</code>, JDBC random load balancing is enabled to randomly and evenly distribute multiple connections of the application to available CNs in the database cluster.</p> <p>Example: <code>jdbc:postgresql://host1:port1,host2:port2,host3:port3/database?autoBalance=shuffle</code>.</p> <p>JDBC periodically obtains the list of available CNs in the entire cluster. For example, the obtained list is <code>host1:port1,host2:port2,host3:port3,host4:port4</code>. The <code>refreshCNIPListTime</code> parameter specifies the interval for obtaining the list, and the default value is <code>10s</code>.</p> <p>For the first connection, <code>host1:port1,host2:port2,host3:port3</code> is used for HA. For subsequent connections, the shuffle algorithm is used to randomly select a CN from the refreshed CN list.</p> <p>4. If this parameter is set to <code>specified</code>, the JDBC load balancing function is enabled and connections are established only on nodes specified in the user URL.</p> <p>Example: <code>jdbc:postgresql://host1:port1,host2:port2,host3:port3,host4:port4/database?autoBalance=specified&priorityServers=2</code>.</p> <p>JDBC identifies <code>host1</code> and <code>host2</code> as the connection nodes in the primary cluster, and <code>host3</code> and <code>host4</code> as the connection nodes in the standby cluster. First, connections are evenly established on <code>host1</code> and <code>host2</code>. If all nodes are faulty, connections are not established on the remaining nodes in the cluster. After the standby node becomes the primary node, connections are evenly established on <code>host3</code> and <code>host4</code>. If all nodes are faulty, connections are not established on the remaining nodes in the cluster.</p>

Parameter	Description
	<p>5. If this parameter is set to false, the JDBC load balancing and priority-based load balancing functions are disabled. The default value is false.</p> <p>CAUTION</p> <ol style="list-style-type: none"> 1. Load balancing is based on the connection level rather than the transaction level. If the connection is persistent and the load on the connection is unbalanced, the load on the CN may be unbalanced. 2. Load balancing can be used only in distributed scenarios and cannot be used in centralized scenarios. 3. When load balancing is enabled, the floating IP address or data IP address can be configured in the URL. If the floating IP address is configured, the system obtains the corresponding data IP address based on the floating IP address and performs load balancing based on the obtained data IP address. Therefore, when configuring the floating IP address or data IP address in the URL, ensure that the network connection of the data IP address is normal. Otherwise, the load balancing function is abnormal. <ul style="list-style-type: none"> ● refreshCNIPListTime: integer type. This parameter specifies the interval at which JDBC periodically checks the status of CNs in the database cluster and obtains the IP address list of available CNs. The default value is 10 seconds. ● hostRecheckSeconds: integer type. After JDBC attempts to connect to a host, the host status is saved: connection success or connection failure. This status is trusted within the duration specified by hostRecheckSeconds. After the duration expires, the status becomes invalid. The default value is 10 seconds. ● ssl: Boolean type. It specifies a connection in SSL mode. When ssl is set to true, the NonValidatingFactory channel and certificate mode are supported. <ol style="list-style-type: none"> 1. For the NonValidatingFactory channel, configure the username and password and set SSL to true. 2. In certification mode, configure the client certificate, key, and root certificate, and set SSL to true. ● sslmode: string type. It specifies the SSL authentication mode. The value can be disable, allow, prefer, require, verify-ca, or verify-full. <ul style="list-style-type: none"> – disable: SSL connection is disabled. – allow: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified. – prefer: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified. – require: The system only attempts to set up an SSL connection. It neither checks whether the server certificate is issued by a trusted CA, nor checks whether the host name of the server is the same as that in the certificate.

Parameter	Description
	<ul style="list-style-type: none"> – verify-ca: attempts to set up an SSL connection and checks whether the server certificate is issued by a trusted CA. – verify-full: The system attempts to set up an SSL connection, checks whether the server certificate is issued by a trusted CA, and checks whether the host name of the server is the same as that in the certificate. • sslcert: string type. It specifies the complete path of the certificate file. The type of the client and server certificates is End Entity. • sslkey: string type. It specifies the complete path of the key file. You need to convert the client certificate to the DER format. For details, see Connecting to a Database (Using SSL). • sslrootcert: string type. It specifies the name of the SSL root certificate. The root certificate type is CA. • sslpassword: string type. It is provided for ConsoleCallbackHandler. • sslpasswordcallback: string type. It specifies the class name of the SSL password provider. The default value is org.postgresql.ssl.jdbc4.LibPQFactory.ConsoleCallbackHandler. • sslfactory: string type. It specifies the class name used by SSLSocketFactory to establish an SSL connection. • sslprivatekeyfactory: string type. This parameter specifies the fully qualified name of the implementation class of the org.postgresql.ssl.PrivateKeyFactory API that implements the private key decryption method. If this parameter is not specified, try the default JDK private key decryption algorithm. If the decryption fails, use org.postgresql.ssl.BouncyCastlePrivateKeyFactory. You need to provide the bcpkix-jdk15on.jar package. The recommended version is 1.65 or later. • sslfactoryarg: string type. The value is an optional parameter of the constructor function of the sslfactory class. (This parameter is not recommended.) • sslhostnameverifier: string type. It specifies the class name of the host name verifier. The API must implement <code>javax.net.ssl.HostnameVerifier</code>. The default value is org.postgresql.ssl.PGjdbcHostnameVerifier. • loginTimeout: integer type. It specifies the waiting time for establishing the database connection, in seconds. When multiple IP addresses are configured in the URL, if the time for obtaining the connection exceeds this value, the connection fails and the subsequent IP addresses are not tried. The default value is 0 (disabled). • connectTimeout: integer type. It specifies the timeout interval for connecting to a server. If the time taken to connect to a server exceeds the value specified, the connection is interrupted. The unit of the timeout interval is second. The value 0 indicates that the timeout mechanism does not take effect. When multiple IP

Parameter	Description
	<p>addresses are configured in the URL, this parameter indicates the timeout interval for connecting to a single IP address. The default value is 0.</p> <ul style="list-style-type: none"> ● socketTimeout: integer type. It specifies the timeout interval for a socket read operation. If the time taken to read data from a server exceeds the value specified, the connection is closed. The unit of the timeout interval is second. The default value 0 indicates that the timeout mechanism does not take effect. ● socketTimeoutInConnecting: integer type. It specifies the timeout interval for a socket read operation during the connection establishment. If the time taken to read data from the server exceeds this value, it searches for the next node for connection. The unit of the timeout interval is second. The default value is 5s. ● statementTimeout: integer type. It specifies the timeout interval for executing a statement in a connection. If the execution time of a statement exceeds this value, the statement execution is canceled. The unit of the timeout interval is millisecond. The default value 0 indicates that the timeout mechanism does not take effect. ● driverInfoMode: string type. This parameter controls the output mode of the driver description information. The value can be postgresql or gaussdb. The default value is postgresql, indicating that the driver description related to PostgreSQL is displayed. If this parameter is set to gaussdb, the driver description related to GaussDB is displayed. ● cancelSignalTimeout: integer type. Cancel messages may cause a block. It controls connectTimeout and socketTimeout in a cancel command. The unit of the timeout interval is second. The default value is 10 seconds. ● tcpKeepAlive: Boolean type. It is used to enable or disable TCP keepalive detection. The default value is false. ● logUnclosedConnections: Boolean type. The client may leak a connection object because it does not call the connection object's <code>close()</code> method. These objects will be collected as garbage and finalized using the <code>finalize()</code> method. If the caller ignores this operation, this method closes the connection. The default value is false. ● assumeMinServerVersion (discarded): string type. This parameter indicates the version of the server to connect. ● ApplicationName: string type. This parameter specifies the name of the application that is being connected. You can query the pgxc_stat_activity table on the CN to view information about the client that is being connected. The name is displayed in the application_name column. The default value is PostgreSQL JDBC Driver.

Parameter	Description
	<ul style="list-style-type: none"> ● connectionExtraInfo: Boolean type. This parameter specifies whether the driver reports the driver deployment path and process owner to the database. The value can be true or false. The default value is false. If connectionExtraInfo is set to true, the JDBC driver reports the driver deployment path, process owner, and URL connection configuration information to the database and displays the information in the connection_info parameter. In this case, you can query the information from PG_STAT_ACTIVITY or PGXC_STAT_ACTIVITY. ● autosave: string type. The value can be always, never, or conservative. It specifies the action that the driver should perform upon a query failure. If autosave is set to always, the JDBC driver sets a savepoint before each query and rolls back to the savepoint if the query fails. If autosave is set to never, there is no savepoint. If autosave is set to conservative, a savepoint is set for each query. However, the system rolls back and retries only when there is an invalid statement. The default value is never. ● protocolVersion: integer type. It specifies the connection protocol version. Only versions 1 and 3 are supported. If it is set to 1, only the V1 server is connected. If it is set to 3, MD5 encryption is used. You must need to set the GUC parameter password_encryption_type to 1 to change the database encryption mode. After the cluster is restarted, create a user who uses MD5 encryption to encrypt passwords. In addition, modify the pg_hba.conf file to change the client connection mode to MD5. Log in as a new user. (You are advised not to set this parameter because the MD5 encryption algorithm has lower security and poses security risks.) NOTE The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm. ● prepareThreshold: integer type. It specifies the number of times that the PreparedStatement object is executed before the prepared statement on the server is used. The default value is 5, indicating that when the same PreparedStatement object is executed for five or more times, the parse message is not sent to the server to parse the statement. Instead, the statement that has been parsed on the server is used. ● preparedStatementCacheQueries: integer type. This parameter specifies the maximum number of queries generated by the cache statement object of each connection. The default value is 256. If the number of queries generated by the statement object is greater than 256, the least recently used queries will be discarded from the cache. The value 0 indicates that the cache function is disabled. ● preparedStatementCacheSizeMiB: integer type. This parameter indicates the maximum size of queries generated by the cache statement object of each connection, in MB. The default value is 5.

Parameter	Description
	<p>If the size of the cached queries exceeds 5 MB, the least recently used query cache will be discarded. The value 0 indicates that the cache function is disabled.</p> <ul style="list-style-type: none"> • databaseMetadataCacheFields: integer type. The default value is 65536. It specifies the maximum number of columns that can be cached in each connection. The value 0 indicates that the cache function is disabled. • databaseMetadataCacheFieldsMiB: integer type. The default value is 5. This parameter indicates the maximum size of columns that can be cached in each connection, in MB. The value 0 indicates that the cache function is disabled. • stringtype: string type. The options are unspecified and varchar. It specifies the type of the PreparedStatement parameter used by the <code>setString()</code> method. If stringtype is set to VARCHAR (default value), these parameters are sent to the server as <code>varchar</code> parameters. If stringtype is set to unspecified, these parameters are sent to the server as an untyped value, and the server attempts to infer their appropriate type. • batchMode: string type. It specifies whether to connect the database in batch mode. The default value is on, indicating that the batch mode is enabled. If batchMode is set to on, the returned result is <code>[count, 0, 0...0]</code>. The first element in the array is the total number of records affected in batches. If batchMode is set to off, the returned result is <code>[1, 1, 1..1]</code>. Each element in the array corresponds to the number of affected records in a single modification. • fetchsize: integer type. It specifies the default fetchsize for statements in the created connection. The default value is 0, indicating that all results are obtained at a time. It is equivalent to defaultRowFetchSize. • rewriteBatchedInserts: Boolean type. During batch import, set this parameter to true to combine <i>N</i> insertion statements into one: insert into TABLE_NAME values(values1, ..., valuesN), ..., (values1, ..., valuesN). To use this parameter, set batchMode to off. The default value is false. • unknownLength: integer type. The default value is Integer.MAX_VALUE. This parameter specifies the length of the unknown length type when the data of some PostgreSQL types (such as <code>TEXT</code>) is returned by functions such as <code>ResultSetMetaData.getColumnDisplaySize</code> and <code>ResultSetMetaData.getPrecision</code>. • defaultRowFetchSize: integer type. It specifies the number of rows read by <code>fetch</code> in <code>ResultSet</code> at a time. Limiting the number of rows read each time in a database access request can avoid unnecessary memory consumption, thereby avoiding out of memory exception. The default value is 0, indicating that all rows are obtained at a time in <code>ResultSet</code>. This parameter cannot be set to a negative value.

Parameter	Description
	<ul style="list-style-type: none"> ● binaryTransfer: Boolean type. This parameter specifies whether data is sent and received in binary format. The default value is false. ● binaryTransferEnable: string type. It specifies types for which binary transmission is enabled. Every two types are separated by commas (,). You can select either the OID or name, for example, binaryTransferEnable=INT4_ARRAY,INT8_ARRAY. For example, if the OID name is BLOB and the OID number is 88, you can configure the OID as follows: binaryTransferEnable=BLOB or binaryTransferEnable=88 ● binaryTransferDisable: string type. It specifies types for which binary transmission is disabled. Every two types are separated by commas (,). You can select either the OID or name. It overwrites the setting of binaryTransferEnable. ● blobMode: string type. It is used to set the data type of parameters bound to the setBinaryStream method. If the value is on, the data type is blob. If the value is off, the data type is bytea. The default value is on. You are advised to set it to on for systems migrated from Oracle or MySQL and to off for systems migrated from PostgreSQL. ● socketFactory: string type. It specifies the name of the class used to create a socket connection with the server. This class must implement the javax.net.SocketFactory API and define a constructor with no parameter or a single string parameter. ● socketFactoryArg: string type. The value is an optional parameter of the constructor function of the socketFactory class and is not recommended. ● receiveBufferSize: integer type. It is used to set SO_RCVBUF on the connection stream. ● sendBufferSize: integer type. It is used to set SO_SNDBUF on the connection stream. ● preferQueryMode: string type. The value can be "extended", "extendedForPrepared", "extendedCacheEverything", or "simple". This parameter specifies the query mode. The default value is extended. In simple mode, only the Q message in text mode can be sent. The parse and bind messages are not supported. In extended mode, parse, bind, and execute messages are used. In extendedForPrepared mode, only the prepared statement object uses extended query, and the statement object uses only simple query. The extendedCacheEverything mode caches the query generated by each statement object. ● ApplicationType: string type. The value can be "not_perfect_sharding_type" or "perfect_sharding_type". It specifies whether to enable distributed write and query. The default value is not_perfect_sharding_type. Distributed write and query are enabled if this parameter is set to not_perfect_sharding_type.

Parameter	Description
	<p>If it is set to perfect_sharding_type, distributed write and query are disabled by default. Distributed write and query can be performed only when /* multinode */ is added to the SQL statement. This parameter is valid only when the database is in the GTM-free scenario.</p> <ul style="list-style-type: none"> priorityServers: integer type. This value is used to specify the first <i>n</i> nodes configured in the URL as the primary cluster to be connected preferentially. The default value is NULL. The value is a number greater than 0 and less than the number of CNs configured in the URL. It is used in streaming DR scenarios. Example: jdbc:postgresql://host1:port1,host2:port2,host3:port3,host4:port4,/database?priorityServers=2. That is, host1 and host2 are primary cluster nodes, and host3 and host4 are DR cluster nodes. usingEip: Boolean type. This value specifies whether to use an elastic IP address for load balancing. The default value is true, indicating that an elastic IP address is used for load balancing. The value false indicates that a data IP address is used for load balancing. If usingEip is set to true or left blank, the host in the URL must use an EIP. If usingEip is set to false, the host in the URL must use a data IP address. Otherwise, the priority load balancing policy will become invalid. traceInterfaceClass: string type. The default value is NULL, which is used to obtain the implementation class of traced. The value is the fully qualified name of the implementation class of the org.postgresql.log.Tracer API that implements the method for obtaining traced. use_boolean: Boolean type. It is used to set the OID type bound to the setBoolean method in extended mode. The default value is false, indicating that the int2 type is bound. The value true indicates that the Boolean type is bound. allowReadOnly: Boolean type. This parameter specifies whether the read-only mode is allowed. The default value is true, indicating that the read-only mode is allowed. If this parameter is set to false, the read-only mode is disabled. TLSCiphersSupported: string type. It is used to set the supported TLS encryption suite. The default value is TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,TLS_DHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384. stripTrailingZeros: Boolean type. The default value is false. If the value is true, trailing 0s of the numeric type are removed. It is valid only for ResultSet.getObject(int columnIndex). enableTimeZone: Boolean type. The default value is true. This parameter specifies whether to enable the time zone setting on the

Parameter	Description
	<p>server. The value true indicates that the JVM time zone is obtained to specify the database time zone. The value false indicates that the database time zone is used.</p> <ul style="list-style-type: none"> ● enableStandbyRead: Boolean type. It specifies whether to enable the read mode of the standby node. The default value is false. The value true indicates that the read mode is enabled, and the value false indicates that the read mode is disabled. ● oracleCompatible: string type. The default value is false. This is used to set the ORA-compatible features of driver APIs. The options are as follows: <ol style="list-style-type: none"> 1. true or on: All ORA-compatible features of drivers are enabled. 2. false or off: All ORA-compatible features of drivers are disabled. 3. "tag1,tag2,tag3": Some ORA-compatible features of drivers are enabled. You can configure one or more tags separated by commas (,). Each tag corresponds to an ORA-compatible feature. Currently, the following tags are supported: <ul style="list-style-type: none"> - getProcedureColumns: The behavior of the DatabaseMetaData#getProcedureColumns API is compatible with behavior ORA. - batchInsertAffectedRows: After reWriteBatchedInserts is enabled, the result returned by the Statement#executeBatch API is compatible with behavior ORA. ● printSqlInLog: Boolean type. It specifies whether to output SQL statements in exception information or logs. The value is true (enabled) or false (disabled). The default value is true. ● parseCandidatesByDomain: Boolean type. Specifies whether to obtain standby nodes based on domain names. The default value is false. The value is true (enabled) or false (disabled). After this function is enabled, you need to configure the host information in the URL in the format of domain name plus port number. The driver obtains the IP address based on the domain name, generates a standby node set, and works with the autoBalance parameter for load balancing. ● primaryDomains: integer type. Specifies the first <i>n</i> domain names configured in the URL as the primary cluster to be preferentially connected. The default value is 0 (disabled). To enable the function, the value must be greater than 0 and less than the number of domain names configured in the URL. Example: jdbc:postgresql://domain1:port1,domain2:port2,domain3:port3,domain4:port4,/database?primaryDomains=2. That is, domain1 and domain2 correspond to the primary cluster, and the IP addresses corresponding to domain1 and domain2 are preferentially connected. If a primary/standby switchover occurs, domain3 and domain4 are marked as the primary cluster, and connections are preferentially established to domain3 and domain4.

Parameter	Description
	<ul style="list-style-type: none"> priorityDomains: integer type. This parameter specifies the first <i>n</i> node names configured in a URL as the node names to be preferentially connected. The default value is 0. To enable the function, the value must be greater than 0 and less than the number of domain names configured in the URL. If primaryDomains is configured, the value must be less than the value of primaryDomains. Example: <code>jdbc:postgresql://domain1:port1,domain2:port2,domain3:port3,domain4:port4,/database?primaryDomains=2&priorityDomains=1</code>. That is, domain1 and domain2 correspond to the primary cluster but the IP address corresponding to domain1 is preferentially connected. The system attempts to connect to domain2 only when domain1 cannot be connected. If a primary/standby switchover occurs, domain3 and domain4 are marked as the primary cluster. However, the IP address corresponding to domain3 is preferentially connected. If domain3 cannot be connected, the IP address corresponding to domain4 is connected. refreshDomainResolveTime: integer type. The default value is 10, in seconds. The minimum value is 1. This parameter indicates the interval for updating the domain name resolution result and takes effect only when parseCandidatesByDomain is set to true. The domain name resolution update time involved in the URL is set to a specified value and is periodically updated in the asynchronous thread.
user	Database user.
password	Password of the database user.

 NOTE

After the **uppercaseAttributeName** parameter is enabled, if the database contains metadata with a mixture of uppercase and lowercase letters, only the metadata in lowercase letters can be queried and output in uppercase letters. Before using the metadata, ensure that the metadata is stored in lowercase letters to prevent data errors.

Examples

Example 1: Connect to a database.

```
// The following uses gsjdbc4.jar as an example:
// The following code encapsulates database connection operations into an API. The database can then be
// connected using an authorized username and a password.
public static Connection getConnect(String username, String passwd)
{
    // Driver class.
    String driver = "org.postgresql.Driver";
    // Database connection descriptor.
    String sourceURL = "jdbc:postgresql://$ip:$port/postgres";
    Connection conn = null;
```

```
try
{
    // Load the driver.
    Class.forName(driver);
}
catch( Exception e )
{
    e.printStackTrace();
    return null;
}

try
{
    // Create a connection.
    conn = DriverManager.getConnection(sourceURL, username, passwd);
    System.out.println("Connection succeed!");
}
catch(Exception e)
{
    e.printStackTrace();
    return null;
}

return conn;
}
```

Example 2: Use the Properties object as a parameter to create a connection.

// The following code uses the Properties object as a parameter to establish a connection:

```
public static Connection getConnectUseProp(String username, String passwd)
{
    // Driver class.
    String driver = "org.postgresql.Driver";
    // Database connection descriptor.
    String sourceURL = "jdbc:postgresql://$ip:$port/postgres?autoBalance=true";
    Connection conn = null;
    Properties info = new Properties();

    try
    {
        // Load the driver.
        Class.forName(driver);
    }
    catch( Exception e )
    {
        e.printStackTrace();
        return null;
    }

    try
    {
        info.setProperty("user", username);
        info.setProperty("password", passwd);
        // Create a connection.
        conn = DriverManager.getConnection(sourceURL, info);
        System.out.println("Connection succeed!");
    }
    catch(Exception e)
    {
        e.printStackTrace();
        return null;
    }

    return conn;
}
```

For details about common parameters, see [Common JDBC Parameters](#).

5.3.5 Connecting to a Database (Using SSL)

When establishing connections to the GaussDB server using JDBC, you can enable SSL connections to encrypt client and server communications for security of sensitive data transmission on the Internet.

This section describes how applications configure the client in SSL mode through JDBC. For details about how to configure the server, contact the administrator.

To use the method described in this section, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

Configuring the Client

Different from `mysql`-based programs, JDBC supports server certificate validation by default. If you use a certificate issued by a global or regional certificate authority (CA), Java applications do not need to do anything because Java has copies of most certificates issued by the CA. If a self-signed license is in use, a client program must be configured based on the `openssl` or Java `keytool` for license authentication. The procedure is as follows:

NOTE

If the built-in certificate is used, the following steps are valid.

Step 1 Upload the certificate file on the client.

1. Log in to the host where the client resides as a common user.
2. Create the `/tmp/cacert` directory.

```
mkdir /tmp/cacert
```
3. Save the root certificate file, client certificate file, and private key file to the created directory.

Step 2 Import the root certificate to TrustStore.

```
openssl x509 -in cacert.pem -out cacert.crt.der -outform der
```

Generate the intermediate file **cacert.crt.der**.

```
keytool -keystore mytruststore -alias cacert -import -file cacert.crt.der
```

Enter the `trustStorePassword` (for example, `xxxxxxxxxx`) as prompted to generate **mytruststore**.

- **cacert.pem** indicates the root certificate.
- **cacert.crt.der** indicates the intermediate file.
- **mytruststore** indicates the generated keystore name. You can change the name and its alias as needed.

Step 3 Import the client certificate and key to KeyStore.

```
openssl pkcs12 -export -out client.pkcs12 -in client.crt -inkey client.key
```

Enter the client key (for example, `xxxxxxxxxx`) as prompted to generate **client.pkcs12**.

```
keytool -importkeystore -deststorepass xxxxxxxxxxxx -destkeystore client.jks -srckeystore client.pkcs12 -srcstorepass xxxxxxxxxxxx -srcstoretype PKCS12 -alias 1 -destkeypass xxxxxxxxxxxx
```

deststorepass must be consistent with **destkeypass**, and **srcstorepass** must be the same as the export password in the preceding command. Generate **client.jks**.

----End

Example 1: Using the NonValidatingFactory Channel

NOTE

Select either example 1 or example 2.

// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.

// In this example, the username and password are stored in environment variables. Before running this example, set environment variables *EXAMPLE_USERNAME_ENV* and *EXAMPLE_PASSWORD_ENV* in the local environment (set the environment variable names based on the actual situation).

```
public class SSL{
    public static void main(String[] args) {
        Properties urlProps = new Properties();
        String urls = "jdbc:postgresql://$ip:$port/postgres";
        String userName = System.getenv("EXAMPLE_USERNAME_ENV");
        String password = System.getenv("EXAMPLE_PASSWORD_ENV");

        urlProps.setProperty("sslfactory", "org.postgresql.ssl.NonValidatingFactory");
        urlProps.setProperty("user", userName);
        urlProps.setProperty("password", password);
        urlProps.setProperty("ssl", "true");

        try {
            Class.forName("org.postgresql.Driver").newInstance();
        } catch (Exception e) {
            e.printStackTrace();
        }
        try {
            Connection conn;
            conn = DriverManager.getConnection(urls,urlProps);
            conn.close();
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

Example 2: Using a Certificate

// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.

// In this example, the username and password are stored in environment variables. Before running this example, set environment variables *EXAMPLE_USERNAME_ENV* and *EXAMPLE_PASSWORD_ENV* in the local environment (set the environment variable names based on the actual situation).

```
public class SSL{
    public static void main(String[] args) {
        Properties urlProps = new Properties();
        String urls = "jdbc:postgresql://$ip:$port/postgres";
        String userName = System.getenv("EXAMPLE_USERNAME_ENV");
        String password = System.getenv("EXAMPLE_PASSWORD_ENV");

        urlProps.setProperty("sslcert", "client.crt");
        urlProps.setProperty("sslkey", "client.key.pk8");
        urlProps.setProperty("sslrootcert", "cacert.pem");
        urlProps.setProperty("user", userName);
        urlProps.setProperty("ssl", "true");
    }
}
```

```
/* sslmode can be set to require, verify-ca, or verify-full. Select one from the following three
examples: */
/* ===== Example 2.1: Set sslmode to require to use the certificate for authentication.
*/
urlProps.setProperty("sslmode", "require");
/* ===== Example 2.2: Set sslmode to verify-ca to use the certificate for
authentication. */
urlProps.setProperty("sslmode", "verify-ca");
/* ===== Example 2.3: Set sslmode to verify-full to use the certificate (in the Linux
OS) for authentication. */
urls = "jdbc:postgresql://world:8000/postgres";
urlProps.setProperty("sslmode", "verify-full");

try {
    Class.forName("org.postgresql.Driver").newInstance();
} catch (Exception e) {
    e.printStackTrace();
}
try {
    Connection conn;
    conn = DriverManager.getConnection(urls,urlProps);
    conn.close();
} catch (Exception e) {
    e.printStackTrace();
}
}
}
/**
 * Note: Convert the client key to the DER format.
 * openssl pkcs8 -topk8 -outform DER -in client.key -out client.key.pk8 -nocrypt
 * openssl pkcs8 -topk8 -inform PEM -in client.key -outform DER -out client.key.der -v1 PBE-MD5-DES
 * openssl pkcs8 -topk8 -inform PEM -in client.key -outform DER -out client.key.der -v1 PBE-SHA1-3DES
 * The preceding algorithms are not recommended due to their low security.
 * If the customer needs to use a higher-level private key encryption algorithm, the following private key
encryption algorithms can be used after the BouncyCastle or a third-party private key is used to decrypt the
password package:
 * openssl pkcs8 -in client.key -topk8 -outform DER -out client.key.der -v2 AES128
 * openssl pkcs8 -in client.key -topk8 -outform DER -out client.key.der -v2 aes-256-cbc -iter 1000000
 * openssl pkcs8 -in client.key -topk8 -out client.key.der -outform Der -v2 aes-256-cbc -v2prf
hmacWithSHA512
 * Enable BouncyCastle: Introduce the bcpkix-jdk15on.jar package for projects that use JDBC. The
recommended version is 1.65 or later.
 */
```

NOTICE

When JDBC establishes a connection in SSL mode, a strong random number is obtained on the client. During the connection establishment, the error information shown in the figure may be displayed.

```

The random number generation on the client is too slow to meet product requirements. The entropy source is insufficient. As a result, the service fails to be started. This problem exists in some Linux environments.

Recommended solution: Start the `haveged` service on the client and increase the entropy value of the system entropy pool to improve the speed of reading random numbers. The startup command is as follows:

```
systemctl start haveged
```

5.3.6 Connecting to a Database (Using UDS)

The Unix domain socket is used for data exchange between different processes on the same host. You can add `unixsocket` to obtain the socket factory.

The `unixsocket-core-XXX.jar`, `unixsocket-common-XXX.jar`, and `unixsocket-native-common-XXX.jar` JAR packages need to be referenced. In addition, you need to add `socketFactory=org.newsclub.net.unix.AFUNIXSocketFactory $FactoryArg&socketFactoryArg= [path-to-the-unix-socket]` to the URL connection string.

Example:

```
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.util.Properties;

public class Test {
    public static void main(String[] args) {
        String driver = "org.postgresql.Driver";
        String userName = System.getenv("EXAMPLE_USERNAME_ENV");
```

```
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Connection conn;
try {
    Class.forName(driver).newInstance();
    Properties properties = new Properties();
    properties.setProperty("user", userName);
    properties.setProperty("password", password);
    conn = DriverManager.getConnection("jdbc:postgresql://$ip.$port/postgres?
socketFactory=org.newsclub +
    ".net.unix" +
    ".AFUNIXSocketFactory$FactoryArg&socketFactoryArg=/data/tmp/s.PGSQL.8000",
    properties);
    System.out.println("Connection Successful!");
    Statement statement = conn.createStatement();
    statement.executeQuery("select 1");
} catch (Exception e) {
    e.printStackTrace();
}
}
```

NOTICE

- Set the **socketFactoryArg** parameter based on the actual path. The value must be the same as that of the GUC parameter **unix_socket_directory**.
- The connection host name must be set to **localhost**.

5.3.7 Running SQL Statements

Running a Common SQL Statement

To enable an application to operate data in the database by running SQL statements (statements that do not need to transfer parameters), perform the following operations:

Operations such as SELECT, UPDATE, INSERT, and DELETE can be performed on XML data.

Step 1 Create a statement object by calling the `createStatement` method in `Connection`.

// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.

// In this example, the username and password are stored in environment variables. Before running this example, set environment variables `EXAMPLE_USERNAME_ENV` and `EXAMPLE_PASSWORD_ENV` in the local environment (set the environment variable names based on the actual situation).

```
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Connection conn = DriverManager.getConnection("url",userName,password);
Statement stmt = conn.createStatement();
```

Step 2 Run the SQL statement by calling the `executeUpdate` method in `Statement`.

```
int rc = stmt.executeUpdate("CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name VARCHAR(32));");
```

 NOTE

- If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. The VACUUM operation is not supported in a transaction block. If one of the statements fails, the entire request will be rolled back.
- Use semicolons (;) to separate statements. Stored procedures, functions, and anonymous blocks do not support multi-statement execution. When **preferQueryMode** is set to **simple**, the statement does not execute the parsing logic, and the semicolons (;) cannot be used to separate statements in this scenario.
- The slash (/) can be used as the terminator for creating a single stored procedure, function, anonymous block, or package body. When **preferQueryMode** is set to **simple**, the statement does not execute the parsing logic, and the slash (/) cannot be used as the terminator in this scenario.
- When **prepareThreshold** is set to **1**, each SQL statement executed by the statement is cached because cached statements are not evicted by default (default value of **preferQueryMode**). As a result, memory bloat may occur. In this case, set **preferQueryMode** to **extendedCacheEverything** to evict cached statements.

Step 3 Close the statement object.

```
stmt.close();
```

----End

Running a Prepared SQL Statement

Prepared statements are compiled and optimized once but can be used in different scenarios by assigning multiple values. Using prepared statements improves execution efficiency. If you want to run a statement for several times, use a precompiled statement. Perform the following operations:

Step 1 Create a prepared statement object by calling the `prepareStatement` method in `Connection`.

```
PreparedStatement pstmt = con.prepareStatement("UPDATE customer_t1 SET c_customer_name = ?  
WHERE c_customer_sk = 1");
```

Step 2 Set parameters by calling the `setShort` method in `PreparedStatement`.

```
pstmt.setShort(1, (short)2);
```

 CAUTION

After binding parameters are set in `PreparedStatement`, a B packet or U packet is constructed and sent to the server when the SQL statement is executed. However, the maximum length of a B packet or U packet cannot exceed 1023 MB. If the data bound at a time is too large, an exception may occur because the packet is too long. Therefore, when setting binding parameters in `PreparedStatement`, you need to evaluate and control the size of the bound data to avoid exceeding the upper limit of the packet.

Step 3 Run the prepared statement by calling the `executeUpdate` method in `PreparedStatement`.

```
int rowcount = pstmt.executeUpdate();
```

Step 4 Close the prepared statement object by calling the `close` method in `PreparedStatement`.

```
pstmt.close();
```

----End

Calling a Stored Procedure

To call an existing stored procedure through JDBC in GaussDB, perform the following operations:

Step 1 Create a call statement object by calling the `prepareCall` method in `Connection`.

```
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Connection myConn = DriverManager.getConnection("url",userName,password);
CallableStatement cstmt = myConn.prepareCall("{? = CALL TESTPROC(?,?,?)}");
```

Step 2 Set parameters by calling the `setInt` method in `CallableStatement`.

```
cstmt.setInt(2, 50);
cstmt.setInt(1, 20);
cstmt.setInt(3, 90);
```

Step 3 Register an output parameter by calling the `registerOutParameter` method in `CallableStatement`.

```
cstmt.registerOutParameter(4, Types.INTEGER); // Register an OUT parameter of the integer type.
```

Step 4 Call the stored procedure by calling the `execute` method in `CallableStatement`.

```
cstmt.execute();
```

Step 5 Obtain the output parameter by calling the `getInt` method in `CallableStatement`.

```
int out = cstmt.getInt(4); // Obtain the OUT parameter.
```

Example:

```
// The following stored procedure (containing the OUT parameter) has been created:
create or replace procedure testproc
(
  psv_in1 in integer,
  psv_in2 in integer,
  psv_inout in out integer
)
as
begin
  psv_inout := psv_in1 + psv_in2 + psv_inout;
end;
/
```

Step 6 Close the call statement by calling the `close` method in `CallableStatement`.

```
cstmt.close();
```

 NOTE

- Many database classes such as Connection, Statement, and ResultSet have a close() method. Close these classes after using their objects. Closing Connection will close all the related Statements, and closing a Statement will close its ResultSet.
- Some JDBC drivers support named parameters, which can be used to set parameters by name rather than sequence. If a parameter has the default value, you do not need to specify any parameter value but can use the default value directly. Even though the parameter sequence changes during a stored procedure, the application does not need to be modified. Currently, the GaussDB JDBC driver does not support this method.
- GaussDB does not support functions containing OUT parameters, or stored procedures and function parameters containing default values.
- When you bind parameters in `myConn.prepareCall("{? = CALL TESTPROC(?,?,?)}")` during a stored procedure calling, you can bind parameters and register the first parameter as the output parameter according to the placeholder sequence or the fourth parameter as the output parameter according to the parameter sequence in the stored procedure. The preceding example registers the fourth parameter.

NOTICE

- If JDBC is used to call a stored procedure whose returned value is a cursor, the returned cursor cannot be used.
 - A stored procedure and an SQL statement must be run separately.
 - Output parameters must be registered for parameters of the inout type in the stored procedure.
-

----End

Batch Processing

When a prepared statement processes multiple pieces of similar data, the database creates only one execution plan. This improves compilation and optimization efficiency. Perform the following operations:

Step 1 Create a prepared statement object by calling the `prepareStatement` method in Connection.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.  
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).  
String userName = System.getenv("EXAMPLE_USERNAME_ENV");  
String password = System.getenv("EXAMPLE_PASSWORD_ENV");  
Connection conn = DriverManager.getConnection("url",userName,password);  
PreparedStatement pstmt = conn.prepareStatement("INSERT INTO customer_t1 VALUES (?)");
```

Step 2 Call `setShort` to set parameters for each piece of data, and call `addBatch` to confirm that the setting is complete.

```
pstmt.setShort(1, (short)2);  
pstmt.addBatch();
```

Step 3 Perform batch processing by calling the `executeBatch` method in PreparedStatement.

```
int[] rowcount = pstmt.executeBatch();
```

Step 4 Close the prepared statement object by calling the close method in PreparedStatement.

```
pstmt.close();
```

 **NOTE**

Do not terminate a batch processing action when it is ongoing; otherwise, database performance will deteriorate. Therefore, disable automatic commit during batch processing. Manually commit several rows at a time. The statement for disabling automatic commit is `conn.setAutoCommit(false);`.

----End

Adding Single-Shard Execution Syntaxes to Statements

Step 1 Set the `nodeName` parameter by calling `setClientInfo("nodeName","dnx")` in Connection.

```
Connection conn = getConnection();  
conn.setClientInfo("nodeName","datanode1");
```

Step 2 Execute the SQL statements by using the `executeQuery(String sql)` and `execute(String sql)` methods in Statement and the `executeQuery()` and `execute()` methods in PreparedStatement.

```
PreparedStatement pstmt = conn.prepareStatement("select * from test");  
pstmt.execute();  
pstmt.executeQuery();  
Statement stmt=conn.createStatement();  
stmt.execute("select * from test");  
stmt.executeQuery("select * from test");
```

Step 3 Set the parameter to an empty string to disable it.

```
conn.setClientInfo("nodeName","");
```

NOTICE

1. This function is adapted based on the single-shard execution function of the kernel. Therefore, before using this function, check whether the database kernel supports single-shard execution.
2. After the parameter is enabled, you must manually disable it. Otherwise, the execution of other query statements will be affected.
3. Once this parameter is enabled, all statements of the current connection will be executed on a specified DN.
4. After the parameter is enabled, the cache mechanism of PreparedStatement will be affected, cached statements will be cleared, and subsequent statements executed for single-shard queries will not be cached until the parameter is disabled.
5. The parameter is a connection parameter. Therefore, the parameter value takes effect once. The API cannot be used to execute the statements on different shards at the same time.

----End

5.3.8 Processing Data in a Result Set

Setting a Result Set Type

Different types of result sets apply to different application scenarios. Applications select proper types of result sets based on requirements. Before running an SQL statement, you must create a statement object. Some methods of creating statement objects can set the type of a result set. [Table 5-5](#) lists result set parameters. The related Connection methods are as follows:

```
// Create a Statement object. This object will generate a ResultSet object with a specified type and
concurrency.
createStatement(int resultSetType, int resultSetConcurrency);

// Create a PreparedStatement object. This object will generate a ResultSet object with a specified type and
concurrency.
prepareStatement(String sql, int resultSetType, int resultSetConcurrency);

// Create a CallableStatement object. This object will generate a ResultSet object with a specified type and
concurrency.
prepareCall(String sql, int resultSetType, int resultSetConcurrency);
```

Table 5-5 Result set types

Parameter	Description
resultSetType	<p>Type of a result set. There are three types of result sets:</p> <ul style="list-style-type: none"> • ResultSet.TYPE_FORWARD_ONLY: The ResultSet object can only be navigated forward. It is the default value. • ResultSet.TYPE_SCROLL_SENSITIVE: You can view the modified result by scrolling to the modified row. • ResultSet.TYPE_SCROLL_INSENSITIVE: The ResultSet object is insensitive to changes in the underlying data source. <p>NOTE After a result set has obtained data from the database, the result set is insensitive to data changes made by other transactions, even if the result set type is ResultSet.TYPE_SCROLL_SENSITIVE. To obtain up-to-date data of the record pointed by the cursor from the database, call the <code>refreshRow()</code> method in a ResultSet object.</p>
resultSetConcurrency	<p>Concurrency type of a result set. There are two types of concurrency.</p> <ul style="list-style-type: none"> • ResultSet.CONCUR_READ_ONLY: Data in a result set cannot be updated except that an updated statement has been created in the result set data. • ResultSet.CONCUR_UPDATEABLE: changeable result set. The concurrency type for a result set object can be updated if the result set is scrollable.

Positioning a Cursor in a Result Set

ResultSet objects include a cursor pointing to the current data row. The cursor is initially positioned before the first row. The next method moves the cursor to the next row from its current position. When a ResultSet object does not have a next row, a call to this method returns **false**. Therefore, this method is used in the while loop for result set iteration. However, the JDBC driver provides more cursor positioning methods for scrollable result sets, which allows positioning cursor in the specified row. [Table 5-6](#) describes these methods.

Table 5-6 Methods for positioning a cursor in a result set

Method	Description
next()	Moves cursor to the next row from its current position.
previous()	Moves cursor to the previous row from its current position.
beforeFirst()	Places cursor before the first row.
afterLast()	Places cursor after the last row.
first()	Places cursor to the first row.
last()	Places cursor to the last row.
absolute(int)	Places cursor to a specified row.
relative(int)	Moves the row specified by the forward parameter (that is, the value is 1 , which is equivalent to next()) or backward (that is, the value is -1 , which is equivalent to previous()).

Obtaining the Cursor Position from a Result Set

This cursor positioning method can be used to change the cursor position for a scrollable result set. The JDBC driver provides a method to obtain the cursor position in a result set. [Table 5-7](#) describes these methods.

Table 5-7 Methods for obtaining a cursor position in a result set

Method	Description
isFirst()	Checks whether it is in the first row.
isLast()	Checks whether it is in the last row.
isBeforeFirst()	Checks whether it is before the first row.
isAfterLast()	Checks whether it is after the last row.

Method	Description
getRow()	Obtains its current row number.

Obtaining Data from a Result Set

ResultSet objects provide a variety of methods to obtain data from a result set. [Table 5-8](#) describes the common methods for obtaining data. If you want to know more about other methods, see JDK official documents.

Table 5-8 Common methods for obtaining data from a result set

Method	Description
int getInt(int columnIndex)	Retrieves the value of the column designated by a column index in the current row as an integer.
int getInt(String columnLabel)	Retrieves the value of the column designated by a column label in the current row as an integer.
String getString(int columnIndex)	Retrieves the value of the column designated by a column index in the current row as a string.
String getString(String columnLabel)	Retrieves the value of the column designated by a column label in the current row as a string.
Date getDate(int columnIndex)	Retrieves the value of the column designated by a column index in the current row as a date.
Date getDate(String columnLabel)	Retrieves the value of the column designated by a column name in the current row as a date.

5.3.9 Closing a Connection

After you complete required data operations in a database, close the database connection.

Call the close method to close the database connection.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.  
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).  
String userName = System.getenv("EXAMPLE_USERNAME_ENV");  
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
```

```
Connection conn = DriverManager.getConnection(sourceURL, userName, password);  
conn.close();
```

5.3.10 Log Management

The GaussDB JDBC driver uses log records to help solve problems when the GaussDB JDBC driver is used in applications. GaussDB JDBC supports the following log management methods:

1. Use the SLF4J log framework for interconnecting with applications.
2. Use the JdkLogger log framework for interconnecting with applications.

SLF4J and JdkLogger are mainstream frameworks for Java application log management in the industry. For details about how to use these frameworks, see the official documents (SLF4J: <http://www.slf4j.org/manual.html>; JdkLogger: <https://docs.oracle.com/javase/8/docs/technotes/guides/logging/overview.html>).

Method 1: Use the SLF4J log framework for interconnecting with applications.

When a connection is set up, **logger=Slf4JLogger** is configured in the URL.

The SLF4J may be implemented by using Log4j or Log4j2. When the Log4j is used to implement the SLF4J, the following JAR packages need to be added: **log4j-*.jar**, **slf4j-api-*.jar**, and **slf4j-log4j-*.jar** (* varies according to versions), and configuration file **log4j.properties**. If the Log4j2 is used to implement the SLF4J, you need to add the following JAR packages: **log4j-api-*.jar**, **log4j-core-*.jar**, **log4j-slf4j18-impl-*.jar**, and **slf4j-api-*.alpha1.jar** (* varies according to versions), and configuration file **log4j2.xml**.

This method supports log management and control. The SLF4J can implement powerful log management and control functions through related configurations in files. This method is recommended.

Example:

```
public static Connection GetConnection(String username, String passwd){  
  
    String sourceURL = "jdbc:postgresql://$ip:$port/postgres?logger=Slf4JLogger";  
    Connection conn = null;  
  
    try{  
        // Create a connection.  
        conn = DriverManager.getConnection(sourceURL,username,passwd);  
        System.out.println("Connection succeed!");  
    }catch (Exception e){  
        e.printStackTrace();  
        return null;  
    }  
    return conn;  
}
```

Example of **log4j.properties**:

```
log4j.logger.org.postgresql=ALL, log_gsjdbc  
  
# Default file output configuration  
log4j.appender.log_gsjdbc=org.apache.log4j.RollingFileAppender  
log4j.appender.log_gsjdbc.Append=true  
log4j.appender.log_gsjdbc.File=gsjdbc.log  
log4j.appender.log_gsjdbc.Threshold=TRACE  
log4j.appender.log_gsjdbc.MaxFileSize=10MB  
log4j.appender.log_gsjdbc.MaxBackupIndex=5
```

```
log4j.appender.log_gsjdbc.layout=org.apache.log4j.PatternLayout
log4j.appender.log_gsjdbc.layout.ConversionPattern=%d %p %t %c - %m%n
log4j.appender.log_gsjdbc.File.Encoding = UTF-8
```

Example of **log4j2.xml**:

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration status="OFF">
  <appenders>
    <Console name="Console" target="SYSTEM_OUT">
      <PatternLayout pattern="%d %p %t %c - %m%n"/>
    </Console>
    <File name="FileTest" fileName="test.log">
      <PatternLayout pattern="%d %p %t %c - %m%n"/>
    </File>
    <!-- JDBC driver log file output configuration. Log rewinding is supported. When the log size exceeds
10 MB, a new file is created. The new file is named in the format of yyyy-mm-dd-file ID. -->
    <RollingFile name="RollingFileJdbc" fileName="gsjdbc.log" filePattern="%d{yyyy-MM-dd}-%i.log">
      <PatternLayout pattern="%d %p %t %c - %m%n"/>
      <Policies>
        <SizeBasedTriggeringPolicy size="10 MB"/>
      </Policies>
    </RollingFile>
  </appenders>
  <loggers>
    <root level="all">
      <appender-ref ref="Console"/>
      <appender-ref ref="FileTest"/>
    </root>
    <!-- JDBC driver logs. The log level is all. All logs can be viewed and exported to the gsjdbc.log file. -->
    <!-- If opengaussjdbc.jar is used, replace org.postgresql with com.huawei.opengauss.jdbc.Driver. -->
    <logger name="org.postgresql" level="all" additivity="false">
      <appender-ref ref="RollingFileJdbc"/>
    </logger>
  </loggers>
</configuration>
```

Method 2: Use the JdkLogger log framework for interconnecting with applications.

The default Java logging framework stores its configurations in a file named **logging.properties**. Java installs the global configuration file in the folder in the Java installation directory. The **logging.properties** file can also be created and stored with a single project.

Configuration example of **logging.properties**:

```
# Specify the processing program as a file.
handlers= java.util.logging.FileHandler

# Specify the default global log level.
.level= ALL

# Specify the log output control standard.
java.util.logging.FileHandler.level=ALL
java.util.logging.FileHandler.pattern = gsjdbc.log
java.util.logging.FileHandler.limit = 500000
java.util.logging.FileHandler.count = 30
java.util.logging.FileHandler.formatter = java.util.logging.SimpleFormatter
java.util.logging.FileHandler.append=false
```

Code example:

```
System.setProperty("java.util.logging.FileHandler.pattern","jdbc.log");
FileHandler fileHandler = new FileHandler(System.getProperty("java.util.logging.FileHandler.pattern"));
Formatter formatter = new SimpleFormatter();
fileHandler.setFormatter(formatter);
Logger logger = Logger.getLogger("org.postgresql");
logger.addHandler(fileHandler);
logger.setLevel(Level.ALL);
logger.setUseParentHandlers(false);
```

Link trace function

The GaussDB JDBC driver provides the application-to-database link trace function to associate discrete SQL statements on the database side with application requests. This function requires application developers to implement the `org.postgresql.log.Tracer` API class and specify the permission name of the API implementation class in the URL.

URL example:

```
String URL = "jdbc:postgresql://$ip:$port/postgres?tracelInterfaceClass=xxx.xxx.xxx.OpenGaussTraceImpl";
```

The `org.postgresql.log.Tracer` API class is defined as follows:

```
public interface Tracer {  
    // Retrieves the value of traceId.  
    String getTraceId();  
}
```

Example of the `org.postgresql.log.Tracer` API implementation class:

```
import org.postgresql.log.Tracer;  
  
public class OpenGaussTraceImpl implements Tracer {  
    private static MDC mdc = new MDC();  
  
    private final String TRACE_ID_KEY = "traceId";  
  
    public void set(String traceId) {  
        mdc.put(TRACE_ID_KEY, traceId);  
    }  
  
    public void reset() {  
        mdc.clear();  
    }  
  
    @Override  
    public String getTraceId() {  
        return mdc.get(TRACE_ID_KEY);  
    }  
}
```

Example of context mapping which is used to store trace IDs generated for different requests:

```
import java.util.HashMap;  
  
public class MDC {  
    static final private ThreadLocal<HashMap<String, String>> threadLocal = new ThreadLocal<>();  
  
    public void put(String key, String val) {  
        if (key == null || val == null) {  
            throw new IllegalArgumentException("key or val cannot be null");  
        } else {  
            if (threadLocal.get() == null) {  
                threadLocal.set(new HashMap<>());  
            }  
            threadLocal.get().put(key, val);  
        }  
    }  
  
    public String get(String key) {  
        if (key == null) {  
            throw new IllegalArgumentException("key cannot be null");  
        } else if (threadLocal.get() == null) {  
            return null;  
        } else {  
            return threadLocal.get().get(key);  
        }  
    }  
}
```

```
public void clear() {
    if (threadLocal.get() == null) {
        return;
    } else {
        threadLocal.get().clear();
    }
}
```

Example of using **traceld**:

```
String traceld = UUID.randomUUID().toString().replaceAll("-", "");
openGaussTrace.set(traceld);
pstmt = con.prepareStatement("select * from test_trace_id where id = ?");
pstmt.setInt(1, 1);
pstmt.execute();
pstmt = con.prepareStatement("insert into test_trace_id values(?,?)");
pstmt.setInt(1, 2);
pstmt.setString(2, "test");
pstmt.execute();
openGaussTrace.reset();
```

NOTE

- When the link trace function is used, the link function at the application layer is guaranteed by services.
- The application must expose the API for obtaining **traceld** to the JDBC and configure the API implementation class to the JDBC connection string.
- SQL statements of the same request must use the same **traceld**.
- The value of **traceld** transferred by the application cannot exceed 32 bytes. Otherwise, the extra bytes will be truncated.

5.3.11 Examples: Common Operations

Example 1: Creating a Database Connection, Creating a Table, and Inserting Data

This example illustrates how to develop applications based on the JDBC interface provided by GaussDB. Before executing the example, load the driver. For details about how to obtain and load the driver, see [JDBC Package, Driver Class, and Environment Class](#).

```
//DBtest.java
/* The following uses gsjdbc4.jar as an example: */
// This example illustrates the main processes of JDBC-based development, covering database connection
// creation, table creation, and data insertion.
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.CallableStatement;
import java.sql.Types;

public class DBTest {
```

```
// Create a database connection.
public static Connection GetConnection(String username, String passwd) {
    String driver = "org.postgresql.Driver";
    String sourceURL = "jdbc:postgresql://$ip:$port/postgres";
    Connection conn = null;
    try {
        // Load the database driver.
        Class.forName(driver).newInstance();
    } catch (Exception e) {
        e.printStackTrace();
        return null;
    }

    try {
        // Create a database connection.
        conn = DriverManager.getConnection(sourceURL, username, passwd);
        System.out.println("Connection succeed!");
    } catch (Exception e) {
        e.printStackTrace();
        return null;
    }

    return conn;
};

// Run a common SQL statement to create table customer_t1.
public static void CreateTable(Connection conn) {
    Statement stmt = null;
    try {
        stmt = conn.createStatement();

        // Run a common SQL statement.
        int rc = stmt
            .executeUpdate("CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name
VARCHAR(32));");

        stmt.close();
    } catch (SQLException e) {
        if (stmt != null) {
            try {

/**
 * Main process. Call static methods one by one.
 * @param args
 */
public static void main(String[] args) {
    // Create a database connection.
    String userName = System.getenv("EXAMPLE_USERNAME_ENV");
    String password = System.getenv("EXAMPLE_PASSWORD_ENV");
    Connection conn = GetConnection(userName, password);

    // Create a table.
    CreateTable(conn);

    // Insert data in batches.
    BatchInsertData(conn);

    // Run a prepared statement to update data.
    ExecPreparedSQL(conn);

    // Create a stored procedure.
    CreateCallable(conn);

    // Run a stored procedure.
    ExecCallableSQL(conn);

    // Close the connection to the database.
    try {
        conn.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
}
```

Example 2: High Client Memory Usage

In this example, **setFetchSize** adjusts the memory usage of the client by using the database cursor to obtain server data in batches. It may increase network interaction and damage some performance.

The cursor is valid within a transaction. Therefore, disable automatic commit and then manually commit the code.

```
// Disable automatic commit.
conn.setAutoCommit(false);

// Create a table.
Statement st = conn.createStatement();
```

```
st.execute("create table mytable (col1 int);");
// Insert 200 rows of data into the table.
PreparedStatement pstmt = conn.prepareStatement("insert into mytable values (?)");
for (int i = 0; i < 200; i++) {
    pstmt.setInt(1, i + 1);
    pstmt.addBatch();
}
pstmt.executeBatch();
conn.commit();
pstmt.close();

// Open the cursor and obtain 50 rows of data each time.
st.setFetchSize(50);
ResultSet rs = st.executeQuery("SELECT * FROM mytable");
while (rs.next())
{
    System.out.print("a row was returned.");
}
conn.commit();
rs.close();

// Disable the server cursor.
st.setFetchSize(0);
rs = st.executeQuery("SELECT * FROM mytable");
while (rs.next())
{
    System.out.print("many rows were returned.");
}
conn.commit();
rs.close();

// Close the statement.
st.close();
conn.close();
```

Enable automatic commit.

```
conn.setAutoCommit(true);
```

Example 3: Using Common Data Types

```
// Example of the bit type. Note that the value range of the bit type is [0,1].
Statement st = conn.createStatement();
String sqlstr = "create or replace function fun_1()\n" +
    "returns bit AS $$\n" +
    "select col_bit from t_bit limit 1;\n" +
    "$$\n" +
    "LANGUAGE SQL;";
st.execute(sqlstr);
CallableStatement c = conn.prepareCall("{ ? = call fun_1() }");
// Register the output type, which is a bit string.
c.registerOutParameter(1, Types.BIT);
c.execute();
// Use the Boolean type to obtain the result.
System.out.println(c.getBoolean(1));

// Example of using the money type
// Example of using a column of the money type in the table structure.
st.execute("create table t_money(id int,col1 money)");
PreparedStatement pstmt = conn.prepareStatement("insert into t_money values(1,?)");
// Use PGObject to assign a value. The value range is [-92233720368547758.08,92233720368547758.07].
PGObject minMoney = new PGObject();
minMoney.setType("money");
minMoney.setValue("-92233720368547758.08");
pstmt setObject(1, minMoney);
pstmt.execute();
// Use PGMoney to assign a value. The value range is [-9999999.99,9999999.99].
pstmt.setObject(1,new PGMoney(9999999.99));
pstmt.execute();
```

```
// Example of using the function whose return value is money.
st.execute("create or replace function func_money() " +
"return money " +
"as declare " +
"var1 money; " +
"begin " +
" select col1 into var1 from t_money limit 1; " +
" return var1; " +
"end;");
CallableStatement cs = conn.prepareCall("{? = call func_money()}");
cs.registerOutParameter(1,Types.DOUBLE);
cs.execute();
cs.getObject(1);
```

Example 4: Obtaining the Driver Version

```
Driver.getGSVersion();
```

5.3.12 Example: Retrying SQL Queries for Applications

If the primary DN is faulty and cannot be restored within 10s, the standby DN is automatically promoted to primary to ensure the normal running of the GaussDB cluster. Jobs running during the failover will fail and those started after the failover will not be affected. To prevent upper-layer services from being affected by the DN failover, refer to the following example to construct an SQL retry mechanism at the service layer. Before executing the example, load the driver. For details about how to obtain and load the driver, see [JDBC Package, Driver Class, and Environment Class](#).

```
// The following uses gsjdbc4.jar as an example:
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;

    }
}
}
```

5.3.13 Example: Logical Replication Code

The example demonstrates how to use the logical replication function through the JDBC APIs. Before executing the example, load the driver. For details about how to obtain and load the driver, see [JDBC Package, Driver Class, and Environment Class](#).

For details about the configuration options of logical replication, see section "Logical Replication > Logical Decoding" in *Feature Guide*. In addition, the following configuration items are added for streaming decoding tools such as JDBC:

1. Decoding thread concurrency

Set **parallel-decode-num** to specify the number of decoder threads for parallel decoding. The value is an integer ranging from 1 to 20. The value **1** indicates that decoding is performed based on the original serial logic. Other values indicate that parallel decoding is enabled. The default value is **1**. When this parameter is set to **1**, do not configure the following options: **decode-style**, **sending-batch**, and **parallel-queue-size**.

2. Decoding format

Configure **decode-style** to specify the decoding format. The value can be 'j', 't' or 'b' of the char type, indicating the JSON, text, or binary format, respectively. The default value is 'b', indicating binary decoding. This option is set only when parallel decoding is allowed and binary decoding is supported only in the parallel decoding scenario. For the JSON and text formats corresponding to the binary format, in the decoding result sent in batches, the uint32 consisting of the first four bytes of each decoding statement indicates the total number of bytes of the statement (the four bytes occupied by the uint32 are excluded, and **0** indicates that the decoding of this batch ends). The 8-byte uint64 indicates the corresponding LSN (**begin** corresponds to

first_lsn, commit corresponds to **end_lsn**, and other values correspond to the LSN of the statement).

 **NOTE**

The binary encoding rules are as follows:

1. The first four bytes represent the total number of bytes of the decoding result of statements following the statement-level delimiter letter P (excluded) or the batch end character F (excluded). If the value is 0, the decoding of this batch ends.
2. The next eight bytes (uint64) indicate the corresponding LSN (**begin** corresponds to **first_lsn**, **commit** corresponds to **end_lsn**, and other values correspond to the LSN of the statement).
3. The next one-byte letter can be **B**, **C**, **I**, **U**, or **D**, representing BEGIN, COMMIT, INSERT, UPDATE, or DELETE.
4. If **B** is used in the step 3:
 1. The next eight bytes (uint64) indicate the CSN.
 2. The next eight bytes (uint64) indicate **first_lsn**.
 3. (Optional) If the next one-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length for committing the transaction. The following characters with the same length are the timestamp character string.
 4. (Optional) If the next one-byte letter is **N**, the following four bytes (uint32) indicate the length of the transaction username. The following characters with the same length are the transaction username.
5. If **C** is used in the step 3:
 1. (Optional) If the next one-byte letter is **X**, the following eight bytes (uint64) indicate the XID.
 2. (Optional) If the next one-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length. The following characters with the same length are the timestamp character string.
 3. When logs are sent in batches, decoding results of other transactions may still exist after a COMMIT log is decoded. If the next 1-byte letter is **P**, the batch still needs to be decoded. If the letter is **F**, the batch decoding ends.
6. If **I**, **U**, or **D** is used in the step 3:
 1. The following two bytes (uint16) indicate the length of the schema name.
 2. The schema name is read based on the preceding length.
 3. The following two bytes (uint16) indicate the length of the table name.
 4. The table name is read based on the preceding length.
 5. (Optional) If the next one-byte letter is **N**, it indicates a new tuple. If the letter is **O**, it indicates an old tuple. In this case, the new tuple is sent first.
 1. The following two bytes (uint16) indicate the number of columns to be decoded for the tuple, which is recorded as **attrnum**.
 2. The following procedure is repeated for *attrnum* times:
 1. The next two bytes (uint16) indicate the length of the column name.
 2. The column name is read based on the preceding length.
 3. The following four bytes (uint32) indicate the OID of the current column type.
 4. The next four bytes (uint32) indicate the length of the value (stored in the character string format) in the current column. If the value is **0xFFFFFFFF**, it indicates null. If the value is 0, it indicates a character string whose length is 0.
 5. The column value is read based on the preceding length.
 6. Because there may still be a decoding statement after, if the next one-byte letter is **P**, it indicates that the batch still needs to be decoded, and if the next one-byte letter is **F**, it indicates that decoding of the batch ends.

3. Decoding only on the standby node
Configure the **standby-connection** option to specify whether to perform decoding only on the standby node. The value is of the Boolean type (**0** or **1**). The value **true** (or **1**) indicates that only the standby node can be connected for decoding. When the primary node is connected for decoding, an error is reported and the system exits. The value **false** (or **0**) indicates that there is no restriction. The default value is **false** (or **0**).
4. Batch sending
Configure **sending-batch** to specify whether to send results in batches. The value is an integer ranging from 0 to 1. The value **0** indicates that decoding results are sent one by one. The value **1** indicates that decoding results are sent in batches when the accumulated size of decoding results reaches 1 MB. The default value is **0**. This parameter can be set only during parallel decoding. In the scenario where batch sending is enabled, if the decoding format is 'j' or 't', before each original decoding statement, a uint32 type is added indicating the length of the decoding result (excluding the current uint32 type), and a uint64 type is added, indicating the LSN corresponding to the current decoding result.
5. Length of the parallel decoding queue
Configure **parallel-queue-size** to specify the length of the queue for interaction among parallel logical decoding threads. The value ranges from 2 to 1024 and must be a power of 2. The default value is **128**. The queue length is positively correlated with the memory usage during decoding.
6. Memory threshold for logical decoding
The **max-txn-in-memory** configuration item specifies the memory threshold for caching the intermediate decoding result of a single transaction, in MB. The value ranges from 0 to 100 during serial decoding. The default value is **0**, indicating that the memory usage is not controlled. The **max-reorderbuffer-in-memory** configuration item specifies the memory threshold for caching intermediate decoding results of all transactions, in GB. The value ranges from 0 to 100 during serial decoding. The default value is **0**, indicating that the memory usage is not controlled. When the memory usage exceeds the threshold, intermediate decoding results are written into a temporary file during decoding, affecting the logical decoding performance.
7. Logical decoding sending timeout threshold
The **sender-timeout** configuration item specifies the heartbeat timeout threshold between the kernel and client. If no message is received from the client within the period, the logical decoding stops and disconnects from the client. The unit is ms, and the value range is [0,2147483647]. The default value depends on the value of the GUC parameter **logical_sender_timeout**.
8. User blacklist options for logical decoding
Use the user blacklist for logical decoding. The transaction operations of blacklisted users are filtered from the logical decoding result. The options are as follows:
 - a. **exclude-userids**: specifies the OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not check whether the user OIDs exist. The OIDs of the same service user on different DNs may be different. Therefore, the OID of the service user on each DN needs to be transferred for logical decoding of directly connected DNs in distributed

- mode. Otherwise, the logical decoding results of some DNs may be filtered while those of some DNs are not filtered.
- b. **exclude-users**: specifies blacklisted usernames. Multiple usernames are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.
 - c. **dynamic-resolution**: specifies whether to dynamically parse blacklisted usernames. The default value is **true**. If the parameter is set to **false**, an error is reported and the logical decoding exits when the decoding detects that the user does not exist in blacklist **exclude-users**. If the parameter is set to **true**, decoding continues when it detects that the user does not exist in blacklist **exclude-users**.
9. Output options for transaction logical logs
 - a. **include-xids**: specifies whether the BEGIN logical log of a transaction outputs the transaction ID. The default value is **true**.
 - b. **include-timestamp**: specifies whether the BEGIN logical log of a transaction outputs the time when the transaction is committed. The default value is **false**.
 - c. **include-user**: specifies whether the BEGIN logical log of a transaction outputs the username of the transaction. The default value is **false**. The username of a transaction refers to the authorized user, that is, the login user who executes the session corresponding to the transaction. The username does not change during the execution of the transaction.
 10. By default, **socketTimeout** of the logical decoding connection is set to **10s**. When the primary node is overloaded during decoding on the standby node, the connection may be closed due to timeout. You can set **withStatusInterval(10000,TimeUnit.MILLISECONDS)** to adjust the timeout interval.
 11. Heartbeat log output option

enable-heartbeat: specifies whether to generate heartbeat logs. The default value is **false**.

 NOTE

If the heartbeat log output option is enabled, heartbeat logs will be generated. The heartbeat logs can be parsed as follows: For a binary heartbeat log message, it starts with a character 'h' and then the heartbeat log content: an 8-byte uint64 string, an 8-byte uint64 string, and an 8-byte int64 string. For the first 8-byte uint64 string, in the decoding scenario where DNs are directly connected, this string is an LSN, indicating the end position of the WAL read when the heartbeat logical log is sent; in the decoding scenario where distributed strong consistency is required, this string is a CSN, indicating the decoding log transaction CSN that has been sent when the heartbeat logical log is sent. For the second 8-byte uint64 string, in the decoding scenario where DNs are directly connected, this string is an LSN, indicating the location of the WAL that has been flushed to disks when the heartbeat logical log is sent; in the decoding scenario where distributed strong consistency is required, this string is a CSN, indicating the CSN to be obtained by the next transaction committed by the cluster. The last 8-byte int64 string indicates the generation timestamp (starting from January 1, 1970) of the latest decoded transaction log or checkpoint log. Then, it ends with character 'F'. TEXT/JSON heartbeat log messages that are sent in batches end with '0'. There is no such terminator for each TEXT/JSON heartbeat log message. The message content is transmitted in big-endian mode. The following figure shows the format. (In consideration of forward compatibility, the LSN naming mode is retained. The actual meaning depends on the specific scenario.)

The decoding performance (Xlog consumption) is greater than or equal to 100 Mbps in the following standard parallel decoding scenario: 16-core CPU, 128 GB memory, network bandwidth > 200 Mbps, 10 to 100 columns in a table, 0.1 KB to 1 KB data in a single row, INSERT as main DML operations, less than 4096 statements in a single transaction, **parallel-decode-num** set to **8**, decoding format as **'b'**, and batch sending function enabled. To ensure that the decoding performance meets the requirements and minimize the impact on services, you are advised to set up only one parallel decoding connection on a standby node to ensure that the CPU, memory, and bandwidth resources are sufficient.

Note: The logical replication class PGReplicationStream is a non-thread-safe class. Concurrent calls may cause data exceptions.

```
// The following uses gsjdbc4.jar as an example:
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
// Logical replication function example: file name, LogicalReplicationDemo.java
// Prerequisite: The IP address of the JDBC user machine has been added to the database whitelist. The following content has been added to pg_hba.conf:
// Assume that the IP address of the JDBC user machine is 10.10.10.10.
//host all all 10.10.10.10/32 sha256
//host replication all 10.10.10.10/32 sha256

                // decoding transaction to disks is 100 MB.
                    .withSlotOption("max-reorderbuffer-in-memory", 50) // The total memory threshold for
                // flushing decoding transactions that are being handled to disks is 50 GB.
                    .withSlotOption("exclude-users", 'userA') // The logical log of the transaction executed by
```

```
user A is not returned.
        .withSlotOption("include-user", true) // The BEGIN logical log of the transaction contains
the username.
        .withSlotOption("enable-heartbeat", true) // Enable the heartbeat log output option.
        .start();
    while (true) {
        ByteBuffer byteBuffer = stream.readPending();

        if (byteBuffer == null) {
            TimeUnit.MILLISECONDS.sleep(10L);
            continue;
        }

        int offset = byteBuffer.arrayOffset();
        byte[] source = byteBuffer.array();
        int length = source.length - offset;
        System.out.println(new String(source, offset, length));

        // If the LSN needs to be flushed, call the following APIs based on the service requirements:
        // LogSequenceNumber lastRecv = stream.getLastReceiveLSN();
        // stream.setFlushedLSN(lastRecv);
        // stream.forceUpdateStatus();

    }
    } else if (testMode == TEST_MODE_DROP_SLOT) {
        conn.getReplicationAPI()
            .dropReplicationSlot("replication_slot");
    }
    } catch (Exception e) {
        e.printStackTrace();
        return;
    }
}
}
```

Example of the decoding result in text format (that is, 't' format):

```
BEGIN CSN: 2014 first_lsn: 0/2816A28
table public t1 INSERT: a[integer]:1 b[integer]:2 c[text]:'hello'
COMMIT XID: 15504
BEGIN CSN: 2015 first_lsn: 0/2816C20
table public t1 UPDATE: old-key: a[integer]:1 new-tuple: a[integer]:1 b[integer]:5 c[text]:'hello'
COMMIT XID: 15505
BEGIN CSN: 2016 first_lsn: 0/2816D60
table public t1 DELETE: a[integer]:1
COMMIT XID: 15506
```

Example of the decoding result in JSON format (that is, 'j' format):

```
BEGIN CSN: 2014 first_lsn: 0/2816A28
{"table_name":"public.t1","op_type":"INSERT","columns_name":["a","b","c"],"columns_type":
["integer","integer","text"],"columns_val":["1","1","hello"],"old_keys_name":[],"old_keys_type":
[],"old_keys_val":[]}
COMMIT XID: 15504
BEGIN CSN: 2015 first_lsn: 0/2816C20
{"table_name":"public.t1","op_type":"UPDATE","columns_name":["a","b","c"],"columns_type":
["integer","integer","text"],"columns_val":["1","5","hello"],"old_keys_name":["a"],"old_keys_type":
["integer"],"old_keys_val":["1"]}
COMMIT XID: 15505
BEGIN CSN: 2016 first_lsn: 0/2816D60
{"table_name":"public.t1","op_type":"DELETE","columns_name":[],"columns_type":[],"columns_val":
[],"old_keys_name":["a"],"old_keys_type":["integer"],"old_keys_val":["1"]}
COMMIT XID: 15506
```

5.3.14 Example: Parameters for Connecting to the Database in Different Scenarios

NOTE

In the example, **host:port** represents a node, where **host** indicates the name or IP address of the server where the database resides, and **port** indicates the port number of the server where the database resides.

DR

A customer has two database clusters. Cluster A is the production cluster, and cluster B is the DR cluster. When the customer performs a DR switchover, cluster A becomes the DR cluster, and cluster B becomes the production cluster. In this case, to avoid application restart or re-release caused by configuration file modification, the customer can write clusters A and B to the connection string when initializing the configuration file. In this case, if the primary cluster cannot be connected, the driver attempts to connect to the DR cluster. Assume that cluster A is {node1,node2,node3} and cluster B is {node4,node5,node6}.

Take the dual-cluster Dorado as an example. To connect to the new primary cluster only after the primary/standby switchover, you can set the URL as follows:

```
jdbc:postgresql://node1,node2,node3,node4,node5,node6/database
```

Load Balancing

A customer has a database cluster that contains the following nodes: {node1,node2,node3,node4,node5,node6,node7,node8,node9,node10,node11,node12}.

1. The customer establishes 120 persistent connections in application A and expects that the connections on application A can be evenly distributed on each node in the current cluster. The URL can be configured as follows:

```
jdbc:postgresql://node1,node2,node3/database?autoBalance=true
```
2. The customer develops two applications B and C and wants the three applications to be evenly distributed on specified nodes. For example, the connections of application A are distributed on {node1,node2,node3,node4}. The connections of application B are distributed on {node5,node6,node7,node8}. The connections of application C are distributed on {node9,node10,node11,node12}. The URLs can be configured as follows:
Application A: **`jdbc:postgresql://node1,node2,node3,node4,node5/database?autoBalance=priority4`**
Application B: **`jdbc:postgresql://node5,node6,node7,node8,node9/database?autoBalance=priority4`**
Application C: **`jdbc:postgresql://node9,node10,node11,node12,node1/database?autoBalance=priority4`**
3. The customer develops more applications, uses the same connection configuration string, and expects that the application connections can be evenly distributed on each node in the cluster. The URL can be configured as follows:

```
jdbc:postgresql://node1,node2,node3,node4/database?autoBalance=shuffle
```
4. If the customer does not want to use the load balancing function, configure the URL as follows:

```
jdbc:postgresql://node1/database
```

Or

```
jdbc:postgresql://node1/database?autoBalance=false
```

NOTE

When the **autoBalance** parameter is enabled, the interval for the JDBC to refresh the available CN list is 10s by default. You can use **refreshCNIPListTime** to set the interval:

```
jdbc:postgresql://node1,node2,node3,node4/database?autoBalance=true&refreshCNIPListTime=3
```

Log Diagnosis

To locate faults, a customer can enable the trace log function for diagnosis. The URL can be configured as follows:

```
jdbc:postgresql://node1/database?loggerLevel=trace
```

High Performance

A customer may execute the same SQL statement for multiple times with different input parameters. To improve the execution efficiency, the **prepareThreshold** parameter can be enabled to avoid repeatedly generating execution plans. The URL can be configured as follows:

```
jdbc:postgresql://node1/database?prepareThreshold=5
```

A customer queries 10 million data records at a time. To prevent memory overflow caused by simultaneous return of the data records, the **defaultRowFetchSize** parameter can be used. The URL can be configured as follows:

```
jdbc:postgresql://node1/database?defaultRowFetchSize=50000
```

A customer needs to insert 10 million data records in batches. To improve efficiency, the **batchMode** parameter can be used. The URL can be configured as follows:

```
jdbc:postgresql://node1/database?batchMode=on
```

5.3.15 JDBC Interface Reference

This section describes common JDBC interfaces. For more interfaces, check JDK1.8 (software package) and JDBC 4.2.

5.3.15.1 java.sql.Connection

java.sql.Connection is an API for connecting to a database.

Table 5-9 Support status for java.sql.Connection

Method Name	Return Type	Support JDBC 4
abort(Executor executor)	void	Yes
clearWarnings()	void	Yes
close()	void	Yes

Method Name	Return Type	Support JDBC 4
commit()	void	Yes
createArrayOf(String typeName, Object[] elements)	Array	Yes
createBlob()	Blob	Yes
createClob()	Clob	Yes
createSQLXML()	SQLXML	Yes
createStatement()	Statement	Yes
createStatement(int resultSetType, int resultSetConcurrency)	Statement	Yes
createStatement(int resultSetType, int resultSetConcurrency, int resultSetHoldability)	Statement	Yes
getAutoCommit()	Boolean	Yes
getCatalog()	String	Yes
getClientInfo()	Properties	Yes
getClientInfo(String name)	String	Yes
getHoldability()	int	Yes
getMetaData()	DatabaseMetaData	Yes
getNetworkTimeout()	int	Yes
getSchema()	String	Yes
getTransactionIsolation()	int	Yes
getTypeMap()	Map<String,Class<?>>	Yes
getWarnings()	SQLWarning	Yes
isClosed()	Boolean	Yes
isReadOnly()	Boolean	Yes
isValid(int timeout)	Boolean	Yes
nativeSQL(String sql)	String	Yes
prepareCall(String sql)	CallableStatement	Yes
prepareCall(String sql, int resultSetType, int resultSetConcurrency)	CallableStatement	Yes

Method Name	Return Type	Support JDBC 4
prepareCall(String sql, int resultSetType, int resultSetConcurrency, int resultSetHoldability)	CallableStatement	Yes
prepareStatement(String sql)	PreparedStatement	Yes
prepareStatement(String sql, int autoGeneratedKeys)	PreparedStatement	Yes
prepareStatement(String sql, int[] columnIndexes)	PreparedStatement	Yes
prepareStatement(String sql, int resultSetType, int resultSetConcurrency)	PreparedStatement	Yes
prepareStatement(String sql, int resultSetType, int resultSetConcurrency, int resultSetHoldability)	PreparedStatement	Yes
prepareStatement(String sql, String[] columnNames)	PreparedStatement	Yes
releaseSavepoint(Savepoint savepoint)	void	Yes
rollback()	void	Yes
rollback(Savepoint savepoint)	void	Yes
setAutoCommit(boolean autoCommit)	void	Yes
setClientInfo(Properties properties)	void	Yes
setClientInfo(String name,String value)	void	Yes
setHoldability(int holdability)	void	Yes
setNetworkTimeout(Executor executor, int milliseconds)	void	Yes
setReadOnly(boolean readOnly)	void	Yes
setSavepoint()	Savepoint	Yes
setSavepoint(String name)	Savepoint	Yes
setSchema(String schema)	void	Yes

Method Name	Return Type	Support JDBC 4
setTransactionIsolation(int level)	void	Yes
setTypeMap(Map<String,Class<?>> map)	void	Yes

NOTICE

- The autocommit mode is used by default within the API. If you disable it by running **setAutoCommit(false)**, all the statements executed later will be packaged in explicit transactions, and you cannot execute statements that cannot be executed within transactions.

5.3.15.2 java.sql.CallableStatement

java.sql.CallableStatement is an API for executing stored procedures.

Table 5-10 Support status for java.sql.CallableStatement

Method Name	Return Type	Support JDBC 4
getArray(int parameterIndex)	Array	Yes
getBigDecimal(int parameterIndex)	BigDecimal	Yes
getBlob(int parameterIndex)	Blob	Yes
getBoolean(int parameterIndex)	Boolean	Yes
getByte(int parameterIndex)	byte	Yes
getBytes(int parameterIndex)	byte[]	Yes
getClob(int parameterIndex)	Clob	Yes
getDate(int parameterIndex)	Date	Yes
getDate(int parameterIndex, Calendar cal)	Date	Yes
getDouble(int parameterIndex)	double	Yes
getFloat(int parameterIndex)	float	Yes
getInt(int parameterIndex)	int	Yes
getLong(int parameterIndex)	long	Yes

Method Name	Return Type	Support JDBC 4
getObject(int parameterIndex)	Object	Yes
getObject(int parameterIndex, Class<T> type)	Object	Yes
getShort(int parameterIndex)	short	Yes
getSQLXML(int parameterIndex)	SQLXML	Yes
getString(int parameterIndex)	String	Yes
getNString(int parameterIndex)	String	Yes
getTime(int parameterIndex)	Time	Yes
getTime(int parameterIndex, Calendar cal)	Time	Yes
getTimestamp(int parameterIndex)	Timestamp	Yes
getTimestamp(int parameterIndex, Calendar cal)	Timestamp	Yes
registerOutParameter(int parameterIndex, int type)	void	Yes
registerOutParameter(int parameterIndex, int sqlType, int type)	void	Yes
wasNull()	Boolean	Yes

 **NOTE**

- The batch operation of statements containing OUT parameter is not allowed.
- The following methods are inherited from java.sql.Statement: close, execute, executeQuery, executeUpdate, getConnection, getResultSet, getUpdateCount, isClosed, setMaxRows, and setFetchSize.
- The following methods are inherited from java.sql.PreparedStatement: addBatch, clearParameters, execute, executeQuery, executeUpdate, getMetaData, setBigDecimal, setBoolean, setByte, setBytes, setDate, setDouble, setFloat, setInt, setLong, setNull, setObject, setString, setTime, and setTimestamp.
- The registerOutParameter(int parameterIndex, int sqlType, int type) method is used only to register the composite data type.

5.3.15.3 java.sql.DatabaseMetaData

java.sql.DatabaseMetaData is an API for defining database objects.

Table 5-11 Support status for java.sql.DatabaseMetaData

Method Name	Return Type	Support JDBC 4
allProceduresAreCallable()	Boolean	Yes
allTablesAreSelectable()	Boolean	Yes
autoCommitFailureClosesAllResultSets()	Boolean	Yes
dataDefinitionCausesTransactionCommit()	Boolean	Yes
dataDefinitionIgnoredInTransactions()	Boolean	Yes
deletesAreDetected(int type)	Boolean	Yes
doesMaxRowSizeIncludeBlobs()	Boolean	Yes
generatedKeyAlwaysReturned()	Boolean	Yes
getBestRowIdentifier(String catalog, String schema, String table, int scope, boolean nullable)	ResultSet	Yes
getCatalogs()	ResultSet	Yes
getCatalogSeparator()	String	Yes
getCatalogTerm()	String	Yes
getClientInfoProperties()	ResultSet	Yes
getColumnPrivileges(String catalog, String schema, String table, String columnNamePattern)	ResultSet	Yes
getConnection()	Connection	Yes
getCrossReference(String parentCatalog, String parentSchema, String parentTable, String foreignCatalog, String foreignSchema, String foreignTable)	ResultSet	Yes

Method Name	Return Type	Support JDBC 4
getDefaultTransactionIsolation()	int	Yes
getExportedKeys(String catalog, String schema, String table)	ResultSet	Yes
getExtraNameCharacters()	String	Yes
getFunctionColumns(String catalog, String schemaPattern, String functionNamePattern, String columnNamePattern)	ResultSet	Yes
getFunctions(String catalog, String schemaPattern, String functionNamePattern)	ResultSet	Yes
getIdentifierQuoteString()	String	Yes
getImportedKeys(String catalog, String schema, String table)	ResultSet	Yes
getIndexInfo(String catalog, String schema, String table, boolean unique, boolean approximate)	ResultSet	Yes
getMaxBinaryLiteralLength()	int	Yes
getMaxCatalogNameLength()	int	Yes
getMaxCharLiteralLength()	int	Yes
getMaxColumnNameLength()	int	Yes
getMaxColumnsInGroupBy()	int	Yes
getMaxColumnsInIndex()	int	Yes
getMaxColumnsInOrderBy()	int	Yes
getMaxColumnsInSelect()	int	Yes
getMaxColumnsInTable()	int	Yes
getMaxConnections()	int	Yes
getMaxCursorNameLength()	int	Yes
getMaxIndexLength()	int	Yes
getMaxLogicalLobSize()	default long	Yes

Method Name	Return Type	Support JDBC 4
getMaxProcedureNameLength()	int	Yes
getMaxRowSize()	int	Yes
getMaxSchemaNameLength()	int	Yes
getMaxStatementLength()	int	Yes
getMaxStatements()	int	Yes
getMaxTableNameLength()	int	Yes
getMaxTablesInSelect()	int	Yes
getMaxUserNameLength()	int	Yes
getNumericFunctions()	String	Yes
getPrimaryKeys(String catalog, String schema, String table)	ResultSet	Yes
getPartitionTablePrimaryKeys(String catalog, String schema, String table)	ResultSet	Yes
getProcedureColumns(String catalog, String schemaPattern, String procedureNamePattern, String columnNamePattern)	ResultSet	Yes
getProcedures(String catalog, String schemaPattern, String procedureNamePattern)	ResultSet	Yes
getProcedureTerm()	String	Yes
getSchemas()	ResultSet	Yes
getSchemas(String catalog, String schemaPattern)	ResultSet	Yes
getSchemaTerm()	String	Yes
getSearchStringEscape()	String	Yes
getSQLKeywords()	String	Yes
getSQLStateType()	int	Yes
getStringFunctions()	String	Yes
getSystemFunctions()	String	Yes

Method Name	Return Type	Support JDBC 4
getTablePrivileges(String catalog, String schemaPattern, String tableNamePattern)	ResultSet	Yes
getTimeDateFunctions()	String	Yes
getTypeInfo()	ResultSet	Yes
getUDTs(String catalog, String schemaPattern, String typeNamePattern, int[] types)	ResultSet	Yes
getURL()	String	Yes
getVersionColumns(String catalog, String schema, String table)	ResultSet	Yes
insertsAreDetected(int type)	Boolean	Yes
locatorsUpdateCopy()	Boolean	Yes
othersDeletesAreVisible(int type)	Boolean	Yes
othersInsertsAreVisible(int type)	Boolean	Yes
othersUpdatesAreVisible(int type)	Boolean	Yes
ownDeletesAreVisible(int type)	Boolean	Yes
ownInsertsAreVisible(int type)	Boolean	Yes
ownUpdatesAreVisible(int type)	Boolean	Yes
storesLowerCaseIdentifiers()	Boolean	Yes
storesMixedCaseIdentifiers()	Boolean	Yes
storesUpperCaseIdentifiers()	Boolean	Yes
supportsBatchUpdates()	Boolean	Yes
supportsCatalogsInDataManipulation()	Boolean	Yes
supportsCatalogsInIndexDefinitions()	Boolean	Yes

Method Name	Return Type	Support JDBC 4
supportsCatalogsInPrivilegeDefinitions()	Boolean	Yes
supportsCatalogsInProcedureCalls()	Boolean	Yes
supportsCatalogsInTableDefinitions()	Boolean	Yes
supportsCorrelatedSubqueries()	Boolean	Yes
supportsDataDefinitionAndDataManipulationTransactions()	Boolean	Yes
supportsDataManipulationTransactionsOnly()	Boolean	Yes
supportsGetGeneratedKeys()	Boolean	Yes
supportsMixedCaseIdentifiers()	Boolean	Yes
supportsMultipleOpenResults()	Boolean	Yes
supportsNamedParameters()	Boolean	Yes
supportsOpenCursorsAcrossCommit()	Boolean	Yes
supportsOpenCursorsAcrossRollback()	Boolean	Yes
supportsOpenStatementsAcrossCommit()	Boolean	Yes
supportsOpenStatementsAcrossRollback()	Boolean	Yes
supportsPositionedDelete()	Boolean	Yes
supportsPositionedUpdate()	Boolean	Yes
supportsRefCursors()	Boolean	Yes
supportsResultSetConcurrency(int type, int concurrency)	Boolean	Yes
supportsResultSetType(int type)	Boolean	Yes
supportsSchemasInIndexDefinitions()	Boolean	Yes

Method Name	Return Type	Support JDBC 4
supportsSchemasInPrivilegeDefinitions()	Boolean	Yes
supportsSchemasInProcedureCalls()	Boolean	Yes
supportsSchemasInTableDefinitions()	Boolean	Yes
supportsSelectForUpdate()	Boolean	Yes
supportsStatementPooling()	Boolean	Yes
supportsStoredFunctionsUsingCallSyntax()	Boolean	Yes
supportsStoredProcedures()	Boolean	Yes
supportsSubqueriesInComparisons()	Boolean	Yes
supportsSubqueriesInExists()	Boolean	Yes
supportsSubqueriesInIns()	Boolean	Yes
supportsSubqueriesInQuantifieds()	Boolean	Yes
supportsTransactionIsolationLevel(int level)	Boolean	Yes
supportsTransactions()	Boolean	Yes
supportsUnion()	Boolean	Yes
supportsUnionAll()	Boolean	Yes
updatesAreDetected(int type)	Boolean	Yes
getTables(String catalog, String schemaPattern, String tableNamePattern, String[] types)	ResultSet	Yes
getColumns(String catalog, String schemaPattern, String tableNamePattern, String columnNamePattern)	ResultSet	Yes

storesUpperCaseQuotedIdentifiers()	Boolean	Yes
storesLowerCaseQuotedIdentifiers()	Boolean	Yes
storesMixedCaseQuotedIdentifiers()	Boolean	Yes
supportsAlterTableWithAddColumn()	Boolean	Yes
supportsAlterTableWithDropColumn()	Boolean	Yes
supportsColumnAliasing()	Boolean	Yes
nullPlusNonNullIsNull()	Boolean	Yes
supportsConvert()	Boolean	Yes
supportsConvert(int fromType, int toType)	Boolean	Yes

Method Name	Return Type	Support JDBC 4
supportsTableCorrelationNames()	Boolean	Yes
supportsDifferentTableCorrelationNames()	Boolean	Yes
supportsExpressionsInOrderBy()	Boolean	Yes
supportsOrderByUnrelated()	Boolean	Yes
supportsGroupBy()	Boolean	Yes
supportsGroupByUnrelated()	Boolean	Yes
supportsGroupByBeyondSelect()	Boolean	Yes
supportsLikeEscapeClause()	Boolean	Yes
supportsMultipleResultSets()	Boolean	Yes
supportsMultipleTransactions()	Boolean	Yes
supportsNonNullableColumns()	Boolean	Yes
supportsMinimumSQLGrammar()	Boolean	Yes
supportsCoreSQLGrammar()	Boolean	Yes
supportsExtendedSQLGrammar()	Boolean	Yes
supportsANSI92EntryLevelSQL()	Boolean	Yes
supportsANSI92IntermediateSQL()	Boolean	Yes
supportsANSI92FullSQL()	Boolean	Yes
supportsIntegrityEnhancementFacility()	Boolean	Yes
supportsOuterJoins()	Boolean	Yes
supportsFullOuterJoins()	Boolean	Yes
supportsLimitedOuterJoins()	Boolean	Yes
isCatalogAtStart()	Boolean	Yes
supportsSchemasInDataManipulation()	Boolean	Yes

Method Name	Return Type	Support JDBC 4
supportsSavepoints()	Boolean	Yes
supportsResultSetHoldability(int holdability)	Boolean	Yes
getResultSetHoldability()	int	Yes
getDatabaseMajorVersion()	int	Yes
getDatabaseMinorVersion()	int	Yes
getJDBCMinorVersion()	int	Yes
getJDBCMajorVersion()	int	Yes
getJDBCMajorVersion()	int	Yes

 **NOTE**

The `getPartitionTablePrimaryKeys(String catalog, String schema, String table)` API is used to obtain the primary key column of a partitioned table that contains global indexes. An example is as follows:

```
PgDatabaseMetaData dbmd = (PgDatabaseMetaData)conn.getMetaData();
dbmd.getPartitionTablePrimaryKeys("catalogName", "schemaName", "tableName");
```

5.3.15.4 java.sql.Driver

`java.sql.Driver` is a database driver API.

Table 5-12 Support status for `java.sql.Driver`

Method Name	Return Type	Support JDBC 4
acceptsURL(String url)	Boolean	Yes
connect(String url, Properties info)	Connection	Yes
jdbcCompliant()	Boolean	Yes
getMajorVersion()	int	Yes
getMinorVersion()	int	Yes
getParentLogger()	Logger	Yes
getPropertyInfo(String url, Properties info)	DriverPropertyInfo[]	Yes

5.3.15.5 java.sql.PreparedStatement

`java.sql.PreparedStatement` is an API for preparing statements.

Table 5-13 Support status for java.sql.PreparedStatement

Method Name	Return Type	Support JDBC 4
clearParameters()	void	Yes
execute()	Boolean	Yes
executeQuery()	ResultSet	Yes
excuteUpdate()	int	Yes
executeLargeUpdate()	long	No
getMetaData()	ResultSetMetaData	Yes
getParameterMetaData()	ParameterMetaData	Yes
setArray(int parameterIndex, Array x)	void	Yes
setAsciiStream(int parameterIndex, InputStream x, int length)	void	Yes
setBinaryStream(int parameterIndex, InputStream x)	void	Yes
setBinaryStream(int parameterIndex, InputStream x, int length)	void	Yes
setBinaryStream(int parameterIndex, InputStream x, long length)	void	Yes
setBlob(int parameterIndex, InputStream inputStream)	void	Yes
setBlob(int parameterIndex, InputStream inputStream, long length)	void	Yes
setBlob(int parameterIndex, Blob x)	void	Yes
setCharacterStream(int parameterIndex, Reader reader)	void	Yes

Method Name	Return Type	Support JDBC 4
setCharacterStream(int parameterIndex, Reader reader, int length)	void	Yes
setClob(int parameterIndex, Reader reader)	void	Yes
setClob(int parameterIndex, Reader reader, long length)	void	Yes
setClob(int parameterIndex, Clob x)	void	Yes
setDate(int parameterIndex, Date x, Calendar cal)	void	Yes
setNull(int parameterIndex, int sqlType)	void	Yes
setNull(int parameterIndex, int sqlType, String typeName)	void	Yes
setObject(int parameterIndex, Object x)	void	Yes
setObject(int parameterIndex, Object x, int targetSqlType)	void	Yes
setObject(int parameterIndex, Object x, int targetSqlType, int scaleOrLength)	void	Yes
setSQLXML(int parameterIndex, SQLXML xmlObject)	void	Yes
setTime(int parameterIndex, Time x)	void	Yes
setTime(int parameterIndex, Time x, Calendar cal)	void	Yes

Method Name	Return Type	Support JDBC 4
setTimestamp(int parameterIndex, Timestamp x)	void	Yes
setTimestamp(int parameterIndex, Timestamp x, Calendar cal)	void	Yes
setUnicodeStream(int parameterIndex, InputStream x, int length)	void	Yes
setURL(int parameterIndex, URL x)	void	Yes
setBoolean(int parameterIndex, boolean x)	void	Yes
setBigDecimal(int parameterIndex, BigDecimal x)	void	Yes
setByte(int parameterIndex, byte x)	void	Yes
setBytes(int parameterIndex, byte[] x)	void	Yes
setDate(int parameterIndex, Date x)	void	Yes
setDouble(int parameterIndex, double x)	void	Yes
setFloat(int parameterIndex, float x)	void	Yes
setInt(int parameterIndex, int x)	void	Yes
setLong(int parameterIndex, long x)	void	Yes
setShort(int parameterIndex, short x)	void	Yes
setString(int parameterIndex, String x)	void	Yes

Method Name	Return Type	Support JDBC 4
setNString(int parameterIndex, String x)	void	Yes
addBatch()	void	Yes
executeBatch()	int[]	Yes

 **NOTE**

- Execute addBatch() and execute() only after executing clearBatch().
- Batch is not cleared by calling executeBatch(). Clear batch by explicitly calling clearBatch().
- After bounded variables of a batch are added, if you want to reuse these values, you do not need to use set*() again. Instead, add a batch.
- The following methods are inherited from java.sql.Statement: close, execute, executeQuery, executeUpdate, getConnection, getResultSet, getUpdateCount, isClosed, setMaxRows, and setFetchSize.
- The executeLargeUpdate() method can only be used in JDBC 4.2 or later.

5.3.15.6 java.sql.ResultSet

java.sql.ResultSet is an execution result set API.

Table 5-14 Support status for java.sql.ResultSet

Method Name	Return Type	Support JDBC 4
absolute(int row)	Boolean	Yes
afterLast()	void	Yes
beforeFirst()	void	Yes
cancelRowUpdates()	void	Yes
clearWarnings()	void	Yes
close()	void	Yes
deleteRow()	void	Yes
findColumn(String columnLabel)	int	Yes
first()	Boolean	Yes
getArray(int columnIndex)	Array	Yes
getArray(String columnLabel)	Array	Yes

Method Name	Return Type	Support JDBC 4
getAsciiStream(int columnIndex)	InputStream	Yes
getAsciiStream(String columnLabel)	InputStream	Yes
getBigDecimal(int columnIndex)	BigDecimal	Yes
getBigDecimal(String columnLabel)	BigDecimal	Yes
getBinaryStream(int columnIndex)	InputStream	Yes
getBinaryStream(String columnLabel)	InputStream	Yes
getBlob(int columnIndex)	Blob	Yes
getBlob(String columnLabel)	Blob	Yes
getBoolean(int columnIndex)	Boolean	Yes
getBoolean(String columnLabel)	Boolean	Yes
getBytes(int columnIndex)	byte[]	Yes
getBytes(String columnLabel)	byte[]	Yes
getByte(int columnIndex)	byte	Yes
getByte(String columnLabel)	byte	Yes
getCharacterStream(int columnIndex)	Reader	Yes
getCharacterStream(String columnLabel)	Reader	Yes
getClob(int columnIndex)	Clob	Yes
getClob(String columnLabel)	Clob	Yes
getConcurrency()	int	Yes
getCursorName()	String	Yes
getDate(int columnIndex)	Date	Yes

Method Name	Return Type	Support JDBC 4
getDate(int columnIndex, Calendar cal)	Date	Yes
getDate(String columnLabel)	Date	Yes
getDate(String columnLabel, Calendar cal)	Date	Yes
getDouble(int columnIndex)	double	Yes
getDouble(String columnLabel)	double	Yes
getFetchDirection()	int	Yes
getFetchSize()	int	Yes
getFloat(int columnIndex)	float	Yes
getFloat(String columnLabel)	float	Yes
getInt(int columnIndex)	int	Yes
getInt(String columnLabel)	int	Yes
getLong(int columnIndex)	long	Yes
getLong(String columnLabel)	long	Yes
getMetaData()	ResultSetMetaData	Yes
getObject(int columnIndex)	Object	Yes
getObject(int columnIndex, Class<T> type)	<T> T	Yes
getObject(int columnIndex, Map<String,Class<?>> map)	Object	Yes
getObject(String columnLabel)	Object	Yes
getObject(String columnLabel, Class<T> type)	<T> T	Yes

Method Name	Return Type	Support JDBC 4
getObject(String columnLabel, Map<String,Class<?>> map)	Object	Yes
getRow()	int	Yes
getShort(int columnIndex)	short	Yes
getShort(String columnLabel)	short	Yes
getSQLXML(int columnIndex)	SQLXML	Yes
getSQLXML(String columnLabel)	SQLXML	Yes
getStatement()	Statement	Yes
getString(int columnIndex)	String	Yes
getString(String columnLabel)	String	Yes
getNString(int columnIndex)	String	Yes
getNString(String columnLabel)	String	Yes
getTime(int columnIndex)	Time	Yes
getTime(int columnIndex, Calendar cal)	Time	Yes
getTime(String columnLabel)	Time	Yes
getTime(String columnLabel, Calendar cal)	Time	Yes
getTimestamp(int columnIndex)	Timestamp	Yes
getTimestamp(int columnIndex, Calendar cal)	Timestamp	Yes
getTimestamp(String columnLabel)	Timestamp	Yes

Method Name	Return Type	Support JDBC 4
getTimestamp(String columnLabel, Calendar cal)	Timestamp	Yes
getType()	int	Yes
getWarnings()	SQLWarning	Yes
insertRow()	void	Yes
isAfterLast()	Boolean	Yes
isBeforeFirst()	Boolean	Yes
isClosed()	Boolean	Yes
isFirst()	Boolean	Yes
isLast()	Boolean	Yes
last()	Boolean	Yes
moveToCurrentRow()	void	Yes
moveToInsertRow()	void	Yes
next()	Boolean	Yes
previous()	Boolean	Yes
refreshRow()	void	Yes
relative(int rows)	Boolean	Yes
rowDeleted()	Boolean	Yes
rowInserted()	Boolean	Yes
rowUpdated()	Boolean	Yes
setFetchDirection(int direction)	void	Yes
setFetchSize(int rows)	void	Yes
updateArray(int columnIndex, Array x)	void	Yes
updateArray(String columnLabel, Array x)	void	Yes
updateAsciiStream(int columnIndex, InputStream x, int length)	void	Yes
updateAsciiStream(String columnLabel, InputStream x, int length)	void	Yes

Method Name	Return Type	Support JDBC 4
updateBigDecimal(int columnIndex, BigDecimal x)	void	Yes
updateBigDecimal(String columnLabel, BigDecimal x)	void	Yes
updateBinaryStream(int columnIndex, InputStream x, int length)	void	Yes
updateBinaryStream(String columnLabel, InputStream x, int length)	void	Yes
updateBoolean(int columnIndex, boolean x)	void	Yes
updateBoolean(String columnLabel, boolean x)	void	Yes
updateByte(int columnIndex, byte x)	void	Yes
updateByte(String columnLabel, byte x)	void	Yes
updateBytes(int columnIndex, byte[] x)	void	Yes
updateBytes(String columnLabel, byte[] x)	void	Yes
updateCharacterStream(int columnIndex, Reader x, int length)	void	Yes
updateCharacterStream(String columnLabel, Reader reader, int length)	void	Yes
updateDate(int columnIndex, Date x)	void	Yes
updateDate(String columnLabel, Date x)	void	Yes
updateDouble(int columnIndex, double x)	void	Yes
updateDouble(String columnLabel, double x)	void	Yes

Method Name	Return Type	Support JDBC 4
updateFloat(int columnIndex, float x)	void	Yes
updateFloat(String columnLabel, float x)	void	Yes
updateInt(int columnIndex, int x)	void	Yes
updateInt(String columnLabel, int x)	void	Yes
updateLong(int columnIndex, long x)	void	Yes
updateLong(String columnLabel, long x)	void	Yes
updateNull(int columnIndex)	void	Yes
updateNull(String columnLabel)	void	Yes
updateObject(int columnIndex, Object x)	void	Yes
updateObject(int columnIndex, Object x, int scaleOrLength)	void	Yes
updateObject(String columnLabel, Object x)	void	Yes
updateObject(String columnLabel, Object x, int scaleOrLength)	void	Yes
updateRow()	void	Yes
updateShort(int columnIndex, short x)	void	Yes
updateShort(String columnLabel, short x)	void	Yes
updateSQLXML(int columnIndex, SQLXML xmlObject)	void	Yes
updateSQLXML(String columnLabel, SQLXML xmlObject)	void	Yes
updateString(int columnIndex, String x)	void	Yes

Method Name	Return Type	Support JDBC 4
updateString(String columnLabel, String x)	void	Yes
updateTime(int columnIndex, Time x)	void	Yes
updateTime(String columnLabel, Time x)	void	Yes
updateTimestamp(int columnIndex, Timestamp x)	void	Yes
updateTimestamp(String columnLabel, Timestamp x)	void	Yes
wasNull()	Boolean	Yes

 **NOTE**

- One statement cannot have multiple open ResultSets.
- The cursor that is used for traversing the ResultSet cannot be open after being committed.

5.3.15.7 java.sql.ResultSetMetaData

java.sql.ResultSetMetaData describes the information about ResultSet objects.

Table 5-15 Support status for java.sql.ResultSetMetaData

Method Name	Return Type	Support JDBC 4
getCatalogName(int column)	String	Yes
getColumnClassName(int column)	String	Yes
getColumnCount()	int	Yes
getColumnDisplaySize(int column)	int	Yes
getColumnLabel(int column)	String	Yes
getColumnName(int column)	String	Yes
getColumnType(int column)	int	Yes
getColumnTypeName(int column)	String	Yes

Method Name	Return Type	Support JDBC 4
getPrecision(int column)	int	Yes
getScale(int column)	int	Yes
getSchemaName(int column)	String	Yes
getTableName(int column)	String	Yes
isAutoIncrement(int column)	Boolean	Yes
isCaseSensitive(int column)	Boolean	Yes
isCurrency(int column)	Boolean	Yes
isDefinitelyWritable(int column)	Boolean	Yes
isNullable(int column)	int	Yes
isReadOnly(int column)	Boolean	Yes
isSearchable(int column)	Boolean	Yes
isSigned(int column)	Boolean	Yes
isWritable(int column)	Boolean	Yes

5.3.15.8 java.sql.Statement

java.sql.Statement is an SQL statement API.

Table 5-16 Support status for java.sql.Statement

Method Name	Return Type	Support JDBC 4
addBatch(String sql)	void	Yes
clearBatch()	void	Yes
clearWarnings()	void	Yes
close()	void	Yes
closeOnCompletion()	void	Yes
execute(String sql)	Boolean	Yes
execute(String sql, int autoGeneratedKeys)	Boolean	Yes
execute(String sql, int[] columnIndexes)	Boolean	Yes

Method Name	Return Type	Support JDBC 4
execute(String sql, String[] columnNames)	Boolean	Yes
executeBatch()	Boolean	Yes
executeQuery(String sql)	ResultSet	Yes
executeUpdate(String sql)	int	Yes
executeUpdate(String sql, int autoGeneratedKeys)	int	Yes
executeUpdate(String sql, int[] columnIndexes)	int	Yes
executeUpdate(String sql, String[] columnNames)	int	Yes
getConnection()	Connection	Yes
getFetchDirection()	int	Yes
getFetchSize()	int	Yes
getGeneratedKeys()	ResultSet	Yes
getMaxFieldSize()	int	Yes
getMaxRows()	int	Yes
getMoreResults()	Boolean	Yes
getMoreResults(int current)	Boolean	Yes
getResultSet()	ResultSet	Yes
getResultSetConcurrency()	int	Yes
getResultSetHoldability()	int	Yes
getResultSetType()	int	Yes
getQueryTimeout()	int	Yes
getUpdateCount()	int	Yes
getWarnings()	SQLWarning	Yes
isClosed()	Boolean	Yes

Method Name	Return Type	Support JDBC 4
isCloseOnCompletion()	Boolean	Yes
isPoolable()	Boolean	Yes
setCursorName(String name)	void	Yes
setEscapeProcessing(boolean enable)	void	Yes
setFetchDirection(int direction)	void	Yes
setMaxFieldSize(int max)	void	Yes
setMaxRows(int max)	void	Yes
setPoolable(boolean poolable)	void	Yes
setQueryTimeout(int seconds)	void	Yes
setFetchSize(int rows)	void	Yes
cancel()	void	Yes
executeLargeUpdate(String sql)	long	No
getLargeUpdateCount()	long	No
executeLargeBatch()	long	No
executeLargeUpdate(String sql, int autoGeneratedKeys)	long	No
executeLargeUpdate(String sql, int[] columnIndexes)	long	No
executeLargeUpdate(String sql, String[] columnNames)	long	No

 NOTE

- Using `setFetchSize` can reduce the memory occupied by result sets on the client. Result sets are packaged into cursors and segmented for processing, which will increase the communication traffic between the database and the client, affecting performance.
- Database cursors are valid only within their transactions. If `setFetchSize` is set, set `setAutoCommit(false)` and commit transactions on the connection to flush service data to a database.
- The `LargeUpdate` method can only be used in JDBC 4.2 or later.

5.3.15.9 javax.sql.ConnectionPoolDataSource

This section describes **javax.sql.ConnectionPoolDataSource**, the interface for data source connection pools.

Table 5-17 Support status for javax.sql.ConnectionPoolDataSource

Method Name	Return Type	Support JDBC 4
<code>getPooledConnection()</code>	<code>PooledConnection</code>	Yes
<code>getPooledConnection(String user,String password)</code>	<code>PooledConnection</code>	Yes

5.3.15.10 javax.sql.DataSource

This section describes **javax.sql.DataSource**, the interface for data sources.

Table 5-18 Support status for javax.sql.DataSource

Method Name	Return Type	Support JDBC 4
<code>getConnection()</code>	<code>Connection</code>	Yes
<code>getConnection(String username,String password)</code>	<code>Connection</code>	Yes
<code>getLoginTimeout()</code>	<code>int</code>	Yes
<code>getLogWriter()</code>	<code>PrintWriter</code>	Yes
<code>setLoginTimeout(int seconds)</code>	<code>void</code>	Yes
<code>setLogWriter(PrintWriter out)</code>	<code>void</code>	Yes

5.3.15.11 javax.sql.PooledConnection

This section describes **javax.sql.PooledConnection**, the connection interface created by a connection pool.

Table 5-19 Support status for javax.sql.PooledConnection

Method Name	Return Type	Support JDBC 4
addConnectionEventListener (ConnectionEventListener listener)	void	Yes
close()	void	Yes
getConnection()	Connection	Yes
removeConnectionEventListener (ConnectionEventListener listener)	void	Yes

5.3.15.12 javax.naming.Context

This section describes **javax.naming.Context**, the context interface for connection configuration.

Table 5-20 Support status for javax.naming.Context

Method Name	Return Type	Support JDBC 4
bind(Name name, Object obj)	void	Yes
bind(String name, Object obj)	void	Yes
lookup(Name name)	Object	Yes
lookup(String name)	Object	Yes
rebind(Name name, Object obj)	void	Yes
rebind(String name, Object obj)	void	Yes
rename(Name oldName, Name newName)	void	Yes
rename(String oldName, String newName)	void	Yes
unbind(Name name)	void	Yes
unbind(String name)	void	Yes

5.3.15.13 javax.naming.spi.InitialContextFactory

This section describes **javax.naming.spi.InitialContextFactory**, the initial context factory interface.

Table 5-21 Support status for javax.naming.spi.InitialContextFactory

Method Name	Return Type	Support JDBC 4
getInitialContext(Hashtable<?,?> environment)	Context	Yes

5.3.15.14 CopyManager

CopyManager is an API class provided by the JDBC driver in GaussDB. It is used to import data to GaussDB clusters in batches.

Inheritance Relationship of CopyManager

The CopyManager class is in the **org.postgresql.copy** package and inherits the java.lang.Object class. The declaration of the class is as follows:

```
public class CopyManager
extends Object
```

Constructor Method

```
public CopyManager(BaseConnection connection)
throws SQLException
```

Common Methods

Table 5-22 Common methods of CopyManager

Return Value	Method	Description	throws
CopyIn	copyIn(String sql)	-	SQLException
long	copyIn(String sql, InputStream from)	Uses COPY FROM STDIN to quickly load data to tables in the database from InputStream.	SQLException,IOE xception
long	copyIn(String sql, InputStream from, int bufferSize)	Uses COPY FROM STDIN to quickly load data to tables in the database from InputStream.	SQLException,IOE xception

Return Value	Method	Description	throws
long	copyIn(String sql, Reader from)	Uses COPY FROM STDIN to quickly load data to tables in the database from Reader.	SQLException,IOException
long	copyIn(String sql, Reader from, int bufferSize)	Uses COPY FROM STDIN to quickly load data to tables in the database from Reader.	SQLException,IOException
CopyOut	copyOut(String sql)	-	SQLException
long	copyOut(String sql, OutputStream to)	Sends the result set of COPY TO STDOUT from the database to the OutputStream class.	SQLException,IOException
long	copyOut(String sql, Writer to)	Sends the result set of COPY TO STDOUT from the database to the Writer class.	SQLException,IOException

5.3.15.15 PGReplicationConnection

PGReplicationConnection is an API class provided by the JDBC driver in GaussDB. It is used to implement functions related to logical replication.

Inheritance Relationship of PGReplicationConnection

PGReplicationConnection is a logical replication API. Its implementation class is PGReplicationConnectionImpl, which is in the **org.postgresql.replication** package. The declaration of the class is as follows:

```
public class PGReplicationConnection implements PGReplicationConnection
```

Constructor Method

```
public PGReplicationConnection(BaseConnection connection)
```

Common Methods

Table 5-23 Common methods of PGReplicationConnection

Return Value	Method	Description	Throws
ChainedCreateReplicationSlotBuilder	createReplicationSlot()	Creates a logical replication slot. Only cluster-level (CSN-based) logical replication slots can be created for connecting to CNs, and replication slots with the same name can be created on other CNs and primary DNs. Only local (LSN-based) logical replication slots can be created for connecting to DNs. For details about how to create an LSN-based logical replication slot on a CN or a CSN-based logical replication slot on a DN, see the SQL function <code>pg_create_logical_replication_slot</code> for logical replication.	-

Return Value	Method	Description	Throws
void	dropReplication-Slot(String slotName)	<p>Deletes a logical replication slot. When you connect to a CN to delete a logical replication slot, if the logical replication slot is an LSN-based logical replication slot, only the replication slot of the current node is deleted. Replication slots with the same name on other nodes are not affected. When a CSN-based logical replication slot with the same name exists on other nodes, no error is reported because some nodes do not have replication slots. In addition, replication slots with the same name on all nodes are successfully deleted. If no replication slot exists on any node, an error is reported. If an LSN-based logical replication slot remains on the current CN and a CSN-based logical replication slot with the same name remains on other nodes, connecting to a CN to delete a</p>	SQLException,IOE xception

Return Value	Method	Description	Throws
		replication slot will delete only the local LSN-based logical replication slot. After the deletion is complete, perform the deletion operation again to delete the replication slots with the same name on other nodes.	
ChainedStreamBuilder	replicationStream()	Enables logical replication.	-

5.3.15.16 PGReplicationStream

PGReplicationStream is an API class provided by the GaussDB JDBC driver. It is used to operate logical replication streams.

Inheritance Relationship of PGReplicationStream

PGReplicationStream is a logical replication API. Its implementation class is V3PGReplicationStream, which is in the **org.postgresql.core.v3.replication** package. The declaration of the class is as follows:

```
public class V3PGReplicationStream implements PGReplicationStream
```

Constructor Method

```
public V3PGReplicationStream(CopyDual copyDual, LogSequenceNumber startLSN, long updateIntervalMs, ReplicationType replicationType)
```

Common Methods

Table 5-24 Common methods of PGReplicationConnection

Return Value	Method	Description	throws
void	close()	Ends the logical replication and releases resources.	SQLException

Return Value	Method	Description	throws
void	forceUpdateStatus()	Forcibly sends the LSN status received, flushed, and applied last time to the backend.	SQLException
LogSequenceNumber	getLastAppliedLSN()	Obtains the LSN when the primary node replays logs last time.	-
LogSequenceNumber	getLastFlushedLSN()	Obtains the LSN flushed by the primary node last time, that is, the LSN pushed by the current logical decoding.	-
LogSequenceNumber	getLastReceiveLSN()	Obtains the last received LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots).	-
boolean	isClosed()	Determines whether the replication stream is disabled.	-
ByteBuffer	read()	Reads the next WAL record from the backend. If the data cannot be read, this method blocks the I/O read.	SQLException
ByteBuffer	readPending()	Reads the next WAL record from the backend. If the data cannot be read, this method does not block the I/O read.	SQLException
void	setAppliedLSN(LogSequenceNumber applied)	Sets the applied LSN.	-

Return Value	Method	Description	throws
void	setFlushedLSN(LogSequenceNumber flushed)	Updates the LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots), which is sent to the backend at the next update to update the LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots) on the server.	-

5.3.15.17 ChainedStreamBuilder

ChainedStreamBuilder is an API class provided by the GaussDB JDBC driver. It is used to build replication streams.

Inheritance Relationship of ChainedStreamBuilder

ChainedStreamBuilder is a logical replication API. Its implementation class is ReplicationStreamBuilder, which is in the **org.postgresql.replication.fluent** package. The declaration of the class is as follows:

```
public class ReplicationStreamBuilder implements ChainedStreamBuilder
```

Constructor Method

```
public ReplicationStreamBuilder(final BaseConnection connection)
```

Common Methods

Table 5-25 Common methods of ReplicationStreamBuilder

Return Value	Method	Description	throws
ChainedLogicalStreamBuilder	logical()	Creates a logical replication stream.	-
ChainedPhysicalStreamBuilder	physical()	Creates a physical replication stream.	-

5.3.15.18 ChainedCommonStreamBuilder

ChainedCommonStreamBuilder is an API class provided by the GaussDB JDBC driver. It is used to specify common parameters for logical and physical replication.

Inheritance Relationship of ChainedCommonStreamBuilder

ChainedCommonStreamBuilder is an API for logical replication. The implementation abstract class is AbstractCreateSlotBuilder. The inheritance class is LogicalCreateSlotBuilder which is in the **org.postgresql.replication.fluent.logical** package. The declaration of this class is as follows:

```
public class LogicalCreateSlotBuilder
    extends AbstractCreateSlotBuilder<ChainedLogicalCreateSlotBuilder>
    implements ChainedLogicalCreateSlotBuilder
```

Constructor Method

```
public LogicalCreateSlotBuilder(BaseConnection connection)
```

Common Methods

Table 5-26 Common methods of LogicalCreateSlotBuilder

Return Value	Method	Description	throws
T	withSlotName(String slotName)	Specifies the name of a replication slot.	-
ChainedLogicalCreateSlotBuilder	withOutputPlugin(String outputPlugin)	Plug-in name. Currently, mppdb_decoding is supported.	-
void	make()	Creates a slot with the specified parameters in the database.	SQLException
ChainedLogicalCreateSlotBuilder	self()	Returns the implementation of ChainedLogicalCreateSlotBuilder.	-

5.3.16 Common JDBC Parameters

allowReadOnly

Principle: Checks whether the transaction access mode can be modified through **setReadOnly**. If the value is **true**, the transaction access mode can be modified. If the value is **false**, the transaction access mode cannot be modified through this API. To modify the transaction access mode, execute the statements: SET SESSION CHARACTERISTICS AS TRANSACTION + READ ONLY / READ WRITE.

Suggestion: The default value **true** is recommended.

autoBalance

Principle: If this parameter is set to **true**, **balance**, or **roundrobin**, the JDBC load balancing function is enabled to balance multiple connections of applications to available CNs in the database cluster. When a connection is established for the first time, the IP address configured in the JDBC connection string is used to establish the connection. As long as the connection can be established using one of the IP addresses, the internal available CN list is updated. Then, connections are established based on the CN list instead of the IP addresses in the JDBC connection string.

Suggestion: The recommended value is **true**.

refreshCNIpListTime

Principle: When a new connection is established, the system checks whether the interval between the current time and the last update time is greater than the value of this parameter. If yes, the system queries the available CN list in the database and updates the CN list of JDBC. If the interval exceeds the value of this parameter but no new connection is established, the system does not update the CN list.

Suggestion: The default value is **10s**. You are advised to adjust the value based on service requirements. This parameter must be used together with **autoBalance**.

fetchsize

Principle: After **fetchsize** is set to n and the database server executes a query, JDBC communicates with the server when the caller executes `resultset.next()`, fetches n pieces of data to the JDBC client, and returns the first piece of data to the caller. When the caller fetches the $(n+1)$ th data record, the caller fetches data from the database server again.

Function: Prevents the database from transmitting all results to the client at a time, which exhausts the memory resources of the client.

Suggestion: You are advised to set this parameter based on the amount of data queried by services and the memory of the client. When setting **fetchsize**, disable automatic commit (set **autocommit** to **false**). Otherwise, the setting of **fetchsize** does not take effect.

defaultRowFetchSize

Function: The default value of **fetchsize** is **0**. Setting **defaultRowFetchSize** will change the default value of **fetchsize**.

batchMode

Function: This parameter specifies whether to connect the database in batch mode. The default value is **on**. After the function is enabled, the batch update performance is improved, and the return value is also batch updated. For example, if three data records are inserted in batches, the return value is **[3,0,0]** when the function is enabled, and the return value is **[1,1,1]** when the function is disabled.

Suggestion: If the service framework (such as hibernate) checks the return value during batch update, you can set this parameter to solve the problem.

loginTimeout

Function: Controls the time for establishing a connection with the database. The time includes connectTimeout and socketTimeout. If the time elapsed exceeds the threshold, the connection exits. The calculation formula is as follows:

loginTimeout = **connectTimeout** x Number of nodes + Connection authentication time + Initialization statement execution time. The default value is 0.

Suggestion: After this parameter is set, an asynchronous thread is started each time a connection is established. If there are a large number of connections, the client pressure may increase. You can adjust the configuration based on service requirements.

NOTICE

This parameter sets the time for attempting to connect to all IP addresses in a list. If this parameter is set to a small value, the subsequent IP addresses in the list may fail to be connected. For example, if three IP addresses are set, **loginTimeout** is set to 5s, and it takes 5s to connect to the first two IP addresses, the third IP address cannot be connected.

cancelSignalTimeout

Function: Cancel messages may cause a block. This parameter controls **connectTimeout** and **socketTimeout** in a cancel command, in seconds. It is used to prevent timeout detection from being performed when the connection is canceled due to timeout.

Suggestion: The default value is 10s. You are advised to adjust the value based on service requirements.

connectTimeout

Function: Controls the socket timeout threshold during connection setup. In this case, this timeout threshold is the time when the JDBC connects to the database through the socket, not the time when the connection object is returned. If the time elapsed exceeds the threshold, JDBC searches for the next IP address.

Suggestion: This parameter determines the maximum timeout interval for establishing a TCP connection on each node. If a network fault occurs on a node, it attempts to connect to the node until the time specified by **connectTimeout** elapses, and then attempts to connect to the next node. Considering the network jitter and delay, you are advised to set this parameter to 3s.

socketTimeout

Function: Controls the timeout threshold of socket operations. If the time of executing service statements or reading data streams from the network exceeds the threshold (that is, when the statement execution time exceeds the specified threshold and no data is returned), the connection is interrupted.

Suggestion: This parameter specifies the maximum execution time of a single SQL statement. If the execution time of a single SQL statement exceeds the value of

this parameter, an error is reported and the statement exits. You are advised to set this parameter based on service characteristics. If this parameter is not set, the default value **0** is used, indicating that the execution of SQL statement does not time out.

socketTimeoutInConnecting

Function: Controls the socket operation timeout value during connection establishment. If the time of reading data streams from the network exceeds the threshold, it attempts to search for the next node for connection.

Suggestion: This parameter affects only the socket timeout value during the connection establishment. If this parameter is not set, the default value **5s** is used.

autosave

Function: If the value is **always**, you can set a savepoint before each statement in a transaction. If an error is reported during statement execution in a transaction, the system returns to the latest savepoint. In this way, subsequent statements in the transaction can be properly executed and committed. The default value is **never**.

Suggestion: You are advised not to set this parameter to avoid severe performance deterioration.

currentSchema

Function: Specifies the schema of the current connection. If this parameter is not set, the default schema is the username used for the connection.

Suggestion: You are advised to set this parameter to the schema where the service data is located. If the schema name contains special characters except letters, digits, and underscores (`_`), you are advised to enclose the schema name in quotation marks. Note that the schema name is case sensitive after quotation marks are added. If multiple schemas need to be configured, separate them with commas (`,`). Schemas containing special characters also need to be enclosed in quotation marks.

prepareThreshold

Function: The default value is **5**. If an SQL statement is executed for multiple consecutive times in a session and the number of execution times specified by **prepareThreshold** is reached, JDBC does not send the PARSE command to the SQL statement but caches the SQL statement to improve the execution speed.

Suggestion: The default value is **5**. Adjust the value based on service requirements.

preparedStatementCacheQueries

Function: Specifies the number of queries cached in each connection. The default value is **256**. If more than 256 different queries are used in the `prepareStatement()` call, the least recently used query cache will be discarded.

Suggestion: The default value is **256**. Adjust the value based on service requirements. This parameter is used together with **prepareThreshold**.

blobMode

Function: Sets the **setBinaryStream** method to assign values to different types of data. The value **on** indicates that values are assigned to BLOB data. The value **off** indicates that values are assigned to bytea data. The default value is **on**. For example, you can assign values to parameters in the **preparestatement** and **callablestatement** objects.

Suggestion: The default value is **true**.

setAutocommit

Function: If the value is **true**, a transaction is automatically started when each statement is executed. After the execution is complete, the transaction is automatically committed. That is, each statement is a transaction. If the value is **false**, a transaction is automatically started. However, you need to manually commit the transaction.

Suggestion: Adjust the value based on service characteristics. If autocommit needs to be disabled for performance or other purposes, the application must ensure that transactions can be committed. For example, explicitly commit translations after specifying service SQL statements. Particularly, ensure that all transactions are committed before the client exits.

5.3.17 FAQs

5.3.17.1 Incorrect batchMode Settings

Symptom

Set the URL parameters **batchMode** to **on** and **reWriteBatchedInserts** to **true**, and use JDBC to insert data in batches. As a result, an exception is thrown, indicating that the number of bound parameters is inconsistent with the number of parameters required by the statement.

```
bind message supplies * parameters, but prepared statement "" requires *
```

Example 1:

```
// conn is a created connection object. The URL parameters for creating the connection contain
// &batchMode=on&reWriteBatchedInserts=true.
// Bind parameters in batches and then execute the statement. The number of bound parameters does not
// match the number of columns in the rewritten INSERT statement. As a result, an exception is thrown.
// java.sql.BatchUpdateException: bind message supplies 3 parameters, but prepared statement "" requires 6
PreparedStatement stmt = conn.prepareStatement("insert into test_tbl values (?, ?, ?)");

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();
```

```
stmt.setInt(1, 1);  
stmt.setString(2, "aaa");  
stmt.setString(3, "bbb");  
stmt.addBatch();  
  
stmt.executeBatch();
```

Cause Analysis

When **reWriteBatchedInserts** is set to **true**, the batch statement combines multiple SQL statements into one. As a result, the number of reserved parameter columns in the statement changes. If **batchMode** is set to **on**, parameters are bound based on the SQL statements before combination. As a result, the number of bound parameters is inconsistent with the number of parameters required by the statement.

Solution

If **reWriteBatchedInserts** is set to **true**, set **batchMode** to **off**.

5.3.17.2 Error Is Reported When Verification Is Enabled for Data Insertion in the Hibernate Framework

Symptom

The customer migrates data from the ORA-compatible database to GaussDB. The table structure is migrated using the DRS tool. After the migration, the original service code of the customer is unavailable, and an error is reported when the Hibernate framework verifies the table structure.

```
Schema-validation: wrong column type encountered in column [execute_time] in table [abnormal_event];  
found [int8 (Types#BIGINT)], but expecting [int4 (Types#INTEGER)]
```

Example:

- The structure of the **Student** table in the ORA-compatible database is as follows:
id number(15,0)
sid number(15,0)
age number(10,0)
- After GaussDB is migrated using DRS, the **Student** table structure is as follows:
id bigint
sid bigint
age Integer
- When the **Student** entity class information in the actual database is as follows:
Long id
Long sid
Long age -- An error is reported when the Hibernate framework verifies the table structure.

Configuration file **hibernate.cfg.xml**:

```
<hibernate-configuration>  
  <session-factory>  
    <!-- GaussDB connection information -->  
    <property name="connection.driver_class">org.postgresql.Driver</property>  
    <property name="connection.url">jdbc:postgresql://x.x.x.xx/postgres?currentSchema=public</  
property>
```

```
<property name="connection.username">xxxxxx</property>
<property name="connection.password">xxxxxx</property>

<!-- The following configurations are optional: -->

<!-- Specify whether to support dialects. -->
<!-- In pgSQL-compatible mode, the following configuration must exist: -->
<property name="dialect">org.hibernate.dialect.PostgreSQL92Dialect</property>
<!-- In ORA-compatible mode, you are advised to change the configuration as follows: -->
<!-- <property name="dialect">org.hibernate.dialect.OracleDialect</property>-->

<property name="met"></property>

<!-- Specify whether to print SQL statements when CURD is executed. -->
<property name="show_sql">true</property>
<!-- The table is created automatically. -->
<!-- <property name="hbm2ddl.auto">create</property>-->
<!-- Enable the verification when inserting data. -->
<property name="hbm2ddl.auto">validate</property>
<!-- Disable the verification. -->
<!-- <property name="hbm2ddl.auto">none</property>-->

<!-- Resource registration (entity class mapping file) -->
<mapping resource="student.xml"/>
</session-factory>
</hibernate-configuration>
```

Main function for inserting data:

```
// Create the object to be tested.
Student student = new Student();
student.setId(20L);
student.setAge(222L);
student.setSid(222L);

// Start a transaction and obtain data based on the session.
Configuration conf = new Configuration().configure();
SessionFactory sessionFactory = conf.buildSessionFactory();
Session session = sessionFactory.openSession();
Transaction transaction = session.beginTransaction();

// Save data using sessions.
session.save(student);

// Commit a transaction.
transaction.commit();

// After the operation is complete, close the session connection object.
session.close();
```

Cause Analysis

1. If the data can be successfully inserted into the ORA-compatible database and passes the verification: When verifying data, the Hibernate framework compares **TypeCode** of the inserted data type `java.lang.long` with that of the number type in the table structure. If they are inconsistent, the Hibernate framework compares **sqlType** of the inserted data of the long type with **Type** of the table structure and the long type is converted to number (19,0) (the mapping is maintained by the `org.hibernate.dialect.OracleDialect`). The type of the table structure is number, and number(19,0) starts with **number**. Therefore, the verification is successful. When the ORA-compatible database is used, the service code involves data of the integer type. You can use the long type in Java to insert the data.
2. If the GaussDB verification is different and the data is inserted successfully after the verification is disabled: When the Hibernate framework verifies the

inserted data, the service code is of the `java.lang.long` type, which corresponds to **TypeCode** of the table data type `bigint`. Therefore, no error is reported. If the table data type is `integer`, the system checks **TypeCode** of the `java.lang.long` type in the service code and compares it with that of the `integer` type in the table data. If they are inconsistent, the system converts the `long` type to `int8` based on the `org.hibernate.dialect.PostgreSQLDialect` mapping, the table data type `integer` is converted to `int4`, which cannot be matched. As a result, the verification fails. When GaussDB is used, the service code involves data of the `integer` type. Therefore, the Java `integer` corresponding to the table type must be used.

Solution

You can use the following methods to rectify the fault:

- Disable the verification function.
- Modify the service code at the customer side and use the corresponding Java `integer` for different table data types.

5.3.18 Mapping for JDBC Data Types

The index relationships among data types, Java variable types, and JDBC types are as follows:

Compatibility Mode	GaussDB Data Type	Java Variable Type	JDBC Type Index
ORA/MYSQL	oid	<code>java.lang.Long</code>	<code>java.sql.Types.BIGINT</code>
ORA/MYSQL	numeric	<code>java.math.BigDecimal</code>	<code>java.sql.Types.NUMERIC</code>
ORA/MYSQL	tinyint	<code>java.lang.Integer</code>	<code>java.sql.Types.TINYINT</code>
ORA/MYSQL	smallint	<code>java.lang.Integer</code>	<code>java.sql.Types.SMALLINT</code>
ORA/MYSQL	bigint	<code>java.lang.Long</code>	<code>java.sql.Types.BIGINT</code>
ORA/MYSQL	float4	<code>java.lang.Float</code>	<code>java.sql.Types.REAL</code>
ORA/MYSQL	float8	<code>java.lang.Double</code>	<code>java.sql.Types.DOUBLE</code>
ORA/MYSQL	char	<code>java.lang.String</code>	<code>java.sql.Types.CHAR</code>
ORA/MYSQL	character	<code>java.lang.String</code>	<code>java.sql.Types.CHAR</code>
ORA/MYSQL	bpchar	<code>java.lang.String</code>	<code>java.sql.Types.CHAR</code>
ORA/MYSQL	character varying	<code>java.lang.String</code>	<code>java.sql.Types.VARCHAR</code>
ORA/MYSQL	varchar	<code>java.lang.String</code>	<code>java.sql.Types.VARCHAR</code>
ORA/MYSQL	text	<code>java.lang.String</code>	<code>java.sql.Types.VARCHAR</code>
ORA/MYSQL	name	<code>java.lang.String</code>	<code>java.sql.Types.VARCHAR</code>

Compatibility Mode	GaussDB Data Type	Java Variable Type	JDBC Type Index
ORA/MYSQL	bytea	byte[]	java.sql.Types.BINARY
ORA/MYSQL	blob	java.sql.Blob	java.sql.Types.BLOB
ORA/MYSQL	clob	java.sql.Clob	java.sql.Types.CLOB
ORA/MYSQL	boolean	java.lang.Boolean	java.sql.Types.BIT
MYSQL	date	java.sql.Date	java.sql.Types.DATE
ORA/MYSQL	time	java.sql.Time	java.sql.Types.TIME
ORA/MYSQL	timetz	java.sql.Time	java.sql.Types.TIME
ORA/MYSQL	timestamp	java.sql.Timestamp	java.sql.Types.TIMESTAMP
ORA/MYSQL	smalldatetime	java.sql.Timestamp	java.sql.Types.TIMESTAMP
ORA/MYSQL	timestampz	java.sql.Timestamp	java.sql.Types.TIMESTAMP
ORA/MYSQL	refcursor	java.sql.ResultSet	java.sql.Types.REF_CURSOR -10

5.4 Development Based on ODBC

Open Database Connectivity (ODBC) is a Microsoft API for accessing databases based on the X/OPEN CLI. ODBC APIs alleviate applications from directly operating in databases, and enhance the database portability, extensibility, and maintainability.

Figure 5-2 shows the system structure of ODBC.

Figure 5-2 ODBC system structure

GaussDB supports ODBC 3.5 in the following environments.

Table 5-27 OSs Supported by ODBC

OS	Platform
EulerOS 2.5	x86_64
EulerOS 2.9	Arm64
EulerOS 2.10	x86_64
EulerOS 2.10	Arm64
Windows 7	x86_32
Windows 7	x86_64
Windows Server 2008	x86_32
Windows Server 2008	x86_64
Kylin V10	x86_64
Kylin V10	Arm64
UnionTech V20	x86_64
UnionTech V20	Arm64

The ODBC Driver Manager running on Unix or Linux can be unixODBC or iODBC. unixODBC-2.3.7 is used as the component for connecting to the database.

Windows has a native ODBC Driver Manager. You can locate **Data Sources (ODBC)** by choosing **Control Panel > Administrative Tools**.

 NOTE

The current database ODBC driver is based on an open-source version and may be incompatible with Huawei-developed data types such as tinyint, smalldatetime, and nvarchar2.

5.4.1 ODBC Packages, Dependent Libraries, and Header Files

ODBC Package for the Linux OS

Obtain the package from the release package **GaussDB-Kernel_Database version number_OS version number_64bit_Odbc.tar.gz**. In the Linux OS, header files (including **sql.h** and **sqlext.h**) and the library (**libodbc.so**) are required in application development. These header files and library can be obtained from the unixODBC-2.3.7 installation package.

ODBC Package for the Windows OS

Obtain the package from the release package **GaussDB-Kernel_Database version number_Windows_Odbc_X86.tar.gz** (32-bit) or **GaussDB-Kernel_Database version number_Windows_Odbc_X64.tar.gz** (64-bit). In the Windows OS, the required header files and library files are system-resident.

5.4.2 Development Process

Figure 5-3 ODBC-based application development process

APIs Involved in the Development Process

Table 5-28 API description

Function	API
Allocate a handle.	SQLAllocHandle is a generic function for allocating a handle. It can replace the following functions: <ul style="list-style-type: none"> • SQLAllocEnv: allocates an environment handle. • SQLAllocConnect: allocates a connection handle. • SQLAllocStmt: allocates a statement handle.
Set environment attributes.	SQLSetEnvAttr
Set connection attributes.	SQLSetConnectAttr
Set statement attributes.	SQLSetStmtAttr
Connect to a data source.	SQLConnect
Bind a buffer to a column in the result set.	SQLBindCol
Bind the parameter marker of an SQL statement to a buffer.	SQLBindParameter
Return the error message of the last operation.	SQLGetDiagRec
Prepare an SQL statement for execution.	SQLPrepare
Run a prepared SQL statement.	SQLExecute
Run an SQL statement directly.	SQLExecDirect
Fetch the next row (or rows) from the result set.	SQLFetch
Return data in a column of the result set.	SQLGetData
Get the column information from a result set.	SQLColAttribute
Disconnect from a data source.	SQLDisconnect

Function	API
Release a handle.	<p>SQLFreeHandle is a generic function for releasing a handle. It can replace the following functions:</p> <ul style="list-style-type: none"> • SQLFreeEnv: releases an environment handle. • SQLFreeConnect: releases a connection handle. • SQLFreeStmt: releases a statement handle.

 NOTE

- If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. If one of the statements fails, the entire request will be rolled back.
- ODBC connects applications to the database and delivers the SQL statements sent by an application to the database. It does not parse the SQL syntax. Therefore, when confidential information (such as a plaintext password) is written into the SQL statement sent by an application, the confidential information is exposed in the driver log.

5.4.3 Configuring a Data Source in the Linux OS

The ODBC DRIVER (**psqlodbcw.so**) provided by GaussDB can be used after it has been configured in a data source. To configure a data source, you must configure the **odbc.ini** and **odbcinst.ini** files on the server. The two files are generated during the unixODBC compilation and installation, and are saved in the **/usr/local/etc** directory by default.

Procedure

Step 1 Obtain the source code package of unixODBC by clicking the following link:

Download address: <https://gitee.com/src-openeuler/unixODBC/blob/openEuler-22.03-LTS-SP1/unixODBC-2.3.7.tar.gz>.

After the download, verify the integrity based on the integrity verification algorithm provided by the community.

Step 2 Install unixODBC. It does not matter if unixODBC of another version has been installed.

For example, install unixODBC-2.3.7.

```
tar zxvf unixODBC-2.3.7.tar.gz
cd unixODBC-2.3.7
```

```
./configure --enable-gui=no # To perform compilation on an Arm server, add the configure parameter --  
build=aarch64-unknown-linux-gnu.  
make  
# The installation may require root permissions.  
make install
```

 NOTE

- Currently, unixODBC-2.2.1 is not supported.
- By default, it is installed in the **/usr/local** directory. The data source file is generated in the **/usr/local/etc** directory, and the library file is generated in the **/usr/local/lib** directory.
- You can compile unixODBC with the **--enable-fastvalidate=yes** option to achieve higher performance. However, this option may cause an application that passes an invalid handle to the ODBC API to fail instead of returning an SQL_INVALID_HANDLE error.

Step 3 Replace the GaussDB client driver.

Decompress **GaussDB-Kernel_Database version number_OS version number_64bit_Odbc.tar.gz**. After the decompression, the **lib** and **odbc** folders are generated. The **odbc** folder contains another **lib** folder. Copy all dynamic libraries in the **/lib** and **/odbc/lib** folders to the **/usr/local/lib** directory.

Step 4 Configure a data source.

1. Configure the ODBC driver file.

Add the following content to the **/usr/local/etc/odbcinst.ini** file:

```
[GaussMPP]
Driver64=/usr/local/lib/psqlodbcw.so
setup=/usr/local/lib/psqlodbcw.so
```

For descriptions of the parameters in the **odbcinst.ini** file, see [Table 5-29](#).

Table 5-29 odbcinst.ini configuration parameters

Parameter	Description	Example
[DriverName]	Driver name, corresponding to Driver in DSN.	[DRIVER_N]
Driver64	Path of the dynamic driver library.	Driver64=/usr/local/lib/psqlodbcw.so
setup	Driver installation path, which is the same as the dynamic library path in Driver64.	setup=/usr/local/lib/psqlodbcw.so

2. Configure the data source file.

Add the following content to the **/usr/local/etc/odbc.ini** file:

```
[gaussdb]
Driver=GaussMPP
Servername=127.0.0.1 (database server IP address)
Database=postgres (database name)
Username=omm (database username)
Password= (database user password)
Port=8000 (database listening port)
Sslmode = allow
```

For descriptions of the parameters in the **odbc.ini** file, see [Table 5-30](#).

Table 5-30 odbc.ini configuration parameters

Parameter	Description	Example
[DSN]	Data source name.	[gaussdb]
Driver	Driver name, corresponding to DriverName in odbcinst.ini .	Driver = DRIVER_N
Servename	Server IP address. Multiple IP addresses can be configured.	Servename=127.0.0.1
Database	Name of the database to connect.	Database = postgres
Username	Database username.	Username=omm

Parameter	Description	Example
Password	<p>Database user password.</p> <p>NOTE After a user establishes a connection, the ODBC driver automatically clears their password stored in memory.</p> <p>However, if this parameter is configured, unixODBC will cache data source files, which may cause the password to be stored in the memory for a long time.</p> <p>When you connect to an application, you are advised to send your password through an API instead of writing it in a data source configuration file. After the connection has been established, immediately clear the memory segment where your password is stored.</p> <p>CAUTION The password in the configuration file must comply with the following HTTP rules:</p> <ol style="list-style-type: none"> 1. Characters must comply with the URL encoding specifications. For example, the exclamation mark (!) must be written as %21, and the percent sign (%) must be written as %25. Therefore, pay attention to the characters. 2. A plus sign (+) will be replaced by a space. 	Password=*****

Parameter	Description	Example
Port	Port number of the server. When load balancing is enabled, multiple port numbers can be configured and must correspond to multiple IP addresses. If multiple IP addresses are configured and only one port number is configured when load balancing is enabled, all IP addresses share the same port number by default, that is, the configured port number.	Port=8000
Sslmode	Specifies whether to enable SSL.	Sslmode = allow
Debug	If this parameter is set to 1 , the mylog file of the PostgreSQL ODBC driver will be printed. The directory generated for storing logs is /tmp/ . If this parameter is set to 0 , no directory is generated.	Debug = 1
UseServerSidePrepare	Specifies whether to enable the extended query protocol for the database. The value can be 0 or 1 . The default value is 1 , indicating that the extended query protocol is enabled.	UseServerSidePrepare = 1

Parameter	Description	Example
UseBatchProtocol	<p>Specifies whether to enable the batch query protocol. If it is enabled, DML performance can be improved. The value can be 0 or 1 (default).</p> <ul style="list-style-type: none"> - If this parameter is set to 0, the batch query protocol is disabled (mainly for communication with earlier database versions). - If this parameter is set to 1 and support_batch_bind is set to on, the batch query protocol is enabled. 	UseBatchProtocol = 1
ForExtensionConnector	<p>This parameter specifies whether the savepoint is sent. The default value is 1. If the value is 0, the savepoint is sent. If the value is 1, the savepoint is not sent.</p>	ForExtensionConnector = 1
ConnectionExtraInfo	<p>Specifies whether to display the driver deployment path and process owner in the GUC parameter connection_info.</p> <p>NOTE The default value is 0. If this parameter is set to 1, the ODBC driver reports the driver deployment path and process owner to the database and displays the information in the GUC parameter connection_info. In this case, you can query the information from PG_STAT_ACTIVITY or PGXC_STAT_ACTIVITY.</p>	ConnectionExtraInfo = 1

Parameter	Description	Example
BoolAsChar	If this parameter is set to Yes , the Boolean value is mapped to the SQL_CHAR type. If this parameter is not set, the value is mapped to the SQL_BIT type.	BoolsAsChar = Yes
RowVersioning	When an attempt is made to update a row of data, setting this parameter to Yes allows the application to detect whether the data has been modified by other users.	RowVersioning = Yes
ShowSystemTables	By default, the driver regards the system table as a common SQL table.	ShowSystemTables = Yes
AutoBalance	Specifies whether ODBC controls load balancing. The default value is 0 , indicating that the function is disabled. 1 indicates that the function is enabled. That is, all values except 1 do not take effect.	AutoBalance=1
RefreshCNListTime	Specifies the interval for refreshing the CN list. The value is an integer and the default value is 10 . This parameter can be configured when load balancing is enabled.	RefreshCNListTime=5

Parameter	Description	Example
Priority	<p>This parameter can be configured when load balancing is enabled. The default value is 0, indicating that the function is disabled. 1 indicates that the function is enabled. That is, all values except 1 do not take effect. When Priority is enabled, all connections initiated by applications are preferentially sent to the CNs configured in the configuration file. If all the configured CNs are unavailable, the connections are sent to the remaining CNs.</p>	Priority=1
UsingEip	<p>This parameter can be configured when load balancing is enabled. The default value is 0, indicating that the function is disabled. 1 indicates that the function is enabled. That is, all values except 1 do not take effect. This value specifies whether to use an elastic IP address for load balancing. If UsingEip is enabled, the elastic IP address is used for load balancing. If UsingEip is disabled, the data IP address is used for load balancing.</p>	UsingEip=1

Parameter	Description	Example
MaxCacheQueries	<p>Controls the number of precompiled statements cached for each connection. If this parameter is set to 0, the precompiled statement cache pool is disabled on the client. If this parameter is set to a value greater than 4096, the value 4096 is used. If the number of executed statements exceeds the upper limit specified by MaxCacheQueries, the least recently used statements are eliminated. The default value is 0.</p>	MaxCacheQueries=128
MaxCacheSizeMiB	<p>Controls the total size of precompiled statements cached for each connection. This parameter takes effect when the value of MaxCacheQueries is greater than 0. If the total size of cached statements is greater than the value of MaxCacheSizeMiB, the least recently used statements are eliminated. If this parameter is set to a value greater than 4096, the value 4096 is used. The unit is MB. The default value is 1.</p>	MaxCacheSizeMiB=10

Parameter	Description	Example
TcpUserTimeout	Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an OS that supports the TCP_USER_TIMEOUT socket option. 0 indicates that the default value is used. Ignore this parameter for Unix-domain connections. The unit is millisecond. The default value is 0 .	TcpUserTimeout=5000

Table 3 sslmode options describes the valid values of **Sslmode**.

Table 5-31 sslmode options

sslmode	Whether SSL Encryption Is Enabled	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required and whether the database has a trusted certificate will be verified.

sslmode	Whether SSL Encryption Is Enabled	Description
verify-full	Yes	<p>SSL connection is required. In addition to the check scope specified by verify-ca, the system checks whether the name of the host where the database resides is the same as that in the certificate. If they are different, modify the /etc/hosts file as user root and add the IP address and host name of the connected database node to the file.</p> <p>NOTE This mode does not support the default certificate of the product. Contact the administrator to generate a certificate.</p>

Step 5 Enable the SSL mode. For details, contact the administrator.

Step 6 Configure the database server. For details, contact the administrator.

Step 7 Configure the environment variables on the client.

```
vim ~/.bashrc
```

Add the following information to the configuration file:

```
export LD_LIBRARY_PATH=/usr/local/lib/:$LD_LIBRARY_PATH
export ODBC_SYSINI=/usr/local/etc
export ODBCINI=/usr/local/etc/odbc.ini
```

Step 8 Make the setting take effect.

```
source ~/.bashrc
```

----End

Verifying the Data Source Configuration

After the installation, the generated binary file is stored in the **/usr/bin** directory. You can run the **isql -v gaussdb** command (*gaussdb* is the data source name).

- If the following information is displayed, the configuration is correct and the connection succeeds:

```
+-----+
| Connected!          |
|                    |
| sql-statement      |
| help [tablename]   |
| quit              |
|                    |
+-----+
```

- If error information is displayed, the configuration is incorrect. Check the configuration.
- In a cluster environment, you need to copy and configure the unixODBC file on all nodes.

FAQs

- [UnixODBC][Driver Manager]Can't open lib 'xxx/xxx/psqlodbcw.so' : file not found.
Possible causes:
 - The path configured in the **odbcinst.ini** file is incorrect.
Run **ls** to check the path in the error information, ensuring that the **psqlodbcw.so** file exists and you have execution permissions on it.
 - The dependent library of **psqlodbcw.so** does not exist or is not in system environment variables.
Run the **ldd** command to check the path in the error information. If the unixODBC library such as **libodbc.so.1** is missing, reconfigure unixODBC according to the procedure, ensure that the **lib** directory in the installation path is added to *LD_LIBRARY_PATH*. If the problem persists after reinstallation, manually copy the contents in the **unixodbc/lib** directory of the database installation package to the **lib** directory in the installation path of the unixODBC. If other libraries do not exist, add the **lib** directory under the ODBC driver package to *LD_LIBRARY_PATH*.
- [UnixODBC]connect to server failed: no such file or directory
Possible causes:
 - An incorrect or unreachable database IP address or port was configured.
Check the **Servername** and **Port** configuration items in data sources.
 - Server monitoring is improper.
If **Servername** and **Port** are correctly configured, ensure the proper network adapter and port are monitored by following the database server configurations in the procedure in this section.
 - Firewall and network gatekeeper settings are improper.
Check firewall settings, and ensure that the database communication port is trusted.
Check to ensure network gatekeeper settings are proper (if any).
- [unixODBC]The password-stored method is not supported.
Possible causes:
The **sslmode** configuration item is not configured in the data sources.
Solution:
Set the configuration item to **allow** or a higher level. For details, see [Table 5-31](#).
- Server common name "xxxx" does not match host name "xxxxx"
Possible causes:
When **verify-full** is used for SSL encryption, the driver checks whether the host name in certificates is the same as the actual one.
Solution:
To solve this problem, use **verify-ca** to stop checking host names, or generate a set of server certificates containing the actual host names.
- Driver's SQLAllocHandle on SQL_HANDLE_DBC failed
Possible causes:

The executable file (such as the **isql** tool of unixODBC) and the database driver (**psqlodbcw.so**) depend on different library versions of ODBC, such as **libodbc.so.1** and **libodbc.so.2**. You can verify this problem by using the following method:

```
ldd `which isql` | grep odbc  
ldd psqlodbcw.so | grep odbc
```

If the suffix digits of the outputs **libodbc.so** are different or indicate different physical disk files, this problem exists. Both **isql** and **psqlodbcw.so** require **libodbc.so** to be loaded. If they load different physical files, two sets of function lists with the same name are generated in a visible domain (the **libodbc.so.*** function export lists of unixODBC are the same). This results in conflicts and the database driver cannot be loaded.

Solution:

Uninstall the unnecessary unixODBC, such as **libodbc.so.2**, and create a soft link with the same name and the **.so.2** suffix for the remaining **libodbc.so.1** library.

- **FATAL: Forbid remote connection with trust method!**
For security purposes, the database CN forbids access from other nodes in the cluster without authentication.
To access the CN from inside the cluster, deploy the ODBC program on the host where the CN is located and use 127.0.0.1 as the server address. It is recommended that the service system be deployed outside the cluster. Otherwise, the database performance may be affected.
- **[unixODBC][Driver Manager]Invalid attribute value**
This problem occurs when you use SQL on other GaussDB. The possible cause is that the unixODBC version is not the recommended one. You are advised to run the **odbcinst --version** command to check the unixODBC version.
- **authentication method 10 not supported.**
If this error occurs on an open-source client, the cause may be:
The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

NOTE

- The database stores the hashes of user passwords instead of actual passwords.
- If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
- An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the source version will only have SHA-256 hashes and not support MD5 authentication.
- The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

To solve this problem, you can update the user password (see [ALTER USER](#)) or create a user (see [CREATE USER](#)) having the same permissions as the faulty user.

- **unsupported frontend protocol 3.51: server supports 1.0 to 3.0**
The database version is too early or the database is an open-source database. Use the driver of the required version to connect to the database.
- **FATAL: GSS authentication method is not allowed because XXXX user password is not disabled.**

In **pg_hba.conf** of the target CN, the authentication mode is set to **gss** for authenticating the IP address of the current client. However, this authentication algorithm cannot authenticate clients. Change the authentication algorithm to **sha256** and try again. For details, see [Step 6](#).

- **isql: error while loading shared libraries:xxx**
The dynamic library does not exist in the environment. You need to install the corresponding library.

5.4.4 Configuring a Data Source in the Windows OS

Configure an ODBC data source using the ODBC data source manager preinstalled in the Windows OS.

Procedure

Step 1 Replace the GaussDB client driver.

Decompress the **GaussDB-Kernel_Database version number_Windows_Odbc_X64.tar.gz** (64-bit) driver package or **GaussDB-Kernel_Database version number_Windows_Odbc_X86.tar.gz** (32-bit) driver package, and click **psqlodbc.exe** to install the driver.

Step 2 Open the driver manager.

When configuring the data source, use the ODBC driver manager corresponding to the ODBC version. If the 64-bit ODBC driver is used, the 64-bit ODBC driver manager must be used. Assume that the OS is installed on drive C (if the OS is installed on another drive, change the path accordingly):

- If you want to use 32-bit ODBC driver manager in a 64-bit OS, open **C:\Windows\SysWOW64\odbcad32.exe**. Do not choose **Control Panel > Administrative Tools > Data Sources (ODBC)**.

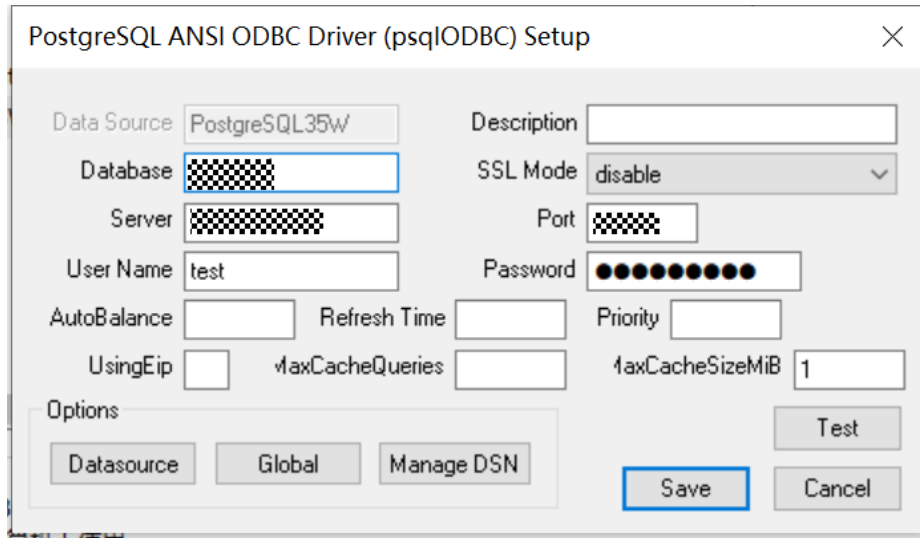

NOTE

WoW64 is short for Windows 32-bit on Windows 64-bit. **C:\Windows\SysWOW64** stores the 32-bit environment on a 64-bit system. **C:\Windows\System32** stores the environment consistent with the current OS. For technical details, see Windows technical documents.

- For a 32-bit OS, open **C:\Windows\System32\odbcad32.exe** or choose **Computer > Control Panel > Administrative Tools > Data Sources (ODBC)** to open Driver Manager.
- For a 64-bit OS, choose **Control Panel > Administrative Tools > Data Sources (ODBC)** to enable driver management.

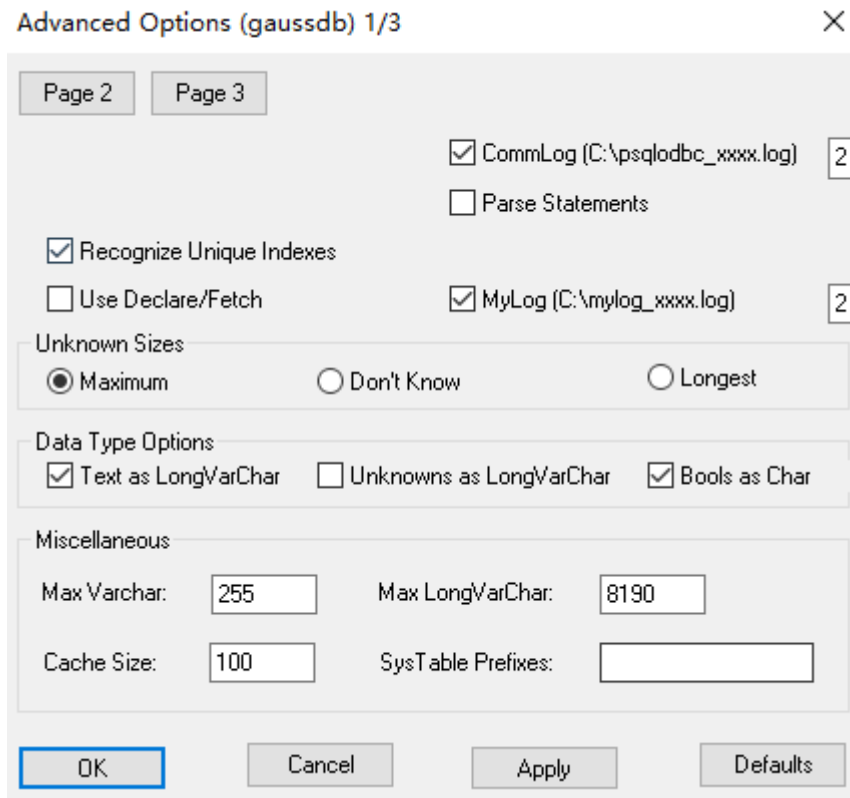

Step 3 Configure a data source.

On the **User DSN** tab, click **Add** and choose **PostgreSQL Unicode** for setup.

For details about the parameters, see [Configuring a Data Source in the Linux OS](#).

You can click **Datasource** to configure whether to print logs.

NOTICE

The entered username and password will be recorded in the Windows registry and you do not need to enter them again when connecting to the database next time. For security purposes, you are advised to delete sensitive information before clicking **Save** and enter the required username and password again when using ODBC APIs to connect to the database.

Step 4 Enable the SSL mode.

Change the value of **SSL Mode** in Step 2 to **require**.

Table 5-32 sslmode options

sslmode	Whether SSL Encryption Is Enabled	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required and whether the database has a trusted certificate will be verified. Currently, Windows ODBC does not support the certificate-based authentication.
verify-full	Yes	SSL connection is required. In addition to the check scope specified by verify-ca , the system checks whether the name of the host where the database resides is the same as that in the certificate. Currently, Windows ODBC does not support the certificate-based authentication.

Step 5 Configure a GaussDB server. For details, contact the administrator.**Step 6** Restart the cluster.

```
gs_om -t stop  
gs_om -t start
```

----End

Verifying the Data Source Configuration

Click **Test**.

- If the following information is displayed, the configuration is correct and the connection succeeds.

- If error information is displayed, the configuration is incorrect. Check the configuration.

FAQs

- connect to server failed: no such file or directory

Possible causes:

- An incorrect or unreachable database IP address or port was configured. Check the **Servername** and **Port** configuration items in data sources.

- Server monitoring is improper.

If **Servername** and **Port** are correctly configured, ensure the proper network adapter and port are monitored by following the database server configurations in the procedure in this section.

- Firewall and network gatekeeper settings are improper.

Check firewall settings, and ensure that the database communication port is trusted.

Check to ensure network gatekeeper settings are proper (if any).

- The password-stored method is not supported.

Possible causes:

sslmode is not configured for the data source. Set this configuration item to **allow** or a higher level to enable SSL connections. For details on **sslmode**, see [Table 5-32](#).

- authentication method 10 not supported.

If this error occurs on an open-source client, the cause may be:

The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

NOTE

- The database stores the hashes of user passwords instead of actual passwords.
- If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
- An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the source version will only have SHA-256 hashes and not support MD5 authentication.
- The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

To solve this problem, you can update the user password (see [ALTER USER](#)) or create a user (see [CREATE USER](#)) having the same permissions as the faulty user.

- unsupported frontend protocol 3.51: server supports 1.0 to 3.0

The database version is too early or the database is an open-source database. Use the driver of the required version to connect to the database.

- FATAL: GSS authentication method is not allowed because XXXX user password is not disabled.

In `pg_hba.conf` of the target CN, the authentication mode is set to `gss` for authenticating the IP address of the current client. However, this authentication algorithm cannot authenticate clients. Change the authentication algorithm to `sha256` and try again. For details, see [Step 5](#).

5.4.5 Example: Common Functions and Batch Binding

NOTE

- Example of the command for compiling ODBC application code in Windows:

```
gcc odbctest.c -o odbctest -lodb32
```

Run the following command:

```
./odbctest.exe
```
- Example of the command for compiling ODBC application code in Linux:

```
gcc odbctest.c -o odbctest -lodb
```

Run the following command:

```
./odbctest
```
- If `sql.h` or API cannot be found during compilation, manually connect to the header file and dynamic library of unixODBC.

```
gcc -I /home/omm/unixodbc/include -L /home/omm/unixodbc/lib odbctest.c -o odbctest -lodb
```

Code for Common Functions

```
// The example shows how to obtain data from GaussDB through ODBC.
// DBtest.c (compile with: libodbc.so)
#ifdef WIN32
#include <windows.h>
#else
#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
SQLHENV     V_OD_Env;    // Handle ODBC environment
```

```
SQLHSTMT V_OD_hstmt; // Handle statement
SQLHDBC V_OD_hdbc; // Handle connection
char typename[100];
SQLINTEGER value = 100;
SQLINTEGER V_OD_erg,V_OD_buffer,V_OD_err,V_OD_id;
int main(int argc,char *argv[])
{
    // 1. Allocate an environment handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_ENV,SQL_NULL_HANDLE,&V_OD_Env);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        printf("Error AllocHandle\n");
        exit(0);
    }
    // 2. Set environment attributes (version information).
    SQLSetEnvAttr(V_OD_Env, SQL_ATTR_ODBC_VERSION, (void*)SQL_OV_ODBC3, 0);
    // 3. Allocate a connection handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_DBC, V_OD_Env, &V_OD_hdbc);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
        exit(0);
    }
    // In this example, the username and password are stored in environment variables. Before running this
    // example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
    // environment (set the environment variable names based on the actual situation).
    char *userName;
    userName = getenv("EXAMPLE_USERNAME_ENV");
    char *password;
    password = getenv("EXAMPLE_PASSWORD_ENV");
    // 4. Set connection attributes.
    SQLSetConnectAttr(V_OD_hdbc, SQL_ATTR_AUTOCOMMIT, (SQLPOINTER *)SQL_AUTOCOMMIT_ON,
0);
    // 5. Connect to the data source. userName and password indicate the username and password for
    // connecting to the database, respectively.
    // If the username and password have been set in the odbc.ini file, you can retain "". However, you are
    // advised not to do so because the username and password will be disclosed if the permission for odbc.ini is
    // abused.
    V_OD_erg = SQLConnect(V_OD_hdbc, (SQLCHAR*) "gaussdb", SQL_NTS,
(SQLCHAR*) userName, SQL_NTS, (SQLCHAR*) password, SQL_NTS);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        printf("Error SQLConnect %d\n",V_OD_erg);
        SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
        exit(0);
    }

}
```

5.4.6 Typical Application Scenarios and Configurations

Log Diagnosis

ODBC logs are classified into unixODBC driver manager logs and psqLODBC driver logs. The former is used to trace whether the application API is successfully executed, and the latter is used to locate problems based on DFX logs generated during underlying implementation.

The unixODBC log needs to be configured in the **odbcinst.ini** file:

```
[ODBC]
Trace=Yes
TraceFile=/path/to/odbctrace.log

[GaussMPP]
Driver64=/usr/local/lib/psqlodbcw.so
setup=/usr/local/lib/psqlodbcw.so
```

For gsqLODBC logs, you only need to add the following content to **odbc.ini**:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 (database server IP address)
...
Debug=1 (Enable the debug log function of the driver.)
```

NOTE

The unixODBC logs are generated in the path configured by **TraceFile**. The psqLODBC generates the **mylog_XXX.log** file in the **/tmp/** directory.

High Performance

If a large amount of data needs to be inserted, you are advised to perform the following operations:

- Set **UseBatchProtocol** to **1** in **odbc.ini** and set **support_batch_bind** in the database.

- The ODBC program binding type must be the same as that in the database.
- The character set of the client is the same as that of the database.
- The transaction is committed manually.

odbc.ini configuration file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 (database server IP address)
...
UseBatchProtocol=1 (enabled by default)
ConnSettings=set client_encoding=UTF8 (Set the character code on the client to be the same as that on the server.)
```

Binding type case:

```
#ifdef WIN32
#include <windows.h>
#endif
#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
#include <string.h>

{"18446744073709551615", "12345"},
{"-1", "12345"},
{"4294967295", "12345"},
{"-1", "-1"},
{"65535", "65535"},
{"-1", "-1"},
{"255", "255"},
};

RETURN_IF_NOT_SUCCESS(execute_cmd(sql_select));
while ( SQL_NO_DATA != SQLFetch(h_stmt))
{
    RETURN_IF_NOT_SUCCESS_I(i, SQLGetData(h_stmt, 1, SQL_C_CHAR, &getValue[0],
MESSAGE_BUFFER_LEN, NULL));
    RETURN_IF_NOT_SUCCESS_I(i, SQLGetData(h_stmt, 2, SQL_C_CHAR, &getValue[1],
MESSAGE_BUFFER_LEN, NULL));

    //RETURN_IF_NOT_STRCMP_I(i, expectValue[i][0], getValue[0]);
    //RETURN_IF_NOT_STRCMP_I(i, expectValue[i][1], getValue[1]);
    i++;
}

RETURN_IF_NOT_SUCCESS(SQLRowCount(h_stmt, &RowCount));
RETURN_IF_NOT(i, RowCount);
SQLCloseCursor(h_stmt);
/* Final step. Delete the table and restore the environment. */
RETURN_IF_NOT_SUCCESS(execute_cmd(sql_drop));
```

```
end_unit_test();  
}
```

NOTE

In the preceding example, the **number** column is defined. When the SQLBindParameter API is called, the performance of binding SQL_NUMERIC is higher than that of SQL_LONG. If char is used, the data type needs to be converted when data is inserted to the database server, causing a performance bottleneck.

Load Balancing

Load balancing can be enabled when there are a large number of concurrent applications.

- Load balancing is to randomly distribute concurrent connections to all CNs to prevent a single CN from being overloaded and improve performance.
- Set **AutoBalance** to **1** to enable load balancing.
- Set **RefreshCNListTime** to **5** as required. The default refresh interval is 10 seconds.
- Set **Priority** to **1** as required. In this case, concurrent connections are preferentially sent to the CNs configured in the configuration file. If all the configured CNs are unavailable, the connections are distributed to the remaining CNs.

Example:

Six CNs, namely, CN1, CN2, CN3, CN4, CN5, and CN6, are configured in the cluster, and four CNs, namely, CN1, CN2, CN3, and CN4, are configured in the configuration file.

Example content of the **odbc.ini** file:

```
[gaussdb]  
Driver=GaussMPP  
Servername=10.145.130.26,10.145.130.27,10.145.130.28,10.145.130.29 (IP address of the database server)  
Database=postgres (database name)  
Username=omm (database username)  
Password= (database user password)  
Port=8000 (database listening port)  
Sslmode=allow  
AutoBalance=1  
RefreshCNListTime=3  
Priority=1
```

If the configuration file and cluster environment are the same as those in the example, concurrent connections are randomly and evenly distributed to CN1, CN2, CN3, and CN4. When CN1, CN2, CN3, and CN4 are all unavailable, concurrent connections are randomly and evenly sent to CN5 and CN6. If any CN among CN1, CN2, CN3, and CN4 becomes available, the connections are not sent to CN5 and CN6 but to the available CN.

5.4.7 ODBC Interface Reference

The ODBC interface is a set of API functions provided to users. This chapter describes its common interfaces. For details on other interfaces, see "ODBC Programmer's Reference" at MSDN ([https://msdn.microsoft.com/en-us/library/windows/desktop/ms714177\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/windows/desktop/ms714177(v=vs.85).aspx)).

5.4.7.1 SQLAllocEnv

In ODBC 3.x, SQLAllocEnv (an ODBC 2.x function) was deprecated and replaced by SQLAllocHandle. For details, see [SQLAllocHandle](#).

5.4.7.2 SQLAllocConnect

In ODBC 3.x, SQLAllocConnect (an ODBC 2.x function) was deprecated and replaced by SQLAllocHandle. For details, see [SQLAllocHandle](#).

5.4.7.3 SQLAllocHandle

Description

Allocates environment, connection, statement, or descriptor handles. This function replaces the deprecated ODBC 2.x functions SQLAllocEnv, SQLAllocConnect, and SQLAllocStmt.

Prototype

```
SQLRETURN SQLAllocHandle(SQLSMALLINT HandleType,
                        SQLHANDLE InputHandle,
                        SQLHANDLE *OutputHandlePtr);
```

Parameters

Table 5-33 SQLAllocHandle parameters

Keyword	Description
HandleType	<p>Type of handle to be allocated by SQLAllocHandle. The value must be one of the following:</p> <ul style="list-style-type: none"> • SQL_HANDLE_ENV (environment handle) • SQL_HANDLE_DBC (connection handle) • SQL_HANDLE_STMT (statement handle) • SQL_HANDLE_DESC (descriptor handle) <p>The handle application sequence is: environment handle > connection handle > statement handle. The handle applied later depends on the handle applied prior to it.</p>
InputHandle	<p>Existing handle to use as a context for the new handle being allocated.</p> <ul style="list-style-type: none"> • If HandleType is set to SQL_HANDLE_ENV, this parameter is set to SQL_NULL_HANDLE. • If HandleType is set to SQL_HANDLE_DBC, this parameter value must be an environment handle. • If HandleType is set to SQL_HANDLE_STMT or SQL_HANDLE_DESC, this parameter value must be a connection handle.

Keyword	Description
OutputHandlePtr	Output parameter: Pointer to a buffer that stores the returned handle in the newly allocated data structure.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If `SQLAllocHandle` returns **SQL_ERROR** when it is used to allocate a non-environment handle, it sets `OutputHandlePtr` to **SQL_NULL_HDBC**, **SQL_NULL_HSTMT**, or **SQL_NULL_HDESC**. The application can then call [SQLGetDiagRec](#), with `HandleType` and `Handle` set to the value of `InputHandle`, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.4 SQLAllocStmt

In ODBC 3.x, `SQLAllocStmt` was deprecated and replaced by `SQLAllocHandle`. For details, see [SQLAllocHandle](#).

5.4.7.5 SQLBindCol

Description

Binds application data buffers to columns in a result set.

Prototype

```
SQLRETURN SQLBindCol(SQLHSTMT StatementHandle,
                    SQLUSMALLINT ColumnNumber,
                    SQLSMALLINT TargetType,
                    SQLPOINTER TargetValuePtr,
                    SQLLEN BufferLength,
                    SQLLEN *StrLen_or_IndPtr);
```

Parameters

Table 5-34 SQLBindCol parameters

Keyword	Description
StatementHandle	Statement handle.
ColumnNumber	Number of the column to be bound. The column number starts with 0 and increases in ascending order. Column 0 is the bookmark column. If no bookmark column is set, column numbers start with 1.
TargetType	C data type in the buffer.
TargetValuePtr	Output parameter: pointer to the buffer bound with the column. The SQLFetch function returns data in the buffer. If this parameter is a null pointer, StrLen_or_IndPtr is a valid value.
BufferLength	Length of the buffer pointed to by TargetValuePtr , in bytes.
StrLen_or_IndPtr	Output parameter: pointer to the length or indicator of the buffer. If the value is null, no length or indicator is used.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLBindCol returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.6 SQLBindParameter

Description

Binds parameter markers in an SQL statement to a buffer.

Prototype

```
SQLRETURN SQLBindParameter(SQLHSTMT StatementHandle,
    SQLUSMALLINT ParameterNumber,
    SQLSMALLINT InputOutputType,
    SQLSMALLINT ValueTpe,
    SQLSMALLINT ParameterType,
    SQLULEN ColumnSize,
    SQLSMALLINT DecimalDigits,
    SQLPOINTER ParameterValuePtr,
    SQLLEN BufferLength,
    SQLLEN *StrLen_or_IndPtr);
```

Parameters

Table 5-35 SQLBindParameter parameters

Keyword	Description
StatementHandle	Statement handle.
ParameterNumber	Parameter marker number, starting with 1 and increasing in ascending order.
InputOutputType	Input/output type of the parameter.
ValueType	C data type of the parameter.
ParameterType	SQL data type of the parameter.
ColumnSize	Size of the column or expression of the corresponding parameter marker.
DecimalDigits	Digital number of the column or expression of the corresponding parameter marker.
ParameterValuePtr	Pointer to the storage parameter buffer.
BufferLength	Length of the ParameterValuePtr buffer in bytes.
StrLen_or_IndPtr	Pointer to the length or indicator of the buffer. If the value is null, no length or indicator is used.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.

- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If `SQLBindParameter` returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call `SQLGetDiagRec`, with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.7 SQLColAttribute

Description

Returns the descriptor information about a column in the result set.

Prototype

```
SQLRETURN SQLColAttribute(SQLHSTMT StatementHandle,
    SQLUSMALLINT ColumnNumber,
    SQLUSMALLINT FieldIdentifier,
    SQLPOINTER CharacterAttributePtr,
    SQLSMALLINT BufferLength,
    SQLSMALLINT *StringLengthPtr,
    SQLLEN *NumericAttributePtr);
```

Parameters

Table 5-36 SQLColAttribute parameters

Keyword	Description
StatementHandle	Statement handle.
ColumnNumber	Column number of the field to be queried, starting with 1 and increasing in ascending order.
FieldIdentifier	Field identifier of ColumnNumber in IRD.
CharacterAttributePtr	Output parameter: pointer to the buffer that returns the FieldIdentifier value.

Keyword	Description
BufferLength	<ul style="list-style-type: none"> Indicates the length of the buffer if FieldIdentifier is an ODBC-defined field and CharacterAttributePtr points to a string or a binary buffer. Ignore this parameter if FieldIdentifier is an ODBC-defined field and CharacterAttributePtr points to an integer.
StringLengthPtr	Output parameter: pointer to a buffer in which the total number of valid bytes (for string data) is stored in *CharacterAttributePtr . Ignore the value of BufferLength if the data is not a string.
NumericAttributePtr	Output parameter: pointer to an integer buffer in which the value of FieldIdentifier in the ColumnNumber row of the IRD is returned.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If `SQLColAttribute` returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.8 SQLConnect

Description

Establishes a connection between a driver and a data source. After the connection is established, the connection handle can be used to access all information about the data source, including its application operating status, transaction processing status, and error information.

Prototype

```
SQLRETURN SQLConnect(SQLHDBC ConnectionHandle,
                    SQLCHAR *ServerName,
                    SQLSMALLINT NameLength1,
                    SQLCHAR *UserName,
                    SQLSMALLINT NameLength2,
                    SQLCHAR *Authentication,
                    SQLSMALLINT NameLength3);
```

Parameters

Table 5-37 SQLConnect parameters

Keyword	Description
ConnectionHandle	Connection handle, obtained from SQLAllocHandle.
ServerName	Name of the data source to connect.
NameLength1	Length of ServerName .
UserName	Username of the database in the data source.
NameLength2	Length of UserName .
Authentication	User password of the database in the data source.
NameLength3	Length of Authentication .

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLConnect returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.9 SQLDisconnect

Description

Closes the connection associated with a database connection handle.

Prototype

```
SQLRETURN SQLDisconnect(SQLHDBC ConnectionHandle);
```

Parameters

Table 5-38 SQLDisconnect parameter

Keyword	Description
ConnectionHandle	Connection handle, obtained from SQLAllocHandle.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLDisconnect returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.10 SQLExecDirect

Description

Executes a prepared statement specified in this parameter. SQLExecDirect is the fastest method for executing only one SQL statement at a time.

Prototype

```
SQLRETURN SQLExecDirect(SQLHSTMT StatementHandle,
                        SQLCHAR *StatementText,
                        SQLINTEGER TextLength);
```

Parameters

Table 5-39 SQLExecDirect parameters

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.
StatementText	SQL statement to be executed. Multiple statements cannot be executed at a time.
TextLength	Length of StatementText .

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_NEED_DATA** indicates that parameters provided before executing the SQL statement are insufficient.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.

Precautions

If SQLExecDirect returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.11 SQLExecute

Description

If a statement contains a parameter marker, the SQLExecute function uses the current value of the parameter marker to execute a prepared SQL statement.

Prototype

```
SQLRETURN SQLExecute(SQLHSTMT StatementHandle);
```

Parameters

Table 5-40 SQLExecute parameter

Keyword	Description
StatementHandle	Statement handle to be executed.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_NEED_DATA** indicates that parameters provided before executing the SQL statement are insufficient.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLExecute returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.12 SQLFetch

Description

Advances the cursor to the next row of the result set and retrieves any bound columns.

Prototype

```
SQLRETURN SQLFetch(SQLHSTMT StatementHandle);
```

Parameters

Table 5-41 SQLFetch parameter

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLFetch returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.13 SQLFreeStmt

In ODBC 3.x, SQLFreeStmt (an ODBC 2.x function) was deprecated and replaced by SQLFreeHandle. For details, see [SQLFreeHandle](#).

5.4.7.14 SQLFreeConnect

In ODBC 3.x, SQLFreeConnect (an ODBC 2.x function) was deprecated and replaced by SQLFreeHandle. For details, see [SQLFreeHandle](#).

5.4.7.15 SQLFreeHandle

Description

Releases resources associated with a specific environment, connection, or statement handle. It replaces the ODBC 2.x functions: SQLFreeEnv, SQLFreeConnect, and SQLFreeStmt.

Prototype

```
SQLRETURN SQLFreeHandle(SQLSMALLINT HandleType,  
                        SQLHANDLE Handle);
```

Parameters

Table 5-42 SQLFreeHandle parameters

Keyword	Description
HandleType	Type of handle to be freed by SQLFreeHandle. The value must be one of the following: <ul style="list-style-type: none">• SQL_HANDLE_ENV• SQL_HANDLE_DBC• SQL_HANDLE_STMT• SQL_HANDLE_DESC If none of them is the value of HandleType , SQLFreeHandle returns SQL_INVALID_HANDLE .
Handle	Name of the handle to be freed.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLFreeHandle returns **SQL_ERROR**, the handle is still valid.

Examples

See [Examples](#).

5.4.7.16 SQLFreeEnv

In ODBC 3.x, SQLFreeEnv (an ODBC 2.x function) was deprecated and replaced by SQLFreeHandle. For details, see [SQLFreeHandle](#).

5.4.7.17 SQLPrepare

Description

Prepares an SQL statement to be executed.

CAUTION

The prepared statements sent by ODBC do not support the kernel reuse plan. As a result, a new plan needs to be generated for each execution, causing high CPU usage. If services have requirements on plan reuse, you are advised to use the JDBC client.

Prototype

```
SQLRETURN SQLPrepare(SQLHSTMT StatementHandle,  
SQLCHAR *StatementText,  
SQLINTEGER TextLength);
```

Parameters

Table 5-43 SQLPrepare parameters

Keyword	Description
StatementHandle	Statement handle.
StatementText	SQL text string.
TextLength	Length of StatementText .

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLPrepare returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.18 SQLGetData

Description

SQLGetData is used to retrieve data for a single column in the result set. It can be called multiple times to partially retrieve variable-length data.

Prototype

```
SQLRETURN SQLGetData(SQLHSTMT StatementHandle,
                    SQLUSMALLINT Col_or_Param_Num,
                    SQLSMALLINT TargetType,
                    SQLPOINTER TargetValuePtr,
                    SQLLEN BufferLength,
                    SQLLEN *StrLen_or_IndPtr);
```

Parameters

Table 5-44 SQLGetData parameters

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.
Col_or_Param_Num	Column number for which the data retrieval is requested. The column number starts with 1 and increases in ascending order. The number of the bookmark column is 0.
TargetType	C data type in the TargetValuePtr buffer. If TargetType is SQL_ARD_TYPE , the driver uses the data type of the SQL_DESC_CONCISE_TYPE field in ARD. If it is SQL_C_DEFAULT , the driver selects a default data type according to the source SQL data type.
TargetValuePtr	Output parameter: pointer to the pointer that points to the buffer where the data is located.
BufferLength	Size of the buffer pointed to by TargetValuePtr .

Keyword	Description
StrLen_or_IndPtr	Output parameter: pointer to the buffer where the length or identifier value is returned.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If `SQLGetData` returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.19 SQLGetDiagRec

Description

Returns the current values of multiple fields in a diagnostic record that contains error, warning, and status information.

Prototype

```
SQLRETURN SQLGetDiagRec(SQLSMALLINT HandleType
                        SQLHANDLE Handle,
                        SQLSMALLINT RecNumber,
                        SQLCHAR *SQLState,
                        SQLINTEGER *NativeErrorPtr,
                        SQLCHAR *MessageText,
                        SQLSMALLINT BufferLength
                        SQLSMALLINT *TextLengthPtr);
```

Parameters

Table 5-45 SQLGetDiagRec parameters

Keyword	Description
HandleType	Handle-type identifier that describes the type of handle for which diagnostics are desired. The value must be one of the following: <ul style="list-style-type: none"> • SQL_HANDLE_ENV • SQL_HANDLE_DBC • SQL_HANDLE_STMT • SQL_HANDLE_DESC
Handle	Handle for the diagnostic data structure. Its type is indicated by HandleType . If HandleType is set to SQL_HANDLE_ENV , Handle may indicate a shared or non-shared environment handle.
RecNumber	Status record from which the application seeks information. Status records are numbered from 1.
SQLState	Output parameter: pointer to a buffer that saves the 5-character SQLSTATE code pertaining to RecNumber .
NativeErrorPtr	Output parameter: pointer to a buffer that saves the native error code.
MessageText	Pointer to a buffer that saves text strings of diagnostic information.
BufferLength	Length of MessageText .
TextLengthPtr	Output parameter: pointer to the buffer, the total number of bytes in the returned MessageText . If the number of bytes available to return is greater than BufferLength , then the diagnostics information text in MessageText is truncated to BufferLength minus the length of the null termination character.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

SQLGetDiagRec does not release diagnostic records for itself. It uses the following return values to report execution results:

- **SQL_SUCCESS** indicates that the function successfully returns diagnostic information.
- **SQL_SUCCESS_WITH_INFO** indicates that the ***MessageText** buffer is too small to hold the requested diagnostic information. No diagnostic records are generated.
- **SQL_INVALID_HANDLE** indicates that the handle indicated by **HandType** and **Handle** is an invalid handle.
- **SQL_ERROR** indicates that the value of **RecNumber** is less than or equal to **0** or the value of **BufferLength** is less than **0**.

If an ODBC function returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, you can call SQLGetDiagRec to obtain the **SQLSTATE** value. [Table 2 SQLSTATE values](#) lists the possible **SQLSTATE** values.

Table 5-46 SQLSTATE values

SQLSTATE	Error	Description
HY000	General error.	An error occurs when there is no specific SQLSTATE.
HY001	Memory allocation error.	The driver is unable to allocate memory required to support execution or completion of the function.
HY008	Operation canceled.	SQLCancel is called to terminate the statement execution, but the StatementHandle function is still called.
HY010	Function sequence error.	The function is called prior to sending data to data parameters or columns being executed.
HY013	Memory management error.	The function fails to be called. The error may be caused by low memory conditions.
HYT01	Connection timeout.	The timeout period expired before the application was able to connect to the data source.
IM001	Function not supported by the driver.	The called function is not supported by the StatementHandle driver.

Examples

See [Examples](#).

5.4.7.20 SQLSetConnectAttr

Description

Sets connection attributes.

Prototype

```
SQLRETURN SQLSetConnectAttr(SQLHDBC ConnectionHandle,
                             SQLINTEGER Attribute,
                             SQLPOINTER ValuePtr,
                             SQLINTEGER StringLength);
```

Parameters

Table 5-47 SQLSetConnectAttr parameters

Keyword	Description
ConnectionHandle	Connection handle.
Attribute	Attribute to set.
ValuePtr	Pointer to the Attribute value. ValuePtr depends on the Attribute value, and can be a 32-bit unsigned integer value or a null-terminated string. If the ValuePtr parameter is driver-specific value, it may be a signed integer.
StringLength	If ValuePtr points to a string or a binary buffer, StringLength is the length of *ValuePtr . If ValuePtr points to an integer, StringLength is ignored.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If `SQLSetConnectAttr` returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL_HANDLE_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.21 SQLSetEnvAttr

Description

Sets environment attributes.

Prototype

```
SQLRETURN SQLSetEnvAttr(SQLHENV EnvironmentHandle,
                        SQLINTEGER Attribute,
                        SQLPOINTER ValuePtr,
                        SQLINTEGER StringLength);
```

Parameters

Table 5-48 SQLSetEnvAttr parameters

Keyword	Description
EnvironmentHandle	Environment handle.
Attribute	Environment attribute to be set. The value must be one of the following: <ul style="list-style-type: none"> • SQL_ATTR_ODBC_VERSION: ODBC version • SQL_CONNECTION_POOLING: connection pool attribute • SQL_OUTPUT_NTS: string type returned by the driver
ValuePtr	Pointer to the Attribute value. ValuePtr depends on the Attribute value, and can be a 32-bit integer value or a null-terminated string.
StringLength	If ValuePtr points to a string or a binary buffer, StringLength is the length of *ValuePtr . If ValuePtr points to an integer, StringLength is ignored.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If SQLSetEnvAttr returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, set **HandleType** and **Handle** to **SQL_HANDLE_ENV** and **EnvironmentHandle**, and obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

See [Examples](#).

5.4.7.22 SQLSetStmtAttr

Description

Sets attributes related to a statement.

Prototype

```
SQLRETURN SQLSetStmtAttr(SQLHENV StatementHandle
                          SQLINTEGER Attribute,
                          SQLPOINTER ValuePtr,
                          SQLINTEGER StringLength);
```

Parameters

Table 5-49 SQLSetStmtAttr parameters

Keyword	Description
StatementHandle	Statement handle.
Attribute	Attribute to set.
ValuePtr	Pointer to the Attribute value. ValuePtr depends on the Attribute value, and can be a 32-bit unsigned integer value or a pointer to a null-terminated string, a binary buffer, or a driver-specified value. If the ValuePtr parameter is driver-specific value, it may be a signed integer.
StringLength	If ValuePtr points to a string or a binary buffer, StringLength is the length of *ValuePtr . If ValuePtr points to an integer, StringLength is ignored.

Return Value

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

Precautions

If `SQLSetStmtAttr` returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to

`SQL_HANDLE_STMT` and `StatementHandle`, respectively, to obtain the `SQLSTATE` value. The `SQLSTATE` value provides the detailed function calling information.

Examples

See [Examples](#).

5.5 Development Based on libpq

`libpq` is a C application programming interface to GaussDB. `libpq` contains a set of library functions that allow client programs to send query requests to GaussDB servers and obtain query results. It is also the underlying engine of other GaussDB application interfaces, such as ODBC. This chapter provides two examples to show how to write code using `libpq`.

5.5.1 libpq Package, Dependent Library, and Header File

Obtain the `libpq` package, dependent library, and header files from the release package `GaussDB-Kernel_Database version number_OS version number_64bit_Libpq.tar.gz`. Client programs that use `libpq` must include the header file `libpq-fe.h` and must connect to the `libpq` library.

5.5.2 Development Process

To compile and develop source programs based on `libpq`, perform the following steps:

1. Decompress the `GaussDB-Kernel_Database version number_OS version number_64bit_Libpq.tar.gz` file. The required header file is stored in the `include` folder, and the `lib` folder contains the required `libpq` library file.

NOTE

In addition to `libpq-fe.h`, the `include` folder contains the header files `postgres_ext.h`, `gs_thread.h`, and `gs_threadlocal.h` by default. These three header files are the dependency files of `libpq-fe.h`.

2. Develop the source program `testlibpq.c`. The source code file needs to reference the header file provided by `libpq`.
Example: `#include <libpq-fe.h>`
3. To compile the `libpq` source program by running `gcc`, use the `-I directory` option to provide the installation location of the header file. (Sometimes the compiler looks for the default directory, so this option can be ignored.)
`gcc -I (Directory where the header file is located) -L (Directory where the libpq library is located) testlibpq.c -lpq`

Example:

```
gcc -I $(GAUSSHOME)/include/libpq -L $(GAUSSHOME)/lib -lpq testlibpq.c -o testlibpq
```

4. If the makefile is used, add the following option to variables `CPPFLAGS`, `LDLFLAGS`, and `LIBS`:

```
CPPFLAGS += -I (Directory of the header file)
LDLFLAGS += -L (Directory of the libpq library)
LIBS += -lpq
```

Example:

```
CPPFLAGS += -I$(GAUSSHOME)/include/libpq
LDLFLAGS += -L$(GAUSSHOME)/lib
```

5.5.3 Examples

Code for Common Functions

Example 1:

```
/*
 * testlibpq.c
 * Note: testlibpq.c source program provides basic and common application scenarios of libpq.
 * The PQconnectdb, PQexec, PQntuples, and PQfinish APIs provided by libpq are used to establish database
 * connections, execute SQL statements, obtain returned results, and clear resources.
 */
#include <stdio.h>
#include <stdlib.h>
#include <libpq-fe.h>
#include <string.h>

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

int
main(int argc, char **argv)
{
    /* The values of variables such as user and passwd must be read from environment variables or
    configuration files. Environment variables need to be configured as required. If no environment variable is
    used, a character string can be directly assigned. */
    const char *conninfo;
    PGconn *conn;
    PGresult *res;
    int nFields;
    int i,j;
    char *passwd = getenv("EXAMPLE_PASSWD_ENV");
    char *port = getenv("EXAMPLE_PORT_ENV");
    char *host = getenv("EXAMPLE_HOST_ENV");
    char *username = getenv("EXAMPLE_USERNAME_ENV");
    char *dbname = getenv("EXAMPLE_DBNAME_ENV");

    /*
     * This value is used when the user provides the value of the conninfo character string in the command
     line.
     * Otherwise, the environment variables or the default values
     * are used for all other connection parameters.
     */
    if (argc > 1)
        conninfo = argv[1];
    else
        sprintf(conninfo,
            "dbname=%s port=%s host=%s application=test connect_timeout=5 sslmode=allow user=%s
password=%s",
            dbname, port, host, username, password);

    /* Connect to the database. */
    conn = PQconnectdb(conninfo);

    /* Check whether the backend connection has been successfully established. */
    if (PQstatus(conn) != CONNECTION_OK)
    {
        fprintf(stderr, "Connection to database failed: %s",
            PQerrorMessage(conn));
        exit_nicely(conn);
    }

    /*
     * Since a cursor is used in the test case, a transaction block is required.
     */
}
```

```
* Put all data in one "select * from pg_database"
* PQexec() is simple and is not recommended.
*/

/* Start a transaction block. */
res = PQexec(conn, "BEGIN");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "BEGIN command failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/*
 * PQclear PGresult should be executed when it is no longer needed, to avoid memory leakage.
 */
PQclear(res);

/*
 * Fetch data from the pg_database system catalog.
 */
res = PQexec(conn, "DECLARE myportal CURSOR FOR select * from pg_database");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "DECLARE CURSOR failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}
PQclear(res);

res = PQexec(conn, "FETCH ALL in myportal");
if (PQresultStatus(res) != PGRES_TUPLES_OK)
{
    fprintf(stderr, "FETCH ALL failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/* First, print out the attribute name. */
nFields = PQnfields(res);
for (i = 0; i < nFields; i++)
    printf("%-15s", PQfname(res, i));
printf("\n\n");

/* Print lines. */
for (i = 0; i < PQntuples(res); i++)
{
    for (j = 0; j < nFields; j++)
        printf("%-15s", PQgetvalue(res, i, j));
    printf("\n");
}

PQclear(res);

/* Close the portal. We do not need to check for errors. */
res = PQexec(conn, "CLOSE myportal");
PQclear(res);

/* End the transaction. */
res = PQexec(conn, "END");
PQclear(res);

/* Close the database connection and clean up the database. */
PQfinish(conn);

return 0;
}
```

Example 2:

```
/*
 * testlibpq2.c Test PQprepare
 * PQprepare creates a prepared statement with specified parameters for PQexecPrepared to execute the
 * prepared statement.
 * Before running this example, create a table and insert data.
 * create table t01(a int, b int);
 * insert into t01 values(1, 23);
 */
#include <stdio.h>
#include <stdlib.h>
#include <libpq-fe.h>
#include <string.h>
int main(int argc, char * argv[])
{
    /* The values of variables such as user and passwd must be read from environment variables or
    configuration files. Environment variables need to be configured as required. If no environment variable is
    used, a character string can be directly assigned. */
    PGconn *conn;
    PGresult * res;
    ConnStatusType pgstatus;
    char connstr[1024];
    char cmd_sql[2048];
    int nParams = 0;
    int paramLengths[5];
    int paramFormats[5];
    Oid paramTypes[5];
    char * paramValues[5];
    int i, cnt;
    char cid[32];
    int k;
    char *passwd = getenv("EXAMPLE_PASSWD_ENV");
    char *port = getenv("EXAMPLE_PORT_ENV");
    char *hostaddr = getenv("EXAMPLE_HOST_ENV");
    char *username = getenv("EXAMPLE_USERNAME_ENV");
    char *dbname = getenv("EXAMPLE_DBNAME_ENV");

    /* Use PQconnectdb to connect to the database. The detailed connection information is as follows:
    connstr */
    sprintf(connstr,
            "hostaddr=%s dbname=%s port=%s user=%s password=%s",
            hostaddr, dbname, port, username, passwd);

    conn = PQconnectdb(connstr);
    pgstatus = PQstatus(conn);
    if (pgstatus == CONNECTION_OK)
    {
        printf("Connect database success!\n");
    }
    else
    {
        printf("Connect database fail:%s\n", PQerrorMessage(conn));
        return -1;
    }

    /* cmd_sql query */
    sprintf(cmd_sql, "SELECT b FROM t01 WHERE a = $1");
    /*Parameter corresponding to $1 in cmd_sql*/
    paramTypes[0] = 23;
    /* PQprepare creates a prepared statement with given parameters. */
    res = PQprepare(conn,
                   "pre_name",
                   cmd_sql,
                   1,
                   paramTypes);
    if (PQresultStatus(res) != PGRES_COMMAND_OK )
    {
        printf("Failed to prepare SQL : %s\n: %s\n", cmd_sql, PQerrorMessage(conn));
        PQfinish(conn);
        return -1;
    }
}
```

```
}
PQclear(res);
paramValues[0] = cid;
for (k=0; k<2; k++)
{
    sprintf(cid, "%d", 1);
    paramLengths[0] = 6;
    paramFormats[0] = 0;
    /*Execute the prepared statement.*/
    res = PQexecPrepared(conn,
                        "pre_name",
                        1,
                        paramValues,
                        paramLengths,
                        paramFormats,
                        0);

    if( (PQresultStatus(res) != PGRES_COMMAND_OK ) && (PQresultStatus(res) != PGRES_TUPLES_OK))
    {
        printf("%s\n",PQerrorMessage(conn));
        PQclear(res);
        PQfinish(conn);
        return -1;
    }
    cnt = PQntuples(res);
    printf("return %d rows\n", cnt);
    for (i=0; i<cnt; i++)
    {
        printf("row %d: %s\n", i, PQgetvalue(res, i, 0));
    }
    PQclear(res);
}

/* The execution is complete. Close the connection. */
PQfinish(conn);
return 0;
}
```

Example 3:

```
/*
 * testlibpq3.c
 * Test PQexecParams.
 * PQexecParams runs a command to bind parameters and requests the query result in binary format.
 *
 * Before running this example, populate a database.
 *
 * CREATE TABLE test1 (i int4, t text);
 *
 * INSERT INTO test1 values (2, 'ho there');
 *
 * Expected output:
 *
 * tuple 0: got
 * i = (4 bytes) 2
 * t = (8 bytes) 'ho there'
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <libpq-fe.h>

/* for ntohl/htonl */
#include <netinet/in.h>
#include <arpa/inet.h>

static void
```

```
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

/*
 * This function is used to print out the query results. The results are in binary format
 * and fetched from the table created in the comment above.
 */
static void
show_binary_results(PGresult *res)
{
    int    i;
    int    i_fnum,
          t_fnum;

    /* Use PQfnumber to avoid assumptions about column order in the result. */
    i_fnum = PQfnumber(res, "i");
    t_fnum = PQfnumber(res, "t");

    for (i = 0; i < PQntuples(res); i++)
    {
        char    *iptr;
        char    *tptr;
        int     ival;

        /* Obtain the column value. (Ignore the possibility that they may be null). */
        iptr = PQgetvalue(res, i, i_fnum);
        tptr = PQgetvalue(res, i, t_fnum);

        /*
         * The binary representation of INT4 is the network byte order,
         * which is better to be replaced with the local byte order.
         */
        ival = ntohl(*(uint32_t *) iptr);

        /*
         * The binary representation of TEXT is text. Since libpq can append a zero byte to it,
         * and think of it as a C string.
         */

        printf("tuple %d: got\n", i);

}
/* Output the binary result. */
show_binary_results(res);

PQclear(res);

/* Close the database connection and clean up the database. */
PQfinish(conn);

return 0;
}
```

5.5.4 libpq Interface Reference

5.5.4.1 Database Connection Control Functions

Database connection control functions control the connections to GaussDB servers. An application can connect to multiple servers at a time. For example, a

client connects to multiple databases. Each connection is represented by a `PGconn` object, which is obtained from the function `PQconnectdb`, `PQconnectdbParams`, or `PQsetdbLogin`. Note that these functions will always return a non-null object pointer, unless memory allocation fails. The API for establishing a connection is stored in the `PGconn` object. The `PQstatus` function can be called to check the return value for a successful connection.

5.5.4.1.1 PQconnectdbParams

Description

Establishes a new connection with the database server.

Prototype

```
PGconn* PQconnectdbParams(const char* const* keywords, const char* const* values, int expand_dbname);
```

Parameter

Table 5-50 PQconnectdbParams parameters

Keyword	Description
keywords	An array of strings, each of which is a keyword.
values	Value assigned to each keyword.
expand_dbname	When expand_dbname is non-zero, the dbname keyword value can be recognized as a connection string. Only dbname that first appears is expanded in this way, and any subsequent dbname value is treated as a database name.

Return Value

`PGconn *` points to the object pointer that contains a connection. The memory is allocated by the function internally.

Precautions

This function establishes a new database connection using the parameters taken from two NULL-terminated arrays. Unlike `PQsetdbLogin`, the parameter set can be extended without changing the function signature. Therefore, use of this function (or its non-blocking analogs `PQconnectStartParams` and `PQconnectPoll`) is preferred for new application programming.

5.5.4.1.2 PQconnectdb

Description

Establishes a new connection with the database server.

Prototype

```
PGconn* PQconnectdb(const char* conninfo);
```

Parameter

Table 5-51 PQconnectdb parameter

Keyword	Description
conninfo	Connection string. For details about the fields in the string, see section 5.6.4.5 .

Return Value

PGconn * points to the object pointer that contains a connection. The memory is allocated by the function internally.

Precautions

- This function establishes a new database connection using the parameters taken from the string **conninfo**.
- The input parameter can be empty, indicating that all default parameters can be used. It can contain one or more values separated by spaces or contain a URL.

Examples

For details, see [Examples](#).

5.5.4.1.3 PQbackendPID

Supplementary Explanation

After GaussDB is multi-thread refactored based on PostgreSQL, the semantic of PQbackendPID is different from that in the native PostgreSQL libpq. In GaussDB, the return value of the PQbackendPID function indicates the slot ID of the background thread, not the backend PID of the background thread. Due to the preceding difference, you are not advised to execute this function by following the PostgreSQL semantics. To obtain the backend PID of the connection, you can use the `pg_backend_pid` system function. In addition, other driver APIs which depend on libpq and have the same names as PostgreSQL's APIs (such as the `get_backend_pid` function of the Python connection driver `psycopg2`) also comply with the preceding rule.

5.5.4.1.4 PQsetdbLogin

Description

Establishes a new connection with the database server.

Prototype

```
PGconn* PQsetdbLogin(const char* pghost, const char* pgport, const char* pgoptions, const char* pgtty,
const char* dbName, const char* login, const char* pwd);
```

Parameter

Table 5-52 PQsetdbLogin parameters

Keyword	Description
pghost	Name of the host to be connected. For details, see the host column described in Connection Parameters .
pgport	Port number of the host server. For details, see the port column described in Connection Parameters .
pgoptions	Command-line options to be sent to the server during running. For details, see the options column described in Connection Parameters .
pgtty	Ignored. (Previously, this option declares the output direction of server logs.)
dbName	Name of the database to be connected. For details, see the dbname column described in Connection Parameters .
login	Username for connection. For details, see the user column described in Connection Parameters .
pwd	Password used for authentication during connection. For details, see the password column described in Connection Parameters .

Return Value

PGconn * points to the object pointer that contains a connection. The memory is allocated by the function internally.

Precautions

- This function is the predecessor of PQconnectdb with a fixed set of parameters. When an undefined parameter is called, its default value is used. Write NULL or an empty string for any one of the fixed parameters that is to be defaulted.
- If the **dbName** value contains an equal sign (=) or a valid prefix in the connection URL, it is taken as a conninfo string and passed to PQconnectdb, and the remaining parameters are consistent with PQconnectdbParams parameters.

5.5.4.1.5 PQfinish

Function

PQfinish is used to close the connection to the server and release the memory used by the PGconn object.

Prototype

```
void PQfinish(PGconn* conn);
```

Parameter

Table 5-53 PQfinish parameter

Keyword	Parameter Description
conn	The object pointer that contains the connection information.

Precautions

If the server connection attempt fails (as indicated by PQstatus), the application should call PQfinish to release the memory used by the PGconn object. The PGconn pointer must not be used again after PQfinish has been called.

Example

For details, see [Examples](#).

5.5.4.1.6 PQreset

Function

PQreset is used to reset the communication port to the server.

Prototype

```
void PQreset(PGconn* conn);
```

Parameter

Table 5-54 PQreset parameter

Keyword	Parameter Description
conn	The object pointer that contains the connection information.

Precautions

This function will close the connection to the server and attempt to establish a new connection to the same server by using all the parameters previously used. This function is applicable to fault recovery after a connection exception occurs.

5.5.4.1.7 PQstatus

Description

Returns the connection status.

Prototype

```
ConnStatusType PQstatus(const PGconn *conn);
```

Parameter

Table 5-55 PQstatus parameter

Keyword	Description
conn	Points to the object pointer that contains the connection information.

Return Value

ConnStatusType indicates the connection status. The enumerated values are as follows:

```
CONNECTION_STARTED
Waiting for the connection to be established.

CONNECTION_MADE
Connection succeeded; waiting to send

CONNECTION_AWAITING_RESPONSE
Waiting for a response from the server.

CONNECTION_AUTH_OK
Authentication received; waiting for backend startup to complete.

CONNECTION_SSL_STARTUP
Negotiating SSL encryption.

CONNECTION_SETENV
Negotiating environment-driven parameter settings.

CONNECTION_OK
Normal connection.

CONNECTION_BAD
Failed connection.
```

Precautions

The connection status can be one of the preceding values. After the asynchronous connection procedure is complete, only two of them, **CONNECTION_OK** and

CONNECTION_BAD, can return. **CONNECTION_OK** indicates that the connection to the database is normal. **CONNECTION_BAD** indicates that the connection to the database fails. Generally, the normal state remains until PQfinish is called. However, a communication failure may cause the connection status to become to **CONNECTION_BAD** before the connection procedure is complete. In this case, the application can attempt to call PQreset to restore the communication.

Examples

For details, see [Examples](#).

5.5.4.2 Database Statement Execution Functions

After the connection to the database server is successfully established, you can use the functions described in this section to execute SQL queries and commands.

5.5.4.2.1 PQexec

Function

PQexec is used to submit a command to the server and wait for the result.

Prototype

```
PGresult* PQexec(PGconn* conn, const char* query);
```

Parameter

Table 5-56 PQexec parameters

Keyword	Parameter Description
conn	The object pointer that contains the connection information.
command	Query string to be executed.

Return Value

PGresult indicates the object pointer that contains the query result.

Precautions

The PQresultStatus function should be called to check the return value for any errors (including the value of a null pointer, in which **PGRES_FATAL_ERROR** will be returned). The PQerrorMessage function can be called to obtain more information about such errors.

NOTICE

The command string can contain multiple SQL commands separated by semicolons (;). Multiple queries sent in a PQexec call are processed in one transaction, unless there are specific BEGIN/COMMIT commands in the query string to divide the string into multiple transactions. Note that the returned PGresult structure describes only the result of the last command executed from the string. If a command fails, the string processing stops and the returned PGresult describes the error condition.

Example

For details, see [Examples](#).

5.5.4.2.2 PQprepare**Description**

Commits a request to create a prepared statement with given parameters and waits for completion.

Prototype

```
PGresult* PQprepare(PGconn* conn, const char* stmtName, const char* query, int nParams, const Oid* paramTypes);
```

Parameter**Table 5-57** PQprepare parameters

Keyword	Description
conn	Points to the object pointer that contains the connection information.
stmtName	Prepared statement to be executed.
query	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Array of the parameter type.

Return Value

PGresult indicates the object pointer that contains the query result.

Precautions

- PQprepare creates a prepared statement for later execution with PQexecPrepared. This function allows commands to be repeatedly executed,

without being parsed and planned each time they are executed. PQprepare is supported only in protocol 3.0 or later. It will fail when protocol 2.0 is used.

- This function creates a prepared statement named **stmtName** from the query string, which must contain an SQL command. **stmtName** can be "" to create an unnamed statement. In this case, any pre-existing unnamed statement will be automatically replaced. Otherwise, this is an error if the statement name has been defined in the current session. If any parameters are used, they are referred to in the query as \$1, \$2, and so on. **nParams** is the number of parameters for which types are pre-specified in the array paramTypes[]. (The array pointer can be **NULL** when **nParams** is **0**.) paramTypes[] specifies the data types to be assigned to the parameter symbols by OID. If **paramTypes** is **NULL**, or any element in the array is **0**, the server assigns a data type to the parameter symbol in the same way as it does for an untyped literal string. In addition, the query can use parameter symbols whose numbers are greater than **nParams**. Data types of these symbols will also be inferred.

NOTICE

You can also execute the **SQLPREPARE** statement to create a prepared statement that is used with PQexecPrepared. Although there is no libpq function of deleting a prepared statement, the SQL DEALLOCATE statement can be used for this purpose.

Examples

For details, see [Examples](#).

5.5.4.2.3 PQresultStatus

Function

PQresultStatus is used to return the result status of a command.

Prototype

```
ExecStatusType PQresultStatus(const PGresult* res);
```

Parameter

Table 5-58 PQresultStatus parameter

Keyword	Parameter Description
res	Object pointer that contains the query result.

Return Value

PQresultStatus indicates the command execution status. The enumerated values are as follows:

PQresultStatus can return one of the following values:

PGRES_EMPTY_QUERY
The string sent to the server was empty.

PGRES_COMMAND_OK
A command that does not return data was successfully executed.

PGRES_TUPLES_OK
A query (such as SELECT or SHOW) that returns data was successfully executed.

PGRES_COPY_OUT
Copy Out (from the server) data transfer started.

PGRES_COPY_IN
Copy In (to the server) data transfer started.

PGRES_BAD_RESPONSE
The response from the server cannot be understood.

PGRES_NONFATAL_ERROR
A non-fatal error (notification or warning) occurred.

PGRES_FATAL_ERROR
A fatal error occurred.

PGRES_COPY_BOTH
Copy In/Out (to and from the server) data transfer started. This state occurs only in streaming replication.

PGRES_SINGLE_TUPLE
PQresult contains a result tuple from the current command. This state occurs in a single-row query.

Precautions

- Note that the SELECT command that happens to retrieve zero rows still returns **PGRES_TUPLES_OK**. **PGRES_COMMAND_OK** is used for commands that can never return rows (such as INSERT or UPDATE, without return clauses). The result status **PGRES_EMPTY_QUERY** might indicate a bug in the client software.
- The result status **PGRES_NONFATAL_ERROR** will never be returned directly by PQexec or other query execution functions. Instead, such results will be passed to the notice processor.

Example

For details, see [Examples](#).

5.5.4.2.4 PQclear

Description

Releases the storage associated with PGresult. Any query result should be released by PQclear when it is no longer needed.

Prototype

```
void PQclear(PGresult* res);
```

Parameter

Table 5-59 PQclear parameter

Keyword	Description
res	Object pointer that contains the query result.

Precautions

PGresult is not automatically released. That is, it does not disappear when a new query is submitted or even if you close the connection. To delete it, you must call PQclear. Otherwise, memory leakage occurs.

Examples

For details, see [Examples](#).

5.5.4.3 Functions for Asynchronous Command Processing

The PQexec function is adequate for committing commands in common, synchronous applications. However, it has several defects, which may be important to some users:

- PQexec waits for the end of the command, but the application may have other work to do (for example, maintaining a user interface). In this case, PQexec would not want to be blocked to wait for the response.
- As the client application is suspended while waiting for the result, it is difficult for the application to determine whether to cancel the ongoing command.
- PQexec can return only one PGresult structure. If the committed command string contains multiple SQL commands, all the PGresult structures except the last PGresult are discarded by PQexec.
- PQexec always collects the entire result of the command and caches it in a PGresult. Although this mode simplifies the error handling logic for applications, it is impractical for results that contain multiple rows.

Applications that do not want to be restricted by these limitations can use the following functions that PQexec is built from: PQsendQuery and PQgetResult. The functions PQsendQueryParams, PQsendPrepare, and PQsendQueryPrepared can also be used with PQgetResult.

5.5.4.3.1 PQsendQuery

Description

Commits a command to the server without waiting for the result. If the query is successful, **1** is returned. Otherwise, **0** is returned.

Prototype

```
int PQsendQuery(PGconn* conn, const char* query);
```

Parameter

Table 5-60 PQsendQuery parameters

Keyword	Description
conn	Points to the object pointer that contains the connection information.
query	Query string to be executed.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

After PQsendQuery is successfully called, call PQgetResult one or more times to obtain the results. PQsendQuery cannot be called again (on the same connection) until PQgetResult returns a null pointer, indicating that the command execution is complete.

5.5.4.3.2 PQsendQueryParams

Function

PQsendQueryParams is used to submit a command and separate parameters to the server without waiting for the result.

Prototype

```
int PQsendQueryParams(PGconn* conn, const char* command, int nParams, const Oid* paramTypes, const char* const* paramValues, const int* paramLengths, const int* paramFormats, int resultFormat);
```

Parameter

Table 5-61 PQsendQueryParams parameters

Keyword	Parameter Description
conn	The object pointer that contains the connection information.
command	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Parameter type.
paramValues	Parameter value.
paramLengths	Parameter length.

Keyword	Parameter Description
paramFormats	Parameter format.
resultFormat	Result format.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

This function is equivalent to PQsendQuery. The only difference is that query parameters can be specified separately from the query string. The parameter processing of this function is similar to that of PQexecParams. It cannot work on connections using protocol v2.0, and it allows only one command to appear in the query string.

5.5.4.3.3 PQsendPrepare

Function

PQsendPrepare is used to send a request to create a prepared statement with given parameters, without waiting for completion.

Prototype

```
int PQsendPrepare(PGconn* conn, const char* stmtName, const char* query, int nParams, const Oid* paramTypes);
```

Parameter

Table 5-62 PQsendPrepare parameters

Keyword	Parameter Description
conn	The object pointer that contains the connection information.
stmtName	Prepared statement to be executed.
query	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Array of the parameter type.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

PQsendPrepare is an asynchronous version of PQprepare. If it can dispatch a request, **1** is returned. Otherwise, **0** is returned. After a successful calling of PQsendPrepare, call PQgetResult to check whether the server successfully created the prepared statement. PQsendPrepare parameters are handled in the same way as PQprepare parameters. Like PQprepare, PQsendPrepare cannot work on connections using protocol v2.0.

5.5.4.3.4 PQsendQueryPrepared

Function

PQsendQueryPrepared is used to send a request to execute a prepared statement with given parameters, without waiting for the result.

Prototype

```
int PQsendQueryPrepared(PGconn* conn, const char* stmtName, int nParams, const char* const* paramValues, const int* paramLengths, const int* paramFormats, int resultFormat);
```

Parameter

Table 5-63 PQsendQueryPrepared parameters

Keyword	Parameter Description
conn	The object pointer that contains the connection information.
stmtName	Prepared statement to be executed.
nParams	Parameter type.
paramValues	Parameter value.
paramLengths	Parameter length.
paramFormats	Parameter format.
resultFormat	Result format.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

PQsendQueryPrepared is similar to PQsendQueryParams, but the command to be executed is specified by naming a previously-prepared statement, instead of providing a query string. PQsendQueryPrepared parameters are handled in the same way as PQexecPrepared parameters. Like PQexecPrepared, PQsendQueryPrepared cannot work on connections using protocol v2.0.

5.5.4.3.5 PQflush

Description

Flushes any queued output data to the server.

Prototype

```
int PQflush(PGconn* conn);
```

Parameter

Table 5-64 PQflush parameter

Keyword	Description
conn	Points to the object pointer that contains the connection information.

Return Value

int indicates the operation result. If the operation is successful (or the send queue is empty), **0** is returned. If the operation fails, **-1** is returned. If all data in the send queue fails to be sent, **1** is returned. (This case occurs only when the connection is non-blocking.) The failure cause is stored in **conn->error_message**.

Precautions

Call PQflush after sending any command or data over a non-blocking connection. If **1** is returned, wait for the socket to become read- or write-ready. If the socket becomes write-ready, call PQflush again. If the socket becomes read-ready, call PQconsumeInput and then call PQflush again. Repeat the operation until the value **0** is returned for PQflush. (It is necessary to check for read-ready and drain the input using PQconsumeInput. This is because the server can block trying to send us data, for example, notification messages, and will not read our data until we read it.) Once PQflush returns **0**, wait for the socket to be read-ready and then read the response as described above.

5.5.4.4 Functions for Canceling Queries in Progress

A client application can use the functions described in this section to cancel a command that is still being processed by the server.

5.5.4.4.1 PQgetCancel

Description

Creates a data structure that contains the information required to cancel a command issued through a specific database connection.

Prototype

```
PGcancel *PQgetCancel(PGconn *conn);
```

Parameter

Table 5-65 PQgetCancel parameter

Keyword	Description
conn	Points to the object pointer that contains the connection information.

Return Value

PGcancel points to the object pointer that contains the cancel information.

Precautions

PQgetCancel creates a PGcancel object for a given PGconn connection object. If the given connection object (**conn**) is NULL or an invalid connection, it will return NULL. The PGcancel object is an opaque structure that cannot be directly accessed by applications. It can be transferred only to PQcancel or PQfreeCancel.

5.5.4.4.2 PQfreeCancel

Function

PQfreeCancel is used to release the data structure created by PQgetCancel.

Prototype

```
void PQfreeCancel(PGcancel* cancel);
```

Parameter

Table 5-66 PQfreeCancel parameter

Keyword	Parameter Description
cancel	Points to the object pointer that contains the cancel information.

Precautions

PQfreeCancel releases a data object previously created by PQgetCancel.

5.5.4.4.3 PQcancel

Function

PQcancel is used to request the server to abandon processing of the current command.

Prototype

```
int PQcancel(PGcancel *cancel, char *errbuf, int errbufsize);
```

Parameter

Table 5-67 PQcancel parameters

Keyword	Parameter Description
cancel	Points to the object pointer that contains the cancel information.
errbuf	Buffer for storing error information.
errbufsize	Size of the buffer for storing error information.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **errbuf**.

Precautions

- Successful sending does not guarantee that the request will have any effect. If the cancellation is valid, the current command is terminated early and an error is returned. If the cancellation fails (for example, because the server has processed the command), no result is returned.
- If **errbuf** is a local variable in a signal handler, you can safely call PQcancel from the signal handler. For PQcancel, the PGcancel object is read-only, so it can also be called from a thread that is separate from the thread that is operating the PGconn object.

5.5.5 Connection Parameters

Table 5-68 Connection parameters

Parameter	Description
host	<p>Name of the host to connect to. If the host name starts with a slash (/), Unix domain socket communications instead of TCP/IP communications are used. The value is the directory where the socket file is stored. If host is not specified, the default behavior is to connect to the Unix-domain socket in the /tmp directory (or the socket directory specified during GaussDB installation). On a machine without a Unix-domain socket, the default behavior is to connect to localhost.</p> <p>You can specify multiple host names by using a character string separated by commas (.). Multiple host names can be specified.</p>
hostaddr	<p>IP address of the host to connect to. The value is in standard IPv4 address format, for example, 172.28.40.9. If a non-null character string is specified, TCP/IP communications are used.</p> <p>You can specify multiple IP addresses by using a character string separated by commas (.). Multiple IP addresses can be specified.</p> <p>Replacing host with hostaddr can prevent applications from querying host names, which may be important for applications with time constraints. However, a host name is required for GSSAPI or SSPI authentication methods. Therefore, the following rules are used:</p> <ol style="list-style-type: none"> 1. If host is specified but hostaddr is not, a query for the host name will be executed. 2. If hostaddr is specified but host is not, the value of hostaddr is the server network address. If the host name is required for authentication, the connection attempt fails. 3. If both host and hostaddr are specified, the value of hostaddr is the server network address. The value of host is ignored unless it is required by authentication, in which case it is used as the host name. <p>NOTICE</p> <ul style="list-style-type: none"> • If host is not the server name in the network address specified by hostaddr, the authentication may fail. • If neither host nor hostaddr is specified, libpq will use a local Unix domain socket for connection. If the machine does not have a Unix domain socket, it will attempt to connect to localhost.
port	<p>Port number of the host server, or the socket file name extension for Unix-domain connections.</p> <p>You can specify multiple port numbers by using a character string separated by commas (.). Multiple port numbers can be specified.</p>
user	<p>Name of the user to be connected. By default, the username is the same as the OS name of the user running the application.</p>

Parameter	Description
dbname	Database name. The default value is the same as the username.
password	Password to be used if the server requires password authentication.
connect_timeout	Maximum timeout period of the connection, in seconds (written as a decimal integer string). The value 0 or null indicates infinity. You are advised not to set the connection timeout period to a value less than 2 seconds.
client_encoding	Client encoding for the connection. In addition to the values accepted by the corresponding server options, you can use auto to determine the correct encoding from the current environment in the client (the <i>LC_CTYPE</i> environment variable in the Unix system).
tty	This parameter can be ignored. (This parameter was used to specify the location to which the debugging output of the server was sent).
options	Adds command-line options to send to the server at runtime.
application_name	Specifies the current user identity for the application_name parameter.
fallback_application_name	Specifies a backup value for the application_name parameter. This value is used if no value is set for application_name through a connection parameter or the <i>PGAPPNAME</i> environment variable. In a common tool program, if you set a default name but do not want the default name to be overwritten by the user, you can specify a backup value.
keepalives	Specifies whether TCP keepalive is enabled on the client side. The default value is 1 , indicating that the function is enabled. The value 0 indicates that the function is disabled. Ignore this parameter for Unix-domain connections.
keepalives_idle	The number of seconds of inactivity after which TCP should send a keepalive message to the server. The value 0 indicates that the default value is used. Ignore this parameter for Unix-domain connections or if keep-alive is disabled.
keepalives_interval	The number of seconds after which a TCP keepalive message that is not acknowledged by the server should be retransmitted. The value 0 indicates that the default value is used. Ignore this parameter for Unix-domain connections or if keep-alive is disabled.
keepalives_count	Controls the number of times that keepalive messages are sent through TCP. The value 0 indicates that the default value is used. Ignore this parameter for Unix-domain connections or if keep-alive is disabled.

Parameter	Description
tcp_user_timeout	Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an OS that supports the TCP_USER_TIMEOUT socket option. The value 0 indicates that the default value is used. Ignore this parameter for Unix-domain connections.
rw_timeout	Sets the read and write timeout interval of the client connection.
sslmode	Specifies whether to enable SSL encryption. <ul style="list-style-type: none"> • disable: SSL connection is disabled. • allow: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified. • prefer: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified. • require: SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified. • verify-ca: SSL connection is required. Currently, Windows ODBC does not support certificate-based authentication. • verify-full: SSL connection is required. Currently, Windows ODBC does not support certificate-based authentication.
sslcompression	If this parameter is set to 1 (default value), the data transmitted over the SSL connection is compressed (this requires that the OpenSSL version be 0.9.8 or later). If it is set to 0 , compression will be disabled (this requires OpenSSL 1.0.0 or later). If a connection without SSL is established, this parameter is ignored. If the OpenSSL version in use does not support this parameter, it will also be ignored. Compression takes up CPU time, but it increases throughput when the bottleneck is the network. If CPU performance is a limiting factor, disabling compression can improve response time and throughput.
sslcert	This parameter specifies the file name of the client SSL certificate. If no SSL connection is established, this parameter is ignored.
sslkey	This parameter specifies the location of the key used for the client certificate. It can specify a key obtained from an external "engine" (the engine is a loadable module of OpenSSL). The description of an external engine should consist of a colon-separated engine name and an engine-related key identifier. If no SSL connection is established, this parameter is ignored.
sslrootcert	This parameter specifies the name of a file that contains the SSL Certificate Authority (CA) certificate. If the file exists, the system authenticates the server certificate issued by one of these authorities.

Parameter	Description
sslcr	This parameter specifies the file name of the SSL Certificate Revocation List (CRL). If a certificate listed in this file exists, the server certificate authentication will be rejected.
requirepeer	This parameter specifies the OS user of the server, for example, requirepeer=postgres . When a Unix domain socket connection is established, if this parameter is set, the client checks whether the server process is running under the specified username at the beginning of the connection. If not, the connection will be interrupted by an error. This parameter can be used to provide server authentication similar to that of the SSL certificate on TCP/IP connections. (Note that if the Unix domain socket is in /tmp or another public writable location, any user can start a server for listening to the location. Use this parameter to ensure that you are connected to a server that is run by a trusted user.) This option is supported only on platforms that implement the peer authentication method.
krbsrvname	This parameter specifies the Kerberos service name used for GSSAPI authentication. For successful Kerberos authentication, this value must match the service name specified in the server configuration.
gsslib	This parameter specifies the GSS library used for GSSAPI authentication. It is used only in the Windows OS. If this parameter is set to gssapi , the libpq is forced to use the GSSAPI library to replace the default SSPI for authentication.
service	This parameter specifies the name of the service for which the additional parameter is used. It specifies a service name in pg_service.conf that holds the additional connection parameters. This allows the application to specify only one service name so that the connection parameters can be centrally maintained.
authtype	authtype is no longer used, so it is marked as a parameter not to be displayed. It is retained in an array so as not to reject the conninfo string from old applications that might still try to set it.
remote_node_name	Specifies the name of the remote node connected to the local node.
localhost	Specifies the local host in a connection channel.
localport	Specifies the local port in a connection channel.
fencedUdfRPCMode	Specifies whether the fenced UDF RPC protocol uses Unix domain sockets or special socket file names. The default value is 0 , indicating that the Unix domain socket mode is used and the file type is .s.PGSQL.%d . To use the fenced UDF mode, set this parameter to 1 . In this case, the file type is .s.fencedMaster_unixdomain .

Parameter	Description
replication	<p>Specifies whether the connection should use replication protocols instead of common protocols. Protocols with this parameter configured are internal protocols used for PostgreSQL replication connections and tools such as pg_basebackup, while they can also be used by third-party applications. The following values, which are case-insensitive, are supported:</p> <ul style="list-style-type: none"> • true, on, yes, and 1 Specify whether the physical replication mode is connected. • database Specifies that the logical replication mode and the database specified by dbname are connected. • false, off, no, and 0 Specify that the connection is a regular connection, which is the default behavior. <p>In physical or logical replication mode, only simple query protocols can be used.</p>
backend_version	Specifies the backend version to be passed to the remote end.
prototype	Sets the current protocol level. The default value is PROTO_TCP .
enable_ce	Specifies whether a client is allowed to connect to a fully-encrypted database. The default value is 0 (disabled). To enable the encrypted equality query, set this parameter to 1 .
connection_info	<p>The value of connection_info is a JSON character string consisting of driver_name, driver_version, driver_path, and os_user.</p> <p>If the value is not null, use connection_info and ignore connectionExtraInf.</p> <p>If the value is null, a connection information string related to libpq is generated. When connectionExtraInf is set to false, the value of connection_info consists of only driver_name and driver_version.</p>
connectionExtraInf	Specifies whether the value of connection_info contains extension information. The default value is 0 . If the value contains other information, set this parameter to 1 .

Parameter	Description
target_session_attrs	<p>Specifies the type of the host to be connected. The connection is successful only when the host type is the same as the configured value. This parameter is verified only when multiple IP addresses are specified. The rules for setting target_session_attrs are as follows:</p> <ul style="list-style-type: none"> • any: All types of hosts can be connected. • read-write: The connection is set up only when the connected host is readable and writable. • read-only: Only readable hosts can be connected. • primary (default value): Only the primary node in the primary/standby systems can be connected. • standby: Only the standby node in the primary/standby systems can be connected. • prefer-standby: The system first attempts to find a standby node for connection. If all hosts in the hosts list fail to be connected, try the any mode.

5.6 Psycopg-based Development

Psycopg is a Python API used to execute SQL statements and provides a unified access API for GaussDB. Applications can perform data operations based on psycopg. Psycopg2 is the encapsulation of libpq and is implemented using the C language, which is efficient and secure. It provides cursors on both clients and servers, asynchronous communication and notification, and the COPY TO and COPY FROM functions. It supports multiple types of Python out-of-the-box and adapts to GaussDB data types. Through the flexible object adaptation system, you can extend and customize the adaptation. Psycopg2 is compatible with Unicode.

GaussDB supports the psycopg2 feature and allows psycopg2 to be connected in SSL mode.

Table 5-69 Platforms supported by psycopg

OS	Platform	Python Version
EulerOS 2.5	<ul style="list-style-type: none"> • Arm64 • x86_64 	3.8.5
EulerOS 2.9	<ul style="list-style-type: none"> • Arm64 • x86_64 	3.7.4
EulerOS 2.10, Kylin V10, and UnionTech20	<ul style="list-style-type: none"> • Arm64 • x86_64 	3.7.9
EulerOS 2.11 and SUSE 12.5	<ul style="list-style-type: none"> • Arm64 • x86_64 	3.9.11

NOTICE

During pycopg2 compilation, OpenSSL of GaussDB is linked. OpenSSL of GaussDB may be incompatible with OpenSSL of the OS. If incompatibility occurs, for example, "version 'OPENSSL_1_1_1f' not found" is displayed, use the environment variable `LD_LIBRARY_PATH` to isolate the OpenSSL provided by the OS and the OpenSSL on which GaussDB depends.

For example, when the application software **client.py** that calls pycopg2 is executed, the environment variable is explicitly assigned to the application software.

```
export LD_LIBRARY_PATH=/path/to/gaussdb/libs:$LD_LIBRARY_PATH python client.py
```

In the preceding command, **/path/to/pycopg2/lib** indicates the directory where the OpenSSL library on which GaussDB depends is located. Change it as required.

5.6.1 Development Process

Figure 5-4 Application development process based on pycopg2

5.6.2 Development Procedure

Step 1 Prepare related drivers and dependent libraries. Obtain them from the release package **GaussDB-Kernel_Database version number_OS version number_64bit_Python.tar.gz**.

After the decompression, the following folders are generated:

- **psycopg2**: **psycopg2** library file
- **lib**: **lib** library file

Step 2 Load the driver.

- Before using the driver, perform the following operations:
 - a. Decompress the driver package of the corresponding version.

```
tar zxvf xxxx-Python.tar.gz
```
 - b. Copy **psycopg2** to the **site-packages** folder in the Python installation directory as the **root** user.

```
su root  
cp psycopg2 $(python3 -c 'import site; print(site.getsitepackages()[0])') -r
```
 - c. Change the **psycopg2** directory permission to **755**.

```
chmod 755 $(python3 -c 'import site; print(site.getsitepackages()[0])')/psycopg2 -R
```
 - d. Add the **psycopg2** directory to the environment variable **\$PYTHONPATH** and validate it.

```
export PYTHONPATH=$(python3 -c 'import site; print(site.getsitepackages()[0])'):$PYTHONPATH
```
 - e. For non-database users, configure the **lib** directory in **LD_LIBRARY_PATH** after decompression.

```
export LD_LIBRARY_PATH=path/to/lib:$LD_LIBRARY_PATH
```
- Load a database driver before creating a database connection:

```
import psycopg2
```

Step 3 Connect to a database.

Connect to the database in non-SSL mode.

1. Use the `psycopg2.connect` function to obtain the connection object.
2. Use the connection object to create a cursor object.

Connect to the database in SSL mode.

When you use `psycopy2` to connect to the GaussDB server, you can enable SSL to encrypt the communication between the client and server. To enable SSL, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

1. Use the `.ini` file (the **configparser** package of Python can parse this type of configuration file) to save the configuration information about the database connection.
2. Add SSL connection parameters **sslmode**, **sslcert**, **sslkey**, and **sslrootcert** to the connection options.
 - a. **sslmode**: For details about the options, see [Table 5-70](#).
 - b. **sslcert**: client certificate path.
 - c. **sslkey**: client key path.
 - d. **sslrootcert**: root certificate path.

3. Use the `psycopg2.connect` function to obtain the connection object.
4. Use the connection object to create a cursor object.

CAUTION

To use SSL to connect to the database, ensure that the Python interpreter is compiled in the mode of generating a dynamic link library (.so) file. You can perform the following steps to check the connection mode of the Python interpreter:

1. Run the **import ssl** command in the Python interpreter to import SSL.
2. Run the **ps ux** command to query the PID of the Python interpreter. Assume that the PID is *********.
3. In the Python interpreter CLI, run the **pmap -p ***** | grep ssl** command and check whether the command output contains the path related to **libssl.so**. If yes, the Python interpreter is compiled in dynamic link mode.

Table 5-70 sslmode options

sslmode	Whether SSL Encryption Is Enabled	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required, but only data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required, and the validity of the server CA must be verified.
verify-full	Yes	The SSL connection must be enabled, which is not supported by GaussDB currently.

Step 4 Run SQL statements.

1. Construct an operation statement and use `%s` as a placeholder. During execution, `psycopg2` will replace the placeholder with the parameter value. You can add the `RETURNING` clause to obtain the automatically generated column values.

2. Use the `cursor.execute` method to execute one row of SQL statement, and use the `cursor.executemany` method to execute multiple rows of SQL statements.

Step 5 Process the result set.

1. `cursor.fetchone()`: fetches the next row in a query result set and returns a sequence. If no data is available, null is returned.
2. `cursor.fetchall()`: fetches all remaining rows in a query result and returns a list. An empty list is returned when no rows are available.

 **NOTE**

For database-specific data types, such as `tinyint`, the corresponding columns in the query result are character strings.

Step 6 Close the connection.

After you complete required data operations in a database, close the database connection. Call the close method such as `connection.close()` to close the connection.

 **CAUTION**

This method closes the database connection and does not automatically call `commit()`. If you just close the database connection without calling `commit()` first, changes will be lost.

----End

5.6.3 Examples: Common Operations

```
import psycopg2
import os

# Obtain the username and password from environment variables.
user = os.getenv('user')
password = os.getenv('password')

# Create a connection object.
conn=psycopg2.connect(database="database", user=user, password=password, host="localhost", port=port)
cur=conn.cursor() # Create a pointer object.

# Create a connection object (using SSL).
conn = psycopg2.connect(dbname="database", user=user, password=password, host="localhost", port=port,
    sslmode="verify-ca", sslcert="client.crt", sslkey="client.key", sslrootcert="cacert.pem")
Note: If sslcert, sslkey, and sslrootcert are not set, the following files in the .postgresql directory of the
current user are used by default: client.crt, client.key, and root.crt.

# Create a table.
cur.execute("CREATE TABLE student(id integer,name varchar,sex varchar);")

# Insert data.
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(1,'Aspirin','M'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(2,'Taxol','F'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(3,'Dixheral','M'))

# Insert data in batches.
stus = ((4,'John','M'),(5,'Alice','F'),(6,'Peter','M'))
cur.executemany("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",stus)
```

```
# Obtain the result.
cur.execute('SELECT * FROM student')
results=cur.fetchall()
print (results)

# Perform a commit.
conn.commit()

# Insert a data record.
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(7,'Lucy','F'))

# Perform a rollback.
conn.rollback()

# Close the connection.
cur.close()
conn.close()

Common connection modes of psycopg2
1. conn = psycopg2.connect(dbname="dbname", user=user, password=password, host="localhost",
port=port)
2. conn = psycopg2.connect(f"dbname=dbname user={user} password={password} host=localhost
port=port")
3. Using logs
import logging
import psycopg2
from psycopg2.extras import LoggingConnection
import os

# Obtain the username and password from environment variables.
user = os.getenv('user')
password = os.getenv('password')

logging.basicConfig(level=logging.DEBUG) # Log level
logger = logging.getLogger(__name__)

db_settings = {
    "user": user,
    "password": password,
    "host": "localhost",
    "database": "dbname",
    "port": port
}

# LoggingConnection records all SQL statements by default. You can filter unnecessary or sensitive SQL
statements. Example of filtering password-related SQL statements:
class SelfLoggingConnection(LoggingConnection):

    def filter(self, msg, curs):
        if db_settings['password'] in msg.decode():
            return b'queries containing the password will not be recorded'
        return msg

conn = psycopg2.connect(connection_factory=SelfLoggingConnection, **db_settings)
conn.initialize(logger)
```

NOTE

- By default, **LoggingConnection** records all SQL information and does not anonymize sensitive information. You can use the filter function to define the output SQL content.
- The log function is an additional function provided by psycopg2 for developers to explicitly debug full SQL statements. By default, the log function is not used. This function prints SQL statements before psycopg2 executes SQL statements. However, the SQL statements can be printed only when the log level is **DEBUG**. This function is not a default function. It is used only when there are special requirements. You are advised not to use this function unless there are special requirements. For details, visit <https://www.psycopg.org/docs/extras.html?highlight=loggingconnection>.

5.6.4 Psycopg API Reference

Psycopg APIs are a set of methods provided for users. This section describes some common APIs.

5.6.4.1 psycopg2.connect()

Description

This method creates a database session and returns a new connection object.

Prototype

```
import os
conn=psycopg2.connect(dbname="test",user=os.getenv('user'),password=os.getenv('password'),host="127.0.0.1",port="5432")
```

Parameters

Table 5-71 psycopg2.connect parameters

Keyword	Description
dbname	Database name.
user	Username.
password	Password.
host	IP address of the database. You can specify multiple IP addresses and separate them with commas (.). By default, the Unix domain socket is used.
port	Connection port number. The default value is 5432 . If the host has multiple IP addresses and the port numbers are the same, specify one port number. Otherwise, the port numbers must correspond to the IP addresses one by one and are separated by commas (.).
sslmode	SSL mode, which is used for SSL connection.
sslcert	Path of the client certificate, which is used for SSL connection.
sslkey	Path of the client key, which is used for SSL connection.
sslrootcert	Path of the root certificate, which is used for SSL connection.
hostaddr	IP address of the database.
connect_timeout	Client connection timeout interval.
client_encoding	Encoding format of the client.
application_name	Value of application_name .

Keyword	Description
fallback_application_name	Rollback value of application_name .
keepalives	Determines whether to enable the TCP connection on the client. The default value is 1 , indicating that the TCP connection is enabled. The value 0 indicates that the TCP connection is disabled. If the Unix domain socket connection is used, ignore this parameter.
options	Specifies the command line options sent to the server when the connection starts.
keepalives_idle	Describes inactivity before keepalive messages are sent to the server. If keepalive is disabled, ignore this parameter.
keepalives_interval	Determines whether keepalive messages that are not confirmed by the server need to be resent. If keepalive is disabled, ignore this parameter.
keepalives_count	Specifies the number of TCP connections that may be lost before the client is disconnected from the server.
replication	Ensures that the connection uses the replication protocol instead of the common protocol.
requiressl	Supports the SSL mode.
sslcompression	Specifies the SSL compression. If this parameter is set to 1 , the data sent through the SSL connection is compressed. If this parameter is set to 0 , the compression is disabled. If no SSL connection is established, ignore this parameter.
sslcrl	Specifies the path of the certificate revocation list (CRL), which is used to check whether the SSL server certificate is available.
requirepeer	Specifies the OS username of the server.

Keyword	Description
target_session_attrs	<p>Specifies the type of the host to be connected. The connection is successful only when the host type is the same as the configured value. This parameter is verified only when multiple IP addresses are specified. The rules for setting target_session_attrs are as follows:</p> <ul style="list-style-type: none"> • any: All types of hosts can be connected. • read-write: The connection is set up only when the connected host is readable and writable. • read-only: Only readable hosts can be connected. • primary (default value): Only the primary node in the primary/standby systems can be connected. • standby: Only the standby node in the primary/standby systems can be connected. • prefer-standby: The system first attempts to find a standby node for connection. If all hosts in the hosts list fail to be connected, try the any mode.

Return Value

Connection object (for connecting to a database instance)

Example

For details, see [Examples: Common Operations](#).

5.6.4.2 connection.cursor()

Function

This method returns a new cursor object.

Prototype

```
cursor(name=None, cursor_factory=None, scrollable=None, withhold=False)
```

Parameter

Table 5-72 connection.cursor parameters

Keyword	Description
name	Cursor name. The default value is None .
cursor_factory	Creates a non-standard cursor. The default value is None .
scrollable	Sets the SCROLL option. The default value is None .

Keyword	Description
withhold	Sets the HOLD option. The default value is False .

Return Value

Cursor object (used for cursors that are programmed using Python in the entire database)

Example

For details, see [Examples: Common Operations](#).

5.6.4.3 cursor.execute(query,vars_list)

Function

This method executes the parameterized SQL statements (that is, placeholders instead of SQL literals). The pycogp2 module supports placeholders marked with %s.

Prototype

```
cursor.execute(query,vars_list)
```

Parameters

Table 5-73 cursor.execute parameters

Keyword	Description
query	SQL statement to be executed.
vars_list	Variable list, which matches the %s placeholder in the query.

Return Value

None

Example

For details, see [Examples: Common Operations](#).

5.6.4.4 cursor.executemany(query,vars_list)

Function

This method executes an SQL command against all parameter sequences or mappings found in the sequence SQL.

Prototype

```
curosr.executemany(query,vars_list)
```

Parameter

Table 5-74 curosr.executemany parameters

Keyword	Description
query	SQL statement that you want to execute.
vars_list	Variable list, which matches the %s placeholder in the query.

Return Value

None

Example

For details, see [Examples: Common Operations](#).

5.6.4.5 connection.commit()

Function

This method commits the currently pending transaction to the database.

 **CAUTION**

By default, Psycopg opens a transaction before executing the first command. If **commit()** is not called, the effect of any data operation will be lost.

Prototype

```
connection.commit()
```

Parameter

None

Return Value

None

Example

For details, see [Examples: Common Operations](#).

5.6.4.6 connection.rollback()

Function

This method rolls back the current pending transaction.

CAUTION

If you close the connection using **close()** but do not commit the change using **commit()**, an implicit rollback will be performed.

Prototype

```
connection.rollback()
```

Parameter

None

Return Value

None

Example

For details, see [Examples: Common Operations](#).

5.6.4.7 cursor.fetchone()

Function

This method extracts the next row of the query result set and returns a tuple.

Prototype

```
cursor.fetchone()
```

Parameter

None

Return Value

A single tuple is the first result in the result set. If no more data is available, **None** is returned.

Example

For details, see [Examples: Common Operations](#).

5.6.4.8 cursor.fetchall()

Function

This method gets all the (remaining) rows of the query result and returns them as a list of tuples.

Prototype

```
cursor.fetchall()
```

Parameter

None

Return Value

Tuple list, which contains all results of the result set. An empty list is returned when no rows are available.

Example

For details, see [Examples: Common Operations](#).

5.6.4.9 cursor.close()

Function

This method closes the cursor of the current connection.

Prototype

```
cursor.close()
```

Parameter

None

Return Value

None

Example

For details, see [Examples: Common Operations](#).

5.6.4.10 connection.close()

Function

This method closes the database connection.

 CAUTION

This method closes the database connection and does not automatically call **commit()**. If you just close the database connection without calling **commit()** first, changes will be lost.

Prototype

```
connection.close()
```

Parameter

None

Return Value

None

Example

For details, see [Examples: Common Operations](#).

5.7 ECPG-based Development

Embedded SQL C Preprocessor (ECPG) for GaussDB Kernel is an embedded SQL preprocessor for C programs. An embedded SQL program consists of code written in an ordinary programming language, in this case C, mixed with SQL commands in specially marked sections. To build the program, the source code (*.pgc) is first passed through the embedded SQL preprocessor, which converts it to an ordinary C program (*.c), and afterwards it can be processed by a C compiler. Converted ECPG applications call functions in the libpq library through the embedded SQL library (ecpglib), and communicate with the GaussDB Kernel server using the normal frontend-backend protocol.

Programs written for the embedded SQL interface are normal C programs with special code inserted to perform database-related actions. This special code always has the form:

```
EXEC SQL ...;
```

These statements syntactically take the place of a C statement. Depending on the particular statement, they can appear at the global level or within a function. Embedded SQL statements follow the case-sensitivity rules of normal SQL code, and allow nested C code-style comments (part of the SQL standard). However, the C part of the program follows the standards of the C program and does not support nested comments.

5.7.1 Development Process

Figure 5-5 ECPG-based development process

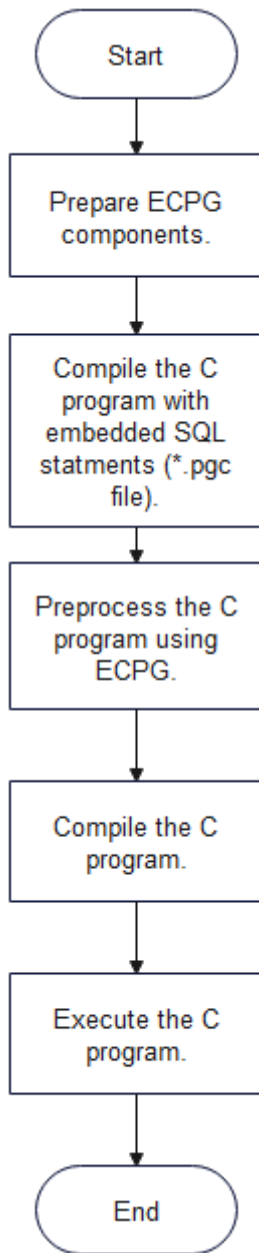

Figure 5-6 Embedded SQL-C program development process

5.7.2 ecpg Components

- Platforms supported by ecpg

Table 5-75 Platforms supported by ecpg

OS	Platform
EulerOS V2.0SP5	x86_64
EulerOS V2.0SP9	Arm64

- ecpg components
 - ecpg: an executable binary file used to preprocess C programs with embedded SQL statements.
 - libecpg: dynamic library provided by ecpg to implement connections, SQL statements, and transactions, including **libecpg.so**, **libecpg.so.6**, and **libecpg.so.6.4**. It is referenced by the **-lecp** parameter during C program compilation and execution.
 - libpgtypes: dynamic library provided by ecpg for operating data of the numeric, date, timestamp, and interval types, including **libpgtypes.so**, **libecpg.so.6**, and **libecpg.so.6.4**. The library is referenced by the **-lpgtypes** parameter during C program compilation and execution.

- Paths for obtaining ecpg components
 - ecpg binary file: `$GAUSSHOME/bin`
 - Dynamic library on which ecpg depends: `$GAUSSHOME/lib`
 - Header file required by ecpg: `$GAUSSHOME/include/ecpg`

5.7.3 ecpg Preprocessing and Compiling

Prepare C programs with embedded SQL statements with the extension `.pgc`. ecpg converts them into C programs that can be compiled by the C compiler.

The generated C program is compiled into an executable file by the GCC compiler. The executable file is run to enable the client program to access the database. For details, see [Examples](#).

- ecpg preprocessing and C compilation process
 - a. Preprocessing: `ecpg -I $GAUSSHOME/include -o test.c test.pgc`
To execute ecpg preprocessing, run the following command:
`ecpg [OPTION]...`
The options are as follows:
 - **-o OUTFILE**: writes the result to OUTFILE, which is a C file.
 - **-I DIRECTORY**: path of the header file.
 - **-c**: automatically generates a C file.
 - **--version**: checks the current ecpg version.
 - b. Compilation: `gcc -I $GAUSSHOME/include/ecpg -I $GAUSSHOME/include -I $GAUSSHOME/include/postgresql/server/ -L $GAUSSHOME/lib -lecpg -lrt -lpq -lpqtypes -lpthread test_ecpg.c -o test_ecpg`
 - c. Execution: `./test`

NOTICE

- ecpg is a compilation preprocessing tool. If an error message is displayed indicating that the related header file or function implementation cannot be found during preprocessing or compilation, you can specify the header file or link the dynamic library as required.
- ecpg requires compilation preprocessing tools such as GCC and ld. You are advised to use GCC 7.3.0.
- Other dynamic libraries and header files on which ecpg depends are usually stored in `$GAUSSHOME/include/libpq` and `$GAUSSHOME/include`.
- Common dynamic library dependencies during compilation include: `-lpq`, `-lpq_ce`, and `-lpthread`. If the libpq communications library is required during development, connect to `-lpq` and `-lpq_ce`. If the multi-thread connection is required during development, connect to `-lpthread`.

5.7.4 Managing Database Connections

This section describes how to establish and switch a database connection.

5.7.4.1 Connecting to a Database

Connect to a database.

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name];
```

The *target* can be declared using the following methods. The italic part is a variable. Change it based on the actual situation.

- *dbname*[@*hostname*][:*port*]
- tcp:postgresql://*hostname*[:*port*][/*dbname*][?*options*]
- unix:postgresql://*hostname*[:*port*][/*dbname*][?*options*]
- An SQL string containing one of the above forms

There are also different ways to specify the username:

- *username*/*password*
- *username* SQLIDENTIFIED BY *password*
- *username* USING *password*

As mentioned above, the **username** and **password** parameters can be an SQL identifier, an SQL string, or a reference to a character variable.

connection_name indicates the connection name. If a program uses only one connection, you can omit it. The most recently opened connection becomes the current connection.

Example:

```
#include <stdlib.h>
EXEC SQL CONNECT TO mydb@sql.mydomain.com;

EXEC SQL CONNECT TO unix:postgresql://sql.mydomain.com/mydb AS myconnection USER username;

EXEC SQL BEGIN DECLARE SECTION;
/* The values of target, user, and passwd must be read from environment variables or configuration files.
Environment variables need to be configured as required. If no environment variable is used, a character
string can be directly assigned. */
const char *target = getenv("EXAMPLE_TARGET_ENV");
const char *user = getenv("EXAMPLE_USERNAME_ENV");
const char *passwd = getenv("EXAMPLE_PASSWD_ENV");
EXEC SQL END DECLARE SECTION;
...
EXEC SQL CONNECT TO :target USER :user USING :passwd;
/* or EXEC SQL CONNECT TO :target USER :user/:passwd; */
```

For details about the complete example, see the connection syntax example in [CONNECT](#).

NOTE

- In the last form, character variables are referenced. For details about how to reference C variables in SQL statements, see [Host Variables](#).
- The format of the connection target is not described in the SQL standard. Therefore, to develop a portable application, you can use the method in the last example to encapsulate the connection target string into a variable.

NOTICE

- If **ip-port** is specified in the connection statement, username and password must be specified. This rule is determined by the GaussDB Kernel kernel communication authentication. If **ip-port** is not specified, the local *\$PGPORT* (UDS) is used for communication.
- If the SSL protocol is used for connection, run the **tcp:postgresql://hostname[:port]/[dbname][?options]** command and set **sslmode** to **disable** \require in **options**.

5.7.4.2 Managing Connections

SQL statements in embedded SQL programs are by default executed on the current connection, that is, the most recently opened one. If an application needs to manage multiple connections, use either of the following methods:

- Method 1: Explicitly select a connection for each SQL statement.

```
EXEC SQL AT connection-name SELECT ...;
```

This method is particularly suitable if the application needs to use several connections in mixed order.

If the application uses multiple threads of execution, they cannot share a connection concurrently. You must either explicitly control access to the connection (using mutexes) or use a connection for each thread.

- Method 2: Execute a statement to switch the connection.

```
EXEC SQL SET CONNECTION connection-name;
```

This method is particularly suitable if many statements are executed on the same connection.

An example of managing connections is as follows:

```
#include <stdio.h>
EXEC SQL BEGIN DECLARE SECTION;
char dbname[1024];
EXEC SQL END DECLARE SECTION;

int main()
{
    EXEC SQL CONNECT TO testdb1 AS con1 USER testuser;
    EXEC SQL CONNECT TO testdb2 AS con2 USER testuser;
    EXEC SQL CONNECT TO testdb3 AS con3 USER testuser;

    /* This query will be executed in the most recently opened database testdb3. */
    EXEC SQL SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb3)\n", dbname);

    /* Use AT to run a query in testdb2. */
    EXEC SQL AT con2 SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb2)\n", dbname);

    /* Switch to connection to testdb1. */
    EXEC SQL SET CONNECTION con1;

    EXEC SQL SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb1)\n", dbname);

    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

Example output:

```
current=testdb3 (should be testdb3)
current=testdb2 (should be testdb2)
current=testdb1 (should be testdb1)
```

NOTICE

- In multi-thread mode, different threads cannot use the same connection name. The connection name of each thread must be unique.
- A connection must be established and closed in the same process or thread.

5.7.5 Running SQL Commands

The format of embedded SQL commands is EXEC SQL [Command]. In embedded SQL applications, you can run common standard SQL statements supported by GaussDB Kernel or extended SQL statements provided by ECPG.

5.7.5.1 Running SQL Statements

Step 1 Create a table.

```
EXEC SQL CREATE TABLE foo (a int, b varchar);
```

Step 2 Insert a row.

```
EXEC SQL INSERT INTO foo VALUES (5, 'abc');
```

Step 3 Delete a row.

```
EXEC SQL DELETE FROM foo WHERE a = 5;
```

Step 4 Update table data.

```
EXEC SQL UPDATE foo SET b = 'gdp' WHERE a = 7;
```

Step 5 Query data in a single row.

```
EXEC SQL SELECT a INTO :var_a FROM foo WHERE b = 'def';
```

----End

A complete example is as follows:

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

int main ()
{
    ECPGdebug (1, stderr);

    EXEC SQL BEGIN DECLARE SECTION;
    int var_a;
    EXEC SQL END DECLARE SECTION;

    EXEC SQL CONNECT TO postgres;
    // Create a table.
    EXEC SQL CREATE TABLE foo (a int, b varchar);
    // Insert data.
    EXEC SQL INSERT INTO foo VALUES (5, 'abc');
    EXEC SQL INSERT INTO foo VALUES (6, 'def');
    EXEC SQL INSERT INTO foo VALUES (7, 'ghi');

    // Delete a row.
    EXEC SQL DELETE FROM foo WHERE a = 5;
    // Update table data.
```

```
EXEC SQL UPDATE foo SET b = 'gdp' WHERE a = 7;
// Query table data in a single row.
EXEC SQL SELECT a INTO :var_a FROM foo WHERE b = 'def';
// Print the query results.
printf("select res is %d\n", var_a);

EXEC SQL DISCONNECT;

return 0;
}
```

5.7.5.2 Using Cursors

To retrieve a result set holding multiple rows, an application has to declare a cursor and fetch each row from the cursor.

Step 1 Declare a cursor.

```
EXEC SQL DECLARE c CURSOR FOR select * from tb1;
```

Step 2 Open a cursor.

```
EXEC SQL OPEN c;
```

Step 3 Fetch a row of data from a cursor.

```
EXEC SQL FETCH 1 in c into :a, :str;
```

Step 4 Close a cursor.

```
EXEC SQL CLOSE c;
```

----End

For details about how to use cursors, see [DECLARE](#). For details about the [FETCH](#) command, see [FETCH](#).

A complete example is as follows:

```
#include <string.h>
#include <stdlib.h>

int main(void)
{
    exec sql begin declare section;
        int *a = NULL;
        char *str = NULL;
    exec sql end declare section;

    int count = 0;
    exec sql connect to postgres ;
    exec sql set autocommit to off;
    exec sql begin;
    exec sql drop table if exists tb1;
    exec sql create table tb1(id int, info text);
    exec sql insert into tb1 (id, info) select generate_series(1, 100000), 'test';
    exec sql select count(*) into :a from tb1;
    printf ("a is %d\n", *a);
    exec sql commit;

    // Define a cursor.
    exec sql declare c cursor for select * from tb1;
    // Open the cursor.
    exec sql open c;
    exec sql whenever not found do break;
    while(1) {
        // Capture data.
        exec sql fetch 1 in c into :a, :str;
        count++;
        if (count == 100000) {
            printf("Fetch res: a is %d, str is %s", *a, str);
        }
    }
}
```

```
    }  
  }  
  // Close the cursor.  
  exec sql close c;  
  exec sql set autocommit to on;  
  exec sql drop table tb1;  
  exec sql disconnect;  
  
  ECPGfree_auto_mem();  
  return 0;  
}
```

5.7.5.3 Transaction

In the default mode, statements are committed only when EXEC SQL COMMIT is issued. The embedded SQL interface also supports autocommit of transactions by executing the **EXEC SQL SET AUTOCOMMIT TO ON** statement. In autocommit mode, each command is automatically committed unless it is inside an explicit transaction block. This mode can be explicitly turned off by using **EXEC SQL SET AUTOCOMMIT TO OFF**.

Common transaction management commands are as follows:

- **EXEC SQL COMMIT**: commits an ongoing transaction.
- **EXEC SQL ROLLBACK**: rolls back an ongoing transaction.
- **EXEC SQL SET AUTOCOMMIT TO ON**: enables the autocommit mode.
- **SET AUTOCOMMIT TO OFF**: disables the autocommit mode. This is the default mode.

5.7.5.4 Prepared Statements

Prepared statements can be used when the value passed to an SQL statement is unknown at compile time or the same statement will be used multiple times.

- Statements are prepared using the **PREPARE** command. For the values that are not known yet, use the placeholder (?).
EXEC SQL PREPARE stmt1 FROM "SELECT oid, datname FROM pg_database WHERE oid = ?";
- If a statement returns a single row, the application can call EXECUTE after PREPARE to execute the statement, supplying the actual values for the placeholders with a USING clause:
EXEC SQL EXECUTE stmt1 INTO :dboid, :dbname USING 1;
- If a statement returns multiple rows, the application can use a cursor declared based on the prepared statement. To bind input parameters, the cursor must be opened with a USING clause:
EXEC SQL PREPARE stmt1 FROM "SELECT oid, datname FROM pg_database WHERE oid > ?";
EXEC SQL DECLARE foo_bar CURSOR FOR stmt1;
/* When the end of the result set is reached, exit the while loop. */
EXEC SQL WHENEVER NOT FOUND DO BREAK;
EXEC SQL OPEN foo_bar USING 100;
...
while (1)
{
 EXEC SQL FETCH NEXT FROM foo_bar INTO :dboid, :dbname;
 ...
}
EXEC SQL CLOSE foo_bar;
- When a prepared statement is no longer needed, it should be deallocated.
EXEC SQL DEALLOCATE PREPARE name;

5.7.5.5 Embedded SQL Commands

5.7.5.5.1 ALLOCATE DESCRIPTOR

Function

Allocates a newly named SQL descriptor area.

Syntax

```
ALLOCATE DESCRIPTOR name
```

Parameter Description

name

SQL descriptor name. It is case sensitive and is an SQL identifier or a host variable.

Example

```
EXEC SQL ALLOCATE DESCRIPTOR mydesc;
```

Helpful Links

[DEALLOCATE DESCRIPTOR](#), [GET DESCRIPTOR](#), and [SET DESCRIPTOR](#)

5.7.5.5.2 CONNECT

Description

Establishes a connection between the client and the SQL server.

Syntax

```
CONNECT TO connection_target [ AS connection_name ] [ USER connection_user ]
```

Parameters

- **connection_target**
Specifies the target server to be connected in one of the following formats:
 - [*database_name*] [@ *host*] [: *port*]: connection over TCP/IP.
 - unix: postgresql://*host* [: *port*] / [*database_name*] [? *connection_option*]: connection over Unix domain sockets.
 - tcp: postgresql://*host* [: *port*] / [*database_name*] [? *connection_option*]: connection over TCP/IP.
 - **SQL string constant**: one of the preceding forms.
- **connection_name**
An optional identifier used for the connection, which can be referenced in other commands. It can be an SQL identifier or a host variable.
- **connection_user**
Username for database connection.

You can use *user_name/password*, *user_name* **SQLIDENTIFIED BY** *password*, or *user_name* **USING** *password* to specify the username and password.

The username and password can be SQL identifiers, string constants, or host variables.

NOTE

In the preceding parameters, the information in italics refers to variables. Replace them based on the actual situation.

Examples

Here are several variants of specifying connection parameters:

```
EXEC SQL CONNECT TO "connectdb" AS main;
EXEC SQL CONNECT TO "connectdb" AS second;
EXEC SQL CONNECT TO 'connectdb' AS main;
EXEC SQL CONNECT TO REGRESSDB1 as main;
EXEC SQL CONNECT TO connectdb AS :id;
EXEC SQL CONNECT TO connectdb AS main USER connectuser/connectdb;
EXEC SQL CONNECT TO connectdb AS main USER connectuser USING "connectdb";
EXEC SQL CONNECT TO connectdb AS main;
EXEC SQL CONNECT TO tcp:postgresql://localhost/connectdb USER connectuser IDENTIFIED BY *****;
EXEC SQL CONNECT TO tcp:postgresql://localhost:$PORT/connectdb USER connectuser SQLIDENTIFIED BY
*****;
EXEC SQL CONNECT TO unix:postgresql://localhost/connectdb USER connectuser SQLIDENTIFIED BY
"*****";
EXEC SQL CONNECT TO unix:postgresql://localhost/connectdb USER connectuser USING "*****";
```

Example of the connection syntax:

```
#include <stdlib.h>
#include <string.h>
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    // Define the host by defining columns such as database and password required by the connection string.
    // The actual values are read from environment variables or configuration files. Environment variables need to
    // be configured as required. If no environment variable is used, a character string can be directly assigned.
    exec sql begin declare section;
        const int max_str_len = 200;
        char db[max_str_len] = getenv("EXAMPLE_DATABASENAME_ENV");
        char pw[max_str_len] = getenv("EXAMPLE_PASSWD_ENV");
        char new_pw[max_str_len] = getenv("EXAMPLE_NEW_PASSWD_ENV");
    exec sql end declare section;

    // Print debug logs.
    ECPGdebug(1, stderr);

    // The connection statement involves the database, username, and password. The user must be created
    // in advance and have related operation permissions.

    // Connection mode: EXEC SQL CONNECT TO [ database_name ] [ @host ] [ :port ] [ USER
    connection_user ]
    // Case 1: Use the default local connection mode to connect to the postgres database.
    exec sql connect to postgres;
    // Case 2: Use the default local connection mode to connect to the postgres database. The connection
    // alias is conn1.
    exec sql connect to postgres as conn1;
    // Case 3: Use the ip+port mode (localhost indicates the local IP address listened by the database, and
    // $PORT indicates the listening port of the database) to connect to the connectdb database, specify the
    // database alias, and specify the user password.
    exec sql connect to connectdb@localhost:$PORT as conn2 user connectuser using :pw;
    // Case 4: Use the ip+port mode (127.0.0.1 indicates the local IP address listened by the database, and
    // $PORT indicates the listening port of the database) to connect to the connectdb database, specify the
    // database alias, and specify the user password.
```

```
exec sql connect to connectdb@127.0.0.1:$PORT as conn3 user connectuser sqlidentified by :pw;
// Case 5: Close the connection to the database.
exec sql disconnect postgres;
exec sql disconnect conn1;
exec sql disconnect conn2;
exec sql disconnect conn3;

// Connection mode: EXEC SQL CONNECT TO <tcp|unix>:<gaussdb|postgres>://host
[ :port ]/[ database_name ][ ?connection_option ]
// Case 1: Replace the URL variables with the host variables pw and db.
strcpy(pw, new_pw);
strcpy(db, "tcp:postgres://localhost/connectdb");
exec sql connect to :db user connectuser using :pw;
// Case 2: 127.0.0.1 indicates the IP address listened by the database, and connectdb indicates the
database.
exec sql connect to tcp:postgres://127.0.0.1/connectdb as conn4 user connectuser using :pw;
// Case 3: 127.0.0.1 indicates the IP address listened by the database, connectdb indicates the database,
and connect_timeout=14 indicates the connection string configuration parameter.
exec sql connect to tcp:gaussdb://localhost/connectdb?connect_timeout=14 as conn5 user connectuser
sqlidentified by :pw;
// Case 4: Close all connections.
exec sql close all;

// Connect to the database and execute the service.
exec sql connect to tcp:postgres://127.0.0.1/connectdb as conn4 user connectuser using :pw;
exec sql set autocommit = on;
exec sql create table t1(a int);
exec sql insert into t1 values(1),(2);
exec sql select a from t1 where a > 1;
exec sql drop table t1;
exec sql disconnect current;
return 0;
}
```

Example of using a host variable to specify connection parameters:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
/* The values of dbname, user, and pwd must be read from environment variables or configuration files.
Environment variables need to be configured as required. If no environment variable is used, a character
string can be directly assigned. */
char *dbname = getenv("EXAMPLE_DBNAME_ENV"); /* Database name */
char *user = getenv("EXAMPLE_USERNAME_ENV"); /* Username for connection */
char *pwd = getenv("EXAMPLE_PASSWD_ENV"); /* Password */
char *connection = "tcp:postgres://localhost:$PORT/testdb"; /* Connection string */
char ver[256]; /* Buffer for storing version strings */
EXEC SQL END DECLARE SECTION;

ECPGdebug(1, stderr);
EXEC SQL CONNECT TO :dbname;
EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
EXEC SQL SELECT version() INTO :ver;
EXEC SQL DISCONNECT;

printf("version: %s\n", ver);
EXEC SQL CONNECT TO :connection USER :user USING :pwd;
EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
EXEC SQL SELECT version() INTO :ver;
EXEC SQL DISCONNECT;

printf("version: %s\n", ver);
return 0;
}
```

Helpful Links

[DISCONNECT](#) and [SET CONNECTION](#)

5.7.5.5.3 DEALLOCATE DESCRIPTOR

Function

Deallocates a SQL descriptor area.

Syntax

```
DEALLOCATE DESCRIPTOR name
```

Parameter Description

name

SQL descriptor name. It is case sensitive and is an SQL identifier or a host variable.

Example

```
DEALLOCATE DESCRIPTOR mydesc;
```

Helpful Links

[ALLOCATE DESCRIPTOR](#), [GET DESCRIPTOR](#), and [SET DESCRIPTOR](#)

5.7.5.5.4 DECLARE

Description

Declares a cursor for iterating over the result set of a prepared statement. This command is slightly semantically different from the SQL command **DECLARE**: Whereas the latter executes a query and prepares the result set for retrieval, this embedded SQL command merely declares a name as a "loop variable" for iterating over the result set of a query; the actual execution happens when the cursor is opened with the **OPEN** command.

Syntax

```
DECLARE cursor_name [ BINARY ] [ NO SCROLL ] CURSOR [ { WITH | WITHOUT } HOLD ] FOR  
prepared_name  
DECLARE cursor_name [ BINARY ] [ NO SCROLL ] CURSOR [ { WITH | WITHOUT } HOLD ] FOR query
```

Parameters

- **cursor_name**
Cursor name, which is case sensitive. It can be an SQL identifier or a host variable.
- **prepared_name**
Name of the prepared query, which can be an SQL identifier or a host variable.
- **query**

A SELECT command for providing the rows to be returned by the cursor.

 **NOTE**

For details about the cursor options, see [DECLARE](#).

Examples

Examples of declaring a cursor used for query:

```
EXEC SQL DECLARE C CURSOR FOR SELECT * FROM My_Table;  
EXEC SQL DECLARE C CURSOR FOR SELECT Item1 FROM T;  
EXEC SQL DECLARE cur1 CURSOR FOR SELECT version();
```

Example of declaring a cursor for a prepared statement:

```
EXEC SQL PREPARE stmt1 AS SELECT version();  
EXEC SQL DECLARE cur1 CURSOR FOR stmt1;
```

Helpful Links

[OPEN](#)

5.7.5.5.5 DESCRIBE

Function

Retrieves metadata information for the result columns contained in prepared statements.

Syntax

```
DESCRIBE [ OUTPUT ] prepared_name USING SQL DESCRIPTOR descriptor_name  
DESCRIBE [ OUTPUT ] prepared_name INTO SQL DESCRIPTOR descriptor_name  
DESCRIBE [ OUTPUT ] prepared_name INTO sqlda_name
```

Parameter Description

- **prepared_name**
Name of a prepared statement, which can be an SQL identifier or a host variable.
- **descriptor_name**
Descriptor name, which is case sensitive. It can be an SQL identifier or a host variable.
- **sqlda_name**
Name of an SQLDA variable.

Example

```
EXEC SQL ALLOCATE DESCRIPTOR mydesc;  
EXEC SQL PREPARE stmt1 FROM :sql_stmt;  
EXEC SQL DESCRIBE stmt1 INTO SQL DESCRIPTOR mydesc;  
EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :charvar = NAME;  
EXEC SQL DEALLOCATE DESCRIPTOR mydesc;
```

Helpful Links

[ALLOCATE DESCRIPTOR](#) and [GET DESCRIPTOR](#)

5.7.5.5.6 DISCONNECT

Function

Closes one or all database connections.

Syntax

```
DISCONNECT connection_name  
DISCONNECT [ CURRENT ]  
DISCONNECT DEFAULT  
DISCONNECT ALL
```

Parameter Description

- **connection_name**
Name of the database connection established by the CONNECT command.
- **current**
Closes the current connection, which can be a recently opened connection or a connection set by the SET CONNECTION command. This is also the default if no parameter is passed to the DISCONNECT command.
- **default**
Closes the default connection.
- **all**
Closes all open connections.

Example

```
#include <stdio.h>  
#include <stdlib.h>  
#include <string.h>  
  
int main(void)  
{  
    /* Create the testdb database in advance. */  
    EXEC SQL CONNECT TO testdb AS DEFAULT USER testuser;  
    EXEC SQL CONNECT TO testdb AS con1 USER testuser;  
    EXEC SQL CONNECT TO testdb AS con2 USER testuser;  
    EXEC SQL CONNECT TO testdb AS con3 USER testuser;  
    EXEC SQL DISCONNECT CURRENT; /* Close connection 3. */  
    EXEC SQL DISCONNECT DEFAULT; /* Close the default connection. */  
    EXEC SQL DISCONNECT ALL; /* Close connections 2 and 1. */  
    return 0;  
}
```

Helpful Links

[CONNECT](#) and [SET CONNECTION](#)

5.7.5.5.7 EXECUTE IMMEDIATE

Function

Immediately prepares and executes a dynamically specified SQL statement without retrieving result rows.

Syntax

```
EXECUTE IMMEDIATE string
```

Parameter Description

string

A C string or host variable that contains the SQL statement to be executed.

Example

The following is an example of executing the INSERT statement using EXECUTE IMMEDIATE and a host variable named **command**:

```
sprintf(command, "INSERT INTO test (name, amount, letter) VALUES ('r1', 1, 'f');  
EXEC SQL EXECUTE IMMEDIATE :command;
```

5.7.5.5.8 GET DESCRIPTOR

Function

Retrieves information about a query result set and stores it into host variables. A descriptor area is typically populated using FETCH or SELECT before using this command to transfer the information into host language variables. This command can be in either of the following formats:

- Retrieves the descriptor "header" items, which applies to the result set in its entirety.
- Retrieves information about a particular column, requiring the column number as additional parameter.

Syntax

```
GET DESCRIPTOR descriptor_name VALUE column_number :cvariable = descriptor_item [, ... ]  
GET DESCRIPTOR descriptor_name:cvariable = descriptor_header_item [, ... ]
```

Parameter Description

- **descriptor_name**
SQL descriptor name.
- **descriptor_header_item**
Identifies which header item is to be retrieved. Currently, only COUNT that is used to obtain the number of columns in the result set is supported.
- **column_number**
Number of the column about which information is to be retrieved. The count starts at 1.
- **descriptor_item**
Identifies which information item about a column is to be retrieved.
- **cvariable**
A host variable that will receive the data retrieved from the descriptor area.

Example

Retrieve the number of columns in a result set.

```
EXEC SQL GET DESCRIPTOR d :d_count = COUNT;
```

Retrieve the data length in the first column.

```
EXEC SQL GET DESCRIPTOR d VALUE 1 :d_returned_octet_length = RETURNED_OCTET_LENGTH;
```

Retrieve the data body of the second column as a string.

```
EXEC SQL GET DESCRIPTOR d VALUE 2 :d_data = DATA;
```

Execute **SELECT current_database();**. The number of columns, column data length, and column data are displayed.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    int d_count;
    char d_data[1024];
    int d_returned_octet_length;
EXEC SQL END DECLARE SECTION;
EXEC SQL CONNECT TO testdb AS con1 USER testuser;
EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
EXEC SQL ALLOCATE DESCRIPTOR d;

    /* Declare and open a cursor, and allocate a descriptor to the cursor. */
EXEC SQL DECLARE cur CURSOR FOR SELECT current_database();
EXEC SQL OPEN cur;
EXEC SQL FETCH NEXT FROM cur INTO SQL DESCRIPTOR d;

    /* Obtain the total number of columns. */
EXEC SQL GET DESCRIPTOR d :d_count = COUNT;
printf("d_count = %d\n", d_count);

    /* Obtain the length of a returned column. */
EXEC SQL GET DESCRIPTOR d VALUE 1 :d_returned_octet_length = RETURNED_OCTET_LENGTH;
printf("d_returned_octet_length = %d\n", d_returned_octet_length);

    /* Fetch the returned column as a string. */
EXEC SQL GET DESCRIPTOR d VALUE 1 :d_data = DATA;
printf("d_data = %s\n", d_data);

    /* Closed */
EXEC SQL CLOSE cur;
EXEC SQL COMMIT;

EXEC SQL DEALLOCATE DESCRIPTOR d;
EXEC SQL DISCONNECT ALL;
return 0;
}
```

The following is the command output.

```
d_count          = 1
d_returned_octet_length = 6
d_data           = testdb
```

Helpful Links

[ALLOCATE DESCRIPTOR](#), [DEALLOCATE DESCRIPTOR](#), and [SET DESCRIPTOR](#)

5.7.5.5.9 OPEN

Description

Opens a cursor and optionally binds actual values to placeholders in the cursor declaration. The cursor must have been declared using the **DECLARE** command. Executing the **OPEN** command triggers the query on the server.

Syntax

```
OPEN cursor_name  
OPEN cursor_name USING value [, ... ]  
OPEN cursor_name USING SQL_DESCRIPTOR descriptor_name
```

Parameters

- **cursor_name**
Name of the cursor to be opened. It can be an SQL identifier or a host variable.
- **value**
A value that is to be bound to a placeholder in the cursor declaration. It can be an SQL constant, a host variable, or a host variable with an indicator.
- **descriptor_name**
Name of the descriptor that contains the value to be bound to the placeholder in the cursor declaration. It can be an SQL identifier or a host variable.

Examples

```
EXEC SQL OPEN a;  
EXEC SQL OPEN d USING 1, 'test';  
EXEC SQL OPEN c1 USING SQL_DESCRIPTOR mydesc;  
EXEC SQL OPEN :curname1;
```

Helpful Links

[DECLARE](#)

5.7.5.5.10 PREPARE

Description

Prepares the statement to be executed.

Syntax

```
PREPARE name FROM string
```

Parameters

- **name**
An identifier for the prepared query.
- **string**

A C string or host variable that contains a prepared statement, which can be SELECT, INSERT, UPDATE, or DELETE.

Examples

```
char *stmt = "SELECT * FROM test1 WHERE a = ? AND b = ?";
EXEC SQL ALLOCATE DESCRIPTOR outdesc;
EXEC SQL PREPARE foo FROM :stmt;
EXEC SQL EXECUTE foo USING SQL DESCRIPTOR indesc INTO SQL DESCRIPTOR outdesc;
```

NOTICE

The PREPARE statement provided by ecpg is not equivalent to the PREPARE syntax provided by the kernel. Example:

GaussDB Kernel kernel syntax:

```
PREPARE name [ ( data_type [, ...] ) ] AS statement
```

Embedded SQL statement:

```
EXEC SQL PREPARE I (int, int) AS INSERT INTO T VALUES ( $1, $2 );
EXEC SQL EXECUTE I(1, 2);
```

When the preceding statement is executed, an error message "too few arguments on" is reported. ecpg provides a dynamic SQL statement to solve the problem in the **PREPARE name [(data_type [, ...])] AS statement** syntax scenario.

Example of using dynamic SQL syntax rules to solve the preceding problem:

```
EXEC SQL PREPARE I AS INSERT INTO T VALUES ( $1, $2 );
EXEC SQL EXECUTE I using 1, 2;
```

5.7.5.5.11 SET AUTOCOMMIT

Function

Sets the autocommit behavior of the current database session. By default, embedded SQL programs do not automatically commit, so you need to explicitly issue COMMIT. This command can change the session to the automatic commit mode so that each individual statement is implicitly committed.

Syntax

```
SET AUTOCOMMIT { = | TO } { ON | OFF }
```

5.7.5.5.12 SET CONNECTION

Function

Sets a database connection.

Syntax

```
SET CONNECTION [ TO | = ] connection_name
```

Parameter Description

- **connection_name**
Name of a database connection established by the CONNECT command.

Example

```
EXEC SQL SET CONNECTION TO con2;  
EXEC SQL SET CONNECTION = con1;
```

Helpful Links

[CONNECT](#) and [DISCONNECT](#)

5.7.5.5.13 SET DESCRIPTOR

Description

Populates an SQL descriptor area, which is usually used to bind parameters in a prepared query execution. This command can be in either of the following formats:

- Applies to the descriptor "header", which is independent of specific data.
- Assigns a value to specific data identified by a number.

Syntax

```
SET DESCRIPTOR descriptor_name descriptor_header_item = value [, ... ]  
SET DESCRIPTOR descriptor_name VALUE number descriptor_item = value [, ...]
```

Parameters

- **descriptor_name**
SQL descriptor name.
- **descriptor_header_item**
Identifies the header information item to be set. Currently, only COUNT that can be used to set the number of descriptor items is supported.
- **number**
Number of descriptor items to be set. The count starts at 1.
- **descriptor_item**
Identifies which descriptor item is to be set. Currently, only DATA, TYPE, and LENGTH are supported.
- **value**
Value to be stored in the descriptor item. The value can be an SQL constant or a host variable.

Examples

```
EXEC SQL SET DESCRIPTOR indesc COUNT = 1;  
EXEC SQL SET DESCRIPTOR indesc VALUE 1 DATA = 2;  
EXEC SQL SET DESCRIPTOR indesc VALUE 1 DATA = :val1;  
EXEC SQL SET DESCRIPTOR indesc VALUE 2 INDICATOR = :val1, DATA = 'some string';  
EXEC SQL SET DESCRIPTOR indesc VALUE 2 INDICATOR = :val2null, DATA = :val2;
```

Helpful Links

[ALLOCATE DESCRIPTOR](#), [DEALLOCATE DESCRIPTOR](#), and [GET DESCRIPTOR](#)

5.7.5.5.14 TYPE

Function

Defines a new data type. This command is identified only when `ecpg` is run with the `-c` option.

Syntax

```
TYPE type_name IS ctype
```

Parameter Description

type_name

Data type name

ctype

C type description.

Example

```
EXEC SQL TYPE customer IS
struct
{
    varchar name[50];
    int    phone;
};

EXEC SQL TYPE cust_ind IS
struct ind
{
    short name_ind;
    short phone_ind;
};

EXEC SQL TYPE c IS char reference;
EXEC SQL TYPE ind IS union { int integer; short smallint; };
EXEC SQL TYPE intarray IS int[AMOUNT];
EXEC SQL TYPE str IS varchar[BUFFERSIZ];
EXEC SQL TYPE string IS char[11];
```

Example of using EXEC SQL TYPE (note that the `-c` parameter needs to be added in the `ecpg` preprocessing phase when the following example is used):

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

EXEC SQL WHENEVER SQLERROR SQLPRINT;
EXEC SQL TYPE tt IS
struct
{
    varchar v[256];
    int    i;
};
EXEC SQL TYPE tt_ind IS
struct ind {
    short v_ind;
    short i_ind;
};

int main(void)
{
```

```
EXEC SQL BEGIN DECLARE SECTION;
  tt t;
  tt_ind t_ind;
EXEC SQL END DECLARE SECTION;
EXEC SQL CONNECT TO testdb AS con1;
EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
EXEC SQL SELECT current_database(), 256 INTO :t_ind LIMIT 1;

printf("t.v = %s\n", t.v.arr);
printf("t.i = %d\n", t.i);

printf("t_ind.v_ind = %d\n", t_ind.v_ind);
printf("t_ind.i_ind = %d\n", t_ind.i_ind);

EXEC SQL DISCONNECT con1;

return 0;
}
```

The output of this example is as follows.

```
t.v = testdb
t.i = 256
t_ind.v_ind = 0
t_ind.i_ind = 0
```

5.7.5.5.15 VAR

Function

Assigns a new C data type to a host variable. The host variable must have been declared in a DECLARE segment.

NOTE

- Exercise caution when using VAR. Using VAR to change the data type may cause the memory address to be invalid. As a result, the data variable is invalid and the value cannot be assigned.
- If the data type has been defined in the host variable DECLARE segment, you do not need to use the VAR statement.

Syntax

```
VAR varname IS ctype
```

Parameter Description

- **varname**
Name of a C variable.
- **ctype**
C type description.

Example

```
EXEC SQL BEGIN DECLARE SECTION;
  short a;
EXEC SQL END DECLARE SECTION;
EXEC SQL VAR a IS int;
```

5.7.5.5.16 WHENEVER

Description

Defines a behavior that is called when an SQL execution exception occurs (row not found, SQL alarm, or error).

Syntax

```
WHENEVER { NOT FOUND | SQLERROR | SQLWARNING } action
```

Parameters

For details about the parameter description, see [Setting Callbacks](#).

Examples

```
EXEC SQL WHENEVER NOT FOUND CONTINUE;
EXEC SQL WHENEVER NOT FOUND DO BREAK;
EXEC SQL WHENEVER SQLWARNING SQLPRINT;
EXEC SQL WHENEVER SQLWARNING DO warn();
EXEC SQL WHENEVER SQLERROR sqlprint;
EXEC SQL WHENEVER SQLERROR SQLCALL print2();
EXEC SQL WHENEVER SQLERROR DO handle_error("select");
EXEC SQL WHENEVER SQLERROR DO sqlnotice(NULL, NONO);
EXEC SQL WHENEVER SQLERROR DO sqlprint();
EXEC SQL WHENEVER SQLERROR GOTO error_label;
EXEC SQL WHENEVER SQLERROR STOP;
```

Use `WHENEVER NOT FOUND BREAK` to handle the looping of the result set.

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

int main(void)
{
    EXEC SQL CONNECT TO testdb AS con1;
    EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
    EXEC SQL ALLOCATE DESCRIPTOR d;
    EXEC SQL DECLARE cur CURSOR FOR SELECT current_database(), 'hoge', 256;
    EXEC SQL OPEN cur;

    /* When the end of the result set is reached, exit the loop. */
    EXEC SQL WHENEVER NOT FOUND DO BREAK;

    while (1)
    {
        EXEC SQL FETCH NEXT FROM cur INTO SQL DESCRIPTOR d;
        exec sql get descriptor d value 1 :d1=DATA;
        exec sql get descriptor d value 2 :d2=DATA;
        printf("d1 is %s,%s\n", d1, d2) ;
    }
    EXEC SQL CLOSE cur;
    EXEC SQL COMMIT;
    EXEC SQL DEALLOCATE DESCRIPTOR d;
    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

5.7.6 Querying the Result Set

- The `SELECT` statement that returns the result of a single row can be directly executed using `EXEC SQL`. For details, see [Running SQL Commands](#).

Example:

```
/* Create a table and insert data. */
EXEC SQL CREATE TABLE test_table (number1 integer, number2 integer);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (2, 1);

/* The query result is in a single row. :num is the host variable. */
EXEC SQL SELECT number1 INTO :num FROM test_table WHERE number2 = 1;
```

- To process a multi-row result set, you must use a cursor. For details, see [Using Cursors](#). (In special cases, an application can fetch multiple rows of results at a time and write them to the host variable of the array type. For details, see [Host Variables with Non-Primitive Types](#).)

Example:

```
/* Create a table and insert data. */
EXEC SQL CREATE TABLE test_table (number1 integer, number2 integer);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (2, 1);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (3, 1);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (4, 1);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (5, 1);

/* Define the host variable. */
EXEC SQL BEGIN DECLARE SECTION;
int v1;
int v2;
EXEC SQL END DECLARE SECTION;

/* Declare a cursor. */
EXEC SQL DECLARE test_bar CURSOR FOR SELECT number1, number2 FROM test_table ORDER BY
number1;
/* Open the cursor. */
EXEC SQL OPEN test_bar;
/* When the cursor reaches the end of the result set, exit the loop. */
EXEC SQL WHENEVER NOT FOUND DO BREAK;
/* Obtain the query result set. */
while(1)
{
EXEC SQL FETCH NEXT FROM test_bar INTO :v1, :v2;
printf("number1 = %d, number2 = %d\n",v1,v2);
}
/* Close the cursor. */
EXEC SQL CLOSE test_bar;
```

5.7.7 Closing a Database Connection

Close the database connection after the database is used.

Close a connection.

```
EXEC SQL DISCONNECT [connection];
```

Declare the connection by using the following methods:

- connection-name
- default
- current
- all

5.7.8 Host Variables

This section describes how to use host variables to pass data between C programs and embedded SQL programs. In C programs with embedded SQL statements, we use the C language as the host language and regard EXEC SQL [Command] statements as embedded SQL statements of the host language. Therefore,

variables used for embedded SQL statements in C programs are called host variables.

5.7.8.1 Overview

Passing data between a C program and SQL statements is particularly simple in embedded SQL. Instead of having the program paste data into the statements, you can simply write the name of a C variable into the SQL statement, prefixed by a colon. The following is an example.

```
EXEC SQL INSERT INTO sometable VALUES (:v1, 'foo', :v2);
```

This statement references two C variables named v1 and v2 and uses a regular SQL string, indicating that you are not restricted to use one kind of data or the other.

5.7.8.2 DECLARE Section

To implement data interaction between a C program with embedded SQL statements and a database, for example, to pass parameters in a query of the C program to the database, or to pass data from the database back to the program, the C variables that are intended to contain this data need to be declared in specially marked sections, so that the embedded SQL preprocessor is made aware of them.

This section starts with:

```
EXEC SQL BEGIN DECLARE SECTION;
```

And ends with:

```
EXEC SQL END DECLARE SECTION;
```

Between them, there must be regular C variable declarations. An example is as follows:

```
int x = 4;  
char foo[16], bar[16];
```

NOTICE

- The type of the host variables declared between the start and end of the marked section must be one of the supported data types. For details, see [Table 5-76](#).
- You can also declare variables with the following syntax which implicitly creates a DECLARE section: EXEC SQL int i = 4.
- Variables that are not intended to be used in SQL commands can be declared normally outside these special sections.
- The definition of a structure or union also must be listed inside a DECLARE section. Otherwise, the preprocessor cannot process these types.

5.7.8.3 Retrieving Query Results

To retrieve the results of a query, embedded SQL provides special variants of the usual commands **SELECT** and **FETCH**. These commands have a special INTO clause that specifies which host variables the retrieved values are to be stored in. **SELECT** is used for a query that returns only a single row, and **FETCH** is used for a query that returns multiple rows, using a cursor.

- Here is an example using the command **SELECT**:

```

/*
 * Assume a table:
 * CREATE TABLE test1 (a int, b varchar(50));
 */
EXEC SQL BEGIN DECLARE SECTION;
  int v1;
  VARCHAR v2;
EXEC SQL END DECLARE SECTION;

...

EXEC SQL SELECT a, b INTO :v1, :v2 FROM test;
    
```

The INTO clause appears between the SELECT list and the FROM clause. The number of elements in the SELECT list and the list after INTO (also called the target list) must be equal.

- Here is an example using the command **FETCH**:

```

EXEC SQL BEGIN DECLARE SECTION;
  int v1;
  VARCHAR v2;
EXEC SQL END DECLARE SECTION;

...

EXEC SQL DECLARE foo CURSOR FOR SELECT a, b FROM test;
...
do
{
  ...
  EXEC SQL FETCH NEXT FROM foo INTO :v1, :v2;
  ...
} while (...);
    
```

The INTO clause appears after all SQL clauses.

5.7.8.4 Type Mapping

When ecpg applications exchange values between the GaussDB Kernel server and the C program, such as when retrieving query results from the server or executing SQL statements with input parameters, the values need to be converted between GaussDB Kernel data types and host language variable types (C language data types, concretely). There are two data types available: Simple GaussDB Kernel data types, such as integer and text, can be directly read and written by applications. Other GaussDB Kernel data types, such as timestamp and numeric, can be accessed only by using special library functions. For details, see [ECPG API Reference](#).

Table 5-76 Mapping between GaussDB Kernel data types and C variable types

GaussDB Kernel Data Type	Host Variable Type
smallint	short
integer	int
bigint	long long int
boolean	boolean
character(n), varchar(n), text	char[n+1], VARCHAR[n+1]
double precision	double

GaussDB Kernel Data Type	Host Variable Type
real	float
smallserial	short
serial	int
bigserial	long long int
oid	unsigned int
name	char[NAMEDATALEN]
date	date [a]
timestamp	timestamp [a]
interval	interval [a]
decimal	decimal [a]
numeric	numeric [a]

 **NOTE**

[a] This type can be accessed through [Accessing Special Data Types](#).

NOTICE

- Currently, only basic data types of the C language can be used or combined. The string data type in the C++ language cannot be used as the host variable type.
- Currently, ecpg maps only common data types of GaussDB Kernel SQL. For details about the supported data types, see [Table 5-76](#).

5.7.8.5 Handling Character Strings

To handle SQL character string data types, such as varchar and text, there are two possible methods to declare the host variables.

1. Method 1: Use char[] (a char string), which is the most common method for processing character data in C programs.

```
EXEC SQL BEGIN DECLARE SECTION;  
char str[50];  
EXEC SQL END DECLARE SECTION;
```

Note that you have to take care of the length yourself. If you use this host variable as the target variable of a query which returns a string with more than 49 characters, a buffer overflow occurs.

2. Method 2: Use the VARCHAR type, which is a special type provided by ecpg. The definition on an array of type VARCHAR is converted into a named struct for every variable. The statement is as follows:

```
VARCHAR var[180];
```

It will be converted into:

```
struct varchar_var
{
    int len;
    char arr[180];
} var;
```

To store a string in a VARCHAR host variable, the host variable has to be declared as a string including the zero-byte terminator. **arr** stores the string including a terminating zero byte. **len** stores the length of the string stored in **arr** without the terminating zero byte. The terminator is not included when the length is calculated. When a host variable is used as input for a query, if the values of **strlen(arr)** and **len** are different, the shorter one is used.

CAUTION

- VARCHAR can be written in upper or lower case, but not in mixed case.
 - char and VARCHAR host variables can also hold values of other SQL types, which will be stored in their string forms.
-

5.7.8.6 Host Variables with Non-Primitive Types

Non-primitive host variables can be arrays, typedefs, structures, and pointers.

- Arrays

There are two use cases for arrays as host variables. The first case is to store some text strings in `char[]` or `VARCHAR[]`. The second case is to retrieve multiple rows from a query result without using a cursor. Without an array, to process a query result consisting of multiple rows, it is required to use a cursor and the **FETCH** command. But with array host variables, multiple rows can be received at once. The length of the array has to be defined to be able to accommodate all rows, otherwise a buffer overflow will occur.

For example, scan the `pg_database` system catalog and display the OIDs and names of all available databases.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

int main(void)
{
    EXEC SQL BEGIN DECLARE SECTION;
    int dbid[8];
    char dbname[8][16];
    int i;
    EXEC SQL END DECLARE SECTION;

    memset(dbname, 0, sizeof(char)* 16 * 8);
    memset(dbid, 0, sizeof(int) * 8);
    * Connect to the testdb database. The testdb database must be created in advance. */
    EXEC SQL CONNECT TO testdb;
    /* Retrieve multiple rows to arrays at a time. */
    EXEC SQL SELECT oid,datname INTO :dbid, :dbname FROM pg_database;
    for (i = 0; i < 8; i++)
        printf("oid=%d, dbname=%s\n", dbid[i], dbname[i]);
    EXEC SQL COMMIT;
    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

Example output (the exact value depends on the local environment):

```
oid=1, dbname=template1
oid=11510, dbname=template0
oid=11511, dbname=postgres
oid=313780, dbname=testdb
oid=0, dbname=
oid=0, dbname=
oid=0, dbname=
```

- Structures

A structure whose member names match the column names of a query result, can be used to retrieve multiple columns at once. The structure enables handling multiple column values in a single host variable.

The following example retrieves OIDs, names, and sizes of the available databases from the `pg_database` system catalog and using the `pg_database_size()` function. In this example, a structure variable `dbinfo_t` with members whose names match each column in the `SELECT` result is used to retrieve one result row without putting multiple host variables in the `FETCH` statement.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct
{
    int oid;
    char datname[65];
    long long int size;
} dbinfo_t;

dbinfo_t dbval;
EXEC SQL END DECLARE SECTION;
memset(&dbval, 0, sizeof(dbinfo_t));

EXEC SQL DECLARE cur1 CURSOR FOR SELECT oid, datname, pg_database_size(oid) AS size FROM
pg_database;
EXEC SQL OPEN cur1;

/* Exit the while loop when the end of the result set is reached. */
EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    /* Fetch multiple columns into one structure. */
    EXEC SQL FETCH FROM cur1 INTO :dbval;
    /* Print the members of the structure. */
    printf("oid=%d, datname=%s, size=%lld\n", dbval.oid, dbval.datname, dbval.size);
}
EXEC SQL CLOSE cur1;
```

Example output (the exact value depends on the local environment):

```
oid=1, datname=template1, size=4324580
oid=11510, datname=template0, size=4243460
oid=11511, datname=postgres, size=4324580
oid=313780, datname=testdb, size=8183012
```

Structure host variables "absorb" as many columns in the query result as the structure columns. Additional columns can be allocated to other host variables. The above program could also be restructured like this, with the **size** variable outside the structure:

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct
{
    int oid;
    char datname[65];
} dbinfo_t;

dbinfo_t dbval;
```

```
long long int size;
EXEC SQL END DECLARE SECTION;

memset(&dbval, 0, sizeof(dbinfo_t));

EXEC SQL DECLARE cur1 CURSOR FOR SELECT oid, datname, pg_database_size(oid) AS size FROM
pg_database;
EXEC SQL OPEN cur1;

/* Exit the while loop when the end of the result set is reached. */
EXEC SQL WHENEVER NOT FOUND DO BREAK;
while (1)
{
/* Fetch multiple columns into one structure. */
EXEC SQL FETCH FROM cur1 INTO :dbval, :size;
/* Print the members of the structure. */
printf("oid=%d, datname=%s, size=%lld\n", dbval.oid, dbval.datname, size);
}

EXEC SQL CLOSE cur1;
```

- **typedef**

Use the `typedef` keyword to map new types to existing types.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef char mychartype[40];
typedef long serial_t;
EXEC SQL END DECLARE SECTION;
```

You can also run the following command:

```
EXEC SQL TYPE serial_t IS long;
```

This declaration does not need to be part of a `DECLARE` section.

- **Pointers**

You can declare pointers to the most common types.

```
EXEC SQL BEGIN DECLARE SECTION;
int *intp;
char **charp;
EXEC SQL END DECLARE SECTION;
```

5.7.8.7 Accessing Special Data Types

ecpg supports the numeric, decimal, date, timestamp, and interval data types. These data types cannot be mapped to primitive host variable types because they have a complex internal structure. Applications deal with these types by declaring host variables in special types and accessing them using functions in the `pgtypes` library. For details about the functions in the `pgtypes` library, see [ECPG API Reference](#).

- **timestamp,date**

First, the program must include the header file for the timestamp type.

```
#include <pgtypes_timestamp.h>
```

Then, declare a host variable of the timestamp type in the `DECLARE` section.

```
EXEC SQL BEGIN DECLARE SECTION;
timestamp ts;
EXEC SQL END DECLARE SECTION;
```

After the value is read to the host variable, the `pgtypes` library function is used for processing. In the following example, the

`PGTYPEStimestamp_to_asc()` function is used to convert the timestamp value to the text format:

```
EXEC SQL SELECT now()::timestamp INTO :ts;
printf("ts = %s\n", PGTYPEStimestamp_to_asc(ts));
```

Example output:

```
ts = 2022-06-27 18:03:56.949343
```

In addition, the date type can be processed in the same way. The program must contain the **pgtypes_data.h** header file, declare a host variable as the date type, and use the `PGTYPEdata_to_asc()` function to convert the variable to the text format.

- interval

The handling of the interval type is also similar to the timestamp and date types. However, to allocate memory for an interval type value explicitly, the memory space for the variable must be allocated from the heap memory.

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <pgtypes_interval.h>
int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    interval *in;
EXEC SQL END DECLARE SECTION;
    /* Connect to the testdb database. The testdb database must be created in advance.*/
EXEC SQL CONNECT TO testdb;
    in = PGTYPEinterval_new();
EXEC SQL SELECT '1 min'::interval INTO :in;
    printf("interval = %s\n", PGTYPEinterval_to_asc(in));
    PGTYPEinterval_free(in);
EXEC SQL COMMIT;
EXEC SQL DISCONNECT ALL;
    return 0;
}
```

- numeric,decimal

The handling of the numeric and decimal types is similar to the interval type: It requires defining a pointer, allocating some memory space from the heap, and accessing the variable using the `pgtypes` library functions.

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <pgtypes_numeric.h>
EXEC SQL WHENEVER SQLERROR STOP;
int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    numeric *num;
    numeric *num2;
    decimal *dec;
EXEC SQL END DECLARE SECTION;

    /* Connect to the testdb database. The testdb database must be created in advance.*/
EXEC SQL CONNECT TO testdb;

    num = PGTYPEnumeric_new();
    dec = PGYPESdecimal_new();

EXEC SQL SELECT 12.345::numeric(4,2), 23.456::decimal(4,2) INTO :num, :dec;
    printf("numeric = %s\n", PGTYPEnumeric_to_asc(num, 0));
    printf("numeric = %s\n", PGTYPEnumeric_to_asc(num, 1));
    printf("numeric = %s\n", PGTYPEnumeric_to_asc(num, 2));
    /* Convert decimal to numeric to show a decimal value. */
    num2 = PGTYPEnumeric_new();
    PGTYPEnumeric_from_decimal(dec, num2);
    printf("decimal = %s\n", PGTYPEnumeric_to_asc(num2, 0));
    printf("decimal = %s\n", PGTYPEnumeric_to_asc(num2, 1));
    printf("decimal = %s\n", PGTYPEnumeric_to_asc(num2, 2));
    PGTYPEnumeric_free(num2);
    PGYPESdecimal_free(dec);
}
```

```
PGTYPESnumeric_free(num);  
  
EXEC SQL COMMIT;  
EXEC SQL DISCONNECT ALL;  
return 0;  
}
```

5.7.8.8 Handling Non-Primitive SQL Data Types

This section describes how to handle non-scalar and user-defined SQL-level data types in ecpg applications. Note that this is distinct from the handling of host variables of non-primitive types described in [Host Variables with Non-Primitive Types](#).

- Arrays

Multi-dimensional SQL-level arrays are not directly supported in ecpg. One-dimensional SQL-level arrays can be mapped into C array host variables and vice-versa. However, when creating a statement, ecpg does not know the types of the columns, so that it cannot check if a C array is input into a corresponding SQL-level array. When processing the output of an SQL statement, ecpg has to check if both are arrays.

Example:

```
CREATE TABLE t3 (  
  ii integer[]  
);  
testdb=> SELECT * FROM t3;  
  ii  
-----  
{1,2,3,4,5}  
(1 row)
```

The following example retrieves the fourth element of an array and stores it in a host variable of the int type:

```
EXEC SQL BEGIN DECLARE SECTION;  
  int ii;  
EXEC SQL END DECLARE SECTION;  
  
EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii[4] FROM t3;  
EXEC SQL OPEN cur1;  
  
EXEC SQL WHENEVER NOT FOUND DO BREAK;  
  
while (1)  
{  
  EXEC SQL FETCH FROM cur1 INTO :ii ;  
  printf("ii=%d\n", ii);  
}  
EXEC SQL CLOSE cur1;
```

Example output:

```
ii=4
```

To map multiple array elements to the multiple elements in an array type host variable, each element of the array column and each element of the host variable array must be managed separately. Example:

```
EXEC SQL BEGIN DECLARE SECTION;  
  int ii_a[8];  
EXEC SQL END DECLARE SECTION;  
  
EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii[1], ii[2], ii[3], ii[4] FROM t3;  
EXEC SQL OPEN cur1;  
  
EXEC SQL WHENEVER NOT FOUND DO BREAK;  
while (1)
```

```
{
  EXEC SQL FETCH FROM cur1 INTO :ii_a[0], :ii_a[1], :ii_a[2], :ii_a[3];
  ...
}
```

Note:

```
EXEC SQL BEGIN DECLARE SECTION;
  int ii_a[8];
EXEC SQL END DECLARE SECTION;

EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii FROM t3;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
  /* Error */
  EXEC SQL FETCH FROM cur1 INTO :ii_a;
  ...
}
```

It does not work out because you cannot map an array type column to an array host variable directly.

- Composite types

Composite types are not directly supported in ecpg. For example, you cannot declare member variables as date type in a structure. However, you can access each attribute separately or use the external string representation.

In the following example, each attribute can be accessed separately:

```
CREATE TYPE comp_t AS (intval integer, textval varchar(32));
CREATE TABLE t4 (compval comp_t);
INSERT INTO t4 VALUES ( (256, 'PostgreSQL') );
```

The following program retrieves data from the example table by selecting each attribute of the `comp_t` type separately:

```
EXEC SQL BEGIN DECLARE SECTION;
  int intval;
  varchar textval[33];
EXEC SQL END DECLARE SECTION;

/* Put each element of the composite type column in the SELECT list. */
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).intval, (compval).textval FROM t4;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;
while (1)
{
  /* Fetch each element of the composite type column into host variables. */
  EXEC SQL FETCH FROM cur1 INTO :intval, :textval;
  printf("intval=%d, textval=%s\n", intval, textval.arr);
}
EXEC SQL CLOSE cur1;
```

The host variables storing values in the **FETCH** command can be gathered into one structure. For more details about the host variables in the structure form, see [Handling Character Strings](#). In the following example, the two host variables, `intval` and `textval`, become members of the `comp_t` structure, and the structure is specified in the **FETCH** command:

```
EXEC SQL BEGIN DECLARE SECTION;
  typedef struct
  {
    int intval;
    varchar textval[33];
  } comp_t;
  comp_t compval;
EXEC SQL END DECLARE SECTION;
```

```
/* Put each element of the composite type column in the SELECT list. */
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).intval, (compval).textval FROM t4;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;
while (1)
{
    /* Put all values in the SELECT list into one structure. */
    EXEC SQL FETCH FROM cur1 INTO :compval;
    printf("intval=%d, textval=%s\n", compval.intval, compval.textval.arr);
}
EXEC SQL CLOSE cur1;
```

Although a structure is used in the **FETCH** command, the attribute names in the **SELECT** clause are specified one by one. This can be enhanced by using a ***** to ask for all attributes of the composite type value. For example:

```
...
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).* FROM t4;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    /* Put all values in the SELECT list into one structure. */
    EXEC SQL FETCH FROM cur1 INTO :compval;
    printf("intval=%d, textval=%s\n", compval.intval, compval.textval.arr);
}
...
```

In this way, composite types can be mapped into structures, even though `ecpg` does not understand the composite type itself.

- User-defined base types

When `ecpg` uses host variables to store query results, only the data types provided by `ecpg` are supported. Data types created using `CREATE TYPE` cannot be mapped using host variables.

The external string representation of that type is `(%lf,%lf)`, which is defined in function `complex_in()`. The following example inserts complex type values **(1,1)** and **(3,3)** into columns **a** and **b** and then queries them from the table:

```
EXEC SQL BEGIN DECLARE SECTION;
    varchar a[64];
    varchar b[64];
EXEC SQL END DECLARE SECTION;
EXEC SQL INSERT INTO test_complex VALUES ('(1,1)', '(3,3)');
EXEC SQL DECLARE cur1 CURSOR FOR SELECT a, b FROM test_complex;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    EXEC SQL FETCH FROM cur1 INTO :a, :b;
    printf("a=%s, b=%s\n", a.arr, b.arr);
}
EXEC SQL CLOSE cur1;
```

Example output:
a=(1,1), b=(3,3)

5.7.9 Executing Dynamic SQL Statements

In most cases, the SQL statements executed by an application are known when the application is written. However, in some cases, SQL statements are constructed at run time or provided by external sources. In these cases, the SQL statements

cannot be directly embedded into the C source code, but dynamic SQL statements allow you to call the provided SQL statements in a string variable.

5.7.9.1 Executing a Statement Without a Result Set

An example of running the **EXECUTE IMMEDIATE** command is as follows:

```
EXEC SQL BEGIN DECLARE SECTION;
  const char *stmt = "CREATE TABLE test1 (...);";
EXEC SQL END DECLARE SECTION;
EXEC SQL EXECUTE IMMEDIATE :stmt;
```

EXECUTE IMMEDIATE can be used for SQL statements that do not return a result set, such as DDL, INSERT, UPDATE, and DELETE statements. However, statements for retrieving data, such as SELECT statements, cannot be executed in this way.

5.7.9.2 Executing a Statement with Input Parameters

Prepare a normal statement and execute a specific version of it by replacing its parameters (with question marks). Use the EXECUTE statement to execute the prepared statement by specifying parameters in the USING clause. Example:

```
EXEC SQL BEGIN DECLARE SECTION;
  const char *stmt = "INSERT INTO test1 VALUES(?, ?);";
EXEC SQL END DECLARE SECTION;
/* PREPARE Prepare a statement for execution. */
EXEC SQL PREPARE mystmt FROM :stmt;
...
/* Single quotation marks are valid characters. If a character string is used, use double quotation marks.*/
EXEC SQL EXECUTE mystmt USING 42, 'foobar';

/* When you no longer need a prepared statement, you should deallocate it.*/
EXEC SQL DEALLOCATE PREPARE name;
```

5.7.9.3 Executing a Statement with a Result Set

EXECUTE can be used to execute SQL statements with a result set. To save the result, add an INTO clause. Example:

```
EXEC SQL BEGIN DECLARE SECTION;
  const char *stmt = "SELECT a, b, c FROM test1 WHERE a > ?";
  int v1, v2;
  VARCHAR v3[50];
EXEC SQL END DECLARE SECTION;

EXEC SQL PREPARE mystmt FROM :stmt;
...
EXEC SQL EXECUTE mystmt INTO :v1, :v2, :v3 USING 37;
```

NOTE

The EXECUTE statement supports the INTO and USING clauses.

If a query may return multiple result rows, use cursors. For details about cursors, see [Using Cursors](#). Example:

```
EXEC SQL BEGIN DECLARE SECTION;
  char dbaname[128];
  char datname[128];
  char *stmt = "SELECT u.username as dbaname, d.datname "
    " FROM pg_database d, pg_user u "
    " WHERE d.datdba = u.usesysid";
EXEC SQL END DECLARE SECTION;

EXEC SQL CONNECT TO testdb AS con1 USER testuser;

EXEC SQL PREPARE stmt1 FROM :stmt;
```

```
EXEC SQL DECLARE cursor1 CURSOR FOR stmt1;
EXEC SQL OPEN cursor1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    EXEC SQL FETCH cursor1 INTO :dbaname,:datname;
    printf("dbaname=%s, datname=%s\n", dbaname, datname);
}
EXEC SQL CLOSE cursor1;

EXEC SQL COMMIT;
EXEC SQL DISCONNECT ALL;
```

5.7.10 Error Handling

There are two non-exclusive methods to handle errors and warnings in an embedded SQL program:

- Callbacks can be configured to handle errors or warnings using the `WHENEVER` command.
- Detailed information about the errors or warnings can be obtained from the `sqlca` variable.

5.7.10.1 Setting Callbacks

One simple method to catch errors and warnings is to set a specific action to be executed whenever a particular condition occurs. To set the callback, run the following command:

```
EXEC SQL WHENEVER condition action;
```

condition can be one of the following:

- **SQLERROR**: The specified action is called whenever an error occurs during the execution of an SQL statement.
- **SQLWARNING**: The specified action is called whenever a warning occurs during the execution of an SQL statement.
- **NOT FOUND**: The specified action is called whenever an SQL statement retrieves or affects zero rows.

action can be one of the following:

- **CONTINUE**: ignores the callback error condition and continues the execution. It is usually used to stop a break condition. This is the default value.
- **GOTO label/GO TO label**: jumps to a specified label (using the C goto statement).
- **SQLPRINT**: prints a message to the standard error.
- **STOP**: calls `exit(1)` to terminate the program.
- **DO BREAK**: executes the C statement `BREAK`. This statement is used only in loops or switch statements.

Example:

```
/* It prints a simple message when a warning occurs and aborts the program when an error happens. */
EXEC SQL WHENEVER SQLWARNING SQLPRINT;
EXEC SQL WHENEVER SQLERROR STOP;
```

NOTICE

- The statement EXEC SQL WHENEVER is a directive of the SQL preprocessor, not a C statement. The error or warning actions that it sets apply to all embedded SQL statements that appear below the point where the handler is set, unless a different action was set for the same condition between the first EXEC SQL WHENEVER and the SQL statement causing the condition, regardless of the flow of control in the C program. Therefore, neither of the following C programs can achieve the expected effect:

```
/*
 * ERROR
 */
int main(int argc, char *argv[])
{
    ...
    if (verbose) {
        EXEC SQL WHENEVER SQLWARNING SQLPRINT;
    }
    ...
    EXEC SQL SELECT ...;
    ...
}
/*
 * ERROR
 */
int main(int argc, char *argv[])
{
    ...
    set_error_handler();
    ...
    EXEC SQL SELECT ...;
    ...
}
static void set_error_handler(void)
{
    EXEC SQL WHENEVER SQLERROR STOP;
}
```

- DO BREAK can be used only in the while, for, and switch scenarios. After DO BREAK is used, use the CONTINUE statement to ignore it.

5.7.10.2 sqlca

The embedded SQL API provides a global variable *sqlca* (short for SQL communication area). *sqlca* covers warnings and errors. If multiple warnings or errors occur during the execution of a statement, then *sqlca* will only contain information about the last one. In a multithreaded program, every thread automatically gets its own copy of *sqlca*.

The data structure is as follows:

```
struct
{
    char sqlcaid[8];
    long sqlabc;
    long sqlcode;
    struct
    {
        int sqlerrm;
        char sqlerrmc[SQLERRMC_LEN];
    } sqlerrm;
    char sqlerrp[8];
    long sqlerrd[6];
    char sqlwarn[8];
}
```

```
char sqlstate[5];
} sqlca;
```

If no error occurred in the last SQL statement, **sqlca.sqlcode** will be **0** and **sqlca.sqlstate** will be **00000**. If a warning or error occurred, then **sqlca.sqlcode** will be negative and **sqlca.sqlstate** will be different from **00000**. For details about the values of **SQLSTATE** and **SQLCODE**, see [SQLSTATE and SQLCODE](#).

If the last SQL statement was successful, then **sqlca.sqlerrd[1]** contains the OID of the processed row, if applicable, and **sqlca.sqlerrd[2]** contains the number of processed or returned rows, if applicable to the command.

In case of an error or warning, **sqlca.sqlerrm.sqlerrmc** will contain a string that describes the error. **sqlca.sqlerrm.sqlerrml** contains the length of the error message that is stored in **sqlca.sqlerrm.sqlerrmc**, that is, the result of **strlen()**. Note that some messages are too long to fit in the fixed-size **sqlerrmc** array; they will be truncated.

When a warning is generated, **sqlca.sqlwarn[2]** is set to **W**.

The fields **sqlcaid**, **sqlcabc**, **sqlerrp**, and the remaining elements of **sqlerrd** and **sqlwarn** currently contain no useful information.

Example:

```
/* Integrate WHENEVER and sqlca to implement error handling. */
EXEC SQL WHENEVER SQLERROR SQLCALL print_sqlca();

void print_sqlca()
{
    fprintf(stderr, "==== sqlca ====\n");
    fprintf(stderr, "sqlcode: %ld\n", sqlca.sqlcode);
    fprintf(stderr, "sqlerrm.sqlerrml: %d\n", sqlca.sqlerrm.sqlerrml);
    fprintf(stderr, "sqlerrm.sqlerrmc: %s\n", sqlca.sqlerrm.sqlerrmc);
    fprintf(stderr, "sqlerrd: %ld %ld %ld %ld %ld %ld\n", sqlca.sqlerrd[0], sqlca.sqlerrd[1], sqlca.sqlerrd[2],
        sqlca.sqlerrd[3], sqlca.sqlerrd[4], sqlca.sqlerrd[5]);
    fprintf(stderr, "sqlwarn: %d %d %d %d %d %d %d %d\n", sqlca.sqlwarn[0], sqlca.sqlwarn[1],
        sqlca.sqlwarn[2],
        sqlca.sqlwarn[3], sqlca.sqlwarn[4], sqlca.sqlwarn[5],
        sqlca.sqlwarn[6], sqlca.sqlwarn[7]);
    fprintf(stderr, "sqlstate: %5s\n", sqlca.sqlstate);
    fprintf(stderr, "=====\n");
}
```

The output is similar to the following (here is a misspelled table name):

```
==== sqlca ====
sqlcode: -400
sqlerrm.sqlerrml: 49
sqlerrm.sqlerrmc: relation "pg_databasep" does not exist on line 38
sqlerrd: 0 0 0 0 0
sqlwarn: 0 0 0 0 0 0 0
sqlstate: 42P01
=====
```

5.7.10.3 SQLSTATE and SQLCODE

SQLSTATE is a five-character array. The five characters contain digits or upper-case letters that represent codes of various error and warning conditions. SQLSTATE has a hierarchical scheme: the first two characters indicate the general class of the condition, the last three characters indicate a subclass of the general condition. For example, the code 00000 indicates the success state.

SQLCODE is a simple integer. The value 0 indicates success, a positive value indicates success with additional information, a negative value indicates an error.

The SQL standard only defines the positive value +100, which indicates that the last command returned or affected zero rows, and no specific negative values.

Table 5-77 Mapping between SQLSTATE and SQLCODE

SQLCODE Value	SQLSTATE Value	Description
0 (ECPG_NO_ERROR)	SQLSTATE 00000	Indicates no error.
100 (ECPG_NOT_FOUND)	SQLSTATE 02000	<p>This is a harmless condition indicating that the last command retrieved or processed zero rows, or that you are at the end of the cursor.</p> <p>When processing a cursor in a loop, you could use this code as a way to detect when to abort the loop. An example is as follows:</p> <pre>while (1) { EXEC SQL FETCH ... ; if (sqlca.sqlcode == ECPG_NOT_FOUND) break; }</pre> <p>Actually, WHENEVER NOT FOUND DO BREAK effectively does this internally, so there is usually no advantage in writing this out explicitly.</p>
-12 (ECPG_OUT_OF_MEMORY)	SQLSTATE YE001	Indicates that your virtual memory is exhausted. The numeric value is defined as -ENOMEM .
-200 (ECPG_UNSUPPORTED)	SQLSTATE YE000	Indicates that the preprocessor has generated something that the library does not know about.
-201 (ECPG_TOO_MANY_ARGUMENTS)	SQLSTATE 07001 or 07002	Indicates that the command specified more host variables than the command expected.
-202 (ECPG_TOO_FEW_ARGUMENTS)	SQLSTATE 07001 or 07002	Indicates that the command specified fewer host variables than the command expected.
-203 (ECPG_TOO_MANY_MATCHES)	SQLSTATE 21000	Indicates that a query has returned multiple rows, but the statement is ready to store only one result row.
-204 (ECPG_INT_FORMAT)	SQLSTATE 42804	The host variable is of the int type and the data in the database is of a different type and contains a value that cannot be interpreted as an int. The library uses strtol() for this conversion.

SQLCODE Value	SQLSTATE Value	Description
-205 (ECPG_UINT_FORMAT)	SQLSTATE 42804	The host variable is of the unsigned int type and the data in the database is of a different type and contains a value that cannot be interpreted as an unsigned int. The library uses strtoul() for this conversion.
-206 (ECPG_FLOAT_FORMAT)	SQLSTATE 42804	The host variable is of the float type and the data in the database is of another type and contains a value that cannot be interpreted as a float value. The library uses strtod() for this conversion.
-207 (ECPG_NUMERIC_FORMAT)	SQLSTATE 42804	The host variable is of the numeric type and the data in the database is of another type and contains a value that cannot be interpreted as a numeric value.
-208 (ECPG_INTERVAL_FORMAT)	SQLSTATE 42804	The host variable is of the interval type and the data in the database is of another type and contains a value that cannot be interpreted as an interval value.
-209 (ECPG_DATE_FORMAT)	SQLSTATE 42804	The host variable is of the date type and the data in the database is of another type and contains a value that cannot be interpreted as a date value.
-210 (ECPG_TIMESTAMP_FORMAT)	SQLSTATE 42804	The host variable is of the timestamp type and the data in the database is of another type and contains a value that cannot be interpreted as a timestamp value.
-211 (ECPG_CONVERT_BOOLEAN)	SQLSTATE 42804	The host variable is of the Boolean type, but the data in the database is neither 't' nor 'f'.
-212 (ECPG_EMPTY)	SQLSTATE YE000	The statement sent to the SQL server was empty. (This usually does not occur in an embedded SQL program, so it may point to an internal error.)
-213 (ECPG_MISSING_INDICATOR)	SQLSTATE 22002	A null value was returned and no null indicator variable was provided.
-214 (ECPG_NO_ARRAY)	SQLSTATE 42804	An ordinary variable was used in a place that requires an array.
-215 (ECPG_DATA_NOT_ARRAY)	SQLSTATE 42804	The database returned an ordinary variable in a place that requires array value.

SQLCODE Value	SQLSTATE Value	Description
-216 (ECPG_ARRAY_INSERT)	SQLSTATE 42804	The value cannot be inserted into the array.
-220 (ECPG_NO_CONN)	SQLSTATE 08003	The program tried to access a connection that does not exist.
-221 (ECPG_NOT_CONN)	SQLSTATE YE000	The program tried to access a connection that does exist but is not open. (This is an internal error.)
-230 (ECPG_INVALID_STMT)	SQLSTATE 26000	The statement you are trying to use has not been prepared.
-239 (ECPG_INFORMIX_DUPLICATE_KEY)	SQLSTATE 23505	Duplicate key error, violation of unique constraint.
-240 (ECPG_UNKNOWN_DESCRIPTOR)	SQLSTATE 33000	The specified descriptor was not found. The statement you are trying to use has not been prepared.
-241 (ECPG_INVALID_DESCRIPTOR_INDEX)	SQLSTATE 07009	The specified descriptor was out of range.
-242 (ECPG_UNKNOWN_DESCRIPTOR_ITEM)	SQLSTATE YE000	An invalid descriptor item was requested. (This is an internal error.)
-243 (ECPG_VAR_NOT_NUMERIC)	SQLSTATE 07006	During the execution of a dynamic statement, the database returned a numeric value and the host variable was not numeric.
-244 (ECPG_VAR_NOT_CHARACTER)	SQLSTATE 07006	During the execution of a dynamic statement, the database returned a non-numeric value and the host variable was numeric.
-284 (ECPG_INFORMIX_SUBSELECT_NOT_ONE)	SQLSTATE 21000	The result of the subquery was not a single row.
-400 (ECPG_PGSQL)	-	Some error caused by the SQL server. This message contains an error message from the SQL server.
-401 (ECPG_TRANS)	SQLSTATE 08007	The SQL server notified that the transaction cannot be started, committed, or rolled back.

SQLCODE Value	SQLSTATE Value	Description
-402 (ECPG_CONNECT)	SQLSTATE 08001	The connection attempt to the database did not succeed.
-403 (ECPG_DUPLICATE_KEY)	SQLSTATE 23505	Duplicate key error, violation of unique constraint.
-404 (ECPG_SUBSELECT_NOT_ONE)	SQLSTATE 21000	The result of the subquery was not a single row.
-602 (ECPG_WARNING_UNKNOWN_PORTAL)	SQLSTATE 34000	An invalid cursor name was specified.
-603 (ECPG_WARNING_IN_TRANSACTION)	SQLSTATE 25001	A transaction is in progress.
-604 (ECPG_WARNING_NO_TRANSACTION)	SQLSTATE 25P01	There is no active (in-progress) transaction.
-605 (ECPG_WARNING_PORTAL_EXISTS)	SQLSTATE 42P03	An existing cursor name was specified.

⚠ CAUTION

- The SQLSTATE codes 22002, 07001, 07002, 07006, 07009, 33000, 42601, 42804, 42P03, YE000 and YE001 are newly added to `ecpg` for embedded SQL statements. Other SQLSTATE codes are inherited from the kernel SQLSTATE codes.
 - If the value of **SQLSCODE** is **-400**, `ecpg` detects that the kernel server returns an error. The error code of the kernel SQLSTATE is used.
-

5.7.11 Preprocessor Directives

This section describes the preprocessing instructions provided by `ECPG`. The preprocessing instructions are used to process program instructions for macro definition, file inclusion, and conditional compilation.

5.7.11.1 Including Files

To include an external file in an embedded SQL program, use the following statements:

```
EXEC SQL INCLUDE filename;  
EXEC SQL INCLUDE <filename>;  
EXEC SQL INCLUDE "filename";
```

 NOTE

- ECPG searches for files in the following sequence:
 1. Current directory
 2. /usr/local/include
 3. GaussDB Kernel directory, which is defined at build time
 4. /usr/include
- When **EXEC SQL INCLUDE** *filename* is used, only the current directory is searched.
- In each directory, ECPG will first look for the file name as given, and if not found will append .h to the file name and try again (unless the specified file name already has that suffix).
- The file name is case sensitive.

5.7.11.2 Directives: ifdef, ifndef, else, elif, and endif

ecpg provides ifdef, ifndef, else, elif, and endif conditional compilation instructions. During preprocessing, different parts of the program are compiled based on different conditions. When using the program, you need to add the EXEC SQL prefix keyword.

Example:

```
EXEC SQL ifndef TZVAR;
EXEC SQL SET TIMEZONE TO 'GMT';
EXEC SQL elif TZNAME;
EXEC SQL SET TIMEZONE TO TZNAME;
EXEC SQL else;
EXEC SQL SET TIMEZONE TO TZVAR;
EXEC SQL endif;
```

5.7.11.3 Directives: define and undef

Similar to the directive **#define** that is known from C, embedded SQL has a similar concept.

```
EXEC SQL DEFINE name;
EXEC SQL DEFINE name value;
EXEC SQL UNDEF name;
```

Example:

```
/* Define a name. */
EXEC SQL DEFINE HAVE_FEATURE;

/* Define constants. */
EXEC SQL DEFINE MYNUMBER 12;
EXEC SQL DEFINE MYSTRING 'abc';

/* Use undef to remove a previous definition. */
EXEC SQL UNDEF MYNUMBER;
```

You can also use the C versions **#define** and **#undef** in your embedded SQL program. The difference is where your defined values get evaluated. If you use **EXEC SQL DEFINE**, then ecpg evaluates the definitions and substitutes the values. In the following example, ecpg does the substitution and the compiler will never see any name or identifier **MYNUMBER**:

```
EXEC SQL DEFINE MYNUMBER 12;
...
EXEC SQL UPDATE Tbl SET col = MYNUMBER;
```

NOTICE

Note that you cannot use **#define** for a constant that you are going to use in an embedded SQL query because in this case the embedded SQL precompiler is not able to see this declaration.

5.7.12 Using Library Functions

- `ECPGdebug(int on, FILE *stream)`: If the first parameter of the function is not 0, the debug log function is enabled. The second parameter indicates the standard output stream of the log to be printed. Debug logs are executed on the standard output stream. The logs contain all input SQL statements and results from the GaussDB Kernel server.

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "sqlca.h"

int main()
{
    ECPGdebug(1, stderr);
    EXEC SQL CONNECT postgres;
    EXEC SQL SET AUTOCOMMIT TO ON;
    EXEC SQL CREATE TABLE T1(a int);
    return (0);
}
```

- `ECPGget_PGconn(const char *connection_name)`: returns the database connection handle identified by the given name. If `connection_name` is set to **NULL**, the current connection handle is returned. If no connection handle can be identified, the function returns **NULL**.

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "sqlca.h"

int main()
{
    ECPGdebug(1, stderr);
    EXEC SQL CONNECT TO postgres as con1;
    EXEC SQL SET AUTOCOMMIT TO ON;
    EXEC SQL DROP TABLE IF EXISTS T1;
    PGconn *conn;
    conn = ECPGget_PGconn("con1");
    printf("conn = %p\n", conn);
    conn = ECPGget_PGconn(NULL);
    printf("conn = %p\n", conn);
    EXEC SQL CREATE TABLE T1(a int);
    return (0);
}
```

- `ECPGtransactionStatus(const char *connection_name)`: returns the current transaction status of the `connection_name` connection. The possible return values are as follows:

```
PQTRANS_IDLE, /* connection idle */
PQTRANS_ACTIVE, /* command in progress */
PQTRANS_INTRANS, /* idle, within transaction block */
PQTRANS_INERROR, /* idle, within failed transaction */
PQTRANS_UNKNOWN /* cannot determine status */
```

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "sqlca.h"

int main()
{
    ECPGdebug(1, stderr);
    EXEC SQL CONNECT TO postgres as con1;
    EXEC SQL DROP TABLE IF EXISTS T1;
    int a = ECPGtransactionStatus("con1");
    printf("%d\n", a);
    EXEC SQL CREATE TABLE T1(a int);
    EXEC SQL COMMIT;
    return (0);
}
```

- `ECPGfree_auto_mem()`: releases all memory allocated for output host variables. This function is called (`return\exit`) when the program ends.

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "sqlca.h"

int main()
{
    EXEC SQL BEGIN DECLARE SECTION;
    int *ip1=0;
    char **cp2=0;
    int *ipointer1=0;
    int *ipointer2=0;
    int colnum;
    EXEC SQL END DECLARE SECTION;
    int i;

    ECPGdebug(1, stderr);

    EXEC SQL WHENEVER SQLERROR DO sqlprint();
    EXEC SQL CONNECT TO REGRESSDB1;

    EXEC SQL SET DATESTYLE TO postgres;

    EXEC SQL CREATE TABLE test (a int, b text);
    EXEC SQL INSERT INTO test VALUES (1, 'one');
    EXEC SQL INSERT INTO test VALUES (2, 'two');
    EXEC SQL INSERT INTO test VALUES (NULL, 'three');
    EXEC SQL INSERT INTO test VALUES (NULL, NULL);

    EXEC SQL ALLOCATE DESCRIPTOR mydesc;
    EXEC SQL SELECT * INTO SQL DESCRIPTOR mydesc FROM test;
    EXEC SQL GET DESCRIPTOR mydesc :colnum=COUNT;
    EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :ip1=DATA, :ipointer1=INDICATOR;
    EXEC SQL GET DESCRIPTOR mydesc VALUE 2 :cp2=DATA, :ipointer2=INDICATOR;

    printf("Result (%d columns):\n", colnum);
    for (i=0; i < sqlca.sqlerrd[2]; ++i)
    {
        if (ipointer1[i]) printf("NULL, ");
        else printf("%d, ", ip1[i]);

        if (ipointer2[i]) printf("NULL, ");
        else printf("%s, ", cp2[i]);
        printf("\n");
    }
    ECPGfree_auto_mem();
    printf("\n");

    EXEC SQL DEALLOCATE DESCRIPTOR mydesc;
```

```
EXEC SQL ROLLBACK;  
EXEC SQL DISCONNECT;  
return 0;  
}
```

5.7.13 SQL Descriptor Area

An SQL descriptor area (SQLDA) is a more sophisticated method for processing the result of a SELECT, FETCH or a DESCRIBE statement. An SQLDA groups the data of one row of data together with metadata items into one data structure. ecpg provides two ways to use descriptor areas: named SQLDA and C-structure SQLDA.

5.7.13.1 Named SQLDA

A named SQLDA consists of a header and one or more item descriptor areas. The header contains information concerning the entire descriptor area, and each item descriptor area describes a column in the result row.

- Before using an SQLDA, you need to allocate it.
EXEC SQL ALLOCATE DESCRIPTOR identifier;
- When you no longer need the SQLDA, deallocate it in time.
EXEC SQL DEALLOCATE DESCRIPTOR identifier;
- To use a descriptor area, declare it using the INTO clause.
EXEC SQL FETCH NEXT FROM mycursor INTO SQL DESCRIPTOR mydesc;

If the result set is empty, the descriptor area still contains the metadata from the query.

- For a prepared query that has not been executed, you can use DESCRIBE to obtain the metadata of its result set.
EXEC SQL BEGIN DECLARE SECTION;
char *sql_stmt = "SELECT * FROM table1";
EXEC SQL END DECLARE SECTION;

```
EXEC SQL PREPARE stmt1 FROM :sql_stmt;  
EXEC SQL DESCRIBE stmt1 INTO SQL DESCRIPTOR mydesc;
```

In DESCRIBE and FETCH statements, the INTO and USING keywords are used similarly: they produce a result set and metadata in a descriptor area.

- Retrieve the value in a descriptor area from the header and store it into a host variable.
EXEC SQL GET DESCRIPTOR name :hostvar = field;
- Currently, only one header descriptor area **COUNT** is defined, which tells how many item descriptor areas exist (that is, how many columns are contained in the result). The host variable must be of the integer type. Retrieve a specific value from the item descriptor area.
EXEC SQL GET DESCRIPTOR name VALUE num :hostvar = field;

num can be a character integer or a host variable that contains an integer.

Possible data types are as follows:

- **CARDINALITY** (integer): number of rows in the result set
- **DATA**: actual data item (therefore, the data type of this field depends on the query)
- **DATETIME_INTERVAL_CODE** (integer): When **TYPE** is **9**, **DATETIME_INTERVAL_CODE** will have a value of **1** for DATE, **2** for TIME, **3** for TIMESTAMP, **4** for TIME WITH TIME ZONE, or **5** for TIMESTAMP WITH TIME ZONE.

- INDICATOR (integer): indicator (indicating a null value or a value truncation)
- LENGTH (integer): data length in characters
- NAME(string): column name
- OCTET_LENGTH (integer): length of the character representation of the data in bytes
- PRECISION (integer): precision (for the numeric type)
- RETURNED_LENGTH (integer): data length in characters
- RETURNED_OCTET_LENGTH (integer): length of the character representation of the data in bytes
- SCALE (integer): ratio (for the numeric type)
- TYPE (integer): numeric code of the data type of the column
- Retrieve the column value and store it in a host variable.

```
EXEC SQL GET DESCRIPTOR mydesc VALUE num :hostvar = field
```

num can be a character integer or a host variable that contains an integer. Possible columns are as follows:

- DATA
- Actual data item (the data type of this column depends on the query)
- NAME(string)
- Field name
- Manually create a descriptor area to provide input parameters for a query or cursor.

```
EXEC SQL SET DESCRIPTOR name VALUE numfield = :hostvar;
```
- Retrieve multiple rows of records in a FETCH statement and use a host variable of the array type to store data.

```
EXEC SQL BEGIN DECLARE SECTION;  
int id[5];  
EXEC SQL END DECLARE SECTION;  
EXEC SQL FETCH 5 FROM mycursor INTO SQL DESCRIPTOR mydesc;  
EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :id = DATA;
```

5.7.13.2 SQLDA

SQLDA is a C language structure used to store a query result set. A structure stores a record of a result set.

```
EXEC SQL include sqllda.h;  
sqllda_t *mysqllda;  
EXEC SQL FETCH 3 FROM mycursor INTO DESCRIPTOR mysqllda;
```

Note that the SQL keyword is omitted. The paragraphs about the use cases of the INTO and USING keywords in section [Named SQLDA](#) also apply here. In a DESCRIBE statement, if the INTO keyword is used, the DESCRIPTOR keyword can be omitted.

```
EXEC SQL DESCRIBE prepared_statement INTO mysqllda;
```

- Procedure
 - a. Prepare a query and declare a cursor for it.
 - b. Declare an SQLDA for the result row.
 - c. Declare SQLDA for input parameters, initialize parameters, and allocate memory.

- d. Open a cursor with the input SQLDA.
 - e. Fetch rows from the cursor and store them in the output SQLDA.
 - f. Read the value from the output SQLDA to the host variable.
 - g. Close the cursor.
 - h. Deallocate the memory allocated to the SQLDA.
- There are three types of SQLDA data structures: `sqlda_t`, `sqlvar_t`, and `struct sqlname`.

a. `sqlda_t`

The definition of `sqlda_t` is as follows:

```
struct sqlda_struct
{
    char        sqldaid[8];
    long        sqldabc;
    short       sqln;
    short       sqld;
    struct sqlda_struct *desc_next;
    struct sqlvar_struct sqlvar[1];
};
typedef struct sqlda_struct sqlda_t;
```

The structure members are described as follows:

- **sqldaid**: contains a string "SQLDA".
 - **sqldabc**: contains the size (in bytes) of the allocated space.
 - **sqln**: contains the number of input parameters for a parameterized query in case it is passed into OPEN, DECLARE or EXECUTE statements using the USING keyword. When it is used as the output of a SELECT, EXECUTE, or FETCH statement, its value is the same as that of **sqld**.
 - **sqld**: contains the number of fields in a result set.
 - **desc_next**: If the query returns more than one record, multiple linked SQLDA structures are returned, and **desc_next** holds a pointer to the next SQLDA structure in the list.
 - **sqlvar**: indicates the array of the columns in the result set.
- b. `sqlvar_t`

The structure type `sqlvar_t` holds a column value and metadata (such as type and length). The definition of this type is as follows:

```
struct sqlvar_struct
{
    short       sqltype;
    short       sqllen;
    char        *sqldata;
    short       *sqlind;
    struct sqlname sqlname;
};
typedef struct sqlvar_struct sqlvar_t;
```

The structure members are described as follows:

- **sqltype**: contains the type identifier of the field.
- **sqllen**: contains the binary length of the field, for example, 4 bytes for `ECPGt_int`.

- **sqldata**: points to the data. For details about the data format, see [Type Mapping](#).
 - **sqlind**: points to a null indicator. The value **0** indicates not null, and the value **-1** indicates null.
 - **sqlname**: indicates the name of the field.
- c. struct sqlname
- A struct sqlname structure holds a column name. It is treated as a member of the sqlvar_t structure. The definition of this type is as follows:
- ```
#define NAMEDATALEN 64
struct sqlname
{
 short length;
 char data[NAMEDATALEN];
};
```
- The structure members are described as follows:
- **length**: contains the length of the field name.
  - **data**: contains the actual field name.
- Use an SQLDA to retrieve a result set.
- The general procedure for retrieving a query result set through an SQLDA is as follows:
- a. Declare an sqlda\_t structure to receive the result set.
  - b. Execute the **FETCH**, **EXECUTE**, or **DESCRIBE** command to process a query for which an SQLDA has been declared.
  - c. Check the number of records in the result set by looking at sqln, a member of the sqlda\_t structure.
  - d. Fetch the values of each column from sqlvar[0], sqlvar[1], ..., members of the sqlda\_t structure.
  - e. Go to next row (sqlda\_t) by following the desc\_next pointer, a member of the sqlda\_t structure.
  - f. Repeat the preceding steps as required.

**Example:**

```
/* Declare an sqlda_t structure to receive the result set. */
sqlda_t *sqlda1;
/* Next, specify an SQLDA in a command. This is an example of the FETCH command. */
EXEC SQL FETCH NEXT FROM cur1 INTO DESCRIPTOR sqlda1;
/* Run a loop to retrieve rows along the linked list. */
sqlda_t *cur_sqlda;
for (cur_sqlda = sqlda1;
 cur_sqlda != NULL;
 cur_sqlda = cur_sqlda->desc_next)
{
 ...
}
/* Inside the loop, run another loop to retrieve the data of each column in the row (sqlvar_t). */
for (i = 0; i < cur_sqlda->sqln; i++)
{
 sqlvar_t v = cur_sqlda->sqlvar[i];
 char *sqldata = v.sqldata;
 short sqlllen = v.sqlllen;
 ...
}
/* To fetch the values of a column, check the value of the sqltype member of the sqlvar_t structure.
```

```
Then, switch to an appropriate method based on the column type to copy data from the sqlvar field to a host variable. */
char var_buf[1024];
switch (v.sqltype)
{
 case ECPGt_char:
 memset(&var_buf, 0, sizeof(var_buf));
 memcpy(&var_buf, sqldata, (sizeof(var_buf) <= sqlllen ? sizeof(var_buf) - 1 : sqlllen));
 break;

 case ECPGt_int:
 memcpy(&intval, sqldata, sqlllen);
 sprintf(var_buf, sizeof(var_buf), "%d", intval);
 break;

 ...
}
```

- Use an SQLDA to pass query parameters.

The general procedure for passing input parameters to a prepared query using an SQLDA is as follows:

- a. Create a prepared query (prepared statement).
- b. Declare an sqlda\_t structure as an SQLDA.
- c. Allocate a memory area for the SQLDA.
- d. Set (copy) the input values in the allocated memory.
- e. Open a cursor declaring the SQLDA.

Example:

```
/* First, create a prepared statement. */
EXEC SQL BEGIN DECLARE SECTION;

```

## Example Code of the pgtypes Library Function

Example 1: Use library functions to perform different operations on time and date types. For details, see [Using Library Functions](#).

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <limits.h>
#include <pgtypes_date.h>
#include <pgtypes_timestamp.h>

char *dates[] = { "19990108foobar",
 "19990108 foobar",
 "1999-01-08 foobar",
 "January 8, 1999",
 "1999-01-08",
 "1/8/1999",
 "1/18/1999",
 "01/02/03",
 "1999-Jan-08",
 "Jan-08-1999",
 "08-Jan-1999",
 "99-Jan-08",
 "08-Jan-99",
 "08-Jan-06",
 "Jan-08-99",
 "19990108",
 "990108",
 "1999.008",
 "J2451187",
 "January 8, 99 BC",
 NULL
 };

/* The value cannot conflict with the value of times of libc. */
static char *times[] = { "0:04",
```

```
 "1:59 PDT",
 "13:24:40 -8:00",
 "13:24:40.495+3",
 NULL
 };

char *intervals[] = { "1 minute",
 "1 12:59:10",
 "2 day 12 hour 59 minute 10 second",
 "1 days 12 hrs 59 mins 10 secs",
 "1 days 1 hours 1 minutes 1 seconds",
 "1 year 59 mins",
 "1 year 59 mins foobar",
 NULL
};

int main(void)
{
 exec sql begin declare section;
 date date1;
 timestamp ts1, ts2;
 char *text;
 interval *i1;
 date *dc;
 exec sql end declare section;

 int i, j;
 char *endptr;

 ECPGdebug(1, stderr);

 /* Parse a timestamp from its textual representation and convert the date into a character string. */
 ts1 = PGTYPEStimestamp_from_asc("2003-12-04 17:34:29", NULL);

## 5.7.15 ecpg and Pro\*C Compatibility Comparison

ecpg, provided by GaussDB, is an embedded SQL preprocessor for C programs. It differs from the Pro\*C preprocessor of the ORA-compatible database in the behavior and semantics of compiling and executing commands, syntax, and embedded statements.

Comparison between ecpg and Pro\*C:

- Currently, ecpg does not support EXEC SQL CONTEXT ALLOCATE, EXEC SQL CONTEXT USE, and EXEC SQL Context FREE.

### NOTE

Currently, ecpg does not support context allocation, use, and release. ecpg has an independent memory management mechanism. In multi-thread mode, ecpg independently establishes connections, executes SQL statements, and releases related resources in each thread. This usage mode is the same as the processing logic for each thread to allocate and release contexts in Pro\*C multi-thread mode.

- Currently, ecpg does not support EXEC SQL COMMIT WORK RELEASE.

 **NOTE**

In ecpg, after the COMMIT statement is executed, the **RELEASE** option is not available. You need to execute the EXEC SQL DISCONNECT and EXEC SQL CLOSE statements to release related resources. In Pro\*C, EXEC SQL COMMIT has the **RELEASE** option, which is used to release all resource information such as connections and cursors held by the program.

- Currently, ecpg does not support EXEC SQL ENABLE THREAD.

 **NOTE**

To enable macro definition in the ecpg compilation options, you need to define ENABLE\_THREAD\_SAFETY in the .pgc file of the main function.

## 5.7.16 ECPG API Reference

The ECPG API reference describes the data type-related interfaces provided by the pgtypes library for users to use in embedded SQL-C programs. The pgtypes library maps SQL data types to C data types and provides some interfaces to implement basic functions and calculations.

### 5.7.16.1 Interval Type

[Table 5-78](#) lists the common APIs for interval data provided by ecpg.

**Table 5-78** Common interval type APIs

| API                                                            | Description                                                          | Description                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------------------|----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| interval*<br>PGTYPEInterval_new(void)                          | Returns a pointer to an allocated interval variable.                 | This function creates an interval variable on the heap. The return value is of the interval* type.                                                                                                                                                                                                 |
| void<br>PGTYPEInterval_free(interval* inval)                   | Releases the memory that has been allocated to an interval variable. | This function releases the memory allocated to the interval* variable created by the PGTYPEInterval_new function.                                                                                                                                                                                  |
| interval*<br>PGTYPEInterval_from_asc(char* str, char** endptr) | Parses an interval from its textual representation.                  | This function parses the input string <b>str</b> and returns a pointer to an allocated interval variable. Currently, ecpg parses the entire character string and does not support storing the address of the first invalid character in <b>*endptr</b> . <b>endptr</b> can be set to <b>NULL</b> . |

| API                                                                 | Description                                                               | Description                                                                                                    |
|---------------------------------------------------------------------|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| char*<br>PGTYPEInterval_to_asc(interval* span)                      | Converts a variable of the interval type into its textual representation. | This function converts the interval variable to which the span points into a char*.                            |
| int<br>PGTYPEInterval_copy(interval* intvlsrc, interval* intvldest) | Copies a variable of the interval type.                                   | This function copies the interval variable that intvlsrc points to into the variable that intvldest points to. |

## Examples

For details, see [Examples](#).

### 5.7.16.2 Numeric Type

[Table 5-79](#) lists the common APIs for numeric (numeric or decimal) data provided by ecpg.

**Table 5-79** Common numeric type APIs

| API                                      | Description                                               | Description                                                                                     |
|------------------------------------------|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| numeric*<br>PGTYPEnumeric_new(void)      | Requests a pointer to a newly allocated numeric variable. | This function creates a numeric variable on the heap. The return value is of the numeric* type. |
| decimal*<br>PGTYPEdecimal_new(void)      | Requests a pointer to a newly allocated decimal variable. | This function creates a decimal variable on the heap. The return value is of the decimal* type. |
| void<br>PGTYPEnumeric_free(numeric* var) | Frees the memory of a variable of the numeric type.       | This function frees a numeric* variable created by using the PGTYPEnumeric_new function.        |
| void<br>PGTYPEdecimal_free(decimal*)     | Frees the memory of a variable of the decimal type.       | This function frees a decimal* variable created by using the PGTYPEdecimal_new function.        |

| API                                                                      | Description                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| numeric*<br>PGTYPEsnumeric_from_asc(char* str, char** endptr)            | Converts a string to the numeric type.                                                                             | For example, the valid formats are -2, .794, +3.44, 592.49E07 or -32.84e-4. If the value could be parsed successfully, a valid pointer is returned; otherwise, a null pointer is returned. ecpg only parses complete character strings. Currently, ecpg does not support storing the address of the first invalid character in *endptr. However, endptr can be set to null. |
| char*<br>PGTYPEsnumeric_to_asc(numeric* num, int dscale)                 | Returns a pointer to a string allocated by malloc that contains the string representation of the numeric type num. | The numeric value will be printed using dscale decimal places and will be rounded if necessary.                                                                                                                                                                                                                                                                             |
| int<br>PGTYPEsnumeric_add(numeric* var1, numeric* var2, numeric* result) | Adds two numeric variables to the third numeric variable.                                                          | This function adds the variables <i>var1</i> and <i>var2</i> to the result variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.                                                                                                                                                                                                |
| int<br>PGTYPEsnumeric_sub(numeric* var1, numeric* var2, numeric* result) | Subtracts two numeric variables and returns the result to the third numeric variable.                              | This function subtracts <i>var2</i> from <i>var1</i> . The result of this operation is stored in the variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.                                                                                                                                                                      |
| int<br>PGTYPEsnumeric_mul(numeric* var1, numeric* var2, numeric* result) | Multiplies two numeric variables and returns the result to the third numeric variable.                             | This function multiplies variables <i>var1</i> and <i>var2</i> . The result of this operation is stored in the variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.                                                                                                                                                            |

| API                                                                             | Description                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| int<br>PGTYPESnumeric_div(nu<br>meric* var1, numeric*<br>var2, numeric* result) | Divides two numeric variables and returns the result to the third numeric variable. | This function divides variable <i>var1</i> by variable <i>var2</i> . The result of this operation is stored in the variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.                                                                                                                                                                                                                                        |
| int<br>PGTYPESnumeric_cmp(n<br>umeric* var1, numeric*<br>var2)                  | Compares two numeric variables.                                                     | This function compares two numeric variables. If an error occurs, <i>INT_MAX</i> is returned. On success, this function returns one of the following three possible results: <ul style="list-style-type: none"> <li>• If <i>var1</i> is greater than <i>var2</i>, <b>1</b> is returned.</li> <li>• If <i>var1</i> is smaller than <i>var2</i>, <b>-1</b> is returned.</li> <li>• If <i>var1</i> and <i>var2</i> are equal, <b>0</b> is returned.</li> </ul> |
| int<br>PGTYPESnumeric_from_i<br>nt(signed int int_val,<br>numeric* var)         | Converts an int variable into a numeric variable.                                   | This function accepts a signed int variable and stores it in the numeric variable <i>var</i> . The function returns <b>0</b> on success and <b>-1</b> in case of failure.                                                                                                                                                                                                                                                                                   |
| int<br>PGTYPESnumeric_from_l<br>ong(signed long int<br>long_val, numeric* var)  | Converts a long int variable into a numeric variable.                               | This function accepts a long int variable and stores it in the numeric variable <i>var</i> . The function returns <b>0</b> on success and <b>-1</b> in case of failure.                                                                                                                                                                                                                                                                                     |
| int<br>PGTYPESnumeric_copy(n<br>umeric* src, numeric*<br>dst)                   | Copies a numeric variable to another one.                                           | This function copies the value of the variable that <b>src</b> points to into the variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error.                                                                                                                                                                                                                                                              |

| API                                                       | Description                                                   | Description                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------------|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| int<br>PGTYPESnumeric_from_double(double d, numeric* dst) | Converts a double-precision variable into a numeric variable. | This function accepts a double-precision variable and stores the result in the variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error.                                                                                                                                                     |
| int<br>PGTYPESnumeric_to_double(numeric* nv, double* dp)  | Converts a numeric variable into a double-precision variable. | This function converts the numeric value in the variable that <b>nv</b> points to into a double-precision variable that <b>dp</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> . |
| int<br>PGTYPESnumeric_to_int(numeric* nv, int* ip)        | Converts a numeric variable into an int variable.             | This function converts the numeric value in the variable that <b>nv</b> points to into an int variable that <b>ip</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> .             |
| int<br>PGTYPESnumeric_to_long(numeric* nv, long* ip)      | Converts a numeric variable into a long int variable.         | This function converts the numeric value in the variable that <b>nv</b> points to into a long int variable that <b>ip</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> .         |

| API                                                            | Description                                          | Description                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------------|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| int<br>PGTYPESnumeric_to_decimal(numeric* src, decimal* dst)   | Converts a numeric variable into a decimal variable. | This function converts the numeric value in the variable that <b>src</b> points to into a decimal variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> . |
| int<br>PGTYPESnumeric_from_decimal(decimal* src, numeric* dst) | Converts a decimal variable into a numeric variable. | This function converts the decimal value in the variable that <b>src</b> points to into a numeric variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow).                                                                                                             |

## Examples

For details, see [Examples](#).

### 5.7.16.3 Date Type

[Table 5-80](#) lists the common date type APIs provided by ecpg.

**Table 5-80** Common date type APIs

| API                             | Description                                                     | Description                                                                               |
|---------------------------------|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| date*<br>PGTYPESdate_new(void)  | Returns a pointer to an allocated date variable.                | This function creates a date variable on the heap. The return value is of the date* type. |
| void<br>PGTYPESdate_free(date*) | Releases the memory that has been allocated to a date variable. | Frees a date* variable created using the PGTYPESdate_free function.                       |

| API                                                            | Description                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>date<br/>PGTYPESdate_from_asc(char* str, char** endptr)</p> | <p>Parses a date from its textual representation.</p>                                | <p>This function accepts a C string <b>str</b> and a pointer to a C string <b>endptr</b>. <b>ecpg</b> converts the date expressed in text into a character string. Currently, ECPG does not support storing the address of the first invalid character in <b>*endptr</b>. However, <b>endptr</b> can be set to null.</p> <p>Note that the function always assumes MDY-formatted dates and there is currently no variable to change that within <b>ecpg</b>.</p> |
| <p>char*<br/>PGTYPESdate_to_asc(date dDate)</p>                | <p>Returns the textual representation of a date variable.</p>                        | <p>This function accepts the date <b>dDate</b> as its unique parameter. It will output the date in the YYYY-MM-DD format.</p>                                                                                                                                                                                                                                                                                                                                   |
| <p>date<br/>PGTYPESdate_from_timestamp(timestamp dt)</p>       | <p>Extracts the date part from a timestamp.</p>                                      | <p>This function accepts a timestamp as its unique parameter and returns the extracted date part from the timestamp.</p>                                                                                                                                                                                                                                                                                                                                        |
| <p>void<br/>PGTYPESdate_julmdy(date jd, int* mdy)</p>          | <p>Extracts the values of day, month, and year from a variable of the date type.</p> | <p>This function accepts the date <b>jd</b> and a pointer to an array of three integer values <b>mdy</b>. The variable name indicates the sequence. <b>mdy[0]</b> indicates the month, <b>mdy[1]</b> indicates the day, and <b>mdy[2]</b> indicates the year.</p>                                                                                                                                                                                               |

| API                                                  | Description                                                     | Description                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------------------|-----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| void<br>PGTYPEdate_mdyjul(int<br>* mdy, date* jdate) | Creates a date using the specified integer value.               | This function accepts an array consisting of three integers ( <b>mdy</b> ) as its first parameter. The three integers are used to indicate the day, month, and year, respectively. The second parameter is a pointer to a variable of the date type, which is used to store the result of the operation.                                                     |
| int<br>PGTYPEdate_dayofweek(date d)                  | Returns a number indicating the day of a week for a date value. | This function accepts the date variable <b>d</b> as its unique parameter and returns an integer indicating the day of the week.                                                                                                                                                                                                                              |
| void<br>PGTYPEdate_today(date<br>* d)                | Returns the current date.                                       | This function accepts a pointer to a date variable <b>d</b> and sets the parameter to the current date. <ul style="list-style-type: none"> <li>● <b>0</b>: Sunday</li> <li>● <b>1</b>: Monday</li> <li>● <b>2</b>: Tuesday</li> <li>● <b>3</b>: Wednesday</li> <li>● <b>4</b>: Thursday</li> <li>● <b>5</b>: Friday</li> <li>● <b>6</b>: Saturday</li> </ul> |

| API                                                                                | Description                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>int<br/>PGTYPESdate_defmt_asc(<br/>date* d, const char* fmt,<br/>char* str)</p> | <p>Converts a C char* string to a value of the date type using a format mask.</p> | <p>This function accepts a pointer <b>d</b> pointing to a date value for storing the operation result, a format mask <b>fmt</b> for parsing the date, and a C char* string <b>str</b> containing the textual representation of the date. The textual representation is expected to match the format mask. However, you do not need to have a 1:1 mapping of the string to the format mask. The function only analyzes the sequential order and looks for the literals "yy" or "yyyy" that indicate the position of the year, "mm" indicating the position of the month and "dd" indicating the position of the day.</p> <p>Example of valid input (fmt, str):<br/>yy/mm/dd 1994, February 3rd</p> |

| API                                                                                 | Description                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| int<br>PGTYPEStdate_fmt_asc(<br>da t dDate, const char*<br>fmtstring, char* outbuf) | Converts a variable of the date type into its textual representation using a format mask. | This function accepts the date <b>dDate</b> to be converted, the format mask <b>fmtstring</b> , and the string <b>outbuf</b> of the textual representation of the date to be saved.<br><br>The function returns <b>0</b> on success and a negative value in case of error.<br><br>Example of valid input:<br>112359 //mddy<br>59/11/23 //yy/mm/dd<br>Nov.23,1959 //mmm.dd,yyyy<br>Mon,Nov.23,1959 //<br>ddd,mmm.dd,yyyy<br><br>Format:<br><ul style="list-style-type: none"> <li>• <b>dd</b>: indicates the day of a month.</li> <li>• <b>mm</b>: indicates the month of a year.</li> <li>• <b>yy</b>: indicates a two-digit year.</li> <li>• <b>yyyy</b>: indicates a four-digit year.</li> <li>• <b>ddd</b>: indicates the day of a week.</li> <li>• <b>mmm</b>: indicates the month.</li> </ul> |

## Examples

For details, see [Examples](#).

### 5.7.16.4 Timestamp Type

[Table 5-81](#) lists the common APIs for timestamp data provided by ecpg.

**Table 5-81** Common timestamp type APIs

| API                                                              | Description                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------------------------------|-------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| timestamp<br>PGTYPEStimestamp_from_asc(char *str, char **endptr) | Parses a timestamp from its textual representation into a timestamp variable. | This function accepts a string <b>str</b> to parse and a pointer to a C char* <b>endptr</b> . It returns the parsed timestamp on success and <b>PGTYPEStimestamp</b> in case of error. In addition, <b>errno</b> is set to <b>PGTYPEStimestamp</b> when an error occurs.<br><br>The valid input of <b>PGTYPEStimestamp_from_asc</b> is as follows:<br>1999-01-08 04:05:06<br>January 8 04:05:06 1999 PST<br>1999-Jan-08 04:05:06.789-8<br>1999-01-08 04:05:06.789 (time zone specifier ignored)<br>J2451187 04:05-08:00<br>1999-01-08 04:05:00 (time zone specifier ignored) |
| char<br>*PGTYPEStimestamp_to_asc(timestamp tstamp)               | Converts a date to a C char* string.                                          | This function accepts the timestamp <b>tstamp</b> as its unique parameter and returns an allocated string containing the textual representation of the timestamp. The result must be released using <b>PGTYPEStimestamp_free()</b> .                                                                                                                                                                                                                                                                                                                                         |
| void<br>PGTYPEStimestamp_current(timestamp *ts)                  | Returns the current timestamp.                                                | This function obtains the current timestamp and saves it to the timestamp variable that <b>ts</b> points to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| API                                                                                            | Description                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                   |

## Examples

For details, see [Examples](#).

## 5.8 Development Based on the Go Driver

### 5.8.1 Setting Up the Go Driver Environment

#### Go Driver Package

Obtain the package from the release package **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Go.tar.gz**. Decompress the package to obtain the Go driver source code package.

---

**NOTICE**

Users are not involved in the driver development and can call Go driver 1.13 or later. The runtime library needs to be updated to 1.18 or later.

---

## Environment Class

- **Configure the Go environment.**

You need to configure the following parameters in the environment variables:

- **GO111MODULE:** Set **GO111MODULE** to **on** when installing the Go driver by importing a file online. If you do not want to reconstruct the **go mod** project, set **GO111MODULE** to **off** and manually download the dependency package. The dependency package must be at the same level as the driver root directory and service code.
- **GOPROXY:** When importing data online, you need to configure the path that contains the Go driver package.
- You can configure other Go environment variables based on your scenario parameters.

Run the **go env** command to view the Go environment variable configuration result and check whether the Go version is 1.13 or later.

- **Install the Go driver.**

- Download the Go driver package to the local host. The Go driver repository address is <https://open.codehub.huawei.com/OpenSourceCenter/openGauss-connector-go-pq/>.
- Go to the root path of the Go driver code and run the **go mod tidy** command to download related dependencies. You need to configure **GOPATH=\${Path for storing the Go driver dependency package}** in the environment variables.
- If the dependencies have been downloaded to the local host, you can add a line "Replace the Go driver package with the local Go driver package address through replace" to **go.mod**, indicating that all import Go driver packages in the code are stored in the local path and the dependencies are not downloaded from the proxy.

---

 **CAUTION**

When you run the **go mod tidy** command to download dependencies, some of them may be downloaded as an earlier version. If the earlier version has vulnerabilities, you can change the dependency version in the **go.mod** file and update the dependency to the version after the vulnerability is fixed to avoid risks.

---

## Driver Class

When creating a database connection, you need to enter the database driver name **gaussdb**.

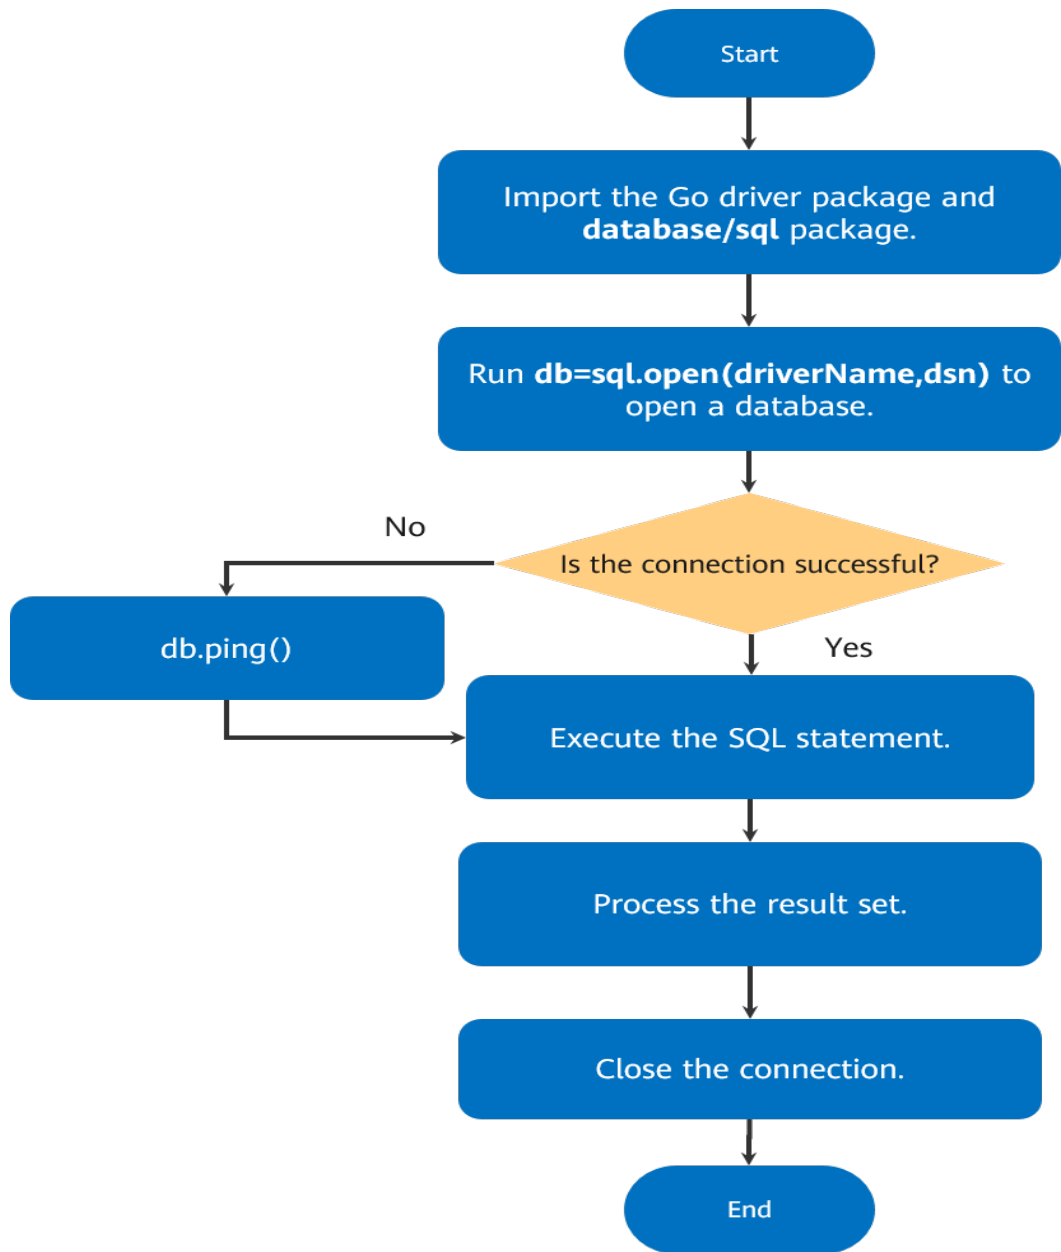

**NOTICE**

- The Go driver provided by the database does not adapt to mature ORM frameworks (such as XORM) in the industry. As such, the driver name input during database connection creation must be compatible with Postgres and PostgreSQL.
  - The Go driver of the database cannot coexist with that of PostgreSQL.
- 

## 5.8.2 Development Process

The Go driver of the database complies with the rule of the Go language third-party library. You only need to import the driver to the application program and save the driver code in the directory specified by *GOPATH*.

Figure 5-7 Application development process based on Go

According to [Figure 5-7](#), the Go driver application development process depends on the native SQL package of Go driver and the driver developed by GaussDB. The SQL package provides standard APIs that are used for the implementation of GaussDB for users.

### 5.8.3 Connecting to a Database

The Go driver provides the following method to generate a database connection object:

```
func Open(driverName, dataSourceName string) (*DB, error)
```

Parameter description:

- **driverName** indicates the driver name. The database driver name is **opengauss**, which is compatible with Postgres.
- **dataSourceName** indicates the data source to be connected. The value can be in DSN or URL format.
  - DSN format: `key1 = value1 key2 = value2...` Different groups of keywords are separated by space. The space on the left and right of the equal sign (=) is optional.
  - URL format: `driverName://[userspec@][hostspec][/dbname][?paramspec]`  
In the preceding information, **driverName** indicates the driver name. The database driver name is "**opengauss**", which is compatible with "**postgres**" and "**postgresql**".  
**userspec** indicates `user[:password]`. When a URL is used for connection, the password cannot contain separators in the URL string. If the password contains separators, the DSN format is recommended.  
**hostspec** indicates `[host][:port][, ...]`.  
**dbname** indicates the database name. Note: The initial user cannot be used for remote login. **paramspec** indicates `name=value[&...]`.

#### NOTICE

- In the DSN format, if there are multiple IP addresses:
  - When the value of **num(ip)** is the same as that of **num(port)**, the IP address matches the port number.
  - When the value of **num(ip)** is greater than that of **num(port)**, the IP address that cannot match the port number matches the first port number. For example, the matching condition of **host = ip1, ip2, ip3 port = port1, port2** is **ip1:port1, ip2:port2, ip3:port1**.
  - When the value of **num(ip)** is smaller than that of **num(port)**, the extra port numbers are discarded. For example, the mapping result of **host = ip1, ip2, ip3 port = port1, port2, port3, port4** is **ip1:port1, ip2:port2, ip3:port3**.
- In the URL format, if there are multiple IP addresses:
  - In the URL, *ip.port* must appear in pairs, that is, the value of **num(ip)** is the same as that of **num(port)**. Use commas (,) to separate multiple pairs. Example: **opengauss://user:password@ip1:port1, ip2:port2, ip3:port3/postgres**.
  - The URL contains only multiple IP addresses. The port number is specified by the environment variable or uses the default value **5432**. For example, in the case of **opengauss://user:password@ip1, ip2, ip3/postgres**, if the environment variable is set as **PGPORT = "port1, port2"**, the mapping is **ip1:port1, ip2:port2, ip3:port1**. If the environment variable is not set, the mapping is **ip1:5432, ip2:5432, ip3:5432**.

## Parameters

**Table 5-82** Database connection parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| host            | IP address of the host server, which can also be specified by the environment variable <code>PGHOST</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| port            | Port number of the host server, which can also be specified by the environment variable <code>PGPORT</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| dbname          | Database name, which can also be specified by the environment variable <code>PGDATABASE</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| user            | Username to be connected, which can also be specified by the environment variable <code>PGUSER</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| password        | Password of the user to be connected                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| connect_timeout | Timeout interval for connecting to the server, which can also be specified by the environment variable <code>PGCONNECT_TIMEOUT</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| sslmode         | SSL encryption mode, which can also be specified by the environment variable <code>PGSSLMODE</code><br>Value range: <ul style="list-style-type: none"><li>● <b>disable</b>: SSL connection is disabled.</li><li>● <b>allow</b>: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.</li><li>● <b>prefer</b>: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.</li><li>● <b>require</b>: SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.</li><li>● <b>verify-ca</b>: SSL connection is required, and whether the server certificate is issued by a trusted CA is verified.</li><li>● <b>verify-full</b>: SSL connection is required, and whether the server certificate is issued by a trusted CA and whether the host name of the server is the same as that in the certificate are verified.</li></ul> |
| sslkey          | Key location of the client certificate. If SSL connection is required and this parameter is not specified, you can set the environment variable <code>PGSSLKEY</code> to specify the location.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sslcert                        | File name of the client SSL certificate, which can also be specified by the environment variable <code>PGSSLCERT</code>                                                                                                                                                                                                                                             |
| sslrootcert                    | Name of the file that contains the SSL CA certificate, which can also be specified by the environment variable <code>PGSSLROOTCERT</code>                                                                                                                                                                                                                           |
| sslcrl                         | File name of the SSL CRL. If a certificate listed in this file exists, the server certificate authentication will be rejected and the connection will fail. The value can also be specified by the environment variable <code>PGSSLCRL</code> .                                                                                                                     |
| sslpassword                    | <p>Passphrase used to decrypt a key into plaintext. If this parameter is specified, the SSL key is an encrypted file. Currently, the SSL key supports DES encryption and AES encryption.</p> <p><b>NOTE</b><br/>The DES encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.</p> |
| disable_prepared_binary_result | <p>The value of this parameter is a string. If it is set to <b>yes</b>, the connection should not use the binary format when the query results are received from prepared statements. This parameter is used only for debugging.</p> <p>Value range: <b>yes</b> and <b>no</b>.</p>                                                                                  |
| binary_parameters              | Specifies whether <code>[]byte</code> is always sent in binary format. The value is a string. Value range: <b>yes</b> and <b>no</b> . If this parameter is set to <b>yes</b> , you are advised to bind parameters based on <code>[]byte</code> to reduce internal type conversion.                                                                                  |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| target_session_attrs | <p>Connection type of the database, which can also be specified by the environment variable <code>PGTARGETSESSIONATTRS</code>. This parameter is used to identify the primary and standby nodes. There are six value options, namely, <b>any</b>, <b>master</b>, <b>slave</b>, <b>preferSlave</b>, <b>read-write</b>, and <b>read-only</b>. The default value is <b>any</b>.</p> <ul style="list-style-type: none"> <li>● <b>any</b>: attempts to connect to any DN in the URL connection string.</li> <li>● <b>master</b>: attempts to connect to a primary node in the URL connection string. If the primary node cannot be found, an exception is thrown.</li> <li>● <b>slave</b>: attempts to connect to a standby node in the URL connection string. If the standby node cannot be found, an exception is thrown.</li> <li>● <b>preferSlave</b>: attempts to connect to a standby DN (if available) in the URL connection string. Otherwise, it connects to the primary DN.</li> <li>● <b>read-write</b>: specifies that only the primary node can be connected.</li> <li>● <b>read-only</b>: specifies that only the standby node can be connected.</li> </ul> |
| loggerLevel          | <p>Log level, which is used to print debugging information. The value can also be specified by the environment variable <code>PGLOGGERLEVEL</code>. The value can be <b>trace</b>, <b>debug</b>, <b>info</b>, <b>warn</b>, <b>error</b>, or <b>none</b>, in descending order of priority.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| application_name     | <p>Name of the Go driver that is being connected. The default value is <b>go-driver</b>. You are advised not to configure this parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| RuntimeParams        | <p>Runtime parameter to be set to the session default value on a connection, for example, <b>search_path</b>, <b>application_name</b>, or <b>timezone</b>. For details about the parameters, see the default settings of the client connection. You can run the <b>SHOW</b> command to check whether the parameters are set successfully.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| autoBalance | <p>Character string type. Use this parameter to enable load balancing connections in the distributed environment. The value can be <b>true</b>, <b>balance</b>, <b>roundrobin</b>, <b>shuffle</b>, <b>priorityn</b>, or <b>false</b>. The default value is <b>false</b>.</p> <ol style="list-style-type: none"> <li> <p>If this parameter is set to <b>true</b>, <b>balance</b>, or <b>roundrobin</b>, the Go SQL load balancing function is enabled to balance multiple connections of an application to each CN available in the cluster.</p> <p>Example: <b>gauss://user:password@host1:port1,host2:port2/database?autoBalance=true</b></p> <p>The driver periodically obtains the list of available CNs in the entire cluster. For example, the obtained list is <b>host1:port1,host2:port2,host3:port3,host4:port4</b>. The <b>refreshCNlpsTime</b> parameter specifies the interval for obtaining the list, and the default value is <b>10s</b>.</p> <p>When <b>autoBalance</b> is enabled on <b>host1</b> and <b>host2</b>, HA is implemented only for the first connection. The driver will select available CNs from <b>host1</b>, <b>host2</b>, <b>host3</b>, and <b>host4</b> in sequence to update the available CN list and <b>Connector.Connect</b> will be called on <b>host1</b>, <b>host2</b>, <b>host3</b>, and <b>host4</b> using the RoundRobin algorithm.</p> </li> <li> <p><b>priorityn</b> indicates that the driver priority-based load balancing function is enabled. Multiple connections of an application are balanced to the first <i>n</i> available CNs configured in the URL. When the first <i>n</i> CNs are unavailable, connections are randomly allocated to other available CNs in the database cluster. <i>n</i> is a number not less than 0 and less than the number of CNs configured in the URL.</p> <p>Example: <b>gauss://user:password@host1:port1,host2:port2,host3:port3/database?autoBalance=priority2</b></p> <p>The driver periodically obtains the list of available CNs in the entire cluster (defined by <b>refreshCNlpsTime</b>). For example, the obtained list is <b>host1:port1,host2:port2,host3:port3,host4:port4,host5:port5,host6:port6</b>, where <b>host1</b> and <b>host2</b> are in <b>AZ1</b>, and <b>host3</b> and <b>host4</b> are in <b>AZ2</b>.</p> </li> </ol> |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <p>The driver preferentially selects <b>host1</b> and <b>host2</b> for load balancing. If both <b>host1</b> and <b>host2</b> are unavailable, the driver randomly selects a CN from <b>host3</b>, <b>host4</b>, <b>host5</b>, and <b>host6</b> for connection.</p> <p>3. If this parameter is set to <b>shuffle</b>, the driver random load balancing is enabled to randomly and evenly distribute multiple connections of the application to available CNs in the database cluster.<br/>Example: <b>gauss://user:password@host1:port1,host2:port2,host3:port3/database?autoBalance=shuffle</b></p> <p>The driver periodically obtains the list of available CNs in the entire cluster. For example, the obtained list is <b>host1:port1,host2:port2,host3:port3,host4:port4</b>. The <b>refreshCNlpsTime</b> parameter specifies the interval for obtaining the list, and the default value is <b>10s</b>.</p> <p>For the first connection, <b>host1:port1,host2:port2,host3:port3</b> is used for HA. For subsequent connections, the shuffle algorithm is used to randomly select a CN from the refreshed CN list.</p> <p>4. If this parameter is set to <b>false</b> in the centralized scenarios, the driver load balancing and priority-based load balancing functions are disabled. The default value is <b>false</b>.</p> <p><b>CAUTION</b><br/>Load balancing is based on the connection level rather than the transaction level. If the connection is persistent and the load on the connection is unbalanced, the load on the CN may be unbalanced.<br/>Load balancing can be used only in distributed scenarios and cannot be used in centralized scenarios.</p> <p><b>NOTE</b><br/>Load balancing is based on the connection level rather than the transaction level. If the connection is persistent and the load on the connection is unbalanced, the load on the CN may be unbalanced.<br/>Load balancing can be used only in distributed scenarios and cannot be used in centralized scenarios.</p> |

| Parameter   | Description                                                                                                                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| recheckTime | Integer type. Use this parameter to specify the interval at which the driver periodically checks the status of CNs in the database cluster and obtains the IP address list of available CNs. The value ranges from 5s to 60s and the default value is <b>10s</b> .                   |
| usingEip    | Boolean type. This value specifies whether to use an elastic IP address for load balancing. The default value is <b>true</b> , indicating that an elastic IP address is used for load balancing. The value <b>false</b> indicates that a data IP address is used for load balancing. |

### Example 1:

```
// Multiple IP addresses and ports (ip:port) are used as an example. In this example, the username and
// password are stored in environment variables. Before running this example, set environment variables in the
// local environment (set the environment variable name based on the actual situation).
func main() {

## 5.8.4 Connecting to a Database (Using SSL)

The Go driver supports SSL connections to the database. After the SSL mode is enabled, if the Go driver connects to the database server in SSL mode, the Go driver uses the standard TLS 1.3 protocol by default, and the TLS version must be 1.2 or later. This section describes how applications configure the client in SSL mode through the Go driver. For details about how to configure the server, contact the administrator. To use the method described in this section, you must have the

server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

#### NOTE

In SSL-based certificate authentication mode, you do not need to specify the user password in the connection string.

## Configuring the Client

Upload the **client.key**, **client.crt**, and **ca.cert.pem** files generated during server configuration to the client. For details about server configuration, contact the administrator.

### Example 1:

```
// Mutual authentication is used as an example. In this example, the username and password are stored in
// environment variables. Before running this example, set environment variables in the local environment (set
// the environment variable name based on the actual situation).
func main() {
 hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment
 // variable.
 port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment
 // variable.
 username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username written into the
 // environment variable.
 passwd := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the
 // environment variable.
 sslpasswd := os.Getenv("GOSSLPASSWD") // GOSSLPASSWD indicates the passphrase written into the
 // environment variable.
 dsnStr := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "
 sslcert=certs/client.crt sslkey=certs/client.key sslpassword=" + sslpasswd
 parameters := []string {
 "sslmode=require",
 "sslmode=verify-ca sslrootcert=certs/ca.cert.pem",
 }

 for _, param := range parameters {
 db, err := sql.Open("opengauss", dsnStr+param)
 if err != nil {
 log.Fatal(err)
 }

 var f1 int
 err = db.QueryRow("select 1").Scan(&f1)
 if err != nil {
 log.Fatal(err)
 } else {
 fmt.Printf("RESULT: select 1: %d\n", f1)
 }
 }

 db.Close()
}
```

### Example 2:

```
// For example, verify sslpassword. In this example, the username and password are stored in environment
// variables. Before running this example, set environment variables in the local environment (set the
// environment variable name based on the actual situation).
func main() {
 hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment
 // variable.
 port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment
 // variable.
 username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username written into the
 // environment variable.
```

```

passwd := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the
environment variable.
dsnStr := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "
dbname=postgres"

sslpasswd := os.Getenv("GOSSLPASSWD") // GOSSLPASSWD indicates the passphrase written into the
environment variable.
connStrs := []string {
 " sslmode=verify-ca sslcert=certs/client_rsa.crt sslkey=certs/client_rsa.key sslpassword=" + sslpasswd + "
sslrootcert=certs/cacert_rsa.pem",
 " sslmode=verify-ca sslcert=certs/client_ecdsa.crt sslkey=certs/client_ecdsa.key sslpassword=" + sslpasswd +
" sslrootcert=certs/cacert_ecdsa.pem",
}
for _, connStr := range connStrs {
 db, err := sql.Open("opengauss", dsnStr + connStr)
 if err != nil {
 log.Fatal(err)
 }
 var f1 int
 err = db.QueryRow("select 1").Scan(&f1)
 if err != nil {
 if !strings.HasPrefix(err.Error(), "connect failed.") {
 log.Fatal(err)
 }
 }
}
db.Close()
}

```

## 5.8.5 Go APIs

### 5.8.5.1 sql.Open

The following table describes sql.Open.

| Method                                  | Description                                                                                        | Return Value  |
|-----------------------------------------|----------------------------------------------------------------------------------------------------|---------------|
| Open(driverName, dataSourceName string) | Opens a database based on a specified database driver and the dedicated data source of the driver. | *DB and error |

For details about driverName and dataSourceName, see [Connecting to a Database](#).

### 5.8.5.2 type DB

The following table describes type DB.

| Method          | Description                                                                               | Return Value  |
|-----------------|-------------------------------------------------------------------------------------------|---------------|
| (db *DB)Begin() | Starts a transaction. The isolation level of the transaction is determined by the driver. | *Tx and error |

|                                                                              |                                                                                                                                                                                                                           |                  |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| (db *DB)BeginTx(ctx context.Context, opts *TxOptions)                        | Starts a transaction with a specified transaction isolation level. A specified context is used until the transaction is committed or rolled back. If the context is canceled, the SQL package rolls back the transaction. | *Tx and error    |
| (db *DB)Close()                                                              | Closes the database and releases all the opened resources.                                                                                                                                                                | error            |
| (db *DB)Exec(query string, args ...interface{})                              | Performs an operation that does not return rows of data.                                                                                                                                                                  | Result and error |
| (db *DB)ExecContext(ctx context.Context, query string, args ...interface{})  | Performs an operation that does not return rows of data in a specified context.                                                                                                                                           | Result and error |
| (db *DB)Ping()                                                               | Checks whether the database connection is still valid and establishes a connection if necessary.                                                                                                                          | error            |
| (db *DB)PingContext(ctx context.Context)                                     | Checks whether the database connection is still valid in a specified context and establishes a connection if necessary.                                                                                                   | error            |
| (db *DB)Prepare(query string)                                                | Creates a prepared statement for subsequent queries or executions.                                                                                                                                                        | *Stmt and error  |
| (db *DB)PrepareContext(ctx context.Context, query string)                    | Creates a prepared statement for subsequent queries or executions in a specified context.                                                                                                                                 | *Stmt and error  |
| (db *DB)Query(query string, args ...interface{})                             | Executes a query and returns multiple rows of data.                                                                                                                                                                       | *Rows and error  |
| (db *DB)QueryContext(ctx context.Context, query string, args ...interface{}) | Executes a query and returns multiple rows of data in a specified context.                                                                                                                                                | *Rows and error  |
| (db *DB)QueryRow(query string, args ...interface{})                          | Executes a query that returns only one row of data.                                                                                                                                                                       | *Row             |

|                                                                                 |                                                                            |      |
|---------------------------------------------------------------------------------|----------------------------------------------------------------------------|------|
| (db *DB)QueryRowContext(ctx context.Context, query string, args ...interface{}) | Executes a query that returns only one row of data in a specified context. | *Row |
|---------------------------------------------------------------------------------|----------------------------------------------------------------------------|------|

 **NOTE**

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in **type Rows**. If the result is not obtained through the Next() API, unexpected errors may occur.

## Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ctx       | Specified context.                                                                                                                                                                                                                                                                                                                         |
| query     | Executed SQL statement.                                                                                                                                                                                                                                                                                                                    |
| args      | Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see <a href="#">Examples</a> .                                                                                                                                                                         |
| opts      | Transaction isolation level and transaction access mode. The transaction isolation level (opts.Isolation) supports sql.LevelReadUncommitted, sql.LevelReadCommitted, sql.LevelRepeatableRead, and sql.LevelSerializable. The transaction access mode ( <b>opts.ReadOnly</b> ) can be <b>true</b> (read only) or <b>false</b> (read write). |

## Examples

```
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables in the local environment (set the environment variable names based on
// the actual situation).
func main() {
 hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment
 // variable.
 port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment
 // variable.
 username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username written into the
 // environment variable.
 passwd := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the
 // environment variable.
 str := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "
 dbname=postgres sslmode=disable"
 db, err := sql.Open("opengauss", str)
 if err != nil {
 log.Fatal(err)
 }
}
```

```
}
defer db.Close()

err = db.Ping()
if err != nil {
 log.Fatal(err)
}
 err = db.Exec("drop table if exists testuser.test")
 err = db.Exec("create table test(id int, name char(10))")

// Binding by location
 err = db.Exec("insert into test(id, name) values(:1, :2)", 1, "Zhang San")
if err != nil {
 log.Fatal(err)
}

// Binding by name
 err = db.Exec("insert into test(id, name) values(:id, :name)", sql.Named("id", 1), sql.Named("name",
"Zhang San"))
if err != nil {
 log.Fatal(err)
}
}
```

### 5.8.5.3 type Stmt

The following table describes type Stmt.

| Method           | Description                            | Return Value |
|------------------|----------------------------------------|--------------|
| (s *Stmt)Close() | Closes a specified prepared statement. | error        |

|                                                 |                                                                                                                                                                                                                                                                                         |                  |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <code>(s *Stmt)Exec(args ...interface{})</code> | Executes a prepared statement with specified parameters and returns a <b>Result</b> value. The Prepare-Bind-Execute (PBE) feature is supported. PBE is a method of sending and executing queries. The CN can receive PBE packets through complex query protocols to execute statements. | Result and error |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|

|  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |
|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
|  | <p><b>NOTE</b></p> <ol style="list-style-type: none"><li>1. The placeholder of a precompiled statement can be a dollar sign (\$) or a question mark (?).</li><li>2. The number of placeholders in a precompiled statement is determined by the database. When the number of table columns exceeds the database limit or does not match the number of current table columns, the server returns an error.</li><li>3. Batch PBE processing supports addition, deletion, and modification. During the batch operation, the maximum length of a U packet is limited to 1 GB minus 1 byte, that is, 0x3fffffff bytes. If the length exceeds the limit, "bind message length XXX too long. This can be caused by very large or incorrect length specifications on InputStream parameters" will be reported.</li><li>4. When a record is inserted, the performance of PBE deteriorates greatly compared with that of a single-query statement (conn.simpleExec). Therefore, you are advised to use single-query statements, rather than the PBE statement.</li><li>5. After the underlying error processing of the driver is reconstructed, the PBE performance decreases by less than 5%.</li></ol> |  |
|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|

|                                                                     |                                                                                                                              |                  |
|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|------------------|
| (s *Stmt)ExecContext(ctx context.Context, args ...interface{})      | Executes a prepared statement with specified parameters in a specified context and returns a <b>Result</b> value.            | Result and error |
| (s *Stmt)Query(args ...interface{})                                 | Executes a prepared statement with specified parameters and returns <b>*Rows</b> as the query result.                        | *Rows and error  |
| (s *Stmt)QueryContext(ctx context.Context, args ...interface{})     | Executes a prepared statement with specified parameters in a specified context and returns <b>*Rows</b> as the query result. | *Rows and error  |
| (s *Stmt)QueryRow(args ...interface{})                              | Executes a prepared statement with specified parameters and returns <b>*Row</b> as the result.                               | *Row             |
| (s *Stmt)QueryRowContext (ctx context.Context, args ...interface{}) | Executes a prepared statement with specified parameters in a specified context and returns <b>*Row</b> as the result.        | *Row             |

 **NOTE**

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in **type Rows**. If the result is not obtained through the Next() API, unexpected errors may occur.

## Parameters

| Parameter | Description                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ctx       | Specified context.                                                                                                                                                            |
| query     | Executed SQL statement.                                                                                                                                                       |
| args      | Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see <b>Examples</b> in section "type DB." |

### 5.8.5.4 type Tx

The following table describes type Tx.

| Method                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                    | Return Value     |
|------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| (tx *Tx)Commit()                                                             | Commits a transaction.                                                                                                                                                                                                                                                                                                                                                                         | error            |
| (tx *Tx)Exec(query string, args ...interface{})                              | Performs an operation that does not return rows of data.                                                                                                                                                                                                                                                                                                                                       | Result and error |
| (tx *Tx)ExecContext(ctx context.Context, query string, args ...interface{})  | Performs an operation that does not return rows of data in a specified context.                                                                                                                                                                                                                                                                                                                | Result and error |
| (tx *Tx)Prepare(query string)                                                | Creates a prepared statement for subsequent queries or executions. The returned statement is executed within a transaction and cannot be used when the transaction is committed or rolled back.                                                                                                                                                                                                | *Stmt and error  |
| (tx *Tx)PrepareContext(ctx context.Context, query string)                    | Creates a prepared statement for subsequent queries or executions. The returned statement is executed within a transaction and cannot be used when the transaction is committed or rolled back.<br><br>The specified context will be used in the preparation phase, not in the transaction execution phase. The statement returned by this method will be executed in the transaction context. | *Stmt and error  |
| (tx *Tx)Query(query string, args ...interface{})                             | Executes a query that returns rows of data.                                                                                                                                                                                                                                                                                                                                                    | *Rows and error  |
| (tx *Tx)QueryContext(ctx context.Context, query string, args ...interface{}) | Executes a query that returns rows of data in a specified context.                                                                                                                                                                                                                                                                                                                             | *Rows and error  |

|                                                                                 |                                                                                                                                                                                                                             |       |
|---------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| (tx *Tx)QueryRow(query string, args ...interface{})                             | Executes a query that returns only one row of data.                                                                                                                                                                         | *Row  |
| (tx *Tx)QueryRowContext(ctx context.Context, query string, args ...interface{}) | Executes a query that returns only one row of data in a specified context.                                                                                                                                                  | *Row  |
| (tx *Tx) Rollback()                                                             | Rolls back a transaction.                                                                                                                                                                                                   | error |
| (tx *Tx)Stmt(stmt *Stmt)                                                        | Returns a transaction-specific prepared statement for an existing statement.<br><br>Example:<br>str, err := db.Prepare("insert into t1 values(:1, :2)")<br>tx, err := db.Begin()<br>res, err := tx.Stmt(str).Exec(1, "aaa") | *Stmt |
| (tx *Tx)StmtContext(ctx context.Context, stmt *Stmt)                            | Returns a transaction-specific prepared statement for an existing statement in a specified context.                                                                                                                         | *Stmt |

 **NOTE**

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in [type Rows](#). If the result is not obtained through the Next() API, unexpected errors may occur.

## Parameters

| Parameter | Description                                                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ctx       | Specified context.                                                                                                                                                                     |
| query     | Executed SQL statement.                                                                                                                                                                |
| args      | Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see <a href="#">Examples</a> in section "type DB." |
| stmt      | Existing prepared statement, which is generally the prepared statement returned by the PREPARE statement                                                                               |

### 5.8.5.5 type Rows

The following table describes type Rows.

| Method                              | Description                                                                                                                                                     | Return Value            |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| (rs *Rows)Close()                   | Closes <b>Rows</b> to stop the iteration of the data set.                                                                                                       | error                   |
| (rs *Rows)ColumnTypes()             | Returns column information.                                                                                                                                     | []*ColumnType and error |
| (rs *Rows)Columns()                 | Returns the name of each column.                                                                                                                                | []string and error      |
| (rs *Rows)Err()                     | Returns any errors that occur during iteration.                                                                                                                 | error                   |
| (rs *Rows)Next()                    | Prepares the next data row to be read with the Scan method. If there is an additional result set, <b>true</b> is returned. Otherwise, <b>false</b> is returned. | boolean                 |
| (rs *Rows)Scan(dest ...interface{}) | Copies the columns of the current iterated row of data to the value specified by <b>dest</b> .                                                                  | error                   |
| (rs *Rows)NextResultSet()           | Specifies whether there is an additional result set.                                                                                                            | boolean                 |

### Parameters

| Parameter | Description                                                                           |
|-----------|---------------------------------------------------------------------------------------|
| dest      | The column to be queried needs to be copied to the value specified by this parameter. |

### 5.8.5.6 type Row

The following table describes type Row.

| Method                            | Description                                                                           | Return Value |
|-----------------------------------|---------------------------------------------------------------------------------------|--------------|
| (r *Row)Scan(dest ...interface{}) | Copies the columns in the current row of data to the value specified by <b>dest</b> . | error        |
| (r *Row)Err()                     | Returns errors that occur during execution.                                           | error        |

## Parameter Description

| Parameter | Description                                                                           |
|-----------|---------------------------------------------------------------------------------------|
| dest      | The column to be queried needs to be copied to the value specified by this parameter. |

### 5.8.5.7 type ColumnType

The following table describes type ColumnType.

| Method                             | Description                                                                                                                                          | Return Value                       |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| (ci *ColumnType)DatabaseTypeName() | Returns the name of the column-type database system. If an empty string is returned, driver-type names are not supported.                            | error                              |
| (ci *ColumnType)DecimalSize()      | Returns the scale and precision of the decimal type. If the value of <b>ok</b> is <b>false</b> , the specified type is unavailable or not supported. | precision, scale int64, ok boolean |
| (ci *ColumnType)Length()           | Returns the length of the data column type. If the value of <b>ok</b> is <b>false</b> , the specified type does not have a length.                   | length int64, ok boolean           |
| (ci *ColumnType)ScanType()         | Returns a Go type that can be used for scanning by using Rows.Scan.                                                                                  | reflect.Type                       |
| (ci *ColumnType)Name()             | Returns the name of a data column.                                                                                                                   | string                             |

### 5.8.5.8 type Result

The following table describes type Result.

| Method                     | Description                                                                                                  | Return Value    |
|----------------------------|--------------------------------------------------------------------------------------------------------------|-----------------|
| (res Result)RowsAffected() | Returns the number of rows affected by the INSERT, DELETE, UPDATE, SELECT, MOVE, FETCH, and COPY operations. | int64 and error |

## 5.9 Debugging

To control the output of log files and better understand the operating status of the database, modify specific configuration parameters in the **postgresql.conf** file in the instance data directory.

**Table 5-83** describes the adjustable configuration parameters.

**Table 5-83** Configuration parameters

| Parameter           | Description                                      | Value Range                                                                                                                                                                                                                                                                             | Remarks                                                                                                                           |
|---------------------|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| client_min_messages | Level of messages to be sent to clients.         | <ul style="list-style-type: none"> <li>• DEBUG5</li> <li>• DEBUG4</li> <li>• DEBUG3</li> <li>• DEBUG2</li> <li>• DEBUG1</li> <li>• LOG</li> <li>• NOTICE</li> <li>• WARNING</li> <li>• ERROR</li> <li>• FATAL</li> <li>• PANIC</li> </ul> Default value: <b>NOTICE</b>                  | Messages of the set level or lower will be sent to clients. The lower the level is, the fewer the messages will be sent.          |
| log_min_messages    | Level of messages to be recorded in server logs. | <ul style="list-style-type: none"> <li>• DEBUG5</li> <li>• DEBUG4</li> <li>• DEBUG3</li> <li>• DEBUG2</li> <li>• DEBUG1</li> <li>• INFO</li> <li>• NOTICE</li> <li>• WARNING</li> <li>• ERROR</li> <li>• LOG</li> <li>• FATAL</li> <li>• PANIC</li> </ul> Default value: <b>WARNING</b> | Messages higher than the set level will be recorded in logs. The higher the level is, the fewer the server logs will be recorded. |

| Parameter                              | Description                                                                                                                                                                                                                                                                 | Value Range                                                                                                                                                                                                                                                                  | Remarks                                                                                                                                              |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_min_error_statement                | Level of SQL error statements to be recorded in server logs.                                                                                                                                                                                                                | <ul style="list-style-type: none"> <li>DEBUG5</li> <li>DEBUG4</li> <li>DEBUG3</li> <li>DEBUG2</li> <li>DEBUG1</li> <li>INFO</li> <li>NOTICE</li> <li>WARNING</li> <li>ERROR</li> <li>FATAL</li> <li>PANIC</li> </ul> Default value: ERROR                                    | SQL error statements of the set level or higher will be recorded in server logs.<br>Only a system administrator is allowed to modify this parameter. |
| log_min_duration_statement             | Minimum execution duration of a statement. If the execution duration of a statement is equal to or longer than the set milliseconds, the statement and its duration will be recorded in logs. Enabling this function can help you track the query attempts to be optimized. | INT type<br>Default value: -1<br>Unit: millisecond                                                                                                                                                                                                                           | The value <b>-1</b> indicates that the function is disabled.<br>Only a system administrator is allowed to modify this parameter.                     |
| log_connections/<br>log_disconnections | Specifies whether to record a server log message when each session is connected or disconnected.                                                                                                                                                                            | <ul style="list-style-type: none"> <li><b>on</b>: The system records a log server when each session is connected or disconnected.</li> <li><b>off</b>: The system does not record a log server when each session is connected or disconnected.</li> </ul> Default value: off | -                                                                                                                                                    |

| Parameter     | Description                                                          | Value Range                                                                                                                                                                                                                                                                                                                                                             | Remarks                                                                                                                                                                                                                                                                       |
|---------------|----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log_duration  | Specifies whether to record the duration of each executed statement. | <ul style="list-style-type: none"> <li>• <b>on</b>: The system records the duration of each executed statement.</li> <li>• <b>off</b>: The system does not record the duration of each executed statement.</li> </ul> Default value: off                                                                                                                                | Only a system administrator is allowed to modify this parameter.                                                                                                                                                                                                              |
| log_statement | SQL statements to be recorded in logs.                               | <ul style="list-style-type: none"> <li>• <b>none</b>: The system does not record any SQL statements.</li> <li>• <b>ddl</b>: The system records data definition statements.</li> <li>• <b>mod</b>: The system records data definition statements and data operation statements.</li> <li>• <b>all</b>: The system records all statements.</li> </ul> Default value: none | Only a system administrator is allowed to modify this parameter.                                                                                                                                                                                                              |
| log_hostname  | Specifies whether to record host names.                              | <ul style="list-style-type: none"> <li>• <b>on</b>: The system records host names.</li> <li>• <b>off</b>: The system does not record host names.</li> </ul> Default value: off                                                                                                                                                                                          | By default, connection logs only record the IP addresses of connected hosts. With this function, the host names will also be recorded.<br><br>This parameter has an impact on viewing audit results, <b>PG_STAT_ACTIVITY</b> , and the GUC parameter <b>log_line_prefix</b> . |

**Table 5-84** describes the preceding parameter levels.

**Table 5-84** Description of log level parameters

| Level      | Description                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| DEBUG[1-5] | Provides information that can be used by developers. Level 1 is the lowest level whereas level 5 is the highest level.                           |
| INFO       | Provides information about users' hidden requests, for example, information about the VACUUM VERBOSE process.                                    |
| NOTICE     | Provides information that may be important to users, for example, truncations of long identifiers or indexes created as a part of a primary key. |
| WARNING    | Provides warning information for users, for example, COMMIT out of transaction blocks.                                                           |
| ERROR      | Reports an error that causes a command to terminate.                                                                                             |
| LOG        | Reports information that administrators may be interested in, for example, the activity levels of check points.                                  |
| FATAL      | Reports the reason that causes a session to terminate.                                                                                           |
| PANIC      | Reports the reason that causes all sessions to terminate.                                                                                        |

# 6 SQL Optimization

---

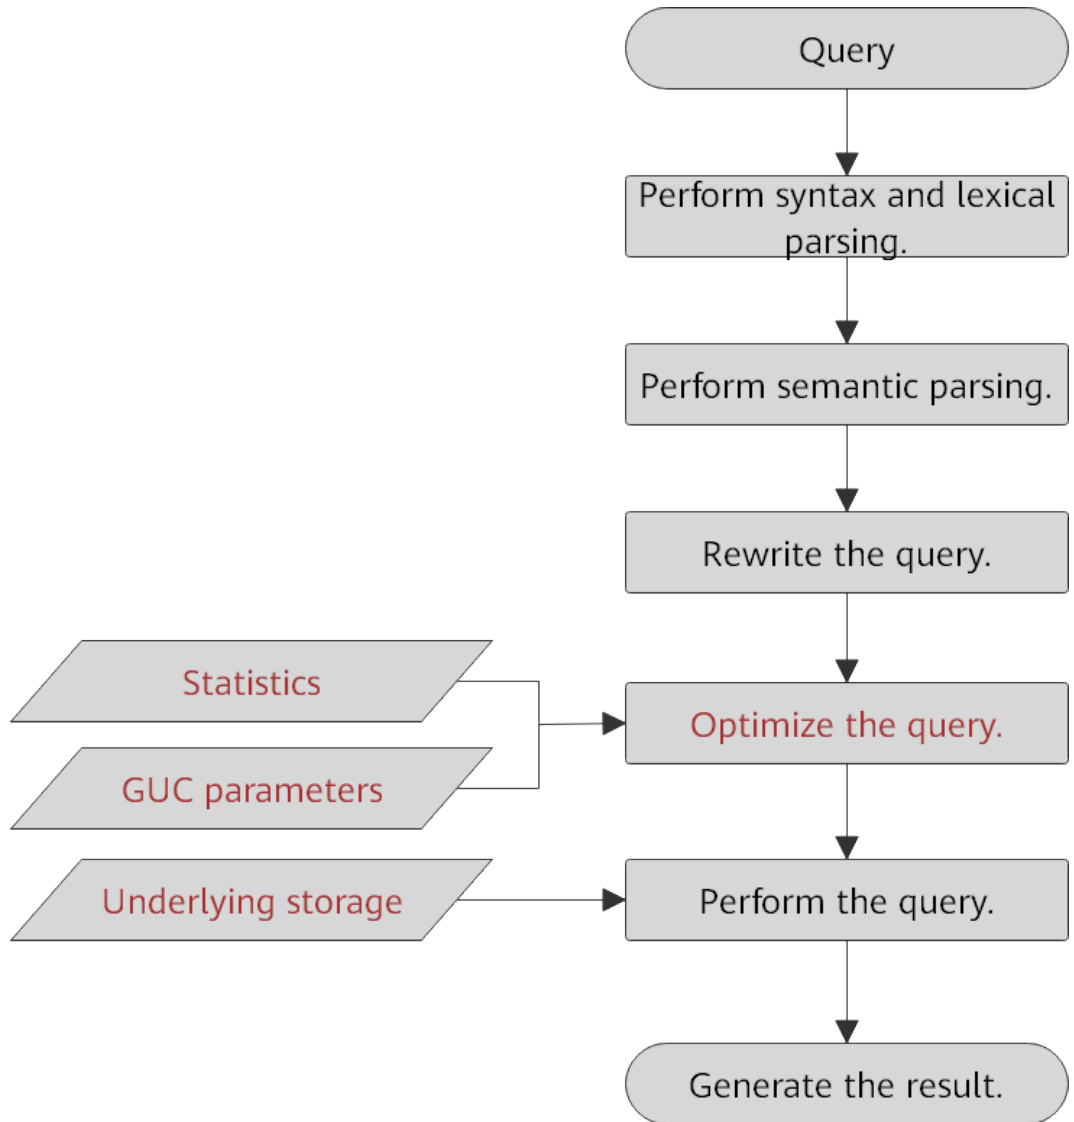

The aim of SQL optimization is to maximize the utilization of resources, including CPU, memory, disk I/O, and network I/O. All optimization methods are intended for resource utilization. To maximize resource utilization is to run SQL statements as efficiently as possible to achieve the highest performance at a lower cost. For example, when performing a typical point query, you can use a combination of Seq Scan and filter (that is, read each tuple and match the point query condition). You can also use Index Scan, which can implement the query at a lower cost but achieve the same effect.

You can determine a proper cluster deployment solution and table definition based on hardware resources and service characteristics. This is the basis of meeting performance requirements. The following performance tuning sections assume that you have finished installation based on a proper cluster solution in the software installation guide and performed database design based on the guide for database design and development.

## 6.1 Query Execution Process

The process from receiving SQL statements to the statement execution by the SQL engine is shown in [Figure 6-1](#) and described in [Table 6-1](#). The texts in red are steps where database administrators can optimize queries.

**Figure 6-1** Execution process of query-related SQL statements by the SQL engine

**Table 6-1** Execution process of query-related SQL statements by the SQL engine

| Step                                   | Description                                                                                                                             |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 1. Perform syntax and lexical parsing. | Converts the input SQL statements from the string data type to the formatted structure stmt based on the specified SQL statement rules. |
| 2. Perform semantic parsing.           | Converts the formatted structure obtained from the previous step into objects that can be recognized by the database.                   |
| 3. Rewrite the query statements.       | Converts the output of the previous step into the structure that optimizes the query execution.                                         |

| Step                   | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4. Optimize the query. | Determines the execution mode of SQL statements (the execution plan) based on the result obtained from the previous step and the internal database statistics. For details about how the internal database statistics and GUC parameters affect the query optimization (execution plan), see <a href="#">Optimizing Queries Using Statistics</a> and <a href="#">Optimizing Queries Using GUC Parameters</a> . |
| 5. Perform the query.  | Executes the SQL statements based on the execution path specified in the previous step. Selecting a proper underlying storage mode improves the query execution efficiency.                                                                                                                                                                                                                                    |

## Optimizing Queries Using Statistics

The GaussDB optimizer is a typical cost-based optimization (CBO). By using CBO, the database calculates the number of tuples and the execution cost for each execution step under each execution plan based on the number of table tuples, column width, NULL record ratio, and characteristic values, such as distinct, MCV, and HB values, and certain cost calculation methods. The database then selects the execution plan that takes the lowest cost for the overall execution or for the return of the first tuple. These characteristic values are the statistics, which is the core for optimizing a query. Accurate statistics helps the analyzer select the most appropriate query plan. Generally, you can collect statistics of a table or that of some columns in a table using ANALYZE. You are advised to periodically execute ANALYZE or execute it immediately after you modified most contents in a table.

## Optimizing Queries Using GUC Parameters

Optimizing queries aims to select an efficient execution mode.

Take the following SQL statement as an example:

```
select count(1)
from customer inner join store_sales on (ss_customer_sk = c_customer_sk);
```

During execution of **customer inner join store\_sales**, GaussDB supports nested loop, merge join, and hash join. The optimizer estimates the result set size and the execution cost of each join mode based on the statistics on the **customer** and **store\_sales** tables. It then compares the costs and selects the one costing the least.

As mentioned above, the execution cost is calculated based on certain methods and statistics. If the actual execution cost cannot be accurately estimated, you need to optimize the execution plan by setting GUC parameters. For example, the **random\_page\_cost** parameter indicates the optimizer's calculation of the cost of a non-sequentially-fetched disk page. The default value is **4**. When the random read speed of a machine disk (for example, an SSD) is high, you can decrease the value of this parameter. After the change, the cost of index scanning is reduced, and the index scanning mode is preferred when a plan is generated.

## Optimizing Queries by Rewriting SQL Statements

Besides the preceding methods that improve the performance of the execution plan generated by the SQL engine, database administrators can also enhance SQL statement performance by rewriting SQL statements while retaining the original service logic based on the execution mechanism of the database and abundant practices.

This requires that database administrators know the customer services well and have professional knowledge of SQL statements. Below chapters will describe some common SQL rewriting scenarios.

## 6.2 Introduction to the SQL Execution Plan

### 6.2.1 Overview

The SQL execution plan is a node tree, which displays detailed procedure when GaussDB runs an SQL statement. A database operator indicates one step.

You can run the **EXPLAIN** command to view the execution plan generated for each query by an optimizer. The output of EXPLAIN has one row for each execution node, showing the basic node type and the cost estimation that the optimizer made for the execution of this node, as shown below.

```
gaussdb=# explain select * from t1,t2 where t1.c1=t2.c2;
 QUERY PLAN

Streaming (type: GATHER) (cost=14.17..29.07 rows=20 width=180)
Node/s: All datanodes
-> Hash Join (cost=13.29..27.75 rows=20 width=180)
 Hash Cond: (t2.c2 = t1.c1)
 -> Streaming(type: REDISTRIBUTE) (cost=0.00..14.31 rows=20 width=104)
 Spawn on: All datanodes
 -> Seq Scan on t2 (cost=0.00..13.13 rows=20 width=104)
 -> Hash (cost=13.13..13.13 rows=21 width=76)
 -> Seq Scan on t1 (cost=0.00..13.13 rows=20 width=76)
(9 rows)
```

- Nodes at the bottom level are scan nodes. They scan tables and return raw rows. The types of scan nodes (sequential scans and index scans) vary depending on the table access methods. Objects scanned by the bottom layer nodes may not be row-store data (not directly read from a table), such as VALUES clauses and functions that return rows, which have their own types of scan nodes.
- If the query requires join, aggregation, sorting, or other operations on the raw rows, there will be other nodes above the scan nodes to perform these operations. In addition, there is more than one way to perform these operations, so different types of execution nodes may be displayed here.
- The first row (the upper-layer node) estimates the total execution cost of the execution plan. Such an estimate indicates the value that the optimizer tries to minimize.

### Execution Plan Display Format

GaussDB provides four display formats: normal, pretty, summary, and run.

- normal: indicates that the default printing format is used.
- pretty: indicates that the new plan display format improved by GaussDB is used. The new format contains a plan node ID, directly and effectively analyzing performance.
- summary: indicates that the printing information analysis is added based on the pretty format.
- run: indicates that the information based on the summary format is exported as a CSV file for further analysis.

An example of an execution plan using the pretty format is as follows.

```
gaussdb=# explain select * from t1,t2 where t1.c1=t2.c2;
id | operation | E-rows | E-width | E-costs
---+-----+-----+-----+-----
 1 | -> Streaming (type: GATHER) | 20 | 180 | 29.07
 2 | -> Hash Join (3,5) | 20 | 180 | 27.75
 3 | -> Streaming(type: REDISTRIBUTE) | 20 | 104 | 14.31
 4 | -> Seq Scan on t2 | 20 | 104 | 13.13
 5 | -> Hash | 21 | 76 | 13.13
 6 | -> Seq Scan on t1 | 20 | 76 | 13.13
(6 rows)

Predicate Information (identified by plan id)

 2 --Hash Join (3,5)
 Hash Cond: (t2.c2 = t1.c1)
(2 rows)
```

You can change the display format of execution plans by setting the GUC parameter **explain\_perf\_mode**. Later examples use the pretty format by default.

## Execution Plan Information

In addition to setting different display formats for an execution plan, you can use different EXPLAIN syntax to display execution plan information in detail. The following lists the common EXPLAIN syntax. For details about more EXPLAIN syntax, see [EXPLAIN](#).

- EXPLAIN *statement*: only generates an execution plan and does not execute. The *statement* indicates SQL statements.
- EXPLAIN ANALYZE *statement*: generates and executes an execution plan, and displays the execution summary. Then actual execution time statistics are added to the display, including the total elapsed time expended within each plan node (in milliseconds) and the total number of rows it actually returned.
- EXPLAIN PERFORMANCE *statement*: generates and executes the execution plan, and displays all execution information.

To measure the run time cost of each node in the execution plan, the current execution of EXPLAIN ANALYZE or EXPLAIN PERFORMANCE adds profiling overhead to query execution. Executing EXPLAIN ANALYZE or EXPLAIN PERFORMANCE on a query sometimes takes longer time than executing the query normally. The amount of time that exceeds depends on the complexity of the query itself and the platform used.

Therefore, if an SQL statement is not finished after being running for a long time, run the **EXPLAIN** command to view the execution plan and then locate the fault. If the SQL statement has been properly executed, execute the EXPLAIN ANALYZE

or EXPLAIN PERFORMANCE statement to check the execution plan and information to locate the fault.

## 6.2.2 Description

As described in [Overview](#), EXPLAIN displays the execution plan, but will not actually run SQL statements. EXPLAIN ANALYZE and EXPLAIN PERFORMANCE both will actually run SQL statements and return the execution information. This section describes the execution plan and execution information in detail.

### Execution Plans

The following SQL statement is used as an example:

```
select * from t1,t2 where t1.c1=t2.c2;
```

Run the **EXPLAIN** command and the output is as follows:

```
gaussdb=# EXPLAIN SELECT * FROM t1,t2 WHERE t1.c1 = t2.c2;
 QUERY PLAN

Hash Join (cost=23.73..341.30 rows=16217 width=180)
 Hash Cond: (t1.c1 = t2.c2)
 -> Seq Scan on t1 (cost=0.00..122.17 rows=5317 width=76)
 -> Hash (cost=16.10..16.10 rows=610 width=104)
 -> Seq Scan on t2 (cost=0.00..16.10 rows=610 width=104)
(5 rows)
```

#### Interpretation of the execution plan column (horizontal):

- **id**: ID of a node corresponding to each execution operator
- **operation**: name of an execution operator

Streaming is a special operator. It implements the core data shuffle function of the distributed architecture. Streaming has three types, which correspond to different data shuffle functions in the distributed architecture:

  - Streaming (type: GATHER): The CN collects data from DNs.
  - Streaming (type: REDISTRIBUTE): Data is redistributed to all the DNs based on selected columns.
  - Streaming (type: BROADCAST): Data on the current DN is broadcast to other DNs.
- **E-rows**: number of output rows estimated by each operator
- **E-memory**: estimated memory used by each operator on a DN. Only operators executed on DNs are displayed. In certain scenarios, the memory upper limit enclosed in parentheses will be displayed following the estimated memory usage. This column is displayed only when the memory usage estimation function is enabled after the **enable\_dynamic\_workload** parameter is set to **on** and the estimated value of an operator is greater than 0.
- **E-width**: estimated width of an output tuple of each operator
- **E-costs**: execution cost estimated by each operator
  - **E-costs** is measured by the optimizer based on an overhead unit. Usually, fetching a disk page is defined as a unit. Other overhead parameters are set based on the unit.

- The overhead of each node (specified by **E-costs**) includes the overheads of all its child nodes.
- Such an overhead reflects only what the optimizer is concerned about, but does not consider the time for transferring result rows to the client. Although the time may play a very important role in the actual total time, it is ignored by the optimizer, because it cannot be changed by modifying the plan.

#### Interpretation of the execution plan level (vertical):

##### 1. Layer 1: **Seq Scan on t2**

The table scan operator scans the table **t2** using Seq Scan. At this layer, data in the table **t2** is read from a buffer or disk, and then transferred to the upper-layer node for calculation.

##### 2. Layer 2: **Hash**

Hash operator. It is used to calculate the hash value of the operator transferred from the lower layer for subsequent hash join operations.

##### 3. Layer 3: **Seq Scan on t1**

The table scan operator scans the table **t1** using Seq Scan. At this layer, data in the table **t1** is read from a buffer or disk, and then transferred to the upper-layer node for hash join calculation.

##### 4. Layer 4: **Hash Join**

Join operator. It is used to join data in the **t1** and **t2** tables using the hash join method and output the result data.

#### Keywords in the execution plan:

##### 1. Table access modes

- Seq Scan  
Scans all rows of the table in sequence.
- Index Scan

The optimizer uses a two-step plan: the child plan node visits an index to find the locations of rows matching the index condition, and then the upper plan node actually fetches those rows from the table itself. Fetching rows separately is much more expensive than reading them sequentially, but because not all pages of the table have to be visited, this is still cheaper than a sequential scan. The upper-layer planning node sorts index-identified rows based on their physical locations before reading them. This minimizes the independent capturing overhead.

If there are separate indexes on multiple columns referenced in WHERE, the optimizer might choose to use an AND or OR combination of the indexes. However, this requires the visiting of both indexes, so it is not necessarily a win compared to using just one index and treating the other condition as a filter.

The following index scans featured with different sorting mechanisms are involved:

- Bitmap index scan  
Fetches data pages using a bitmap.

- Index scan using index\_name  
Uses simple index search, which fetches data from an index table in the sequence of index keys. This mode is commonly used when only a small amount of data needs to be fetched from a large data table or when the ORDER BY condition is used to match the index sequence to reduce the sorting time.
  - Index-Only Scan  
Scans the index that contains all required data, instead of referencing a table.
  - Bitmap Heap Scan  
Reads pages from bitmaps created by other operations and filters out the rows that do not meet the conditions. Bitmap heap scan can avoid random I/Os and accelerate read speed.
  - TID Scan  
Scans a table by a tuple ID.
  - Index Ctid Scan  
Scans a table based on the CTID index.
  - CTE Scan  
Specifies that CTE evaluates subquery operations and stores query results as a temporary table. The temporary table is scanned by the CTE Scan operator.
  - Foreign Scan  
Reads data from a remote data source.
  - Function Scan  
Obtains result sets returned by functions and returns them as the rows read from tables.
  - Sample Scan  
Queries and returns sampled data.
  - Subquery Scan  
Reads subquery results.
  - Values Scan  
Reads constants as part of the **VALUES** command.
  - WorkTable Scan  
Scans a work table. Data is read in the middle of an operation which is usually a recursive operation declared using WITH RECURSIVE.
2. Table connection modes
- Nested Loop  
A nested loop is used for queries that have a smaller dataset connected. In a nested loop join, the foreign table drives the internal table and each row returned from the foreign table should have a matching row in the internal table. The returned result set of all queries should be less than 10,000. The table that returns a smaller subset will work as a foreign table, and indexes are recommended for connection columns of the internal table.

- (Sonic) Hash Join  
A hash join is used for large tables. The optimizer uses a hash join, in which rows of one table are entered into an in-memory hash table, after which the other table is scanned and the hash table is probed for matches to each row. Sonic and non-Sonic hash joins differ in their hash table structures, which do not affect the execution result set.
  - Merge Join  
In most cases, the execution performance of a merge join is lower than that of a hash join. However, if the source data has been pre-sorted and no more sorting is required during the merge join, its performance excels.
3. Operators
- sort  
Sorts the result set.
  - filter  
The EXPLAIN output shows the WHERE clause being applied as a filter condition attached to the Seq Scan plan node. This means that the plan node checks the condition for each row it scans, and returns only the ones that meet the condition. The estimated number of output rows has been reduced because of the WHERE clause. However, the scan will still have to visit all 10,000 rows, as a result, the cost is not decreased. It increases a bit (by 10,000 x **cpu\_operator\_cost**) to reflect the extra CPU time spent on checking the WHERE condition.
  - LIMIT  
Limits the number of output execution results. If a LIMIT condition is added, not all rows are retrieved.
  - Append  
Appends sub-operation results.
  - Aggregate  
Aggregates the results generated from querying rows. It can be an aggregation of statements such as GROUP BY, UNION, and SELECT DISTINCT.
  - BitmapAnd  
Specifies the AND operation of a bitmap, which is used to form a bitmap that matches more complex conditions.
  - BitmapOr  
Specifies the OR operation of a bitmap, which is used to form a bitmap that matches more complex conditions.
  - Gather  
Gathers data of parallel threads.
  - Group  
Groups rows to perform the GROUP BY operation.
  - GroupAggregate  
Aggregates the pre-sorted rows of the GROUP BY operation.
  - Hash  
Hashes rows for the parent query. It is usually used to perform the JOIN operation.

- HashAggregate  
Aggregates the result rows of GROUP BY by using a hash table.
  - Merge Append  
Merges subquery results in a way that preserves the sort order. It can be used to merge sorted rows in a table partition.
  - ProjectSet  
Executes a function on the returned result set.
  - Recursive Union  
Performs a union operation on all steps of a recursive function.
  - SetOp  
Specifies a set operation, such as INTERSECT or EXCEPT.
  - Unique  
Removes duplicates from an ordered result set.
  - HashSetOp  
Specifies a strategy for set operations such as INTERSECT or EXCEPT. It uses Append to avoid pre-sorted input.
  - LockRows  
Locks problematic rows to prevent other queries from writing, but allows reading.
  - Materialize  
Stores subquery results in the memory so that the parent query can quickly access and obtain the subquery results.
  - Result  
Returns a value (such as a hard-coded value) without scanning.
  - WindowAgg  
Specifies a window aggregate function, which is generally triggered by the OVER statement.
  - Merge  
Performs a merge operation.
  - StartWith Operator  
Specifies the hierarchical query operator, which is used to perform recursive query operations.
  - Rownum  
Filters the row number in the query result. It usually appears in the ROWNUM clause.
  - Index Cond  
Specifies the index scan conditions.
  - Unpivot  
Specifies a transpose operator.
4. Partition pruning
- Iterations

Specifies the number of iterations performed by the partition iteration operator on level-1 partitions. If **PART** is displayed, dynamic pruning is used.

For example, **Iterations: 4** indicates that the iteration operator needs to traverse four level-1 partitions. **Iterations: PART** indicates that the number of level-1 partitions to be traversed is determined by parameter conditions of the partition key.

- Selected Partitions

Specifies the selected level-1 partitions for pruning. **m..n** indicates that partitions **m** to **n** are selected. Multiple consecutive partitions are separated by commas (,).

For example, **Selected Partitions: 2..4,7** indicates that partitions 2, 3, 4, and 7 are selected.

5. Other keywords

- Partitioned

Indicates operations on a specific partition.

- Partition Iterator

Partition iterator, which usually indicates that a subquery is an operation on a partition.

- InitPlan

Indicates a non-related subplan.

- Remote Query

Indicates a query statement pushed down to a DN.

- Exec Nodes

Indicates nodes where plans are executed.

- Data Node Scan on

Indicates that a statement has been pushed down to a DN for execution.

## Execution Information

In SQL optimization process, you can use EXPLAIN ANALYZE or EXPLAIN PERFORMANCE to check the SQL statement execution information. By comparing estimation differences between actual implementation and the optimizer, basis for service optimization is provided. EXPLAIN PERFORMANCE provides the execution information on each DN, whereas EXPLAIN ANALYZE does not.

The following SQL statement is used as an example:

```
select count(1) from t1;
```

The output of running EXPLAIN PERFORMANCE is as follows:

```
gaussdb=# explain performance select count(1) from t1;
 id | operation | A-time | A-rows | E-rows | E-distinct | Peak Memory | E-memory | A-
width | E-width | E-costs
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
 1 | -> Aggregate | 9.326 | 1 | 1 | | 14KB | | | 8 |
209.10
 2 | -> Streaming (type: GATHER) | 9.281 | 2 | 2 | | 80KB | | | 8 |
209.10
 3 | -> Aggregate | [5.981,6.491] | 2 | 2 | | [13KB, 13KB] | 1MB | |
```

```

8 | 209.01
4 | -> Seq Scan on public.t1 | [2.553,2.909] | 20000 | 20000 | | [15KB, 15KB] | 1MB
| | 0 | 184.00
(4 rows)

(14 rows)
```

The preceding example shows that the execution information can be classified into the following seven aspects.

1. The plan is displayed as a table, which contains 11 columns: **id**, **operation**, **A-time**, **A-rows**, **E-rows**, **E-distinct**, **Peak Memory**, **E-memory**, **A-width**, **E-width**, and **E-costs**. The meanings of the plan-type columns (**id**, **operation**, or columns started with **E**) are the same as those when EXPLAIN is executed. For details, see [Execution Plans](#). The definition of **A-time**, **A-rows**, **E-distinct**, **Peak Memory**, and **A-width** are described as follows:
  - **A-time**: execution completion time of the operator. Generally, **A-time** of the operator is two values enclosed with square brackets ([ ]), indicating the shortest time and longest time for completing the operator on all DNs, respectively.
  - **A-rows**: number of actual output tuples of the operator
  - **E-distinct**: estimated distinct value of the Hash Join operator
  - **Peak Memory**: peak memory of the operator on each DN
  - **A-width**: actual tuple width in each row of the current operator. This parameter is valid only for heavy memory operators, including (Vec)HashJoin, (Vec)HashAgg, (Vec)HashSetOp, (Vec)Sort, and (Vec)Materialize. The (Vec)HashJoin calculation width is the width of its right subtree operator and will be displayed on the right subtree.
2. **Predicate Information (identified by plan id)**:  
This part displays the static information that does not change in the plan execution process, such as some join conditions and filter information.
3. **Memory Information (identified by plan id)**:  
This part displays the memory usage information printed by certain operators (mainly Hash and Sort), including **peak memory**, **control memory**, **operator**

**memory, width, auto spread num, and early spilled;** and spill details, including **spill Time(s), inner/outer partition spill num, temp file num,** spilled data volume, and **written disk IO** [*min, max*].

4. **Targetlist Information (identified by plan id):**

This part displays the target columns provided by each operator.

5. **DataNode Information (identified by plan id):**

The execution time, CPU, and buffer usage of each operator are printed in this part.

6. **User Define Profiling:**

This part displays CNs and DNs, DN and DN connection time, and some execution information at the storage layer.

7. **=====  
Query Summary  
=====**

The total execution time and network traffic, including the maximum and minimum execution time in the initialization and end phases on each DN, the time in the initialization, execution, and end phases on each CN, the system available memory and statement estimation memory information during the current statement execution, are printed in this part.

---

**NOTICE**

- The difference between **A-rows** and **E-rows** shows the deviation between the optimizer estimation and actual execution. Generally, if the deviation is larger, the plan generated by the optimizer is more improper, and more manual intervention and optimization are required.
  - If the difference of the **A-time** values is larger, the operator computing skew (difference between execution time on different DNs) is larger, and more manual intervention and optimization are required.
  - **Max Query Peak Memory** is often used to estimate the consumed memory of SQL statements, and is also used as an important basis for setting a running memory parameter during SQL statement optimization. Generally, the output from EXPLAIN ANALYZE or EXPLAIN PERFORMANCE is provided for the input for further optimization.
- 

## 6.3 Optimization Process

You can analyze slow SQL statements to optimize them.

### Procedure

- Step 1** Collect all table statistics associated with the SQL statements. In a database, statistics indicate the source data of a plan generated by an optimizer. If no collection statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance. According to past experience, about 10% performance problems occurred because no statistics are collected. For details, see [Updating Statistics](#).
- Step 2** View the execution plan to find out the cause. If the SQL statements have been running for a long period of time and not ended, run the **EXPLAIN** command to

view the execution plan and then locate the fault. If the SQL statement has been properly executed, run the **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** command to check the execution plan and information to locate the fault. For details about the execution plan, see [Introduction to the SQL Execution Plan](#).

**Step 3** [Review and modify a table definition](#).

**Step 4** For details about **EXPLAIN** or **EXPLAIN PERFORMANCE**, the reason why SQL statements are slowly located, and how to solve this problem, see [Typical SQL Optimization Methods](#).

**Step 5** Generally, some SQL statements can be converted to its equivalent statements in all or certain scenarios by rewriting queries. SQL statements are simpler after they are rewritten. Some execution steps can be simplified to improve the performance. Query rewriting methods are universal in all databases. [Experience in Rewriting SQL Statements](#) describes several tuning methods by rewriting SQL statements.

----End

## 6.4 Updating Statistics

In a database, statistics indicate the source data of a plan generated by an optimizer. If no statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance.

### Context

The **ANALYZE** statement collects statistic about table contents in databases, which will be stored in the **PG\_STATISTIC** system catalog. Then, the query optimizer uses the statistics to work out the most efficient execution plan.

After executing batch insertions and deletions, you are advised to execute the **ANALYZE** statement on the table or the entire library to update statistics. By default, 30,000 rows of statistics are sampled. That is, the default value of the GUC parameter **default\_statistics\_target** is **100**. If the total number of rows in the table exceeds 1,600,000, you are advised to set **default\_statistics\_target** to **-2**, indicating that 2% of the statistics are collected.

For an intermediate table generated during the execution of a batch script or stored procedure, you also need to run the **ANALYZE** statement.

If there are multiple inter-related columns in a table and the conditions or grouping operations based on these columns are involved in the query, collect statistics about these columns so that the query optimizer can accurately estimate the number of rows and generate an effective execution plan.

If the table has a GSI, perform **ANALYZE** on the base table first and then on the GSI.

### Procedure

Run the following commands to update the statistics about a table or the entire database:

```
ANALYZE tablename; -- Update statistics about a table.
ANALYZE; -- Update statistics about the entire database.
```

Run the following command to update statistics about the GSI on the table:

```
ANALYZE GLOBAL INDEX indexname FOR TABLE tablename;
```

#### NOTE

To update the statistics about the GSI, perform ANALYZE on the base table first.

Run the following statements to perform statistics-related operations on multiple columns:

```
ANALYZE tablename ((column_1, column_2)); -- Collect statistics about column_1 and
column_2 of tablename.
```

```
ALTER TABLE tablename ADD STATISTICS ((column_1, column_2); -- Declare statistics about column_1
and column_2 of tablename.
```

```
ANALYZE tablename; -- Collect statistics about one or more columns.
```

```
ALTER TABLE tablename DELETE STATISTICS ((column_1, column_2); --Delete statistics about column_1
and column_2 of tablename or their statistics declaration.
```

---

#### NOTICE

After the statistics are declared for multiple columns by executing the ALTER TABLE *tablename* ADD STATISTICS statement, the system collects the statistics about these columns next time **ANALYZE** is performed on the table or the entire database.

To collect the statistics, run the **ANALYZE** command.

---

#### NOTE

Use **EXPLAIN** to show the execution plan of each SQL statement. If **rows=10** (the default value, probably indicating that the table has not been analyzed) is displayed in the **SEQ SCAN** output of a table, execute the ANALYZE statement for this table.

## 6.5 Reviewing and Modifying a Table Definition

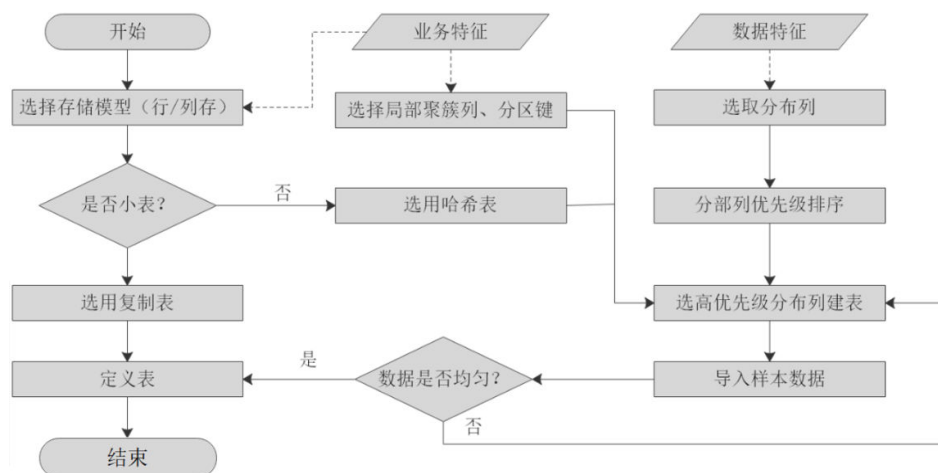

### 6.5.1 Overview

In a distributed framework, data is distributed on DNs. Data on one or more DNs is stored on a physical storage device. To properly define a table, you must:

1. **Evenly distribute data on each DN** to avoid the available capacity decrease of a cluster caused by insufficient storage space of the storage device associated with a DN. Specifically, select a proper distribution key to avoid data skew.
2. **Evenly assign table scanning tasks on each DN** to avoid that a single DN is overloaded by the table scanning tasks. Specifically, do not select columns in the equivalent filter of a base table as the distribution key.
3. **Reduce the data volume scanned** by using the partition pruning mechanism.
4. **Minimize random I/Os** by using clustering.
5. **Avoid data shuffle** to reduce the network pressure by selecting the **join-condition** or **group by** column as the distribution key.

The distribution key is the core for defining a table. **Figure 6-2** shows the procedure of defining a table. The table definition is created during the database design and is reviewed and modified during the SQL statement optimization.

**Figure 6-2** Procedure of defining a table

## 6.5.2 Selecting a Distribution Mode

In replication mode, full data in a table is copied to each DN in the cluster. This mode is used for tables containing a small volume of data. Full data in a table stored on each each DN avoids data redistribution during the join operation. This reduces network costs and plan segment (each having a thread), but generates much redundant data. Generally, this mode is only used for small dimension tables.

In hash mode, hash values are generated for one or more columns. You can obtain the storage location of a tuple based on the mapping between DNs and the hash values. In a hash table, I/O resources on each node can be used during data read/write, which improves the read/write speed of a table. Generally, a table containing a large amount data is defined as a hash table.

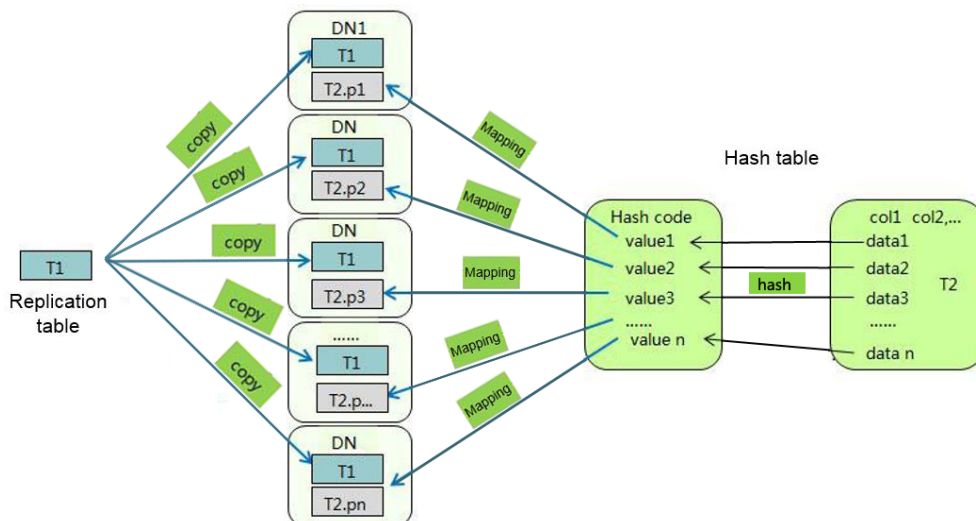

Range distribution and list distribution are user-defined distribution policies. Values in a distribution key are within a certain range or fall into a specific value range of the corresponding target DN. The two distribution modes facilitate flexible data management which, however, requires users equipped with certain data abstraction capability.

| Policy      | Description                                                                                            | Application Scenario                          |
|-------------|--------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| Hash        | Table data is distributed on all DNs in the cluster.                                                   | Fact tables containing a large amount of data |
| Replication | Full data in a table is stored on every DN in the cluster.                                             | Small tables and dimension tables             |
| Range       | Table data is mapped to specified columns based on the range and distributed to the corresponding DNs. | Users need to customize distribution rules.   |

| Policy | Description                                                                                              | Application Scenario                        |
|--------|----------------------------------------------------------------------------------------------------------|---------------------------------------------|
| List   | Table data is mapped to specified columns based on specific values and distributed to corresponding DNs. | Users need to customize distribution rules. |

As shown in [Figure 6-3](#), T1 is a replication table and T2 is a hash table.

**Figure 6-3** Replication tables and hash tables

**NOTE**

- When you insert, modify, or delete data in a replication table, if you use the shippable or immutable function to encapsulate components that cannot be pushed down, data on different DNs in the replication table may be inconsistent.
- If statements with unstable results, such as window functions, rownum, and limit clauses and user-defined functions, are used to insert or modify data in a replication table, data on different nodes may be different.

### 6.5.3 Selecting Distribution Keys

Selecting a distribution key for a hash table is essential. Details are as follows:

1. **Ensure that the column values are discrete so that data can be evenly distributed to each DN.** You can select the primary key of the table as the distribution key. For example, for a person information table, choose the ID card number column as the distribution key.
2. **Do not select the column that has a constant filter.** For example, if a constant constraint (for example, zqdh='000001') exists on the zqdh column in some queries on the dwcjk table, you are not advised to use zqdh as the distribution key.
3. **Select the join condition as the distribution key,** so that join tasks can be pushed down to DNs to execute, reducing the amount of data transferred between the DNs.

For a hash table, an improper distribution key may cause data skew or poor I/O performance on certain DNs. Therefore, you need to check the table to ensure that

data is evenly distributed on each DN. You can run the following SQL statement to check for data skew:

```
select
xc_node_id, count(1)
from tablename
group by xc_node_id
order by xc_node_id desc;
```

**xc\_node\_id** corresponds to a DN. Generally, **over 5% difference between the amount of data on different DNs is regarded as data skew. If the difference is over 10%, choose another distribution key.**

Multiple distribution keys can be selected in GaussDB to evenly distribute data.

You can select the distribution key of the range or list distribution table as required. In addition to selecting a proper distribution key, pay attention to the impact of distribution rules on data distribution.

## 6.5.4 Using Partitioned Tables

Partitioning refers to splitting what is logically one large table into smaller physical pieces based on specific schemes. The table based on the logic is called a partitioned table, and a physical piece is called a partition. Data is stored on these physical partitions, instead of the logical partitioned table. A partitioned table has the following advantages over an ordinary table:

1. High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
2. High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
3. Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.

GaussDB supports range partitioned tables, list partitioned tables, and hash partitioned tables.

- Range partitioned table: Data in different ranges is mapped to different partitions. The range is determined by the partition key specified during the partitioned table creation. The partition key is usually a date. For example, sales data is partitioned by month.
- List partitioned table: Key values contained in the data are stored in different partitions, and the data is mapped to each partition in sequence. The key values contained in the partitions are specified when the partitioned table is created.
- Hash partitioned table: Data is mapped to each partition based on the internal hash algorithm. The number of partitions is specified when the partitioned table is created.

## 6.5.5 Selecting a Data Type

Use the following principles to select efficient data types:

1. **Select data types that facilitate data calculation.**

Generally, the calculation of integers (including common comparison calculations, such as =, >, <, ≥, ≤, and ≠ and GROUP BY) is more efficient than that of strings and floating point numbers.

2. **Select data types with a short length.**

Data types with short length reduce both the data file size and the memory used for computing, improving the I/O and computing performance. For example, use **SMALLINT** instead of **INT**, and **INT** instead of **BIGINT**.

3. **Use the same data type for a join.**

You are advised to use the same data type for a join. To join columns with different data types, the database needs to convert them to the same type, which leads to additional performance overheads.

## 6.6 Typical SQL Optimization Methods

SQL optimization involves continuous analysis and trying. Queries are run before they are used for services to determine whether the performance meets requirements. If it does not, queries will be optimized by **checking the execution plan** and identifying the causes. Then, the queries will be run and optimized again until they meet the requirements.

### 6.6.1 Optimizing SQL Self-Diagnosis

Performance issues may occur when you query data or run the **INSERT**, **DELETE**, **UPDATE**, or **CREATE TABLE AS** statement.

Alarms that can trigger SQL self diagnosis depend on the settings of the GUC parameter **resource\_track\_level**. If **resource\_track\_level** is set to **query**, alarms about the failures in collecting column statistics and pushing down SQL statements will trigger the diagnosis. If **resource\_track\_level** is set to **operator**, all alarms will trigger the diagnosis.

Whether an SQL plan will be diagnosed depends on the settings of the GUC parameter **resource\_track\_cost**. An SQL plan will be diagnosed only if its execution cost is greater than **resource\_track\_cost**. You can use the **EXPLAIN** keyword to check the plan execution cost.

The SQL self-diagnosis function is affected by the **enable\_analyze\_check** parameter. Ensure that the function is enabled before using it.

If a large number of statements are executed, certain data may fail to be collected due to memory control. In this case, you can increase the value of **instr\_unique\_sql\_count**.

## Alarms

Currently, the following performance alarms will be reported:

- Some column statistics are not collected.

An alarm will be reported if some column statistics are not collected.

Example alarms:

No statistics about a table are not collected.

```
Statistic Not Collect:
schema_test.t1
```

The statistics about a single column are not collected.

```
Statistic Not Collect:
 schema_test.t2(c1,c2)
```

The statistics about multiple columns are not collected.

```
Statistic Not Collect:
 schema_test.t3((c1,c2))
```

The statistics about a single column and multiple columns are not collected.

```
Statistic Not Collect:
 schema_test.t4(c1,c2) schema_test.t4((c1,c2))
```

- SQL statements are not pushed down.  
The cause details are displayed in the alarms. For details about the optimization, see [Optimizing Statement Pushdown](#).
  - If the pushdown failure is caused by functions, the function names are displayed in the alarm.
  - If a syntax does not support pushdown, an alarm is generated, indicating that the syntax does not support pushdown.

Example alarms:

```
SQL is not plan-shipping, reason : "With Recursive" can not be shipped"
SQL is not plan-shipping, reason : "Function now() can not be shipped"
SQL is not plan-shipping, reason : "Function string_agg() can not be shipped"
```

- In a hash join, the larger table is used as the inner table.

An alarm will be reported if the number of rows in the inner table reaches or exceeds 10 times of that in the outer table, more than 100,000 inner-table rows are processed on each DN in average, and the join statement has spilled to disks. You can check whether a hash join is used. For details about the optimization, see [Hint-based Tuning](#).

Example alarms:

```
PlanNode[7] Large Table is INNER in HashJoin "Hash Aggregate"
```

- **nestloop** is used in a large-table equivalent join.

An alarm will be reported if **nestloop** is used in an equivalent join where more than 100,000 larger-table rows are processed on each DN in average. You can check whether **nestloop** is used. For details about the optimization, see [Hint-based Tuning](#).

Example alarms:

```
PlanNode[5] Large Table with Equal-Condition use Nestloop"Nested Loop"
```

- A large table is broadcasted.

An alarm will be reported if more than 100 thousand of rows are broadcast on each DN in average. For details about the optimization, see [Hint-based Tuning](#).

Example alarms:

```
PlanNode[5] Large Table in Broadcast "Streaming(type: BROADCAST dop: 1/2)"
```

- Data skew occurs.

An alarm will be reported if the number of rows processed on any DN exceeds 100 thousand, and the number of rows processed on a DN reaches or exceeds 10 times of that processed on another DN.

Example alarms:

```
PlanNode[6] DataSkew:"Seq Scan", min_dn_tuples:0, max_dn_tuples:524288
```

- Estimation is inaccurate.

An alarm will be reported if the number of rows estimated by the optimizer is greater than 100,000 compared with the actual number of rows and the estimated number of rows is 10 times or more than the actual number of rows. For details about the optimization, see [Hint-based Tuning](#).

Example alarms:

```
PlanNode[5] Inaccurate Estimation-Rows: "Hash Join" A-Rows:0, E-Rows:52488
```

## Restrictions

1. An alarm contains a maximum of 2048 characters. If the length of an alarm exceeds this value (for example, a large number of long table names and column names are displayed in the alarm when their statistics are not collected), a warning instead of an alarm will be reported.  

```
WARNING, "Planner issue report is truncated, the rest of planner issues will be skipped"
```
2. If a query statement contains the **Limit** operator, alarms of operators lower than **Limit** will not be reported.
3. For alarms about data skew and inaccurate estimation, only alarms on the lower-layer nodes in a plan tree will be reported. This is because the same alarms on the upper-level nodes may be triggered by problems on the lower-layer nodes. For example, if data skew occurs on the **Scan** node, data skew may also occur in operators (for example, **Hashagg**) at the upper layer.

## 6.6.2 Optimizing Statement Pushdown

### Statement Pushdown

Currently, the GaussDB optimizer can use three methods to develop statement execution policies in the distributed framework: generating a statement pushdown plan, a distributed execution plan, or a distributed execution plan for sending statements.

- A statement pushdown plan pushes query statements from a CN down to DNs for execution and returns the execution results to the CN.
- In a distributed execution plan, a CN compiles and optimizes query statements, generates a plan tree, and then sends the plan tree to DNs for execution. After the statements have been executed, execution results will be returned to the CN.
- A distributed execution plan for sending statements pushes queries that can be pushed down (mostly base table scanning statements) to DNs for execution. Then, the plan obtains the intermediate results and sends them to the CN, on which the remaining queries are to be executed.

The third policy sends many intermediate results from DNs to the CN for further execution. In this case, the CN performance bottleneck (in bandwidth, storage, and computing) is caused by statements that cannot be pushed down to DNs. Therefore, you are advised not to use the query statements where only the third policy applies.

Statements cannot be pushed down if they have **functions that do not support pushdown** or **syntax that does not support pushdown**. Generally, you can rewrite the execution statements to solve the problem.

## Typical Scenarios of Statement Pushdown

In the GaussDB optimizer, if you want to support statement pushdown, set the GUC parameter **enable\_fast\_query\_shipping** to **on**. Generally, no execution plan operator is displayed after the **EXPLAIN** statement. If the keyword similar to "Data Node Scan on" exists, the statement has been pushed down to DNs for execution. The following describes statement pushdown and its supported scope from three scenarios.

### 1. Pushdown of single-table query statements

In a distributed database, to query a single table, whether the current statement can be pushed down depends on whether the CN needs to participate in calculation instead of simply collecting data. If the CN needs to further calculate the DN result, the statement cannot be pushed down. Generally, statements with keywords such as **agg**, **windows function**, **limit/offset**, **sort**, **distinct** cannot be pushed down.

- Pushdown: Simple queries can be pushed down without further calculation on the CN.

```
gaussdb=# explain select * from t where c1 > 1;
 QUERY PLAN

Data Node Scan on "__REMOTE_FQS_QUERY__" (cost=0.00..0.00 rows=0 width=0)
 Node/s: All datanodes
(2 rows)
```

- Non-pushdown: A CN with the **limit** clause cannot simply send statements to DNs and collect data, which is inconsistent with the semantics of the **limit** clause.

```
gaussdb=# explain select * from t limit 1;
 QUERY PLAN

Limit (cost=0.00..0.00 rows=1 width=12)
-> Data Node Scan on "__REMOTE_LIMIT_QUERY__" (cost=0.00..0.00 rows=1 width=12)
 Node/s: All datanodes
(3 rows)
```

- Non-pushdown: A CN with the aggregate function cannot simply push down statements. Instead, it needs to further aggregate the results collected from DNs.

```
gaussdb=# explain select sum(c1), count(*) from t;
 QUERY PLAN

Aggregate (cost=0.10..0.11 rows=1 width=20)
-> Data Node Scan on "__REMOTE_GROUP_QUERY__" (cost=0.00..0.00 rows=20 width=4)
 Node/s: All datanodes
(3 rows)
```

### 2. Pushdown of multi-table query statements

In the multi-table query scenario, whether a statement can be pushed down depends on the **join** condition and distribution columns. That is, if the **join** condition matches the distribution columns of the table, the statement can be pushed down. Otherwise, the statement cannot be pushed down. Generally, a replication table can be pushed down.

- Create two hash distribution tables.  
gaussdb=# create table t(c1 int, c2 int, c3 int)distribute by hash(c1);  
CREATE TABLE  
gaussdb=# create table t1(c1 int, c2 int, c3 int)distribute by hash(c1);  
CREATE TABLE
- Pushdown: The **join** condition meets the hash distribution key attributes of two tables.  
gaussdb=# explain select \* from t1 join t on t.c1 = t1.c1;  
QUERY PLAN  
-----  
Data Node Scan on "\_REMOTE\_FQS\_QUERY\_" (cost=0.00..0.00 rows=0 width=0)  
Node/s: All datanodes  
(2 rows)
- Non-pushdown: The **join** condition does not meet the hash distribution key attribute. That is, **t1.c2** is not the distribution key of **t1**.  
gaussdb=# explain select \* from t1 join t on t.c1 = t1.c2;  
QUERY PLAN  
-----  
Hash Join (cost=0.25..0.53 rows=20 width=24)  
Hash Cond: (t1.c2 = t.c1)  
-> Data Node Scan on t1 "\_REMOTE\_TABLE\_QUERY\_" (cost=0.00..0.00 rows=20 width=12)  
Node/s: All datanodes  
-> Hash (cost=0.00..0.00 rows=20 width=12)  
-> Data Node Scan on t "\_REMOTE\_TABLE\_QUERY\_" (cost=0.00..0.00 rows=20 width=12)  
Node/s: All datanodes  
(7 rows)
- Delete two hash distribution tables.  
gaussdb=# DROP TABLE t;  
DROP TABLE  
gaussdb=# DROP TABLE t1;  
DROP TABLE

### 3. Special scenarios

In some special scenarios, for example, a statement containing the WITH RECURSIVE clause cannot be pushed down.

## Checking Whether the Execution Plan Has Been Pushed Down

Perform the following procedure to quickly determine whether the execution plan can be pushed down:

- Step 1** Set the GUC parameter **enable\_fast\_query\_shipping** to **off** to use the distributed framework policy for the query optimizer.

```
SET enable_fast_query_shipping = off;
```

- Step 2** View the execution plan.

If the execution plan contains Data Node Scan nodes, the SQL statements cannot be pushed down to DNs. If the execution plan contains Streaming nodes, the SQL statements can be pushed down to DNs.

For example:

```
gaussdb=# select
count(ss.ss_sold_date_sk order by ss.ss_sold_date_sk)c1
from store_sales ss, store_returns sr
where
sr.sr_customer_sk = ss.ss_customer_sk;
```

The execution plan is as follows, which indicates that the SQL statement cannot be pushed down.

```

QUERY PLAN

Aggregate
-> Hash Join
Hash Cond: (ss.ss_customer_sk = sr.sr_customer_sk)
-> Data Node Scan on store_sales "_REMOTE_TABLE_QUERY_"
Node/s: All datanodes
-> Hash
-> Data Node Scan on store_returns "_REMOTE_TABLE_QUERY_"
Node/s: All datanodes
(8 rows)

----End

```

## Syntax That Does Not Support Pushdown

SQL syntax that does not support pushdown is described using the following table definition examples:

```

gaussdb=# CREATE TABLE CUSTOMER1
(
 C_CUSTKEY BIGINT NOT NULL
, C_NAME VARCHAR(25) NOT NULL
, C_ADDRESS VARCHAR(40) NOT NULL
, C_NATIONKEY INT NOT NULL
, C_PHONE CHAR(15) NOT NULL
, C_ACCTBAL DECIMAL(15,2) NOT NULL
, C_MKTSEGMENT CHAR(10) NOT NULL
, C_COMMENT VARCHAR(117) NOT NULL
)
DISTRIBUTE BY hash(C_CUSTKEY);
gaussdb=# CREATE TABLE test_stream(a int, b float); -- float does not support redistribution.
gaussdb=# CREATE TABLE sal_emp (c1 integer[]) DISTRIBUTE BY replication;

```

- The **returning** statement cannot be pushed down.

```

gaussdb=# explain update customer1 set C_NAME = 'a' returning c_name;
QUERY PLAN

```

```

Update on customer1 (cost=0.00..0.00 rows=30 width=187)
Node/s: All datanodes
Node expr: c_custkey
-> Data Node Scan on customer1 "_REMOTE_TABLE_QUERY_" (cost=0.00..0.00 rows=30 width=187)
Node/s: All datanodes
(5 rows)

```

- If an SQL statement contains the aggregate functions using **ORDER BY**, this statement cannot be pushed down.

```

gaussdb=# explain verbose select count (c_custkey order by c_custkey) from customer1;

```

```

QUERY PLAN

Aggregate (cost=2.50..2.51 rows=1 width=8)
Output: count(customer1.c_custkey ORDER BY customer1.c_custkey)
-> Data Node Scan on customer1 "_REMOTE_TABLE_QUERY_" (cost=0.00..0.00 rows=30 width=8)
Output: customer1.c_custkey
Node/s: All datanodes
Remote query: SELECT c_custkey FROM ONLY public.customer1 WHERE true
(6 rows)

```

- If an SQL statement contains **COUNT(DISTINCT expr)** and columns in **COUNT(DISTINCT expr)** do not support redistribution, this statement cannot be pushed down.

```

gaussdb=# explain verbose select count(distinct b) from test_stream;
QUERY PLAN

```

```

Aggregate (cost=2.50..2.51 rows=1 width=8)
Output: count(DISTINCT test_stream.b)
-> Data Node Scan on test_stream "_REMOTE_TABLE_QUERY_" (cost=0.00..0.00 rows=30 width=8)
Output: test_stream.b

```

- Node/s: All datanodes  
Remote query: SELECT b FROM ONLY public.test\_stream WHERE true  
(6 rows)
- A statement containing **DISTINCT ON** cannot be pushed down.  
gaussdb=# explain verbose select distinct on (c\_custkey) c\_custkey from customer1 order by c\_custkey;  
QUERY PLAN  
----- Unique (cost=49.83..54.83 rows=30 width=8)  
Output: customer1.c\_custkey  
-> Sort (cost=49.83..52.33 rows=30 width=8)  
Output: customer1.c\_custkey  
Sort Key: customer1.c\_custkey  
-> Data Node Scan on customer1 "\_REMOTE\_TABLE\_QUERY\_" (cost=0.00..0.00 rows=30 width=8)  
Output: customer1.c\_custkey  
Node/s: All datanodes  
Remote query: SELECT c\_custkey FROM ONLY public.customer1 WHERE true  
(9 rows)
- A statement containing array expressions cannot be pushed down.  
gaussdb=# explain verbose select array[c\_custkey,1] from customer1 order by c\_custkey;  
QUERY PLAN  
----- Sort (cost=49.83..52.33 rows=30 width=8)  
Output: (ARRAY[customer1.c\_custkey, 1::bigint]), customer1.c\_custkey  
Sort Key: customer1.c\_custkey  
-> Data Node Scan on "\_REMOTE\_SORT\_QUERY\_" (cost=0.00..0.00 rows=30 width=8)  
Output: (ARRAY[customer1.c\_custkey, 1::bigint]), customer1.c\_custkey  
Node/s: All datanodes  
Remote query: SELECT ARRAY[c\_custkey, 1::bigint], c\_custkey FROM ONLY public.customer1 WHERE true ORDER BY 2  
(7 rows)
- The following table describes the scenarios where a statement containing **WITH RECURSIVE** cannot be pushed down in the current version, as well as the causes.

| No. | Scenario                           | Cause of Not Supporting Pushdown                                                                                                                                                                                                                       |
|-----|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | The query contains foreign tables. | LOG: SQL can't be shipped, reason: RecursiveUnion contains ForeignScan is not shippable (In this table, LOG describes the cause of not supporting pushdown.)<br><br>In the current version, queries containing foreign tables do not support pushdown. |
| 2   | Multiple node groups exist.        | LOG: SQL can't be shipped, reason: With-Recursive under multi-nodegroup scenario is not shippable<br><br>In the current version, pushdown is supported only when all base tables are stored and computed in the same node group.                       |

| No. | Scenario                                                                                                                             | Cause of Not Supporting Pushdown                                                                                                                                                                                                                                                                                                                                                                                             |
|-----|--------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | UNION does not contain ALL, and deduplication is required.                                                                           | <p>LOG: SQL can't be shipped, reason: With-Recursive does not contain "ALL" to bind recursive &amp; none-recursive branches</p> <p>For example:</p> <pre>WITH recursive t_result AS ( SELECT dm,sj_dm,name,1 as level FROM test_rec_part WHERE sj_dm &gt; 10 UNION SELECT t2.dm,t2.sj_dm,t2.name  ' &gt; '   t1.name,t1.level+1 FROM t_result t1 JOIN test_rec_part t2 ON t2.sj_dm = t1.dm ) SELECT * FROM t_result t;</pre> |
| 4   | A base table contains a system catalog.                                                                                              | <p>LOG: SQL can't be shipped, reason: With-Recursive contains system table is not shippable</p> <p>Example:</p> <pre>WITH RECURSIVE x(id) AS ( select count(1) from pg_class where oid=1247 UNION ALL SELECT id+1 FROM x WHERE id &lt; 5 ), y(id) AS ( select count(1) from pg_class where oid=1247 UNION ALL SELECT id+1 FROM x WHERE id &lt; 10 ) SELECT y.*, x.* FROM y LEFT JOIN x USING (id) ORDER BY 1;</pre>          |
| 5   | Only <b>VALUES</b> is used for scanning base tables. In this case, the statement can be executed on the CN, and DNs are unnecessary. | <p>LOG: SQL can't be shipped, reason: With-Recursive contains only values rte is not shippable</p> <p>Example:</p> <pre>WITH RECURSIVE t(n) AS ( VALUES (1) UNION ALL SELECT n+1 FROM t WHERE n &lt; 100 ) SELECT sum(n) FROM t;</pre>                                                                                                                                                                                       |

| No. | Scenario                                                                                                                                                     | Cause of Not Supporting Pushdown                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

That is, a <b>recursive</b> is nested in the recursion part of another <b>recursive</b> . | <p>LOG: SQL can't be shipped, reason: Recursive CTE references recursive CTE "cte"</p> <p>Example:</p> <pre>with recursive cte as ( select * from rec_tb4 where id&lt;4 union all select h.id,h.parentID,h.name from ( with recursive cte as ( select * from rec_tb4 where id&lt;4 union all select h.id,h.parentID,h.name from rec_tb4 h inner join cte c on h.id=c.parentID ) ) SELECT id ,parentID,name from cte order by parentID ) h inner join cte c on h.id=c.parentID ) SELECT id ,parentID,name from cte order by parentID,1,2,3;</pre> |

Delete the table.

```
gaussdb=# DROP TABLE CUSTOMER1;
DROP TABLE
gaussdb=# DROP TABLE test_stream;
DROP TABLE
gaussdb=# DROP TABLE sa_emp;
DROP TABLE
```

## Functions That Do Not Support Pushdown

The following describes the volatility of functions. In GaussDB, every function has a volatility classification, with the possibilities being:

- **IMMUTABLE**  
Indicates that the function always returns the same result if the parameter values are the same.
- **STABLE**  
Indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same parameter value, but its result varies by SQL statements.
- **VOLATILE**  
Indicates that the function value can change in a single table scan and no optimization is performed.

The volatility of a function can be obtained by querying for its **provolatile** column in **pg\_proc**. The value **i** indicates immutable, **s** indicates stable, and **v** indicates volatile. The valid values of the **proshippable** column in **pg\_proc** are **t**, **f**, and

**NULL.** This column and the **provolatile** column together describe whether a function is pushed down.

- If the **provolatile** of a function is **i**, the function can be pushed down regardless of the value of **proshippable**.
- If the **provolatile** of a function is **s** or **v**, the function can be pushed only if the value of **proshippable** is **t**.
- CTEs containing **random**, **exec\_hadoop\_sql**, or **exec\_on\_extension** are not pushed down, because pushdown may lead to incorrect results.

When creating a customized function, you can specify the values of **provolatile** and **proshippable**. For details, see [CREATE FUNCTION](#).

In scenarios where a function does not support pushdown, perform one of the following as required:

- If it is a system function, replace it with a functionally equivalent one.
- If it is a customized function, check whether its **provolatile** and **proshippable** are correctly defined.

## Example: Customized Functions

Define a customized function that generates fixed output for a certain input as the **immutable** type.

Take the sales information of TPC Benchmark DS (TPC-DS) as an example. If you want to write a function to calculate the discount data of a product, you can define the function as follows:

```
CREATE FUNCTION func_percent_2 (NUMERIC, NUMERIC) RETURNS NUMERIC
AS 'SELECT $1 / $2 WHERE $2 > 0.01'
LANGUAGE SQL
VOLATILE;
```

Run the following statements:

```
SELECT func_percent_2(ss_sales_price, ss_list_price)
FROM store_sales;
```

The execution plan is as follows.

```
Data Node Scan on store_sales " REMOTE_TABLE_QUERY "
 Output: func_percent_2(store_sales.ss_sales_price, store_sales.ss_list_price)
 Remote query: SELECT ss_sales_price, ss_list_price FROM ONLY store_sales WHERE true
(3 rows)
```

**func\_percent\_2** is not pushed down, and **ss\_sales\_price** and **ss\_list\_price** are executed on a CN. In this case, a large amount of resources on the CN is consumed, and the performance deteriorates as a result.

In this example, the function generates the same output when the same input is provided. Therefore, we can modify the function to the following one:

```
CREATE FUNCTION func_percent_1 (NUMERIC, NUMERIC) RETURNS NUMERIC
AS 'SELECT $1 / $2 WHERE $2 > 0.01'
LANGUAGE SQL
IMMUTABLE;
```

Run the following statement:

```
SELECT func_percent_1(ss_sales_price, ss_list_price)
FROM store_sales;
```

The execution plan is as follows.

```
Data Node Scan
Output: (func_percent_1(store_sales.ss_sales_price, store_sales.ss_list_price))
Remote query: SELECT func_percent_1(ss_sales_price, ss_list_price) AS func_percent_1 FROM store_sales
(3 rows)
```

The func\_percent\_1 function is pushed down to DNs for execution.

## 6.6.3 Optimizing Subqueries

### Context

When an application runs an SQL statement to operate the database, a large number of subqueries are used because they are more clear than table join. Especially in complicated query statements, subqueries have more complete and independent semantics, which makes SQL statements clearer and easier to understand. Therefore, subqueries are widely used.

In GaussDB, subqueries can also be called sublinks based on the location of subqueries in SQL statements.

- Subquery: corresponds to a range table (RangeTblEntry) in the query parse tree. That is, a subquery is a SELECT statement following immediately after the FROM keyword.
- Sublink: corresponds to an expression in the query parsing tree. That is, a sublink is a statement in the WHERE or ON clause or in the target list.

In conclusion, a subquery is a RangeTblEntry and a sublink is an expression in the query parsing tree. A sublink can be found in constraint conditions and expressions. In GaussDB, sublinks can be classified into the following types:

- exist\_sublink: corresponds to the **EXIST** and **NOT EXIST** statements.
- any\_sublink: corresponds to the *op* ANY(SELECT...) statement. *op* can be the <, >, or = operator. IN/NOT IN (SELECT...) also belongs to this type.
- all\_sublink: corresponds to the *op* ALL(SELECT...) statement. *op* can be the <, >, or = operator.
- rowcompare\_sublink: corresponds to the RECORD *op* (SELECT...) statement.
- expr\_sublink: corresponds to the (SELECT with a single target list item...) statement.
- array\_sublink: corresponds to the ARRAY(SELECT...) statement.
- cte\_sublink: corresponds to the WITH(...) query statement.

The exist\_sublink and any\_sublink are pulled up by the optimization engine of GaussDB. In addition, expr\_sublink can also be pulled up. However, because of the flexible use of subqueries in SQL statements, complex subqueries may affect query performance. If you do not want to pull up expr\_sublink, set the GUC parameter **rewrite\_rule**. Subqueries are classified into non-correlated subqueries and correlated subqueries.

- **Non-correlated subqueries**

The execution of a subquery is independent from attributes of the outer query. In this way, a subquery can be executed before outer queries.

Example:

```

gaussdb=# select t1.c1,t1.c2
from t1
where t1.c1 in (
 select c2
 from t2
 where t2.c2 IN (2,3,4)
);

```

QUERY PLAN

---

```

Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Right Semi Join
 Hash Cond: (t2.c2 = t1.c1)
 -> Streaming(type: REDISTRIBUTE)
 Spawn on: All datanodes
 -> Seq Scan on t2
 Filter: (c2 = ANY ('{2,3,4}'::integer[]))
 -> Hash
 -> Seq Scan on t1
(10 rows)

```

– **Correlated subqueries**

The execution of a subquery depends on some attributes (used as AND conditions of the subquery) of outer queries. In the following example, **t1.c1** in the **t2.c1 = t1.c1** condition is a correlated attribute. Such a subquery depends on outer queries and needs to be executed once for each outer query.

Example:

```

gaussdb=# select t1.c1,t1.c2
from t1
where t1.c1 in (
 select c2
 from t2
 where t2.c1 = t1.c1 AND t2.c2 in (2,3,4)
);

```

QUERY PLAN

---

```

Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on t1
 Filter: (SubPlan 1)
 SubPlan 1
 -> Result
 Filter: (t2.c1 = t1.c1)
 -> Materialize
 -> Streaming(type: BROADCAST)
 Spawn on: All datanodes
 -> Seq Scan on t2
 Filter: (c2 = ANY ('{2,3,4}'::integer[]))
(12 rows)

```

## Sublink Optimization on GaussDB

To optimize a sublink, a subquery is pulled up to join with tables in outer queries, preventing the subquery from being converted into a plan involving subplans and broadcast. You can run the EXPLAIN statement to check whether a sublink is converted into the combination of a subplan and broadcast.

Example

- **Sublink-release scenarios supported by GaussDB**

- Pulling up the IN sublink

- The subquery cannot contain columns in the outer query (columns in more outer queries are allowed).
    - The subquery cannot contain volatile functions.

The following is an example.

- Pulling up the EXISTS sublink

The WHERE clause must contain a column in the outer query. Other parts of the subquery cannot contain the column. Other restrictions are as follows:

- The subquery must contain the FROM clause.
    - The subquery cannot contain the WITH clause.
    - The subquery cannot contain aggregate functions.
    - The subquery cannot contain a SET, SORT, LIMIT, WindowAgg, or HAVING operation.
    - The subquery cannot contain volatile functions.

The following is an example.

- Pulling up an equivalent correlated query containing aggregate functions

The WHERE condition of the subquery must contain a column from the outer query. Equivalence comparison must be performed between this

column and related columns in tables of the subquery. These conditions must be connected using AND. Other parts of the subquery cannot contain the column. Other restrictions are as follows:

- The columns in the expression in the WHERE condition of the subquery must exist in tables.
- After the SELECT keyword of the subquery, there must be only one output column. The output column must be an aggregate function (for example, MAX), and the parameter (for example, **t2.c2**) of the aggregate function cannot be columns of a table (for example, **t1**) in outer queries. The aggregate function cannot be COUNT.

For example, the following subquery can be pulled up:

```
select * from t1 where c1 >(
 select max(t2.c1) from t2 where t2.c1=t1.c1
);
```

The following subquery cannot be pulled up because the subquery has no aggregate function:

```
select * from t1 where c1 >(
 select t2.c1 from t2 where t2.c1=t1.c1
);
```

The following subquery cannot be pulled up because the subquery has two output columns:

```
select * from t1 where (c1,c2) >(
 select max(t2.c1),min(t2.c2) from t2 where t2.c1=t1.c1
);
```

- The subquery must be a FROM clause.
- The subquery cannot contain a GROUP BY, HAVING, or SET operation.
- The subquery can only be an inner join.

For example, the following subquery cannot be pulled up:

```
select * from t1 where c1 >(
 select max(t2.c1) from t2 full join t3 on (t2.c2=t3.c2) where t2.c1=t1.c1
);
```

- The target list of the subquery cannot contain the function that returns a set.
- The WHERE condition of the subquery must contain a column from the outer query. Equivalence comparison must be performed between this column and related columns in tables of the subquery. These conditions must be connected using AND. Other parts of the subquery cannot contain the column. For example, the following innermost sublink can be pulled up:

```
select * from t3 where t3.c1=(
 select t1.c1
 from t1 where c1 >(
 select max(t2.c1) from t2 where t2.c1=t1.c1
));
```

If another condition is added to the subquery in the previous example, the subquery cannot be pulled up because the subquery references to the column in the outer query. Example:

```
select * from t3 where t3.c1=(
 select t1.c1
 from t1 where c1 >(
```

```
select max(t2.c1) from t2 where t2.c1=t1.c1 and t3.c1>t2.c2
));
```

- Pulling up a sublink in the OR clause

If the WHERE condition contains an EXIST correlated sublink connected by OR:

Example:

```
select a, c from t1
where t1.a = (select avg(a) from t3 where t1.b = t3.b) or
exists (select * from t4 where t1.c = t4.c);
```

The process of pulling up such a sublink is as follows:

- Extract **opExpr** from the OR clause in the WHERE condition. The value is **t1.a = (select avg(a) from t3 where t1.b = t3.b)**.
- The **opExpr** contains a subquery. If the subquery can be pulled up, the subquery is rewritten as **select avg(a), t3.b from t3 group by t3.b**, generating the NOT NULL condition **t3.b is not null**. The **opExpr** is replaced by this NOT NULL condition. In this case, the SQL statement changes to:

```
select a, c
from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b) as t3 on (t1.a = avg
and t1.b = t3.b)
where t3.b is not null or exists (select * from t4 where t1.c = t4.c);
```

- Extract the EXISTS sublink **exists (select \* from t4 where t1.c = t4.c)** from the OR clause to check whether the sublink can be pulled up. If it can be pulled up, it is converted into **select t4.c from t4 group by t4.c**, generating the NOT NULL condition **t4.c is not null**. In this case, the SQL statement changes to:

```
select t1.a, t1.c from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b) as t3 on
(t1.a = avg and t1.b = t3.b) left join (select t5.c from t5 group by t5.c) as t5 on (t1.c =
t5.c) where t3.b is not null or t5.c is not null;
```

- **Sublink-release scenarios not supported by GaussDB**

Except the sublinks described above, all the other sublinks cannot be pulled up. In this case, a join subquery is planned as the combination of subplans and broadcast. As a result, if inner tables have a large amount of data, query performance may be poor.

If a correlated subquery joins with two tables in outer queries, the subquery cannot be pulled up. You need to change the outer query into a WITH clause and then perform the join.

Example:

```
select distinct t1.a, t2.a
from t1 left join t2 on t1.a=t2.a and not exists (select a,b from test1 where test1.a=t1.a and
test1.b=t2.a);
```

The outer query is changed into:

```
with temp as
(
select * from (select t1.a as a, t2.a as b from t1 left join t2 on t1.a=t2.a)
)
select distinct a,b
from temp
where not exists (select a,b from test1 where temp.a=test1.a and temp.b=test1.b);
```

- The subquery (without COUNT) in the target list cannot be pulled up.

Example:

```
gaussdb=# explain (costs off)
select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
from t1
where t1.c2 > 10;
```

The execution plan is as follows:

```
gaussdb=# explain (costs off)
select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
from t1
where t1.c2 > 10;
```

```
QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on t1
Filter: (c2 > 10)
SubPlan 1
-> Result
Filter: (t1.c1 = t2.c1)
-> Materialize
-> Streaming(type: BROADCAST)
Spawn on: All datanodes
-> Seq Scan on t2
(11 rows)
```

The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met. Therefore, use a right outer join to join **t2** and **t1** so that the SSQ can return padding values when the condition **t1.c1=t2.c1** is not met.

#### NOTE

ScalarSubQuery (SSQ) and Correlated-ScalarSubQuery (CSSQ) are described as follows:

- SSQ: a sublink that returns a scalar value of a single row with a single column
- CSSQ: an SSQ containing correlation conditions

The preceding SQL statement can be changed into:

```
with ssq as
(
select * from t1 where t1.c2 > 10
)
select t2.c2,ssq.c2 from t2 right join ssq on ssq.c1 = t2.c1;
```

The execution plan after the change is as follows:

```
QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Right Join
Hash Cond: (t2.c1 = t1.c1)
-> Seq Scan on t2
-> Hash
-> Seq Scan on t1
Filter: (c2 > 10)
(8 rows)
```

In the preceding example, the SSQ in the target list is pulled up to right join, preventing poor performance caused by the plan involving subplans and broadcast when the table (**t2**) in the subquery is too large.

- The subquery (with COUNT) in the target list cannot be pulled up.

Example:

```
select (select count(*) from t2 where t2.c1=t1.c1) cnt, t1.c1, t3.c1
from t1,t3
where t1.c1=t3.c1 order by cnt, t1.c1;
```

The execution plan is as follows:

```

QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Sort
 Sort Key: ((SubPlan 1)), t1.c1
 -> Hash Join
 Hash Cond: (t1.c1 = t3.c1)
 -> Seq Scan on t1
 -> Hash
 -> Seq Scan on t3
 SubPlan 1
 -> Aggregate
 -> Result
 Filter: (t2.c1 = t1.c1)
 -> Materialize
 -> Streaming(type: BROADCAST)
 Spawn on: All datanodes
 -> Seq Scan on t2
(17 rows)

```

The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met. Therefore, use left outer join to join **T1** and **T2** so that SSQ can return padding values when the condition **t1.c1=t2.c1** is not met. However, COUNT is used, which requires that **0** is returned when the condition is not met. Therefore, case-when NULL then 0 else count(\*) can be used.

The preceding SQL statement can be changed into:

```

with ssq as
(
 select count(*) cnt, c1 from t2 group by c1
)
select case when
 ssq.cnt is null then 0
 else ssq.cnt
end cnt, t1.c1, t3.c1
from t1 left join ssq on ssq.c1 = t1.c1,t3
where t1.c1 = t3.c1
order by ssq.cnt, t1.c1;

```

The execution plan after the change is as follows:

```

QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Sort
 Sort Key: (count(*)), t1.c1
 -> Hash Join
 Hash Cond: (t1.c1 = t3.c1)
 -> Hash Left Join
 Hash Cond: (t1.c1 = t2.c1)
 -> Seq Scan on t1
 -> Hash
 -> HashAggregate
 Group By Key: t2.c1
 -> Seq Scan on t2
 -> Hash
 -> Seq Scan on t3
(15 rows)

```

- Non-equivalent correlated subqueries cannot be pulled up.

Example:

```

select t1.c1, t1.c2
from t1
where t1.c1 = (select agg() from t2.c2 > t1.c2);

```

Non-equivalent correlated subqueries cannot be pulled up. You can perform join twice (one CorrelationKey and one rownum self-join) to rewrite the statement.

You can rewrite the statement in either of the following ways:

- Subquery rewriting

```
select t1.c1, t1.c2
from t1, (
 select t1.rowid, agg() aggref
 from t1,t2
 where t1.c2 > t2.c2 group by t1.rowid
) dt /* derived table */
where t1.rowid = dt.rowid AND t1.c1 = dt.aggref;
```
- CTE rewriting

```
WITH dt as
(
 select t1.rowid, agg() aggref
 from t1,t2
 where t1.c2 > t2.c2 group by t1.rowid
)
select t1.c1, t1.c2
from t1, dt
where t1.rowid = dt.rowid AND
t1.c1 = dt.aggref;
```

#### NOTICE

- Currently, GaussDB does not have an effective way to provide globally unique row IDs for tables and intermediate result sets. Therefore, the rewriting is difficult. It is recommended that this issue is avoided at the service layer or by using **t1.xc\_nodeid + t1.ctid** to associate row IDs. However, the high repetition rate of **xc\_nodeid** leads to low association efficiency, and **xc\_node\_id+ctid** cannot be used as the join condition of a hash join.
- If the AGG type is COUNT(\*), **0** is used for data padding when CASE-WHEN is not matched. If the type is not COUNT(\*), **NULL** is used.
- CTE rewriting works better by using sharescan.

## More Optimization Examples

Example 1: Change the base table to a replication table and create an index on the filter column.

```
create table master_table (a int);
create table sub_table(a int, b int);
select a from master_table group by a having a in (select a from sub_table);
```

In this example, a correlated subquery is contained. To improve the query performance, you can change **sub\_table** to a replication table and create an index on the **a** column.

Example 2: Modify the SELECT statement to change the subquery to a join relationship between the main table and the parent query, or modify the subquery to improve the query performance. Ensure that the subquery to be used is semantically correct.

```
gaussdb=# explain (costs off)select * from master_table as t1 where t1.a in (select t2.a from sub_table as t2
where t1.a = t2.b);
 QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on master_table t1
 Filter: (SubPlan 1)
 SubPlan 1
 -> Result
 Filter: (t1.a = t2.b)
 -> Materialize
 -> Streaming(type: BROADCAST)
 Spawn on: All datanodes
 -> Seq Scan on sub_table t2
(11 rows)
```

In the preceding example, a subplan is used. To remove the subplan, you can modify the statement as follows:

```
gaussdb=# explain(costs off) select * from master_table as t1 where exists (select t2.a from sub_table as t2
where t1.a = t2.b and t1.a = t2.a);
 QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Semi Join
 Hash Cond: (t1.a = t2.b)
 -> Seq Scan on master_table t1
 -> Hash
 -> Streaming(type: REDISTRIBUTE)
 Spawn on: All datanodes
 -> Seq Scan on sub_table t2
(9 rows)
```

In this way, the subplan is replaced by the semi-join between the two tables, greatly improving the execution efficiency.

## 6.6.4 Optimizing Statistics

### Context

GaussDB generates optimal execution plans based on the cost estimation. Optimizers need to estimate the number of data rows and the cost based on statistics collected using ANALYZE. Therefore, the statistics is vital for the estimation of the number of rows and cost. Global statistics are collected using ANALYZE: **relpages** and **reltuples** in the **pg\_class** table; **stadiinct**, **stanullfrac**, **stanumbersN**, **stavaluesN**, and **histogram\_bounds** in the **pg\_statistic** table.

### Example 1: Poor Query Performance Due to the Lack of Statistics

In most cases, the lack of statistics about tables or columns involved in the query greatly affects the query performance.

The table structure is as follows:

```
CREATE TABLE LINEITEM
(
 L_ORDERKEY BIGINT NOT NULL
, L_PARTKEY BIGINT NOT NULL
, L_SUPPKEY BIGINT NOT NULL
, L_LINENUMBER BIGINT NOT NULL
, L_QUANTITY DECIMAL(15,2) NOT NULL
, L_EXTENDEDPRICE DECIMAL(15,2) NOT NULL
```

```
, L_DISCOUNT DECIMAL(15,2) NOT NULL
, L_TAX DECIMAL(15,2) NOT NULL
, L_RETURNFLAG CHAR(1) NOT NULL
, L_LINESTATUS CHAR(1) NOT NULL
, L_SHIPDATE DATE NOT NULL
, L_COMMITDATE DATE NOT NULL
, L_RECEIPTDATE DATE NOT NULL
, L_SHIPINSTRUCT CHAR(25) NOT NULL
, L_SHIPMODE CHAR(10) NOT NULL
, L_COMMENT VARCHAR(44) NOT NULL
) distribute by hash(L_ORDERKEY);

CREATE TABLE ORDERS
(
O_ORDERKEY BIGINT NOT NULL
, O_CUSTKEY BIGINT NOT NULL
, O_ORDERSTATUS CHAR(1) NOT NULL
, O_TOTALPRICE DECIMAL(15,2) NOT NULL
, O_ORDERDATE DATE NOT NULL
, O_ORDERPRIORITY CHAR(15) NOT NULL
, O_CLERK CHAR(15) NOT NULL
, O_SHIPPRIORITY BIGINT NOT NULL
, O_COMMENT VARCHAR(79) NOT NULL
) distribute by hash(O_ORDERKEY);
```

The query statements are as follows:

```
explain verbose select
count(*) as numwait
from
lineitem l1,
orders
where
o_orderkey = l1.l_orderkey
and o_orderstatus = 'F'
and l1.l_receiptdate > l1.l_commitdate
and not exists (
select
*
from
lineitem l3
where
l3.l_orderkey = l1.l_orderkey
and l3.l_suppkey <> l1.l_suppkey
and l3.l_receiptdate > l3.l_commitdate
)
order by
numwait desc;
```

If such an issue occurs, you can use the following methods to check whether statistics in tables or columns has been collected using ANALYZE.

1. Execute EXPLAIN VERBOSE to analyze the execution plan and check the warning information:

```
WARNING:Statistics in some tables or columns(public.lineitem.l_receiptdate,
public.lineitem.l_commitdate, public.lineitem.l_orderkey, public.lineitem.l_suppkey,
public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.
HINT:Do analyze for them in order to generate optimized plan.
```

2. Check whether the following information exists in the log file in the **pg\_log** directory. If it does, the poor query performance was caused by the lack of statistics in some tables or columns.

```
2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] LOG:Statistics in some tables
or columns(public.lineitem.l_receiptdate, public.lineitem.l_commitdate, public.lineitem.l_orderkey,
public.linei
tem.l_suppkey, public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.
2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] HINT:Do analyze for them in
order to generate optimized plan.
```

By using any of the preceding methods, you can identify tables or columns whose statistics have not been collected using ANALYZE. You can execute ANALYZE to warnings or tables and columns recorded in logs to resolve the problem.

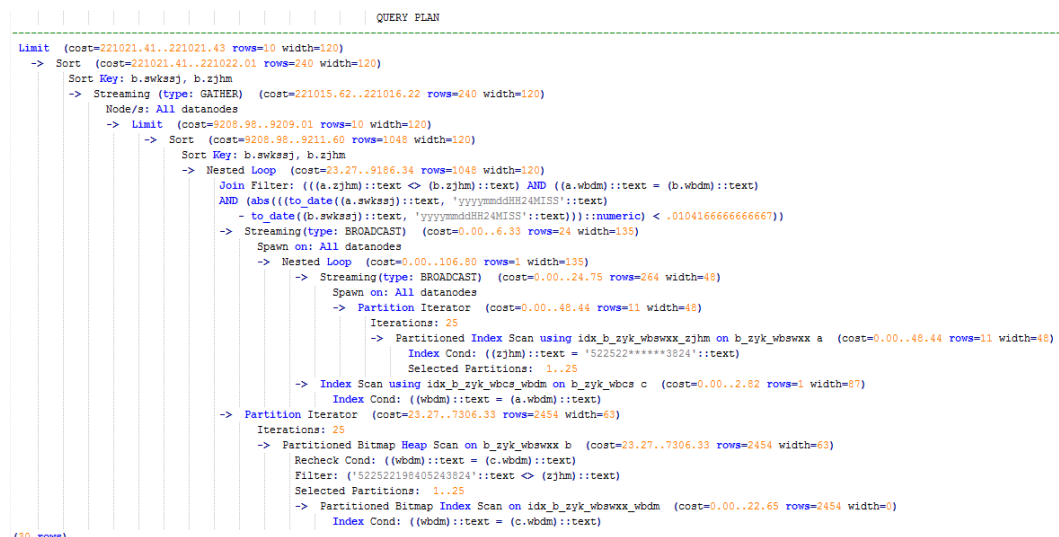

## Example 2: Optimization is Not Accurate When Intermediate Results Exist in the Query Where JOIN Is Used for Multiple Tables

**Symptom:** Query the personnel who have registered in an Internet cafe within 15 minutes before and after the registration of a specified person.

```
SELECT
C.WBM,
C.DZQH,
C.DZ,
B.ZJHM,
B.SWKSSJ,
B.XWSJ
FROM
b_zyk_wbswxx A,
b_zyk_wbswxx B,
b_zyk_wbcs C
WHERE
A.ZJHM = '522522*****3824'
AND A.WBDM = B.WBDM
AND A.WBDM = C.WBDM
AND abs(to_date(A.SWKSSJ,'yyyymmddHH24MISS') - to_date(B.SWKSSJ,'yyyymmddHH24MISS')) <
INTERVAL '15 MINUTES'
ORDER BY
B.SWKSSJ,
B.ZJHM
limit 10 offset 0
;
```

Figure 6-4 shows the execution plan. This query takes about 12s.

Figure 6-4 Using an unlogged table (1)

### Optimization analysis:

1. In the execution plan, index scan is used for node scanning, the **Join Filter** calculation in the external **NEST LOOP JOIN** statement consumes most of the

query time, and the calculation uses the string addition and subtraction, and unequal-value comparison.

2. Use an unlogged table to record the Internet access time of the specified person. The start time and end time are processed during data insertion, and this reduces subsequent addition and subtraction operations.

```
// Create a temporary unlogged table.
CREATE UNLOGGED TABLE temp_tsw
(
 ZJHM NVARCHAR2(18),
 WBDM NVARCHAR2(14),
 SWKSSJ_START NVARCHAR2(14),
 SWKSSJ_END NVARCHAR2(14),
 WBM NVARCHAR2(70),
 DZQH NVARCHAR2(6),
 DZ NVARCHAR2(70),
 IPDZ NVARCHAR2(39)
)
;
// Insert the Internet access record of the specified person, and process the start time and end time.
INSERT INTO
temp_tsw
SELECT
A.ZJHM,
A.WBDM,
to_char((to_date(A.SWKSSJ,'yyyymmddHH24MISS') - INTERVAL '15
MINUTES'),'yyyymmddHH24MISS'),
to_char((to_date(A.SWKSSJ,'yyyymmddHH24MISS') + INTERVAL '15
MINUTES'),'yyyymmddHH24MISS'),
B.WBM,B.DZQH,B.DZ,B.IPDZ
FROM
b_zyk_wbswxx A,
b_zyk_wbcs B
WHERE
A.ZJHM='522522*****3824' AND A.WBDM = B.WBDM
;

// Query the personnel who have registered in an Internet cafe before and after 15 minutes of the
registration of the specified person. Convert their ID card number format to int8 in comparison.
SELECT
A.WBM,
A.DZQH,
A.DZ,
A.IPDZ,
B.ZJHM,
B.XM,
to_date(B.SWKSSJ,'yyyymmddHH24MISS') as SWKSSJ,
to_date(B.XWSJ,'yyyymmddHH24MISS') as XWSJ,
B.SWZDH
FROM temp_tsw A,
b_zyk_wbswxx B
WHERE
A.ZJHM <> B.ZJHM
AND A.WBDM = B.WBDM
AND (B.SWKSSJ)::int8 > (A.swkssj_start)::int8
AND (B.SWKSSJ)::int8 < (A.swkssj_end)::int8
order by
B.SWKSSJ,
B.ZJHM
limit 10 offset 0
;
```

The query takes about 7s. [Figure 6-5](#) shows the execution plan.

Figure 6-5 Using an unlogged table (2)

```

QUERY PLAN

Limit (cost=13546726.90..13546726.92 rows=10 width=190)
-> Sort (cost=13546726.90..13546727.50 rows=240 width=190)
 Sort Key: b.swksaj, b.zjhm
 -> Streaming (type: GATHER) (cost=13546721.11..13546721.71 rows=240 width=190)
 Node/s: All datanodes
 -> Limit (cost=564446.71..564446.74 rows=10 width=190)
 -> Sort (cost=564446.71..564453.53 rows=2726 width=190)
 Sort Key: b.swksaj, b.zjhm
 -> Hash Join (cost=533030.40..564387.81 rows=2726 width=190)
 Hash Cond: ((a.wbdm)::text = (b.wbdm)::text)
 Join Filter: (((a.zjhm)::text <> (b.zjhm)::text) AND ((b.swksaj)::bigint > (a.swksaj_start)::bigint) AND ((b.swksaj)::bigint < (a.swksaj_end)::bigint))
 -> Streaming (type: BROADCAST) (cost=0.00..120.00 rows=240 width=256)
 Spawn on: All datanodes
 -> Seq Scan on temp_tsw a (cost=0.00..10.10 rows=10 width=256)
 -> Hash (cost=465892.40..465892.40 rows=5371040 width=77)
 -> Partition Iterator (cost=0.00..465892.40 rows=5371040 width=77)
 Iterations: 25
 -> Partitioned Seq Scan on b_zyk_wbswxx b (cost=0.00..465892.40 rows=5371040 width=77)
 Selected Partitions: 1..25

```

3. In the previous plan, a hash join has been executed, and a Hash table has been created for the large table `b_zyk_wbswxx` (Internet access information in the Internet cafe). The table contains large amounts of data, so the creation takes long time.

`temp_tsw` (Internet access user information) contains only hundreds of records, and an equal-value connection is created between `temp_tsw` and `b_zyk_wbswxx` (Internet access information in the Internet cafe) using `wbdm` (an Internet cafe code). Therefore, if `JOIN` is changed to `NEST LOOP JOIN`, index scan can be used for node scanning, and the performance will be boosted.

4. Execute the following statement to change `JOIN` to `NEST LOOP JOIN`.  
SET enable\_hashjoin = off;

Figure 6-6 shows the execution plan. The query takes about 3s.

Figure 6-6 Using an unlogged table (3)

```

QUERY PLAN

Limit (cost=240002336196.14..240002336196.17 rows=10 width=190)
-> Sort (cost=240002336196.14..240002336196.74 rows=240 width=190)
 Sort Key: b.swksaj, b.zjhm
 -> Streaming (type: GATHER) (cost=240002336190.35..240002336190.95 rows=240 width=190)
 Node/s: All datanodes
 -> Limit (cost=10000097341.26..10000097341.29 rows=10 width=190)
 -> Sort (cost=10000097341.26..10000097348.08 rows=2726 width=190)
 Sort Key: b.swksaj, b.zjhm
 -> Nested Loop (cost=10000000000.00..10000097282.36 rows=2726 width=190)
 -> Streaming (type: BROADCAST) (cost=0.00..120.00 rows=240 width=256)
 Spawn on: All datanodes
 -> Seq Scan on temp_tsw a (cost=0.00..10.10 rows=10 width=256)
 -> Partition Iterator (cost=0.00..9648.34 rows=273 width=77)
 Iterations: 25
 -> Partitioned Index Scan using idx_b_zyk_wbswxx_wbdm on b_zyk_wbswxx b (cost=0.00..9648.34 rows=273 width=77)
 Index Cond: ((wbdm)::text = (a.wbdm)::text)
 Filter: (((a.zjhm)::text <> (zjhm)::text) AND ((swksaj)::bigint > (a.swksaj_start)::bigint) AND ((swksaj)::bigint < (a.swksaj_end)::bigint))
 Selected Partitions: 1..25

```

5. Save the query result set in the unlogged table for paging display.

If paging display needs to be achieved on the upper-layer application page, change the `offset` value to determine the result set on the target page. In this way, the previous query statement will be executed every time after a page turning operation, which causes long response latency.

To resolve this problem, the unlogged table is recommended to save the result set.

```

// Create an unlogged table to save the result set.
CREATE UNLOGGED TABLE temp_result
(
WBM NVARCHAR2(70),
DZQH NVARCHAR2(6),
DZ NVARCHAR2(70),
IPDZ NVARCHAR2(39),

```

```
ZJHM NVARCHAR2(18),
XM NVARCHAR2(30),
SWKSSJ date,
XWSJ date,
SWZDH NVARCHAR2(32)
);

// Insert the result set to the unlogged table. The insertion takes about 3s.
INSERT INTO
temp_result
SELECT
A.WBM,
A.DZQH,
A.DZ,
A.IPDZ,
B.ZJHM,
B.XM,
to_date(B.SWKSSJ,'yyyymmddHH24MISS') as SWKSSJ,
to_date(B.XWSJ,'yyyymmddHH24MISS') as XWSJ,
B.SWZDH
FROM temp_tsw A,
b_zyk_wbswxx B
WHERE
A.ZJHM <> B.ZJHM
AND A.WBDM = B.WBDM
AND (B.SWKSSJ)::int8 > (A.swkssj_start)::int8
AND (B.SWKSSJ)::int8 < (A.swkssj_end)::int8
;

// Perform paging query on the result set. The paging query takes about 10 ms.
SELECT
*
FROM
temp_result
ORDER BY
SWKSSJ,
ZJHM
LIMIT 10 OFFSET 0;
```

---

**CAUTION**

Collecting more accurate statistics usually improves the query performance, but may also deteriorate the performance. If the performance deteriorates, you can:

- Restore to the default statistics.
  - Use hints to force the optimizer to use the optimal query plan. (For details, see [Hint-based Tuning](#).)
- 

## 6.6.5 Optimizing Operators

### Background

A query statement needs to go through multiple operator procedures to generate the final result. Sometimes, the overall query performance deteriorates due to long execution time of certain operators, which are regarded as bottleneck operators. In this case, you need to execute the **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** command to view the bottleneck operators, and then perform optimization.

For example, in the following execution process, the execution time of the Hashagg operator accounts for about 66% [(51016-13535)/56476 ≈ 66%] of the

total execution time. Therefore, the Hashagg operator is the bottleneck operator for this query. Optimize this operator first.

| id | operation                                               | A-time                   | A-rows    | E-rows    | Peak Memory          | E-memory | A-width  | E-width | E-costs          |
|----|---------------------------------------------------------|--------------------------|-----------|-----------|----------------------|----------|----------|---------|------------------|
| 1  | -> Row Adapter                                          | 56476.397                | 10000000  | 237060    | 192KB                |          |          |         | 20   2093222.75  |

| 3  | -> Vector Hash Aggregate                                | [55124.685, 55132.180]   | 10000000  | 237060    | [29349KB, 29441KB]   | 16MB     | [20, 20] |         | 20   20918405.50 |
| 4  | -> Vector Streaming (type: REDISTRIBUTE)                | [52519.781, 53709.779]   | 339364604 | 4856184   | [12192KB, 12192KB]   | 1MB      |          |         | 20   10461210.85 |
| 5  | -> Vector Hash Aggregate                                | [135675.625, 135675.625] | 339364604 | 4856184   | [732850KB, 746964KB] | 16MB     | [20, 20] |         | 20   10461210.85 |
| 6  | -> Vector Partition Iterator                            | [9035.202, 11565.884]    | 97000000  | 935838097 | [9KB, 9KB]           | 1MB      |          |         | 20   10195891.68 |
| 7  | -> Partitioned CStore Scan on xuji_e_mp_day_energy_mv_1 | [9015.645, 11535.346]    | 97000000  | 935838097 | [845KB, 845KB]       | 1MB      |          |         | 20   10195891.68 |

## Example

Example 1: Scan the base table. For queries requiring large volume of data filtering, such as point queries or queries that need range scanning, a full table scan using SeqScan will take a long time. To facilitate scanning, you can create indexes on the condition column and select IndexScan for index scanning.

```
gaussdb=# explain (analyze on,costs off) select * from t1 where c2=10004;
```

| id | operation                   | A-time          | A-rows | Peak Memory | A-width |
|----|-----------------------------|-----------------|--------|-------------|---------|
| 1  | -> Streaming (type: GATHER) | 20.040          | 5      | 85KB        |         |
| 2  | -> Seq Scan on t1           | [17.239,17.376] | 5      | [18KB,18KB] |         |

(2 rows)

Predicate Information (identified by plan id)

```
2 --Seq Scan on t1
 Filter: (c2 = 10004)
 Rows Removed by Filter: 90002
(3 rows)
```

```
gaussdb=# create index idx on t1(c2);
CREATE INDEX
```

```
gaussdb=# explain (analyze on,costs off) select * from t1 where c2=10004;
```

| id | operation                     | A-time        | A-rows | Peak Memory | A-width |
|----|-------------------------------|---------------|--------|-------------|---------|
| 1  | -> Streaming (type: GATHER)   | 3.206         | 5      | 85KB        |         |
| 2  | -> Index Scan using idx on t1 | [0.122,0.146] | 5      | [73KB,73KB] |         |

(2 rows)

Predicate Information (identified by plan id)

```
2 --Index Scan using idx on t1
 Index Cond: (c2 = 10004)
(2 rows)
```

In this example, the full table scan filters large amounts of data and returns 5 records. After an index has been created on the **c2** column, the scanning efficiency is significantly boosted and the duration of IndexScan is reduced from 20 ms to 3 ms.

Example 2: If NestLoop is used for joining tables with a large number of rows, the join may take a long time. In the following example, NestLoop takes 5s. If **enable\_mergejoin** is set to **off** to disable merge join and **enable\_nestloop** is set to **off** to disable NestLoop so that the optimizer selects hash join, the join duration is reduced to 86 ms.

```
gaussdb=# explain analyze select count(*) from t2,t1 where t1.c1=t2.c2;
```

| id | operation                   | A-time              | A-rows | E-rows | Peak Memory | A-width | E-width | E-costs     |
|----|-----------------------------|---------------------|--------|--------|-------------|---------|---------|-------------|
| 1  | -> Aggregate                | 5070.296            | 1      | 1      | 14KB        |         |         | 8   2148.49 |
| 2  | -> Streaming (type: GATHER) | 5070.219            | 2      | 2      | 81KB        |         |         | 8   2148.49 |
| 3  | -> Aggregate                | [4828.705,5062.289] | 2      | 2      | [11KB,11KB] |         |         | 8           |

```

| 2148.40
4 | -> Nested Loop (5,6) | [4828.565,5062.142] | 996 | 40 | [4KB,4KB] |
| 0 | 2148.34
5 | -> Seq Scan on t1 | [13.574,14.508] | 90007 | 20000 | [15KB,15KB] |
| 4 | 184.00
6 | -> Materialize | [1508.956,1579.488] | 22413670 | 20 | [35KB,36KB] |
| 4 | 14.37
7 | -> Streaming(type: REDISTRIBUTE) | [55.825,56.842] | 498 | 20 | [44KB,44KB] |
| 4 | 14.31
8 | -> Seq Scan on t2 | [0.105,0.132] | 498 | 20 | [13KB,13KB] | | 4

7 | -> Streaming(type: REDISTRIBUTE) | [55.601,55.771] | 498 | 20 | [44KB,44KB] | |
| 4 | 14.31
8 | -> Seq Scan on t2 | [0.118,0.143] | 498 | 20 | [13KB,13KB] | | 4 |
| 13.13
(8 rows)

Predicate Information (identified by plan id)

4 --Hash Join (5,6)
 Hash Cond: (t1.c1 = t2.c2)
(2 rows)

```

Example 3: Generally, query performance can be improved by selecting **HashAgg**. If **Sort** and **GroupAgg** are used for a large result set, you need to set **enable\_sort** to **off**. **HashAgg** consumes less time than **Sort** and **GroupAgg**.

```

gaussdb=# explain analyze select count(*) from t1 group by c2;
 id | operation | A-time | A-rows | E-rows | Peak Memory | E-memory | A-width | E-
width | E-costs
-----+-----+-----+-----+-----+-----+-----+-----
1 | -> GroupAggregate | 244.817 | 40000 | 5000 | 15KB | | 12 |
2131.52
2 | -> Sort | 156.344 | 40000 | 10000 | 5603KB | | 12 |
2131.52
3 | -> Streaming (type: GATHER) | 91.595 | 40000 | 10000 | 82KB | |
| 12 | 1442.14

```

```

4 | -> GroupAggregate | [90.317,96.852] | 40000 | 10000 | [12KB,12KB] | 16MB |
| 12 | 973.39
5 | -> Sort | [59.775,64.724] | 90007 | 20000 | [5MB,5MB] | 16MB |
[896220,903920] | 4 | 873.39
6 | -> Seq Scan on t1 | [18.092,21.033] | 90007 | 20000 | [12KB,12KB] | 1MB |
| 4 | 184.00
(6 rows)

```

After the parameters are set:

```

gaussdb=# set enable_sort=off;
SET
gaussdb=# explain analyze select count(*) from t1 group by c2;
id | operation | A-time | A-rows | E-rows | Peak Memory | E-memory | A-width | E-
width | E-costs
-----+-----+-----+-----+-----+-----+-----+-----+-----
1 | -> HashAggregate | 228.260 | 40000 | 5000 | 6663KB | | | 12 | 752.75
2 | -> Streaming (type: GATHER) | 95.506 | 40000 | 10000 | 82KB | | | 12 |
752.75
3 | -> HashAggregate | [63.974,71.290] | 40000 | 10000 | [3MB,3MB] | 16MB | [20,20] |
12 | 284.00
4 | -> Seq Scan on t1 | [17.578,21.204] | 90007 | 20000 | [12KB,12KB] | 1MB | | 4 |
184.00
(4 rows)

```

## 6.7 Experience in Rewriting SQL Statements

Based on the SQL execution mechanism and a large number of practices, SQL statements can be optimized by following certain rules to enable the database to execute SQL statements more quickly and obtain correct results. You can comply with these rules to improve service query efficiency.

- Replace **UNION** with **UNION ALL**.  
**UNION** eliminates duplicate rows while merging two result sets but **UNION ALL** merges the two result sets without deduplication. Therefore, replace **UNION** with **UNION ALL** if you are sure that the two result sets do not contain duplicate rows based on the service logic.
- Add **NOT NULL** to the join columns.  
If there are many NULL values in the **JOIN** columns, you can add the filter criterion **IS NOT NULL** to filter data in advance to improve the **JOIN** efficiency.
- Convert **NOT IN** to **NOT EXISTS**.  
**nestloop anti join** must be used to implement **NOT IN**, and **hash anti join** is required for **NOT EXISTS**. If no NULL value exists in the **JOIN** columns, **NOT IN** is equivalent to **NOT EXISTS**. Therefore, if you are sure that no NULL value exists, you can convert **NOT IN** to **NOT EXISTS** to generate **hash join** and to improve the query performance.

As shown in the following statement, the **t2.d2** column does not contain null values (it is set to **NOT NULL**) and **NOT EXISTS** is used for the query.

```
SELECT * FROM t1 WHERE NOT EXISTS (SELECT * FROM t2 WHERE t1.c1=t2.d2);
```

The generated execution plan is as follows:

**Figure 6-7 NOT EXISTS** execution plan

```

id | operation
-----+-----
 1 | -> Streaming (type: GATHER)
 2 | -> Hash Anti Join (3, 4)
 3 | -> Seq Scan on t1
 4 | -> Hash
 5 | -> Streaming (type: REDISTRIBUTE)
 6 | -> Seq Scan on t2
(6 rows)

Predicate Information (identified by plan id)
-----+-----
 2 --Hash Anti Join (3, 4)
 Hash Cond: (t1.c1 = t2.d2)
(2 rows)

```

- Use **hashagg**.  
If a plan involving groupAgg and SORT operations generated by the **GROUP BY** statement is poor in performance, you can set **work\_mem** to a larger value to generate a **hashagg** plan, which does not require sorting and improves the performance.
- Replace functions with **CASE** statements.  
The GaussDB performance greatly deteriorates if a large number of functions are called. In this case, you can modify the pushdown functions to **CASE** statements.
- Do not use functions or expressions for indexes.  
Using functions or expressions for indexes stops indexing. Instead, it enables scanning on the full table.
- Do not use the !=, <, or > operator, NULL, OR, or implicit parameter conversion in WHERE clauses.
- If the values of >= and <= are the same in WHERE condition, change the condition to = because range equivalence class derivation is not supported currently.  
For example, change **SELECT \* FROM t1 WHERE c1 >= 1 AND c1 <= 1** to **SELECT \* FROM t1 WHERE c1 = 1**.  
For range queries, the optimizer has a larger error when calculating selectivity than equivalent queries. Therefore, change range queries to equivalent queries as much as possible.
- Split complex SQL statements.  
You can split an SQL statement into several ones and save the execution result to a temporary table if the SQL statement is too complex to be tuned using the solutions above, including but not limited to the following scenarios:
  - The same subquery is involved in multiple SQL statements of a job and the subquery contains large amounts of data.
  - Incorrect plan cost causes a small hash bucket of subquery. For example, the actual number of rows is 10 million, but only 1000 rows are in hash bucket.
  - Functions such as **substr** and **to\_number** cause incorrect measures for subqueries containing large amounts of data.

- **BROADCAST** subqueries are performed on large tables in multi-DN environment.

## 6.8 Configuring Key Parameters for SQL Tuning

This section describes key CN configuration parameters that affect GaussDB SQL performance optimization. Contact the administrator to configure parameters.

**Table 6-2** CN parameters

| Parameter/<br>Reference Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enable_nestloop=on            | <p>Specifies how the optimizer uses Nest Loop Join. If this parameter is set to <b>on</b>, the optimizer preferentially uses Nest Loop Join. If it is set to <b>off</b>, the optimizer preferentially uses other methods, if any.</p> <p><b>NOTE</b><br/>If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement:<br/>SET enable_nestloop to off;</p> <p>You can determine whether to disable this function based on the actual requirements. Generally, among the three join modes (Nested Loop, Merge Join, and Hash Join), Nested Loop is applicable to scenarios with small data volume or indexes, and Hash Join is applicable to big data analysis scenarios.</p>                               |
| enable_bitmapscan=on          | <p>Specifies whether the optimizer uses bitmap scan. If the value is <b>on</b>, bitmap scan is used. If the value is <b>off</b>, it is not used.</p> <p><b>NOTE</b><br/>If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement:<br/>SET enable_bitmapscan to off;</p> <p>The bitmap scan applies only in the query condition <b>where a &gt; 1 and b &gt; 1</b> and indexes are created on columns <b>a</b> and <b>b</b>. However, the performance of bitmapscan is sometimes inferior to that of indexscan. During tuning, if the query performance is poor and bitmapscan operators are in the execution plan, set this parameter to <b>off</b> and check whether the performance is improved.</p> |

| Parameter/<br>Reference Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enable_fast_query_shipping=on | <p>Specifies whether the optimizer uses a distribution framework to execute quick execution plans. If the value is <b>on</b>, the execution plan is generated on both CNs and DN. If the value is <b>off</b>, the distribution framework is used, that is, the execution plan is generated on the CN and then sent to the DN for execution.</p> <p><b>NOTE</b><br/>If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement:<br/>SET enable_fast_query_shipping to off;</p> |
| enable_hashagg=on             | Specifies whether the optimizer uses hash aggregate plans.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| enable_hashjoin=on            | Specifies whether the optimizer uses hash join plans.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| enable_mergejoin=on           | Specifies whether the optimizer uses merge join plans.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| enable_indexscan=on           | Specifies whether the optimizer uses index scan plans.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| enable_indexonlyscan=on       | Specifies whether the optimizer uses index-only scan plans.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| enable_gsiscan=off            | Specifies whether the optimizer uses GSI scan plans.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| enable_seqscan=on             | Specifies whether the optimizer uses sequential scan plans. It is impossible to suppress sequential scans entirely, but setting this variable to <b>off</b> encourages the optimizer to choose other methods if available.                                                                                                                                                                                                                                                                                                                                                                       |
| enable_sort=on                | Specifies the optimizer sorting order. It is impossible to fully suppress explicit sorting, but setting this variable to <b>off</b> encourages the optimizer to choose other methods if available.                                                                                                                                                                                                                                                                                                                                                                                               |
| enable_broadcast=on           | Specifies whether the optimizer uses data broadcast. In data broadcast, a large amount of data is transferred on the network. When the number of transmission nodes (stream) is large and the estimation is inaccurate, set this parameter to <b>off</b> and check whether the performance is improved.                                                                                                                                                                                                                                                                                          |

| Parameter/<br>Reference Value | Description                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rewrite_rule                  | Specifies whether the optimizer enables the following: LAZYAGG, MAGICSET, PARTIALPUSH, DISABLEREP, UNIQUECHECK, INTARGETLIST, PREDPUSH, PREDPUSHFORCE, PREDPUSHNORMAL, DISABLE_PULLUP_EXPR_SUBLINK, SUBLINK_PULLUP_ENHANCED, DISABLE_PULLUP_NOT_IN_SUBLINK, DISABLE_ROWNUM_PUSHDOWN, and DISABLE_WINDOWAGG_PUSHDOWN rewriting rules                                                      |
| sql_beta_feature              | Specifies whether the optimizer enables the SEL_SEMI_POISSON, NO_UNIQUE_INDEX_FIRST, JOIN_SEL_WITH_CAST_FUNC, SEL_EXPR_INSTR, PARAM_PATH_GEN, RAND_COST_OPT, PARAM_PATH_OPT, PAGE_EST_OPT, CANONICAL_PATHKEY, INDEX_COST_WITH_INDEX_COST_WITH_LEAF_PAGES_ONLY, PREDPUSH_SAME_LEVEL, PARTITION_FDW_ON, DISABLE_BITMAP_COST_WITH_LOSSY_PAGES, or ENABLE_UPSERT_EXECUTE_GPLAN beta feature. |
| enable_inner_unique_opt       | Specifies whether the optimizer uses Inner Unique.                                                                                                                                                                                                                                                                                                                                       |

## 6.9 Hint-based Tuning

### 6.9.1 Plan Hint Optimization

In plan hints, you can specify a join order; join, stream, and scan operations, the number of rows in a result, and redistribution skew information to tune an execution plan, improving query performance.

GaussDB also provides the SQL patch function. You can create an SQL patch to make hints take effect without modifying service statements.

#### Description

Plan hints are specified in the following format after keywords such as SELECT, INSERT, UPDATE, DELETE, and MERGE:

```
/*+ <plan hint>*/
```

You can specify multiple hints for a query plan and separate them with spaces. A hint specified for a query plan does not apply to its subquery plans. To specify a hint for a subquery, add the hint following the **SELECT** of this subquery.

Example:

```
select /*+ <plan_hint1> <plan_hint2> */ * from t1, (select /*+ <plan_hint3> */ * from t2) where 1=1;
```

In the preceding command, *<plan\_hint1>* and *<plan\_hint2>* are the hints of a query, and *<plan\_hint3>* is the hint of its subquery.

You can use the EXPLAIN syntax to analyze the plan hint optimization effect. You can use EXPLAIN to view the plan of the target SQL statement after the plan hint is used and check whether the plan meets the requirements to verify the plan hint effect. EXPLAIN has multiple plan display modes, which are controlled by **explain\_perf\_mode**. In some examples in this section, **explain\_perf\_mode** is set to **pretty** to display complete plan information. In some examples, **explain\_perf\_mode** is set to **normal** to simplify the output information.

---

#### NOTICE

If a hint is specified in the **CREATE VIEW** statement, the hint will be applied each time this view is used.

If the random plan function is enabled (**plan\_mode\_seed** is set to a value other than 0), the specified hint will not be used.

---

## Scope

Currently, the following hints are supported:

- Join order hints (**leading**).
- Join operation hints, excluding the **semi join**, **anti join**, and **unique plan** hints.
- Rows hints.
- Stream operation hints.
- Scan operation hints, supporting only the **tablescan**, **indexscan**, **indexonlyscan**, and **gsi** hints.
- Sublink name hints.
- Skew hints, supporting only the skew in the redistribution involving Join or HashAgg.
- Hints of the GUC parameter that takes effect in a query. The hints do not take effect if they are used in views.
- Hints that use the custom plan or generic plan and are valid only for query statements executed by PBE.
- Hints specifying not to expand subqueries.
- Hints specifying that the current query statement does not enter the global plan cache. The hints are valid only when **enable\_global\_plancache** is enabled and the current statement is executed by PBE.
- Hints for internal table materialization.
- **Bitmapscan** hints
- Hints of the Agg method

## Precautions

- Hints do not support **Sort**, **Setop**, or **Subplan**.

- Hints do not support SMP or Node Groups.

## Example

Create tables and indexes.

```
create table t1(c1 int, c2 int, c3 int);
create table t2(c1 int, c2 int, c3 int);
create table t3(c1 int, c2 int, c3 int);
create index it1 on t1(c1,c2);
create index it2 on t2(c1,c2);
create index it3 on t1(c3,c2);
-- The following TPC-H data table needs to be inserted with 10 times of the data to match the provided
plan example.

## 6.9.2 Hint Specifying the Query Block Where the Hint Is Located

### Function

This function allows users to use `@queryblock` in hints to implement block-level hint control. Users can specify the query block to which the hint takes effect. For example, you can specify the hint of an inner query block in the outer query block.

### Syntax

Add `@queryblock` at the beginning of the hint parameter. `Hint_SEPC` is a specific hint.

```
Hint_SEPC([@queryblock])
```

### Parameter Description

`Hint_SEPC` is the hint name, and `@queryblock` can be left empty. If `@queryblock` is left empty, the hint takes effect in the current query block declared by the hint. If `@queryblock` is left empty and `Hint_SPEC` has no parameter, use `Hint_SPEC` instead of `Hint_SPEC()`. Parentheses are unnecessary. The following describes how to name a query block and how to make a hint take effect. Some hints do not take effect only at the outermost layer and cannot be specified using `@queryblock`. For details, see the syntax description of each hint.

- Query the name of a query block.
  - Each query block must have a name, so as to accurately specify a hint. There are two naming methods: user-specified and system-specified.
    - You can use the `blockname` hint to specify the block to be queried. For details, see [Sublink Name Hints](#).
    - If no alias is specified for a query block, the default block name is automatically generated based on the processing sequence. Generally, the default alias of each query block consists of the first three letters of the query block name, `$`, and the number of the query block. For example, the alias of the first `SELECT` query block is `sel$1`. In pretty mode, you can use the `explain` method with a specified block name to view the name of the query block where the processing operator of each table is located. In distributed scenarios, only stream plans can be displayed in pretty mode. You can set `enable_fast_query_shipping` to generate stream plans.

```
gaussdb=# set explain_perf_mode = pretty;
SET
gaussdb=# set enable_fast_query_shipping = off;
SET
gaussdb=# explain (blockname on,costs off) select * from t1, (select c1 from t2 group by c1)
sub1 where t1.c1 = sub1.c1;
 id | operation | Query Block
-----+-----+-----
 1 | -> Streaming (type: GATHER) | sel$1
 2 | -> Hash Join (3,4) | sel$1
 3 | -> Seq Scan on t1@"sel$1" | sel$1
 4 | -> Hash |
 5 | -> HashAggregate | sel$2
```

```
6 | -> Seq Scan on t2@"sel$2" | sel$2
(6 rows)
```

You can see that Seq Scan of **t2** is located in the **sel\$2** query block.

- **@queryblock** specifies the query block.

For the preceding example, if you want to modify the indexscan mode in **t2**, run the following command:

```
select /*+indexscan(@sel$2 t2) tablescan(t1)*/ * from t1, (select c1 from t2 group by c1) sub1 where
t1.c1 = sub1.c1;
```

Both indexscan and tablescan are scan hints. For details about scan hints, see [Scan Operation Hints](#). You can specify the hint of indexscan(**@sel\$2 t2**) in the **sel\$1** query block to move the hint to the **sel\$2** query block. The hint takes effect for **t2**. If the **sel\$2** query block is promoted **sel\$1** during subsequent rewriting, the hint is also promoted together to **sel\$1** and continues to take effect for **t2**.

```
gaussdb=# explain (blockname on,costs off) select /*+indexscan(@sel$2 t2) tablescan(t1)*/ * from t1,
(select c1 from t2 group by c1) sub1 where t1.c1 = sub1.c1;
id | operation | Query Block
-----+-----+-----
1 | -> Streaming (type: GATHER) | sel$1
2 | -> Hash Join (3,4) | sel$1
3 | -> Seq Scan on t1@"sel$1" | sel$1
4 | -> Hash |
5 | -> HashAggregate | sel$2
6 | -> Index Only Scan using it2 on t2@"sel$2" | sel$2
(6 rows)
```

**CAUTION**

Sometimes, query rewriting in the optimizer phase expands some query blocks. As a result, the plan does not display related query blocks in the explain method. The hint specifies a query block based on the name of the query block before the optimizer phase. If a query block to be queried may be expanded in the planning phase, you can add the `no_expand` hint (see [Hints Specifying Not to Expand Subqueries](#)) to prevent it from being expanded.

1. The `sel$2` query block is a simple query. The optimizer performs query rewriting during subsequent processing, and `t1` is promoted to `sel$1` for processing. Therefore, the operation in the `sel$2` query block is not displayed in the plan.

```
gaussdb=# explain (blockname on, costs off) select * from t2, (select c1 from t1 where t1.c3 = 2) sub1
where t2.c1 = sub1.c1;
id | operation | Query Block
-----+-----+-----
 1 | -> Streaming (type: GATHER) | sel$1
 2 | -> Nested Loop (3,4) | sel$1
 3 | -> Index Scan using it3 on t1@"sel$2" | sel$1
 4 | -> Index Scan using it2 on t2@"sel$1" | sel$1
(4 rows)
```

2. The `sel$2` query block is a simple query. During subsequent processing, the optimizer skips query rewriting because of the `no_expand` hint, and `t1` is still processed in the original query block.

```
gaussdb=# explain (blockname on, costs off) select /*+ no_expand*/ c1 from t1 where
t1.c3 = 2) sub1 where t2.c1 = sub1.c1;
id | operation | Query Block
-----+-----+-----
 1 | -> Streaming (type: GATHER) | sel$1
 2 | -> Nested Loop (3,4) | sel$1
 3 | -> Index Scan using it3 on t1@"sel$2" | sel$2
 4 | -> Index Scan using it2 on t2@"sel$1" | sel$1
(4 rows)
```

3. Because `t1` is processed in the `sel$2` query block after the `no_expand` hint is added, you can use `@sel$2` to specify the query block for the hint.

```
explain (blockname on, costs off) select /*+ tablescan(@sel$2 t1)*/ * from t2, (select c1 from t1 where
t1.c3 = 2) sub1 where t2.c1 = sub1.c1;
id | operation | Query Block
-----+-----+-----
 1 | -> Streaming (type: GATHER) | sel$1
 2 | -> Nested Loop (3,4) | sel$1
 3 | -> Seq Scan on t1@"sel$2" | sel$1
 4 | -> Index Scan using it2 on t2@"sel$1" | sel$1
(4 rows)
```

4. The query block number in the view depends on the sequence of the statement using the view. Therefore, do not use hints to specify query blocks when creating a view. The behavior is uncontrollable.

```
gaussdb=# create view v1 as select /*+ no_expand */ c1 from t1 where c1 in (select /*+ no_expand */ c1
from t2 where t2.c3=4);
CREATE VIEW
gaussdb=# explain (blockname on, costs off) select * from v1;
id | operation | Query Block
-----+-----+-----
 1 | -> Streaming (type: GATHER) | sel$1
 2 | -> Seq Scan on t1@"sel$2" | sel$2
 3 | -> Materialize [2, SubPlan 1] |
 4 | -> Streaming(type: BROADCAST) |
 5 | -> Seq Scan on t2@"sel$3" | sel$3
(5 rows)

Predicate Information (identified by plan id)
```

```

2 --Seq Scan on t1@"sel$2"
 Filter: (hashed SubPlan 1)
5 --Seq Scan on t2@"sel$3"
 Filter: (c3 = 4)
(4 rows)
```

In this case, the statements in **v1** belong to **sel\$2** and **sel\$3**.

5. Some hints take effect only at the outermost layer and cannot be specified using **@queryblock**. For details, see the syntax description of each hint.

## 6.9.3 Hint Specifying the Query Block and Schema of a Table

### Function

In a query, the table name can be duplicate in different query blocks and different schemas. Therefore, when specifying a table in a query, you can use a hint to specify the query block and schema where the table is located to avoid ambiguity. This function is applicable to all hints whose table names need to be specified.

### Syntax

When specifying a table using a hint, specify a schema using a period (*schema*) and a query block using the at sign (*@queryblock*). Both the schema and query block can be left empty.

```
[schema.]relname[@queryblock]
```

### Parameters

- **relname** indicates the name of the table in the query. If the table has an alias, use the alias first. In this case, **relname** is set to the alias. If the table name contains special characters, such as at sign (@) and period (.), **relname** must be enclosed in double quotation marks (") to avoid conflict with the declaration of the query block and schema names. For example, if the table name is **relnametest@1**, enter "**relnametest@1**".
- **schema** indicates the schema where the table is located. It can be left empty. If no schema is specified, the hint searches all schemas for **relname**.
- **queryblock** indicates the query block where the table is located. It can be left empty. If no query block is specified, the hint searches all query blocks for **relname**.

### Example

1. **t1** of **sel\$2** is promoted to **sel\$1** for processing, and **t1** is unclear.  

```
gaussdb=# explain(blockname on,costs off) select /*+ tablescan(t1)*/ * from t1, (select c2 from t1
where c1=1) tt1 where t1.c1 = tt1.c2;
WARNING: Error hint: TableScan(t1), relation name "t1" is ambiguous.
...
```
2. **t1@sel\$2** is specified to perform tablescan on **t1** of **sel\$2** (Filter: (c1 = 1)).  

```
gaussdb=# explain(blockname on,costs off) select /*+ tablescan(t1@sel$2)*/ * from t1, (select c2 from
t1 where c1=1) tt1 where t1.c1 = tt1.c2;
id | operation | Query Block
-----+-----+-----
1 | -> Streaming (type: GATHER) | sel$1
2 | -> Nested Loop (3,5) | sel$1
```

```
3 | -> Streaming(type: REDISTRIBUTE) | sel$1
4 | -> Seq Scan on t1@"sel$2" | sel$1
5 | -> Index Scan using it1 on t1@"sel$1" | sel$1
(5 rows)

Predicate Information (identified by plan id)

4 --Seq Scan on t1@"sel$2"
 Filter: (c1 = 1)
5 --Index Scan using it1 on t1@"sel$1"
 Index Cond: (c1 = public.t1.c2)
(4 rows)
```

## 6.9.4 Join Order Hints

### Function

Specifies the join order and outer/inner tables.

### Syntax

- Specify only the join order.

```
leading([@queryblock] join_table_list)
```

- Specify the join order and outer/inner tables. The outer/inner tables are specified by the outermost parentheses.

```
leading([@queryblock] (join_table_list))
```

### Parameters

*join\_table\_list* specifies the tables to be joined. The values can be table names or table aliases. If a subquery is pulled up, the value can also be the subquery alias. Separate the values with spaces. You can add parentheses to specify the join priorities of tables.

For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.

---

#### NOTICE

A table name or alias can only be a string without a schema name.

An alias (if any) is used to represent a table.

---

To prevent semantic errors, tables in the list must meet the following requirements:

- The tables must exist in the query or its subquery to be pulled up.
- The table names must be unique in the query or subquery to be pulled up. If they are not, their aliases must be unique.
- A table appears only once in the list.
- An alias (if any) is used to represent a table.

For example:

**leading(t1 t2 t3 t4 t5):** t1, t2, t3, t4, and t5 are joined. The join sequence and outer/inner tables are not specified.

**leading((t1 t2 t3 t4 t5)):** t1, t2, t3, t4, and t5 are joined in sequence. The table on the right is used as the inner table in each join.

**leading(t1 (t2 t3 t4) t5):** First, t2, t3, and t4 are joined and the outer/inner tables are not specified. Then, the result is joined with t1 and t5, and the outer/inner tables are not specified.

**leading((t1 (t2 t3 t4) t5)):** First, t2, t3, and t4 are joined and the outer/inner tables are not specified. Then, the result is joined with t1, and (t2 t3 t4) is used as the inner table. Finally, the result is joined with t5, and t5 is used as the inner table.

**leading((t1 (t2 t3) t4 t5)) leading((t3 t2)):** First, t2 and t3 are joined and t2 is used as the inner table. Then, the result is joined with t1, and (t2 t3) is used as the inner table. Finally, the result is joined with t4 and then t5, and the table on the right in each join is used as the inner table.

## Example

Hint the query plan in [Example](#) as follows:

```
explain
select /*+ leading((((store_sales store) promotion) item) customer) ad2) store_returns) leading((store
store_sales)*/ i_product_name product_name ...
```

First, **store\_sales** and **store** are joined and **store\_sales** is the inner table. Then, the result is joined with **promotion**, **item**, **customer**, **ad2**, and **store\_returns** in sequence. The optimized plan is as follows:

```
WARNING: Duplicated or conflict hint: Leading(store_sales store), will be discarded.
```

| id | operation                                                         | E-rows | E-width | E-costs |
|----|-------------------------------------------------------------------|--------|---------|---------|
| 1  | -> Streaming (type: GATHER)                                       | 2      | 880     | 78.79   |
| 2  | -> HashAggregate                                                  | 2      | 880     | 78.15   |
| 3  | -> Nested Loop (4,24)                                             | 2      | 776     | 78.11   |
| 4  | -> Streaming (type: REDISTRIBUTE)                                 | 2      | 784     | 71.39   |
| 5  | -> Nested Loop (6,23)                                             | 2      | 784     | 70.75   |
| 6  | -> Streaming (type: REDISTRIBUTE)                                 | 2      | 424     | 64.04   |
| 7  | -> Nested Loop (8,22)                                             | 2      | 424     | 63.67   |
| 8  | -> Streaming (type: REDISTRIBUTE)                                 | 2      | 424     | 56.96   |
| 9  | -> Nested Loop (10,12)                                            | 2      | 424     | 56.59   |
| 10 | -> Streaming (type: BROADCAST)                                    | 2      | 208     | 13.67   |
| 11 | -> Seq Scan on item                                               | 1      | 208     | 13.36   |
| 12 | -> Materialize                                                    | 20     | 216     | 42.81   |
| 13 | -> Hash Join (14,20)                                              | 20     | 216     | 42.79   |
| 14 | -> Streaming (type: REDISTRIBUTE)                                 | 20     | 220     | 29.35   |
| 15 | -> Hash Join (16,17)                                              | 20     | 220     | 27.73   |
| 16 | -> Seq Scan on store                                              | 20     | 166     | 13.13   |
| 17 | -> Hash                                                           | 21     | 62      | 14.31   |
| 18 | -> Streaming (type: REDISTRIBUTE)                                 | 20     | 62      | 14.31   |
| 19 | -> Seq Scan on store_sales                                        | 20     | 62      | 13.13   |
| 20 | -> Hash                                                           | 21     | 4       | 13.13   |
| 21 | -> Seq Scan on promotion                                          | 20     | 4       | 13.13   |
| 22 | -> Index Scan using customer_pkey on customer                     | 1      | 8       | 3.35    |
| 23 | -> Index Scan using customer_address_pkey on customer_address ad2 | 1      | 368     | 3.35    |
| 24 | -> Index Only Scan using store_returns_pkey on store_returns      | 1      | 8       | 3.35    |

(24 rows)

For details about the warning at the top of the plan, see [Hint Errors, Conflicts, and Other Warnings](#).

## 6.9.5 Join Operation Hints

### Function

These hints specify the join method, which can be nested loop join, hash join, or merge join.

### Syntax

```
[no] nestloop|hashjoin|mergejoin([@queryblock] table_list)
```

### Parameter Description

- For details about `@queryblock`, see [Hint Specifying the Query Block Where the Hint Is Located](#). `@queryblock` can be omitted, indicating that the hint takes effect in the current query block.
- `no` indicates that the specified hint will not be used for a join.
- `table_list` specifies the tables to be joined. The values are the same as those of [join\\_table\\_list](#) but contain no parentheses.

For example:

**no nestloop(t1 t2 t3):** `nestloop` is not used for joining `t1`, `t2`, and `t3`. The three tables may be joined in either of the two ways: Join `t2` and `t3`, and then `t1`; join `t1` and `t2`, and then `t3`. This hint takes effect only for the last join. If necessary, you can hint other joins. For example, you can add `no nestloop(t2 t3)` to join `t2` and `t3` first and to forbid the use of `nestloop`.

### Example

Hint the query plan in [Example](#) as follows:

```
explain
select /*+ nestloop(store_sales store_returns item) */ i_product_name product_name ...
```

`nestloop` is used for the last join between `store_sales`, `store_returns`, and `item`. The optimized plan is as follows:

| id | operation                                                         | E-rows | E-width | E-costs |
|----|-------------------------------------------------------------------|--------|---------|---------|
| 1  | -> HashAggregate                                                  | 1      | 880     | 53.76   |
| 2  | -> Streaming (type: GATHER)                                       | 2      | 880     | 53.76   |
| 3  | -> HashAggregate                                                  | 2      | 880     | 53.11   |
| 4  | -> Nested Loop (5,20)                                             | 2      | 776     | 53.07   |
| 5  | -> Streaming(type: REDISTRIBUTE)                                  | 2      | 416     | 46.36   |
| 6  | -> Nested Loop (7,19)                                             | 2      | 416     | 45.99   |
| 7  | -> Streaming(type: REDISTRIBUTE)                                  | 2      | 258     | 39.27   |
| 8  | -> Nested Loop (9,18)                                             | 2      | 258     | 38.99   |
| 9  | -> Streaming(type: REDISTRIBUTE)                                  | 2      | 262     | 32.28   |
| 10 | -> Nested Loop (11,17)                                            | 2      | 262     | 32.00   |
| 11 | -> Streaming(type: REDISTRIBUTE)                                  | 2      | 262     | 25.28   |
| 12 | -> Nested Loop (13,16)                                            | 2      | 262     | 25.00   |
| 13 | -> Nested Loop (14,15)                                            | 2      | 270     | 21.64   |
| 14 | -> Seq Scan on item                                               | 1      | 208     | 13.36   |
| 15 | -> Index Scan using store_sales_pkey on store_sales               | 1      | 62      | 8.27    |
| 16 | -> Index Only Scan using store_returns_pkey on store_returns      | 1      | 8       | 3.35    |
| 17 | -> Index Scan using customer_pkey on customer                     | 1      | 8       | 3.35    |
| 18 | -> Index Only Scan using promotion_pkey on promotion              | 1      | 4       | 3.35    |
| 19 | -> Index Scan using store_pkey on store                           | 1      | 166     | 3.35    |
| 20 | -> Index Scan using customer_address_pkey on customer_address ad2 | 1      | 368     | 3.35    |

(20 rows)

## 6.9.6 Rows Hints

### Function

These hints specify the number of rows in an intermediate result set. Both absolute values and relative values are supported.

### Syntax

```
rows([@queryblock] table_list #|+|-* const)
```

### Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **#**, **+**, **-**, and **\*** are operators used for hinting the estimation. **#** indicates that the original estimation is used without any calculation. **+**, **-**, and **\*** indicate that the original estimation is calculated using these operators. The minimum calculation result is 1. *table\_list* specifies the tables to be joined. The values are the same as those of **table\_list** in [Join Operation Hints](#).
- *const* can be any non-negative number and supports scientific notation.

For example:

**rows(t1 #5)**: The result set of **t1** is five rows.

**rows(t1 t2 t3 \*1000)**: The result set of joined **t1**, **t2**, and **t3** is multiplied by 1000.

### Suggestion

- The hint using **\*** for two tables is recommended. This hint will be triggered if the two tables appear on two sides of a join. For example, if the hint is **rows(t1 t2 \* 3)**, the join result of **(t1 t3 t4)** and **(t2 t5 t6)** will be multiplied by 3 because **t1** and **t2** appear on both sides of the join.
- **rows** hints can be specified for the result sets of a single table, multiple tables, function tables, and subquery scan tables.

### Example

Hint the query plan in [Example](#) as follows:

```
explain
select /*+ rows(store_sales store_returns *50) */ i_product_name product_name ...
```

Multiply the result set of joined **store\_sales** and **store\_returns** by 50. The optimized plan is as follows.

| id | operation                                                         | E-rows | E-width | E-costs |
|----|-------------------------------------------------------------------|--------|---------|---------|
| 1  | -> Streaming (type: GATHER)                                       | 4      | 880     | 58.44   |
| 2  | -> HashAggregate                                                  | 4      | 880     | 57.15   |
| 3  | -> Nested Loop (4,20)                                             | 5      | 776     | 57.07   |
| 4  | -> Streaming(type: REDISTRIBUTE)                                  | 2      | 784     | 50.34   |
| 5  | -> Nested Loop (6,19)                                             | 2      | 784     | 49.71   |
| 6  | -> Streaming(type: REDISTRIBUTE)                                  | 2      | 424     | 43.00   |
| 7  | -> Nested Loop (8,18)                                             | 2      | 424     | 42.63   |
| 8  | -> Streaming(type: REDISTRIBUTE)                                  | 2      | 266     | 35.91   |

| 15 | -> Index Scan using store_sales_pkey on store_sales               | 1      | 62      | 8.27    |
| 16 | -> Index Scan using customer_pkey on customer                     | 1      | 8       | 3.35    |
| 17 | -> Index Only Scan using promotion_pkey on promotion              | 1      | 4       | 3.35    |
| 18 | -> Index Scan using store_pkey on store                           | 1      | 166     | 3.35    |
| 19 | -> Index Scan using customer_address_pkey on customer_address ad2 | 1      | 368     | 3.35    |
| 20 | -> Index Only Scan using store_returns_pkey on store_returns      | 1      | 8       | 3.35    |

(20 rows)

The estimation value after the hint in row 11 is **360**, and the original value is rounded off to 7.

## 6.9.7 Stream Operation Hints

### Function

These hints specify a streaming operation, which can be **broadcast** or **redistribute**. You can also directly specify a method to generate a gather plan.

### Syntax

```
[no] broadcast|redistribute([@queryblock] table_list)
gather([@queryblock] REL|JOIN|ALL)
```

### Parameter Description

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **broadcast** and **redistribute**
  - **no** specifies that the specified hint will not be used for a stream operation.
  - *table\_list* specifies the table on which a stream operation is to be performed or the tables to be joined. For details, see [Parameter Description](#).
- **gather**

The gather hint can specify the following plan generation modes:

  - **REL**: Only the gather path based on the base table is generated, and then the remaining plan is executed on the CN.
  - **JOIN**: A join-based gather path is generated as much as possible and is added to the join subplan that can be pushed down (the join subplan does not contain the redistribution node), and the remaining plan is executed on the CN. For a join plan that requires node redistribution, such a join-based gather path cannot be generated. Instead, a base table-based gather path is generated.

**CAUTION**

After **Hint(JOIN)** is specified, the plan expected by **Hint(JOIN)** cannot be generated if the distribution table and replication table are joined, because the optimizer has found a better plan for replacement.

- **ALL:** The **Gather Rel** or **Gather Join** path is selected based on the optimal mode.

**Example**

Hint the query plan in **Example** as follows:

```
explain
select /*+ no redistribute(store_sales store_returns item store) leading(((store_sales store_returns item
store) customer)) */ i_product_name product_name ...
```

In the original plan, the join result of **store\_sales**, **store\_returns**, **item**, and **store** is redistributed before it is joined with **customer**. After the hinting, the redistribution is disabled and the join order is retained. The optimized plan is as follows:

| id | operation                                                         | E-rows | E-width | E-costs |
|----|-------------------------------------------------------------------|--------|---------|---------|
| 1  | -> HashAggregate                                                  | 1      | 880     | 62.28   |
| 2  | -> Streaming (type: GATHER)                                       | 2      | 880     | 62.28   |
| 3  | -> HashAggregate                                                  | 2      | 880     | 61.63   |
| 4  | -> Nested Loop (5,21)                                             | 2      | 776     | 61.59   |
| 5  | -> Streaming (type: REDISTRIBUTE)                                 | 2      | 416     | 54.88   |
| 6  | -> Nested Loop (7,20)                                             | 2      | 416     | 54.51   |

| 11 | -> Nested Loop (12,15)                                            | 2      | 262     | 25.00   |
| 12 | -> Nested Loop (13,14)                                            | 2      | 270     | 21.64   |
| 13 | -> Seq Scan on item                                               | 1      | 208     | 13.36   |
| 14 | -> Index Scan using store_sales_pkey on store_sales               | 1      | 62      | 8.27    |
| 15 | -> Index Only Scan using store_returns_pkey on store_returns      | 1      | 8       | 3.35    |
| 16 | -> Index Scan using store_pkey on store                           | 1      | 166     | 3.35    |
| 17 | -> Materialize                                                    | 40     | 8       | 15.23   |
| 18 | -> Streaming (type: BROADCAST)                                    | 40     | 8       | 15.18   |
| 19 | -> Seq Scan on customer                                           | 20     | 8       | 13.13   |
| 20 | -> Index Only Scan using promotion_pkey on promotion              | 1      | 4       | 3.35    |
| 21 | -> Index Scan using customer_address_pkey on customer_address ad2 | 1      | 368     | 3.35    |

(21 rows)

Specify the gather hint for a statement.

1. Generate the gather plan **/\* + GATHER(REL)\*/** based on the base table.

```
gaussdb=# explain select /*+ GATHER(REL)*/ from t1, t2, t3 where t1.c2 = t2.c2 and t2.c2 = t3.c2;
```

| id | operation                   | E-rows | E-width | E-costs |
|----|-----------------------------|--------|---------|---------|
| 1  | -> Hash Join (2,8)          | 20     | 36      | 44.10   |
| 2  | -> Hash Join (3,5)          | 20     | 24      | 29.22   |
| 3  | -> Streaming (type: GATHER) | 20     | 12      | 14.35   |
| 4  | -> Seq Scan on t1           | 20     | 12      | 13.13   |
| 5  | -> Hash                     | 20     | 12      | 14.35   |
| 6  | -> Streaming (type: GATHER) | 20     | 12      | 14.35   |
| 7  | -> Seq Scan on t2           | 20     | 12      | 13.13   |
| 8  | -> Hash                     | 20     | 12      | 14.35   |
| 9  | -> Streaming (type: GATHER) | 20     | 12      | 14.35   |
| 10 | -> Seq Scan on t3           | 20     | 12      | 13.13   |

(10 rows)

Predicate Information (identified by plan id)

|   |                            |
|---|----------------------------|
| 1 | --Hash Join (2,8)          |
|   | Hash Cond: (t1.c2 = t3.c2) |
| 2 | --Hash Join (3,5)          |
|   | Hash Cond: (t1.c2 = t2.c2) |

(4 rows)

2. Generate the join gather plan **/\*+ GATHER(REL)\*** that can be pushed down.

```
gaussdb=# explain select /*+ GATHER(JOIN)* */ from t1, t2, t3 where t1.c1 = t2.c1 and t2.c2 = t3.c2;
```

| id | operation                   | E-rows | E-width | E-costs |
|----|-----------------------------|--------|---------|---------|
| 1  | -> Hash Join (2,7)          | 20     | 36      | 42.37   |
| 2  | -> Streaming (type: GATHER) | 20     | 24      | 27.49   |
| 3  | -> Hash Join (4,5)          | 20     | 24      | 26.56   |

## 6.9.8 Scan Hints

### Description

These hints specify a scan operation, which can be **tablescan**, **indexscan**, **indexonlyscan** or **gsi**.

### Syntax

```
[no] tablescan|indexscan|indexonlyscan|gsi([@queryblock] table [index])
```

### Parameters

- **no** indicates that the specified hint will not be used for a join.

- For details about `@queryblock`, see [Hint Specifying the Query Block Where the Hint Is Located](#). `@queryblock` can be omitted, indicating that the hint takes effect in the current query block.
- `table` specifies the table to be scanned. You can specify only one table. Use a table alias (if any) instead of a table name.
- `index` indicates the index for `indexscan`, `indexonlyscan` or `gsi`. You can specify only one index.

 NOTE

- Index scan, index-only scan, and GSI hints can be used only when the hint index belongs to the hint table.
- Scan operation hints can be used for row-store tables and subquery tables.
- The index-only scan plan can be generated by the index scan hint, but the index-only hint can generate only the index-only plan.
- When index scan is compatible with index-only scan, some plan changes may occur. For example, `cost_model_version` is added for escape. This parameter can be used to determine whether index scan is compatible with index-only scan. Index scan is compatible with index-only scan when the parameter value is greater than 2 or equal to 0.
- If a GSI can be used for a query, using the GSI hint will generate an index-only scan query plan that uses the GSI, but not a query plan that uses a common index.
- If no queryblock, table, or index is specified for a GSI hint, the GSI hint takes effect across queryblocks.
- Valid GSIs can be directly queried on DNs.
- In the current version, GSIs cannot be used for table access by index row ID.

## Example

To specify an index-based hint for a scan, create an index named `i` on the `i_item_sk` column of the `item` table.

```
create index i on item(i_item_sk);
```

Hint the query plan in [Example](#) as follows:

```
explain
select /*+ indexscan(item i) */ i_product_name product_name ...
```

`item` is scanned based on an index. The optimized plan is as follows.

```
WARNING: Error hint: IndexScan(item i), index "i" doesn't exist.
```

| id | operation                                                         | E-rows | E-width | E-costs |
|----|-------------------------------------------------------------------|--------|---------|---------|

## 6.9.9 Sublink Name Hints

### Function

These hints specify the name of a sublink block.

### Syntax

```
blockname ([@queryblock] table)
```

### Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** specifies the name you have specified for a sublink block.

#### NOTE

- The **blockname** hint is used by an outer query only when the corresponding sublink is not pulled up. Currently, only the **Agg** equivalent join, **IN**, and **EXISTS** sublinks can be pulled up. This hint is usually used together with the hints described in the previous sections.
- The subquery after the **FROM** keyword is hinted by using the subquery alias. In this case, **blockname** becomes invalid.
- If a sublink contains multiple tables, the tables will be joined with the outer-query tables in a random sequence after the sublink is pulled up. In this case, **blockname** also becomes invalid.

### Examples

```
explain select /*+nestloop(store_sales tt) */ * from store_sales where ss_item_sk in (select /*+blockname(tt)*/ i_item_sk from item group by 1);
```

**tt** indicates the sublink block name. After being pulled up, the sublink is joined with the outer-query table **store\_sales** by using **nestloop**. The optimized plan is as follows:

```
gaussdb=# explain select /*+nestloop(store_sales tt) */ * from store_sales wh
id | operation | E-rows | E-width | E-costs
---+-----+-----+-----+-----
 1 | -> Streaming (type: GATHER) | 20 | 212 | 30.02
 2 | -> Nested Loop Semi Join (3, 4) | 20 | 212 | 28.47
 3 | -> Seq Scan on store_sales | 20 | 212 | 13.13
 4 | -> Materialize | 20 | 4 | 13.41
 5 | -> HashAggregate | 20 | 4 | 13.26
 6 | -> Seq Scan on item | 20 | 4 | 13.13
(6 rows)
```

**CAUTION**

When the blockname hint is specified using **@queryblock** instead of taking effect in the current query block, for example, **blockname(@sel\$2 new\_qb\_name)**, other hints cannot be specified using **@new\_qb\_name**. In this case, **new\_qb\_name** is only used as the name of the sublink and can be specified using hints.

- The following specifies block **bn2** using **blockname(@sel\$2 bn2)**. As a result, **TableScan(@bn2 t2)** cannot find the queryblock by using **@bn2**. The query block should be specified by using **@sel\$2**. The following specifies block **bn3** using the **blockname(bn3)** hint. The hint takes effect in the current query block and changes the name of the query block. Therefore, **tablescan(@bn3 t3@bn3)** can find the query block specified by using **@bn3**.

```
gaussdb=# explain select /*+ blockname(@sel$2 bn2) tablescan(@bn2 t2) tablescan(@sel$2 t2@bn2)
indexscan(@sel$2 t2@sel$2) tablescan(@bn3 t3@bn3)*/ c2 from t1 where c1 in (select /*+ */t2.c1
from t2 where t2.c2 = 1 group by 1) and c3 in (select /*+ blockname(bn3)*/t3.c3 from t3 where t3.c2
= 1 group by 1);
```

```
WARNING: hint: TableScan(@bn2 t2) does not match any query block
```

```
WARNING: Error hint: TableScan(@"sel$2" t2@bn2), relation name "t2@bn2" is not found.
```

- The following specifies the sublink block **bn2** by using **blockname(@sel\$2 bn2)**. When the sublink is promoted, **hashjoin(t1 bn2)** can be used to specify the operation of the promoted sublink.

```
gaussdb=# explain select /*+ blockname(@sel$2 bn2) hashjoin(t1 bn2) nestloop(t1 bn3) nestloop(t1
sel$3)*/ c2 from t1 where c1 in (select /*+ */t2.c1 from t2 where t2.c2 = 1 group by 1) and c3 in
(select /*+ blockname(bn3)*/t3.c3 from t3 where t3.c2 = 1 group by 1);
```

```
WARNING: Duplicated or conflict hint: NestLoop(t1 "sel$3"), will be discarded.
```

## 6.9.10 Skew Hints

### Description

Specifies redistribution keys containing skew data and skew values, and are used to optimize redistribution involving Join or HashAgg.

### Syntax

- Specify single-table skew.  
skew( [@queryblock] table (column) [(value)])
- Specify intermediate result skew.  
skew( [@queryblock] (join\_rel) (column) [(value)])

### Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** specifies the table where skew occurs.
- **join\_rel** specifies two or more joined tables. For example, **(t1 t2)** indicates that the result of joining **t1** and **t2** tables contains skew data.
- **column** specifies one or more columns where skew occurs.
- **value** specifies one or more skew values.

 NOTE

- Skew hints are used only if redistribution is required and the specified skew information matches the redistribution information.
- Skew hints are controlled by the GUC parameter **skew\_option**. If the parameter is disabled, skew hints cannot be used for solving skew.
- Currently, skew hints support only the table relationships of the ordinary table and subquery types. Hints can be specified for base tables, subqueries, and **WITH ... AS** clauses. Unlike other hints, a subquery can be used in skew hints regardless of whether it is pulled up.
- Use an alias (if any) to specify a table where data skew occurs.
- You can use a name or an alias to specify a skew column as long as it is not ambiguous. The columns in skew hints cannot be expressions. If data skew occurs in the redistribution that uses an expression as a redistribution key, set the redistribution key as a new column and specify the column in skew hints.
- The number of skew values must be an integer multiple of the number of columns. Skew values must be grouped based on the column sequence, with each group containing a maximum of 10 values. You can specify duplicate values to group skew columns having different number of skew values. For example, the **c1** and **c2** columns of the **t1** table contain skew data. The skew value of the **c1** column is **a1**, and the skew values of the **c2** column are **b1** and **b2**. In this case, the skew hint is **skew(t1 (c1 c2)((a1 b1)(a1 b2)))**. **(a1 b1)** is a value group, where **NULL** is allowed as a skew value. Each hint can contain a maximum of 10 groups and the number of groups should be an integer multiple of the number of columns.
- In the redistribution optimization of Join, a skew value must be specified for skew hints. The skew value can be left empty for HashAgg.
- If multiple tables, columns, or values are specified, separate items of the same type with spaces.
- The type of skew values cannot be forcibly converted in hints. To specify a string, enclose it with single quotation marks (' ').

Example:

- Specify single-table skew.

Each skew hint describes the skew information of one table relationship. To describe the skews of multiple table relationships in a query, specify multiple skew hints.

Skew hints have the following formats:

- One skew value in one column: **skew(t (c1) (v1))**  
Description: The **v1** value in the **c1** column of the **t** table relationship causes skew in query execution.
- Multiple skew values in one column: **skew(t (c1) (v1 v2 v3 ...))**  
Description: Values including **v1**, **v2**, and **v3** in the **c1** column of the **t** table relationship cause skew in query execution.
- Multiple columns, each having one skew value: **skew(t (c1 c2) (v1 v2))**  
Description: The **v1** value in the **c1** column and the **v2** value in the **c2** column of the **t** table relationship cause skew in query execution.
- Multiple columns, each having multiple skew values: **skew(t (c1 c2) ((v1 v2) (v3 v4) (v5 v6) ...))**  
Description: Values including **v1**, **v3**, and **v5** in the **c1** column and values including **v2**, **v4**, and **v6** in the **c2** column of the **t** table relationship cause skew in query execution.

#### NOTICE

In the last format, parentheses for skew value groups can be omitted, for example, **skew(t (c1 c2) (v1 v2 v3 v4 v5 v6 ...))**. In a skew hint, either use parentheses for all skew value groups or for none of them.

Otherwise, a syntax error will be generated. For example, **skew(t (c1 c2) (v1 v2 v3 v4 (v5 v6) ...))** will generate an error.

- Specify intermediate result skew.

If data skew does not occur in base tables but in an intermediate result during query execution, specify skew hints of the intermediate result to solve the skew. **skew((t1 t2) (c1) (v1))**

Description: Data skew occurs after the table relationships **t1** and **t2** are joined. The **c1** column of the **t1** table contains skew data and its skew value is **v1**.

**c1** can exist only in a table relationship of **join\_rel**. If there is another column having the same name, use aliases to avoid ambiguity.

### Suggestion

- For a multi-level query, write the hint on the layer where data skew occurs.
- For a listed subquery, you can specify the subquery name in a hint. If you know data skew occurs on which base table, directly specify the table.
- Aliases are preferred when you specify a table or column in a hint.

## 6.9.11 Parameterized Path Hint

### Function

Specifies the parameterized path and the conditional predicate pushdown method.

### Syntax

```
predpush([@queryblock] src1 src2)
predpush([@queryblock] src, dest)
```

### Parameter Description

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **src**, **src1**, and **src2** indicate the set of candidates tables pushed down by **predpush**.
- **dest** indicates the specified destination table pushed down by **predpush**.
- If **predpush** does not contain commas (,), all tables are candidates table. If **predpush** contains commas (,), both candidates tables and destination tables are specified.

 NOTE

Use the **predpush** hint to move the filter expression as close to the data source as possible to optimize the query.

- Before using the **predpush** hint, ensure that the **rewrite\_rule** GUC parameter contains the **PREDPUSH|REDPUSHFORCE|PREDPUSHNORMAL** option.
- **subquery\_block** can also be a view or materialized view.

## Examples

Use the **predpush** hint to improve the statement execution efficiency. Example:

```
create table pt2(a int, b int);
create table pt3(a int, b int);
create table pt4(a int, b int);
create index t4_a_idx on pt4(a);
create index t3_a_idx on pt3(a, b);
create index t2_a_idx on pt2(a);
set rewrite_rule='predpushforce';
set enable_fast_query_shipping = off;
set explain_perf_mode=pretty;
gaussdb=# explain (costs off) SELECT /*+PREDPUSH(pt2 st3) */ *
FROM pt2,
 (SELECT /*+ indexscan(pt3) indexscan(pt4) */sum(pt3.b), pt3.a FROM pt3, pt4 where pt3.a = pt4.a
GROUP BY pt3.a) st3
WHERE st3.a = pt2.a;
id | operation
-----+-----
 1 | -> Streaming (type: GATHER)
 2 | -> Nested Loop (3,4)
 3 | -> Seq Scan on pt2
 4 | -> HashAggregate
 5 | -> Nested Loop (6,7)
 6 | -> Index Only Scan using t3_a_idx on pt3
 7 | -> Index Only Scan using t4_a_idx on pt4
(7 rows)
Predicate Information (identified by plan id)

 6 --Index Only Scan using t3_a_idx on pt3
 Index Cond: (a = pt2.a)
 7 --Index Only Scan using t4_a_idx on pt4
 Index Cond: (a = pt2.a)
(4 rows)
```

If the **predpush** hint is not used, pt3 and pt4 in the subquery are not processed outside the query block before being joined. As a result, the returned result set is large, causing performance waste.

However, as shown in the preceding plan, after the **predpush** hint is used, condition filtering is performed on pt3 and pt4 based on pt2 before they are joined. The result set returned after joining is small, which effectively improves the performance.

### 6.9.12 Hint Errors, Conflicts, and Other Warnings

Plan hints change an execution plan. You can run **EXPLAIN** to view the changes.

Hints containing errors are invalid and do not affect statement execution. The errors will be displayed in different ways based on statement types. Hint errors in an **EXPLAIN** statement are displayed as a warning on the interface. Hint errors in other statements will be recorded in debug1-level logs containing the **PLANHINT** keyword.

Hint error types are as follows:

- Syntax errors

An error will be reported if the syntax tree fails to be reduced. The No. of the row generating an error is displayed in the error details.

For example, the hint keyword is incorrect, no table or only one table is specified in the **leading** or **join** hint, or no tables are specified in other hints. The parsing of a hint is terminated immediately after a syntax error is detected. Only the hints that have been parsed successfully are valid.

Example:

```
leading((t1 t2)) nestloop(t1) rows(t1 t2 #10)
```

The syntax of **nestloop(t1)** is wrong and its parsing is terminated. Only **leading(t1 t2)** that has been successfully parsed before **nestloop(t1)** is valid.

- Semantic errors

- An error will be reported if the specified tables do not exist, multiple tables are found based on the hint setting, or a table is used more than once in the **leading** or **join** hint.
- An error will be reported if the index specified in a scan hint does not exist.
- If multiple tables with the same name exist after a subquery is pulled up and some of them need to be hinted, add aliases for them to avoid name duplication.

- Duplicated or conflicted hints

If hint duplication or conflicts occur, only the first hint takes effect. A message will be displayed to describe the situation.

- Hint duplication indicates that a hint is used more than once in the same query, for example, **nestloop(t1 t2) nestloop(t1 t2)**.
- A hint conflict indicates that the functions of two hints with the same table list conflict with each other.

For example, if **nestloop (t1 t2) hashjoin (t1 t2)** is used, **hashjoin (t1 t2)** becomes invalid. **nestloop(t1 t2)** does not conflict with **no mergejoin(t1 t2)**.

---

#### NOTICE

The table list in the **leading** hint is disassembled. For example, **leading ((t1 t2 t3))** will be disassembled as **leading((t1 t2)) leading(((t1 t2) t3))**, which will conflict with **leading((t2 t1))** (if any). In this case, the latter **leading(t2 t1)** becomes invalid. If two hints use duplicated table lists and only one of them has the specified outer/inner table, the one without a specified outer/inner table becomes invalid.

- A hint becomes invalid after a sublink is pulled up.

In this case, a message will be displayed. Generally, such invalidation occurs when a sublink contains multiple tables to be joined. After the sublink is pulled up, the tables will not be join members.

- Unsupported column types

- Skew hints are specified to optimize redistribution. They will be invalid if their corresponding columns do not support redistribution.
- Hints are not used.
  - If a **hashjoin** or **mergejoin** hint is specified for non-equivalent joins, it will not be used.
  - If an **indexscan** or **indexonlyscan** hint is specified for a table that does not have an index, it will not be used.
  - The GSI hint is used for tables that do not contain GSIs.
  - If an IndexScan, IndexOnlyScan or GSI hint is specified for a full-table scan, it will not be used. Generally, index paths are generated only when filter conditions are used on index columns. Indexes are not used during a full table scan.
  - The specified IndexOnlyScan hint is used only when the output column contains only indexes.
  - The GSI hint is used only when queries can be pushed down to GSIs.
  - In equivalent joins, only the joins containing equivalence conditions are valid. Therefore, the **leading**, **join**, and **rows** hints specified for the joins without an equivalence condition will not be used. For example, **t1**, **t2**, and **t3** are to be joined, and the join between **t1** and **t3** does not contain an equivalence condition. In this case, **leading(t1 t3)** will not be used.
  - To generate a streaming plan, if the distribution key of a table is the same as its join key, **redistribute** specified for this table will not be used. If the distribution key and join key are different for this table but the same for the other table in the join, **redistribute** specified for this table will be used but **broadcast** will not.
  - If no sublink is pulled up, the specified **blockname** hint will not be used.
  - Skew hints are not used possibly because:
    - The plan does not require redistribution.
    - The columns specified by hints contain distribution keys.
    - Skew information specified in hints is incorrect or incomplete, for example, no value is specified for join optimization.
    - Skew optimization is disabled by GUC parameters.

## 6.9.13 GUC Parameter Hints

### Description

Sets GUC parameters related to query optimization. The settings take effect during the query execution. For details about the application scenarios of hints, see the description of each GUC parameter.

### Syntax

```
set([@queryblock] param value)
```

## Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block. This hint takes effect only when it specifies the outermost queryblock.
- **param** indicates the parameter name.
- **value** indicates the value of a parameter.
- Currently, the following parameters can be set and take effect by using hints:
  - Boolean type  
enable\_bitmapscan, enable\_hashagg, enable\_hashjoin, enable\_indexscan, enable\_indexonlyscan, enable\_gsiscan, enable\_material, enable\_mergejoin, enable\_nestloop, enable\_index\_nestloop, enable\_seqscan, enable\_sort, enable\_tidscan, enable\_stream\_operator, enable\_stream\_recursive, enable\_broadcast, enable\_fast\_query\_shipping, enable\_trigger\_shipping, enable\_remotejoin, enable\_remotegroup, enable\_remotelimit, enable\_remotesort, and enable\_inner\_unique\_opt
  - Integer type  
best\_agg\_plan and query\_dop
  - Floating point type  
cost\_weight\_index, default\_limit\_rows, seq\_page\_cost, random\_page\_cost, cpu\_tuple\_cost, cpu\_index\_tuple\_cost, cpu\_operator\_cost, and effective\_cache\_size
  - Character string type  
node\_name  
By setting **node\_name**, you can deliver the current SQL statement to the DN corresponding to **node\_name** for execution.

Example:

```
select /*+ set(node_name datanode1) */ from table_name;
```

In the preceding command, **datanode1** indicates the name of the DN queried from the **pgxc\_node** system catalog (without quotation marks), and **table\_name** indicates the table name. This query is directly performed on **datanode1**.

#### NOTICE

- **node\_name** can be set only by using the SELECT statement. If it is set by using other statements, it does not take effect.
- **node\_name** can only be set to the name of a DN and cannot be set to the name of a CN.
- **node\_name** cannot be modified by using the SET statement and can only be used in plan hints.
- **node\_name** cannot be modified by using **gs\_guc**.
- **node\_name** supports only simple query statements and does not support complex query statements (such as UNION and UNION ALL), subqueries, and multi-table associations.
- This operation can be performed by common users.
- This operation cannot be performed together with row-level security. If they are performed together, an error will be reported.

#### NOTE

- If you set a parameter that is not in the whitelist and the parameter value is invalid or the hint syntax is incorrect, the query execution is not affected. Run **explain(verbose on)**. An error message is displayed, indicating that hint parsing fails.
- The GUC parameter hint takes effect only in the outermost query. That is, the GUC parameter hint in the subquery does not take effect.
- The GUC parameter hint in the view definition does not take effect.
- In the CREATE TABLE ... AS ... statement, the outermost GUC parameter hint takes effect.

## 6.9.14 Hints for Selecting the Custom Plan or Generic Plan

### Function

For query statements and DML statements executed in PBE mode, the optimizer generates a custom plan or generic plan based on factors such as rules, costs, and parameters. You can use the hint of **use\_cplan** or **use\_gplan** to specify the plan to execute.

### Syntax

- To select the custom plan, run the following statement:  
`use_cplan`
- To select the generic plan, run the following statement:  
`use_gplan`

#### NOTE

- For SQL statements that are executed in non-PBE mode, setting this hint does not affect the execution mode.
- This hint has a higher priority than cost-based selection and the **plan\_cache\_mode** parameter. That is, this hint does not take effect for statements for which **plan\_cache\_mode** cannot be forcibly set to specify an execution mode.

## Example

Forcibly use the custom plan.

```
set enable_fast_query_shipping = off;
create table t (a int, b int, c int);
prepare p as select /*+ use_cplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filtering condition is the actual value of the input parameter, that is, the plan is a custom plan.

```
QUERY PLAN

Streaming (type: GATHER) (cost=0.06..13.26 rows=1 width=12)
 Node/s: datanode1
 -> Seq Scan on t (cost=0.00..13.16 rows=1 width=12)
 Filter: (a = 1)
(4 rows)
```

Forcibly use the generic plan.

```
deallocate p;
prepare p as select /*+ use_gplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filtering condition is the input parameter to be added, that is, the plan is a generic plan.

```
QUERY PLAN

Streaming (type: GATHER) (cost=0.06..13.26 rows=1 width=12)
 Node/s: All datanodes
 -> Seq Scan on t (cost=0.00..13.16 rows=1 width=12)
 Filter: (a = $1)
(4 rows)
```

## 6.9.15 Hints Specifying Not to Expand Subqueries

### Function

When the database optimizes the query logic, some subqueries can be promoted to the upper layer to avoid nested execution. However, for some subqueries that have a low selection rate and can use indexes to filter access pages, nested execution does not cause too much performance deterioration, while after the promotion, the query search scope is expanded, which may cause performance deterioration. In this case, you can use the **no\_expand** hint for debugging. This hint is not recommended in most cases.

### Syntax

```
no_expand[(@queryblock)]
```

### Parameter Description

For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block. If it is not specified, **no\_expand** does not have parentheses ().

## Example

Normal query execution:

```
explain select * from t1 where t1.c1 in (select t2.c1 from t2);
```

Plan

```

QUERY PLAN

Streaming (type: GATHER) (cost=16.98..34.28 rows=40 width=12)
 Node/s: All datanodes
 -> Hash Semi Join (cost=16.36..32.72 rows=40 width=12)
 Hash Cond: (t1.c1 = t2.c1)
 -> Seq Scan on t1 (cost=0.00..16.16 rows=40 width=12)
 -> Hash (cost=16.16..16.16 rows=40 width=4)
 -> Seq Scan on t2 (cost=0.00..16.16 rows=40 width=4)
(7 rows)

```

After `no_expand` is added:

```
explain select * from t1 where t1.c1 in (select /*+ no_expand*/ t2.c1 from t2);
```

Plan

```

QUERY PLAN

Streaming (type: GATHER) (cost=17.38..34.33 rows=20 width=12)
 Node/s: All datanodes
 -> Seq Scan on t1 (cost=16.88..33.08 rows=20 width=12)
 Filter: (hashed SubPlan 1)
 SubPlan 1
 -> Materialize (cost=0.00..16.48 rows=640 width=4)
 -> Streaming(type: BROADCAST) (cost=0.00..16.29 rows=160 width=4)
 Spawn on: All datanodes
 -> Seq Scan on t2 (cost=0.00..16.16 rows=40 width=4)
(9 rows)

```

## 6.9.16 Hints Specifying Not to Use Global Plan Cache

### Function

When global plan cache is enabled, you can use the `no_gpc` hint to force a single query statement not to share the plan cache globally. Only the plan cache within the current session lifecycle is retained.

### Syntax

```
no_gpc
```

#### NOTE

This parameter takes effect only for statements executed by PBE when `enable_global_plancache` is set to `on`.

### Example

```

gaussdb=# deallocate all;
DEALLOCATE ALL
gaussdb=# prepare p1 as insert /*+ no_gpc */ into t1 select c1,c2 from t2 where c1=$1;
PREPARE
gaussdb=# execute p1(3);
INSERT 0 1
gaussdb=# select * from db_perf.global_plancache_status where schema_name='public' order by 1,2;
nodename | query | refcount | valid | databaseid | schema_name | params_num | func_id | pkg_id | stmt_id
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
(0 rows)

```

No result exists in the `dbe_perf.global_plancache_status` view, that is, no plan is cached globally.

## 6.9.17 Hint of Parameterized Paths at the Same Level

### Function

The `predpush_same_level` and `nestloop_index` hints are used to specify the generation of parameterized paths between tables or materialized views at the same level.

For details about cross-layer parameterized path hints, see [Parameterized Path Hint](#).

### Syntax

```
predpush_same_level([@queryblock] src, dest)
predpush_same_level([@queryblock] src1 src2 ..., dest)
[no] nestloop_index([@queryblock] dest[, index_list]) -- With indexes
[no] nestloop_index([@queryblock] dest[, (src1 src2 ...)]) -- With tables
```

#### NOTE

The `predpush_same_level` parameter takes effect only when the `predpushforce` option in `rewrite_rule` is enabled.

`nestloop_index` has no requirement on `rewrite_rule`.

### Parameter Description

- **no** indicates that the parameterized path of hints is not used.
- For details about `@queryblock`, see [Hint Specifying the Query Block Where the Hint Is Located](#). `@queryblock` can be omitted, indicating that the hint takes effect in the current query block.
- **dest** is the target table of the parameterized path, that is, the table where the indexes are located.
- **src** is the parameter table of the parameterized path.
- **index\_list** is the index sequence used by the parameterized path, which consists of character strings separated by spaces.

### Examples

To view the following plan example, you need to set the following parameters:

```
set enable_fast_query_shipping = off;
set enable_stream_operator = on;
```

1. Examples of `nestloop_index`:

- Transfer **t2.c1** and **t3.c2** of **t2** and **t3** to the **t1** table for index scanning (parameterized path).  
gaussdb=# explain (costs off) select /\*+nestloop\_index(t1,(t2 t3)) \*/ from t1,t2,t3 where t1.c1 = t2.c1 and t1.c2 = t3.c2;

QUERY PLAN

```

Streaming (type: GATHER)
 Node/s: All datanodes
 -> Nested Loop
 -> Streaming (type: BROADCAST)
```

```

Spawn on: All datanodes
-> Seq Scan on t3
-> Nested Loop
-> Seq Scan on t2
-> Index Scan using it1 on t1
 Index Cond: ((c1 = t2.c1) AND (c2 = t3.c2))
(10 rows)

```

- Perform an index scan on **it1** of the **t1** table (parameterized path).

```

gaussdb=# explain (costs off) select /*+NestLoop_Index(t1,it1) */ from t1,t2 where t1.c1 = t2.c1;
QUERY PLAN

```

```

Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
-> Seq Scan on t2
-> Index Scan using it1 on t1
 Index Cond: (c1 = t2.c1)
(6 rows)

```

## 2. Example of `predpush_same_level`:

- Prepare parameters.

```

gaussdb=# set rewrite_rule = 'predpushforce';
SET
gaussdb=# set enable_fast_query_shipping=off;
SET

```

- Run the following statement to view the plan:

```

gaussdb=# explain select * from t1, t2 where t1.c1 = t2.c1;
QUERY PLAN

```

```

Streaming (type: GATHER) (cost=16.98..34.22 rows=40 width=24)
Node/s: All datanodes
-> Hash Join (cost=16.36..32.66 rows=40 width=24)
 Hash Cond: (t1.c1 = t2.c1)
-> Seq Scan on t1 (cost=0.00..16.16 rows=40 width=12)
-> Hash (cost=16.16..16.16 rows=40 width=12)
 -> Seq Scan on t2 (cost=0.00..16.16 rows=40 width=12)
(7 rows)

```

- The filter condition **t1.c1 = t2.c2** is displayed on **Join**. In this case, **predpush\_same\_level(t1, t2)** can be used to push the condition down to the scan operator of **t2**.

```

gaussdb=# explain select /*+predpush_same_level(t1, t2)*/ * from t1, t2 where t1.c1 = t2.c1;
QUERY PLAN

```

```

Streaming (type: GATHER) (cost=0.62..70.20 rows=40 width=24)
Node/s: All datanodes
-> Nested Loop (cost=0.00..68.64 rows=40 width=24)
-> Seq Scan on t1 (cost=0.00..16.16 rows=40 width=12)
-> Index Scan using it2 on t2 (cost=0.00..3.27 rows=1 width=12)
 Index Cond: (c1 = t1.c1)
(6 rows)

```

#### NOTICE

- You can specify multiple **src** parameters in the same condition.
- If the specified **src** and **dest** conditions do not exist or do not meet the parameterized path requirements, this hint does not take effect.
- If a stream operator exists on the **dest** scanning operator, this hint does not take effect.

## 6.9.18 Hint for Setting Slow SQL Control Rules

### Function

Users can set the execution time, maximum execution time, and maximum IOPS for SQL statements marked as slow SQL statements.

### Syntax

```
wlmrule("time_limit,max_execute_time,max_iops")
```

#### NOTE

This parameter is valid only for SELECT statements executed by non-sysadmin or non-monitoradmin users when **enable\_thread\_pool** is set to **on**.

- **time\_limit**: execution time of an SQL statement marked as a slow statement. The value ranges from **0** to *INT\_MAX*. This parameter takes effect on both CNs and DN.
- **max\_execute\_time**: maximum execution time of an SQL statement. If the execution time exceeds the value of this parameter, the SQL statement is forcibly canceled and exits. The value ranges from **0** to *INT\_MAX*. This parameter takes effect only on DN. If the value of **max\_execute\_time** is less than or equal to the value of **time\_limit**, the rule does not take effect.
- **max\_iops**: maximum IOPS of an SQL statement marked as a slow SQL statement. This parameter is valid only when **use\_workload\_manager** is set to **on**. The IOPS limit applies logical I/O control. For details about the definition of IOPS, see the definition of **io\_control\_unit**. The value can be **Low**, **Medium**, **High**, **None**, or **0-INT\_MAX**. This parameter takes effect only on DN.

### Example

```
select /*+ wlmrule("100,500,1") */ * from t2 order by b limit 1;
```

It indicates that the execution time of the current statement marked as a slow SQL statement is 100 ms, the maximum execution time is 500 ms, and the maximum IOPS is 1.

## 6.9.19 Bitmap Scan Hints

### Function

These hints generate a bitmap scan path by using the specified index on the target table. The path that meets the hint requirement is selected from the paths that can be generated by the optimizer.

### Syntax

```
[no] bitmapscan([@queryblock] table [index_list])
```

## Parameter Description

- **no** indicates that the scan of hints is not used.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** indicates the target table of the bitmap scan.
- **index\_list** indicates the index used by the bitmap scan.

## Example

```
gaussdb=# explain(costs off) select /*+ BitmapScan(t1 it1 it3)*/ from t1 where (t1.c1 = 5 or t1.c2=6) or (t1.c3=3 or t1.c2=7);
```

```

QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Bitmap Heap Scan on t1
 Recheck Cond: ((c1 = 5) OR (c2 = 6) OR (c3 = 3) OR (c2 = 7))
 -> BitmapOr
 -> Bitmap Index Scan on it1
 Index Cond: (c1 = 5)
 -> Bitmap Index Scan on it3
 Index Cond: (c2 = 6)
 -> Bitmap Index Scan on it3
 Index Cond: (c3 = 3)
 -> Bitmap Index Scan on it3
 Index Cond: (c2 = 7)
(13 rows)

```

### NOTE

The path that meets the bitmap scan hint is selected from the existing index paths. Because the index path construction space is large and the optimizer prunes the paths, if any index path is not generated, the path cannot be constructed.

## 6.9.20 Hint for Inner Table Materialization During Join

### Function

These hints materialize inner tables when specifying the inner tables to be joined.

### Syntax

```
[no] materialize_inner([@queryblock] inner_table_list)
```

## Parameter Description

- **no** indicates that the materialization of hints is not used.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **inner\_table\_list**: a list of inner tables to be materialized during the join operation. The value is a character string separated by spaces.

## Example

Table **t1** is an inner table to be materialized, and the result of (t1 t2) is materialized as a joined inner table.

```
gaussdb=# explain (costs off) select /*+materialize_inner(t1) materialize_inner(t1 t2)*/ * from t1,t2,t3
where t1.c3 = t2.c3 and t2.c2=t3.c2 and t1.c2=5;
```

```
QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
 Join Filter: (t2.c2 = t3.c2)
 -> Seq Scan on t3
 -> Materialize
 -> Streaming(type: BROADCAST)
 Spawn on: All datanodes
 -> Nested Loop
 Join Filter: (t1.c3 = t2.c3)
 -> Seq Scan on t2
 -> Materialize
 -> Streaming(type: BROADCAST)
 Spawn on: All datanodes
 -> Index Scan using it3 on t1
 Index Cond: (c2 = 5)
(16 rows)
```

## 6.9.21 AGG Hint

### Function

You can specify the AGG method when performing the AGG algorithm.

### Syntax

```
use_hash_agg[(@queryblock)], use_sort_agg[(@queryblock)]
```

### Parameter Description

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block. If it is not specified, the hint does not have parentheses ().

## Example

- Use hash aggregation.

```
gaussdb=# explain (costs off) select c1 from t2 where c1 in(select /*+ use_hash_agg */ t1.c1 from
t1,t3 where t1.c1=t3.c1 group by 1);
```

```
QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Join
 Hash Cond: (t2.c1 = t1.c1)
 -> Seq Scan on t2
 -> Hash
 -> HashAggregate
 Group By Key: t1.c1
 -> Hash Join
 Hash Cond: (t1.c1 = t3.c1)
 -> Seq Scan on t1
 -> Hash
```

```

-> Seq Scan on t3
(13 rows)
2. Use use_sort_agg for aggregation and then perform merge join.
gaussdb=# explain (costs off) select c1 from t2 where c1 in(select /*+ use_sort_agg */ t1.c1 from t1,t3
where t1.c1=t3.c1 group by 1);
QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Join
Hash Cond: (t2.c1 = t1.c1)
-> Seq Scan on t2
-> Hash
-> Group
Group By Key: t1.c1
-> Sort
Sort Key: t1.c1
-> Hash Join
Hash Cond: (t1.c1 = t3.c1)
-> Seq Scan on t1
-> Hash
-> Seq Scan on t3
(15 rows)

```

## 6.10 Checking the Implicit Conversion Performance

In some scenarios, implicit data type conversion may cause performance problems. For example:

```

SET enable_fast_query_shipping = off;
CREATE TABLE t1(c1 VARCHAR, c2 VARCHAR);
CREATE INDEX on t1(c1);
EXPLAIN verbose SELECT * FROM t1 WHERE c1 = 10;

```

The execution plan of the preceding query is as follows.

```

QUERY PLAN

Streaming (type: GATHER) (cost=0.06..13.29 rows=1 width=64)
Output: c1, c2
Node/s: All datanodes
-> Seq Scan on public.t1 (cost=0.00..13.20 rows=1 width=64)
Output: c1, c2
Distribute Key: c1
Filter: ((t1.c1)::bigint = 10)
(7 rows)

```

The data type of **c1** is **varchar**. When the filter criterion is **c1 = 10**, the optimizer implicitly converts the data type of **c1** to **bigint** by default. As a result, the following two consequences occur:

- DN tailoring is not allowed. The plan is delivered to all DNs for execution.
- The Index Scan mode cannot be used to scan data in the plan.

These may cause performance problems.

After knowing the causes, you can rewrite the SQL statements. In the preceding scenario, you only need to convert the constant display in the filter criteria to the **varchar** type. The result is as follows:

```

EXPLAIN verbose SELECT * FROM t1 WHERE c1 = 10::varchar;

```

```

QUERY PLAN

Streaming (type: GATHER) (cost=0.06..8.36 rows=1 width=64)
 Output: c1, c2
 Node/s: datanode2
 -> Index Scan using t1_c1_idx on public.t1 (cost=0.00..8.27 rows=1 width=64)
 Output: c1, c2
 Distribute Key: c1
 Index Cond: ((t1.c1)::text = '10'::text)
(7 rows)
```

To identify the performance impact of implicit type conversion in advance, you can use the GUC parameter **check\_implicit\_conversions**. After this parameter is enabled, the system checks the index columns that are implicitly converted in the query in the path generation phase. If no candidate index scan path is generated for the index columns, an error message is displayed. For example:

```
SET check_implicit_conversions = on;
SELECT * FROM t1 WHERE c1 = 10;
ERROR: There is no optional index path for index column: "t1"."c1".
```

#### NOTE

- The **check\_implicit\_conversions** parameter is used only to check for potential performance problems caused by implicit type conversion. In the formal production environment, set this parameter to **off** (default value) to disable it.
- When enabling **check\_implicit\_conversions**, you must disable **enable\_fast\_query\_shipping**. Otherwise, you cannot view the result of restoring the implicit type conversion.
- A candidate path of a table may include multiple possible data scan modes such as sequential scan and index scan. A table scan mode used in the final execution plan is determined by the cost of the execution plan. Therefore, even if a candidate path for index scan is generated, other scan modes may also be used in the final execution plan.

## 6.11 Tuning with SQL PATCH

SQL PATCH is designed for database administrators (DBAs), O&M personnel, and other roles who need to optimize SQL statements. If performance problems caused by poor plans of service statements are identified through other O&M views or fault locating methods, you can create an SQL patch to optimize service statements based on hints. Currently, the following hints are supported: number of rows, scanning mode, join mode, join sequence, PBE custom/generic plan selection, statement-level parameter setting, and parameterized path. In addition, in case that services are unavailable due to internal system errors that are triggered by specific statements, you can create SQL patches to rectify single-point failures without changing service statements. In this way, errors can be reported in advance to avoid greater loss.

### Constraints

1. Patches can be created only by unique SQL ID. If unique SQL IDs conflict, SQL patches that are used for hint-based optimization may affect performance but do not affect semantic correctness.
2. Only hints that do not change SQL semantics can be used as patches. SQL rewriting is not supported.

3. This tool is not applicable to logical backup and restoration.
4. SQL patches cannot be created on DNs.
5. Only the initial user, O&M administrator, monitoring administrator, and system administrator have the permission to perform this operation.
6. Patches are not shared between databases. When creating SQL patches, you need to connect to the target database. If the CN where the SQL PATCH is created is removed and a full build is triggered, the SQL PATCH in the target CN of the full build is inherited. Therefore, you are advised to create the corresponding SQL PATCH on each CN.
7. CNs do not share SQL patches because their unique SQL IDs are different. You need to manually create SQL patches on different CNs.
8. SQL patches in a stored procedure and global SQL patches cannot coexist.
9. SQL patches cannot be used for precompiled statements that are executed using the PREPARE + EXECUTE syntax.
10. It is not recommended that the SQL patches be used in the database for a long time. It should be used only as a workaround. If the database service is unavailable due to a kernel fault triggered by a specific statement or SQL hints are used for performance tuning, you must rectify the service fault or upgrade the kernel as soon as possible. After the upgrade, the method of generating unique SQL IDs may change. Therefore, the workaround may become invalid.
11. Currently, except DML statements, unique SQL IDs of SQL statements (such as CREATE TABLE) are generated by hashing the statement text. Therefore, SQL PATCH is sensitive to uppercase and lowercase letters, spaces, and line breaks. That is, even statements of different texts have the same semantics, you still need to create different SQL patches for them. For DML operations, SQL PATCH can take effect for the same statement with different input parameters, regardless of uppercase letters, lowercase letters, and spaces.

## Example

The SQL patch is implemented based on the unique SQL ID. Therefore, you need to enable related O&M parameters (**enable\_resource\_track = on**, **instr\_unique\_sql\_count > 0**) for the SQL patch to take effect. The unique SQL ID can be obtained from both the WDR and slow SQL view. You need to specify the unique SQL ID when creating the SQL patch. For SQL statements in a stored procedure, you need to set **instr\_unique\_sql\_track\_type** to **'all'** and query unique SQL ID in the `db_perf.statement_history` view.

The following provides a simple example.

Scenario 1: Use SQL PATCH to optimize specific statements based on hints.

```
gaussdb=# create table hint_t1(a int, b int, c int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# create index on hint_t1(a);
CREATE INDEX
gaussdb=# insert into hint_t1 values(1,1,1);
INSERT 0 1
gaussdb=# analyze hint_t1;
ANALYZE
gaussdb=# set track_stmt_stat_level = 'L1,L1'; -- Enable full SQL statistics.
SET
```

```

gaussdb=# set enable_fast_query_shipping = off; -- Disable statement pushdown so that plans are
generated on the CN.
SET
gaussdb=# set explain_perf_mode = normal; --Adjust the plan display format.
SET
gaussdb=# select * from hint_t1 where hint_t1.a = 1; -- Execute SQL statements.
 a | b | c
---+---+---
 1 | 1 | 1
(1 row)
gaussdb=# \x --Switch to the extended display mode to facilitate plan observation.
Expanded display is on.
gaussdb=# select unique_query_id, query, query_plan from db_perf.statement_history where query like
'%hint_t1%';-- Obtain the query plan and unique SQL ID. This statement needs to query the slow SQL view
db_perf.statement_history in the postgres database.
-[RECORD 1]---+-----
unique_query_id | 3929365485

## 6.12 Optimization Cases

### 6.12.1 Case: Selecting an Appropriate Distribution Key

#### Symptom

Tables are defined as follows:

```
CREATE TABLE t1 (a int, b int);
CREATE TABLE t2 (a int, b int);
```

The following query is executed:

```
SELECT * FROM t1, t2 WHERE t1.a = t2.b;
```

#### Optimization Analysis

If **a** is the distribution key of **t1** and **t2**:

```
CREATE TABLE t1 (a int, b int) DISTRIBUTE BY HASH (a);
CREATE TABLE t2 (a int, b int) DISTRIBUTE BY HASH (a);
```

Then **Streaming** exists in the execution plan and the data volume is heavy among DNs, as shown in [Figure 6-8](#).

**Figure 6-8** Selecting an appropriate distribution key (1)

```
openGauss=> explain select * from t1, t2 where t1.a = t2.b;
QUERY PLAN

Streaming (type: GATHER) (cost=245.40..582.15 rows=240 width=16)
Node/s: All datanodes
-> Hash Join (cost=10.22..24.26 rows=10 width=16)
 Hash Cond: (t1.a = t2.b)
 -> Seq Scan on t1 (cost=0.00..10.10 rows=10 width=8)
 -> Hash (cost=3.79..3.79 rows=10 width=8)
 -> Streaming(type: REDISTRIBUTE) (cost=0.00..3.79 rows=10 width=8)
 Spawn on: All datanodes
 -> Seq Scan on t2 (cost=0.00..10.10 rows=10 width=8)
(9 rows)
```

If **a** is the distribution key of **t1** and **b** is the distribution key of **t2**:

```
CREATE TABLE t1 (a int, b int) DISTRIBUTE BY HASH (a);
CREATE TABLE t2 (a int, b int) DISTRIBUTE BY HASH (b);
```

Then **Streaming** does not exist in the execution plan, and the data volume among DN is decreasing and the query performance is increasing, as shown in **Figure 6-9**.

**Figure 6-9** Selecting an appropriate distribution key (2)

```
openGauss=> explain select * from t1, t2 where t1.a = t2.b;
QUERY PLAN

Streaming (type: GATHER) (cost=245.40..491.10 rows=240 width=16)
Node/s: All datanodes
-> Hash Join (cost=10.22..20.46 rows=10 width=16)
 Hash Cond: (t1.a = t2.b)
 -> Seq Scan on t1 (cost=0.00..10.10 rows=10 width=8)
 -> Hash (cost=10.10..10.10 rows=10 width=8)
 -> Seq Scan on t2 (cost=0.00..10.10 rows=10 width=8)
(7 rows)
```

## 6.12.2 Case: Creating an Appropriate Index

### Symptom

Query the information about all personnel in the sales department.

```
-- Create a table.
CREATE TABLE staffs (staff_id NUMBER(6) NOT NULL, first_name VARCHAR2(20), last_name
VARCHAR2(25), employment_id VARCHAR2(10), section_id NUMBER(4), state_name VARCHAR2(10), city
VARCHAR2(10));
CREATE TABLE sections (section_id NUMBER(4), place_id NUMBER(4), section_name VARCHAR2(20));
CREATE TABLE states (state_id NUMBER(4));
CREATE TABLE places (place_id NUMBER(4), state_id NUMBER(4));
-- Query before optimization.
EXPLAIN SELECT staff_id,first_name,last_name,employment_id,state_name,city
FROM staffs,sections,states,places
WHERE sections.section_name='Sales'
AND staffs.section_id = sections.section_id
AND sections.place_id = places.place_id
AND places.state_id = states.state_id
ORDER BY staff_id;
-- Query after optimization.
CREATE INDEX loc_id_pk ON places(place_id);
CREATE INDEX state_c_id_pk ON states(state_id);
```

```
EXPLAIN SELECT staff_id,first_name,last_name,employment_id,state_name,city
FROM staffs,sections,states,places
WHERE sections.section_name='Sales'
AND staffs.section_id = sections.section_id
AND sections.place_id = places.place_id
AND places.state_id = states.state_id
ORDER BY staff_id;
```

## Optimization Analysis

The original execution plan is as follows before creating the **places.place\_id** and **states.state\_id** indexes:

| id | operation                        | E-rows | E-width | E-costs |
|----|----------------------------------|--------|---------|---------|
| 1  | -> Streaming (type: GATHER)      | 2      | 254     | 54.08   |
| 2  | -> Sort                          | 2      | 254     | 53.90   |
| 3  | -> Nested Loop (4,5)             | 2      | 254     | 53.88   |
| 4  | -> Seq Scan on staffs            | 20     | 266     | 13.13   |
| 5  | -> Materialize                   | 4      | 12      | 40.37   |
| 6  | -> Streaming(type: BROADCAST)    | 4      | 12      | 40.36   |
| 7  | -> Nested Loop (8,9)             | 2      | 12      | 40.20   |
| 8  | -> Seq Scan on states            | 20     | 12      | 13.13   |
| 9  | -> Materialize                   | 2      | 24      | 26.69   |
| 10 | -> Streaming(type: REDISTRIBUTE) | 2      | 24      | 26.68   |
| 11 | -> Nested Loop (12,14)           | 2      | 24      | 26.57   |
| 12 | -> Streaming(type: REDISTRIBUTE) | 1      | 24      | 13.28   |
| 13 | -> Seq Scan on sections          | 1      | 24      | 13.16   |
| 14 | -> Seq Scan on places            | 20     | 24      | 13.13   |

(14 rows)

Predicate Information (identified by plan id)

```
3 --Nested Loop (4,5)
 Join Filter: (sections.section_id = staffs.section_id)
7 --Nested Loop (8,9)
 Join Filter: (places.state_id = states.state_id)
11 --Nested Loop (12,14)
 Join Filter: (sections.place_id = places.place_id)
13 --Seq Scan on sections
 Filter: ((section_name)::text = 'Sales'::text)
```

(8 rows)

The optimized execution plan is as follows (two indexes have been created on the **places.place\_id** and **states.state\_id** columns):

| id | operation                                        | E-rows | E-width | E-costs |
|----|--------------------------------------------------|--------|---------|---------|
| 1  | -> Streaming (type: GATHER)                      | 2      | 254     | 42.26   |
| 2  | -> Sort                                          | 2      | 254     | 42.08   |
| 3  | -> Nested Loop (4,5)                             | 2      | 254     | 42.06   |
| 4  | -> Seq Scan on staffs                            | 20     | 266     | 13.13   |
| 5  | -> Materialize                                   | 4      | 12      | 28.55   |
| 6  | -> Streaming(type: BROADCAST)                    | 4      | 12      | 28.54   |
| 7  | -> Nested Loop (8,13)                            | 2      | 12      | 28.38   |
| 8  | -> Streaming(type: REDISTRIBUTE)                 | 2      | 24      | 21.66   |
| 9  | -> Nested Loop (10,12)                           | 2      | 24      | 21.56   |
| 10 | -> Streaming(type: REDISTRIBUTE)                 | 1      | 24      | 13.28   |
| 11 | -> Seq Scan on sections                          | 1      | 24      | 13.16   |
| 12 | -> Index Scan using loc_id_pk on places          | 1      | 24      | 8.27    |
| 13 | -> Index Only Scan using state_c_id_pk on states | 1      | 12      | 3.35    |

(13 rows)

Predicate Information (identified by plan id)

```
3 --Nested Loop (4,5)
 Join Filter: (sections.section_id = staffs.section_id)
11 --Seq Scan on sections
```

```

Filter: ((section_name)::text = 'Sales'::text)
12 --Index Scan using loc_id_pk on places
 Index Cond: (place_id = sections.place_id)
13 --Index Only Scan using state_c_id_pk on states
 Index Cond: (state_id = places.state_id)
(8 rows)

```

### 6.12.3 Case: Adjusting Distribution Keys

#### Symptom

During a site test, the information is displayed after **EXPLAIN ANALYZE** is run:

| id | operation                           | A-time                | A-rows   | E-rows  | Peak Memory       | E-memory | A-width  | E-width | E-costs      |
|----|-------------------------------------|-----------------------|----------|---------|-------------------|----------|----------|---------|--------------|
| 1  | Streaming (type: GATHER)            | [94158,404]           | 0        | 670912  | 292KB             |          |          |         |              |
| 2  | Insert on temp_calc_emprate0101_t3  | [93259,538,93430,438] | 310      | 670912  | [1108KB, 1108KB]  | 1MB      |          | 73      | 102576573.63 |
| 3  | Streaming (type: REDISTRIBUTE)      | [93259,507,93410,400] | 310      | 670912  | [2091KB, 2093KB]  | 1MB      |          | 73      | 102534641.63 |
| 4  | Subquery Scan on **\$SELECT**       | [93212,430,93419,995] | 310      | 670912  | [7KB, 7KB]        | 1MB      |          | 73      | 102533776.79 |
| 5  | HashAggregate                       | [93212,425,93419,980] | 310      | 670912  | [145KB, 197KB]    | 16MB     | [65, 65] | 45      | 102533645.74 |
| 6  | Streaming (type: REDISTRIBUTE)      | [93212,374,93419,924] | 5886     | 670994  | [2091KB, 2093KB]  | 1MB      |          | 45      | 102533305.05 |
| 7  | Hash Join (S,12)                    | [2657,406,93339,924]  | 5886     | 670994  | [20KB, 20KB]      | 1MB      |          | 45      | 102532655.39 |
| 8  | Seq Scan on s_riskrate_setting a    | [38,885,2940,983]     | 17753227 | 7859418 | [612KB, 903KB]    | 1MB      |          | 56      | 215264,71    |
| 9  | Hash                                | [1241,536,2713,381]   | 8536241  | 8536241 | [1031KB, 97803KB] | 16MB     | [48, 48] | 46      | 50870,88     |
| 10 | Streaming (type: REDISTRIBUTE)      | [210,226,2617,195]    | 8536241  | 8536241 | [2091KB, 2093KB]  | 1MB      |          | 46      | 50870,88     |
| 11 | Seq Scan on temp_calc_emprate0101 b | [86,790,141,293]      | 8536241  | 8536241 | [16KB, 16KB]      | 1MB      |          | 46      | 11564,79     |

According to the execution information, Hash Join becomes the performance bottleneck of the whole plan. Based on the execution time of Hash Join **[2657.406,93339.924]** (for details about the value, see [Description](#)), it can be seen that severe skew occurs on different DN's during the Hash Join operation.

In the memory information (as shown in the following figure), it can be seen that the data skew occurs in the memory usage of each node.

```

..... Memory Information (identified by plan id)

Coordinator:
--Query Peak Memory: 4MB
Datanode:
--Max Query Peak Memory: 118MB
--Min Query Peak Memory: 24MB
-- 12 --Hash
..... Max Buckets: 131072 Max Batches: 1 Max Memory Usage: 91857kB
..... Min Buckets: 131072 Min Batches: 1 Min Memory Usage: 0kB
(8 rows)

```

#### Optimization Analysis

The preceding two features indicate that this SQL statement has extremely serious computing unbalance. The further lower-layer analysis on the Hash Join operator shows that serious computing skew **[38.885,2940.983]** occurs in **Seq Scan on s\_riskrate\_setting**. Based on the description of the Scan, we can infer that the performance problems of this plan lie in data skew occurred in the **s\_riskrate\_setting** table. Later, it is proved that serious data skew occurred in the **s\_riskrate\_setting** table. After performance optimization, the execution time is reduced from 94s to 50s.

### 6.12.4 Case: Adjusting the GUC Parameter best\_agg\_plan

#### Symptom

The **agg\_t1** table is defined as follows:

```
create table agg_t1(a int, b int, c int) distribute by hash(a);
```

Assume that the distribution key of the result set provided by the agg lower-layer operator is **setA**, and the **group by** column of the agg operation is **setB**, the agg operations can be performed in two scenarios in the Stream framework.

1. **setA** is a subset of **setB**.

In this scenario, the aggregation result of the lower-layer is correct and can be directly used by upper-level operators. Example:

```
gaussdb=# explain select a, count(1) from agg_t1 group by a;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
1 | -> Streaming (type: GATHER) | 20 | 12 | 14.23
2 | -> HashAggregate | 20 | 12 | 13.30
3 | -> Seq Scan on agg_t1 | 20 | 4 | 13.13
(3 rows)
```

2. **setA** is not a subset of **setB**.

In this scenario, the Stream execution framework is classified into the following three plans:

- hashagg + gather(redistribute) + hashagg;
- redistribute + hashagg(+gather);
- hashagg + redistribute + hashagg(+gather).

GaussDB provides the GUC parameter **best\_agg\_plan** to intervene the execution plan, and forces the plan to generate the corresponding execution plan. This parameter can be set to **0, 1, 2, 3**.

- When the parameter is set to **1**, the first plan is forcibly generated.
- When the parameter is set to **2** and if the **group by** column can be redistributed, the second plan is forcibly generated. Otherwise, the first plan is generated.
- When the parameter is set to **3** and if the **group by** column can be redistributed, the third plan is generated. Otherwise, the first plan is generated.
- When the parameter is set to **0**, the query optimizer chooses the most optimal plan by the three preceding plans' evaluation cost.

For details, see the following figure.

```
gaussdb=# set best_agg_plan to 1;
SET
gaussdb=# explain select b,count(1) from t1 group by b;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
1 | -> HashAggregate | 8 | 4 | 15.83
2 | -> Streaming (type: GATHER) | 25 | 4 | 15.83
3 | -> HashAggregate | 25 | 4 | 14.33
4 | -> Seq Scan on t1 | 30 | 4 | 14.14
(4 rows)
gaussdb=# set best_agg_plan to 2;
SET
gaussdb=# explain select b,count(1) from t1 group by b;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
1 | -> Streaming (type: GATHER) | 30 | 4 | 15.85
2 | -> HashAggregate | 30 | 4 | 14.60
3 | -> Streaming(type: REDISTRIBUTE) | 30 | 4 | 14.45
4 | -> Seq Scan on t1 | 30 | 4 | 14.14
(4 rows)
gaussdb=# set best_agg_plan to 3;
SET
gaussdb=# explain select b,count(1) from t1 group by b;
id | operation | E-rows | E-width | E-costs
```

```

-----+-----+-----+-----+
1 | -> Streaming (type: GATHER) | 30 | 4 | 15.84
2 | -> HashAggregate | 30 | 4 | 14.59
3 | -> Streaming(type: REDISTRIBUTE) | 25 | 4 | 14.59
4 | -> HashAggregate | 25 | 4 | 14.33
5 | -> Seq Scan on t1 | 30 | 4 | 14.14
(5 rows)

```

## Optimization

Generally, the optimizer chooses an optimal execution plan, but the cost estimation, especially that of the intermediate result set, has large deviations, which may result in large deviations in agg calculation. In this case, you need to use **best\_agg\_plan** to adjust the agg calculation model.

When the aggregation convergence ratio is very small, that is, the number of result sets does not become small obviously after the agg operation (5 times is a critical point), you can select the redistribute+hashagg or hashagg+redistribute+hashagg execution mode.

### 6.12.5 Case: Rewriting SQL and Deleting Subqueries (1)

#### Symptom

```

select
 1,
 (select count(*) from customer_address_001 a4 where a4.ca_address_sk = a.ca_address_sk) as GZCS
from customer_address_001 a;

```

This SQL performance is poor. SubPlan exists in the execution plan as follows:

```

openGauss=# explain select 1,(select count(*)
openGauss(# from customer_address_001 a4
openGauss(# where a4.ca_address_sk = a.ca_address_sk
openGauss(#) as GZCS from customer_address_001 a;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+
1 | -> Streaming (type: GATHER) | 320 | 4 | 4529.27
2 | -> Seq Scan on customer_address_001 a | 320 | 4 | 4496.27
3 | -> Aggregate [2, SubPlan 1] | 32 | 4 | 139.50
4 | -> Result | 10240 | 4 | 138.69
5 | -> Materialize | 10240 | 4 | 138.69
6 | -> Streaming(type: BROADCAST) | 10240 | 4 | 137.09
7 | -> Seq Scan on customer_address_001 a4 | 320 | 4 | 32.32
(7 rows)

```

## Optimization

The core of this optimization is to eliminate subqueries. Based on the service scenario analysis, **a.ca\_address\_sk** is not null. In terms of SQL syntax, you can rewrite the SQL statement as follows:

```

select
count(*)
from customer_address_001 a4, customer_address_001 a
where a4.ca_address_sk = a.ca_address_sk
group by a.ca_address_sk;

```

#### NOTE

To ensure that the modified statements have the same functions, **not null** is added to **customer\_address\_001.ca\_address\_sk**.

## 6.12.6 Case: Rewriting SQL Statements to Eliminate Pruning Interference

### Symptom

In a test at a site, **ddw\_f10\_op\_cust\_asset\_mon** is a partitioned table and the partitioning key is **year\_mth** whose value is a combined string of month and year values.

The following figure shows the tested SQL statements:

```
select count(1) from t_ddw_f10_op_cust_asset_mon b1 where b1.year_mth between
to_char(add_months(to_date('20170222','yyyymmdd'), -11), 'yyyymm') and substr('20170222', 1, 6);
```

The test result shows the Scan operation on the tables in the SQL statement takes 135s. This may be the performance bottleneck.

#### NOTE

**add\_months** is a local adaptation function.

```
CREATE OR REPLACE FUNCTION ADD_MONTHS(date, integer) RETURNS date AS $$ SELECT
CASE WHEN (EXTRACT(day FROM $1) = EXTRACT(day FROM (date_trunc('month', $1) + INTERVAL
'1 month - 1 day')) THEN date_trunc('month', $1) + CAST($2 + 1 || ' month - 1 day' as interval)
ELSE $1 + CAST($2 || ' month' as interval) END $$ LANGUAGE SQL IMMUTABLE;
```

### Optimization

According to the statement execution plan, the base table filter is displayed as follows:

```
Filter: (((year_mth)::text <= '201702'::text) AND ((year_mth)::text >=
to_char(add_months(to_date('20170222'::text, 'YYYYMMDD'::text), (-11)), 'YYYYMM'::text)))
```

The query condition expression `to_char(add_months(to_date('20170222','yyyymmdd'),-11),'yyyymm')` exists in the filter condition, and this non-constant expression cannot be used for pruning. Therefore, all data of query statements in the partitioned tables is scanned.

`to_date` and `to_char` are stable functions as queried in `pg_proc`. According to the function behavior described in the database, this type of functions cannot be converted to Const values in the preprocessing phase, which is the root cause why partition pruning cannot be performed.

Based on the preceding analysis, the optimization expression can be used for partition pruning, which is the key to performance optimization. The original SQL statements can be written to as follows:

```
select count(1) from t_ddw_f10_op_cust_asset_mon b1 where b1.year_mth
between(substr(ADD_MONTHS('20170222'::date, -11), 1, 4)||substr(ADD_MONTHS('20170222'::date, -11),
6, 2)) and substr('20170222', 1, 6);
```

The execution time of modified SQL statements is reduced from 135s to 18s.

## 6.12.7 Case: Rewriting SQL Statements and Deleting in-clause

### Symptom

in-clause/any-clause is a common SQL statement constraint. Sometimes, the clause following **in** or **any** is a constant. For example:

```
select count(1) from calc_empfyc_c1_result_tmp_t1 where ls_pid_cusr1 in ('20120405', '20130405');
```

or

```
select count(1) from calc_empfyc_c1_result_tmp_t1 where ls_pid_cusr1 in any('20120405', '20130405');
```

Sometimes, the **in** or **any** clause is used as follows:

```
SELECT ls_pid_cusr1,COALESCE(max(round((current_date-bthdate)/365)),0)FROM
calc_empfyc_c1_result_tmp_t1 t1,p10_md_tmp_t2 t2WHERE t1.ls_pid_cusr1 = any(values(id),(id15))GROUP
BY ls_pid_cusr1;
```

**id** and **id15** are columns in **p10\_md\_tmp\_t2**, and **t1.ls\_pid\_cusr1 = any(values(id),(id15))** is equivalent to **t1.ls\_pid\_cusr1 = id** or **t1.ls\_pid\_cusr1 = id15**.

Therefore, join-condition is essentially an inequality, and nestloop must be used for this unequal join operation. The corresponding execution plan is as follows.

```
Streaming (type: GATHER) (cost=1641429284.14..1641429283.98 rows=3840 width=49)
Node/s: All DataNodes
-> Insert on channel.calc_empfyc_c1_result_tmp (cost=1641429280.14..1641429283.98 rows=3840 width=49)
-> HashAggregate (cost=1641429280.14..1641429283.98 rows=3840 width=25)
-> Output: t1.ls_pid_cusr1, COALESCE(max(max(round(((('2017-03-29 00:00:00'::timestamp without time zone - t2.bthdate) / 365)::double precision))::numeric, 0))), 0)::numeric)
Group By Key: t1.ls_pid_cusr1
-> Streaming (type: REDISTRIBUTE) (cost=820714640.07..820714642.69 rows=3968 width=25)
Output: t1.ls_pid_cusr1, max(round(((('2017-03-29 00:00:00'::timestamp without time zone - t2.bthdate) / 365)::double precision))::numeric, 0))
Distribute Key: t1.ls_pid_cusr1
Spawn on: All DataNodes
-> HashAggregate (cost=820714640.07..820714640.69 rows=3968 width=25)
Output: t1.ls_pid_cusr1, max(round(((('2017-03-29 00:00:00'::timestamp without time zone - t2.bthdate) / 365)::double precision))::numeric, 0))
Group By Key: t1.ls_pid_cusr1
-> Nested Loop (cost=0.00..615567760.93 rows=875293350960 width=25)
Output: t1.ls_pid_cusr1, t2.bthdate
Join Filter: (SubPlan 1)
-> Seq Scan on channel.p10_md_tmp_t2 t2 (cost=0.00..127030.52 rows=448523360 width=64)
Output: t2.id, t2.id15, t2.bthdate, t2.name
-> Materialize (cost=0.00..147.29 rows=282608 width=17)
Output: t1.ls_pid_cusr1
-> Streaming (type: BROADCAST) (cost=0.00..127.56 rows=282608 width=17)
Output: t1.ls_pid_cusr1
Spawn on: All DataNodes
-> Seq Scan on channel.calc_empfyc_c1_result_tmp_t1 t1 (cost=0.00..1.62 rows=3947 width=17)
Output: t1.ls_pid_cusr1
SubPlan 1
-> Values Scan on "VALUES" (cost=0.00..0.01 rows=64 width=38)
Output: "VALUES".column1
```

### Optimization

The test result shows that both result sets are too large. As a result, nestloop is time-consuming with more than one hour to return results. Therefore, the key to performance optimization is to eliminate nestloop, using more efficient hash join. From the perspective of semantic equivalence, the SQL statements can be written as follows:

```
selectls_pid_cusr1,COALESCE(max(round(ym/365)),0)from(
(
SELECT
ls_pid_cusr1,(current_date-bthdate) as ym
FROM calc_empfyc_c1_result_tmp_t1
t1,p10_md_tmp_t2 t2
WHERE t1.ls_pid_cusr1 = t2.id and t1.ls_pid_cusr1 != t2.id15
)
union all
(
SELECT
ls_pid_cusr1,(current_date-bthdate) as
ym
FROM calc_empfyc_c1_result_tmp_t1 t1,p10_md_tmp_t2 t2
WHERE
t1.ls_pid_cusr1 = id15
))GROUP BY ls_pid_cusr1;
```

The optimized SQL query consists of two equivalent join subqueries, and each subquery can be used for hash join in this scenario. The optimized execution plan is as follows.

| id | operation                                              | A-time              | A-rows    | E-rows    | Peak Memory      | Errors | A-width  |
|----|--------------------------------------------------------|---------------------|-----------|-----------|------------------|--------|----------|
| 1  | -> Streaming (type: GATHER)                            | 6737.281            | 0         | 192       | 292KB            |        |          |
| 2  | -> Insert on channel.calc_empfyc_cl_result_age_tmp     | [4665.024,4990.666] | 0         | 192       | [1108KB, 1108KB] | 1MB    |          |
| 3  | -> HashAggregate                                       | [4664.996,4990.641] | 0         | 192       | [12KB, 12KB]     | 1MB    |          |
| 4  | -> Streaming (type: REDISTRIBUTE)                      | [4664.991,4990.637] | 0         | 3392      | [2090KB, 2090KB] | 1MB    |          |
| 5  | -> HashAggregate                                       | [3416.939,4958.348] | 0         | 3392      | [14KB, 14KB]     | 16MB   |          |
| 6  | -> Append                                              | [3416.936,4958.340] | 0         | 4011      | [1KB, 1KB]       | 1MB    |          |
| 7  | -> Hash Join (8,9)                                     | [2011.226,3080.697] | 0         | 3947      | [6KB, 6KB]       | 1MB    |          |
| 8  | -> Seq Scan on channel.p10_md_tmp_t2 t2                | [803.782,1238.984]  | 443525717 | 443523360 | [12KB, 12KB]     | 1MB    |          |
| 9  | -> Hash                                                | [4.357,328.979]     | 252608    | 252608    | [482KB, 482KB]   | 16MB   | [58, 59] |
| 10 | -> Streaming (type: BROADCAST)                         | [2.345,326.320]     | 252608    | 252608    | [2090KB, 2090KB] | 1MB    |          |
| 11 | -> Seq Scan on channel.calc_empfyc_cl_result_tmp_t1 t1 | [0.011,0.030]       | 3947      | 3947      | [11KB, 11KB]     | 1MB    |          |
| 12 | -> Hash Join (13,14)                                   | [1376.258,2066.110] | 0         | 64        | [5KB, 5KB]       | 1MB    |          |
| 13 | -> Seq Scan on channel.p10_md_tmp_t2 t2                | [777.552,1388.499]  | 443525717 | 443523360 | [12KB, 12KB]     | 1MB    |          |
| 14 | -> Hash                                                | [2.812,4.217]       | 252608    | 252608    | [482KB, 482KB]   | 16MB   | [58, 57] |
| 15 | -> Streaming (type: BROADCAST)                         | [1.276,1.868]       | 252608    | 252608    | [2090KB, 2090KB] | 1MB    |          |
| 16 | -> Seq Scan on channel.calc_empfyc_cl_result_tmp_t1 t1 | [0.010,0.033]       | 3947      | 3947      | [11KB, 11KB]     | 1MB    |          |

Before the optimization, no result is returned for more than 1 hour. After the optimization, the result is returned within 7s.

### 6.12.8 Case: Modifying the GUC Parameter rewrite\_rule

rewrite\_rule contains multiple query rewriting rules: magicset, partialpush, uniquecheck, disablerep, intargetlist, and predpush. The following describes the application scenarios of some important rules.

#### Preparing the Case Environment

To demonstrate rule application scenarios, you need to prepare the following table creation statements:

```
-- Clean the environment.
DROP SCHEMA IF EXISTS rewrite_rule_guc_test CASCADE;
CREATE SCHEMA rewrite_rule_guc_test;
SET current_schema=rewrite_rule_guc_test;
-- Create a test table.
CREATE TABLE t(c1 INT, c2 INT, c3 INT, c4 INT);
CREATE TABLE t1(c1 INT, c2 INT, c3 INT, c4 INT);
CREATE TABLE t2(c1 INT, c2 INT, c3 INT, c4 INT);
```

#### partialpush: Partial Pushdown

Queries are pushed down to DNs for distributed execution, greatly accelerating queries. If a query statement contains a factor that cannot be pushed down, the entire statement cannot be pushed down. As a result, a stream plan cannot be generated and executed on DNs for the distributed execution, and the performance is poor.

The following is an example:

```
gaussdb=# set rewrite_rule='none';
SET
gaussdb=# explain (verbose on, costs off) select group_concat(tt.c1, tt.c2) from (select t1.c1,t2.c2 from
t1,t2 where t1.c1=t2.c2) tt(c1,c2);
QUERY PLAN

Aggregate
Output: group_concat(t1.c1, t2.c2 SEPARATOR ',')
-> Hash Join
Output: t1.c1, t2.c2
Hash Cond: (t1.c1 = t2.c2)
-> Data Node Scan on t1 "_REMOTE_TABLE_QUERY_"
Output: t1.c1
Node/s: All datanodes
Remote query: SELECT c1 FROM ONLY public.t1 WHERE true
-> Hash
Output: t2.c2
-> Data Node Scan on t2 "_REMOTE_TABLE_QUERY_"
Output: t2.c2
```

```
Node/s: All datanodes
Remote query: SELECT c2 FROM ONLY public.t2 WHERE true
```

The `group_concat()` function cannot be pushed down. As a result, the remote query plan is executed:

1. Deliver the **select c1 from t1 where true** statement to DNs to read all data in the **t1** table.
2. Deliver the **select c2 from t2 where true** statement to DNs to read all data in the **t2** table.
3. Perform HASH JOIN on the CN.
4. Perform the `group_concat` calculation and return the final result.

This plan is slow because a large amount of data is transmitted over the network and then HASH JOIN is executed on the CN. As a result, cluster resources cannot be fully used.

**partialpush** is added to push the preceding 1, 2, and 3 operations down to DNs for distributed execution, greatly improving statement performance.

```
gaussdb=# set rewrite_rule='partialpush';
SET
gaussdb=# explain (verbose on, costs off) select two_sum(tt.c1, tt.c2) from (select t1.c1,t2.c2 from t1,t2
where t1.c1=t2.c2) tt(c1,c2);
QUERY PLAN
```

```

Subquery Scan on tt
 Output: two_sum(tt.c1, tt.c2)
 -> Streaming (type: GATHER) -- The Gather plan is executed on DNs in a distributed manner:
 Output: t1.c1, t2.c2
 Node/s: All datanodes
 -> Nested Loop
 Output: t1.c1, t2.c2
 Join Filter: (t1.c1 = t2.c2)
 -> Seq Scan on public.t1
 Output: t1.c1, t1.c2, t1.c3
 Distribute Key: t1.c1
 -> Materialize
 Output: t2.c2
 -> Streaming(type: REDISTRIBUTE)
 Output: t2.c2
 Distribute Key: t2.c2
 Spawn on: All datanodes
 Consumer Nodes: All datanodes
 -> Seq Scan on public.t2
 Output: t2.c2
 Distribute Key: t2.c1
```

(21 rows)

## intargetlist: Target Column Subquery Performance Improvement

The query performance can be greatly improved by converting the subquery in the target column to JOIN. The following is an example:

```
gaussdb=# set rewrite_rule='none';
SET
gaussdb=# explain (verbose on, costs off) select c1,(select avg(c2) from t2 where t2.c2=t1.c2) from t1
where t1.c1<100 order by t1.c2;
QUERY PLAN
```

```

Streaming (type: GATHER)
 Output: t1.c1, ((SubPlan 1)), t1.c2
 Merge Sort Key: t1.c2
 Node/s: All datanodes
```

```

-> Sort
 Output: t1.c1, ((SubPlan 1)), t1.c2
 Sort Key: t1.c2
-> Seq Scan on public.t1
 Output: t1.c1, (SubPlan 1), t1.c2
 Distribute Key: t1.c1
 Filter: (t1.c1 < 100)
 SubPlan 1
 -> Aggregate
 Output: avg(t2.c2)
 -> Result
 Output: t2.c2
 Filter: (t2.c2 = t1.c2)
 -> Materialize
 Output: t2.c2
 -> Streaming(type: BROADCAST)
 Output: t2.c2
 Spawn on: All datanodes
 Consumer Nodes: All datanodes
 -> Seq Scan on public.t2
 Output: t2.c2
 Distribute Key: t2.c1
 (26 rows)

```

Because the subquery (**select avg(c2) from t2 where t2.c2=t1.c2**) in the target column cannot be pulled up, execution of the subquery is triggered each time a row of data of **t1** is scanned, and the query efficiency is low. If the **intargetlist** parameter is enabled, the subquery is converted to JOIN to improve the query performance.

```

gaussdb=# set rewrite_rule='intargetlist';
SET
gaussdb=# explain (verbose on, costs off) select c1,(select avg(c2) from t2 where t2.c2=t1.c2) from t1
where t1.c1<100 order by t1.c2;
QUERY PLAN

Streaming (type: GATHER)
 Output: t1.c1, (avg(t2.c2)), t1.c2
 Merge Sort Key: t1.c2
 Node/s: All datanodes
-> Sort
 Output: t1.c1, (avg(t2.c2)), t1.c2
 Sort Key: t1.c2
-> Hash Right Join
 Output: t1.c1, (avg(t2.c2)), t1.c2
 Hash Cond: (t2.c2 = t1.c2)
-> Streaming(type: BROADCAST)
 Output: (avg(t2.c2)), t2.c2
 Spawn on: All datanodes
 Consumer Nodes: All datanodes
-> HashAggregate
 Output: avg(t2.c2), t2.c2
 Group By Key: t2.c2
-> Streaming(type: REDISTRIBUTE)
 Output: t2.c2
 Distribute Key: t2.c2
 Spawn on: All datanodes
 Consumer Nodes: All datanodes
-> Seq Scan on public.t2
 Output: t2.c2
 Distribute Key: t2.c1
-> Hash
 Output: t1.c1, t1.c2
-> Seq Scan on public.t1
 Output: t1.c1, t1.c2
 Distribute Key: t1.c1
 Filter: (t1.c1 < 100)
(31 rows)

```

## uniquecheck: Performance Improvement of Subqueries Without Aggregate Functions

Ensure that each condition has only one line of output. The subqueries with aggregate functions can be automatically pulled up. For subqueries without aggregate functions, the following is an example:

```
select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c2) ;
```

Rewrite as follows:

```
select t1.c1 from t1 join (select t2.c1 from t2 where t2.c1 is not null group by t2.c1(unique check)) tt(c1) on tt.c1=t1.c1;
```

Note that unique check in the preceding SQL statement indicates that **t2.c1** needs to be checked. If the SQL statement is abnormal, the SQL statement cannot be directly executed. To ensure semantic equivalence, the subquery **tt** must ensure that each **group by t2.c1** has only one line of output. Enable the **uniquecheck** query rewriting parameter to ensure that the query can be pulled up and equivalent. If more than one row of data is output at run time, an error is reported.

```
gaussdb=# set rewrite_rule='uniquecheck';
SET
gaussdb=# explain verbose select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c1) ;
QUERY PLAN
```

```

Streaming (type: GATHER)
Output: t1.c1
Node/s: All datanodes
-> Nested Loop
Output: t1.c1
Join Filter: (t1.c1 = subquery."?column?")
-> Seq Scan on public.t1
Output: t1.c1, t1.c2, t1.c3
Distribute Key: t1.c1
-> Materialize
Output: subquery."?column?", subquery.c1
-> Subquery Scan on subquery
Output: subquery."?column?", subquery.c1
-> HashAggregate
Output: t2.c1, t2.c1
Group By Key: t2.c1
Filter: (t2.c1 IS NOT NULL)
Unique Check Required -- If more than one row of data is output during running, an
error is reported.
-> Index Only Scan using t2idx on public.t2
Output: t2.c1
Distribute Key: t2.c1
```

(21 rows)

Note: Because **group by t2.c1 unique check** occurs before the filter condition **tt.c1=t1.c1**, an error may be reported after the query that does not report an error is rewritten. An example is as follows:

There are tables **t1** and **t2**. The data in the tables is as follows:

```
gaussdb=# select * from t1 order by c2;
c1 | c2 | c3
----+----+----
1 | 1 | 1
2 | 2 | 2
3 | 3 | 3
4 | 4 | 4
5 | 5 | 5
6 | 6 | 6
```

```
7 | 7 | 7
8 | 8 | 8
9 | 9 | 9
10 | 10 | 10
(10 rows)
```

```
gaussdb=# select * from t2 order by c1;
```

```
c1 | c2 | c3

1 | 1 | 1
2 | 2 | 2

```
gaussdb=# set rewrite_rule='uniquecheck';
```

```
SET
```

```
gaussdb=# select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c2) ;
ERROR: more than one row returned by a subquery used as an expression
```

## predpush, predpushnormal, and predpushforce: Condition Pushdown to Subqueries

Generally, the optimizer performs optimization by query block, and different query blocks are independently optimized. If a predicate condition involving cross-query blocks exists, it is difficult to consider the location of a predicate application from a global perspective. The predpush may push down the predicate to the subquery block, so that performance can be improved in a scenario in which the data volume in the parent query block is relatively small and an index can be used in the subquery. There are three rewriting rules related to predpush:

- **predpushnormal**: attempts to push predicates down to subqueries. The STREAM operators, such as BROADCAST, are used to implement distributed plans.
- **predpushforce**: attempts to push down predicates to subqueries and uses the index of the parameterized path for scanning as much as possible.
- **predpush**: selects an optimal distributed plan from predpushnormal and predpushforce at a cost, but increases optimization time.

The following is an example of a plan for disabling and enabling the query rewriting rule:

```
gaussdb=# set enable_fast_query_shipping = off; -- Disable FQS optimization.
SET
gaussdb=# show rewrite_rule;
rewrite_rule

magicset
(1 row)

gaussdb=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1 =
t1.c1;
 QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
 Join Filter: (t1.c1 = t2.c1)
 -> HashAggregate
 Group By Key: t2.c1
 -> Seq Scan on t2
 -> Seq Scan on t1
(8 rows)

gaussdb=# set rewrite_rule='predpushnormal';
SET
gaussdb=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1 =
t1.c1;
 QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
 -> Seq Scan on t1
 -> HashAggregate
 Group By Key: t2.c1
 -> Result
 Filter: (t1.c1 = t2.c1)
 -> Seq Scan on t2
(9 rows)

-- You can see that the filter criteria are pushed to the subquery for execution.
```

```
gaussdb=# set rewrite_rule='predpushforce';
SET

gaussdb=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1 =
t1.c1;
 QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
 -> Seq Scan on t1
 -> HashAggregate
 Group By Key: t2.c1
 -> Index Scan using t2_c1_idx on t2
 Index Cond: (t1.c1 = c1)
(8 rows)

-- When used together with predpush hints, you can see that parameterized paths are used.

gaussdb=# set rewrite_rule = 'predpush';
SET
gaussdb=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1 =
t1.c1;
 QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
 -> Seq Scan on t1
 -> HashAggregate
 Group By Key: t2.c1
 -> Result
 Filter: (t1.c1 = t2.c1)
 -> Seq Scan on t2
(9 rows)
```

## Forbidding Pullup of Subquery Parameter `disablerep` for Replication Tables

When querying a replication table, the query actually takes effect on a DN only. Pulling up the subquery parameter **disablerep** may deteriorate the performance. The following is an example:

```
gaussdb=# create table t_rep(a int) distribute by replication;
CREATE TABLE
gaussdb=# create table t_dis(a int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# set rewrite_rule = '';
SET
gaussdb=# explain (costs off) select * from t_dis where a = any(select a from t_rep) or a > 100;
 QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Left Join
 Hash Cond: (t_dis.a = subquery.a)
 Filter: ((subquery.a IS NOT NULL) OR (t_dis.a > 100))
 -> Seq Scan on t_dis
 -> Hash
 -> Subquery Scan on subquery
 Filter: (Hash By subquery.a)
 -> HashAggregate
 Group By Key: t_rep.a
 -> Seq Scan on t_rep
(12 rows)
```

For a replication table, the data stored on all DN nodes is the same. Therefore, you do not need to scan the replication table on all nodes.

```
gaussdb=# set rewrite_rule = disablerep;
SET
gaussdb=# explain (costs off) select * from t_dis where a = any(select a from t_rep) or a > 100;
QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on t_dis
 Filter: ((hashed SubPlan 1) OR (a > 100))
 SubPlan 1
 -> Seq Scan on t_rep
(6 rows)
```

## 6.12.9 Using DN Gather to Reduce Stream Nodes in the Plan

The DN Gather is used to remove the stream nodes from the distribution plan and send data to a node for calculation. This reduces the cost of data redistribution during the execution of the distribution plan and improves the single query performance and the overall throughput capability of the system. However, DN Gather is oriented to small-data-volume scenarios of TP. For small-data-volume queries, performance can be improved because the cost of data redistribution is reduced and the computing power of a single node is sufficient. Multi-node parallel computing is more advantageous for large-data-volume computing. You need to enable and disable DN Gather to determine which one is faster. (The default value of **dngather\_min\_rows** is **500**. The following uses the default value.) Some cases are provided as follows.

### Preparing the Case Environment

To facilitate case demonstration, you need to prepare the following table creation statements:

```
-- Clean the environment.
DROP SCHEMA IF EXISTS dn_gather_test CASCADE;
CREATE SCHEMA dn_gather_test;
SET current_schema=dn_gather_test;
-- Create a test table.
CREATE TABLE t1(a INT, b INT, c INT, d INT);
CREATE TABLE t2(a INT, b INT, c INT, d INT);
CREATE TABLE t3(a INT, b INT, c INT, d INT);
CREATE TABLE t4(a INT, b INT, c INT, d INT);
```

### Gather Join

To converge the join results to a single DN, the following conditions must be met:

- The number of data rows estimated by the optimizer before and after join is less than the threshold.
- The subnodes of Join are all stream nodes.

For example, the subnodes of Join are all stream nodes, and broadcast is disabled.

```
gaussdb=# set enable_broadcast=false;
SET
gaussdb=# set explain_perf_mode=pretty;
SET
gaussdb=# set enable_dngather=false;
SET
```

```

gaussdb=# explain select count(*) from t1, t2 where t1.b = t2.b;
id | operation | E-rows | E-width | E-costs

```

## Union/Union all

To converge union/union all results to a single DN, the following condition must be met:

- At least one subnode must meet the requirements in the three cases (Gather Join, Gather Groupby/Agg, and Gather window function).

For example, all the subnodes of Join are stream nodes, and broadcast is disabled.

```

gaussdb=# set explain_perf_mode=pretty;
SET
gaussdb=# set enable_broadcast=false;
SET
gaussdb=# set enable_dngather=false;
SET
gaussdb=# explain select t1.a, t2.b from t1, t2 where t1.b = t2.b union all select t3.a, t3.b from t3, t4 where t3.b = t4.b;

# 7 SQL Reference

---

## 7.1 SQL

### What Is SQL?

SQL is a standard computer language used to control the access to databases and manage data in databases.

SQL provides different statements to enable you to:

- Query data.
- Insert, update, and delete rows.
- Create, replace, modify, and delete objects.
- Control the access to a database and its objects.
- Maintain the consistency and integrity of a database.

SQL consists of commands and functions that are used to manage databases and database objects. SQL can also forcibly implement the rules for data types, expressions, and texts. Therefore, [SQL Reference](#) describes data types, expressions, functions, and operators in addition to SQL syntax.

### Development of SQL Standards

Released SQL standards are as follows:

- 1986: ANSI X3.135-1986, ISO/IEC 9075:1986, SQL-86
- 1989: ANSI X3.135-1989, ISO/IEC 9075:1989, SQL-89
- 1992: ANSI X3.135-1992, ISO/IEC 9075:1992, SQL-92 (SQL2)
- 1999: ISO/IEC 9075:1999, SQL:1999 (SQL3)
- 2003: ISO/IEC 9075:2003, SQL:2003 (SQL4)
- 2011: ISO/IEC 9075:200N, SQL:2011 (SQL5)

### SQL Standards Supported by GaussDB

By default, GaussDB supports most features of SQL5.

## 7.2 Keywords

The SQL contains reserved keywords and non-reserved keywords. Standards require that reserved keywords not be used as other identifiers. Non-reserved keywords have special meanings only in a specific environment and can be used as identifiers in other environments.

---

### NOTICE

1. Currently, the non-reserved keywords have the following restrictions when being used as the identifier of a database object:
  1. It cannot be directly used as a column alias. That is, usage similar to `SELECT 1 ABORT` may cause errors.
  2. Keywords `ENTITYESCAPING`, `NOENTITYESCAPING`, and `WELLFORMED` cannot be used as identifiers of table names, column names, table aliases, column aliases, and function names if they are not enclosed in double quotation marks.
  3. The `RAW` keyword without double quotation marks cannot be used as the identifier of a table name or function name.
  4. The `SET` keyword without double quotation marks cannot be used as an identifier of a table alias. That is, usage similar to `SELECT * FROM T1 SET` may cause errors.
  5. Keywords such as `BEGIN`, `BY`, `CLOSE`, `CURSOR`, `DECLARE`, `DELETE`, `EXECUTE`, `FUNCTION`, `IF`, `IMMEDIATE`, `INSERT`, `LOOP`, `MOVE`, `OF`, `REF`, `RELEASE`, `RETURN`, `SAVEPOINT`, `STRICT`, `TYPE`, and `UPDATE` without double quotation marks cannot be used as variable names.
  6. When the `SYS_REFCURSOR` keyword is used as the identifier of a database object, if double quotation marks are not attached, a database object named **REFCURSOR** is created. If double quotation marks are attached, a database object named **SYS\_REFCURSOR** is created.
2. Similar to the non-reserved keywords, the non-reserved (cannot be a function or type) keywords cannot be directly used as column aliases, either.
3. The reserved keyword `CURRENT_TIMESTAMP` without double quotation marks (""") cannot be used as a function name.

---

## Identifier Naming Conventions

Identifier naming must comply with the following rules:

- An identifier name can only contain letters, digits, underscores (`_`), and dollar signs (`$`).
- An identifier name must start with a letter or an underscore (`_`).

### NOTE

- The naming rules are recommended but not required.
- In special cases, double quotation marks (") can be used to avoid special character errors.

## SQL Keywords

**Table 7-1** SQL keywords

| Keyword   | GaussDB      | SQL:1999     | SQL-92       |
|-----------|--------------|--------------|--------------|
| ABORT     | Non-reserved | N/A          | N/A          |
| ABS       | N/A          | Non-reserved | N/A          |
| ABSOLUTE  | Non-reserved | Reserved     | Reserved     |
| ACCESS    | Non-reserved | N/A          | N/A          |
| ACCOUNT   | Non-reserved | N/A          | N/A          |
| ACTION    | Non-reserved | Reserved     | Reserved     |
| ADA       | N/A          | Non-reserved | Non-reserved |
| ADD       | Non-reserved | Reserved     | Reserved     |
| ADMIN     | Non-reserved | Reserved     | N/A          |
| AFTER     | Non-reserved | Reserved     | N/A          |
| AGGREGATE | Non-reserved | Reserved     | N/A          |
| ALGORITHM | Non-reserved | N/A          | N/A          |
| ALIAS     | N/A          | Reserved     | N/A          |

## 7.3 Data Type

Data type is a basic attribute of data that used to distinguish different types of data. Different data types occupy different storage space and support different operations. Data is stored in data tables in the database. Each column of a data table specifies a data type and data must be stored according to data types.

GaussDB supports implicit conversions between certain data types. For details, see [PG\\_CAST](#).

### 7.3.1 Numeric Types

[Table 7-2](#) lists all available types. For arithmetic operators and related built-in functions, see [Arithmetic Functions and Operators](#).

**Table 7-2** Integer types

| Name     | Description                     | Storage Space | Range              |
|----------|---------------------------------|---------------|--------------------|
| TINYINT  | Tiny integer, also called INT1  | 1 byte        | 0 ~ +255           |
| SMALLINT | Small integer, also called INT2 | 2 bytes       | -32,768 to +32,767 |

| Name           | Description                                        | Storage Space | Range                                                                                                       |
|----------------|----------------------------------------------------|---------------|-------------------------------------------------------------------------------------------------------------|
| INTEGER        | Typical choice for integers, also called INT4      | 4 bytes       | -2,147,483,648 to +2,147,483,647                                                                            |
| BINARY_INTEGER | Alias of INTEGER.                                  | 4 bytes       | -2,147,483,648 to +2,147,483,647                                                                            |
| BIGINT         | Big integer, also called INT8                      | 8 bytes       | -9,223,372,036,854,775,808 to +9,223,372,036,854,775,807                                                    |
| int16          | A 16-byte integer cannot be used to create tables. | 16 bytes      | -170,141,183,460,469,231,731,687,303,715,884,105,728 ~ +170,141,183,460,469,231,731,687,303,715,884,105,727 |

Example:

```
-- Create a table containing TINYINT data.
gaussdb=# CREATE TABLE int_type_t1
(
 IT_COL1 TINYINT
);

-- Insert data.
gaussdb=# INSERT INTO int_type_t1 VALUES(10);

-- View data.
gaussdb=# SELECT * FROM int_type_t1;
it_col1

10
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE int_type_t1;
-- Create a table containing TINYINT, INTEGER, and BIGINT data.
gaussdb=# CREATE TABLE int_type_t2
(
 a TINYINT,
 b TINYINT,
 c INTEGER,
 d BIGINT
);

-- Insert data.
gaussdb=# INSERT INTO int_type_t2 VALUES(100, 10, 1000, 10000);

-- View data.
gaussdb=# SELECT * FROM int_type_t2;
 a | b | c | d
-----+-----+-----+-----
100 | 10 | 1000 | 10000
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE int_type_t2;
```

 **NOTE**

- Numbers of the TINYINT, SMALLINT, INTEGER, BIGINT, or INT16 type, that is, integers can be stored. Saving a number with a decimal in any of the data types will result in errors.
- The INTEGER type is the common choice, as it offers the best balance between range, storage size, and performance. Generally, use the SMALLINT type only if you are sure that the value range is within the SMALLINT value range. The storage speed of INTEGER is much faster. BIGINT is used only when the range of INTEGER is not large enough.

**Table 7-3** Arbitrary precision types

| Name                                  | Description                                                                                                                                                                         | Storage Space                                                                                                                                  | Range                                                                                                                          |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| NUMERIC[(p[,s])],<br>DECIMAL[(p[,s])] | The value range of <b>p</b> is [1,1000], and the value range of <b>s</b> is [0,p].<br><b>NOTE</b><br><b>p</b> indicates the total digits, and <b>s</b> indicates the decimal digit. | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified. |
| NUMBER[(p[,s])]                       | Alias of the NUMERIC type.                                                                                                                                                          | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified. |

**Example:**

```
-- Create a table.
gaussdb=# CREATE TABLE decimal_type_t1
(
 DT_COL1 DECIMAL(10,4)
);

-- Insert data.
gaussdb=# INSERT INTO decimal_type_t1 VALUES(123456.122331);

-- Query data in the table.
gaussdb=# SELECT * FROM decimal_type_t1;
 dt_col1

123456.1223
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE decimal_type_t1;
-- Create a table.
gaussdb=# CREATE TABLE numeric_type_t1
(
 NT_COL1 NUMERIC(10,4)
);
```

```
-- Insert data.
gaussdb=# INSERT INTO numeric_type_t1 VALUES(123456.12354);

-- Query data in the table.
gaussdb=# SELECT * FROM numeric_type_t1;
 nt_col1

123456.1235
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE numeric_type_t1;
```

 **NOTE**

- Compared to the integer types, the arbitrary precision numbers require larger storage space and have lower storage efficiency, operation efficiency, and poorer compression ratio results. The INTEGER type is the common choice when number types are defined. Arbitrary precision numbers are used when numbers exceed the maximum range indicated by the integers.
- When NUMERIC/DECIMAL is used for defining a column, you are advised to specify the precision (p) and scale (s) for the column.

**Table 7-4** Sequence integer

| Name        | Description               | Storage Space | Range                                                     |
|-------------|---------------------------|---------------|-----------------------------------------------------------|
| SMALLSERIAL | Two-byte serial integer   | 2 bytes.      | -32,768 to +32,767.                                       |
| SERIAL      | Four-byte serial integer  | 4 bytes.      | -2,147,483,648 to +2,147,483,647.                         |
| BIGSERIAL   | Eight-byte serial integer | 8 bytes.      | -9,223,372,036,854,775,808 to +9,223,372,036,854,775,807. |

**Example:**

```
-- Create a table.
gaussdb=# CREATE TABLE smallserial_type_tab(a SMALLSERIAL);

-- Insert data.
gaussdb=# INSERT INTO smallserial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO smallserial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM smallserial_type_tab;
 a

 1
 2
(2 rows)

-- Create a table.
gaussdb=# CREATE TABLE serial_type_tab(b SERIAL);

-- Insert data.
gaussdb=# INSERT INTO serial_type_tab VALUES(default);
```

```

-- Insert data again.
gaussdb=# INSERT INTO serial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM serial_type_tab;
 b

 1
 2
(2 rows)

-- Create a table.
gaussdb=# CREATE TABLE bigserial_type_tab(c BIGSERIAL);

-- Insert data.
gaussdb=# INSERT INTO bigserial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO bigserial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM bigserial_type_tab;
 c

 1
 2
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE smallserial_type_tab;

gaussdb=# DROP TABLE serial_type_tab;

gaussdb=# DROP TABLE bigserial_type_tab;

```

 **NOTE**

SMALLSERIAL, SERIAL, and BIGSERIAL are not real types. They are concepts used for setting a unique identifier for a table. Therefore, an integer column is created and its default value plans to be read from a sequencer. A NOT NULL constraint is used to ensure NULL is not inserted. In most cases you would also want to attach an **UNIQUE** or **PRIMARY KEY** constraint to prevent duplicate values from being inserted unexpectedly, but this is not automatic. Finally, the sequencer belongs to the column. In this case, when the column or the table is deleted, the sequencer is also deleted. Currently, the **SERIAL** column can be specified only when you create a table. You cannot add the **SERIAL** column in an existing table. In addition, **SERIAL** columns cannot be created in temporary tables. Because SERIAL is not a data type, columns cannot be converted to this type.

**Table 7-5** Floating-point types

| Name                               | Description                                                  | Storage Space | Range                                            |
|------------------------------------|--------------------------------------------------------------|---------------|--------------------------------------------------|
| REAL,<br>FLOAT4                    | Single precision floating points, which is not very precise. | 4 bytes.      | -3.402E+38 to +3.402E+38, 6-bit decimal digits.  |
| DOUBLE<br>PRECISION<br>,<br>FLOAT8 | Double precision floating points, which is not very precise. | 8 bytes.      | -1.79E+308 to +1.79E+308, 15-bit decimal digits. |

| Name             | Description                                                                                                                                                                                                                                                                                                                                                          | Storage Space                                                                                                                                  | Range                                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FLOAT[(p)]       | <p>Floating-point number, which is not very precise. The value range of precision (p) is [1,53].</p> <p><b>NOTE</b><br/>p is the precision, indicating the total number of binary bits.</p>                                                                                                                                                                          | 4 bytes or 8 bytes.                                                                                                                            | <b>REAL</b> or <b>DOUBLE PRECISION</b> is selected as an internal identifier based on precision (p). If no precision is specified, <b>DOUBLE PRECISION</b> is used as the internal identifier.                                                                           |
| BINARY_DOUBLE    | DOUBLE PRECISION alias, compatible with Oracle.                                                                                                                                                                                                                                                                                                                      | 8 bytes.                                                                                                                                       | -1.79E+308 to +1.79E+308, 15-bit decimal digits.                                                                                                                                                                                                                         |
| DEC[(p[,s])]     | <p>The value range of p (precision) is [1,1000], and the value range of s (scale) is [0,p].</p> <p><b>NOTE</b><br/>p indicates the total digits, and s indicates the decimal digit.</p>                                                                                                                                                                              | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.                                                                                                                     |
| INTEGER[(p[,s])] | <p>The value range of p is [1,1000], and the value range of s is [0,p].</p> <p>If the precision and scale are not specified, the precision p is <b>10</b> and the scale s is <b>0</b> by default.</p> <p>If the precision and scale are not specified, this type is mapped to INTEGER. If the precision and scale are specified, this type is mapped to NUMERIC.</p> | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | <p>Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.</p> <p>If the precision and scale are not specified, the value ranges from -2,147,483,648 to +2,147,483,647.</p> |

 NOTE

- For the precision of the floating-point type, only the number of precision bits can be ensured when the data is directly read. When distributed computing is involved, the computation is executed on each DN and is finally aggregated to a CN. Therefore, the error may be amplified as the number of compute nodes increases.
- In [Table 7-5](#), **p** is the precision, indicating the minimum acceptable total number of integral places, and **s** indicates the decimal digit.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE float_type_t2
(
 FT_COL1 INTEGER,
 FT_COL2 FLOAT4,
 FT_COL3 FLOAT8,
 FT_COL4 FLOAT(3),
 FT_COL5 BINARY_DOUBLE,
 FT_COL6 DECIMAL(10,4),
 FT_COL7 INTEGER(6,3)
)DISTRIBUTE BY HASH (ft_col1);

-- Insert data.
gaussdb=# INSERT INTO float_type_t2 VALUES(10,10.365456,123456.1234,10.3214, 321.321, 123.123654,
123.123654);

-- View data.
gaussdb=# SELECT * FROM float_type_t2 ;
ft_col1 | ft_col2 | ft_col3 | ft_col4 | ft_col5 | ft_col6 | ft_col7
-----+-----+-----+-----+-----+-----+-----
 10 | 10.3655 | 123456.1234 | 10.3214 | 321.321 | 123.1237 | 123.124
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE float_type_t2;
```

### 7.3.2 Monetary Types

The money type stores a currency amount with fixed fractional precision.

The range shown in [Table 7-6](#) assumes there are two fractional digits. Input is accepted in a variety of formats, including integer and floating-point literals, as well as typical currency formatting, such as "\$1,000.00". Output is generally in the last format but depends on the locale.

**Table 7-6** Monetary type

| Name  | Description     | Storage Space | Range                                         |
|-------|-----------------|---------------|-----------------------------------------------|
| money | Currency amount | 8 bytes       | -92233720368547758.08 ~ +92233720368547758.07 |

Values of the numeric, int, and bigint data types can be cast to money. Conversion from the real or double precision data type to a money value can be done by casting to numeric type first, for example:

```
gaussdb=# SELECT '12.34'::float8::numeric::money;
money

$12.34
(1 row)
```

However, this is not recommended. Floating point numbers should not be used to handle money due to the potential for rounding errors.

A money value can be cast to numeric without loss of precision. Conversion to other types could potentially lose precision, and must also be done in two stages:

```
gaussdb=# SELECT '52093.89'::money::numeric::float8;
float8

52093.89
(1 row)
```

When a money value is divided by another money value, the result is of the double precision type (that is, the digit type instead of the money type); the currency units cancel each other out in the division.

### 7.3.3 Boolean Types

[Table 7-7](#) lists the Boolean types supported by GaussDB.

**Table 7-7** Boolean type

| Name    | Description | Storage Space | Value                                                                                                                   |
|---------|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------|
| BOOLEAN | Boolean     | 1 byte        | <ul style="list-style-type: none"> <li>• <b>true</b></li> <li>• <b>false</b></li> <li>• <b>null</b>: unknown</li> </ul> |

- Valid literal values for the "true" state include:  
**TRUE**, **t**, **'true'**, **'y'**, **'yes'**, **'1'**, **'TRUE'**, **true**, **on**, and all non-zero values.
- Valid literal values for the "false" state include:  
**FALSE**, **'f'**, **'false'**, **'n'**, **'no'**, **'0'**, **0**, **'FALSE'**, **false**, and **off**.

**TRUE** and **FALSE** are standard expressions, compatible with SQL statements.

### Examples

Boolean values are displayed using the letters t and f.

```
-- Create a table.
gaussdb=# CREATE TABLE bool_type_t1
(
 BT_COL1 BOOLEAN,
 BT_COL2 TEXT
)DISTRIBUTE BY HASH(BT_COL2);

-- Insert data.
gaussdb=# INSERT INTO bool_type_t1 VALUES (TRUE, 'sic est');

gaussdb=# INSERT INTO bool_type_t1 VALUES (FALSE, 'non est');
```

```
-- View data.
gaussdb=# SELECT * FROM bool_type_t1;
 bt_col1 | bt_col2
-----+-----
 t | sic est
 f | non est
(2 rows)

gaussdb=# SELECT * FROM bool_type_t1 WHERE bt_col1 = 't';
 bt_col1 | bt_col2
-----+-----
 t | sic est
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE bool_type_t1;
```

### 7.3.4 Character Types

**Table 7-8** lists the character data types supported by GaussDB. For string operators and related built-in functions, see [Character Processing Functions and Operators](#).

**Table 7-8** Character types

| Name                                | Description                                                                                                                                                    | Storage Space                                                                                                                                                                                                                                                                                    |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CHAR(n)<br>CHARACTER(n)<br>NCHAR(n) | Fixed-length character string, blank padded. <b>n</b> indicates the string length. If it is not specified, the default precision <b>1</b> is used.             | The maximum value of <b>n</b> is <b>10485760</b> (10 MB).                                                                                                                                                                                                                                        |
| VARCHAR(n)<br>CHARACTER VARYING(n)  | Variable-length string. In PostgreSQL-compatible mode, <b>n</b> indicates the string length. In other compatibility modes, <b>n</b> indicates the byte length. | The maximum value of <b>n</b> is <b>10485760</b> (10 MB).<br><br>If <b>n</b> is not specified, the maximum storage length is 1 GB – 85 bytes – Length of the first <i>n</i> columns. For example, the maximum length of (a int, b varchar) is 1,073,741,735 bytes (= 1 GB – 85 bytes – 4 bytes). |

| Name         | Description                                                                                           | Storage Space                                                                                                                                                                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VARCHAR2(n)  | Variable-length string. It is the alias of the VARCHAR(n) type. <b>n</b> indicates the string length. | <p>The maximum value of <b>n</b> is <b>10485760</b> (10 MB).</p> <p>If <b>n</b> is not specified, the maximum storage length is 1 GB – 85 bytes – Length of the first <i>n</i> columns. For example, the maximum length of (a int, b varchar) is 1,073,741,735 bytes (= 1 GB – 85 bytes – 4 bytes).</p> |
| NVARCHAR2(n) | Variable-length string. <b>n</b> indicates the string length.                                         | <p>The maximum value of <b>n</b> is <b>10485760</b> (10 MB).</p> <p>If <b>n</b> is not specified, the maximum storage length is 1 GB – 85 bytes – Length of the first <i>n</i> columns. For example, the maximum length of (a int, b varchar) is 1,073,741,735 bytes (= 1 GB – 85 bytes – 4 bytes).</p> |

| Name | Description      | Storage Space                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLOB | Big text object. | <p>For Astore, the maximum size is 32 TB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 32 TB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the CLOB type may be less than 32 TB minus 1 byte.</p> <p>For Ustore, the maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the CLOB type may be less than 1 GB minus 1 byte.</p> |

| Name | Description             | Storage Space                                                                                                                                                                                                                                                                           |
|------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TEXT | Variable-length string. | The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the TEXT type may be less than 1 GB minus 1 byte. |

 **NOTE**

1. In addition to the restriction on the size of each column, the total size of each tuple cannot exceed 1 GB minus 85 bytes and is affected by the control header information of the column, the control header information of the tuple, and whether null fields exist in the tuple.
2. NCHAR is the alias of the bpchar type, and VARCHAR2(n) is the alias of the VARCHAR(n) type.
3. Only advanced package db\_lob supports CLOBs whose size is greater than 1 GB. System functions do not support CLOBs whose size is greater than 1 GB.
4. In ORA-compatible mode, the received empty string is converted to null by default.
5. GaussDB supports a maximum of 1 GB data transfer, and the maximum size of the result string returned by the function is 1 GB.

GaussDB has two other fixed-length character types, as shown in [Table 7-9](#). The **name** type exists only for the storage of identifiers in the internal system catalogs and is not intended for use by general users. Its length is currently defined as 64 bytes (63 usable characters plus terminator). The type "**char**" only uses one byte of storage. It is internally used in the system catalogs as a simplistic enumeration type.

**Table 7-9** Special character types

| Name   | Description                    | Storage Space |
|--------|--------------------------------|---------------|
| name   | Internal type for object names | 64 bytes      |
| "char" | Single-byte internal type      | 1 byte        |

## Examples

```
-- Create a table.
gaussdb=# CREATE TABLE char_type_t1
(
 CT_COL1 CHARACTER(4)
)DISTRIBUTE BY HASH (CT_COL1);

-- Insert data.
gaussdb=# INSERT INTO char_type_t1 VALUES ('ok');

-- Query data in the table.
gaussdb=# SELECT ct_col1, char_length(ct_col1) FROM char_type_t1;
 ct_col1 | char_length
-----+-----
ok | 4
(1 row)

-- Delete the table.
gaussdb=# DROP TABLE char_type_t1;
-- Create a table.
gaussdb=# CREATE TABLE char_type_t2
(
 CT_COL1 VARCHAR(5)
)DISTRIBUTE BY HASH (CT_COL1);

-- Insert data.
gaussdb=# INSERT INTO char_type_t2 VALUES ('ok');

gaussdb=# INSERT INTO char_type_t2 VALUES ('good');

-- Specify the type length. An error is reported if an inserted string exceeds this length.
gaussdb=# INSERT INTO char_type_t2 VALUES ('too long');
ERROR: value too long for type character varying(5)
CONTEXT: referenced column: ct_col1

-- Specify the type length. A string exceeding this length is truncated.
gaussdb=# INSERT INTO char_type_t2 VALUES ('too long'::varchar(5));

-- Query data.
gaussdb=# SELECT ct_col1, char_length(ct_col1) FROM char_type_t2;
 ct_col1 | char_length
-----+-----
ok | 2
good | 4
too l | 5
(3 rows)

-- Delete data.
gaussdb=# DROP TABLE char_type_t2;
```

## 7.3.5 Binary Types

**Table 7-10** lists the binary types supported by GaussDB.

**Table 7-10** Binary types

| Name  | Description                                                                                                                                                                                                                                                                                                                                                                       | Storage Space                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BLOB  | <p>Binary large object (BLOB).<br/>Currently, BLOB only supports the following external access APIs:</p> <ul style="list-style-type: none"> <li>• DBE_LOB.GET_LENGTH</li> <li>• DBE_LOB.READ</li> <li>• DBE_LOB.WRITE</li> <li>• DBE_LOB.WRITE_APPEND</li> <li>• DBE_LOB.COPY</li> <li>• DBE_LOB.ERASE</li> </ul> <p>For details about the APIs, see <a href="#">DBE_LOB</a>.</p> | <p>For Astore, the maximum size is 32 TB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 32 TB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the BLOB type may be less than 32 TB minus 1 byte.</p> <p>For Ustore, the maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the BLOB type may be less than 1 GB minus 1 byte.</p> |
| RAW   | Variable-length hexadecimal string.                                                                                                                                                                                                                                                                                                                                               | <p>4 bytes plus the actual binary string. The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of this type may be less than 1 GB minus 1 byte.</p>                                                                                                                                                                                                                                                                                        |
| BYTEA | Variable-length binary string.                                                                                                                                                                                                                                                                                                                                                    | <p>4 bytes plus the actual binary string. The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of this type may be less than 1 GB minus 1 byte.</p>                                                                                                                                                                                                                                                                                        |

| Name                            | Description                                                                                                                                                                                                                                                                                                                   | Storage Space                                                                                          |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| BYTEAWITHOUTORDERWITH EQUALCOL  | Variable-length binary character string (new type for the encryption feature. If the encryption type of an encrypted column is specified as deterministic encryption, the column type is BYTEAWITHOUTORDERWITH EQUALCOL). The original data type is displayed when an encrypted table is printed by running the meta command. | 4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes). |
| BYTEAWITHOUTORDERCOL            | Variable-length binary character string (new type for the encryption feature. If the encryption type of the encrypted column is specified as random encryption, the column type is BYTEAWITHOUTORDERCOL). The original data type is displayed when the encryption table is printed by running the meta command.               | 4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes). |
| _BYTEAWITHOUTORDERWITH EQUALCOL | Variable-length binary string, which is a new type for the encryption feature.                                                                                                                                                                                                                                                | 4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes). |
| _BYTEAWITHOUTORDERCOL           | Variable-length binary string, which is a new type for the encryption feature.                                                                                                                                                                                                                                                | 4 bytes plus the actual binary string. The maximum value is 1073741771 bytes (1 GB – 53 bytes).        |

 **NOTE**

- In addition to the size limitation on each column, the total size of each tuple is 1,073,741,823 bytes (1 GB minus 1 bytes).
- BYTEAWITHOUTORDERWITH EQUALCOL, BYTEAWITHOUTORDERCOL, \_BYTEAWITHOUTORDERWITH EQUALCOL, and \_BYTEAWITHOUTORDERCOL cannot be directly used to create a table.
- RAW(*n*), where *n* indicates the recommended byte length and is not used to verify the byte length of the input raw type.
- GaussDB supports a maximum of 1 GB data transfer, and the maximum size of the result string returned by the function is 1 GB.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE blob_type_t1
(
 BT_COL1 INTEGER,
 BT_COL2 BLOB,
 BT_COL3 RAW,
 BT_COL4 BYTEA
) DISTRIBUTE BY REPLICATION;

-- Insert data.
gaussdb=# INSERT INTO blob_type_t1 VALUES(10,empty_blob(),
HEXTORAW('DEADBEEF'),E'\xDEADBEEF');

-- Query data in the table.
gaussdb=# SELECT * FROM blob_type_t1;
bt_col1 | bt_col2 | bt_col3 | bt_col4
-----+-----+-----+-----
 10 | | DEADBEEF | \xdeadbeef
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE blob_type_t1;
```

### 7.3.6 Date/Time Types

**Table 7-11** lists the date/time types that can be used in GaussDB. For the operators and built-in functions of the types, see [Date and Time Processing Functions and Operators](#).

 **NOTE**

If the time format of another database is different from that of GaussDB, modify the value of the **DateStyle** parameter to keep them consistent.

**Table 7-11** Date/Time types

| Name                           | Description                                                                                                                                                                                                                                                                                                                            | Storage Space                            |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| DATE                           | Date. <ul style="list-style-type: none"> <li>• Minimum value: <b>4713-01-01BC</b> (4713 B.C.).</li> <li>• Maximum value: <b>5874897-12-31AD</b> (5874897 A.C.)</li> </ul> <b>NOTE</b><br>For ORA compatibility, the database treats empty strings as <b>NULL</b> and replaces <b>DATE</b> with <b>TIMESTAMP(0) WITHOUT TIME ZONE</b> . | 4 bytes (8 bytes in ORA-compatible mode) |
| TIME [(p)] [WITHOUT TIME ZONE] | Time within one day. <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <ul style="list-style-type: none"> <li>• Minimum value: <b>00:00:00</b>.</li> <li>• Maximum value: <b>24:00:00</b>.</li> </ul>                                                                       | 8 bytes                                  |

| Name                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Storage Space |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| TIME [(p)] [WITH TIME ZONE]        | <p>Time within one day (with time zone).</p> <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <ul style="list-style-type: none"> <li>• Minimum value: <b>00:00:00+1559</b>.</li> <li>• Maximum value: <b>24:00:00</b>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 12 bytes      |
| TIMESTAMP[(p)] [WITHOUT TIME ZONE] | <p>Date and time.</p> <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <ul style="list-style-type: none"> <li>• Minimum value: <b>4713-11-24BC 00:00:00.000000</b> (4713 B.C.).</li> <li>• Maximum value: <b>294277-01-09 AD 00:00:00.000000</b> (294277 A.D.).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | 8 bytes       |
| TIMESTAMP[(p)] [WITH TIME ZONE]    | <p>Date and time (with time zone). <b>TIMESTAMP</b> is also called <b>TIMESTAMPTZ</b>.</p> <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <ul style="list-style-type: none"> <li>• Minimum value: <b>4713-11-24BC 00:00:00.000000</b> (4713 B.C.).</li> <li>• Maximum value: <b>294277-01-09 AD 00:00:00.000000</b> (294277 A.D.).</li> </ul> <p>Time zone update: In some countries or regions, the time zone information is frequently updated due to political, economic, and war factors. Therefore, the database system needs to modify the time zone file to ensure that the time is correct.</p> <p>Currently, the GaussDB time zone type involves only timestamp with timezone. When a new time zone file takes effect, the existing data is not changed, and the new data is adjusted based on the time zone file information.</p> | 8 bytes       |

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Storage Space |

The value ranges from 0 to 6. <b>p</b> takes effect only when <b>FIELDS</b> is set to <b>SECOND, DAY TO SECOND, HOUR TO SECOND, or MINUTE TO SECOND.</b> The digit 0 at the end of a decimal number is not displayed.</li> </ul> | 12 bytes      |
| reltime                        | <p>Relative time interval.</p> <ul style="list-style-type: none"> <li>• The format is as follows: <i>X</i> years <i>X</i> mons <i>X</i> days <i>XX</i>:<i>XX</i>:<i>XX</i>.</li> <li>• The Julian calendar is used. It specifies that a year has 365.25 days and a month has 30 days. The relative time interval needs to be calculated based on the input value.</li> </ul>                                                                                                                                           | 4 bytes       |

| Name    | Description                                                                                                                                                                                                                  | Storage Space |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| abstime | <p>Date and time.</p> <ul style="list-style-type: none"> <li>Format: YYYY-MM-DD hh:mm:ss +timezone.</li> <li>The value range is from 1901-12-13 20:45:53 GMT to 2038-01-18 23:59:59 GMT. The precision is second.</li> </ul> | 4 bytes       |

 **NOTE**

1. The data of the time type automatically ignores all zeros at the end of the data when it is displayed.
2. The default value of **p** is **6**.
3. For the INTERVAL type, the date and time are stored in the int32 and double types in the system. Therefore, the value ranges of the two types are the same as those of the corresponding data type.
4. If the insertion time is out of the range, the system may not report an error, but may not ensure that the operation is normal.

 **NOTE**

If the values of **a\_format\_version** and **a\_format\_dev\_version** are **10c** and **s1**, the default DATE value is determined by the following:

- Year: returned through SYSDATE
- Month: returned through SYSDATE
- Day: 01 (first day of the month)
- Hour, minute, and second: all 0

**Example:**

```
-- Create a table.
gaussdb=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
 coll

2010-12-10
(1 row)

-- Delete a table.
gaussdb=# DROP TABLE date_type_tab;

-- Create a table.
gaussdb=# CREATE TABLE time_type_tab (da time without time zone ,dai time with time zone,dfgh
timestamp without time zone,dfga timestamp with time zone, vbg smalldatetime);

-- Insert data.
gaussdb=# INSERT INTO time_type_tab VALUES ('21:21:21','21:21:21 pst','2010-12-12','2013-12-11
pst','2003-04-12 04:05:06');

-- View data.
gaussdb=# SELECT * FROM time_type_tab;
```

```

-----+-----+-----+-----+-----
21:21:21 | 21:21:21-08 | 2010-12-12 00:00:00 | 2013-12-11 16:00:00+08 | 2003-04-12 04:05:00
(1 row)

-- Delete a table.
gaussdb=# DROP TABLE time_type_tab;

-- Create a table.
gaussdb=# CREATE TABLE day_type_tab (a int,b INTERVAL DAY(3) TO SECOND (4));

-- Insert data.
gaussdb=# INSERT INTO day_type_tab VALUES (1, INTERVAL '3' DAY);

-- View data.
gaussdb=# SELECT * FROM day_type_tab;
a | b
---+-----
1 | 3 days
(1 row)

-- Delete a table.
gaussdb=# DROP TABLE day_type_tab;

-- Create a table.
gaussdb=# CREATE TABLE year_type_tab(a int, b interval year (6));

-- Insert data.
gaussdb=# INSERT INTO year_type_tab VALUES(1,interval '2' year);

-- View data.
gaussdb=# SELECT * FROM year_type_tab;
a | b
---+-----
1 | 2 years
(1 row)

gaussdb=# SELECT TIME 'allballs';
time

00:00:00
(1 row)

-- Delete a table.
gaussdb=# DROP TABLE year_type_tab;
```

## Date Input

Date and time input is accepted in almost any reasonable formats, including ISO 8601, SQL-compatible, and traditional Postgres. The system allows you to customize the sequence of day, month, and year in the date input. Set the **DateStyle** parameter to **MDY** to select month-day-year interpretation, **DMY** to select day-month-year interpretation, or **YMD** to select year-month-day interpretation.

Remember that any date or time literal input needs to be enclosed with single quotation marks ('), and the syntax is as follows:

```
type [(p)] 'value'
```

The **p** that can be selected in the precision statement is an integer, indicating the number of fractional digits in the **seconds** column. [Table 7-12](#) shows the input formats of the date type.

**Table 7-12** Date input formats

| Example          | Description                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1999-01-08       | ISO 8601 (recommended format). January 8, 1999 in any format.                                                                                                      |
| January 8, 1999  | Unambiguous in any <b>datestyle</b> input mode.                                                                                                                    |
| 1/8/1999         | January 8 in MDY mode and August 1 in DMY format.                                                                                                                  |
| 1/18/1999        | January 18 in MDY format, rejected in other formats.                                                                                                               |
| 01/02/03         | <ul style="list-style-type: none"> <li>January 2, 2003 in MDY format.</li> <li>February 1, 2003 in DMY format.</li> <li>February 3, 2001 in YMD format.</li> </ul> |
| 1999-Jan-08      | January 8 in any format.                                                                                                                                           |
| Jan-08-1999      | January 8 in any format.                                                                                                                                           |
| 08-Jan-1999      | January 8 in any format.                                                                                                                                           |
| 99-Jan-08        | January 8 in YMD format, else error.                                                                                                                               |
| 08-Jan-99        | January 8, except error in YMD format.                                                                                                                             |
| Jan-08-99        | January 8, except error in YMD format.                                                                                                                             |

| 990108           | ISO 8601. January 8, 1999 in any format.                                                                                                                           |
| 1999.008         | Year and day of year.                                                                                                                                              |
| J2451187         | Julian date.                                                                                                                                                       |
| January 8, 99 BC | Year 99 B.C.                                                                                                                                                       |

**Example:**

```

-- Create a table.
gaussdb=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
 coll

2010-12-10
(1 row)

-- View the date format.
gaussdb=# SHOW datestyle;
DateStyle

ISO, MDY
(1 row)

```

```

-- Set the date format.
gaussdb=# SET datestyle='YMD';
SET

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES(date '2010-12-11');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
 coll

2010-12-10
2010-12-11
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE date_type_tab;

```

## Time

The time-of-day types are **TIME [(p)] [WITHOUT TIME ZONE]** and **TIME [(p)] [WITH TIME ZONE]**. **TIME** alone is equivalent to **TIME WITHOUT TIME ZONE**.

If a time zone is specified in the input for **TIME WITHOUT TIME ZONE**, it is silently ignored.

For details about the time input types, see [Table 7-13](#). For details about time zone input types, see [Table 7-14](#).

**Table 7-13** Time input types

| Example                              | Description                                                  |
|--------------------------------------|--------------------------------------------------------------|
| 05:06.8                              | ISO 8601                                                     |
| 4:05:06                              | ISO 8601                                                     |
| 4:05                                 | ISO 8601                                                     |
| 040506                               | ISO 8601                                                     |
| 4:05 AM                              | Same as 04:05. Input hours must be less than or equal to 12. |
| 4:05 PM                              | Same as 16:05. Input hours must be less than or equal to 12. |
| 04:05:06.789-8                       | ISO 8601                                                     |
| 04:05:06-08:00                       | ISO 8601                                                     |
| 04:05-08:00                          | ISO 8601                                                     |
| 040506-08                            | ISO 8601                                                     |
| 04:05:06 PST                         | Time zone specified by abbreviation                          |
| 2003-04-12 04:05:06 America/New_York | Time zone specified by full name                             |

**Table 7-14** Time zone input types

| Example          | Description                              |
|------------------|------------------------------------------|
| PST              | Abbreviation (for Pacific Standard Time) |
| America/New_York | Full time zone name                      |
| -8:00            | ISO-8601 offset for PST                  |
| -800             | ISO-8601 offset for PST                  |
| -8               | ISO-8601 offset for PST                  |

Example:

```
gaussdb=# SELECT time '04:05:06';
time

04:05:06
(1 row)

gaussdb=# SELECT time '04:05:06 PST';
time

04:05:06
(1 row)

gaussdb=# SELECT time with time zone '04:05:06 PST';
timetz

04:05:06-08
(1 row)
```

## Special Values

The special values supported by GaussDB are converted to common date/time values when being read. For details, see [Table 7-15](#).

**Table 7-15** Special values

| Input String | Applicable Type           | Description                                    |
|--------------|---------------------------|------------------------------------------------|
| epoch        | date and timestamp        | 1970-01-01 00:00:00+00 (Unix system time zero) |
| infinity     | timestamp                 | Later than any other timestamps                |
| -infinity    | timestamp                 | Earlier than any other timestamps              |
| now          | date, time, and timestamp | Start time of the current transaction          |
| today        | date and timestamp        | Midnight today                                 |
| tomorrow     | date and timestamp        | Midnight tomorrow                              |
| yesterday    | date and timestamp        | Midnight yesterday                             |

| Input String | Applicable Type | Description     |
|--------------|-----------------|-----------------|
| allballs     | time            | 00:00:00.00 UTC |

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE realtime_type_special(col1 varchar(20), col2 date, col3 timestamp, col4 time);

-- Insert data.
gaussdb=# INSERT INTO realtime_type_special VALUES('epoch', 'epoch', 'epoch', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('now', 'now', 'now', 'now');
gaussdb=# INSERT INTO realtime_type_special VALUES('today', 'today', 'today', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('tomorrow', 'tomorrow', 'tomorrow', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('yesterday', 'yesterday', 'yesterday', NULL);

-- View data.
gaussdb=# SELECT * FROM realtime_type_special;

## Interval Input

The input of **reltime** can be any valid interval in text format. It can be a number (negative numbers and decimals are also allowed) or a specific time, which must be in SQL standard format, ISO-8601 format, or POSTGRES format. In addition, the text input needs to be enclosed with single quotation marks (").

For details about interval input, see [Table 7-16](#).

**Table 7-16** Interval input

| Input                          | Output                              | Description                                                                                                                                                                        |
|--------------------------------|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 60                             | 2 mons                              | Numbers are used to indicate intervals. The default unit is day. Decimals and negative numbers are allowed. Particularly, a negative interval syntactically means how long before. |
| 31.25                          | 1 mons 1 days 06:00:00              |                                                                                                                                                                                    |

 -366 | -1 years -18:00:00
 1975.25 | 5 years 4 mons 29 days
-2 YEARS +5 MONTHS 10 DAYS | -1 years -6 mons -25 days -06:00:00
30 DAYS 12:00:00 | 1 mon 12:00:00
P-1.1Y10M | -3 mons -5 days -06:00:00
(6 rows)

-- Drop the table.
gaussdb=# DROP TABLE reltime_type_tab;

```

## 7.3.7 Geometric Types

**Table 7-17** lists the geometric types that can be used in GaussDB. The most fundamental type, the point, forms the basis for all of the other types.

**Table 7-17** Geometric types

| Name    | Storage Space          | Description                       | Representation                      |
|---------|------------------------|-----------------------------------|-------------------------------------|
| point   | 16 bytes               | Point on a plane                  | (x,y)                               |
| lseg    | 32 bytes               | Finite line segment               | ((x1,y1),(x2,y2))                   |
| box     | 32 bytes               | Rectangle                         | ((x1,y1),(x2,y2))                   |
| path    | 16 + 16 <i>n</i> bytes | Closed path (similar to polygon)  | ((x1,y1),...)                       |
| path    | 16 + 16 <i>n</i> bytes | Open path                         | [(x1,y1),...]                       |
| polygon | 40 + 16 <i>n</i> bytes | Polygon (similar to closed paths) | ((x1,y1),...)                       |
| circle  | 24 bytes               | Circle                            | <(x,y),r> (center point and radius) |

A rich set of functions and operators is available in GaussDB to perform various geometric operations, such as scaling, translation, rotation, and determining intersections. For details, see [Geometric Functions and Operators](#).

### Points

Points are the fundamental two-dimensional building block for geometric types. Values of the **point** type are specified using either of the following syntax:

```
(x , y)
x , y
```

**x** and **y** are the respective coordinates, as floating-point numbers. The value type of the points is float8.

Points are output using the first syntax.

Example:

```
gaussdb=# select point(1.1, 2.2);
point

(1.1,2.2)
(1 row)
```

## Line Segments

Line segments (**lseg**) are represented by pairs of points. Values of the **lseg** type are specified using any of the following syntaxes:

```
[(x1 , y1) , (x2 , y2)]
((x1 , y1) , (x2 , y2))
(x1 , y1) , (x2 , y2)
x1 , y1 , x2 , y2
```

**(x1,y1)** and **(x2,y2)** are the end points of the line segment. The value type of the points is float8.

Line segments are output using the first syntax.

Example:

```
gaussdb=# select lseg(point(1.1, 2.2), point(3.3, 4.4));
lseg

[(1.1,2.2),(3.3,4.4)]
(1 row)
```

## Rectangles

Rectangles are represented by pairs of points that are opposite corners of a rectangle. Values of the **box** type are specified using any of the following syntaxes:

```
((x1 , y1) , (x2 , y2))
(x1 , y1) , (x2 , y2)
x1 , y1 , x2 , y2
```

**(x1,y1)** and **(x2,y2)** are any two opposite corners of the rectangle. The value type of the points is float8.

Rectangles are output using the second syntax.

Any two opposite corners can be supplied on input, but in this order, the values will be reordered as needed to store the upper right and lower left corners.

Example:

```
gaussdb=# SELECT box(point(1.1, 2.2), point(3.3, 4.4));
box

(3.3,4.4),(1.1,2.2)
(1 row)
```

## Paths

Paths are represented by lists of connected points. Paths can be open, where the first and last points in the list are considered not connected, or closed, where the first and last points are considered connected.

Values of the **path** type are specified using any of the following syntaxes:

```
[(x1 , y1) , ... , (xn , yn)]
((x1 , y1) , ... , (xn , yn))
(x1 , y1) , ... , (xn , yn)
(x1 , y1 , ... , xn , yn)
x1 , y1 , ... , xn , yn
```

The points are the end points of the line segments comprising the path. The value type of the points is float8. Square brackets ([]) indicate an open path, while parentheses (()) indicate a closed path. When the outermost parentheses are omitted, as in the third through fifth syntax, a closed path is assumed.

Paths are output using the first or second syntax.

Example:

```
gaussdb=# select path(polygon '((0,0),(1,1),(2,0)'));
 path

((0,0),(1,1),(2,0))
(1 row)
```

## Polygons

Polygons are represented by lists of points (the vertexes of the polygon). Polygons are very similar to closed paths, but are stored differently and have their own set of support functions.

Values of the **polygon** type are specified using any of the following syntaxes:

```
((x1 , y1) , ... , (xn , yn))
(x1 , y1) , ... , (xn , yn)
(x1 , y1 , ... , xn , yn)
x1 , y1 , ... , xn , yn
```

A point indicates the vertex of a polygon. The value type of a point is float8.

Polygons are output using the first syntax.

Example:

```
gaussdb=# select polygon(box '((0,0),(1,1)'));
 polygon

((0,0),(0,1),(1,1),(1,0))
(1 row)
```

## Circles

Circles are represented by a center point and radius. Values of the **circle** type are specified using the following syntaxes:

```
< (x , y) , r >
((x , y) , r)
(x , y) , r
x , y , r
```

**(x,y)** is the center point and **r** is the radius of the circle. The value type of the points is float8.

Circles are output using the first syntax.

Example:

```
gaussdb=# select circle(point(0,0),1);
 circle

<(0,0),1>
(1 row)
```

## 7.3.8 Network Address Types

GaussDB offers data types to store IPv4 and MAC addresses.

It is better to use these types instead of plain text types to store network addresses, because these types offer input error checking and specialized operators and functions (see [Network Address Functions and Operators](#)).

**Table 7-18** Network address types

| Name    | Storage Space | Description             |
|---------|---------------|-------------------------|
| cidr    | 7 bytes       | IPv4 networks           |
| inet    | 7 bytes       | IPv4 hosts and networks |
| macaddr | 6 bytes       | MAC address             |

### cidr

The **cidr** type (Classless Inter-Domain Routing) holds an IPv4 network address. The format for specifying networks is **address/y** where **address** is the network represented as an IPv4 address, and **y** is the number of bits in the netmask. If **y** is omitted, it is calculated using assumptions from the older classful network numbering system, except it will be at least large enough to include all of the octets written in the input. For details, see [Table 7-19](#).

**Table 7-19** cidr type input examples

| cidr Input         | cidr Output        | abbrev(cidr)       |
|--------------------|--------------------|--------------------|
| 192.168.100.128/25 | 192.168.100.128/25 | 192.168.100.128/25 |
| 192.168/24         | 192.168.0.0/24     | 192.168.0/24       |
| 192.168/25         | 192.168.0.0/25     | 192.168.0.0/25     |
| 192.168.1          | 192.168.1.0/24     | 192.168.1/24       |
| 192.168            | 192.168.0.0/24     | 192.168.0/24       |
| 10.1.2             | 10.1.2.0/24        | 10.1.2/24          |

| cidr Input  | cidr Output | abbrev(cidr) |
|-------------|-------------|--------------|
| 10.1        | 10.1.0.0/16 | 10.1/16      |
| 10          | 10.0.0.0/8  | 10/8         |
| 10.1.2.3/32 | 10.1.2.3/32 | 10.1.2.3/32  |

## inet

The **inet** type holds an IPv4 host address, and optionally its subnet, all in one field. The subnet is represented by the number of network address bits present in the host address (the "netmask"). If the netmask is 32 and the address is an IPv4 address, then the value does not indicate a subnet, only a single host.

The input format for this type is **address/y** where **address** is an IPv4 address and **y** is the number of bits in the netmask. If the **/y** portion is omitted, the netmask is 32 for an IPv4 address, and the value represents just a single host. On display, the **/y** portion is suppressed if the netmask specifies a single host.

The essential difference between the **inet** and **cidr** data types is that **inet** accepts values with nonzero bits to the right of the netmask, whereas **cidr** does not.

## macaddr

The **macaddr** type stores MAC addresses, known for example from Ethernet card hardware addresses (although MAC addresses are used for other purposes as well). Input is accepted in the following formats:

```
'08:00:2b:01:02:03'
'08-00-2b-01-02-03'
'08002b:010203'
'08002b-010203'
'0800.2b01.0203'
'08002b010203'
```

These examples would all specify the same address. Upper and lower cases are accepted for the digits a through f. Output is always in the first of the forms shown.

## 7.3.9 Bit String Types

Bit strings are strings of 1's and 0's. They can be used to store bit masks.

GaussDB supports two bit string types: **bit(n)** and **bit varying(n)**. Here, *n* is a positive integer. The maximum value of *n* is **83886080**, which is equivalent to 10 MB.

The bit type data must match the length *n* exactly. An error will be reported if the data length of the storage is not matched. Data of the bit varying type is of variable length up to the maximum length *n*. Longer strings will be rejected. Writing **bit** without a length is equivalent to **bit(1)**, while **bit varying** without a length specification means unlimited length.

 NOTE

- If one explicitly casts a bit-string value to **bit(n)**, it will be truncated or zero-padded on the right to be exactly *n* bits, without raising an error.
- Similarly, if one explicitly casts a bit-string value to **bit varying(n)** and the value is more than *n* bits, it will be truncated on the right.
- When the ADMS platform driver version 8.1.3-200 or earlier is used, use **::bit varying** to convert the bit type. Otherwise, an error may occur.

```
-- Create a table.
gaussdb=# CREATE TABLE bit_type_t1
(
 BT_COL1 INTEGER,
 BT_COL2 BIT(3),
 BT_COL3 BIT VARYING(5)
) DISTRIBUTE BY REPLICATION;

-- Insert data.
gaussdb=# INSERT INTO bit_type_t1 VALUES(1, B'101', B'00');

-- Specify the type length. An error is reported if an inserted string exceeds this length.
gaussdb=# INSERT INTO bit_type_t1 VALUES(2, B'10', B'101');
ERROR: bit string length 2 does not match type bit(3)
CONTEXT: referenced column: bt_col2

-- Specify the type length. Data is converted if it exceeds this length.
gaussdb=# INSERT INTO bit_type_t1 VALUES(2, B'10'::bit(3), B'101');

-- View data.
gaussdb=# SELECT * FROM bit_type_t1;
 bt_col1 | bt_col2 | bt_col3
-----+-----+-----
 1 | 101 | 00
 2 | 100 | 101
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE bit_type_t1;
```

## 7.3.10 UUID Type

The data type UUID stores Universally Unique Identifiers (UUID) as defined by RFC 4122, ISO/IEF 9834-8:2005, and related standards. This identifier is a 128-bit quantity that is generated by an algorithm chosen to make it very unlikely that the same identifier will be generated by anyone else in the known universe using the same algorithm.

Therefore, for distributed systems, these identifiers provide a better uniqueness guarantee than sequence generators, which are only unique within a single database.

A UUID is written as a sequence of lower-case hexadecimal digits, in several groups separated by hyphens, specifically a group of 8 digits followed by three groups of 4 digits followed by a group of 12 digits, for a total of 32 digits representing the 128 bits. An example of a UUID in this standard form is:

```
a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
```

GaussDB also accepts the following alternative forms for input: use of upper-case letters and digits, the standard format surrounded by braces, omitting some or all hyphens, adding a hyphen after any group of four digits. An example is provided as follows:

```
A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11
{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}
a0eebc999c0b4ef8bb6d6bb9bd380a11
a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11
```

Output is always in the standard form.

### 7.3.11 JSON/JSONB Types

JavaScript Object Notation (JSON) data can be a single scalar, an array, or a key-value pair object. The array and object can be called a container:

- Scalar: a number, Boolean, string, or null
- Array: defined in a pair of square brackets ([]), in which elements can be any type of JSON data, and are not necessarily of the same type.
- Object: defined in a pair of braces ({}), in which objects are stored in the format of key:value. Each key must be a string enclosed by a pair of double quotation marks (""), and its value can be any type of JSON data. In case of duplicate keys, the last key value will be used.

GaussDB offers two types for storing JSON data: JSON and JSONB. The JSON data type stores a complete copy of the input, retaining the entered spaces, duplicate keys, and sequence, while the JSONB data type stores data in a decomposed binary form, removing semantic-irrelevant details and duplicate keys, and sorting key-values. Therefore, the JSONB data does not need to be parsed.

It can be found that both are of JSON type, and the same strings can be entered as input. The main difference between them is the efficiency. Because JSON data type stores an exact copy of the input text, the data must be parsed on every execution. In contrast, JSONB data is stored in a decomposed binary form and can be processed faster, though this makes it slightly slower to input due to the conversion mechanism. In addition, because the JSONB data type is normalized, it supports more operations, for example, comparing sizes according to a specific rule. JSONB also supports indexing, which is a significant advantage.

#### Input Format

An input must be a JSON-compliant string, which is enclosed in single quotation marks (').

null (null-json): The value can only be **null** in lowercase.

```
gaussdb=# SELECT 'null':json; -- suc
json

null
(1 row)

gaussdb=# SELECT 'NULL':jsonb; -- err
ERROR: invalid input syntax for type json
```

Number (num-json): The value can be a positive or negative integer, decimal fraction, or 0. The scientific notation is supported.

```
gaussdb=# SELECT '1':json;
json

1
(1 row)
```

```
gaussdb=# SELECT '-1.5'::json;
json

-1.5
(1 row)
```

```
gaussdb=# SELECT '-1.5e-5'::jsonb, '-1.5e+2'::jsonb;
jsonb | jsonb
-----+-----
-0.000015 | -150
(1 row)
```

```
gaussdb=# SELECT '001'::json, '+15'::json, 'NaN'::json; -- Redundant leading zeros, plus signs (+), NaN, and
infinity are not supported.
ERROR: invalid input syntax for type json
```

**Boolean (bool-json):** The value can only be **true** or **false** in lowercase.

```
gaussdb=# SELECT 'true'::json;
json

true
(1 row)
```

```
gaussdb=# SELECT 'false'::jsonb;
jsonb

false
(1 row)
```

**String (str-json):** The value must be a string enclosed in double quotation marks ("").

```
gaussdb=# SELECT '"a"'::json;
json

"a"
(1 row)
```

```
gaussdb=# SELECT '"abc"'::jsonb;
jsonb

"abc"
(1 row)
```

**Object (object-json):** The value is enclosed in braces ({}). The key must be a JSON-compliant string, and the value can be any valid JSON string.

```
gaussdb=# SELECT '{}'::json;
json

{}
(1 row)
```

```
gaussdb=# SELECT '{"a": 1, "b": {"a": 2, "b": null}}'::json;
json

{"a": 1, "b": {"a": 2, "b": null}}
(1 row)
```

```
gaussdb=# SELECT '{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}'::jsonb;
jsonb

{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}
(1 row)
```

 CAUTION

- Note that **'null::json** and **null::json** are different, which are similar to the strings **str="null"** and **str=null**.
- For numbers, when scientific notation is used, JSONB expands them, while JSON stores an exact copy of the input text.

## JSONB Advanced Features

- Precautions
  - It cannot be used as a partition key.
  - Foreign tables are not supported.

The main difference between JSON and JSONB lies in the storage mode. JSONB stores parsed binary data, which reflects the JSON hierarchy and facilitates direct access. Therefore, JSONB has many advanced features that JSON does not have.

- Format normalization
  - After the input object-json string is parsed into JSONB binary, semantically irrelevant details are naturally discarded, for example, spaces:
 

```
gaussdb=# SELECT ' [1, " a ", {"a" :1 }] '::jsonb;
 jsonb

[1, " a ", {"a": 1}]
(1 row)
```
  - For object-json, duplicate key-values are deleted and only the last key-value is retained. For example:
 

```
gaussdb=# SELECT '{"a" : 1, "a" : 2} '::jsonb;
 jsonb

{"a": 2}
(1 row)
```
  - For object-json, key-values will be re-sorted. The sorting rule is as follows: 1. Longer key-values are sorted last. 2. If the key-values are of the same length, the key-values with a larger ASCII code are sorted after the key-values with a smaller ASCII code:
 

```
gaussdb=# SELECT '{"aa" : 1, "b" : 2, "a" : 3} '::jsonb;
 jsonb

{"a": 3, "b": 2, "aa": 1}
(1 row)
```
- Size comparison
 

Format normalization ensures that only one form of JSONB data exists in the same semantics. Therefore, sizes may be compared according to a specific rule.

  - First, type comparison: **object-jsonb** > **array-jsonb** > **bool-jsonb** > **num-jsonb** > **str-jsonb** > **null-jsonb**
  - Content comparison if the data type is the same:
    - str-jsonb: The default text sorting rule of the database is used for comparison. A positive value indicates greater than, a negative value indicates less than, and **0** indicates equal.

- num-jsonb: numeric comparison
- bool-jsonb: **true** > **false**
- **array-jsonb**: long elements > short elements. If the lengths are the same, compare each element in sequence.
- **object-jsonb**: If the length of a key-value pair is longer than that of a short key-value pair, the key is compared first, and then the value is compared.

---

 **CAUTION**

For comparison within the object-jsonb type, the final result after format sorting is used for comparison. Therefore, the comparison result may not be intuitive compared with the direct input.

---

- Creating indexes and primary keys

- B-tree index

B-tree indexes and primary keys can be created for the JSONB type.

- Inclusion and existence

Querying whether a JSON contains some elements or whether some elements exist in a JSON is an important capability of JSONB.

```
-- Simple scalar/primitive values contain only the identical value.
gaussdb=# SELECT "'foo'::jsonb @> 'foo'::jsonb;
?column?
```

```

t
(1 row)
```

```
-- The array on the left contains the character string on the right.
gaussdb=# SELECT '[1, "aa", 3]::jsonb ? 'aa';
?column?
```

```

t
(1 row)
```

```
-- The array on the left contains all elements of the array on the right, regardless of the sequence and repetition.
gaussdb=# SELECT '[1, 2, 3]::jsonb @> '[1, 3, 1]::jsonb;
?column?
```

```

t
(1 row)
```

```
-- The object-json on the left contains all key-value pairs of object-json on the right.
gaussdb=# SELECT '{"product": "PostgreSQL", "version": 9.4, "jsonb": true}'::jsonb @>
 '{"version": 9.4}'::jsonb;
?column?
```

```

t
(1 row)
```

```
-- The array on the left does not contain all elements of the array on the right. The three elements on the left are 1, 2, and [1,3], but the elements on the right are 1 and 3.
gaussdb=# SELECT '[1, 2, [1, 3]]::jsonb @> '[1, 3]::jsonb;
?column?
```

```

f
```

```
(1 row)
gaussdb=# SELECT '{"foo": {"bar": "baz"}}::jsonb @> '{"bar": "baz"}::jsonb;
?column?

f
(1 row)
```

For details about the operators, see [JSON/JSONB Functions and Operators](#).

- Functions and operators

For details about the functions and operators supported by the JSON/JSONB type, see [JSON/JSONB Functions and Operators](#).

### 7.3.12 HLL

HyperLoglog (HLL) is an approximation algorithm for efficiently counting the number of distinct values in a dataset. It features faster computing and lower space usage. You only need to store HLL data structures, instead of data sets. When new data is added to a dataset, make hash calculation on the data and insert the result to an HLL. Then, you can obtain the final result based on the HLL.

[Table 7-20](#) compares HLL with other algorithms.

**Table 7-20** Comparison between HLL and other algorithms

| Item                      | Sorting Algorithm     | Hash Algorithm        | HLL                                   |
|---------------------------|-----------------------|-----------------------|---------------------------------------|
| Time complexity           | $O(n \log n)$         | $O(n)$                | $O(n)$                                |
| Space complexity          | $O(n)$                | $O(n)$                | $\log(\log n)$                        |
| Error rate                | 0                     | 0                     | $\approx 0.8\%$                       |
| Storage space requirement | Size of original data | Size of original data | The maximum size is 16 KB by default. |

HLL has advantages over others in the computing speed and storage space requirement. In terms of time complexity, the sorting algorithm needs  $O(n \log n)$  time for sorting, and the hash algorithm and HLL need  $O(n)$  time for full table scanning. In terms of storage space requirements, the sorting algorithm and hash algorithm need to store raw data before collecting statistics, whereas the HLL algorithm needs to store only the HLL data structures rather than the raw data, and thereby occupying a fixed space of about 16 KB.

**NOTICE**

- In the current default specifications, the maximum number of distinct values that can be calculated is about  $1.1e + 15$ , and the error rate is 0.8%. If the calculation result exceeds the maximum, the error rate of the calculation result will increase, or the calculation will fail and an error will be reported.
- When using this feature for the first time, you need to evaluate the distinct values of the service, properly select configuration parameters, and perform verification to ensure that the accuracy meets requirements.
  - By default, the distinct value is  $1.1e + 15$ . If the distinct value is NaN, you need to adjust `log2m` or use another algorithm to calculate the distinct value.
  - The hash algorithm has an extremely low probability of collision. However, you are still advised to select 2 or 3 hash seeds for verification when using the hash algorithm for the first time. If there is only a small difference between the distinct values, you can select any one of the seeds as the hash seed.

**Table 7-21** describes main HLL data structures.

**Table 7-21** Main HLL data structures

| Data Type | Description                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------|
| hll       | The HLL header is a 27-byte field. By default, the data length ranges from 0 KB to 16 KB. The distinct value can be obtained. |

When you create an HLL data type, 0 to 4 input parameters are supported. The parameter meanings and specifications are the same as those of the `hll_empty` function. The first parameter is **log2m**, indicating the logarithm of the number of buckets, and its value ranges from 10 to 16. The second parameter is **log2explicit**, indicating the threshold in explicit mode, and its value ranges from 0 to 12. The third parameter is **log2sparse**, indicating the threshold of the Sparse mode, and its value ranges from 0 to 14. The fourth parameter is **duplicatecheck**, indicating whether to enable duplicatecheck, and its value ranges from 0 to 1. When the input parameter is set to **-1**, the default value of the HLL parameter is used. You can run the `\d` or `\d+` command to view the parameters of the HLL type.

 **NOTE**

When the HLL data type is created, the result varies depending on the input parameter behavior:

- When creating an HLL type, do not set the input parameter or set it to **-1**. Use the default value of the corresponding HLL parameter.
- If a valid value is set for the input parameter, the corresponding HLL parameter uses the input value.
- If the input value is invalid, an error is reported when the HLL type is created.

```
-- Create an HLL table without specifying input parameters.
gaussdb=# create table t1 (id integer, set hll);
```

```
gaussdb=# \d t1
 Table "public.t1"
 Column | Type | Modifiers
-----+-----+-----
 id | integer|
 set | hll |

-- Create an HLL table, specify the first two input parameters, and use the default values for the last two
input parameters.
gaussdb=# create table t2 (id integer, set hll(12,4));
gaussdb=# \d t2
 Table "public.t2"
 Column | Type | Modifiers
-----+-----+-----
 id | integer |
 set | hll(12,4,12,0)|

-- Create an HLL table, specify the third input parameter, and use default values for other parameters.
gaussdb=# create table t3(id int, set hll(-1,-1,8,-1));
gaussdb=# \d t3
 Table "public.t3"
 Column | Type | Modifiers
-----+-----+-----
 id | integer |
 set | hll(14,10,8,0)|

-- When a user creates an HLL table and specifies an invalid input parameter, an error is reported.
gaussdb=# create table t4(id int, set hll(5,-1));
ERROR: log2m = 5 is out of range, it should be in range 10 to 16, or set -1 as default

-- Drop the created HLL table.
gaussdb=# drop table t1,t2,t3;
DROP TABLE
```

** NOTE**

When inserting an HLL object to an HLL table, ensure that the parameters of the HLL type are the same as those of the inserted object. Otherwise, an error is reported.

```
-- Create an HLL table.
gaussdb=# create table t1(id integer, set hll(14));

-- Insert an HLL object to a table. The insertion succeeds because parameter types are consistent.
gaussdb=# insert into t1 values (1, hll_empty(14,-1));

-- Insert an HLL object to a table. The insertion fails because parameter types are inconsistent.
gaussdb=# insert into t1(id, set) values (1, hll_empty(14,5));
ERROR: log2explicit does not match: source is 5 and dest is 10

-- Delete the table.
gaussdb=# drop table t1;
```

The following describes HLL application scenarios:

- Scenario 1: "Hello World"

The following example shows how to use the HLL data type:

```
-- Create an HLL table.
gaussdb=# create table helloworld (id integer, set hll);

-- Insert an empty HLL to the table.
gaussdb=# insert into helloworld(id, set) values (1, hll_empty());

-- Add a hashed integer to the HLL.
gaussdb=# update helloworld set set = hll_add(set, hll_hash_integer(12345)) where id = 1;

-- Add a hashed string to the HLL.
gaussdb=# update helloworld set set = hll_add(set, hll_hash_text('hello world')) where id = 1;

-- Obtain the number of distinct values of the HLL.
```

```
gaussdb=# select hll_cardinality(set) from helloworld where id = 1;
 hll_cardinality

 2
(1 row)
```

```
-- Drop the table.
gaussdb=# drop table helloworld;
```

- Scenario 2: Collect statistics about website visitors.

The following example shows how an HLL collects statistics on the number of users visiting a website within a period of time:

```
-- Create a raw data table to show that a user has visited the website at a certain time:
```

```
gaussdb=# create table facts (
 date date,
 user_id integer
);
```

```
-- Create a raw data table to show that a user has visited the website at a certain time:
```

```
gaussdb=# insert into facts values ('2019-02-20', generate_series(1,100));
gaussdb=# insert into facts values ('2019-02-21', generate_series(1,200));
gaussdb=# insert into facts values ('2019-02-22', generate_series(1,300));
gaussdb=# insert into facts values ('2019-02-23', generate_series(1,400));
gaussdb=# insert into facts values ('2019-02-24', generate_series(1,500));
gaussdb=# insert into facts values ('2019-02-25', generate_series(1,600));
gaussdb=# insert into facts values ('2019-02-26', generate_series(1,700));
gaussdb=# insert into facts values ('2019-02-27', generate_series(1,800));
```

```
-- Create another table and specify an HLL column:
```

```
gaussdb=# create table daily_uniques (
 date date UNIQUE,
 users hll
);
```

```
-- Group data by date and insert the data into the HLL:
```

```
gaussdb=# insert into daily_uniques(date, users)
select date, hll_add_agg(hll_hash_integer(user_id))
from facts
group by 1;
```

```
-- Calculate the numbers of users visiting the website every day.
```

```
gaussdb=# select date, hll_cardinality(users) from daily_uniques order by date;
 date | hll_cardinality
```

```
-----+-----
2019-02-20 | 100
2019-02-21 | 200.217913059312
2019-02-22 | 301.76494508014
2019-02-23 | 400.862858326446
2019-02-24 | 502.626933349694
2019-02-25 | 601.922606454213
2019-02-26 | 696.602316769498
2019-02-27 | 798.111731634412
(8 rows)
```

```
-- Calculate the number of users who had visited the website in the week from February 20, 2019 to February 26, 2019.
```

```
gaussdb=# select hll_cardinality(hll_union_agg(users)) from daily_uniques where date >=
'2019-02-20'::date and date <= '2019-02-26'::date;
 hll_cardinality
```

```

696.602316769498
(1 row)
```

```
-- Calculate the number of users who had visited the website yesterday but have not visited the website today:
```

```
gaussdb=# SELECT date, (#hll_union_agg(users) OVER two_days) - #users AS lost_uniques FROM
daily_uniques WINDOW two_days AS (ORDER BY date ASC ROWS 1 PRECEDING);
```

```
-- The default compatibility (MySQL compatibility) results are as follows:
 date | lost_uniques
```

```
-----+-----
2019-02-20 | 0
2019-02-21 | 0
2019-02-22 | 0
2019-02-23 | 0
2019-02-24 | 0
2019-02-25 | 0
2019-02-26 | 0
2019-02-27 | 0
(8 rows)
```

```
-- Drop the table.
gaussdb=# drop table facts;
gaussdb=# drop table daily_uniques;
```

- Scenario 3: The data to be inserted does not meet the requirements of the HLL data structure.

When inserting data into a column of the HLL type, ensure that the data meets the requirements of the HLL data structure. If the data does not meet the requirements after being parsed, an error will be reported. In the following example, 'E\1234' to be inserted does not meet the requirements of the HLL data structure after being parsed. As a result, an error is reported.

```
gaussdb=# create table test(id integer, set hll);
gaussdb=# insert into test values(1, 'E\1234');
ERROR: not a hll type, size=6 is not enough
gaussdb=# drop table test;
```

## 7.3.13 Range

A range type is a data type that represents the range of a value of an element type (called the *subtype* of a range). For example, the range of timestamp may be used to express a time range in which a conference room is reserved. In this case, the data type is `tsrange` (short for timestamp range), and timestamp is the subtype. The subtype must have an overall order so that the element value can be clearly specified within a range, before, or after.

Range types are useful because they can express multiple element values in a single range value and can clearly express concepts such as range overlapping. The time and date range used for scheduling is the best example, as the range of an instrument is also the example of range type.

### Built-in Range

The following built-in ranges are available:

- `int4range`: integer range.
- `int8range`: bigint range.
- `numrange`: numeric range.
- `tsrange`: range of timestamp without the time zone.
- `tstzrange`: range of timestamp with the time zone
- `daterange`: date range.

In addition, you can define your own range types. For details, see [CREATE TYPE](#).

### Example

```
CREATE TABLE reservation (room int, during tsrange);
INSERT INTO reservation VALUES (1108, '[2010-01-01 14:30, 2010-01-01 15:30)');
```

```
-- Inclusion
SELECT int4range(10, 20) @> 3;
?column?

f
(1 row)
-- Determine whether the two ranges overlap.
SELECT numrange(11.1, 22.2) && numrange(20.0, 30.0);
?column?

t
(1 row)
-- Upper bound extraction
SELECT upper(int8range(15, 25));
upper

25
(1 row)
-- Intersection set
SELECT int4range(10, 20) * int4range(15, 25);
?column?

[15,20)
(1 row)
-- Determine whether the range is empty.
SELECT isempty(numrange(1, 5));
isempty

f
(1 row)
DROP TABLE reservation;
```

See the complete list of operators and functions on a range type in [Range Functions and Operators](#).

## Including and Excluding Bounds

Each non-empty range has two bounds, a lower bound and an upper bound. All values between the upper and lower bounds are included in the range. An inclusion bound means that the bound value itself is included in the range, while an exclusion bound means that the bound value is not included in the range.

In a textual form of a range, an inclusion lower bound is expressed as "[" and an exclusion lower bound is expressed as "(" . Similarly, one including the upper bound is expressed as "]" and one excluding the upper bound is expressed as ")" (for details, see [Range Input/Output](#)).

The `lower_inc` and `upper_inc` functions test the upper and lower bounds of a range value, respectively.

## Infinite (Unbounded) Range

When the lower bound of a range is unbounded, it means that all values less than the upper bound are included in the range. Similarly, when the upper bound of a range is unbounded, all values greater than the lower bound are included in the range. When both the upper and lower bounds are unbounded, all values of the element type are considered within the range. The missing bounds are automatically converted to exclusions. You can think of these missing values as positive infinity or negative infinity, but they are special range type values and are considered to be positive and negative infinity values that go beyond any range element type.

Element types with the infinity values can be used as explicit bound values. For example, in the timestamp range, [today, infinity) does not include a special timestamp value infinity.

The lower\_inf and upper\_inf functions test the infinite upper and lower bounds of a range, respectively.

## Range Input/Output

The input of a range value must follow one of the following formats:

```
(lower-bound, upper-bound)
(lower-bound, upper-bound]
[lower-bound, upper-bound)
[lower-bound, upper-bound]
Empty
```

The output of a range value must follow one of the following formats:

```
[lower-bound, upper-bound)
Empty
```

Parentheses () or square brackets [] indicate whether the upper and lower bounds are excluded or included. Note that the last format is empty, which represents an empty range (a range that does not contain values).

The value of *lower-bound* can be a valid input string of the subtype or null, indicating that there is no lower bound. Similarly, *upper-bound* can be a valid input string of the subtype or null, indicating that there is no upper bound.

Each bound value can be referenced using the quotation marks (") character. This is necessary if the bounds value contains parentheses (), square brackets [], commas (,), quotation marks (""), or backslashes (\). Otherwise, those characters will be considered as the part of the range syntax. To put the quotation mark or backslash in a referenced bound value, put a backslash in front of it (and a pair of double quotation marks in its quoted bound value represents one quotation mark character, which is similar to the single quotation mark rule in SQL character strings). In addition, you can avoid referencing and use backslash escapes to protect all data characters, otherwise they will be used as part of the return syntax. Also, if you want to write a bound value that is an empty string, write "", indicating infinite bounds.

Spaces are allowed before and after a range value, but any space between parentheses or square brackets is used as part of the upper or lower bound value (depending on the element type, the space may or may not represent a value).

Examples:

```
-- All values between 3 (included) and 7 (excluded) are included.
gaussdb=# SELECT '[3,7)':int4range;
int4range

[3,7)
(1 row)
-- All values between 3 (excluded) and 7 (excluded) are included.
gaussdb=# SELECT '(3,7)':int4range;
int4range

[4,7)
(1 row)
-- Only value 4 is included.
gaussdb=# SELECT '[4,4)':int4range;
```

```
int4range

[4,5)
(1 row)
-- No value is included (and will be normalized to null).
gaussdb=# SELECT '[4,4)':int4range;
int4range

Empty
(1 row)
```

## Constructing Range

Each range type has a constructor function with the same name. Using constructor functions is often more convenient than writing a range literal constant because it avoids extra references to bound values. Constructor functions accept two or three parameters. Two parameters form a range in the standard form, where the lower bound is included and the upper bound is excluded, and three parameters form a range according to the bound specified by the third parameter. The third parameter must be one of the following character strings: (), [], or []. For example:

```
-- The complete format is: lower bound, upper bound, and textual parameters indicating the inclusion/
exclusion of bounds.
gaussdb=# SELECT numrange(1.0, 14.0, '[');
numrange

(1.0,14.0]
(1 row)
-- If the third parameter is ignored, it is assumed to be '['.
gaussdb=# SELECT numrange(1.0, 14.0);
numrange

[1.0,14.0)
(1 row)
-- Although '[' is specified here, the value will be converted to the standard format when displayed,
because int8range is a discrete range type.
gaussdb=# SELECT int8range(1, 14, '[');
int8range

[2,15)
(1 row)
-- Using NULL for a bound causes the range to be unbounded on that side.
gaussdb=# SELECT numrange(NULL, 2.2);
numrange

(,2.2)
(1 row)
```

## Discrete Range

A range element type has a well-defined "step" such as integer or date. In these types, if there is no valid value between two elements, they can be said to be adjacent. This is in contrast to a continuous range in which other element values can always be identified between two given values. For example, a range above the numeric type is continuous, and the range of timestamp is also continuous. (Although timestamp has limited precision and can be considered as discrete in theory, it can be considered as continuous because the step is not normally considered.)

Another way to consider discrete range types is to have a clear "next" or "previous" value for each element value. With this idea in mind, you can switch

between inclusion and exclusion expressions of a range bound by replacing it with the original given next or previous element value. For example, in an integer range type, [4,8] and (3,9) represent the same set of values, but not for numeric ranges.

A discrete range type should have a *regularization* function that knows the expected step size of the element type. The regularization function can convert the equivalents of the range type to the same expression, in particular consistent with the inclusion or exclusion bounds. If you do not specify a regularization function, ranges with different formats will always be considered as unequal, even if they actually express the same set of values.

The built-in range types `int4range`, `int8range`, and `daterange` use a regularized form that includes the lower bound and excludes the upper bound, that is, `[]`. However, user-defined range types can use other conventions.

## Index

In addition, B-tree indexed can be created on table columns of the range type. For these index types, basically the only useful range operation is equivalence. Using the corresponding `<` and `>` operators, there is a B-tree sort order for range value definitions, but that order is fairly arbitrary and is often less useful in the reality. The B-tree support for range types is primarily designed to allow sorting within a query, rather than creating an index.

### 7.3.14 Object Identifier Types

Object identifiers (OIDs) are used internally by GaussDB as primary keys for various system catalogs. OIDs are not added to user-created tables by the system. The **OID** type represents an object identifier.

The **OID** type is currently implemented as an unsigned four-byte integer. So, using a user-created table's **OID** column as a primary key is discouraged.

**Table 7-22** Object identifier types

| Name | Reference | Description                                                                                                                                        | Example |
|------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| OID  | N/A       | Numeric object identifier                                                                                                                          | 564182  |
| CID  | N/A       | Command identifier. This is the data type of the system columns <b>cmin</b> and <b>cmax</b> . Command identifiers are 32-bit quantities.           | N/A     |
| XID  | N/A       | A transaction identifier. This is the data type of the system columns <b>xmin</b> and <b>xmax</b> . Transaction identifiers are 64-bit quantities. | N/A     |

| Name          | Reference    | Description                                                                                                                                                                                             | Example                               |
|---------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| TID           | N/A          | Row identifier. This is the data type of the system column <b>ctid</b> . A row ID is a pair (block number, tuple index within block) that identifies the physical location of the row within its table. | N/A                                   |
| REGCONFIG     | pg_ts_config | Text search configuration                                                                                                                                                                               | english                               |
| REGDICTIONARY | pg_ts_dict   | Text search dictionary                                                                                                                                                                                  | simple                                |
| REGOPER       | pg_operator  | Operator name                                                                                                                                                                                           | N/A                                   |
| REGOPERATOR   | pg_operator  | Operator with argument types                                                                                                                                                                            | *(integer,integer) or -(NONE,integer) |
| REGPROC       | pg_proc      | Function name                                                                                                                                                                                           | sum                                   |
| REGPROCEDURE  | pg_proc      | Function with argument types                                                                                                                                                                            | sum(int4)                             |
| REGCLASS      | pg_class     | Relation name                                                                                                                                                                                           | pg_type                               |
| REGTYPE       | pg_type      | Data type name                                                                                                                                                                                          | integer                               |

The **OID** type is used for a column in the database system catalog.

Example:

```
gaussdb=# SELECT oid FROM pg_class WHERE relname = 'pg_type';
oid

1247
(1 row)
```

The alias type for **OID** is **REGCLASS** which allows simplified search for **OID** values.

Example:

```
gaussdb=# SELECT attrelid,attname,attypid,attstattarget FROM pg_attribute WHERE attrelid =
'pg_type'::REGCLASS;
attrelid | attname | attypid | attstattarget
-----+-----+-----+-----
1247 | xc_node_id | 23 | 0
1247 | tableoid | 26 | 0
1247 | cmax | 29 | 0
1247 | xmax | 28 | 0
1247 | cmin | 29 | 0
1247 | xmin | 28 | 0
1247 | oid | 26 | 0
1247 | ctid | 27 | 0
1247 | typname | 19 | -1
```

|      |                |      |    |

### 7.3.15 Pseudo-Types

GaussDB type system contains a number of special-purpose entries that are collectively called pseudo-types. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type.

Each of the available pseudo-types is useful in situations where a function's behavior does not correspond to simply taking or returning a value of a specific SQL data type. [Table 7-23](#) lists all pseudo-types.

**Table 7-23** Pseudo-types

| Name        | Description                                                               |
|-------------|---------------------------------------------------------------------------|
| any         | Indicates that a function accepts any input data type.                    |
| anyelement  | Indicates that a function accepts any data type.                          |
| anyarray    | Indicates that a function accepts any array data type.                    |
| anynonarray | Indicates that a function accepts any non-array data type.                |
| anyenum     | Indicates that a function accepts any enum data type.                     |
| anyrange    | Indicates that a function accepts any range data type.                    |
| cstring     | Indicates that a function accepts or returns a null-terminated C string.  |
| internal    | Indicates that a function accepts or returns a server-internal data type. |

| Name             | Description                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------|
| language_handler | Indicates that a procedural language call handler is declared to return <b>language_handler</b> . |
| fdw_handler      | Indicates that a foreign-data wrapper handler is declared to return <b>fdw_handler</b> .          |
| record           | Identifies a function returning an unspecified row type.                                          |
| trigger          | Indicates that a trigger function is declared to return <b>trigger</b> .                          |
| void             | Indicates that a function returns no value.                                                       |
| opaque           | Indicates an obsolete type name that formerly served all the above purposes.                      |

Functions coded in C (whether built in or dynamically loaded) can be declared to accept or return any of these pseudo data types. It is up to the function author to ensure that the function will behave safely when a pseudo-type is used as an argument type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. At present the procedural languages all forbid use of a pseudo-type as argument type, and allow only **void** and **record** as a result type. Some also support polymorphic functions using the **anyelement**, **anyarray**, **anynonarray**, **anyenum**, and **anyrange** types.

Each location (parameter or return value) declared as the anyelement type is allowed to have any specific actual data type, but they must all be of the same actual type in any given query.

The internal pseudo-type is used to declare functions that are meant only to be called internally by the database system, and not by direct call in an SQL query. If a function has at least one internal-type argument then it cannot be called from SQL. You are advised not to create any function that is declared to return internal unless it has at least one internal argument.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t1 (a int);

-- Insert two data records.
gaussdb=# INSERT INTO t1 values(1),(2);

-- Create the showall() function.
gaussdb=# CREATE OR REPLACE FUNCTION showall() RETURNS SETOF record
AS $$ SELECT count(*) from t1; $$
LANGUAGE SQL;

-- Call the showall() function.
gaussdb=# SELECT showall();
showall

(2)
(1 row)
```

```
-- Delete the function.
gaussdb=# DROP FUNCTION showall();

-- Delete the table.
gaussdb=# DROP TABLE t1;
```

## 7.3.16 XML Type

The XML data type can be used to store Extensible Markup Language (XML) data. The internal format of XML is the same as that of the TEXT data type. Its advantage over storing XML data in a TEXT field is that, XML data supports standard XML operation functions based on LIBXML2 and XML standardization check.

The XML data type can store well-formed documents as defined by the XML standard, as well as content fragments, which are defined by referencing broader "DOCUMENT NODE" XQuery and XPath data models. Roughly speaking, this means that there can be more than one top-level element or character node in a content fragment. The expression **XMLVALUE IS DOCUMENT** can be used to evaluate whether a particular XML value is a complete document or just a document fragment.

The XML parser converts an XML document into an XML DOM object. The document object model (DOM) defines standard methods for accessing and manipulating documents. XML DOM defines standard methods for accessing and manipulating XML documents. XML DOM views XML documents as a tree structure. All elements can be accessed through the DOM tree. You can modify or delete their contents and create new elements. Elements, their text, and their attributes are considered as nodes.

The XML bottom layer uses the same data structure as the TEXT type for storage. The maximum size is 1 GB.

Example:

```
gaussdb=# CREATE TABLE xmltest (id int, data xml);
gaussdb=# INSERT INTO xmltest VALUES (1, 'one');
gaussdb=# INSERT INTO xmltest VALUES (2, 'two');
gaussdb=# SELECT * FROM xmltest ORDER BY 1;
 id | data
----+-----
 1 | one
 2 | two
(2 rows)
gaussdb=# SELECT xmlconcat(xmlcomment('hello'),
 xmlelement(NAME qux, 'xml!'),
 xmlcomment('world'));
 xmlconcat

<!--hello--><qux>xml</qux><!--world-->
(1 row)
gaussdb=# DROP TABLE xmltest;
```

 NOTE

- The XML type does not support the following operations:
  - Logical expressions AND, OR, and NOT
  - Input parameter of a system function that is used as a non-XML operation function
  - Used as a distribution key, partition key, level-2 partition key, primary key, or unique constraint.
  - Implicit conversion related to XML, including the conversion between strings and the XML data type
  - Array expression, row expression, subquery expression, TABLE OF, and TABLE OF INDEX
  - Use columns of the XML data format as common indexes, unique indexes, global indexes, local indexes, and partial indexes.
  - Comparison expressions >, <, >=, <=, =, <>, !=, ^=, <=>, BETWEEN AND, IS DISTINCT FROM, and IS NOT DISTINCT FROM
  - Condition expressions DECODE, NULLIF, GREATEST, and LEAST
  - Used as DISTINCT, GROUP BY, or ORDER BY parameters
  - Aggregate functions including sum, max, min, avg, list\_agg, corr, covar\_pop, covar\_samp, stddev, stddev\_pop, stddev\_samp, var\_pop, var\_samp, variance, bit\_and, bit\_or, bool\_and, bool\_or, every, regr\_avgx, regr\_avgy, regr\_count, regr\_intercept, regr\_r2, regr\_slope, regr\_sxx, regr\_sxy, regr\_syy, rank, and spread
  - ODBC-related APIs with binding parameters
- The XML type supports the following operations:
  - Physical backup and restoration
  - Comparison expressions IS NULL and IS NOT NULL
  - Condition expressions CASE and COALESCE
  - Global temporary tables and local temporary tables
  - Forcible type conversion
  - Expression indexes
  - Input XML values that comply with the XML standard
  - gs\_dump and gs\_restore
  - Parallel query, supporting the Astore and Ustore storage engines
  - Input parameters, output parameters, customized variables, and return values of a user-defined function
  - Input parameters, output parameters, customized variables, and return values of a stored procedure, as well as stored procedures that support autonomous transactions.
  - Character processing function quote\_literal(string text) (explicitly converted to the character type) and quote\_nullable(string text) (explicitly converted to the character type)
  - Aggregate functions count, array\_agg, and checksum (explicitly converted to the character type), and string\_agg (explicitly converted to the character type)
  - JDBC and ODBC operations on XML data types are supported. The SELECT, UPDATE, INSERT, and DELETE operations can be performed on an XML column. You can enter an XML value using the SQL syntax and use the getSQLXML method of the ResultSet class to obtain the XML value. JDBC-related APIs with binding parameters are supported. For example, you can use the setSQLXML method in the PreparedStatement preprocessing API and the getSQLXML(int columnIndex) method in the ResultSet execution result set API.

In the calling process, use the java.sql.SQLXML API class to construct an XML object, set the specified object type to Oid.XML, and send the type ID and XML value to the server. After obtaining the result returned from the server, call

ResultSet.getString. Then, use the java.sql.SQLXML API class to construct an XML object based on the obtained character string. In this case, the system checks whether the content complies with the XML standard again. Therefore, you can also use ResultSet.getString to directly obtain the XML string object.

### 7.3.17 XMLType

The XMLType data type is used to store XMLType data. Currently, data is stored in character strings in the internal format. Its advantage over storing XML data in a TEXT field is that, XML data supports standard XML operation functions based on LIBXML2 and XML standardization check.

The XMLType type can store well-formed "documents" that comply with the XML standard.

The XML parser converts an XML document into an XML DOM object. The document object model (DOM) defines standard methods for accessing and manipulating documents. XML DOM defines standard methods for accessing and manipulating XML documents. XML DOM views XML documents as a tree structure. All elements can be accessed through the DOM tree. You can modify or delete their contents and create new elements. Elements, their text, and their attributes are considered as nodes. The maximum size is 1 GB.

Example:

```
gaussdb=# CREATE TABLE xmltypetest(id int, data xmltype);
gaussdb=# INSERT INTO xmltypetest VALUES (1, '<ss/>');
gaussdb=# INSERT INTO xmltypetest VALUES (2, '<xx/>');
gaussdb=# SELECT * FROM xmltypetest ORDER BY 1;
 id | data
----+-----
 1 | <ss/>
 2 | <xx/>
(2 rows)
gaussdb=# DROP TABLE xmltest;
```

 NOTE

- The XMLType type does not support the following operations:
  - Logical expressions AND, OR, and NOT
  - Input parameter of a system function that is used as a non-XMLType operation function
  - Used as a distribution key, partition key, level-2 partition key, primary key, or unique constraint.
  - Implicit conversion related to XMLType, including the conversion between strings and the XMLType data type.
  - Array expression, row expression, and subquery expression.
  - Use columns of the XMLType data format as common indexes, unique indexes, global indexes, local indexes, and partial indexes.
  - Comparison expressions >, <, >=, <=, =, <>, !=, ^=, <=>, BETWEEN AND, IS DISTINCT FROM, and IS NOT DISTINCT FROM
  - Condition expressions DECODE, NULLIF, GREATEST, and LEAST
  - Used as DISTINCT, GROUP BY, or ORDER BY parameters
  - Aggregate functions sum, max, min, avg, list\_agg, corr, covar\_pop, covar\_samp, stddev, stddev\_pop, stddev\_samp, var\_pop, var\_samp, variance, bit\_and, bit\_or, bool\_and, bool\_or, every, regr\_avgx, regr\_avgy, regr\_count, regr\_intercept, regr\_r2, regr\_slope, regr\_sxx, regr\_sxy, regr\_syy, rank, and spread
  - ODBC-related APIs with binding parameters
- The XMLType type supports the following operations:
  - Physical backup and restoration
  - Comparison expressions IS NULL and IS NOT NULL
  - Condition expressions CASE and COALESCE
  - Global temporary tables and local temporary tables
  - Forcible type conversion
  - Expression indexes
  - Input XMLType values that comply with the XML standard
  - gs\_dump and gs\_restore
  - Parallel query. The Astore and Ustore storage engines are supported.
  - Input parameters, output parameters, customized variables, and return values of a user-defined function
  - Input parameters, output parameters, customized variables, and return values of a stored procedure, as well as stored procedures that support autonomous transactions.
  - Character processing function quote\_literal(string text) (explicitly converted to the character type) and quote\_nullable(string text) (explicitly converted to the character type)
  - Aggregate functions count, array\_agg, and checksum (explicitly converted to the character type), and string\_agg (explicitly converted to the character type)
  - The SELECT, UPDATE, INSERT, and DELETE operations can be performed on an XMLType column. You can enter an XMLType value using the SQL syntax.
- You can create a schema named **xmltype**. In the schema, you can create functions, but cannot use schema.func() to call functions defined in the schema.

## 7.3.18 ACLItem

The aclitem data type is used to store object permission information. Its internal implementation is of the int type and supports the *user1=privs/user2* format.

The `aclitem[]` data type is an array consisting of ACL items. The supported format is `{user1 = privs1/user3, user2 = privs2/user3}`.

In the preceding command, `user1`, `user2`, and `user3` indicate the existing users or roles in the database, and `privs` indicates the permissions supported by the database. For details, see [Table 12-44](#).

Example:

```
-- Create a user.
gaussdb=# CREATE USER user1 WITH PASSWORD 'Aa123456789';
gaussdb=# CREATE USER user2 WITH PASSWORD 'Aa123456789';
gaussdb=# CREATE USER omm WITH PASSWORD 'Aa123456789';

-- Create a data table table_acl that contains three columns of the int, aclitem, and aclitem[] types.
gaussdb=# CREATE TABLE table_acl (id int,priv aclitem,privs aclitem[]);
-- Insert a data record whose content is (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}') into the
table_acl table.
gaussdb=# INSERT INTO table_acl VALUES (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}');
-- Insert a data record whose content is (2,'user1=aw/omm','{omm=d/user2}') into the table_acl table.
gaussdb=# INSERT INTO table_acl VALUES (2,'user1=aw/omm','{omm=d/user2}');

gaussdb=# SELECT * FROM table_acl;
id | priv | privs
-----+-----+-----
 1 | user1=arw/omm | {omm=d/user2,omm=w/omm}
 2 | user1=aw/omm | {omm=d/user2}
(2 rows)

-- Delete the table and user.
gaussdb=# DROP USER user1;
gaussdb=# DROP USER user2;
gaussdb=# DROP USER omm;
gaussdb=# DROP TABLE table_acl;
```

## 7.3.19 Array Types

Array types can be used to store several elements of the same type.

### Array Type Definition

Generally, an array data type is named by adding square brackets ([]) to the end of the data type name of an array element.

Example 1: Create a table named **sal\_emp**. The table has the following columns: **name** of the text type, indicating employee names; **pay\_by\_quarter** of the integer element type, indicating an array of quarterly salaries; **phone\_numbers** of the `varchar(11)` element type, indicating an array of mobile numbers.

```
gaussdb=# CREATE TABLE sal_emp (
name text,
pay_by_quarter integer[], phone_numbers varchar(11)[]
);
gaussdb=# DROP TABLE sal_emp;
```

Example 2: Define an array type in other ways. For details about the definition method and behavior, see the comments in the example.

```
gaussdb=# CREATE TABLE sal_emp (
name text,
pay_by_quarter1 integer[], -- Two-dimensional array of the int type.
pay_by_quarter2 integer[3], -- One-dimensional array of the int type. The size is 3.
pay_by_quarter3 integer[3][3], -- Two-dimensional array of the int type. The size of each dimension is 3.
pay_by_quarter4 integer ARRAY, -- One-dimensional array of the int type.
```

```
pay_by_quarter5 integer ARRAY[3] -- One-dimensional array of the int type. The size is 3.
gaussdb=# DROP TABLE sal_emp;
```

**⚠ CAUTION**

- The definition of the number of dimensions of an array does not take effect (which does not affect the runtime behavior). You are advised to use the method described in example 1 to define the array type and do not use multidimensional array data.
- The definition of the array size does not take effect (which does not affect the runtime behavior). You are advised to use the method described in example 1 to define the array type.
- The maximum number of dimensions of an array is 6.
- The restrictions on the number of array elements are as follows:
  1. The maximum number of elements is 134217727.
  2. The maximum storage space of all elements cannot exceed 1 GB minus 1 byte, that is, 1073741823 bytes.

## Array Constructor

An array constructor is an expression that can build array values. A simple array constructor consists of the keyword ARRAY and an expression list of array element values which are separated by commas and enclosed (,) by square brackets ([]). For example:

```
gaussdb=# SELECT ARRAY[1, 2, 3 + 4];
array

{1,2,7}
(1 row)
```

By default, the element type of an array is the common type of member expressions and is determined by the same rules as the UNION or CASE structure ([UNION, CASE, and Related Constructs](#)). You can construct an array to the desired data type through explicit type conversion. The following is an example:

```
gaussdb=# SELECT ARRAY[1, 2, 3]::varchar[];
array

{1,2,3}
(1 row)
```

```
gaussdb=# SELECT ARRAY['a', 'b', 'c']::varchar[];
array

{a,b,c}
(1 row)
```

In addition to the preset basic types, the table type can also be defined as array types. The following is an example:

```
gaussdb=# CREATE TYPE rec IS (c1 int, c2 int);
gaussdb=# SELECT ARRAY[(1, 1), (2, 2)]::rec[];
array

{"(1,1)","(2,2)"}
(1 row)
```

```
gaussdb=# CREATE TABLE tab (c1 int, c2 int);
gaussdb=# SELECT ARRAY[(1, 1), (2, 2)::tab[]];
array
```

```

{"(1,1)","(2,2)"}
(1 row)
```

```
gaussdb=# DROP TYPE rec;
gaussdb=# DROP TABLE tab;
```

An array must have a type. Therefore, when constructing an empty array, you must construct it as the required type. For example:

```
gaussdb=# SELECT ARRAY[]::int[];
array
```

```

{}
(1 row)
```

You can also construct an array from the result of a subquery. In this case, the array constructor consists of the keyword `ARRAY` and a subquery enclosed in parentheses. The subquery must return only one separate column. The generated one-dimensional array generates an element for each row of the result in the subquery. The element type matches the output column of the subquery. For example:

```
gaussdb=# SELECT ARRAY(SELECT generate_series(1, 6));
array
```

```

{1,2,3,4,5,6}
(1 row)
```

Multidimensional array values can be made by nesting array constructors. The `ARRAY` keyword in the inner constructor can be omitted. For example, the following two examples show the same result:

```
gaussdb=# SELECT ARRAY[ARRAY[1,2], ARRAY[3,4]];
array
```

```

{{1,2},{3,4}}
(1 row)
```

```
gaussdb=# SELECT ARRAY[[1,2], [3,4]];
array
```

```

{{1,2},{3,4}}
(1 row)
```

#### NOTE

- Inner constructors at the same layer must generate subarrays of the same dimension.
- Any type conversion applied to the outer `ARRAY` constructor is automatically applied to all inner constructors.

## String Inputs of the Array Type

To write an array value as a literal constant (constant input), enclose the element values with braces and separate them with commas. The general format of an array constant is as follows:

```
'{ val1 delim val2 delim ... }'
```

In the preceding format, **delim** indicates the delimiter of the element type and is recorded in the **typdelim** column in the `pg_type` catalog of the type. Each **val** can be a constant of the array element type or a subarray. For example:

```
gaussdb=# SELECT '{1, 2, 3}':int[] AS RESULT;
result

{1,2,3}
(1 row)

gaussdb=# SELECT '{{1, 2, 3}, {4, 5, 6}, {7, 8, 9}}':int[] AS RESULT;
result

{{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

Double quotation marks can be used around any element value, and double quotation marks must be used when the element value contains special characters such as commas or braces. The following is an example:

```
gaussdb=# SELECT '{" ", "NULL", null, "\\ ", "{", "}", ", "}'::varchar[] AS RESULT;
result

{" ", "NULL", NULL, "\\ ", "{", "}", ", " }
(1 row)
```

-- This example indicates that there is an array of the varchar type and there are seven varchar elements in total. The elements are as follows:

1. A character string containing a space.
2. A character string containing "NULL".
3. A character string containing NULL.
4. A character string containing a backslash (\).
5. A character string containing a left brace {.
6. A character string containing a right brace }.
7. A character string containing a comma (,).

#### NOTE

- For array string constant inputs, if the array element value is an empty string, contains braces, delimiters, double quotation marks, backslashes, or spaces, or matches the keyword NULL, then element inputs are enclosed in double quotation marks. An additional backslash is input if the element value contains double quotation marks or backslashes.
- The keyword NULL is case-insensitive.
- The input spaces not enclosed in double quotation marks are automatically skipped.
- You are advised to use the array constructor instead of character constants to construct array data.

## String Outputs of the Array Type

The output of an array value consists of the output of the array element type plus some modifiers indicating the array structure. These modifiers consist of braces ({}), around array values plus delimiters between adjacent items. In a multidimensional array, each dimension has its own level of braces and contains delimiters between adjacent braces at the same level.

The data of the array type contains special characters (in the following description). The following is an example of character string output:

```
gaussdb=# SELECT ARRAY['{', '}', 'hello, world', '', '\', ' ', NULL] AS RESULT;
array

{"{", "}", "hello, world", "\\ ", "\\", " ", NULL}
(1 row)
```

 NOTE

For array string constant outputs, if the array element value is an empty string or contains braces, delimiters, double quotation marks, backslashes, or spaces, or the element is NULL, then element outputs are enclosed in double quotation marks. An additional backslash is output if the element value contains double quotation marks or backslashes. This parameter corresponds to the string constant inputs.

## Use of Array Types

The following is an example of using the array type:

```
-- Create a table with array columns and insert some data.
gaussdb=# CREATE TABLE orders (
 name varchar,
 items varchar[]
);
gaussdb=# INSERT INTO orders VALUES('a', ARRAY['Apple', 'Orange', 'Pear']);
gaussdb=# INSERT INTO orders VALUES('b', ARRAY['Mineral water', 'Coke', 'Sprite']);
gaussdb=# INSERT INTO orders VALUES('c', ARRAY['Mouse', 'Keyboard', 'Earphone']);
gaussdb=# INSERT INTO orders VALUES('d', '{Cabbage, Potato, Eggplant}');

-- Query data.
gaussdb=# SELECT * FROM orders ORDER BY name;
 name | items
-----+-----
 a | {Apple,Orange,Pear}
 b | {Mineral water,Coke,Sprite}
 c | {Mouse,Keyboard,Earphone}
 d | {Cabbage,Potato,Eggplant}
(4 rows)

-- Access array elements.
gaussdb=# SELECT items[1] FROM orders ORDER BY name;
 items

 Apple
Mineral water
 Mouse
 Cabbage
(4 rows)

-- If the accessed element exceeds the range or the accessed index is NULL, NULL is returned.
gaussdb=# SELECT items[4] FROM orders ORDER BY name;
 items

(4 rows)

gaussdb=# SELECT items[null] FROM orders ORDER BY name;
 items

(4 rows)

-- Access a subarray.
gaussdb=# SELECT items[1:2] FROM orders ORDER BY name;
 items

 {Apple,Orange}
 {Mineral water,Coke}
 {Mouse,Keyboard}
```

```

{Cabbage,Potato}
(4 rows)

-- Updates the entire array.
gaussdb=# UPDATE orders SET items = ARRAY['Banana', 'Watermelon', 'Strawberry'] WHERE name = 'a';
gaussdb=# SELECT items FROM orders WHERE name = 'a';
 items

{Banana,Watermelon,Strawberry}
(1 row)

-- Updates the elements of an array.
gaussdb=# UPDATE orders SET items[1] = 'Mango' WHERE name = 'a';
gaussdb=# SELECT items FROM orders WHERE name = 'a';
 items

{Mango,Watermelon,Strawberry}
(1 row)

-- Updates the element fragment of an array.
gaussdb=# UPDATE ORDERS SET items[1:2] = ARRAY['Computer', 'Mobile phone'] WHERE name = 'c';
gaussdb=# SELECT items FROM ORDERS WHERE name = 'c';
 items

{Computer,Mobile phone,Earphone}
(1 row)

-- Add an array element. All unassigned elements between the last element of the original array and the
new element are set to NULL.
gaussdb=# UPDATE orders SET items[4] = 'Display' WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
 items

{Computer,Mobile phone,Earphone,Display}
(1 row)

gaussdb=# UPDATE orders SET items[6] = 'Display 2' WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
 items

{Computer,Mobile phone,Earphone,Display,NULL,Display 2}
(1 row)

```

## 7.4 Constant and Macro

[Table 7-24](#) lists the constants and macros that can be used in GaussDB.

**Table 7-24** Constant and macro

| Parameter       | Description                     | Example                                                                             |
|-----------------|---------------------------------|-------------------------------------------------------------------------------------|
| CURRENT_CATALOG | Specifies the current database. | gaussdb=# SELECT CURRENT_CATALOG;<br>current_database<br>-----<br>testdb<br>(1 row) |
| CURRENT_ROLE    | Specifies the current user.     | gaussdb=# SELECT CURRENT_ROLE;<br>current_user<br>-----<br>omm<br>(1 row)           |

| Parameter      | Description                                                   | Example                                                                                         |
|----------------|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| CURRENT_SCHEMA | Specifies the current database mode.                          | gaussdb=# SELECT CURRENT_SCHEMA;<br>current_schema<br>-----<br>public<br>(1 row)                |
| CURRENT_USER   | Specifies the current user.                                   | gaussdb=# SELECT CURRENT_USER;<br>current_user<br>-----<br>omm<br>(1 row)                       |
| LOCALTIMESTAMP | Specifies the current session time (without time zone).       | gaussdb=# SELECT LOCALTIMESTAMP;<br>timestamp<br>-----<br>2015-10-10 15:37:30.968538<br>(1 row) |
| NULL           | This parameter is left blank.                                 | N/A                                                                                             |
| SESSION_USER   | Specifies the current system user.                            | gaussdb=# SELECT SESSION_USER;<br>session_user<br>-----<br>omm<br>(1 row)                       |
| SYSDATE        | Specifies the current system date.                            | gaussdb=# SELECT SYSDATE;<br>sysdate<br>-----<br>2015-10-10 15:48:53<br>(1 row)                 |
| USER           | Specifies the current user, also called <b>CURRENT_USER</b> . | gaussdb=# SELECT USER;<br>current_user<br>-----<br>omm<br>(1 row)                               |

## 7.5 Functions and Operators

Operators can be used to process one or more operands and can be placed before, after, or between operands. Results are returned after the processing.

Functions encapsulate service logic to implement specific functions. A function may or may not have parameters. After a function is executed, the result is returned.

Users can modify system functions. However, after the modification, the meaning of the functions may change, which results in disorder in system control. Therefore, users are not allowed to manually modify system functions.

### NOTE

When the GUC parameter **behavior\_compat\_options** contains the **'enable\_funcname\_with\_argname'** option, the projection alias displays the complete function.

## 7.5.1 Logical Operators

The usual logical operators include AND, OR, and NOT. SQL uses a three-valued logical system with true, false, and null, which represents "unknown". Their priorities are NOT > AND > OR.

**Table 7-25** lists the calculation rules, where a and b represent logical expressions.

**Table 7-25** Operation rules

| a     | b     | a AND b Result | a OR b Result | NOT a Result |
|-------|-------|----------------|---------------|--------------|
| TRUE  | TRUE  | TRUE           | TRUE          | FALSE        |
| TRUE  | FALSE | FALSE          | TRUE          | FALSE        |
| TRUE  | NULL  | NULL           | TRUE          | FALSE        |
| FALSE | FALSE | FALSE          | FALSE         | TRUE         |
| FALSE | NULL  | FALSE          | NULL          | TRUE         |
| NULL  | NULL  | NULL           | NULL          | NULL         |

### NOTE

- The operators AND and OR are commutative, that is, you can switch the left and right operand without affecting the result.
- Operations on XML data are not supported.

## 7.5.2 Comparison Operators

Comparison operators are available for the most data types and return Boolean values.

All comparison operators are binary operators. Only data types that are the same or can be implicitly converted can be compared using comparison operators.

**Table 7-26** describes comparison operators provided by GaussDB.

**Table 7-26** Comparison operations

| Operator | Description              |
|----------|--------------------------|
| <        | Less than                |
| >        | Greater than             |
| <=       | Less than or equal to    |
| >=       | Greater than or equal to |
| =        | Equal to                 |

| Operator      | Description  |
|---------------|--------------|
| <>, !=, or ^= | Not equal to |

- Comparison operators are available for all relevant data types. All comparison operators are binary operators that returned values of Boolean type.
- The calculation priority of the inequality sign is higher than that of the equality sign. If the entered data type is different and cannot be implicitly converted, the comparison fails. For example, an expression such as **1 < 2 < 3** is invalid because the less-than sign (<) cannot be used to compare Boolean values and 3.
- Besides, each comparison operator has a corresponding function in the pg\_proc system catalog. If the value of the **proleakproof** attribute of the corresponding function is **f**, the function is not used to prevent data leakage. If a user only has the permission for a system view, but does not have the permission for the corresponding table, the query plan may not be optimal when the user searches the system view.
- This operator does not support data of the XML type.

### 7.5.3 Character Processing Functions and Operators

String functions and operators provided by GaussDB are for concatenating strings with each other, concatenating strings with non-strings, and matching the patterns of strings. Note: Except length-related functions, other functions and operators of string processing functions do not support parameters greater than 1 GB.

- `bit_length(string)`  
Description: Specifies the number of bits occupied by a string.  
Return type: int  
Example:  

```
gaussdb=# SELECT bit_length('world');
 bit_length

 40
(1 row)
```
- `btrim(string text [, characters text])`  
Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start and end of **string**.  
Return type: text  
Example:  

```
gaussdb=# SELECT btrim('string', 'ing');
 btrim

 sr
(1 row)
```
- `char_length(string)` or `character_length(string)`  
Description: Specifies the number of characters in a string.  
Return type: int

Example:

```
gaussdb=# SELECT char_length('hello');
 char_length

 5
(1 row)
```

- `dump(expr[, return_fmt [, start_position [, length ] ] ])`

Description: Returns the data type code, byte length, and internal representation of the input expression. **return\_fmt** specifies the number system of the internal representation, **start\_position** specifies the byte from which the internal representation starts, and **length** indicates the length of the data to be read.

Return type: text

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `instr(text,text,int,int)`

Description: **instr(string1,string2,int1,int2)** returns the text from **int1** to **int2** in **string1**. The first **int** indicates the start position for matching, and the second **int** indicates the number of matching times.

Return type: int

Example:

```
gaussdb=# SELECT instr('abcdabcdabcd', 'bcd', 2, 2);
 instr

 6
(1 row)
```

- `instrb(text,text,int,int)`

Description: **instrb(string1,string2,int1,int2)** returns the position matching *string2* in *string1* for the *int2*th time from the position specified by *int1*. *int1* indicates the start position for matching, and *int2* indicates the number of matching times. Different from the `instr` function, `instrb` is calculated in bytes and is not affected by the character set in use.

Return type: int

Example:

```
gaussdb=# SELECT instrb('abcdabcdabcd', 'bcd', 2, 2);
 instrb

 6
(1 row)
```

 **NOTE**

- This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s1** in an ORA-compatible database.
  - If the values of *int1* and *int2* are decimals, the values are truncated instead of being rounded off.
- `lengthb(text/bpchar)`

Description: Obtains the number of bytes of a specified string.

Return type: int

Example:

```
gaussdb=# SELECT lengthb('hello');
lengthb

 5
(1 row)
```

- left(str text, n int)

Description: Returns the first *n* characters in a string. When *n* is negative, all but the last **|n|** characters are returned.

Return type: text

Example:

```
gaussdb=# SELECT left('abcde', 2);
left

ab
(1 row)
```

- length(string bytea, encoding name)

Description: Specifies the number of characters in **string** in the given **encoding**. The **string** must be valid in this encoding.

Return type: int

Example:

```
gaussdb=# SELECT length('jose', 'UTF8');
length

 4
(1 row)
```

 **NOTE**

If the length of the bytea type is queried and UTF8 encoding is specified, the maximum length can only be **536870888**.

- lpad(string text, length int [, fill text])

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

Return type: text

 **NOTE**

In the scenario where this function is in an ORA-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on ORA compatibility requirements. During the execution of the lpad function, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the left of the string.
- If the value of *length* is a decimal, the value is truncated instead of being rounded off.

- notlike(x bytea name text, y bytea text)

Description: Compares x and y to check whether they are inconsistent.

Return type: Boolean

Example:

```
gaussdb=# SELECT notlike(1,2);
notlike

t
```

```
(1 row)
gaussdb=# SELECT notlike(1,1);
notlike

 f
(1 row)
```

- `octet_length(string)`

Description: Specifies the number of bytes in a string.

Return type: int

Example:

```
gaussdb=# SELECT octet_length('jose');
octet_length

 4
(1 row)
```

- `overlay(string placing string FROM int [for int])`

Description: Replaces substrings. **FROM int** indicates the start position of the replacement in the first string. **for int** indicates the number of characters replaced in the first string.

Return type: text

Example:

```
gaussdb=# SELECT overlay('hello' placing 'world' from 2 for 3);
overlay

hworldo
(1 row)
```

- `position(substring in string)`

Description: Specifies the position of a substring. Parameters are case-sensitive.

Return type: int. If the character string does not exist, **0** is returned.

Example:

```
gaussdb=# SELECT position('ing' in 'string');
position

 4
(1 row)
```

- `pg_client_encoding()`

Description: Specifies the current client encoding name.

Return type: name

Example:

```
gaussdb=# SELECT pg_client_encoding();
pg_client_encoding

UTF8
(1 row)
```

- `quote_ident(string text)`

Description: Returns the given string suitably quoted to be used as an identifier in an SQL statement string (quotation marks are used as required). Quotation marks are added only if necessary (that is, if the string contains non-identifier characters or would be case-folded). Embedded quotation marks are properly doubled.

Return type: text

Example:

```
gaussdb=# SELECT quote_ident('hello world');
quote_ident

"hello world"
(1 row)
```

- `quote_literal(string text)`

Description: Returns the given string suitably quoted to be used as text in an SQL statement string (quotation marks are used as required). It supports XML data that is explicitly converted to the character type.

Return type: text

Example:

```
gaussdb=# SELECT quote_literal('hello');
quote_literal

'hello'
(1 row)
```

If a command similar to the following exists, the text will be escaped:

```
gaussdb=# SELECT quote_literal(E'O'hello');
quote_literal

'O'hello'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled:

```
gaussdb=# SELECT quote_literal('O\hello');
quote_literal

E'O\\hello'
(1 row)
```

If the parameter is null, **NULL** is returned. If the parameter may be null, you are advised to use **quote\_nullable**.

```
gaussdb=# SELECT quote_literal(NULL);
quote_literal

(1 row)
```

- `quote_literal(value anyelement)`

Description: Converts the given value to text and then quotes it as a literal.

Return type: text

Example:

```
gaussdb=# SELECT quote_literal(42.5);
quote_literal

'42.5'
(1 row)
```

If a command similar to the following exists, the given value will be escaped:

```
gaussdb=# SELECT quote_literal(E'O'42.5');
quote_literal

'O'42.5'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled:

```
gaussdb=# SELECT quote_literal('O\42.5');
quote_literal
```

```

E'O\\42.5'
(1 row)
```

- `quote_nullable(string text)`

Description: Returns the given string suitably quoted to be used as a string in an SQL statement string (quotation marks are used as required).

It supports XML data that is explicitly converted to the character type.

Return type: text

Example:

```
gaussdb=# SELECT quote_nullable('hello');
quote_nullable
```

```

'hello'
(1 row)
```

If a command similar to the following exists, the text will be escaped:

```
gaussdb=# SELECT quote_nullable(E'O\'hello');
quote_nullable
```

```

'O"hello'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled:

```
gaussdb=# SELECT quote_nullable('O\hello');
quote_nullable
```

```

E'O\\hello'
(1 row)
```

If the parameter is null, **NULL** is returned.

```
gaussdb=# SELECT quote_nullable(NULL);
quote_nullable
```

```

NULL
(1 row)
```

- `quote_nullable(value anyelement)`

Description: Converts the given value to text and then quotes it as a literal.

Return type: text

Example:

```
gaussdb=# SELECT quote_nullable(42.5);
quote_nullable
```

```

'42.5'
(1 row)
```

If a command similar to the following exists, the given value will be escaped:

```
gaussdb=# SELECT quote_nullable(E'O\'42.5');
quote_nullable
```

```

'O"42.5'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled:

```
gaussdb=# SELECT quote_nullable('O\42.5');
quote_nullable
```

```

E'O\\42.5'
(1 row)
```

If the parameter is null, **NULL** is returned.

```
gaussdb=# SELECT quote_nullable(NULL);
quote_nullable

NULL
(1 row)
```

- `substring_inner(string [from int] [for int])`

Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of characters truncated.

Return type: text

Example:

```
gaussdb=# SELECT substring_inner('adcde', 2,3);
substring_inner

dcd
(1 row)
```

- `substring(string [from int] [for int])`

Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of characters truncated.

Return type: text

Example:

```
gaussdb=# SELECT substring('Thomas' from 2 for 3);
substring

hom
(1 row)
```

- `substring(string from pattern)`

Description: Extracts substrings matching the POSIX-style regular expression. It returns the text that matches the pattern. If no match record is found, a null value is returned.

Return type: text

Example:

```
gaussdb=# SELECT substring('Thomas' from '...$');
substring

mas
(1 row)
gaussdb=# SELECT substring('foobar' from 'o(.)b');
result

o
(1 row)
gaussdb=# SELECT substring('foobar' from '(o(.)b)');
result

oob
(1 row)
```

#### NOTE

If the POSIX-style regular expression contains any parentheses, the portion of the text that matched the first parenthesized sub-expression (the one whose left parenthesis comes first) is returned. You can put parentheses around the whole expression if you want to use parentheses within it without triggering this exception.

- `substring(string from pattern for escape)`

Description: Extracts substrings matching the SQL regular expression. The declared schema must match the entire data string; otherwise, the function

fails and returns a null value. To indicate the part of the schema that should be returned on success, the schema must contain two occurrences of the escape character followed by a double quotation mark ("). The text matching the portion of the pattern between these marks is returned.

Return type: text

Example:

```
gaussdb=# SELECT substring('Thomas' from '%"o_a#" ' for '#');
substring

oma
(1 row)
```

- `rawcat(raw,raw)`

Description: Indicates the string concatenation function.

Return type: raw

Example:

```
gaussdb=# SELECT rawcat('ab','cd');
rawcat

ABCD
(1 row)
```

- `regexp_like(text,text,text)`

Description: Indicates the mode matching function of a regular expression.

Return type: bool

Example:

```
gaussdb=# SELECT regexp_like('str','[ac]');
regexp_like

f
(1 row)
```

- `regexp_substr(string text, pattern text [, position int [, occurrence int [, flags text]]])`

Description: Extracts substrings from a regular expression. Its function is similar to **substr**. When a regular expression contains multiple parallel brackets, it also needs to be processed.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **occurrence**: sequence number of the matched substring to be extracted. This parameter is optional. The default value is **1**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in [Table 7-27](#).

**Table 7-27** Options supported by flags

| Option | Description                                   |
|--------|-----------------------------------------------|
| 'b'    | Indicates the BRE matching without extension. |

| Option | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'c'    | Indicates the case-sensitive matching.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 'e'    | Indicates the ERE matching with extension.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 'i'    | Indicates the case-insensitive matching.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 'm'    | Indicates the multi-line matching. If <b>flags</b> contains "m", use the multi-line matching. Otherwise, use the single-line matching.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 'n'    | <p>The meanings of the 'n' option are related to the GUC parameter <b>behavior_compat_options</b> and the compatibility mode of the current database.</p> <ul style="list-style-type: none"> <li>If the SQL compatibility mode of the database is <b>ORA</b> or <b>MYSQL</b> and the value of the GUC parameter <b>behavior_compat_options</b> contains <b>aformat_regexp_match</b>, the <b>n</b> option indicates that "." matches the linefeed "\n". If <b>n</b> is not specified, "." does not match the linefeed.</li> <li>In other cases, the "n" option has the same meaning as the "m" option.</li> </ul> |
| 'p'    | Indicates partial linefeed-sensitive matching, which is similar to the linefeed-sensitive matching ('m' or 'n') and affects "." and square bracket expression, but does not affect ^ and \$.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 'q'    | Indicates common character matching.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 's'    | Indicates the single-line matching. The meaning is opposite to those of 'm' and 'n'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 't'    | Indicates the compact matching. The whitespace characters match themselves.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 'w'    | Indicates the reverse partial linefeed-sensitive matching. The meaning is opposite to that of 'p'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 'x'    | Indicates the loose matching. The whitespace characters are ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Return type: text

Example:

```
gaussdb=# SELECT regexp_substr('str','[ac]');
regexp_substr

(1 row)

gaussdb=# SELECT regexp_substr('foobarbaz', 'b(..)', 3, 2) AS RESULT;
result

baz
(1 row)
```

- `regexp_count(string text, pattern text [, position int [, flags text]])`  
Description: obtains the number of substrings used for matching.  
Parameter description:
  - **string**: source character string used for matching.
  - **pattern**: regular expression pattern string used for matching.
  - **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
  - **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in [Table 7-27](#).

 **NOTE**

When the function is in an ORA-compatible database, the value of **a\_format\_version** is **10c**, and the value of **a\_format\_dev\_version** is **s1**, the **pattern** parameter ending with a backslash (`\`) is valid.

Return type: int

Example:

```
gaussdb=# SELECT regexp_count('foobarbaz','b(..)', 5) AS RESULT;
result

1
(1 row)
```

- `regexp_instr(string text, pattern text [, position int [, occurrence int [, return_opt int [, flags text]]]])`  
Description: obtains the position (starting from 1) of the substring that meets the matching condition. If no substring is matched, **0** is returned.  
Parameter description:
  - **string**: source character string used for matching.
  - **pattern**: regular expression pattern string used for matching.
  - **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
  - **occurrence**: sequence number of the matched substring to be replaced. This parameter is optional. The default value is **1**.
  - **return\_opt**: specifies whether to return the position of the first or last character of the matched substring. This parameter is optional. If the value is **0**, the position of the first character (starting from 1) of the matched substring is returned. If the value is greater than 0, the position of the next character of the end character of the matched substring is returned. The default value is **0**.
  - **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in [Table 7-27](#).

Return type: int

Example:

```
gaussdb=# SELECT regexp_instr('foobarbaz','b(..)', 1, 1, 0) AS RESULT;
result

4
```

```
(1 row)
gaussdb=# SELECT regexp_instr('foobarbaz','b(..)', 1, 2, 0) AS RESULT;
result

7
(1 row)
```

- `regexp_matches(string text, pattern text [, flags text])`

Description: Returns all captured substrings resulting from matching a POSIX-style regular expression against **string**. If the pattern does not match, the function returns no rows. If the pattern contains no parenthesized sub-expressions, then each row returned is a single-element text array containing the substring matching the whole pattern. If the pattern contains parenthesized sub-expressions, the function returns a text array whose *n*th element is the substring matching the *n*th parenthesized sub-expression of the pattern.

The optional **flags** argument contains zero or multiple single-letter flags that change the function behavior. **i** indicates that the matching is not related to uppercase and lowercase. **g** indicates that each matched substring is replaced, instead of replacing only the first one.

#### NOTICE

If the last parameter is provided but the parameter value is an empty string (") and the SQL compatibility mode of the database is set to ORA, the returned result is an empty set. This is because the ORA compatible mode treats the empty string (") as **NULL**. To resolve this problem, you can:

- Change the database SQL compatibility mode to TD.
- Do not provide the last parameter or do not set the last parameter to an empty string.

Return type: SETOF text[]

Example:

```
gaussdb=# SELECT regexp_matches('foobarbequebaz', '(bar)(beque)');
regexp_matches

{bar,beque}
(1 row)
gaussdb=# SELECT regexp_matches('foobarbequebaz', 'barbeque');
regexp_matches

{barbeque}
(1 row)
gaussdb=# SELECT regexp_matches('foobarbequebazilbarfonk', '(b[^b]+)(b[^b]+)', 'g');
regexp_matches

{bar,beque}
{bazil,barf}
(2 rows)
```

- `regexp_split_to_array(string text, pattern text [, flags text ])`

Description: Splits **string** using a POSIX-style regular expression as the delimiter. The **regexp\_split\_to\_array** function behaves the same as **regexp\_split\_to\_table**, except that **regexp\_split\_to\_array** returns its result as an array of text.

Return type: text[]

Example:

```
gaussdb=# SELECT regexp_split_to_array('hello world', E'\\s+');
 regexp_split_to_array

 {hello,world}
(1 row)
```

- `regexp_split_to_table(string text, pattern text [, flags text])`

Description: Splits **string** using a POSIX-style regular expression as the delimiter. If there is no match to the pattern, the function returns the string. If there is at least one match, for each match it returns the text from the end of the last match (or the beginning of the string) to the beginning of the match. When there are no more matches, it returns the text from the end of the last match to the end of the string.

The **flags** parameter is a text string containing zero or more single-letter flags that change the function's behavior. **i** indicates case-independent matching. If no parameter is contained, each matched substring, not only the first substring, is replaced by default.

Return type: SETOF text

Example:

```
gaussdb=# SELECT regexp_split_to_table('hello world', E'\\s+');
 regexp_split_to_table

 hello
 world
(2 rows)
```

- `repeat(string text, number int)`

Description: Repeats **string** the specified number of times.

Return type: text

Example:

```
gaussdb=# SELECT repeat('Pg', 4);
 repeat

 PgPgPgPg
(1 row)
```

#### NOTE

The maximum size of memory allocated at a time cannot exceed 1 GB due to the memory allocation mechanism of the database. Therefore, the maximum value of **number** cannot exceed  $(1 \text{ GB} - x) / \text{lengthb}(\text{string}) - 1$ . **x** indicates the length of the header information, which is usually greater than 4 bytes. The value varies among different scenarios.

- `replace(string text, from text, to text)`

Description: Replaces all occurrences in **string** of substring **from** with substring **to**.

Return type: text

Example:

```
gaussdb=# SELECT replace('abcdefabcdef', 'cd', 'XXX');
 replace

 abXXXefabXXXef
(1 row)
```

- `replace(string, substring)`

Description: Deletes all substrings in a string.

String type: text

Substring type: text

Return type: text

Example:

```
gaussdb=# SELECT replace('abcdefabcdef', 'cd');
replace

abefabef
(1 row)
```

- `reverse(str)`

Description: Returns a reversed string (by character).

Return type: text

Example:

```
gaussdb=# SELECT reverse('abcde');
reverse

edcba
(1 row)
```

- `right(str text, n int)`

Description: Returns the last  $n$  characters in a string. When  $n$  is negative, all but the first  $|n|$  characters are returned.

Return type: text

Example:

```
gaussdb=# SELECT right('abcde', 2);
right

de
(1 row)

gaussdb=# SELECT right('abcde', -2);
right

cde
(1 row)
```

- `rpadd(string text, length int [, fill text])`

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

Return type: text

#### NOTE

In the scenario where this function is in an ORA-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on ORA compatibility requirements. During the execution of the `rpadd` function, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the right of the string.
- If the value of *length* is a decimal, the value is truncated instead of being rounded off.
- `substrb(text,int,int)`

Description: Extracts a substring. The first **int** indicates the start position of the subtraction. The second **int** indicates the number of characters subtracted.

Return type: text

Example:

```
gaussdb=# SELECT substrb('string',2,3);
substrb

tri
(1 row)
```

- substrb(text,int)

Description: Extracts a substring. **int** indicates the start position of the extraction.

Return type: text

Example:

```
gaussdb=# SELECT substrb('string',2);
substrb

tring
(1 row)
```

- substr(bytea,from,count)

Description: Extracts a substring from **bytea**. **from** specifies the position where the extraction starts. **count** specifies the length of the extracted substring.

Return type: text

Example:

```
gaussdb=# SELECT substr('string',2,3);
substr

tri
(1 row)
```

- string || string

Description: Concatenates strings.

Return type: text

Example:

```
gaussdb=# SELECT 'MPP' || 'DB' AS RESULT;
result

MPPDB
(1 row)
```

- string || non-string or non-string || string

Description: Concatenates strings and non-strings.

Return type: text

Example:

```
gaussdb=# SELECT 'Value: ' || 42 AS RESULT;
result

Value: 42
(1 row)
```

- split\_part(string text, delimiter text, field int)

Description: Splits **string** on **delimiter** and returns the **field**th column (counting from text of the first appeared delimiter).

Return type: text

Example:

```
gaussdb=# SELECT split_part('abc~@~def~@~ghi', '~@~', 2);
split_part

def
(1 row)
```

- `strpos(string, substring)`

Description: Specifies the position of a substring. It is the same as **position(substring in string)**. However, the parameter sequences of them are reversed.

Return type: int

Example:

```
gaussdb=# SELECT strpos('source', 'rc');
strpos

4
(1 row)
```

- `to_hex(number int or bigint)`

Description: Converts a number to a hexadecimal expression.

Return type: text

Example:

```
gaussdb=# SELECT to_hex(2147483647);
to_hex

7fffffff
(1 row)
```

- `translate(string text, from text, to text)`

Description: Any character in **string** that matches a character in **from** is replaced by the corresponding character in **to**. If **from** is longer than **to**, extra characters occurred in **from** are removed.

Return type: text

Example:

```
gaussdb=# SELECT translate('12345', '143', 'ax');
translate

a2x5
(1 row)
```

- `length(string)`

Description: Obtains the number of characters in a string.

Return type: integer

Example:

```
gaussdb=# SELECT length('abcd');
length

4
(1 row)
```

- `lengthb(string)`

Description: Obtains the number of characters in a string. The value depends on character sets (GBK and UTF8).

Return type: integer

Example:

```
gaussdb=# SELECT lengthb('Chinese');
lengthb

 7
(1 row)
```

- substr(string,from)

Description:

Extracts substrings from a string.

**from** indicates the start position of the extraction.

- If **from** starts at 0, the value **1** is used.
- If the value of **from** is positive, all characters from **from** to the end are extracted.
- If the value of **from** is negative, the last *n* characters in the string are extracted, in which **n** indicates the absolute value of **from**.

Return type: varchar

Example:

If the value of **from** is positive:

```
gaussdb=# SELECT substr('ABCDEF',2);
substr

BCDEF
(1 row)
```

If the value of **from** is negative:

```
gaussdb=# SELECT substr('ABCDEF',-2);
substr

EF
(1 row)
```

- substr(string,from,count)

Description:

Extracts substrings from a string.

**from** indicates the start position of the extraction.

**count** indicates the length of the extracted substring.

- If **from** starts at 0, the value **1** is used.
- If the value of **from** is positive, extract **count** characters starting from **from**.
- If the value of **from** is negative, extract the last **n count** characters in the string, in which **n** indicates the absolute value of **from**.
- If the value of **count** is smaller than **1**, **null** is returned.

Return type: varchar

Example:

If the value of **from** is positive:

```
gaussdb=# SELECT substr('ABCDEF',2,2);
substr

BC
(1 row)
```

If the value of **from** is negative:

```
gaussdb=# SELECT substr('ABCDEF',-3,2);
substr

DE
(1 row)
```

- `substrb(string,from)`

Description: The functionality of this function is the same as that of **SUBSTR(string,from)**. However, the calculation unit is byte.

Return type: bytea

Example:

```
gaussdb=# SELECT substrb('ABCDEF',-2);
substrb

EF
(1 row)
```

- `substrb(string,from,count)`

Description: The functionality of this function is the same as that of **SUBSTR(string,from,count)**. However, the calculation unit is byte.

Return type: bytea

Example:

```
gaussdb=# SELECT substrb('ABCDEF',2,2);
substrb

BC
(1 row)
```

- `to_single_byte(char)`

Description: Converts all multi-byte characters in a string to single-byte characters.

Return type: text

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `to_multi_byte(char)`

Description: Converts all single-byte characters in a string to multi-byte characters.

Return type: text

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `trim([leading |trailing |both] [characters] from string)`

Description: Removes the longest string containing only the characters (a space by default) from the start/end/both ends of the string.

Return type: text

Example:

```
gaussdb=# SELECT trim(BOTH 'x' FROM 'xTomxx');
btrim

Tom
(1 row)
```

```
gaussdb=# SELECT trim(LEADING 'x' FROM 'xTomxx');
ltrim

Tomxx
(1 row)
gaussdb=# SELECT trim(TRAILING 'x' FROM 'xTomxx');
rtrim

xTom
(1 row)
```

- rtrim(string [, characters])

Description: Removes the longest string containing only characters from characters (a space by default) from the end of string.

Return type: text

Example:

```
gaussdb=# SELECT rtrim('TRIMxxxx','x');
rtrim

TRIM
(1 row)
```

- ltrim(string [, characters])

Description: Removes the longest string containing only characters from characters (a space by default) from the start of string.

Return type: text

Example:

```
gaussdb=# SELECT ltrim('xxxxTRIM','x');
ltrim

TRIM
(1 row)
```

- upper(string)

Description: Converts the string into the uppercase.

Return type: text

Example:

```
gaussdb=# SELECT upper('tom');
upper

TOM
(1 row)
```

- lower(string)

Description: Converts the string into the lowercase.

Return type: text

Example:

```
gaussdb=# SELECT lower('TOM');
lower

tom
(1 row)
```

- nls\_upper(string [, nlsparam])

Description: Converts a character string to uppercase letters. You can specify a sorting rule to process special uppercase conversion rules in some languages. The format of **nlsparam** is '**nls\_sort=sort\_name**', where **sort\_name** is replaced by the specific sorting rule name. When the **nlsparam** parameter is not set, this function is equivalent to **upper**.

Return type: text

Example:

```
gaussdb=# SELECT nls_upper('große');
 nls_upper

 GROBE
(1 row)
gaussdb=# SELECT nls_upper('große', 'nls_sort = XGerman');
 nls_upper

 GROSSE
(1 row)
```

 **NOTE**

This function can be used only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `nls_lower(string [, nlsparam])`

Description: Converts a character string to lowercase letters. You can specify a sorting rule to process special lowercase conversion rules in some languages. The format of **nlsparam** is '**nls\_sort=sort\_name**', where **sort\_name** is replaced by the specific sorting rule name. When the **nlsparam** parameter is not set, this function is equivalent to **lower**.

Return type: text

Example:

```
gaussdb=# SELECT nls_lower('INDIVISIBILITY');
 nls_lower

 indivisibility
(1 row)
gaussdb=# SELECT nls_lower('INDIVISIBILITY', 'nls_sort = XTurkish');
 nls_lower

 indivisibility
(1 row)
```

 **NOTE**

This function can be used only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `instr(string,substring[,position,occurrence])`

Description: Queries and returns the value of the substring position that occurs the **occurrence** (1 by default) times from the **position** (1 by default) in the string.

- If the value of **position** is **0**, **0** is returned.
- If the value of **position** is negative, searches backwards from the last *n*th character in the string, in which *n* indicates the absolute value of **position**.

In this function, the calculation unit is character. One Chinese character is one character.

Return type: integer

Example:

```
gaussdb=# SELECT instr('corporate floor','or', 3);
 instr

 5
(1 row)
```

```
gaussdb=# SELECT instr('corporate floor','or',-3,2);
instr

 2
(1 row)
```

- `initcap(string)`

Description: Capitalizes the first letter of each word in a string.

Return type: text

Example:

```
gaussdb=# SELECT initcap('hi THOMAS');
initcap

Hi Thomas
(1 row)
```

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2** in ORA-compatible database, if a case-insensitive character, such as Chinese, is followed by a case-sensitive character, only the first letter of the case-sensitive character is capitalized. Therefore, you are advised to set **a\_format\_version** to **10c** and **a\_format\_dev\_version** to **s2**.

- `ascii(string)`

Description: Indicates the ASCII code of the first character in the string.

Return type: integer

Example:

```
gaussdb=# SELECT ascii('xyz');
ascii

 120
(1 row)
```

- `ascii2(string)`

Description: Returns the decimal code of the first character of the input string in the database character set.

Return type: integer

Example:

```
gaussdb=# SELECT ascii2('xyz');
ascii2

 120
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `asciistr(string)`

Description: Converts non-ASCII characters in the input string to `\XXXX`, where `XXXX` indicates the UTF-16 code unit.

Return type: varchar

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `unistr(string)`

Description: Converts the coding sequence in a string into the corresponding character. Other characters remain unchanged.

Return type: text

 **NOTE**

- This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.
  - The backslash (\) must be followed by four hexadecimal characters to indicate the coding sequence, or another backslash (\) indicates that a single backslash (\) is entered.
  - If the input parameter is of the time type, the time type is implicitly converted to the character string type.
- `vsize(expr)`

Description: Returns the number of bytes of the input expression.

Return type: int

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `replace(string varchar, search_string varchar, replacement_string varchar)`

Description: Replaces all **search\_string** in the string with **replacement\_string**.

Return type: varchar

Example:

```
gaussdb=# SELECT replace('jack and jue','j','bl');
replace

black and blue
(1 row)
```

- `concat(str1,str2)`

Description: Connects `str1` and `str2` and returns the string. Note: **concat** calls the output function of the data type and the return value is immutable. As a result, the optimizer cannot calculate the result in advance when generating a plan. If there are performance requirements, you are advised to use the operator `||`.

---

**NOTICE**

- If **sql\_compatibility** is set to **'MYSQL'** and **str1** or **str2** is set to **NULL**, the returned result is **NULL**.
- The return value of the `concat` function is of the variable-length type. When the `concat` function is compared with table data, the character string length is lost in the combination result. As a result, the comparison results are different.

---

Return type: varchar

Example:

```
gaussdb=# SELECT concat('Hello', ' World!');
concat
```

```

Hello World!
(1 row)
gaussdb=# SELECT concat('Hello', NULL);
concat

(1 row)
gaussdb=# CREATE TABLE test_space(c char(10));
CREATE TABLE
gaussdb=# INSERT INTO test_space VALUES('a');
INSERT 0 1
-- After spaces are padded, the character string is still a fixed-length character string. It is expected
that the result can be found.
gaussdb=# SELECT * FROM test_space WHERE c = 'a ';
 c

 a
(1 row)
-- The combination result is a variable-length character string. The comparison fails and the result
cannot be found.
gaussdb=# SELECT * FROM test_space WHERE c = 'a' || ' ';
 c

(0 rows)
```

- **chr(integer)**

Description: For the UTF-8 character set, the input is encoded as Unicode and a UTF-8 character is returned. For other character sets, an ASCII character is returned.

Return type: text

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an ORA-compatible database, the value is truncated instead of being rounded off if the value of *integer* is a decimal.

Example:

```
gaussdb=# SELECT chr(65);
chr

A
(1 row)

-- If the UTF-8 character set is used (the database character set has been set to UTF-8 during
database creation, the database character set cannot be reset).
gaussdb=# SELECT chr(19968);
chr

—
(1 row)
```

- **chr(cvalue int|bigint)**

Description: Converts *cvalue* to the character of the corresponding byte order and returns the character.

*cvalue* can be converted into a value of the int or bigint type. The value range is  $[0, 2^{32} - 1]$ , corresponding to the range of unsigned int. A character array consisting of one to four bytes is returned based on the value of *n*. The byte arrays returned in different character sets are the same. However, due to different encoding rules, the result of the returned character string varies depending on the character set encoding.

If the character set is a single-byte character set, an ASCII character is returned after  $cvalue \bmod 256$ .

## Precautions:

- If a byte in the input *cvalue* is **0**, the output is truncated.
- If the input does not comply with the encoding rule of the current character set, an error is reported.
- If the input is **NULL** or **0**, **NULL** is returned.

Return type: text

## Example:

```
gaussdb=# SELECT chr(65);
chr

A
(1 row)
gaussdb=# CREATE DATABASE gaussdb_o WITH DBCOMPATIBILITY 'ORA';
gaussdb=# \c gaussdb_o
gaussdb=# SET a_format_version='10c';
gaussdb_o=# SET a_format_dev_version = 's1';
gaussdb_o=# SELECT chr(16705);
chr

AA
(1 row)

-- The output is truncated.
gaussdb_o=# SELECT chr(4259905);
chr

A
(1 row)
gaussdb_o=# \c postgres
gaussdb=# DROP DATABASE gaussdb_o;
```

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an ORA-compatible database, the `chr` function returns a character in the collation based on the input value. If the current character set for database encoding is a multi-byte character set, the return value contains one to four bytes. If the current character set for database encoding is a single-byte character set, the return value is a single byte obtained by performing the mod 256 operation on the input value. Otherwise, if the current character set for database encoding is UTF-8, the input is encoded as Unicode and a UTF-8 character is returned. For other character sets, an ASCII character is returned.

- `regexp_substr(source_char, pattern)`

Description: Extracts substrings from a regular expression. If the SQL syntax is ORA- and MySQL-compatible and the value of the GUC parameter **behavior\_compat\_options** contains **aformat\_regexp\_match**, the period (.) cannot match the '\n' character. If **aformat\_regexp\_match** is not contained, the period (.) matches the '\n' character by default.

Return type: text

## Example:

```
gaussdb=# SELECT regexp_substr('500 Hello World, Redwood Shores, CA', '[^,]+');
"REGEXPR_SUBSTR";
REGEXPR_SUBSTR

, Redwood Shores,
(1 row)
```

- `regexp_replace(string, pattern, replacement [,flags ])`

Description: Replaces substrings matching the POSIX-style regular expression. The source string is returned unchanged if there is no match to the pattern. If

there is a match, the source string is returned with the replacement string substituted for the matching substring.

The replacement string can contain `\n`, where `n` is 1 through 9, to indicate that the source substring matching the `n`th parenthesized sub-expression of the pattern should be inserted, and it can contain `&` to indicate that the substring matching the entire pattern should be inserted.

The optional **flags** argument contains zero or multiple single-letter flags that change the function behavior. The options supported by **flags** and description are shown in [Table 7-27](#).

Return type: varchar

Example:

```
gaussdb=# SELECT regexp_replace('Thomas', '[mN]a.', 'M');
 regexp_replace

ThM
(1 row)
gaussdb=# SELECT regexp_replace('foobarbaz','b(..)', E'X\1Y', 'g') AS
RESULT;
 result

fooXarYXazY
(1 row)
```

- `regexp_replace(string text, pattern text [, replacement text [, position int [, occurrence int [, flags text]]])`

Description: Replaces substrings matching the POSIX-style regular expression. The source string is returned unchanged if there is no match to the pattern. If there is a match, the source string is returned with the replacement string substituted for the matching substring.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **replacement**: character string used to replace the matched substring. This parameter is optional. If no parameter value is specified or the parameter value is null, an empty string is used for replacement.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **occurrence**: sequence number of the matched substring to be replaced. This parameter is optional. The default value is **1**, indicating that the first matched substring is replaced.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in [Table 7-27](#).

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an ORA-compatible database, the default value of **occurrence** is **0**, indicating that all matched substrings are replaced and the pattern parameter ending with a backslash (`\`) is valid.

Return type: text

Example:

```
gaussdb=# SELECT regexp_replace('foobarbaz','b(..)', E'X\1Y', 2, 2, 'n') AS RESULT;
 result
```

```

foobarXazY
(1 row)
```

- `concat_ws(sep text, str"any" [, str"any" [, ...] ])`

Description: Uses the first parameter as the separator, which is associated with all following parameters. The **NULL** parameter is ignored.

#### NOTICE

- If the first parameter value is **NULL**, the returned result is **NULL**.
- If the first parameter is provided but the parameter value is an empty string ('') and the SQL compatibility mode of the database is set to ORA, the returned result is **NULL**. This is because the ORA-compatible mode treats the empty string ('') as **NULL**. To resolve this problem, you can change the SQL compatibility mode of the database to MySQL, TD, or PG.

Return type: text

Example:

```
gaussdb=# SELECT concat_ws(',', 'ABCDE', 2, NULL, 22);
concat_ws

ABCDE,2,22
(1 row)
```

- `nlssort(string text, sort_method text)`

Description: Returns the encoding value of a string in the sorting mode specified by **sort\_method**. The encoding value can be used for sorting and determines the sequence of the string in the sorting mode. Currently, **sort\_method** can be set to **nls\_sort=schinese\_pinyin\_m** or **nls\_sort=generic\_m\_ci**. **nls\_sort=generic\_m\_ci** supports only the case-insensitive order for English characters.

String type: text

sort\_method type: text

Return type: text

Example:

```
gaussdb=# CREATE TABLE test(a text);
gaussdb=# INSERT INTO test(a) VALUES('abc');
gaussdb=# INSERT INTO test(a) VALUES('abC');
gaussdb=# INSERT INTO test(a) VALUES('abc');
gaussdb=# SELECT * FROM test ORDER BY nlssort(a,'nls_sort=schinese_pinyin_m');
 a

abc
abC
abC
(3 rows)
gaussdb=# SELECT * FROM test ORDER BY nlssort(a, 'nls_sort=generic_m_ci');
 a

abC
abc
abC
(3 rows)
gaussdb=# DROP TABLE test;
```

- `convert(string bytea, src_encoding name, dest_encoding name)`

Description: Converts the string to **dest\_encoding**. **src\_encoding** specifies the source code encoding. The string must be valid in this encoding.

Return type: bytea

Example:

```
gaussdb=# SELECT convert('text_in_utf8', 'UTF8', 'GBK');
convert

\x746578745f696e5f75746638
(1 row)
```

 **NOTE**

If the rule for converting between source to target encoding (for example, GBK and LATIN1) does not exist, the string is returned without conversion. See the `pg_conversion` system catalog for details.

Example:

```
gaussdb=# SHOW server_encoding;
server_encoding

LATIN1
(1 row)

gaussdb=# SELECT convert_from('some text', 'GBK');
convert_from

some text
(1 row)

db_latin1=# SELECT convert_to('some text', 'GBK');
convert_to

\x736f6d652074657874
(1 row)

db_latin1=# SELECT convert('some text', 'GBK', 'LATIN1');
convert

\x736f6d652074657874
(1 row)
```

- `convert_from(string bytea, src_encoding name)`

Description: Converts a string using the coding mode of the database.

**src\_encoding** specifies the source code encoding. The string must be valid in this encoding.

Return type: text

Example:

```
gaussdb=# SELECT convert_from('text_in_utf8', 'UTF8');
convert_from

text_in_utf8
(1 row)
```

- `convert_to(string text, dest_encoding name)`

Description: Converts a string to **dest\_encoding**.

Return type: bytea

Example:

```
gaussdb=# SELECT convert_to('some text', 'UTF8');
convert_to

\x736f6d652074657874
(1 row)
```

- string [NOT] LIKE pattern [ESCAPE escape-character]

Description: Specifies the pattern matching function.

If the pattern does not include a percentage sign (%) or an underscore (\_), this mode represents itself only. In this case, the behavior of LIKE is the same as the equal operator. The underscore (\_) in the pattern matches any single character while one percentage sign (%) matches no or multiple characters.

To match with underscores (\_) or percent signs (%), corresponding characters in **pattern** must lead escape characters. The default escape character is a backward slash (\) and can be specified using the **ESCAPE** clause. To match with escape characters, enter two escape characters.

Return type: Boolean

Example:

```
gaussdb=# SELECT 'AA_BBCC' LIKE '%A@_B%' ESCAPE '@' AS RESULT;
result

t
(1 row)
gaussdb=# SELECT 'AA_BBCC' LIKE '%A@_B%' AS RESULT;
result

f
(1 row)
gaussdb=# SELECT 'AA@_BBCC' LIKE '%A@_B%' AS RESULT;
result

t
(1 row)
```

- REGEXP\_LIKE(source\_string, pattern [, match\_parameter])

Description: Indicates the mode matching function of a regular expression.

**source\_string** indicates the source string and **pattern** indicates the matching pattern of the regular expression. **match\_parameter** indicates the matching items and the values are as follows:

- 'i': case-insensitive
- 'c': case-sensitive
- 'n': allowing the metacharacter "." in a regular expression to be matched with a linefeed.
- 'm': allows **source\_string** to be regarded as multiple rows.

If **match\_parameter** is ignored, **case-sensitive** is enabled by default, "." is not matched with a linefeed, and **source\_string** is regarded as a single row.

Return type: Boolean

Example:

```
gaussdb=# SELECT regexp_like('ABC', '[A-Z]');
regexp_like

t
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[D-Z]');
regexp_like

f
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[A-Z]','i');
regexp_like

```

```
t
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[A-Z]');
 regexp_like

t
(1 row)
```

- `format(formatstr text [, str"any" [, ...] ])`

Description: Formats a string.

Return type: text

Example:

```
gaussdb=# SELECT format('Hello %s, %1$s', 'World');
 format

Hello World, World
(1 row)
```

- `md5(string)`

Description: Encrypts a string in MD5 mode and returns a value in hexadecimal form.

 **NOTE**

The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

Return type: text

Example:

```
gaussdb=# SELECT md5('ABC');
 md5

902fbbd2b1df0c4f70b4a5d23525e932
(1 row)
```

- `sha(string) / sha1(string)`

Description: Encrypts a string using SHA1 and returns a hexadecimal number. The sha and sha1 functions are the same.

 **NOTE**

- The SHA1 encryption algorithm is not recommended because it has lower security and poses security risks.
- This function is valid only when GaussDB is compatible with the MY type (that is, `sql_compatibility` is set to 'MYSQL').

Return type: text

Example:

```
gaussdb=# SELECT sha('ABC');
 sha

3c01bdbb26f358bab27f267924aa2c9a03fcfdb8
(1 row)
gaussdb=# SELECT sha1('ABC');
 sha1

3c01bdbb26f358bab27f267924aa2c9a03fcfdb8
(1 row)
```

- `sha2(string, hash_length)`

Description: Encrypts a string in SHA2 mode and returns a value in hexadecimal form.

*hash\_length*: corresponds to an SHA2 algorithm. The value can be **0** (SHA-256), **224** (SHA-224), **256** (SHA-256), **384** (SHA-384), or **512** (SHA-512). For other values, **NULL** is returned.

 **NOTE**

- The SHA-224 encryption algorithm is not recommended because it has lower security and poses security risks.
- The SHA2 function records hash plaintext in logs. Therefore, you are advised not to use this function to encrypt sensitive information such as keys.
- This function is valid only when GaussDB is compatible with MySQL (that is, **sql\_compatibility** is set to 'MYSQL').

Return type: text

Example:

```
gaussdb=# SELECT sha2('ABC',224);
 sha2

107c5072b799c4771f328304cfe1ebb375eb6ea7f35a3aa753836fad
(1 row)
gaussdb=# SELECT sha2('ABC',256);
 sha2

b5d4045c3f466fa91fe2cc6abe79232a1a57cdf104f7a26e716e0a1e2789df78
(1 row)
gaussdb=# SELECT sha2('ABC',0);
 sha2

b5d4045c3f466fa91fe2cc6abe79232a1a57cdf104f7a26e716e0a1e2789df78
(1 row)
```

- **decode(string text, format text)**

Description: Decodes binary data from textual representation.

Return type: bytea

Example:

```
gaussdb=# SELECT decode('MTIzAAE=', 'base64');
 decode

\x3132330001
(1 row)
```

- **similar\_escape(pat text, esc text)**

Description: Converts a regular expression of the SQL:2008 style to the POSIX style.

Return type: text

Example:

```
gaussdb=# select similar_escape('\s+ab','2');
 similar_escape

^(?:\s+ab)$
(1 row)
```

- **find\_in\_set(text, set)**

Description: Finds the position of a given member in a set, counting from 1. If no record is found, 0 is returned. The distributed system does not support the SET data type. An error will be reported when this function is executed.

Return type: int2

- **encode(data bytea, format text)**

Description: Encodes binary data into a textual representation.

Return type: text

Example:

```
gaussdb=# SELECT encode(E'123\000\001', 'base64');
 encode

MTIzAAE=
(1 row)
```

#### NOTE

- For a string containing newline characters, for example, a string consisting of a newline character and a space, the value of **length** and **lengthb** in GaussDB is 2.
- In GaussDB, *n* in the CHAR(*n*) type indicates the number of characters. Therefore, for multiple-octet coded character sets, the length returned by the LENGTHB function may be longer than *n*.
- GaussDB supports multiple types of databases, including ORA, MySQL, TD, and PG. The lexical analyzer of ORA-compatible database is different from that of the other three databases. In an ORA-compatible database, an empty string is considered as **NULL**. Therefore, when an ORA-compatible database is used, if an empty string is used as a parameter in the preceding character operation function, no output is displayed.

Example:

```
gaussdb=# SELECT translate('12345','123','');
 translate

(1 row)
```

This is because the kernel checks whether the input parameter contains **NULL** before calling the corresponding function. If the input parameter contains **NULL**, the kernel does not call the corresponding function. As a result, no output is displayed. In PG-compatible mode, the processing of character strings is the same as that of PostgreSQL. Therefore, the preceding problem does not occur.

## Extension Functions and Operators

- pkg\_bpchar\_opc()

Description: Serves as an extension API to add the comparison operator between bpchar and text or between text and bpchar policies, so as to solve the problem that indexes cannot be matched when data of the bpchar and text types is compared. Only the system administrator can install extensions.

### NOTICE

The extended function is for internal use only. You are advised not to use it.

Example:

The tables **logs\_nchar**, **logs\_char**, **logs\_varchar2**, and **logs\_text** are as follows:

```
/*
logs_nchar table
*/

DROP TABLE IF EXISTS logs_nchar;
CREATE TABLE logs_nchar
(
 log_id NCHAR(16),
 log_message VARCHAR2(255) NOT NULL
);
DROP INDEX IF EXISTS idx_nchar_logid;
```

```
CREATE INDEX idx_nchar_logid ON logs_nchar(log_id);
INSERT INTO logs_nchar VALUES('FE306991300002 ', '111');
INSERT INTO logs_nchar VALUES('FE306991300003 ', '222');
INSERT INTO logs_nchar VALUES('FE306991300004 ', '222');

/*
logs_char table
*/
DROP TABLE IF EXISTS logs_char;
CREATE TABLE logs_char
(
 log_id CHAR(16),
 log_message VARCHAR2(255) NOT NULL
);
DROP INDEX IF EXISTS idx_char_logid;
CREATE INDEX idx_char_logid ON logs_char(log_id);
INSERT INTO logs_char VALUES('FE306991300002 ', '111');
INSERT INTO logs_char VALUES('FE306991300003 ', '222');
INSERT INTO logs_char VALUES('FE306991300004 ', '222');

/*
logs_varchar2 table
*/
DROP TABLE IF EXISTS logs_varchar2;
CREATE TABLE logs_varchar2
(
 log_id VARCHAR2(16),
 log_message VARCHAR2(255) NOT NULL
);
DROP INDEX IF EXISTS idx_varchar2_logid;
CREATE INDEX idx_varchar2_logid ON logs_varchar2(log_id);
INSERT INTO logs_varchar2 VALUES('FE306991300002 ', '111');
INSERT INTO logs_varchar2 VALUES('FE306991300003 ', '222');
INSERT INTO logs_varchar2 VALUES('FE306991300004 ', '222');

/*
logs_text table
*/

DROP TABLE IF EXISTS logs_text;
CREATE TABLE logs_text
(
 log_id text,
 log_message VARCHAR2(255) NOT NULL
);
DROP INDEX IF EXISTS idx_text_logid;
CREATE INDEX idx_text_logid ON logs_text(log_id);
INSERT INTO logs_text VALUES('FE306991300002 ', '111');
INSERT INTO logs_text VALUES('FE306991300003 ', '222');
INSERT INTO logs_text VALUES('FE306991300004 ', '222');
```

Compare the bpchar type with the text type (initial state, forward compatibility).

```
/*
The purpose is to obtain the detailed execution plan of all nodes.
*/
gaussdb=# SET max_datanode_for_plan = 64;
SET
/*
If no extension is installed, when nchar and text are compared, nchar is implicitly converted to text
because there is no bpchar or text index operator. That is, the fixed-length character type is converted
to the variable-length character type. As a result, the execution plan changes and the index cannot be
matched.
*/
gaussdb=# EXPLAIN SELECT * FROM logs_nchar WHERE log_id = RPAD(TRIM('FE306991300002 '),16,
');

 QUERY PLAN

Data Node Scan (cost=0.00..0.00 rows=0 width=0)
```

```

Node/s: All datanodes

Remote SQL: SELECT log_id, log_message FROM public.logs_nchar WHERE log
_id::text = rpad(btrim('FE306991300002 '::text), 16, ' '::text)
Datanode Name: datanode1

(3 rows)

/*
This format is recommended to avoid the following problems: the data type of log_id in the t1 table
is converted to the text type, spaces are reserved during comparison, and data cannot be matched
when the data type of log_id in the t2 table is compared with the data type of log_id in the t1 table.
The type of t1 table is forcibly converted to the bpchar type before the extension is installed, that is,
'FE306991300002' = 'FE306991300002'. Therefore, data is matched.
*/

gaussdb=# DROP TABLE logs_text;

```

 NOTE

- This solves the problem that data and indexes cannot be properly matched when equality matching is performed between the bpchar type (containing multiple spaces) and the text type.
- The UB-tree and B-tree are involved. The comparison symbols include >, >=, <, <=, and <>.
- The impact scope involves implicit conversion between character types. For example, when a variable-length data type is compared with a fixed-length data type, the variable-length data type is preferentially converted to the text type instead of the original bpchar type.
- The pkg\_bpchar\_opc extension is disabled by default. You can check whether the extension is enabled in the pg\_extension system catalog. If the extension data exists, the extension is enabled. If the extension data does not exist, the extension is disabled. When extension is disabled, forward compatibility is maintained. When extension is enabled, compatibility with database ORA is maintained. After the pkg\_bpchar\_opc extension is enabled, you need to set the **max\_datanode\_for\_plan** parameter as required. This parameter specifies the number of execution plans displayed on DNs when the FQS plan is generated. For example, to set **max\_datanode\_for\_plan** to **64**, run the following command:  

```
set max_datanode_for_plan = 64
```

**Table 7-28** Functions supported by pkg\_bpchar\_opc

| Name                       | Description                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| pg_catalog.bpchar_text_lt  | Compares the bpchar type with the text type to check whether the value on the left is less than the value on the right.                |
| pg_catalog.bpchar_text_le  | Compares the bpchar type with the text type to check whether the value on the left is less than or equal to the value on the right.    |
| pg_catalog.bpchar_text_eq  | Compares the bpchar type with the text type and checks whether the value on the left is equal to the value on the right.               |
| pg_catalog.bpchar_text_ge  | Compares the bpchar type with the text type to check whether the value on the left is greater than or equal to the value on the right. |
| pg_catalog.bpchar_text_gt  | Compares the bpchar type with the text type to check whether the value on the left is greater than the value on the right.             |
| pg_catalog.bpchar_text_ne  | Compares the bpchar type with the text type and checks whether the value on the left is different from the value on the right.         |
| pg_catalog.bpchar_text_cmp | Specifies that the index of the bpchar and text types supports comparison functions.                                                   |
| pg_catalog.text_bpchar_lt  | Compares the text type with the bpchar type to check whether the value on the left is less than the value on the right.                |

| Name                       | Description                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| pg_catalog.text_bpchar_le  | Compares the text type with the bpchar type to check whether the value on the left is less than or equal to the value on the right.    |
| pg_catalog.text_bpchar_eq  | Compares the text type with the bpchar type and checks whether the value on the left is equal to the value on the right.               |
| pg_catalog.text_bpchar_ge  | Compares the text type with the bpchar type to check whether the value on the left is greater than or equal to the value on the right. |
| pg_catalog.text_bpchar_gt  | Compares the text type with the bpchar type to check whether the value on the left is greater than the value on the right.             |
| pg_catalog.text_bpchar_ne  | Compares the text type with the bpchar type and checks whether the value on the left is different from the value on the right.         |
| pg_catalog.text_bpchar_cmp | Specifies that the index of the text and bpchar types supports comparison functions.                                                   |
| pg_catalog.hashbpchar_text | Specifies that the hash of the bpchar and text types supports comparison functions.                                                    |
| pg_catalog.hashtextbpchar  | Specifies that the hash of the text and bpchar types supports comparison functions.                                                    |

## 7.5.4 Binary String Functions and Operators

### String Operators

SQL defines some string functions that use keywords, rather than commas, to separate arguments.

- `octet_length(string)`

Description: Specifies the number of bytes in a binary string.

Return type: int

Example:

```
gaussdb=# SELECT octet_length(E'jo\000se'::bytea) AS RESULT;
result

 5
(1 row)
```

- `overlay(string placing string from int [for int])`

Description: Replaces substrings.

Return type: bytea

Example:

```
gaussdb=# SELECT overlay(E'Th\000omas'::bytea placing E'\002\003'::bytea from 2 for 3) AS RESULT;
```

```

result

\x5402036d6173
(1 row)

```

- `position(substring in string)`

Description: Specifies the location of the specified substring.

Return type: int

Example:

```

gaussdb=# SELECT position(E'\000om'::bytea in E'Th\000omas'::bytea) AS RESULT;
result

3
(1 row)

```

- `substring(string [from int] [for int])`

Description: Truncates substrings.

Return type: bytea

Example:

```

gaussdb=# SELECT substring(E'Th\000omas'::bytea from 2 for 3) AS RESULT;
result

\x68006f
(1 row)

```

- `substr(bytea [from int] [for int])`

Description: Truncates substrings.

Return type: bytea

Example:

```

gaussdb=# SELECT substr(E'Th\000omas'::bytea,2, 3) as result;
result

\x68006f
(1 row)

```

- `trim([both] bytes from string)`

Description: Removes the longest string containing only bytes from **bytes** from the start and end of **string**.

Return type: bytea

Example:

```

gaussdb=# SELECT trim(E'\000'::bytea from E'\000Tom\000'::bytea) AS RESULT;
result

\x546f6d
(1 row)

```

## Other Binary String Functions

GaussDB provides common syntax used for calling functions.

- `btrim(string bytea,bytes bytea)`

Description: Removes the longest string containing only bytes from **bytes** from the start and end of **string**.

Return type: bytea

Example:

```

gaussdb=# SELECT btrim(E'\000trim\000'::bytea, E'\000'::bytea) AS RESULT;
result

```

```

\x7472696d
(1 row)
```

- `get_bit(string, offset)`

Description: Extracts bits from a string.

Return type: int

Example:

```
gaussdb=# SELECT get_bit(E'Th\000omas'::bytea, 45) AS RESULT;
result

 1
(1 row)
```

- `get_byte(string, offset)`

Description: Extracts bytes from a string.

Return type: int

Example:

```
gaussdb=# SELECT get_byte(E'Th\000omas'::bytea, 4) AS RESULT;
result

 109
(1 row)
```

- `set_bit(string,offset, newvalue)`

Description: Sets bits in a string.

Return type: bytea

Example:

```
gaussdb=# SELECT set_bit(E'Th\000omas'::bytea, 45, 0) AS RESULT;
result

\x5468006f6d4173
(1 row)
```

- `set_byte(string,offset, newvalue)`

Description: Sets bytes in a string.

Return type: bytea

Example:

```
gaussdb=# SELECT set_byte(E'Th\000omas'::bytea, 4, 64) AS RESULT;
result

\x5468006f406173
(1 row)
```

- `rawcmp`

Description: Specifies the raw data type comparison function.

Parameter: raw, raw

Return type: integer

- `raweq`

Description: Specifies the raw data type comparison function.

Parameter: raw, raw

Return type: Boolean

- `rawge`

Description: Specifies the raw data type comparison function.

- Parameter: raw, raw  
Return type: Boolean
- rawgt  
Description: Specifies the raw data type comparison function.  
Parameter: raw, raw  
Return type: Boolean
  - rawin  
Description: Specifies the raw data type parsing function.  
Parameter:cstring  
Return type:bytea
  - rawle  
Description: Specifies the raw data type parsing function.  
Parameter: raw, raw  
Return type: Boolean
  - rawlike  
Description: Specifies the raw data type parsing function.  
Parameter: raw, raw  
Return type: Boolean
  - rawlt  
Description: Specifies the raw data type parsing function.  
Parameter: raw, raw  
Return type: Boolean
  - rawne  
Description: Compares whether the raw types are the same.  
Parameter: raw, raw  
Return type: Boolean
  - rawnlike  
Description: Checks whether the raw type matches the mode.  
Parameter: raw, raw  
Return type: Boolean
  - rawout  
Description: Specifies the RAW output API.  
Parameter:bytea  
Return type:cstring
  - rawsend  
Description: Converts bytea to the binary type.  
Parameter: raw  
Return type:bytea
  - rawtohex  
Description: Converts the raw format to the hexadecimal format.  
Parameter: text

Return type: text

## 7.5.5 Bit String Functions and Operators

### Bit String Operators

Aside from the usual comparison operators, the following operators can be used. Bit string operands of **&**, **|**, and **#** must be of equal length. In case of bit shifting, the original length of the string is preserved by zero padding (if necessary).

- **||**

Description: Connects bit strings.

Example:

```
gaussdb=# SELECT B'10001' || B'011' AS RESULT;
result

10001011
(1 row)
```

#### NOTE

- A field can have a maximum of 180 consecutive internal joins. A field with excessive joins will be split into joined consecutive strings.  
Example: **str1||str2||str3||str4** is split into **(str1||str2)||str3||str4**.
- In ORA-compatible mode, if bit strings contain a null string, the null string is ignored and other strings are joined. In other compatibility modes, the null string is returned.  
Take **str1||NULL||str2** as an example. **str1str2** is returned in ORA-compatible mode and **NULL** is returned in other compatibility modes.

- **&**

Description: Specifies the AND operation between bit strings.

Example:

```
gaussdb=# SELECT B'10001' & B'01101' AS RESULT;
result

00001
(1 row)
```

- **|**

Description: Specifies the OR operation between bit strings.

Example:

```
gaussdb=# SELECT B'10001' | B'01101' AS RESULT;
result

11101
(1 row)
```

- **#**

Description: Specifies the OR operation between bit strings if they are inconsistent. If the same positions in the two bit strings are both 1 or 0, the position returns **0**.

Example:

```
gaussdb=# SELECT B'10001' # B'01101' AS RESULT;
result

```

- ```
11100
(1 row)
```
- ~

Description: Specifies the NOT operation between bit strings.

Example:

```
gaussdb=# SELECT ~B'10001' AS RESULT;
result
-----
01110
(1 row)
```
- <<

Description: Shifts left in a bit string.

Example:

```
gaussdb=# SELECT B'10001' << 3 AS RESULT;
result
-----
01000
(1 row)
```
- >>

Description: Shifts right in a bit string.

Example:

```
gaussdb=# SELECT B'10001' >> 2 AS RESULT;
result
-----
00100
(1 row)
```

The following SQL-standard functions work on bit strings as well as strings: **length**, **bit_length**, **octet_length**, **position**, **substring**, and **overlay**.

The following functions work on bit strings as well as binary strings: **get_bit** and **set_bit**. When working with a bit string, these functions number the first (leftmost) bit of the string as bit 0.

In addition, it is possible to convert between integral values and type **bit**. Example:

```
gaussdb=# SELECT 44::bit(10) AS RESULT;
result
-----
0000101100
(1 row)

gaussdb=# SELECT 44::bit(3) AS RESULT;
result
-----
100
(1 row)

gaussdb=# SELECT cast(-44 as bit(12)) AS RESULT;
result
-----
111111010100
(1 row)

gaussdb=# SELECT '1110'::bit(4)::integer AS RESULT;
result
-----
14
(1 row)

gaussdb=# select substring('10101111'::bit(8), 2);
substring
```

```
-----  
0101111  
(1 row)
```

NOTE

Casting to just "bit" means casting to bit(1), and so will deliver only the least significant bit of the integer.

7.5.6 Pattern Matching Operators

The database provides three independent methods for implementing pattern matching: SQL LIKE operator, SIMILAR TO operator, and POSIX-style regular expressions. Besides these basic operators, functions can be used to extract or replace matching substrings and to split a string at matching locations.

- LIKE

Description: Specifies whether the string matches the pattern string following LIKE. The LIKE expression returns true if the string matches the supplied pattern. (As expected, the NOT LIKE expression returns false if LIKE returns true, and vice versa.)

Matching rules:

- This operator can succeed only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.
- The underscore (_) represents (matching) any single character. Percentage (%) indicates the wildcard character of any string.
- To match a literal underscore or percent sign, the respective character in pattern must be preceded by the escape character. The default escape character is one backslash but a different one can be selected by using the ESCAPE clause.
- To match with escape characters, enter two escape characters. For example, to write a pattern constant containing a backslash (\), you need to enter two backslashes in SQL statements.

NOTE

When **standard_conforming_strings** is set to **off**, any backslashes you write in literal string constants will need to be doubled. Therefore, writing a pattern matching a single backslash is actually going to write four backslashes in the statement. You can avoid this by selecting a different escape character by using ESCAPE, so that the backslash is no longer a special character of LIKE. But the backslash is still the special character of the character text analyzer. In this case, two backslashes are required. You can also select no escape character by writing **ESCAPE ''**. This effectively disables the escape mechanism, but it does not eliminate the special meaning of underscore and percent signs in the pattern.

- The keyword ILIKE can be used instead of LIKE to make the match case-insensitive.
- Operator ~* is equivalent to LIKE, and operator ~*~* corresponds to ILIKE.

Example:

```
gaussdb=# SELECT 'abc' LIKE 'abc' AS RESULT;  
result  
-----  
t  
(1 row)
```

```

gaussdb=# SELECT 'abc' LIKE 'a%' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' LIKE '_b_' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' LIKE 'c' AS RESULT;
result
-----
f
(1 row)

```

- **SIMILAR TO**

Description: Returns true or false depending on whether the pattern matches the given string. It is similar to LIKE, but differs in that it uses the regular expression understanding pattern defined by the SQL standard.

Matching rules:

- Similar to LIKE, this operator succeeds only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.
- The underscore (_) represents (matching) any single character. Percentage (%) indicates the wildcard character of any string.
- SIMILAR TO supports these pattern-matching metacharacters borrowed from POSIX-style regular expressions:

Metacharacter	Description
	Specifies alternation (either of two alternatives).
*	Specifies repetition of the previous item zero or more times.
+	Specifies repetition of the previous item one or more times.
?	Specifies repetition of the previous item zero or one time.
{m}	Specifies repetition of the previous item exactly <i>m</i> times.
{m,}	Specifies repetition of the previous item <i>m</i> or more times.
{m,n}	Specifies repetition of the previous item at least <i>m</i> times and does not exceed <i>n</i> times.
()	Specifies that parentheses () can be used to group items into a single logical item.

Metacharacter	Description
[...]	Specifies a character class, just as in POSIX-style regular expressions.

- d. A preamble escape character disables the special meaning of any of these metacharacters. The rules for using escape characters are the same as those for LIKE.

Regular expressions:

The **substring(string from pattern for escape)** function extracts a substring that matches an SQL regular expression pattern.

Example:

```
gaussdb=# SELECT 'abc' SIMILAR TO 'abc' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO 'a' AS RESULT;
result
-----
f
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO '%(b|d)%' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO '(b|c)%' AS RESULT;
result
-----
f
(1 row)
```

- POSIX-style regular expressions

Description: A regular expression is a collation that is an abbreviated definition of a set of strings (a regular set). If a string is a member of a regular expression described by a regular expression, the string matches the regular expression. POSIX-style regular expressions provide a more powerful means for pattern matching than the LIKE and SIMILAR TO operators. [Table 7-29](#) lists all available operators for pattern matching using POSIX-style regular expressions.

Table 7-29 Regular expression match operators

Operator	Description	Example
~	Matches a regular expression, which is case-sensitive.	'thomas' ~ '.*thomas.*'
~*	Matches a regular expression, which is case-insensitive.	'thomas' ~* '.*Thomas.*'

Operator	Description	Example
!~	Does not match a regular expression, which is case-sensitive.	'thomas' !~ '.*Thomas.*'
!~*	Does not match a regular expression, which is case-insensitive.	'thomas' !~* '.*vadim.*'

Matching rules:

- a. Unlike LIKE patterns, a regular expression is allowed to match anywhere within a string, unless the regular expression is explicitly anchored to the beginning or end of the string.
- b. Besides the metacharacters mentioned above, POSIX-style regular expressions also support the following pattern matching metacharacters:

Metacharacter	Description
^	Specifies the match starting with a string.
\$	Specifies the match at the end of a string.
.	Matches any single character.

Regular expressions:

POSIX-style regular expressions support the following functions:

- The **substring(string from pattern)** function provides a method for extracting a substring that matches the POSIX-style regular expression pattern.
- The **regexp_count(string text, pattern text [, position int [, flags text]])** function provides the function of obtaining the number of substrings that match the POSIX-style regular expression pattern.
- The **regexp_instr(string text, pattern text [, position int [, occurrence int [, return_opt int [, flags text]]]])** function is used to obtain the position of a substring that matches a POSIX-style regular expression pattern.
- The **regexp_substr(string text, pattern text [, position int [, occurrence int [, flags text]]])** function provides a method to extract a substring that matches a POSIX-style regular expression pattern.
- The **regexp_replace(string, pattern, replacement [,flags])** function replaces the substring that matches the POSIX-style regular expression pattern with the new text.
- The **regexp_matches(string text, pattern text [, flags text])** function returns a text array consisting of all captured substrings that match a POSIX-style regular expression pattern.

- The **regexp_split_to_table(string text, pattern text [, flags text])** function splits a string using a POSIX-style regular expression pattern as a delimiter.
- The **regexp_split_to_array(string text, pattern text [, flags text])** function behaves the same as `regexp_split_to_table`, except that `regexp_split_to_array` returns its result as an array of text.

 **NOTE**

The regular expression split functions ignore zero-length matches, which occur at the beginning or end of a string or after the previous match. This is contrary to the strict definition of regular expression matching. The latter is implemented by **regexp_matches**, but the former is usually the most commonly used behavior in practice.

Example:

```
gaussdb=# SELECT 'abc' ~ 'Abc' AS RESULT;
result
-----
f
(1 row)
gaussdb=# SELECT 'abc' ~* 'Abc' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' !~ 'Abc' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' !~* 'Abc' AS RESULT;
result
-----
f
(1 row)
gaussdb=# SELECT 'abc' ~ '^a' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' ~ '(b|d)' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' ~ '^ (b|c)' AS RESULT;
result
-----
f
(1 row)
```

Although most regular expression searches can be executed quickly, they can still be artificially processed to require any length of time and any amount of memory. It is not recommended that you accept the regular expression search pattern from the non-security pattern source. If you must do this, you are advised to add the statement timeout limit. The search with the SIMILAR TO pattern has the same security risks as the SIMILAR TO provides many capabilities that are the same as those of the POSIX-style regular expression. The LIKE search is much simpler than the other two options. Therefore, it is more secure to accept the non-secure pattern source search.

7.5.7 Arithmetic Functions and Operators

Arithmetic Operators

- +

Description: Addition

Example:

```
gaussdb=# SELECT 2+3 AS RESULT;  
result  
-----  
5  
(1 row)
```

- -

Description: Subtraction

Example:

```
gaussdb=# SELECT 2-3 AS RESULT;  
result  
-----  
-1  
(1 row)
```

- *

Description: Multiplication

Example:

```
gaussdb=# SELECT 2*3 AS RESULT;  
result  
-----  
6  
(1 row)
```

- /

Description: Division (The result is not rounded.)

Example:

```
gaussdb=# SELECT 4/2 AS RESULT;  
result  
-----  
2  
(1 row)  
gaussdb=# SELECT 4/3 AS RESULT;  
result  
-----  
1.3333333333333333  
(1 row)
```

- +/-

Description: Positive/Negative

Example:

```
gaussdb=# SELECT -2 AS RESULT;  
result  
-----  
-2  
(1 row)
```

- %

Description: Modulo (to obtain the remainder)

Example:

```
gaussdb=# SELECT 5%4 AS RESULT;  
result
```

- ```

1
(1 row)
```

@

Description: Absolute value

Example:

```
gaussdb=# SELECT @ -5.0 AS RESULT;
result

5.0
(1 row)
```
- ^
- ```
-----  
8.0000000000000000  
(1 row)
```

^

Description: Power (exponent calculation)

Example:

```
gaussdb=# SELECT 2.0^3.0 AS RESULT;  
result  
-----  
8.0000000000000000  
(1 row)
```
- |/
- ```

5
(1 row)
```

|/

Description: Square root

Example:

```
gaussdb=# SELECT |/ 25.0 AS RESULT;
result

5
(1 row)
```
- ||/
- ```
-----  
3  
(1 row)
```

||/

Description: Cubic root

Example:

```
gaussdb=# SELECT ||/ 27.0 AS RESULT;  
result  
-----  
3  
(1 row)
```
- !
- ```

120
(1 row)
```

!

Description: Factorial

Example:

```
gaussdb=# SELECT 5! AS RESULT;
result

120
(1 row)
```
- !!
- ```
-----  
120  
(1 row)
```

!!

Description: Factorial (prefix operator)

Example:

```
gaussdb=# SELECT !!5 AS RESULT;  
result  
-----  
120  
(1 row)
```
- &
- &

Description: Binary AND

Example:

```
gaussdb=# SELECT 91&15 AS RESULT;
result
-----
    11
(1 row)
```

- |
Description: Binary OR

Example:

```
gaussdb=# SELECT 32|3 AS RESULT;
result
-----
    35
(1 row)
```

- #
Description: Binary XOR

Example:

```
gaussdb=# SELECT 17#5 AS RESULT;
result
-----
    20
(1 row)
```

- ~
Description: Binary NOT

Example:

```
gaussdb=# SELECT ~1 AS RESULT;
result
-----
   -2
(1 row)
```

- <<
Description: Binary shift left

Example:

```
gaussdb=# SELECT 1<<4 AS RESULT;
result
-----
    16
(1 row)
```

- >>
Description: Binary shift right

Example:

```
gaussdb=# SELECT 8>>2 AS RESULT;
result
-----
     2
(1 row)
```

Arithmetic Functions

- abs(x)
Description: Absolute value
Return type: same as the input
Example:

```
gaussdb=# SELECT abs(-17.4);
abs
-----
17.4
(1 row)
```

- **acos(x)**

Description: Arc cosine

Return type: double precision

Example:

```
gaussdb=# SELECT acos(-1);
acos
-----
3.14159265358979
(1 row)
```

- **asin(x)**

Description: Arc sine

Return type: double precision

Example:

```
gaussdb=# SELECT asin(0.5);
asin
-----
.523598775598299
(1 row)
```

- **atan(x)**

Description: Arc tangent

Return type: double precision

Example:

```
gaussdb=# SELECT atan(1);
atan
-----
.785398163397448
(1 row)
```

- **atan2(y, x)**

Description: Arc tangent of y/x

Return type: double precision

Example:

```
gaussdb=# SELECT atan2(2, 1);
atan2
-----
1.10714871779409
(1 row)
```

- **bitand(integer, integer)**

Description: Performs the AND (&) operation on two integers.

Return type: bigint

Example:

```
gaussdb=# SELECT bitand(127, 63);
bitand
-----
63
(1 row)
```

- **cbirt(dp)**

Description: Cubic root

Return type: double precision

Example:

```
gaussdb=# SELECT cbrt(27.0);
cbrt
-----
3
(1 row)
```

- **ceil(x)**

Description: Minimum integer greater than or equal to the parameter

Return type: integer

Example:

```
gaussdb=# SELECT ceil(-42.8);
ceil
-----
-42
(1 row)
```

- **ceiling(dp or numeric)**

Description: Minimum integer (alias of ceil) greater than or equal to the parameter

Return type: same as the input

Example:

```
gaussdb=# SELECT ceiling(-95.3);
ceiling
-----
-95
(1 row)
```

- **cos(x)**

Description: Cosine

Return type: double precision

Example:

```
gaussdb=# SELECT cos(-3.1415927);
cos
-----
-.9999999999999999
(1 row)
```

- **cosh(x)**

Description: Hyperbolic cosine

Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

```
gaussdb=# SELECT cosh(4);
cosh
-----
27.3082328360165
(1 row)
```

 **NOTE**

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- **cot(x)**

Description: Cotangent

Return type: double precision

Example:

```
gaussdb=# SELECT cot(1);
cot
-----
.642092615934331
(1 row)
```

- **degrees(dp)**

Description: Converts radians to angles.

Return type: double precision

Example:

```
gaussdb=# SELECT degrees(0.5);
degrees
-----
28.6478897565412
(1 row)
```

- **div(y numeric, x numeric)**

Description: Integer part of y/x

Return type: numeric

Example:

```
gaussdb=# SELECT div(9,4);
div
----
2
(1 row)
```

- **exp(x)**

Description: Natural exponent

Return type: same as the input

Example:

```
gaussdb=# SELECT exp(1.0);
exp
-----
2.7182818284590452
(1 row)
```

- **floor(x)**

Description: Not larger than the maximum integer of the parameter

Return type: same as the input

Example:

```
gaussdb=# SELECT floor(-42.8);
floor
-----
-43
(1 row)
```

- **int1(in)**

Description: Converts the input text parameter to a value of the int1 type and returns the value.

Return type: int1

Example:

```
gaussdb=# SELECT int1('123');
int1
-----
123
```

```
(1 row)
gaussdb=# SELECT int1('1.1');
int1
-----
1
(1 row)
```

 NOTE

- When **sql_compatibility** is set to **'MYSQL'**, non-integer characters are automatically truncated or the value **0** is returned.
 - When **sql_compatibility** is not set to **'MYSQL'**, an error message is displayed for non-integer characters, indicating that the input is invalid.
- **int2(in)**

Description: Converts the input parameter to a value of the int2 type and returns the value. The supported input parameter types include bigint, float4, float8, int16, integer, numeric, real, and text.

Return type: int2

Example:

```
gaussdb=# SELECT int2('1234');
int2
-----
1234
(1 row)
gaussdb=# SELECT int2(25.3);
int2
-----
25
(1 row)
```

 NOTE

- When **sql_compatibility** is set to **'MYSQL'**, non-integer characters are automatically truncated or the value **0** is returned.
 - When **sql_compatibility** is not set to **'MYSQL'**, an error message is displayed for non-integer characters, indicating that the input is invalid.
- **int4(in)**

Description: Converts the input parameter to a value of the int4 type and returns the value. The supported input parameter types include bit, boolean, char, double precision, int16, numeric, real, smallint, and text

Return type: int4

Example:

```
gaussdb=# SELECT int4('789');
int4
-----
789
(1 row)
gaussdb=# SELECT int4(99.9);
int4
-----
100
(1 row)
```

 NOTE

- When **sql_compatibility** is set to **'MYSQL'**, non-integer characters are automatically truncated or the value **0** is returned.
- When **sql_compatibility** is not set to **'MYSQL'**, an error message is displayed for non-integer characters, indicating that the input is invalid.

- **int8(in)**

Description: Converts the input parameter to a value of the int8 type and returns the value. The supported input parameter types include bit, double precision, int16, integer, numeric, oid, real, smallint, and text.

Return type: int8

Example:

```
gaussdb=# SELECT int8('789');
 int8
-----
 789
(1 row)
gaussdb=# SELECT int8(99.9);
 int8
-----
 99
(1 row)
```

 **NOTE**

- When **sql_compatibility** is set to 'MYSQL', non-integer characters are automatically truncated or the value **0** is returned.
 - When **sql_compatibility** is not set to 'MYSQL', an error message is displayed for non-integer characters, indicating that the input is invalid.
- **float4(in)**

Description: Converts the input parameter to a value of the float4 type and returns the value. The supported input parameter types include bigint, double precision, int16, integer, numeric, smallint, and text.

Return type: float4

Example:

```
gaussdb=# SELECT float4('789');
 float4
-----
 789
(1 row)
gaussdb=# SELECT float4(99.9);
 float4
-----
 99.9
(1 row)
```

- **float8(in)**

Description: Converts the input parameter to a value of the float8 type and returns the value. The supported input parameter types include bigint, int16, integer, numeric, real, smallint, and text.

Return type: float8

Example:

```
gaussdb=# SELECT float8('789');
 float8
-----
 789
(1 row)
gaussdb=# SELECT float8(99.9);
 float8
-----
 99.9
(1 row)
```

- **int16(in)**

Description: Converts the input parameter to a value of the int16 type and returns the value. The supported input parameter types include bigint, Boolean, double precision, integer, numeric, oid, real, smallint, and tinyint.

Return type: int16

Example:

```
gaussdb=# SELECT int16('789');
 int16
-----
   789
(1 row)

gaussdb=# SELECT int16(99.9);
 int16
-----
   100
(1 row)
```

- **numeric(in)**

Description: Converts the input parameter to a value of the numeric type and returns the value. The supported input parameter types include bigint, Boolean, double precision, int16, integer, money, real, and smallint.

Return type: numeric

Example:

```
gaussdb=# SELECT "numeric"('789');
 numeric
-----
   789
(1 row)

gaussdb=# SELECT "numeric"(99.9);
 numeric
-----
   99.9
(1 row)
```

- **oid(in)**

Description: Converts the input parameter to a value of the oid type and returns the value. The supported input parameter types include bigint and int16.

Return type: oid

- **radians(dp)**

Description: Converts angles to radians.

Return type: double precision

Example:

```
gaussdb=# SELECT radians(45.0);
 radians
-----
.785398163397448
(1 row)
```

- **random()**

Description: Random number between 0.0 and 1.0

Return type: double precision

Example:

```
gaussdb=# SELECT random();
 random
```

```
-----
.824823560658842
(1 row)
```

- multiply(x double precision or text, y double precision or text)

Description: product of x and y.

Return type: double precision

Example:

```
gaussdb=# SELECT multiply(9.0, '3.0');
multiply
```

```
-----
27
(1 row)
```

```
gaussdb=# SELECT multiply('9.0', 3.0);
multiply
```

```
-----
27
(1 row)
```

- ln(x)

Description: Natural logarithm

Return type: same as the input

Example:

```
gaussdb=# SELECT ln(2.0);
ln
```

```
-----
.6931471805599453
(1 row)
```

- log(x)

Description: Logarithm with 10 as the base

Return type: same as the input

Example:

```
gaussdb=# SELECT log(100.0);
log
```

```
-----
2.0000000000000000
(1 row)
```

- log(b numeric, x numeric)

Description: Logarithm with b as the base

Return type: numeric

Example:

```
gaussdb=# SELECT log(2.0, 64.0);
log
```

```
-----
6.0000000000000000
(1 row)
```

- mod(x,y)

Description:

Remainder of x/y (model)

If x equals to 0, y is returned.

Return type: same as the parameter type

Example:

```
gaussdb=# SELECT mod(9,4);
mod
```

```
-----
 1
(1 row)
gaussdb=# SELECT mod(9,0);
mod
-----
 9
(1 row)
```

- pi()

Description: π constant value

Return type: double precision

Example:

```
gaussdb=# SELECT pi();
pi
-----
3.14159265358979
(1 row)
```

- power(a double precision, b double precision)

Description: b power of a

Return type: double precision

Example:

```
gaussdb=# SELECT power(9.0, 3.0);
power
-----
729.0000000000000000
(1 row)
```

- remainder(x,y)

Description: Remainder of x/y. If y is 0, an error is reported.

Return type: same as the input (float4, float8, or numeric)

Example:

```
gaussdb=# SELECT remainder(11,4);
remainder
-----
-1
(1 row)
gaussdb=# SELECT remainder(9,0);
ERROR: division by zero
CONTEXT: referenced column: remainder
```

 **NOTE**

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- round(x)

Description: Integer closest to the input parameter

Return type: same as the input (double precision or numeric)

Example:

```
gaussdb=# SELECT round(42.4);
round
-----
 42
(1 row)

gaussdb=# SELECT round(42.6);
round
-----
```

```
43  
(1 row)
```

 **CAUTION**

The output of the float/double type may be **-0**. (This also occurs in functions such as trunc and ceil. If the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database, the returned result is **0**. The following is an example:

```
gaussdb=# SELECT round(-0.2::float8);  
round  
-----  
-0  
(1 row)
```

- round(v numeric, s int)

Description: **s** digits are kept after the decimal point.

Return type: numeric

Example:

```
gaussdb=# SELECT round(42.4382, 2);  
round  
-----  
42.44  
(1 row)
```

 **NOTE**

When the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database, **s** is truncated to an integer. Otherwise, **s** is rounded off to an integer.

When the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s1** in an ORA-compatible database, the round function supports round(timestamp, text) overloading. When **(text, text)** or **(text, ")** is used as the input parameter to call the round function, round(timestamp, text) is preferred.

- setseed(dp)

Description: Sets seed for the following random() calling (between -1.0 and 1.0, inclusive).

Return type: void

Example:

```
gaussdb=# SELECT setseed(0.54823);  
setseed  
-----  
(1 row)
```

- sign(x)

Description: Returns symbols of this parameter.

Return type: **-1** indicates negative numbers. **0** indicates 0, and **1** indicates positive numbers.

Example:

```
gaussdb=# SELECT sign(-8.4);  
sign  
-----  
-1  
(1 row)
```

- **sin(x)**
Description: Sine
Return type: double precision

Example:

```
gaussdb=# SELECT sin(1.57079);
      sin
-----
.999999999979986
(1 row)
```

- **sinh(x)**
Description: Hyperbolic sine
Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

```
gaussdb=# SELECT sinh(4);
      sinh
-----
27.2899171971277
(1 row)
```

 **NOTE**

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- **sqrt(x)**
Description: Square root
Return type: same as the input

Example:

```
gaussdb=# SELECT sqrt(2.0);
      sqrt
-----
1.414213562373095
(1 row)
```

- **tan(x)**
Description: Tangent
Return type: double precision

Example:

```
gaussdb=# SELECT tan(20);
      tan
-----
2.23716094422474
(1 row)
```

- **tanh(x)**
Description: Hyperbolic tangent
Return type: same as the input (double precision or numeric)

Example:

```
gaussdb=# SELECT tanh(0.1);
      tanh
-----
0.0996679946249558171183050836783521835389
(1 row)
```

 **NOTE**

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- `trunc(x)`

Description: Truncates (the integral part).

Return type: same as the input

Example:

```
gaussdb=# SELECT trunc(42.8);
trunc
-----
    42
(1 row)
```

- `trunc(v numeric, s int)`

Description: Truncates a number with **s** digits after the decimal point.

Return type: numeric

Example:

```
gaussdb=# SELECT trunc(42.4382, 2);
trunc
-----
 42.43
(1 row)
```

 **NOTE**

In an ORA-compatible database, this function is valid only when **a_format_version** is set to **10c** and **a_format_dev_version** is a valid value under the compatible configuration item. If the value of **s** is a decimal, the value is truncated instead of being rounded off.

- `width_bucket(op numeric, b1 numeric, b2 numeric, count int)`

Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.

Return type: int

Example:

```
gaussdb=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
width_bucket
-----
            3
(1 row)
```

- `width_bucket(op dp, b1 dp, b2 dp, count int)`

Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.

Return type: int

Example:

```
gaussdb=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
width_bucket
-----
            3
(1 row)
```

- `smgrne(a smgr, b smgr)`

Description: Compares two integers of the `smgr` type to check whether they are different.

- Return type: Boolean
- smgreq(a smgr, b smgr)
Description: Compares two integers of the smgr type to check whether they are equivalent.
Return type: Boolean
- int1abs
Description: Returns the absolute value of data of the uint8 type.
Parameter: tinyint
Return type: tinyint
- int1and
Description: Returns the bitwise AND result of two data records of the uint8 type.
Parameter: tinyint, tinyint
Return type: tinyint
- int1cmp
Description: Returns the comparison result of two data records of the uint8 type. If the value of the first parameter is greater, **1** is returned. If the value of the second parameter is greater, **-1** is returned. If they are the same, **0** is returned.
Parameter: tinyint, tinyint
Return type: integer
- int1div
Description: Returns the result of dividing two data records of the uint8 type. The result is of the float8 type.
Parameter: tinyint, tinyint
Return type: tinyint
- int1eq
Description: Compares two pieces of data of the uint8 type to check whether they are the same.
Parameter: tinyint, tinyint
Return type: Boolean
- int1ge
Description: Determines whether the value of the first parameter is greater than or equal to the value of the second parameter in two data records of the uint8 type.
Parameter: tinyint, tinyint
Return type: Boolean
- int1gt
Description: Performs the greater-than operation on an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: Boolean
- int1larger

Description: Returns the larger value of unsigned one-byte integers.

Parameter: tinyint, tinyint

Return type: tinyint

- int1le

Description: Determines whether the unsigned 1-byte integer is less than or equal to.

Parameter: tinyint, tinyint

Return type: Boolean

- int1lt

Description: Determines whether the unsigned 1-byte integer is less than.

Parameter: tinyint, tinyint

Return type: Boolean

- int1smaller

Description: Returns the smaller of two unsigned one-byte integers.

Parameter: tinyint, tinyint

Return type: tinyint

- int1inc

Description: Performs an addition operation on an unsigned 1-byte integer.

Parameter: tinyint

Return type: tinyint

- int1mi

Description: Performs a minus operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: tinyint

- int1mod

Description: Performs a remainder operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: tinyint

- int1mul

Description: Performs a multiplication operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: tinyint

- int1ne

Description: Performs a not-equal-to operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: Boolean

- int1pl

Description: Performs an addition operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: tinyint

- **int1um**
Description: Returns an unsigned 2-byte integer after subtracting the opposite number from the unsigned 1-byte integer.
Parameter: tinyint
Return type: smallint
- **int1xor**
Description: Performs an exclusive OR operation on an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: tinyint
- **cash_div_int1**
Description: Performs a division operation on the money type.
Parameter: money, tinyint
Return type: money
- **cash_mul_int1**
Description: Performs a multiplication operation on the money type.
Parameter: money, tinyint
Return type: money
- **int1not**
Description: Reverts binary bits of an unsigned 1-byte integer.
Parameter: tinyint
Return type: tinyint
- **int1or**
Description: Performs an OR operation on an unsigned 1-byte integer.
Parameter: tinyint, tinyint
Return type: tinyint
- **int1shl**
Description: Shifts an unsigned 1-byte integer leftwards by a specified number of bits.
Parameter: tinyint, integer
Return type: tinyint
- **int1shr**
Description: Shifts an unsigned 1-byte integer rightwards by a specified number of bits.
Parameter: tinyint, integer
Return type: tinyint
- **analyze_tgtype_for_type(n smallint)**
Description: Parses **pg_trigger.tgtype**, parses *n* by bit, and returns one of **before each row**, **after each row**, **before statement**, **after statement**, and **instead of**.
Return type: varchar2(16)
- **analyze_tgtype_for_event(n smallint)**

Description: Parses **pg_trigger.tgtype**, parses *n* by bit, and returns one or more of **insert**, **update**, **delete**, and **truncate**.

Return type: varchar2(246)

- nanvl(*n2*, *n1*)

Description: Two parameters are entered. The parameters must be of the numeric type or a non-numeric type that can be implicitly converted to the numeric type. If the first parameter **n2** is NaN, **n1** is returned. Otherwise, **n2** is returned.

Return value type: input parameter with a higher priority. The priority is as follows: double precision > float4 > numeric.

Example:

```
gaussdb=# SELECT nanvl('NaN', 1.1);
 nanvl
-----
 1.1
(1 row)
```

 **NOTE**

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

7.5.8 Date and Time Processing Functions and Operators

Date and Time Operators

For details about the time and date operators, see [Table 7-30](#).

 **NOTE**

When the user uses date and time operators, explicit type prefixes are modified for corresponding operands to ensure that the operands parsed by the database are consistent with what the user expects, and no unexpected results occur.

For example, abnormal mistakes will occur in the following example without an explicit data type.

```
SELECT date '2001-10-01' - '7' AS RESULT;
```

Table 7-30 Time and date operators

Operator	Example
+	<pre>gaussdb=# SELECT date '2001-9-28' + integer '7' AS RESULT; result ----- 2001-10-05 (1 row)</pre> <p>NOTE</p> <ul style="list-style-type: none"> • In MySQL compatibility mode, the query result is 2001-10-05. • In ORA compatibility mode, the query result is 2001-10-05 00:00:00.

Operator	Example
	<pre>gaussdb=# SELECT date '2001-09-28' + interval '1 hour' AS RESULT; result ----- 2001-09-28 01:00:00 (1 row)</pre> <pre>gaussdb=# SELECT date '2001-09-28' + time '03:00' AS RESULT; result ----- 2001-09-28 03:00:00 (1 row)</pre> <pre>gaussdb=# SELECT interval '1 day' + interval '1 hour' AS RESULT; result ----- 1 day 01:00:00 (1 row)</pre> <pre>gaussdb=# SELECT timestamp '2001-09-28 01:00' + interval '23 hours' AS RESULT; result ----- 2001-09-29 00:00:00 (1 row)</pre> <pre>gaussdb=# SELECT time '01:00' + interval '3 hours' AS RESULT; result ----- 04:00:00 (1 row)</pre>
-	<pre>gaussdb=# SELECT date '2001-10-01' - date '2001-09-28' AS RESULT; result ----- 3 (1 row)</pre> <pre>gaussdb=# SELECT date '2001-10-01' - integer '7' AS RESULT; result ----- 2001-09-24 00:00:00 (1 row)</pre> <pre>gaussdb=# SELECT date '2001-09-28' - interval '1 hour' AS RESULT; result ----- 2001-09-27 23:00:00 (1 row)</pre> <pre>gaussdb=# SELECT time '05:00' - time '03:00' AS RESULT; result ----- 02:00:00 (1 row)</pre> <pre>gaussdb=# SELECT time '05:00' - interval '2 hours' AS RESULT; result ----- 03:00:00 (1 row)</pre> <pre>gaussdb=# SELECT timestamp '2001-09-28 23:00' - interval '23 hours' AS RESULT; result ----- 2001-09-28 00:00:00 (1 row)</pre>

Operator	Example
	<pre>gaussdb=# SELECT interval '1 day' - interval '1 hour' AS RESULT; result ----- 23:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT timestamp '2001-09-29 03:00' - timestamp '2001-09-27 12:00' AS RESULT; result ----- 1 day 15:00:00 (1 row)</pre>
*	<pre>gaussdb=# SELECT 900 * interval '1 second' AS RESULT; result ----- 00:15:00 (1 row)</pre>
	<pre>gaussdb=# SELECT 21 * interval '1 day' AS RESULT; result ----- 21 days (1 row)</pre>
	<pre>gaussdb=# SELECT double precision '3.5' * interval '1 hour' AS RESULT; result ----- 03:30:00 (1 row)</pre>
/	<pre>gaussdb=# SELECT interval '1 hour' / double precision '1.5' AS RESULT; result ----- 00:40:00 (1 row)</pre>

Time and Date Functions

- age(timestamp, timestamp)**

Description: Subtracts parameters, producing a result in YYYY-MM-DD format. If the result is negative, the returned result is also negative. The input parameters can contain timezone or not.

Return type: interval

Example:

```
gaussdb=# SELECT age(timestamp '2001-04-10', timestamp '1957-06-13');
age
-----
43 years 9 mons 27 days
(1 row)
```
- age(timestamp)**

Description: Subtracts the parameter value from the system time when the current SQL statement starts to be executed. The input parameter may or may not contain a time zone.

Return type: interval

Example:

```
gaussdb=# SELECT age(timestamp '1957-06-13');
      age
-----
60 years 2 mons 18 days
(1 row)
```

- `clock_timestamp()`

Description: Returns the timestamp of the system time when the current function is called. The volatile function obtains the latest timestamp for each scan. Therefore, the result of each call in a query is different.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT clock_timestamp();
      clock_timestamp
-----
2017-09-01 16:57:36.636205+08
(1 row)
```

- `current_date`

Description: Returns the system date when the current SQL statement starts.

Return type: date

Example:

```
gaussdb=# SELECT current_date;
      date
-----
2017-09-01
(1 row)
```

 **NOTE**

When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2** in an ORA-compatible database, the return value type is timestamp.

- `current_time`

Description: Specifies the system time when the current transaction starts.

Return type: time with time zone

Example:

```
gaussdb=# SELECT current_time;
      timetz
-----
16:58:07.086215+08
(1 row)
```

- `current_timestamp`

Description: Returns the system time when the current SQL execution starts. This is a statement-level timestamp. The returned results within the same statement remain unchanged.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT current_timestamp;
      pg_systimestamp
-----
2017-09-01 16:58:19.22173+08
(1 row)
```

- `current_timestamp(precision)`

Description: Returns the system time when the current SQL statement is started, and rounds the microseconds of the result to the specified decimal places.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT current_timestamp(1);
          timestampz
-----
2017-09-01 16:58:19.2+08
(1 row)
```

 **NOTE**

- When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2** in an ORA-compatible database, the **precision** parameter can be an integer of the numeric type. Otherwise, only the int type is supported.
- Zeros at the end of microseconds are not displayed. For example, 2017-09-01 10:32:19.212000 is displayed as 2017-09-01 10:32:19.212.

- **pg_systimestamp()**

Description: Current date and time (start of the current statement).

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_systimestamp();
          pg_systimestamp
-----
2015-10-14 11:21:28.317367+08
(1 row)
```

- **date_part(text, timestamp)**

Description:

Retrieves fields such as year or hour from date/time values.

It is equivalent to **extract(field from timestamp)**.

Timestamp types: abstime, date, interval, reltime, time with time zone, time without time zone, timestamp with time zone, timestamp without time zone

Return type: double precision

Example:

```
gaussdb=# SELECT date_part('hour', timestamp '2001-02-16 20:38:40');
          date_part
-----
                20
(1 row)
```

- **date_part(text, interval)**

Description: Obtains the month. If the value is greater than 12, obtain the remainder after it is divided by 12. It is equivalent to **extract(field from timestamp)**.

Return type: double precision

Example:

```
gaussdb=# SELECT date_part('month', interval '2 years 3 months');
          date_part
-----
                3
(1 row)
```

- **date_trunc(text, timestamp)**

Description: Truncates to the precision specified by **text**.

Return type: interval, timestamp with time zone, timestamp without time zone

Example:

```
gaussdb=# SELECT date_trunc('hour', timestamp '2001-02-16 20:38:40');
 date_trunc
-----
2001-02-16 20:00:00
(1 row)
```

- **trunc(timestamp)**

Description: Truncates to day by default.

Example:

```
gaussdb=# SELECT trunc(timestamp '2001-02-16
20:38:40');
          trunc
-----
2001-02-16 00:00:00
(1 row)
```

- **trunc(arg1, arg2)**

Description: Truncates to the precision specified by **arg2**.

- Type of **arg1**: interval, timestamp with time zone, timestamp without time zone
- Type of **arg2**: text

Return type: interval, timestamp with time zone, timestamp without time zone

Example:

```
gaussdb=# SELECT trunc(timestamp '2001-02-16 20:38:40',
'hour');
          trunc
-----
2001-02-16 20:00:00
(1 row)
```

- **round(arg1, arg2)**

Description: Rounds off to the precision specified by **arg2**.

Type of **arg1**: timestamp without time zone

Type of **arg2**: text

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT round(timestamp '2001-02-16 20:38:40',
'hour');
          round
-----
2001-02-16 21:00:00
(1 row)
```

NOTE

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database.

- **daterange(arg1, arg2)**

Description: Obtains time boundary information.

arg1 type: date

arg2 type: date

Return type: daterange

Example:

```
gaussdb=# select daterange('2000-05-06','2000-08-08');
 daterange
-----
 [2000-05-06,2000-08-08)
(1 row)
```

- `daterange(arg1, arg2, text)`

Description: Obtains time boundary information.

arg1 type: date

arg2 type: date

text type: text

Return type: daterange

Example:

```
gaussdb=# select daterange('2000-05-06','2000-08-08','[]');
 daterange
-----
 [2000-05-06,2000-08-09)
(1 row)
```

- `extract(field from timestamp)`

Description: Obtains the hour.

Return type: double precision

Example:

```
gaussdb=# SELECT extract(hour from timestamp '2001-02-16 20:38:40');
 date_part
-----
      20
(1 row)
```

- `extract(field from interval)`

Description: Obtains the month. If the value is greater than 12, obtain the remainder after it is divided by 12.

Return type: double precision

Example:

```
gaussdb=# SELECT extract(month from interval '2 years 3 months');
 date_part
-----
      3
(1 row)
```

- `isfinite(date)`

Description: Checks whether a date is a finite value. If yes, **t** is returned. Otherwise, **f** is returned.

Return type: Boolean

Example:

```
gaussdb=# SELECT isfinite(date '2001-02-16');
 isfinite
-----
 t
(1 row)
gaussdb=# SELECT isfinite(date 'infinity');
 isfinite
-----
 f
(1 row)
```

- `isfinite(timestamp)`

Description: Checks whether a timestamp is a finite value. If yes, **t** is returned. Otherwise, **f** is returned.

Return type: Boolean

Example:

```
gaussdb=# SELECT isfinite(timestamp '2001-02-16 21:28:30');
isfinite
-----
t
(1 row)
gaussdb=# SELECT isfinite(timestamp 'infinity');
isfinite
-----
f
(1 row)
```

- **isfinite(interval)**

Description: Checks whether the interval is a finite value. If yes, **t** is returned. Currently, **f** cannot be returned. If **'infinity'** is entered, an error is reported.

Return type: Boolean

Example:

```
gaussdb=# SELECT isfinite(interval '4 hours');
isfinite
-----
t
(1 row)
```

- **justify_days(interval)**

Description: Adjusts intervals to 30-day time periods, which are represented as months.

Return type: interval

Example:

```
gaussdb=# SELECT justify_days(interval '35 days');
justify_days
-----
1 mon 5 days
(1 row)
```

- **justify_hours(interval)**

Description: Sets the time interval in days (24 hours is one day).

Return type: interval

Example:

```
gaussdb=# SELECT JUSTIFY_HOURS(INTERVAL '27 HOURS');
justify_hours
-----
1 day 03:00:00
(1 row)
```

- **justify_interval(interval)**

Description: Adjusts **interval** using **justify_days** and **justify_hours**.

Return type: interval

Example:

```
gaussdb=# SELECT JUSTIFY_INTERVAL(INTERVAL '1 MON -1 HOUR');
justify_interval
-----
29 days 23:00:00
(1 row)
```

- **localtime**
Description: Specifies the system time when the current transaction starts.
Return type: time
Example:

```
gaussdb=# SELECT localtime AS RESULT;  
      result  
-----  
16:05:55.664681  
(1 row)
```
- **localtimestamp**
Description: Returns the system date and time when the current SQL query execution starts.
Return type: timestamp
Example:

```
gaussdb=# SELECT localtimestamp;  
      timestamp  
-----  
2017-09-01 17:03:30.781902  
(1 row)
```
- **now()**
Description: Returns the system date and time when the current transaction starts. The results returned in the same transaction are the same.
Return type: timestamp with time zone
Example:

```
gaussdb=# SELECT now();  
      now  
-----  
2017-09-01 17:03:42.549426+08  
(1 row)
```
- **timenow()**
Description: Returns the system date and time when the current SQL query execution starts.
Return type: abstime
Example:

```
gaussdb=# select timenow();  
      timenow  
-----  
2020-06-23 20:36:56+08  
(1 row)
```
- **numtodsinterval(num, interval_unit)**
Description: Converts a number to the interval type. **num** is a numeric-typed number. **interval_unit** is a string in the following format: 'DAY' | 'HOUR' | 'MINUTE' | 'SECOND'
You can set the GUC parameter **IntervalStyle** to **ORA** to be compatible with the interval output format of the function in the Oracle database.
Return type: interval
Example:

```
gaussdb=# SELECT numtodsinterval(100, 'HOUR');  
      numtodsinterval  
-----  
100:00:00
```

```
(1 row)
gaussdb=# SET intervalstyle = oracle;
SET
gaussdb=# SELECT numtodsinterval(100, 'HOUR');
      numtodsinterval
-----
+000000004 04:00:00.000000000
(1 row)
```

 **NOTE**

When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2** in an ORA-compatible database, an error is reported if **interval_unit** is set to **'DAY'** and **num** is set to a value greater than **1000000000**.

- **numtoyminterval(num, interval_unit)**

Description: Converts a number to the interval type. **num** is a number of the numeric type, and **interval_unit** is a string of the fixed format ('YEAR'|'MONTH').

You can set the GUC parameter **IntervalStyle** to **ORA** to be compatible with the interval output format in the Oracle database.

Return type: interval

Example:

```
gaussdb=# SELECT numtoyminterval(100, 'MONTH');
      numtoyminterval
-----
8 years 4 mons
(1 row)

gaussdb=# SET intervalstyle = oracle;
SET
gaussdb=# SELECT numtodsinterval(100, 'MONTH');
      numtoyminterval
-----
8-4
(1 row)
```

 **NOTE**

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

- **new_time(date, timezone1,timezone2)**

Description: Returns the date and time of the time zone specified by **timezone2** when the date and time of the time zone specified by **timezone1** are date.

Return type: timestamp

Example:

```
gaussdb=# select new_time('1997-10-10','AST','EST');
      new_time
-----
1997-10-09 23:00:00
(1 row)
gaussdb=# SELECT NEW_TIME(TO_TIMESTAMP ('10-Sep-02 14:10:10.123000','DD-Mon-RR
HH24:MI:SS.FF'), 'AST', 'PST');
      new_time
-----
2002-09-10 10:10:10.123
(1 row)
```

 NOTE

This function is valid only when the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s2** in an ORA-compatible database.

- **sessiontimezone**

Description: Returns the time zone of the current session. There is no input parameter.

Return type: text

Example:

```
gaussdb=# SELECT SESSIONTIMEZONE;
 session_time_zone
-----
PST8PDT
(1 row)
gaussdb=# SELECT LOWER(SESSIONTIMEZONE);
 lower
-----
@ 8 hours
(1 row)
```

 NOTE

This function is valid only when the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s2** in an ORA-compatible database.

When the value of **set session time zone** is in the GMT+08:00/GMT-08:00 format, the verification fails and an error is reported. This behavior meets the expectation. If the value is 's2' and the "ERROR:invalid value for parameter "TimeZone" :\"GMT-08:00\"" error is reported when you use JDBC to create a connection, the application where the driver is located sends the same time zone parameter in GMT format to GaussDB. You can use either of the following methods to solve the problem:

Method 1: Adjust the time zone of the OS on the application side and set the local time zone to the region format, for example, Asia/Shanghai.

Method 2: Use the JDBC driver that matches the version on the application side. The JDBC driver changes the GMT time zone to a time zone format that can be identified by the database.

- **sys_extract_utc(timestamp| timestamptz)**

Description: Extracts Coordinated Universal Time (UTC, also formerly known as Greenwich Mean Time) from a date-time value with a time zone offset or time zone region name. If no time zone is specified, the date and time are associated with the session time zone. The input parameter can be in timestamp or timestamp format.

Return type: timestamp

Example:

```
gaussdb=# SELECT SYS_EXTRACT_UTC(TIMESTAMP '2000-03-28 11:30:00.00');
 sys_extract_utc
-----
2000-03-28 03:30:00
(1 row)
gaussdb=# SELECT SYS_EXTRACT_UTC(TIMESTAMP '2000-03-28 11:30:00.00 -08:00');
 sys_extract_utc
-----
2000-03-28 19:30:00
(1 row)
```

 NOTE

This function is valid only when the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s2** in an ORA-compatible database.

- `tz_offset('time_zone_name' | '(+/-)hh:mi' | SESSIONTIMEZONE | DBTIMEZONE)`

Description: Returns the UTC offset of the time zone indicated by the input parameter. The input parameter has the preceding four formats.

Return type: text

Example:

```
gaussdb=# SELECT TZ_OFFSET('US/Pacific');
tz_offset
-----
-08:00
(1 row)
gaussdb=# SELECT TZ_OFFSET(sessiontimezone);
tz_offset
-----
+08:00
(1 row)
```

NOTE

This function is valid only when the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s2** in an ORA-compatible database.

- `pg_sleep(seconds)`

Description: Specifies the delay time of the server thread in unit of second.

Note that when the database calls this function, the corresponding transaction snapshot is obtained, which is equivalent to a long transaction. If the input parameter time is too long, the database **oldestxmin** may fail to be executed, affecting the table recycling and query performance.

Return type: void

Example:

```
gaussdb=# SELECT pg_sleep(10);
pg_sleep
-----
(1 row)
```

- `statement_timestamp()`

Description: Current date and time (start of the current statement).

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT statement_timestamp();
statement_timestamp
-----
2017-09-01 17:04:39.119267+08
(1 row)
```

- `sysdate`

Description: Returns the system date and time when the current SQL statement is executed.

Return type: timestamp

Example:

```
gaussdb=# SELECT sysdate;
sysdate
-----
2017-09-01 17:04:49
(1 row)
```

- current_sysdate**

Description: Returns the system date and time when the current SQL query execution starts.

Return type: timestamp

Example:

```
gaussdb=# SELECT current_sysdate();
current_sysdate
-----
2023-06-20 20:09:02
(1 row)
```
 - timeofday()**

Description: Returns the timestamp (such as **clock_timestamp**, but the return type is text) of the system time when the current function is called.

Return type: text

Example:

```
gaussdb=# SELECT totimeofday();
timeofday
-----
Fri Sep 01 17:05:01.167506 2017 CST
(1 row)
```
 - transaction_timestamp()**

Description: Specifies the system date and time when the current transaction starts.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT transaction_timestamp();
transaction_timestamp
-----
2017-09-01 17:05:13.534454+08
(1 row)
```
 - add_months(d,n)**

Description: Returns the date *date* plus *integer* months.

d: indicates the value of the timestamp type and the value that can be implicitly converted to the timestamp type.

n: indicates the value of the INTEGER type and the value that can be implicitly converted to the INTEGER type.

Return type: timestamp

Example:

```
gaussdb=# SELECT add_months(to_date('2017-5-29', 'yyyy-mm-dd'), 11) FROM sys_dummy,
add_months
-----
2018-04-29 00:00:00
(1 row)
```
-  **NOTE**
- In the scenario where this function is in an ORA-compatible database, the value of **a_format_version** is **10c**, and that of **a_format_dev_version** is **s1**:
- If the calculation result is greater than 9999, an error is reported.
 - If the value of *n* is a decimal, the value is truncated instead of being rounded off.
- last_day(d)**

Description: Returns the date of the last day of the month that contains *date*.

Return type: timestamp

Example:

```
gaussdb=# SELECT last_day(to_date('2017-01-01', 'YYYY-MM-DD')) AS cal_result;
   cal_result
-----
2017-01-31 00:00:00
(1 row)
```

- `months_between(d1, d2)`

Description: Calculates the month difference between time points **d1** and **d2**. If both dates are the end of a month or are the same day, an integer is returned. Otherwise, the return value is a decimal and is calculated as 31 days per month.

Return type: numeric

Example:

```
gaussdb=# SELECT months_between(to_date('2022-10-31', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
   months_between
-----
1
(1 row)
```

```
gaussdb=# SELECT months_between(to_date('2022-10-30', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
   months_between
-----
1
(1 row)
```

```
gaussdb=# SELECT months_between(to_date('2022-10-29', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
   months_between
-----
.96774193548387096774
(1 row)
```

 **NOTE**

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database.

- `next_day(x,y)`

Description: Calculates the time of the next week **y** started from **x**.

Return type: timestamp

Example:

```
gaussdb=# SELECT next_day(timestamp '2017-05-25 00:00:00','Sunday')AS cal_result;
   cal_result
-----
2017-05-28 00:00:00
(1 row)
```

- `tinterval(abstime, abstime)`

Description: Creates a time interval with two pieces of absolute time.

Return type: tinterval

Example:

```
gaussdb=# call tinterval(abstime 'May 10, 1947 23:59:12', abstime 'Mon May 1 00:30:30 1995');
   tinterval
-----
["1947-05-10 23:59:12+08" "1995-05-01 00:30:30+08"]
(1 row)
```

- **tintervalend(tinterval)**
Description: Returns the end time of tinterval.
Return type: abstime
Example:

```
gaussdb=# SELECT tintervalend(['Sep 4, 1983 23:59:12' 'Oct4, 1983 23:59:12']);
tintervalend
-----
1983-10-04 23:59:12+08
(1 row)
```
- **tintervalrel(tinterval)**
Description: Calculates and returns the relative time of **tinterval**.
Return type: reltime
Example:

```
gaussdb=# SELECT tintervalrel(['Sep 4, 1983 23:59:12' 'Oct4, 1983 23:59:12']);
tintervalrel
-----
1 mon
(1 row)
```
- **smalldatetime_ge**
Description: Determines whether the first parameter is greater than the second.
Parameter: smalldatetime, smalldatetime
Return type: Boolean
- **smalldatetime_cmp**
Description: Compares two smalldatetime values to check whether they are the same.
Parameter: smalldatetime, smalldatetime
Return type: integer
- **smalldatetime_eq**
Description: Compares two smalldatetime values to check whether they are the same.
Parameter: smalldatetime, smalldatetime
Return type: Boolean
- **smalldatetime_gt**
Description: Determines whether the first parameter is less than the second parameter.
Parameter: smalldatetime, smalldatetime
Return type: Boolean
- **smalldatetime_hash**
Description: Calculates the hash value corresponding to a timestamp.
Parameter: smalldatetime
Return type: integer
- **smalldatetime_in**
Description: Inputs a timestamp.

Parameter: cstring, oid, integer

Return type: smalldatetime

- `smalldatetime_larger`
Description: Returns a larger timestamp.
Parameter: smalldatetime, smalldatetime
Return type: smalldatetime
- `smalldatetime_le`
Description: Determines whether the first parameter is less than the second parameter.
Parameter: smalldatetime, smalldatetime
Return type: Boolean
- `smalldatetime_lt`
Description: Determines whether the first parameter is greater than the second.
Parameter: smalldatetime, smalldatetime
Return type: Boolean
- `smalldatetime_ne`
Description: Compares two timestamps to check whether they are different.
Parameter: smalldatetime, smalldatetime
Return type: Boolean
- `smalldatetime_out`
Description: Converts a timestamp into the external form.
Parameter: smalldatetime
Return type: cstring
- `smalldatetime_send`
Description: Converts a timestamp to the binary format.
Parameter: smalldatetime
Return type: bytea
- `smalldatetime_smaller`
Description: Returns a smaller smalldatetime.
Parameter: smalldatetime, smalldatetime
Return type: smalldatetime
- `smalldatetime_to_abstime`
Description: Converts smalldatetime to abstime.
Parameter: smalldatetime
Return type: abstime
- `smalldatetime_to_time`
Description: Converts smalldatetime to time.
Parameter: smalldatetime

Return type: time without time zone

- `smalldatetime_to_timestamp`

Description: Converts `smalldatetime` to `timestamp`.

Parameter: `smalldatetime`

Return type: `timestamp` without time zone

- `smalldatetime_to_timestamptz`

Description: Converts `smalldatetime` to `timestamptz`.

Parameter: `smalldatetime`

Return type: `timestamp` with time zone

- `smalldatetime_to_varchar2`

Description: Converts `smalldatetime` to `varchar2`.

Parameter: `smalldatetime`

Return type: character varying

 **NOTE**

There are multiple methods for obtaining the current time. Select an appropriate API based on the actual service scenario.

1. The following APIs return values based on the start time of the current transaction:

```

CURRENT_DATE
CURRENT_TIME CURRENT_TIME(precision)
CURRENT_TIMESTAMP(precision)
LOCALTIME
LOCALTIMESTAMP
LOCALTIME(precision)
LOCALTIMESTAMP(precision)
transaction_timestamp()
now()
    
```

The values transferred by **CURRENT_TIME** and **CURRENT_TIMESTAMP(precision)** contain time zone information. The values transferred by **LOCALTIME** and **LOCALTIMESTAMP** do not contain time zone information. **CURRENT_TIME**, **LOCALTIME**, and **LOCALTIMESTAMP** can specify a precision parameter, which rounds the seconds field of the result to the decimal place. If there is no precision parameter, the result is given the full precision that can be obtained.

Because these functions all return results by the start time of the current transaction, their values do not change throughout the transaction. We think this is a feature with the purpose to allow a transaction to have a consistent concept at the "current" time, so that multiple modifications in the same transaction can maintain the same timestamp.

transaction_timestamp() is equivalent to **CURRENT_TIMESTAMP(precision)**, indicating the start time of the transaction where the current statement is located. **now()** is equivalent to **transaction_timestamp()**.

2. The following APIs return the start time of the current statement:

```
statement_timestamp()
```

statement_timestamp() returns the start time of the current statement (more accurately, the time when the last instruction is received from the client). The return values of **statement_timestamp()** and **transaction_timestamp()** are the same during the execution of the first instruction of a transaction, but may be different in subsequent instructions.

3. The following APIs return the actual current time when the function is called:

```
clock_timestamp()
timeofday()
```

clock_timestamp() returns the actual current time, and its value changes even in the same SQL command. Similar to **clock_timestamp()**, **timeofday()** also returns the actual current time. However, the result of **timeofday()** is a formatted text string instead of a timestamp with time zone information.

[Table 7-31](#) shows the templates for truncating date/time values.

Table 7-31 Truncating date/time values

Item	Format	Description
Microsecond	MICROSECON	Truncates date/time values, accurate to the microsecond (000000–999999).
	US	
	USEC	
	USECOND	

Item	Format	Description
Millisecond	MILLISECON	Truncates date/time values, accurate to the millisecond (000–999).
	MS	
	MSEC	
	MSECOND	
Second	S	Truncates date/time values, accurate to the second (00–59).
	SEC	
	SECOND	
Minute	M	Truncates date/time values, accurate to the minute (00–59).
	MI	
	MIN	
	MINUTE	
Hour	H	Truncates date/time values, accurate to the hour (00–23).
	HH	
	HOUR	
	HR	
Day	D	Truncates date/time values, accurate to the day (01-01 to 12-31)
	DAY	
	DD	
	DDD	
	J	
Week	W	Truncates date/time values, accurate to the week (the first day of the current week).
	WEEK	
Month	MM	Truncates date/time values, accurate to the month (the first day of the current month).
	MON	
	MONTH	
Quarter	Q	Truncates date/time values, accurate to the quarter (the first day of the current quarter).
	QTR	
	QUARTER	
Year	Y	Truncates date/time values, accurate to the year (the first day of the current year).
	YEAR	

Item	Format	Description
	YR	
	YYYY	
Decade	DEC	Truncates date/time values, accurate to the decade (the first day of the current decade).
	DECADE	
Century	C	Truncates date/time values, accurate to the century (the first day of the current century).
	CC	
	CENT	
	CENTURY	
Millennium	MIL	Truncates date/time values, accurate to the millennium (the first day of the current millennium).
	MILLENNIA	
	MILLENNIUM	

Table 7-32 Parameters for time truncation and rounding

Item	Format	Description
Minute	M	Truncated or rounded off, accurate to minute (00-59).
	MI	
	MIN	
	MINUTE	
Hour	H	Truncated or rounded off, accurate to hour (00-23).
	HH	
	HOUR	
	HR	
	HH12	
	HH24	
Day	DD	Truncated or rounded off, accurate to day (01-01 to 12-31).
	DDD	
	J	
ISO week	IW	Truncated or rounded off, accurate to week (the first day of the week is Monday).

Item	Format	Description
Week	DAY	Truncated or rounded off, accurate to week (the first day of the week is Sunday).
	DY	
	D	
Week of the month	W	Truncated or rounded off, accurate to week (the first day of the week is the first day of the month).
Week of the year	WW	Truncated or rounded off, accurate to week (the first day of the week is the first day of the year).
Month	MM	Truncated or rounded off, accurate to month (the first day of the month).
	MON	
	MONTH	
	RM	
Quarter	Q	Truncated or rounded off, accurate to quarter (the first day of the quarter).
	QTR	
	QUARTER	
Year	Y	Truncated or rounded off, accurate to year (the first day of the current year).
	YEAR	
	YR	
	YYYY	
	SYYYY	
	YYY	
	YY	
	SYEAR	
Decade	DEC	Truncated or rounded off, accurate to decade (the first day of the current decade).
	DECADE	
Century	C	Truncated or rounded off, accurate to the century (the first day of the century).
	CC	
	CENT	
	CENTURY	
	SCC	

Item	Format	Description
Millennium	MIL	Truncated or rounded off, accurate to millennium (the first day of the millennium).
	MILLENNIA	
	MILLENNIUM	

 NOTE

The behaviors of [Table 7-32](#) are valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database.

- `timestamp_diff(text, timestamp, timestamp)`
Description: Calculates the difference between two timestamps and truncates the difference to the precision specified by text.

Return type: int64

Example:

```
gaussdb=# SELECT timestamp_diff('year','2018-01-01','2020-04-01');
timestamp_diff
-----
          2
(1 row)
gaussdb=# SELECT timestamp_diff('month','2018-01-01','2020-04-01');
timestamp_diff
-----
         27
(1 row)
gaussdb=# SELECT timestamp_diff('quarter','2018-01-01','2020-04-01');
timestamp_diff
-----
          9
(1 row)
gaussdb=# SELECT timestamp_diff('week','2018-01-01','2020-04-01');
timestamp_diff
-----
        117
(1 row)
gaussdb=# SELECT timestamp_diff('day','2018-01-01','2020-04-01');
timestamp_diff
-----
        821
(1 row)
gaussdb=# SELECT timestamp_diff('hour','2018-01-01 10:10:10','2018-01-01 12:12:12');
timestamp_diff
-----
          2
(1 row)
gaussdb=# SELECT timestamp_diff('minute','2018-01-01 10:10:10','2018-01-01 12:12:12');
timestamp_diff
-----
        122
(1 row)
gaussdb=# SELECT timestamp_diff('second','2018-01-01 10:10:10','2018-01-01 10:12:12');
timestamp_diff
-----
        122
(1 row)
gaussdb=# SELECT timestamp_diff('microsecond','2018-01-01 10:10:10','2018-01-01 10:12:12');
timestamp_diff
-----
```

```
122000000
(1 row)
```

TIMESTAMPDIFF

- **TIMESTAMPDIFF**(*unit*, *timestamp_expr1*, *timestamp_expr2*)

The **timestampdiff** function returns the result of **timestamp_expr2** - **timestamp_expr1** in the specified unit. **timestamp_expr1** and **timestamp_expr2** must be value expressions of the **timestamp**, **timestampz**, or **date** type. **unit** specifies the unit of the difference between two dates.

This function is equivalent to **timestamp_diff(text, timestamp, timestamp)**.

NOTE

This function is valid only when GaussDB is compatible with MySQL (that is, **dbcompatibility** is set to **'MYSQL'**).

- **year**

Year.

```
gaussdb=# SELECT TIMESTAMPDIFF(YEAR, '2018-01-01', '2020-01-01');
timestamp_diff
-----
                2
(1 row)
```

- **quarter**

Quarter.

```
gaussdb=# SELECT TIMESTAMPDIFF(QUARTER, '2018-01-01', '2020-01-01');
timestamp_diff
-----
                8
(1 row)
```

- **month**

Month.

```
gaussdb=# SELECT TIMESTAMPDIFF(MONTH, '2018-01-01', '2020-01-01');
timestamp_diff
-----
                24
(1 row)
```

- **week**

Week.

```
gaussdb=# SELECT TIMESTAMPDIFF(WEEK, '2018-01-01', '2020-01-01');
timestamp_diff
-----
               104
(1 row)
```

- **day**

Day.

```
gaussdb=# SELECT TIMESTAMPDIFF(DAY, '2018-01-01', '2020-01-01');
timestamp_diff
-----
               730
(1 row)
```

- **hour**

Hour.

```
gaussdb=# SELECT TIMESTAMPDIFF(HOUR, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
timestamp_diff
-----
          1
(1 row)
```

- minute

Minute.

```
gaussdb=# SELECT TIMESTAMPDIFF(MINUTE, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
timestamp_diff
-----
          61
(1 row)
```

- second

Second.

```
gaussdb=# SELECT TIMESTAMPDIFF(SECOND, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
timestamp_diff
-----
         3661
(1 row)
```

- microseconds

The second field, including fractional parts, is multiplied by 1,000,000.

```
gaussdb=# SELECT TIMESTAMPDIFF(MICROSECOND, '2020-01-01 10:10:10.000000', '2020-01-01
10:10:10.111111');
timestamp_diff
-----
        111111
(1 row)
```

- timestamp_expr with the time zone

```
gaussdb=# SELECT TIMESTAMPDIFF(HOUR, '2020-05-01 10:10:10-01', '2020-05-01 10:10:10-03');
timestamp_diff
-----
          2
(1 row)
```

EXTRACT

- **EXTRACT(*field* FROM *source*)**

The **extract** function retrieves fields such as year or hour from date/time values. **source** must be a value expression of type **timestamp**, **time**, or **interval**. (Expressions of type **date** are cast to **timestamp** and can therefore be used as well.) **field** is an identifier or string that selects what field to extract from the source value. The **extract** function returns values of type **double precision**. The following are valid **field** names:

- century

Century.

The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0. You go from **-1** century to **1** century.

Example:

```
gaussdb=# SELECT EXTRACT(CENTURY FROM TIMESTAMP '2000-12-16 12:21:13');
date_part
-----
        20
(1 row)
```

- **day**
 - For **timestamp** values, the day (of the month) field (1–31)

```
gaussdb=# SELECT EXTRACT(DAY FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
      16
(1 row)
```
 - For **interval** values, the number of days

```
gaussdb=# SELECT EXTRACT(DAY FROM INTERVAL '40 days 1 minute');
date_part
-----
      40
(1 row)
```
- **decade**
 Year divided by 10

```
gaussdb=# SELECT EXTRACT(DECADE FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
     200
(1 row)
```
- **dow**
 Day of the week as Sunday (0) to Saturday (6)

```
gaussdb=# SELECT EXTRACT(DOW FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
       5
(1 row)
```
- **doy**
 Day of the year (1–365 or 366)

```
gaussdb=# SELECT EXTRACT(DOY FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
       47
(1 row)
```
- **epoch**
 - For **timestamp with time zone** values, the number of seconds since 1970-01-01 00:00:00-00 UTC (can be negative).
 For **date** and **timestamp** values, the number of seconds since 1970-01-01 00:00:00-00 local time.
 For **interval** values, the total number of seconds in the interval.

```
gaussdb=# SELECT EXTRACT(EPOCH FROM TIMESTAMP WITH TIME ZONE '2001-02-16
20:38:40.12-08');
date_part
-----
982384720.12
(1 row)
gaussdb=# SELECT EXTRACT(EPOCH FROM INTERVAL '5 days 3 hours');
date_part
-----
      442800
(1 row)
```
 - Way to convert an epoch value back to a timestamp

```
gaussdb=# SELECT TIMESTAMP WITH TIME ZONE 'epoch' + 982384720.12 * INTERVAL '1
second' AS RESULT;
result
-----
2001-02-17 12:38:40.12+08
(1 row)
```

- hour

Hour (0–23)

```
gaussdb=# SELECT EXTRACT(HOUR FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
      20
(1 row)
```

- isodow

Day of the week (1–7)

Monday is 1 and Sunday is 7.

 **NOTE**

This is identical to **dow** except for Sunday.

```
gaussdb=# SELECT EXTRACT(ISODOW FROM TIMESTAMP '2001-02-18 20:38:40');
date_part
-----
      7
(1 row)
```

- isoyear

The ISO 8601 year that the date falls in (not applicable to intervals).

Each ISO year begins with the Monday of the week containing January 4, so in early January or late December the ISO year may be different from the Gregorian year. See [week](#) for more information.

```
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
date_part
-----
    2005
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-01 00:00:40');
date_part
-----
     52
(1 row)
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
date_part
-----
    2006
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-02 00:00:40');
date_part
-----
      1
(1 row)
```

- microseconds

The second field, including fractional parts, is multiplied by 1,000,000.

```
gaussdb=# SELECT EXTRACT(MICROSECONDS FROM TIME '17:12:28.5');
date_part
-----
28500000
(1 row)
```

- millennium

Millennium.

Years in the 1900s are in the second millennium. The third millennium started from January 1, 2001.

```
gaussdb=# SELECT EXTRACT(MILLENNIUM FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
```

- ```

3
(1 row)

```
- **milliseconds**

Second field, including fractional parts, is multiplied by 1000. Note that this includes full seconds.

```

gaussdb=# SELECT EXTRACT(MILLISECONDS FROM TIME '17:12:28.5');
date_part

28500
(1 row)

```
  - **minute**

Minute (0–59).

```

gaussdb=# SELECT EXTRACT(MINUTE FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

38
(1 row)

```
  - **month**

For **timestamp** values, the specific month in the year (1–12).

```

gaussdb=# SELECT EXTRACT(MONTH FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

2
(1 row)

```

For **interval** values, the number of months, modulo 12 (0–11).

```

gaussdb=# SELECT EXTRACT(MONTH FROM INTERVAL '2 years 13 months');
date_part

1
(1 row)

```
  - **quarter**

Quarter of the year (1–4) that the date is in.

```

gaussdb=# SELECT EXTRACT(QUARTER FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

1
(1 row)

```
  - **second**

Second field, including fractional parts (0–59).

```

gaussdb=# SELECT EXTRACT(SECOND FROM TIME '17:12:28.5');
date_part

28.5
(1 row)

```
  - **timezone**

Time zone offset from UTC, measured in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.
  - **timezone\_hour**

Hour component of the time zone offset.
  - **timezone\_minute**

Minute component of the time zone offset.
  - **week**

Number of the week of the year that the day is in. By definition (ISO 8601), the first week of a year contains January 4 of that year. (The ISO-8601 week

starts on Monday.) In other words, the first Thursday of a year is in week 1 of that year.

Because of this, it is possible for early January dates to be part of the 52nd or 53rd week of the previous year, and late December dates to be part of the 1st week of the next year. For example, 2006-01-01 is the 52nd week of 2005, and 2006-01-02 is the first week of 2006. You are advised to use the columns **isoyear** and **week** together to ensure consistency.

```
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
date_part

 2005
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-01 00:00:40');
date_part

 52
(1 row)
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
date_part

 2006
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-02 00:00:40');
date_part

 1
(1 row)
```

- **year**

Year field.

```
gaussdb=# SELECT EXTRACT(YEAR FROM TIMESTAMP '2001-02-16 20:38:40');
date_part

 2001
(1 row)
```

## date\_part

The **date\_part** function is modeled on the traditional Ingres equivalent to the SQL-standard function **extract**:

**date\_part('field', source)**

Note that here the **field** parameter needs to be a string value, not a name. The valid field names for **date\_part** are the same as for **extract**. For details, see [EXTRACT](#).

Example:

```
gaussdb=# SELECT date_part('day', TIMESTAMP '2001-02-16 20:38:40');
date_part

 16
(1 row)
gaussdb=# SELECT date_part('hour', INTERVAL '4 hours 3 minutes');
date_part

 4
(1 row)
```

**Table 7-33** specifies the schema for formatting date and time values.

**Table 7-33** Schema for formatting date and time

| Category              | Format     | Description                                                                                                                                                                                 |
|-----------------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hour                  | HH         | Number of hours in one day (01-12)                                                                                                                                                          |
|                       | HH12       | Number of hours in one day (01-12)                                                                                                                                                          |
|                       | HH24       | Number of hours in one day (00-23)                                                                                                                                                          |
| Minute                | MI         | Minute (00-59)                                                                                                                                                                              |

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an ORA-compatible database, the date and time will be formatted in the specified format.

**Table 7-34** Patterns for formatting date and time

| Item    | Format | Description                                              |
|---------|--------|----------------------------------------------------------|
| Century | SCC    | Century. A hyphen (-) will be displayed before BC years. |

| Item        | Format | Description                                                                             |
|-------------|--------|-----------------------------------------------------------------------------------------|
| Year        | SYYYY  | Returns a numeric year. A hyphen (-) will be displayed before BC years.                 |
|             | RR     | Returns the two-digit year of a date.                                                   |
|             | RRRR   | Returns the four-digit year of a date.                                                  |
|             | YEAR   | Returns the year of the character type.                                                 |
|             | SYEAR  | Returns the year of the character type. A hyphen (-) will be displayed before BC years. |
| Date Format | DL     | Returns the date in the specified long date format.                                     |
|             | DS     | Returns the date in the specified short date format.                                    |
|             | TS     | Returns the time in the specified time format.                                          |
| Second      | FF7    | Microsecond (0000000-9999990)                                                           |
|             | FF8    | Microsecond (00000000-99999900)                                                         |
|             | FF9    | Microsecond (000000000-999999000)                                                       |

 **NOTE**

In the table, the rules for RR to calculate years are as follows:

- If the range of the input two-digit year is between 00 and 49:
  - If the last two digits of the current year are between 00 and 49, the first two digits of the returned year are the same as the first two digits of the current year.
  - If the last two digits of the current year are between 50 and 99, the first two digits of the returned year equal to the first two digits of the current year plus 1.
- If the range of the input two-digit year is between 50 and 99:
  - If the last two digits of the current year are between 00 and 49, the first two digits of the returned year are equal to the first two digits of the current year minus 1.
  - If the last two digits of the current year are between 50 and 99, the first two digits of the returned year are the same as the first two digits of the current year.

 NOTE

In the scenario where this function is in an ORA-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- The **to\_date** and **to\_timestamp** functions support the FX pattern (the input strictly corresponds to a pattern) and the X pattern (decimal point).
- The input pattern can appear only once, indicating that the patterns of the same information cannot appear at the same time. For example, SYYYY and BC cannot be used together.
- The pattern is case insensitive.
- You are advised to use a separator between the input and the pattern. Otherwise, the behavior may not be compatible with database O.

## 7.5.9 Type Conversion Functions

### Type Conversion Functions

- **cash\_words(money)**

Description: Type conversion function, which converts money into text.

Example:

```
gaussdb=# SELECT cash_words('1.23');
 cash_words

One dollar and twenty three cents
(1 row)
```

- **cast(x as y [DEFAULT z ON CONVERSION ERROR][,fmt])**

Description: Converts *x* into the type specified by *y*.

- **DEFAULT z ON CONVERSION ERROR**: This parameter is optional. If the attempt to convert *x* to type *y* fails, *z* is converted to type *y* by default.
- *fmt*: This parameter is optional, which can be specified when *y* is one of the following data types:
  - **int1/int2/int4/int8/int16/float4/float8/numeric**: The function of the optional parameter *fmt* is the same as that in the **to\_number(expr [,fmt])** function.
  - **date/timestamp/timestamp with time zone**: The function of the optional parameter *fmt* is the same as that in the **to\_date(string [,fmt])**/**to\_timestamp(string [,fmt])** /**to\_timestamp\_tz(string [,fmt])** function.

Example:

```
gaussdb=# SELECT cast('22-ocX-1997' as timestamp DEFAULT '22-oct-1997' ON CONVERSION
ERROR, 'DD-Mon-YYYY');
 timestamp

1997-10-22 00:00:00
(1 row)
```

 NOTE

The **DEFAULT z ON CONVERSION ERROR** and *fmt* syntaxes are supported only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an ORA-compatible database.

- **hextoraw(raw)**

Description: Converts a string in hexadecimal format into binary format.

Return type: raw

Example:

```
gaussdb=# SELECT hextoraw('7D');
 hextoraw

 7D
(1 row)
```

- numtoday(numeric)

Description: Converts values of the number type into the timestamp of the specified type.

Return type: timestamp

Example:

```
gaussdb=# SELECT numtoday(2);
 numtoday

 2 days
(1 row)
```

- rawtohex(string)

Description: Converts a string in binary format into hexadecimal format.

The result is the ACSII code of the input characters in hexadecimal format.

Return type: varchar

Example:

```
gaussdb=# SELECT rawtohex('1234567');
 rawtohex

 31323334353637
(1 row)
```

- to\_blob(raw)

Description: Converts the RAW type to the BLOB type.

Return type: BLOB

Example:

```
gaussdb=# SELECT to_blob('0AADD343CDBBD'::RAW(10));
 to_blob

 00AADD343CDBBD
(1 row)
```

#### NOTE

The **to\_blob** function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- to\_bigint(varchar)

Description: Converts the character type to the bigint type.

Return type: bigint

Example:

```
gaussdb=# SELECT to_bigint('123364545554455');
 to_bigint

 123364545554455
(1 row)
```

- to\_binary\_double(expr)

Description: Converts an expression to a value of the float8 type.

**expr**: supports the number, float4, and float8 data types and character strings that can be implicitly converted to numeric types.

Return type: float8

Example:

```
gaussdb=# SELECT to_binary_double('12345678');
to_binary_double

12345678
(1 row)
```

- to\_binary\_double(expr, fmt)

Description: Converts an expression to a value of the float8 type after format matching.

**expr/fmt**: supports character strings of the char, nchar, varchar2, and nvarchar2 types. The **expr** also supports numeric types that can be implicitly converted to character types.

Return type: float8

Example:

```
gaussdb=# SELECT to_binary_double('1,2,3', '9,9,9');
to_binary_double

123
(1 row)
```

- to\_binary\_double(expr default return\_value on conversion error)

Description: Converts an expression to a value of the float8 type. If the conversion fails, the default value **return\_value** is returned.

**expr**: supports the number, float4, and float8 data types and numeric types that can be implicitly converted to character strings.

Note: If **expr** is not of the numeric or character type, an error is reported.

Return type: float8

Example:

```
gaussdb=# SELECT to_binary_double(1e2 default 12 on conversion error);
to_binary_double

100
(1 row)

gaussdb=# SELECT to_binary_double('aa' default 12 on conversion error);
to_binary_double

12
(1 row)
```

- to\_binary\_double(expr default return\_value on conversion error, fmt)

Description: Converts an expression to a value of the float8 type after format matching. If the expression fails to be converted, the default value **return\_value** is returned.

**expr/fmt**: supports the char, nchar, varchar2, and nvarchar2 types. **expr** also supports numeric types that can be implicitly converted to character types.

Return type: float8

Example:

```
gaussdb=# SELECT to_binary_double('12-' default 10 on conversion error, '99S');
to_binary_double

-12
(1 row)
```

```
gaussdb=# SELECT to_binary_double('aa-' default 12 on conversion error, '99S');
to_binary_double

 10
(1 row)
```

 **NOTE**

The `to_binary_double` function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `to_binary_float(expr)`

Description: Converts an expression to a value of the float4 type.

**expr**: supports the number, float4, and float8 data types and character strings that can be implicitly converted to numeric types.

Return type: float4

Example:

```
gaussdb=# SELECT to_binary_float('12345678');
to_binary_float

1.23457e+07
(1 row)
```

- `to_binary_float(expr, fmt)`

Description: Converts an expression to a value of the float4 type after format matching.

**expr/fmt**: supports character strings of the char, nchar, varchar2, and nvarchar2 types. The **expr** also supports numeric types that can be implicitly converted to character types.

Return type: float4

Example:

```
gaussdb=# SELECT to_binary_float('1,2,3', '9,9,9');
to_binary_float

 123
(1 row)
```

- `to_binary_float(expr default return_value on conversion error)`

Description: Converts an expression to a value of the float4 type. If the conversion fails, the default value **return\_value** is returned.

**expr**: supports the number, float4, and float8 data types and numeric types that can be implicitly converted to character strings.

Note: If **expr** is not of the numeric or character type, an error is reported.

Return type: float4

Example:

```
gaussdb=# SELECT to_binary_float(1e2 default 12 on conversion error);
to_binary_float

 100
(1 row)

gaussdb=# SELECT to_binary_float('aa' default 12 on conversion error);
to_binary_float

 12
(1 row)
```

- `to_binary_float(expr default return_value on conversion error, fmt)`

Description: Converts an expression to a value of the float4 type after format matching. If the expression fails to be converted, the default value **return\_value** is returned.

**expr/fmt**: supports character strings of the char, nchar, varchar2, and nvarchar2 types. The **expr** also supports numeric types that can be implicitly converted to character types.

Return type: float4

Example:

```
gaussdb=# SELECT to_binary_float('12-' default 10 on conversion error, '99S');
to_binary_float
```

```

-12
(1 row)
```

```
gaussdb=# SELECT to_binary_float('aa-' default 12 on conversion error, '99S');
to_binary_float
```

```

10
(1 row)
```

 **NOTE**

The to\_binary\_float function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- to\_char(datetime/interval [, fmt])

Description: Converts a DATETIME or INTERVAL value of the DATE/TIMESTAMP/TIMESTAMP WITH TIME ZONE/TIMESTAMP WITH LOCAL TIME ZONE type into the VARCHAR type according to the format specified by **fmt**.

- The optional parameter **fmt** allows for the following types: date, time, week, quarter, and century. Each type has a unique template. The templates can be combined together. Common templates include HH, MI, SS, YYYY, MM, and DD. For details, see [Table 7-33](#).
- A template may have a modification word. FM is a common modification word and is used to suppress the preceding zero or the following blank spaces.

Return type: varchar

Example:

```
gaussdb=# SELECT to_char(current_timestamp,'HH12:MI:SS');
to_char
```

```

10:19:26
(1 row)
```

```
gaussdb=# SELECT to_char(current_timestamp,'FMHH12:FMMI:FMSS');
to_char
```

```

10:19:46
(1 row)
```

- to\_char(double precision/real, text)

Description: Converts the values of the floating point type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(125.8::real, '999D99');
to_char
```

```

```

```
125.80
(1 row)
```

- `to_char` (numeric/smallint/integer/bigint/double precision/real[, fmt])

Descriptions: Converts an integer or a value in floating point format into a string in specified format.

- The optional parameter *fmt* allows for the following types: decimal point, group (thousand) separator, positive/negative sign and currency sign. Each type has a unique template. The templates can be combined together. Common templates include: 9, 0, millesimal sign (.), and decimal point (.). For details, see [Table 7-35](#).
- A template can have a modification word, similar to FM. However, FM does not suppress 0 which is output according to the template.
- Use the template X or x to convert an integer value into a string in hexadecimal format.

Return type: varchar

Example:

```
gaussdb=# SELECT to_char(1485,'9,999');
to_char

1,485
(1 row)
gaussdb=# SELECT to_char(1148.5,'9,999.999');
to_char

1,148.500
(1 row)
gaussdb=# SELECT to_char(148.5,'990999.909');
to_char

0148.500
(1 row)
gaussdb=# SELECT to_char(123,'XXX');
to_char

7B
(1 row)
```

**Table 7-35** fmt parameter of the number type

| Pattern    | Description                                       |
|------------|---------------------------------------------------|
| , (comma)  | Group (thousand) separator                        |
| . (period) | Decimal point                                     |
| \$         | \$ output to the specified position               |
| 0          | Value with leading zeros                          |
| 9          | Value with specified digits                       |
| B          | Space returned when the integer part is 0         |
| C          | Currency symbol (depending on the locale setting) |
| D          | Decimal point (depending on the locale setting)   |

| Pattern  | Description                                                           |
|----------|-----------------------------------------------------------------------|
| EEEE     | Scientific notation                                                   |
| G        | Group separator (depending on the locale setting)                     |
| L        | Currency symbol (depending on the locale setting)                     |
| MI       | Minus sign in the specified position (if the number is less than 0)   |
| PR       | Negative values in angle brackets                                     |
| RN       | Roman numeral (ranging from 1 to 3999)                                |
| S        | Signed number (depending on the locale setting)                       |
| TM       | Standard number in scientific notation                                |
| TM9      | Standard number in scientific notation                                |
| TME      | Standard number in scientific notation                                |
| U        | Currency symbol (depending on the locale setting)                     |
| V        | Decimal with specified number of digits shifted                       |
| PL       | Plus sign in the specified position (if the number is greater than 0) |
| SG       | Plus or minus sign in the specified position                          |
| TH or th | Ordinal number suffix                                                 |

 **NOTE**

This function supports the \$, C, TM, TM9, TME, and U patterns when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an ORA-compatible database. In addition, the **fmt** parameter cannot be set to **TH**, **PL**, or **SG** in this case.

- **to\_char(interval, text)**

Description: Converts the values of the time interval type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(interval '15h 2m 12s', 'HH24:MI:SS');
to_char

15:02:12
(1 row)
```

- **to\_char(integer, text)**

Description: Converts the values of the integer type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(125, '999');
to_char

125
(1 row)
```

- **to\_char(set)**

Description: Converts a value of the SET type to a string. The distributed system does not support the SET data type.

Return value: text

- **to\_char(numeric, text)**

Description: Converts the values of the numeric type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(-125.8, '999D99S');
to_char

125.80-
(1 row)
```

- **to\_char (string)**

Description: Converts the CHAR/VARCHAR/VARCHAR2/CLOB type into the VARCHAR type.

If this function is used to convert data of the CLOB type, and the value to be converted exceeds the value range of the target type, an error is returned.

Return type: varchar

Example:

```
gaussdb=# SELECT to_char('01110');
to_char

01110
(1 row)
```

- **to\_nvarchar2(numeric)**

Description: Converts to the nvarchar2 type.

Parameter: numeric

Return type: nvarchar2

- **to\_char(timestamp, text)**

Description: Converts the values of the timestamp type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(current_timestamp, 'HH12:MI:SS');
to_char

10:55:59
(1 row)
```

 NOTE

- When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, the `to_char` function reports an error for the incorrect format (**fmt**).
- In non-compatible mode, the `to_char` function outputs the incorrect format (**fmt**) without change. For example, if the **fmt** is **FF10**, FF1 is matched for formatted output, and then **0** is output without change.

- `to_nchar (datetime/interval [, fmt])`

Description: Converts a DATETIME or INTERVAL value of the DATE/TIMESTAMP/TIMESTAMP WITH TIME ZONE/TIMESTAMP WITH LOCAL TIME ZONE type into the TEXT type according to the format specified by **fmt**.

- The optional parameter **fmt** allows for the following types: date, time, week, quarter, and century. Each type has a unique template. The templates can be combined together. Common templates include HH, MI, SS, YYYY, MM, and DD. For details, see [Table 7-33](#).
- A template may have a modification word. FM is a common modification word and is used to suppress the preceding zero or the following blank spaces.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(current_timestamp,'HH12:MI:SS');
to_nchar

10:19:26
(1 row)
gaussdb=# SELECT to_nchar(current_timestamp,'FMHH12:FM MI:FMSS');
to_nchar

10:19:46
(1 row)
```

- `to_nchar(double precision/real, text)`

Description: Converts the values of the floating point type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(125.8::real, '999D99');
to_nchar

125.80
(1 row)
```

- `to_nchar (numeric/smallint/integer/bigint/double precision/real[, fmt])`

Descriptions: Converts an integer or a value in floating point format into a string in specified format.

- The optional parameter *fmt* allows for the following types: decimal point, group (thousand) separator, positive/negative sign and currency sign. Each type has a unique template. The templates can be combined together. Common templates include: 9, 0, millesimal sign (,), and decimal point (.). For details, see [Table 7-35](#).
- A template can have a modification word, similar to FM. However, FM does not suppress 0 which is output according to the template.
- Use the template X or x to convert an integer value into a string in hexadecimal format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(1485,'9,999');
to_nchar

1,485
(1 row)
gaussdb=# SELECT to_nchar(1148.5,'9,999.999');
to_nchar

1,148.500
(1 row)
gaussdb=# SELECT to_nchar(148.5,'990999.909');
to_nchar

0148.500
(1 row)
gaussdb=# SELECT to_nchar(123,'XXX');
to_nchar

7B
(1 row)
```

 **NOTE**

This function supports the \$, C, TM, TM9, TME, and U patterns when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an ORA-compatible database. In addition, the **fmt** parameter cannot be set to **TH**, **PL**, or **SG** in this case.

- **to\_nchar(interval, text)**

Description: Converts the values of the time interval type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(interval '15h 2m 12s', 'HH24:MI:SS');
to_nchar

15:02:12
(1 row)
```

- **to\_nchar(integer, text)**

Description: Converts the values of the integer type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(125, '999');
to_nchar

125
(1 row)
```

- **to\_nchar(set)**

Description: Converts a value of the SET type to a string. The distributed system does not support the SET data type.

Return value: text

- **to\_nchar(numeric, text)**

Description: Converts the values of the numeric type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(-125.8, '999D99S');
to_nchar

125.80-
(1 row)
```

- to\_nchar (string)

Description: Converts the CHAR/VARCHAR/VARCHAR2/CLOB type into the TEXT type.

If this function is used to convert data of the CLOB type, and the value to be converted exceeds the value range of the target type, an error is returned.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar('01110');
to_nchar

01110
(1 row)
```

- to\_nchar(timestamp, text)

Description: Converts the values of the timestamp type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(current_timestamp, 'HH12:MI:SS');
to_nchar

10:55:59
(1 row)
```

- to\_clob(char/nchar/varchar/varchar2/nvarchar2/text/raw)

Description: Converts the RAW type or text character set type CHAR/NCHAR/VARCHAR/VARCHAR2/NVARCHAR2/TEXT into the CLOB type.

Return type: CLOB

Example:

```
gaussdb=# SELECT to_clob('ABCDEF'::RAW(10));
to_clob

ABCDEF
(1 row)
gaussdb=# SELECT to_clob('hello111'::CHAR(15));
to_clob

hello111
(1 row)
gaussdb=# SELECT to_clob('gauss123'::NCHAR(10));
to_clob

gauss123
(1 row)
gaussdb=# SELECT to_clob('gauss234'::VARCHAR(10));
to_clob

gauss234
(1 row)
gaussdb=# SELECT to_clob('gauss345'::VARCHAR2(10));
to_clob

```

```

gauss345
(1 row)
gaussdb=# SELECT to_clob('gauss456'::NVARCHAR2(10));
to_clob

gauss456
(1 row)
gaussdb=# SELECT to_clob('World222!'::TEXT);
to_clob

World222!
(1 row)

```

- **to\_date(text)**

Description: Converts values of the text type into the timestamp in the specified format. Currently, only the following two formats are supported:

- Format 1: Date without separators, for example, 20150814. The value must contain the complete year, month, and day.
- Format 2: Date with separators, for example, 2014-08-14. The separator can be any non-digit character.

Return type: timestamp without time zone

Example:

```

gaussdb=# SELECT to_date('2015-08-14');
to_date

2015-08-14 00:00:00
(1 row)

```

- **to\_date(text, text)**

Description: Converts the values of the string type into the dates in the specified format.

Return type: timestamp without time zone

Example:

```

gaussdb=# SELECT to_date('05 Dec 2000', 'DD Mon YYYY');
to_date

2000-12-05 00:00:00
(1 row)

```

 **NOTE**

Case execution environment: The value of **a\_format\_version** is **10c**, the value of **a\_format\_dev\_version** is **s1**, and the value of **nls\_timestamp\_format** is **YYYY-MM-DD HH24:MI:SS**.

- **to\_date(text [DEFAULT return\_value ON CONVERSION ERROR [, fmt]])**

Description: Converts a string *text* into a value of the DATE type according to the format specified by *fmt*. If *fmt* is not specified, **a\_format\_version** is set to **10c**, and **a\_format\_dev\_version** is set to **s1**, the format specified by **nls\_timestamp\_format** is used for conversion. Otherwise, the fixed format (*fmt* = 'yyyy-mm-dd hh24-mi-ss') is used for conversion.

- **text**: any expression that can be calculated to CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT string. If null is entered, null is returned.
- **DEFAULT return\_value ON CONVERSION ERROR**: This parameter is optional, which can be used to specify the return value when *text* fails to be converted to the DATE type. The value of *return\_value* can be an expression or a bound variable that can be converted to the CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT type or null. The method of

converting *return\_value* to the DATE type is the same as that of converting *text* to the DATE type. If *return\_value* fails to be converted to the DATE type, an error is reported.

- *fmt*: This parameter is optional, which specifies the date and time model format of *text*. By default, *text* must comply with the default date format. If *fmt* is set to *J*, *text* must be an integer.

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT to_date('2015-08-14');
 to_date

2015-08-14 00:00:00
(1 row)
gaussdb=# SELECT to_date('05 Dec 2000', 'DD Mon YYYY');
 to_date

2000-12-05 00:00:00
(1 row)
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s1';
SET
gaussdb=# SHOW nls_timestamp_format;
 nls_timestamp_format

DD-Mon-YYYY HH:MI:SS.FF AM
(1 row)
gaussdb=# SELECT to_date('12-jan-2022' default '12-apr-2022' on conversion error);
 to_date

2022-01-12 00:00:00
(1 row)
gaussdb=# SELECT to_date('12-ja-2022' default '12-apr-2022' on conversion error);
 to_date

2022-04-12 00:00:00
(1 row)
gaussdb=# SELECT to_date('2022-12-12' default '2022-01-01' on conversion error, 'yyyy-mm-dd');
 to_date

2022-12-12 00:00:00
(1 row)
```

---

**CAUTION**

- The DEFAULT *return\_value* ON CONVERSION ERROR syntax is supported only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.
- When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, the system may not report an error if the entered year exceeds 9999. For example, the result of **to\_date('9999-12-12', 'yyyy-mm-dd hh24:mi:ss')** is **9999-09-12 12:00:00**. If the value of year exceeds 9999, the number following 9999 will be parsed as the next **fmt**. This restriction also applies to **to\_timestamp**.

- 
- **to\_number** ( *expr* [, *fmt*])

Description: Converts **expr** into a value of the NUMBER type according to the specified format.

For details about the type conversion formats, see [Table 7-36](#).

If a hexadecimal string is converted into a decimal number, the hexadecimal string can include a maximum of 16 bytes if it is to be converted into a sign-free number.

During the conversion from a hexadecimal string to a decimal digit, the format string cannot have a character other than x or X. Otherwise, an error is reported.

Return type: number

Example:

```
gaussdb=# SELECT to_number('12,454.8-', '99G999D9S');
to_number

-12454.8
(1 row)
```

- `to_number(text, text)`

Description: Converts the values of the string type into the numbers in the specified format.

Return type: numeric

Example:

```
gaussdb=# SELECT to_number('12,454.8-', '99G999D9S');
to_number

-12454.8
(1 row)
```

- `to_number(expr [DEFAULT return_value ON CONVERSION ERROR [, fmt]])`

Description: Converts a string *expr* to a value of the numeric type based on the format specified by *fmt*. If *fmt* is not specified, *text* must be a character string that can be directly converted to numeric, for example, '123', '1e2'.

For details about the type conversion formats, see [Table 7-37](#).

- **expr**: an expression that can be converted into a CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT/INT/FLOAT string. If null is entered, null is returned.
- **DEFAULT return\_value ON CONVERSION ERROR**: This parameter is optional, which can be used to specify the return value when *expr* fails to be converted to the numeric type. Similar to *expr*, *return\_value* can be any type that can be converted to a character string. Similar to *expr*, *return\_value* is converted based on the format specified by *fmt*. The system checks whether *return\_value* fails to be converted. If *return\_value* fails to be converted, the function reports an error.
- **fmt**: This parameter is optional, which specifies the conversion format of **expr**.

If any input parameter is **NULL**, **NULL** is returned.

Return type: numeric

Example:

```
gaussdb=# SET a_format_version='10c';
gaussdb=# SET a_format_dev_version='s1';

gaussdb=# SELECT to_number('1e2');
to_number

100
```

```
(1 row)

gaussdb=# SELECT to_number('123.456');
to_number

123.456
(1 row)

gaussdb=# SELECT to_number('123', '999');
to_number

123
(1 row)

gaussdb=# SELECT to_number('123-', '999MI');
to_number

-123
(1 row)

gaussdb=# SELECT to_number('123' default '456-' on conversion error, '999MI');
to_number

-456
(1 row)
```

 NOTE

The DEFAULT *return\_value* ON CONVERSION ERROR syntax is supported only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

- to\_timestamp(double precision)

Description: Converts a Unix century into a timestamp.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT to_timestamp(1284352323);
to_timestamp

2010-09-13 12:32:03+08
(1 row)
```

- to\_timestamp(string [,fmt])

Description: Converts a string into a value of the timestamp type according to the format specified by **fmt**. When **fmt** is not specified, perform the conversion according to the format specified by **nls\_timestamp\_format**.

In **to\_timestamp** in GaussDB:

- If the input year *YYYY* is 0, an error will be reported.
- If the input year *YYYY* is less than 0, specify *SYYYY* in **fmt**. The year with the value of *n* (an absolute value) BC will be output correctly.

Characters in the **fmt** must match the schema for formatting the data and time. Otherwise, an error is reported.

Return type: timestamp without time zone

Example:

```
gaussdb=# SHOW nls_timestamp_format;
nls_timestamp_format

DD-Mon-YYYY HH:MI:SS.FF AM
(1 row)

gaussdb=# SELECT to_timestamp('12-sep-2014');
to_timestamp
```

```

2014-09-12 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('12-Sep-10 14:10:10.123000','DD-Mon-YY HH24:MI:SS.FF');
to_timestamp

2010-09-12 14:10:10.123
(1 row)
gaussdb=# SELECT to_timestamp('-1','YYYY');
to_timestamp

0001-01-01 00:00:00 BC
(1 row)
gaussdb=# SELECT to_timestamp('98','RR');
to_timestamp

1998-01-01 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('01','RR');
to_timestamp

2001-01-01 00:00:00
(1 row)
```

**NOTE**

1. When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, **fmt** supports FF[7-9]. When FF[7-9] is used, and the length of the corresponding position in the string is less than or equal to the number following FF, then, the number can be converted. However, the maximum length of the final conversion result is six digits.
  2. The result returned by the `current_timestamp` function cannot be used as a string parameter.
- `to_timestamp(text [DEFAULT return_value ON CONVERSION ERROR [, fmt]])`  
Description: Converts a string *text* into a value of the DATE type according to the format specified by *fmt*. If *fmt* is not specified, **a\_format\_version** is set to **10c**, and **a\_format\_dev\_version** is set to **s1**, the format specified by **nls\_timestamp\_format** is used for conversion. Otherwise, the fixed format (*fmt* = 'yyyy-mm-dd hh24-mi-ss') is used for conversion.
    - *text*: any expression that can be calculated to CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT string. If null is entered, null is returned.
    - **DEFAULT return\_value ON CONVERSION ERROR**: This parameter is optional, which can be used to specify the return value when *text* fails to be converted to the DATE type. The value of *return\_value* can be an expression or a bound variable that can be converted to the CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT type or null. The method of converting *return\_value* to the timestamp type is the same as that of converting *text* to the timestamp type. If *return\_value* fails to be converted to the timestamp type, an error is reported.
    - *fmt*: This parameter is optional, which specifies the date and time model format of *text*. By default, *text* must comply with the default date format. If *fmt* is set to *J*, *text* must be an integer.

Return type: timestamp without time zone

Example:

```
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s1';
SET
gaussdb=# SELECT to_timestamp('11-Sep-11' DEFAULT '12-Sep-10 14:10:10.123000' ON
```

```
CONVERSION ERROR,'DD-Mon-YY HH24:MI:SS.FF');
to_timestamp

2011-09-11 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('12-Sep-10 14:10:10.123000','DD-Mon-YY HH24:MI:SSXFF');
to_timestamp

2010-09-12 14:10:10.123
(1 row)
```

#### NOTE

The DEFAULT *return\_value* ON CONVERSION ERROR syntax is supported only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

- `to_timestamp(text, text)`

Description: Converts values of the string type into the timestamp of the specified type.

Return type: timestamp

Example:

```
gaussdb=# SELECT to_timestamp('05 Dec 2000', 'DD Mon YYYY');
to_timestamp

2000-12-05 00:00:00
(1 row)
```

- `to_timestamp_tz(text [,text])`

Description: Converts values of the string type into the timestamp of the specified type with the time zone.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT to_timestamp_tz('05 Dec 2001', 'DD Mon YYYY');
to_timestamp_tz

2001-12-05 00:00:00+08:00
(1 row)
```

#### NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s1** in an ORA-compatible database.

- `to_timestamp_tz(string [DEFAULT return_value ON CONVERSION ERROR] [,fmt])`

Description: Converts a string into a value of the timestamp type with the time zone according to the format specified by **fmt**. When **fmt** is not specified, perform the conversion according to the format specified by **nls\_timestamp\_tz\_format**.

**DEFAULT return\_value ON CONVERSION ERROR:** This parameter is optional. If *string* fails to be converted to the timestamp type with time zone, *return\_value* is converted to the timestamp type with time zone.

*fmt*: This parameter is optional, which specifies the date and time model format of *string*. The setting of this parameter is the same as that in the `to_timestamp` function.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT to_timestamp_tz('05 DeX 2000' DEFAULT '05 Dec 2001' ON CONVERSION ERROR,
to_timestamp_tz

2001-12-05 00:00:00+08:00
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s1** in an ORA-compatible database.

- **to\_dsinterval(text)**

Description: Converts characters to the interval type. SQL-compatible and ISO formats are supported.

Return type: interval

Example:

```
gaussdb=# SELECT to_dsinterval('12 1:2:3.456');
to_dsinterval

12 days 01:02:03.456
(1 row)
```

```
gaussdb=# SELECT to_dsinterval('P3DT4H5M6S');
to_dsinterval

3 days 04:05:06
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- **to\_ymininterval(text)**

Description: Converts characters to the interval type. SQL-compatible and ISO formats are supported.

Return type: interval

Example:

```
gaussdb=# SELECT to_ymininterval('1-1');
to_ymininterval

1 year 1 mon
(1 row)
```

```
gaussdb=# SELECT to_ymininterval('P13Y3M4DT4H2M5S');
to_ymininterval

13 years 3 mons
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

**Table 7-36** Template patterns for numeric formatting

| Pattern | Description                 |
|---------|-----------------------------|
| 9       | Value with specified digits |

| Pattern    | Description                                                           |
|------------|-----------------------------------------------------------------------|
| 0          | Values with leading zeros                                             |
| Period (.) | Decimal point                                                         |
| Comma (,)  | Group (thousand) separator                                            |
| PR         | Negative values in angle brackets                                     |
| S          | Signed number (depending on the locale setting)                       |
| L          | Currency symbol (depending on the locale setting)                     |
| D          | Decimal point (depending on the locale setting)                       |
| G          | Group separator (depending on the locale setting)                     |
| MI         | Minus sign in the specified position (if the number is less than 0)   |
| PL         | Plus sign in the specified position (if the number is greater than 0) |
| SG         | Plus or minus sign in the specified position                          |
| RN         | Roman numeral (ranging from 1 to 3999)                                |
| TH or th   | Ordinal number suffix                                                 |
| V          | Decimal with specified number of digits shifted                       |
| x or X     | Hexadecimal-to-decimal conversion identifier                          |

**Table 7-37** Template patterns for to\_number formatting

| Pattern    | Description                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------|
| 9          | Matches a digit. The number of digits "9" can be greater than or equal to that in the corresponding position in <i>expr</i> . |
| 0          | Strictly matches a digit. The number of digits "0" must be equal to that in <i>expr</i> .                                     |
| 5          | Matches digit 0 or 5.                                                                                                         |
| Period (.) | Decimal point in the specified position                                                                                       |
| Comma (,)  | Group (thousand) separator in the specified position. Multiple commas can be specified in <i>fmt</i> .                        |
| B          | No leading sign                                                                                                               |
| PR         | A negative value in angle brackets, or a positive value with no leading sign                                                  |

| Pattern | Description                                                                                         |
|---------|-----------------------------------------------------------------------------------------------------|
| S       | A negative value with the leading minus sign (-) or a positive value with the leading plus sign (+) |
| MI      | A negative value with the leading minus sign (-) or a positive value with no leading sign           |
| \$      | Leading dollar sign                                                                                 |
| L       | Local currency symbol                                                                               |
| C       | Symbol of currency in the specified position (complying with the ISO standard)                      |
| U       | Dual-currency symbol                                                                                |
| D       | Decimal point (uses locale)                                                                         |
| G       | Group separator (complying with the ISO standard). Multiple commas can be specified in <i>fmt</i> . |
| RN / rn | Roman numeral (ranging from 1 to 3999). <i>to_number</i> does not support this format.              |
| V       | <i>to_number</i> does not support this format.                                                      |
| X / x   | Conversion between hexadecimal and decimal                                                          |
| TM      | <i>to_number</i> does not support this format.                                                      |
| FM      | This format can be used only at the beginning of <i>fmt</i> .                                       |
| EEEE    | Conversion based on the scientific notation model                                                   |

 NOTE

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, refer to this table for the setting of *fmt*. Otherwise, refer to the previous table. The *fmt* setting complying with the ISO standard is affected by the values of **LC\_MONETARY** and **LC\_NUMERIC** parameters.

- `cast_varchar2_to_raw_for_histogram(varchar2)`  
Description: Converts from the varchar2 type to the raw type.  
Return type: raw
- `abstime_text`  
Description: Converts abstime to text.  
Parameter: abstime  
Return type: text
- `abstime_to_smalldatetime`  
Description: Converts abstime to smalldatetime.  
Parameter: abstime  
Return type: smalldatetime

- `bigint_tid`  
Description: Converts bigint to tid.  
Parameter: bigint  
Return type: tid
- `bool_int1`  
Description: Converts Boolean to int1.  
Parameter: Boolean  
Return type: tinyint
- `bool_int2`  
Description: Converts Boolean to int2.  
Parameter: Boolean  
Return type: smallint
- `bool_int8`  
Description: Converts Boolean to int8.  
Parameter: Boolean  
Return type: bigint
- `bpchar_date`  
Description: Converts a string to a date.  
Parameter: character  
Return type: date
- `bpchar_float4`  
Description: Converts a string to float4.  
Parameter: character  
Return type: real
- `bpchar_float8`  
Description: Converts a string to float8.  
Parameter: character  
Return type: double precision
- `bpchar_int4`  
Description: Converts a string to int4.  
Parameter: character  
Return type: integer
- `bpchar_int8`  
Description: Converts a string to int8.  
Parameter: character  
Return type: bigint
- `bpchar_numeric`  
Description: Converts a string to numeric.  
Parameter: character  
Return type: numeric

- `bpchar_timestamp`  
Description: Converts a string to a timestamp.  
Parameter: character  
Return type: timestamp without time zone
- `bpchar_to_smalldatetime`  
Description: Converts a string to smalldatetime.  
Parameter: character  
Return type: smalldatetime
- `complex_array_in`  
Description: Converts the external `complex_array` type to the internal `anyarray` array type.  
Parameter: `cstring`, `oid`, `int2vector`  
Return type: `anyarray`
- `date_bpchar`  
Description: Converts the date type to `bpchar`.  
Parameter: date  
Return type: character
- `date_text`  
Description: Converts date to text.  
Parameter: date  
Return type: text
- `date_varchar`  
Description: Converts date to `varchar`.  
Parameter: date  
Return type: character varying
- `f4toi1`  
Description: Forcibly converts `float4` to `uint8`.  
Parameter: real  
Return type: `tinyint`
- `f8toi1`  
Description: Forcibly converts `float8` to `uint8`.  
Parameter: double precision  
Return type: `tinyint`
- `float4_bpchar`  
Description: Converts `float4` to `bpchar`.  
Parameter: real  
Return type: character
- `float4_text`  
Description: Converts `float4` to text.  
Parameter: real  
Return type: text

- float4\_varchar  
Description: Converts float4 to varchar.  
Parameter: real  
Return type: character varying
- float8\_bpchar  
Description: Converts float8 to bpchar.  
Parameter: double precision  
Return type: character
- float8\_interval  
Description: Converts float8 to interval.  
Parameter: double precision  
Return type: interval
- float8\_text  
Description: Converts float8 to text.  
Parameter: double precision  
Return type: text
- float8\_varchar  
Description: Converts float8 to varchar.  
Parameter: double precision  
Return type: character varying
- i1tof4  
Description: Converts uint8 to float4.  
Parameter: tinyint  
Return type: real
- i1tof8  
Description: Converts uint8 to float8.  
Parameter: tinyint  
Return type: double precision
- i1toi2  
Description: Converts uint8 to int16.  
Parameter: tinyint  
Return type: smallint
- i1toi4  
Description: Converts uint8 to int32.  
Parameter: tinyint  
Return type: integer
- i1toi8  
Description: Converts uint8 to int64.  
Parameter: tinyint  
Return type: bigint

- `i2toi1`  
Description: Converts int16 to uint8.  
Parameter: `smallint`  
Return type: `tinyint`
- `i4toi1`  
Description: Converts int32 to uint8.  
Parameter: `integer`  
Return type: `tinyint`
- `i8toi1`  
Description: Converts int64 to uint8.  
Parameter: `bigint`  
Return type: `tinyint`
- `int1_avg_accum`  
Description: Adds the second parameter of the uint8 type to the first parameter. The first parameter is an array of the bigint type.  
Parameter: `bigint[], tinyint`  
Return type: `bigint[]`
- `int1_bool`  
Description: Converts uint8 to Boolean.  
Parameter: `tinyint`  
Return type: `Boolean`
- `int1_bpchar`  
Description: Converts uint8 to bpchar.  
Parameter: `tinyint`  
Return type: `character`
- `int1_mul_cash`  
Description: Returns the product of a parameter of the int8 type and a parameter of the cash type. The return type is cash.  
Parameter: `tinyint, money`  
Return type: `money`
- `int1_numeric`  
Description: Converts uint8 to numeric.  
Parameter: `tinyint`  
Return type: `numeric`
- `int1_nvarchar2`  
Description: Converts uint8 to nvarchar2.  
Parameter: `tinyint`  
Return type: `nvarchar2`
- `int1_text`  
Description: Converts uint8 to text.  
Parameter: `tinyint`

- Return type: text
- int1\_varchar
  - Description: Converts uint8 to varchar.
  - Parameter: tinyint
  - Return type: character varying
- int1in
  - Description: Converts a string into an unsigned 1-byte integer.
  - Parameter:cstring
  - Return type: tinyint
- int1out
  - Description: Converts an unsigned 1-byte integer into a string.
  - Return type:cstring
- int1up
  - Description: Converts an input integer to an unsigned 1-byte integer.
  - Parameter: tinyint
  - Return type: tinyint
- int2\_bool
  - Description: Converts a two-byte signed integer to the Boolean type.
  - Parameter: smallint
  - Return type: Boolean
- int2\_bpchar
  - Description: Converts a signed two-byte integer to the bpchar type.
  - Parameter: smallint
  - Return type: character
- int2\_text
  - Description: Converts a signed two-byte integer to the text type.
  - Parameter: smallint
  - Return type: text
- int2\_varchar
  - Description: Converts a signed two-byte integer to the varchar type.
  - Parameter: smallint
  - Return type: character varying
- int4\_bpchar
  - Description: Converts a signed four-byte integer to bpchar.
  - Parameter: integer
  - Return type: character
- int4\_text
  - Description: Converts a signed four-byte integer to the text type.
  - Parameter: integer
  - Return type: text

- `int4_varchar`  
Description: Converts a signed four-byte integer into varchar.  
Parameter: integer  
Return type: character varying
- `int8_bool`  
Description: Converts an eight-byte signed integer to the Boolean value.  
Parameter: bigint  
Return type: Boolean
- `int8_bpchar`  
Description: Converts an 8-byte signed integer to bpchar.  
Parameter: bigint  
Return type: character
- `int8_text`  
Description: Converts an eight-byte signed integer to the text type.  
Parameter: bigint  
Return type: text
- `int8_varchar`  
Description: Converts an eight-byte signed integer to varchar.  
Parameter: bigint  
Return type: character varying
- `intervaltonum`  
Description: Converts the internal date type to numeric.  
Parameter: interval  
Return type: numeric
- `numeric_bpchar`  
Description: Converts numeric to bpchar.  
Parameter: numeric  
Return type: character
- `numeric_int1`  
Description: Converts numeric to a signed one-byte integer.  
Parameter: numeric  
Return type: tinyint
- `numeric_text`  
Description: Converts numeric to text.  
Parameter: numeric  
Return type: text
- `numeric_varchar`  
Description: Converts numeric to varchar.  
Parameter: numeric  
Return type: character varying

- `nvarchar2in`  
Description: Converts c string to varchar.  
Parameter: cstring, oid, integer  
Return type: nvarchar2
- `nvarchar2out`  
Description: Converts text into a c string.  
Parameter: nvarchar2  
Return type: cstring
- `nvarchar2send`  
Description: Converts varchar to binary.  
Parameter: nvarchar2  
Return type: bytea
- `oidvectorin_extend`  
Description: Converts a string to oidvector.  
Parameter: cstring  
Return type: oidvector\_extend
- `oidvectorout_extend`  
Description: Converts oidvector to a string.  
Parameter: oidvector\_extend  
Return type: cstring
- `oidvectorsend_extend`  
Description: Converts oidvector to a string.  
Parameter: oidvector\_extend  
Return type: bytea
- `reltime_text`  
Description: Converts reltime to text.  
Parameter: reltime  
Return type: text
- `text_date`  
Description: Converts the text type to the date type.  
Parameter: text  
Return type: date
- `text_float4`  
Description: Converts text to float4.  
Parameter: text  
Return type: real
- `text_float8`  
Description: Converts the text type to float8.  
Parameter: text  
Return type: double precision

- `text_int1`  
Description: Converts the text type to int1.  
Parameter: text  
Return type: tinyint
- `text_int2`  
Description: Converts the text type to the int2 type.  
Parameter: text  
Return type: smallint
- `text_int4`  
Description: Converts the text type to int4.  
Parameter: text  
Return type: integer
- `text_int8`  
Description: Converts the text type to the int8 type.  
Parameter: text  
Return type: bigint
- `text_numeric`  
Description: Converts the text type to the numeric type.  
Parameter: text  
Return type: numeric
- `text_timestamp`  
Description: Converts the text type to the timestamp type.  
Parameter: text  
Return type: timestamp without time zone
- `time_text`  
Description: Converts the time type to the text type.  
Parameter: time without time zone  
Return type: text
- `timestamp_text`  
Description: Converts the timestamp type to the text type.  
Parameter: timestamp without time zone  
Return type: text
- `timestamp_to_smalldatetime`  
Description: Converts the timestamp type to the smalldatetime type.  
Parameter: timestamp without time zone  
Return type: smalldatetime
- `timestamp_varchar`  
Description: Converts the timestamp type to varchar.  
Parameter: timestamp without time zone  
Return type: character varying

- `timestampz_to_smalldatetime`  
Description: Converts `timestampz` to `smalldatetime`.  
Parameter: timestamp with time zone  
Return type: `smalldatetime`
- `timestampzone_text`  
Description: Converts the `timestampzone` type to the text type.  
Parameter: timestamp with time zone  
Return type: text
- `timetz_text`  
Description: Converts the `timetz` type to the text type.  
Parameter: time with time zone  
Return type: text
- `to_integer`  
Description: Converts data to the integer type.  
Parameter: character varying  
Return type: integer
- `to_interval`  
Description: Converts to the interval type.  
Parameter: character varying  
Return type: interval
- `to_numeric`  
Description: Converts to the numeric type.  
Parameter: character varying  
Return type: numeric
- `to_text`  
Description: Converts to the text type.  
Parameter: `smallint`  
Return type: text
- `to_ts`  
Description: Converts to the `ts` type.  
Parameter: character varying  
Return type: timestamp without time zone
- `to_varchar2`  
Description: Converts to the `varchar2` type.  
Parameter: timestamp without time zone  
Return type: character varying
- `varchar_date`  
Description: Converts `varchar` to date.  
Parameter: character varying  
Return type: date

- `varchar_float4`  
Description: Converts varchar to float4.  
Parameter: character varying  
Return type: real
- `varchar_float8`  
Description: Converts the varchar type to the float8 type.  
Parameter: character varying  
Return type: double precision
- `varchar_int4`  
Description: Converts the type from varchar to int4.  
Parameter: character varying  
Return type: integer
- `varchar_int8`  
Description: Converts the varchar type to the int8 type.  
Parameter: character varying  
Return type: bigint
- `varchar_numeric`  
Description: Converts varchar to numeric.  
Parameter: character varying  
Return type: numeric
- `varchar_timestamp`  
Description: Converts varchar to timestamp.  
Parameter: character varying  
Return type: timestamp without time zone
- `varchar2_to_smlldatetime`  
Description: Converts varchar2 to smlldatetime.  
Parameter: character varying  
Return type: smalldatetime
- `xidout4`  
Description: The xid output is a four-byte number.  
Parameter: xid32  
Return type:cstring
- `xidsend4`  
Description: Converts xid to the binary format.  
Parameter: xid32  
Return type:bytea
- `treat(expr AS [JSON | REF] schema.type)`  
Description: Converts expr to the type (JSON) specified by the keyword after AS.  
Return value type: JSON.  
Example:

```
gaussdb=# CREATE TABLE json_doc(data CLOB);
gaussdb=# INSERT INTO json_doc VALUES({'name':'a'});
gaussdb=# SELECT treat(data as json) FROM json_doc;
 json

{"name":"a"}
(1 row)
gaussdb=# DROP TABLE json_doc;
DROP TABLE
```

## Encoding Type Conversion

- `convert_to_nocase(text, text)`

Description: Converts a string into a specified encoding type.

Return type: bytea

Example:

```
gaussdb=# SELECT convert_to_nocase('12345', 'GBK');
convert_to_nocase

\x3132333435
(1 row)
```

## 7.5.10 Geometric Functions and Operators

### Geometric Operators

- `+`

Description: Translation

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' + point '(2.0,0)' AS RESULT;
 result

(3,1),(2,0)
(1 row)
```

- `-e`

Description: Translation

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' - point '(2.0,0)' AS RESULT;
 result

(-1,1),(-2,0)
(1 row)
```

- `*`

Description: Scaling out/Rotation

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' * point '(2.0,0)' AS RESULT;
 result

(2,2),(0,0)
(1 row)
```

- `/`

Description: Scaling in/Rotation

Example:

```
gaussdb=# SELECT box '((0,0),(2,2))' / point '(2.0,0)' AS RESULT;
 result
```

- ```
-----
(1,1),(0,0)
(1 row)
```

 - #

Description: Intersection of two figures

Example:

```
gaussdb=# SELECT box '((1,-1),(-1,1))' # box '((1,1),(-2,-2))' AS RESULT;
result
-----
(1,1),(-1,-1)
(1 row)
```
 - #

Description: Number of paths or polygon vertexes

Example:

```
gaussdb=# SELECT # path '((1,0),(0,1),(-1,0))' AS RESULT;
result
-----
3
(1 row)
```
 - @-@

Description: Length or circumference

Example:

```
gaussdb=# SELECT @-@ path '((0,0),(1,0))' AS RESULT;
result
-----
2
(1 row)
```
 - @@

Description: Center of box

Example:

```
gaussdb=# SELECT @@ circle '((0,0),10)' AS RESULT;
result
-----
(0,0)
(1 row)
```
 - <->

Description: Distance between the two figures

Example:

```
gaussdb=# SELECT circle '((0,0),1)' <-> circle '((5,0),1)' AS RESULT;
result
-----
3
(1 row)
```
 - &&

Description: Overlaps? (One point in common makes this true.)

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' && box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```
 - <<

Description: Is strictly left of (no common horizontal coordinate)?

Example:

```
gaussdb=# SELECT circle '((0,0),1)' << circle '((5,0),1)' AS RESULT;
result
-----
t
(1 row)
```

- >>

Description: Is strictly right of (no common horizontal coordinate)?

Example:

```
gaussdb=# SELECT circle '((5,0),1)' >> circle '((0,0),1)' AS RESULT;
result
-----
t
(1 row)
```

- &<

Description: Does not extend to the right of?

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' &< box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```

- &>

Description: Does not extend to the left of?

Example:

```
gaussdb=# SELECT box '((0,0),(3,3))' &> box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```

- <<|

Description: Is strictly below (no common horizontal coordinate)?

Example:

```
gaussdb=# SELECT box '((0,0),(3,3))' <<| box '((3,4),(5,5))' AS RESULT;
result
-----
t
(1 row)
```

- |>>

Description: Is strictly above (no common horizontal coordinate)?

Example:

```
gaussdb=# SELECT box '((3,4),(5,5))' |>> box '((0,0),(3,3))' AS RESULT;
result
-----
t
(1 row)
```

- &<|

Description: Does not extend above?

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' &<| box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```

- |&>

Description: Does not extend below?

Example:

```
gaussdb=# SELECT box '((0,0),(3,3))' |&> box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```
- <^

Description: Is below (allows touching)?

Example:

```
gaussdb=# SELECT box '((0,0),(-3,-3))' <^ box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```
- >^

Description: Is above (allows touching)?

Example:

```
gaussdb=# SELECT box '((0,0),(2,2))' >^ box '((0,0),(-3,-3))' AS RESULT;
result
-----
t
(1 row)
```
- ?#

Description: Intersect?

Example:

```
gaussdb=# SELECT lseg '((-1,0),(1,0))' ?# box '((-2,-2),(2,2))' AS RESULT;
result
-----
t
(1 row)
```
- ?-

Description: Is horizontal?

Example:

```
gaussdb=# SELECT ?- lseg '((-1,0),(1,0))' AS RESULT;
result
-----
t
(1 row)
```
- ?-

Description: Are horizontally aligned?

Example:

```
gaussdb=# SELECT point '(1,0)' ?- point '(0,0)' AS RESULT;
result
-----
t
(1 row)
```
- ?|

Description: Is vertical?

Example:

```
gaussdb=# SELECT ?| lseg '((-1,0),(1,0))' AS RESULT;
result
```

- ```

f
(1 row)
```

• ?|

Description: Are vertically aligned?

Example:

```
gaussdb=# SELECT point '(0,1)' ?| point '(0,0)' AS RESULT;
result

t
(1 row)
```
- ?-|

Description: Are perpendicular?

Example:

```
gaussdb=# SELECT lseg '((0,0),(0,1))' ?-| lseg '((0,0),(1,0))' AS RESULT;
result

t
(1 row)
```
- ?||

Description: Are parallel?

Example:

```
gaussdb=# SELECT lseg '((-1,0),(1,0))' ?|| lseg '((-1,2),(1,2))' AS RESULT;
result

t
(1 row)
```
- @>

Description: Contains?

Example:

```
gaussdb=# SELECT circle '((0,0),2)' @> point '(1,1)' AS RESULT;
result

t
(1 row)
```
- <@

Description: Contained in or on?

Example:

```
gaussdb=# SELECT point '(1,1)' <@ circle '((0,0),2)' AS RESULT;
result

t
(1 row)
```
- ~=

Description: Specifies whether two figures are the same.

Example:

```
gaussdb=# SELECT polygon '((0,0),(1,1))' ~= polygon '((1,1),(0,0))' AS RESULT;
result

t
(1 row)
```

## Geometric Functions

- **area(object)**

Description: Area calculation

Return type: double precision

Example:

```
gaussdb=# SELECT area(box '((0,0),(1,1)')) AS RESULT;
result

1
(1 row)
```

- **center(object)**

Description: Figure center calculation

Return type: point

Example:

```
gaussdb=# SELECT center(box '((0,0),(1,2)')) AS RESULT;
result

(0.5,1)
(1 row)
```

- **diameter(circle)**

Description: Circle diameter calculation

Return type: double precision

Example:

```
gaussdb=# SELECT diameter(circle '((0,0),2.0)') AS RESULT;
result

4
(1 row)
```

- **height(box)**

Description: Vertical size of box

Return type: double precision

Example:

```
gaussdb=# SELECT height(box '((0,0),(1,1)')) AS RESULT;
result

1
(1 row)
```

- **isclosed(path)**

Description: A closed path?

Return type: Boolean

Example:

```
gaussdb=# SELECT isclosed(path '((0,0),(1,1),(2,0)')) AS RESULT;
result

t
(1 row)
```

- **isopen(path)**

Description: An open path?

Return type: Boolean

Example:

```
gaussdb=# SELECT isopen(path '((0,0),(1,1),(2,0)')) AS RESULT;
result

t
(1 row)
```

- **length(object)**

Description: Length calculation

Return type: double precision

Example:

```
gaussdb=# SELECT length(path '((-1,0),(1,0))') AS RESULT;
result

4
(1 row)
```

- **npoints(path)**

Description: Number of points in path

Return type: int

Example:

```
gaussdb=# SELECT npoints(path '((0,0),(1,1),(2,0)')) AS RESULT;
result

3
(1 row)
```

- **npoints(polygon)**

Description: Number of points in polygon

Return type: int

Example:

```
gaussdb=# SELECT npoints(polygon '((1,1),(0,0)')) AS RESULT;
result

2
(1 row)
```

- **pclose(path)**

Description: Converts path to closed.

Return type: path

Example:

```
gaussdb=# SELECT pclose(path '((0,0),(1,1),(2,0)')) AS RESULT;
result

((0,0),(1,1),(2,0))
(1 row)
```

- **popen(path)**

Description: Converts path to open.

Return type: path

Example:

```
gaussdb=# SELECT popen(path '((0,0),(1,1),(2,0)')) AS RESULT;
result

[(0,0),(1,1),(2,0)]
(1 row)
```

- **radius(circle)**

Description: Circle diameter calculation

Return type: double precision

Example:

```
gaussdb=# SELECT radius(circle '((0,0),2.0)') AS RESULT;
result

2
(1 row)
```

- **width(box)**

Description: Horizontal size of box

Return type: double precision

Example:

```
gaussdb=# SELECT width(box '((0,0),(1,1)')) AS RESULT;
result

1
(1 row)
```

## Geometric Type Conversion Functions

- **box(circle)**

Description: Circle to box

Return type: box

Example:

```
gaussdb=# SELECT box(circle '((0,0),2.0)') AS RESULT;
result

(1.41421356237309,1.41421356237309),(-1.41421356237309,-1.41421356237309)
(1 row)
```

- **box(point, point)**

Description: Points to box

Return type: box

Example:

```
gaussdb=# SELECT box(point '(0,0)', point '(1,1)') AS RESULT;
result

(1,1),(0,0)
(1 row)
```

- **box(polygon)**

Description: Polygon to box

Return type: box

Example:

```
gaussdb=# SELECT box(polygon '((0,0),(1,1),(2,0))') AS RESULT;
result

(2,1),(0,0)
(1 row)
```

- **circle(box)**

Description: Box to circle

Return type: circle

Example:

```
gaussdb=# SELECT circle(box '((0,0),(1,1)')) AS RESULT;
result
```

```

<(0.5,0.5),0.707106781186548>
(1 row)
```

- **circle(point, double precision)**  
Description: Center and radius to circle  
Return type: circle  
Example:

```
gaussdb=# SELECT circle(point '(0,0)', 2.0) AS RESULT;
result

<(0,0),2>
(1 row)
```

- **circle(polygon)**  
Description: Polygon to circle  
Return type: circle  
Example:

```
gaussdb=# SELECT circle(polygon '((0,0),(1,1),(2,0))') AS RESULT;
result

<(1,0.3333333333333333),0.924950591148529>
(1 row)
```

- **lseg(box)**  
Description: Box diagonal to line segment  
Return type: lseg  
Example:

```
gaussdb=# SELECT lseg(box '((-1,0),(1,0))') AS RESULT;
result

[(1,0),(-1,0)]
(1 row)
```

- **lseg(point, point)**  
Description: Points to line segment  
Return type: lseg  
Example:

```
gaussdb=# SELECT lseg(point '(-1,0)', point '(1,0)') AS RESULT;
result

[(-1,0),(1,0)]
(1 row)
```

- **slope(point, point)**  
Description: Calculates the slope of a straight line formed by two points.  
Return type: double  
Example:

```
gaussdb=# SELECT slope(point '(1,1)', point '(0,0)') AS RESULT;
result

1
(1 row)
```

- **path(polygon)**  
Description: Polygon to path  
Return type: path

Example:

```
gaussdb=# SELECT path(polygon '((0,0),(1,1),(2,0)')) AS RESULT;
result

(0,0),(1,1),(2,0)
(1 row)
```

- **point(double precision, double precision)**

Description: Points

Return type: point

Example:

```
gaussdb=# SELECT point(23.4, -44.5) AS RESULT;
result

(23.4,-44.5)
(1 row)
```

- **point(box)**

Description: Center of box

Return type: point

Example:

```
gaussdb=# SELECT point(box '((-1,0),(1,0)')) AS RESULT;
result

(0,0)
(1 row)
```

- **point(circle)**

Description: Center of circle

Return type: point

Example:

```
gaussdb=# SELECT point(circle '((0,0),2.0)') AS RESULT;
result

(0,0)
(1 row)
```

- **point(lseg)**

Description: Center of line segment

Return type: point

Example:

```
gaussdb=# SELECT point(lseg '((-1,0),(1,0)')) AS RESULT;
result

(0,0)
(1 row)
```

- **point(polygon)**

Description: Center of polygon

Return type: point

Example:

```
gaussdb=# SELECT point(polygon '((0,0),(1,1),(2,0)')) AS RESULT;
result

(1,0.3333333333333333)
(1 row)
```

- **polygon(box)**

Description: Box to 4-point polygon

Return type: polygon

Example:

```
gaussdb=# SELECT polygon(box '((0,0),(1,1)')) AS RESULT;
result

((0,0),(0,1),(1,1),(1,0))
(1 row)
```

- **polygon(circle)**

Description: Circle to 12-point polygon

Return type: polygon

Example:

```
gaussdb=# SELECT polygon(circle '((0,0),2.0)') AS RESULT;
result

((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),
(1.73205080756888,-0.999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),
(-0.999999999999999,-1.73205080756888),(-1.73205080756888,-1))
(1 row)
```

- **polygon(npts, circle)**

Description: Circle to **npts**-point polygon

Return type: polygon

Example:

```
gaussdb=# SELECT polygon(12, circle '((0,0),2.0)') AS RESULT;
result

((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),
(1.73205080756888,-0.999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),
(-0.999999999999999,-1.73205080756888),(-1.73205080756888,-1))
(1 row)
```

- **polygon(path)**

Description: Path to polygon

Return type: polygon

Example:

```
gaussdb=# SELECT polygon(path '((0,0),(1,1),(2,0)')) AS RESULT;
result

((0,0),(1,1),(2,0))
(1 row)
```

## 7.5.11 Network Address Functions and Operators

### cidr and inet Operators

The operators <<, <<=, >>, and >>= test for subnet inclusion. They consider only the network parts of the two addresses (ignoring any host part) and determine whether one network is identical to or a subnet of the other.

- <

Description: Is less than

Example:

```
gaussdb=# SELECT inet '192.168.1.5' < inet '192.168.1.6' AS RESULT;
result

t
(1 row)
```

- <=

Description: Is less than or equals

Example:

```
gaussdb=# SELECT inet '192.168.1.5' <= inet '192.168.1.5' AS RESULT;
result

t
(1 row)
```

- =

Description: Equals

Example:

```
gaussdb=# SELECT inet '192.168.1.5' = inet '192.168.1.5' AS RESULT;
result

t
(1 row)
```

- >=

Description: Is greater than or equals

Example:

```
gaussdb=# SELECT inet '192.168.1.5' >= inet '192.168.1.5' AS RESULT;
result

t
(1 row)
```

- >

Description: Is greater than

Example:

```
gaussdb=# SELECT inet '192.168.1.5' > inet '192.168.1.4' AS RESULT;
result

t
(1 row)
```

- <>

Description: Does not equal

Example:

```
gaussdb=# SELECT inet '192.168.1.5' <> inet '192.168.1.4' AS RESULT;
result
```

- ```
-----  
t  
(1 row)
```

<<

Description: Is contained in

Example:

```
gaussdb=# SELECT inet '192.168.1.5' << inet '192.168.1/24' AS RESULT;  
result  
-----  
t  
(1 row)
```
- <<=
- >>
- >>=
- ~
- &
- |

Description: Performs an OR operation on each bit of the two network addresses.

Example:

```
gaussdb=# SELECT inet '192.168.1.6' | inet '10.0.0.0' AS RESULT;  
result  
-----  
202.168.1.6  
(1 row)
```

- +

Description: Addition

Example:

```
gaussdb=# SELECT inet '192.168.1.6' + 25 AS RESULT;  
result  
-----  
192.168.1.31  
(1 row)
```

- -

Description: Subtraction

Example:

```
gaussdb=# SELECT inet '192.168.1.43' - 36 AS RESULT;  
result  
-----  
192.168.1.7  
(1 row)
```

- -

Description: Subtraction

Example:

```
gaussdb=# SELECT inet '192.168.1.43' - inet '192.168.1.19' AS RESULT;  
result  
-----  
24  
(1 row)
```

cidr and inet Functions

The **abbrev**, **host**, and **text** functions are primarily intended to offer alternative display formats.

- abbrev(inet)

Description: Abbreviated display format as text

Return type: text

Example:

```
gaussdb=# SELECT abbrev(inet '10.1.0.0/16') AS RESULT;  
result  
-----  
10.1.0.0/16  
(1 row)
```

- abbrev(cidr)

Description: Abbreviated display format as text

Return type: text

Example:

```
gaussdb=# SELECT abbrev(cidr '10.1.0.0/16') AS RESULT;  
result
```

- ```

10.1/16
(1 row)
```

  - **broadcast(inet)**  
Description: Broadcast address for networks  
Return type: inet  
Example:  

```
gaussdb=# SELECT broadcast('192.168.1.5/24') AS RESULT;
result

192.168.1.255/24
(1 row)
```
  - **family(inet)**  
Description: Extracts family of addresses, 4 for IPv4.  
Return type: int  
Example:  

```
gaussdb=# SELECT family('127.0.0.1') AS RESULT;
result

4
(1 row)
```
  - **host(inet)**  
Description: Extracts IP addresses as text.  
Return type: text  
Example:  

```
gaussdb=# SELECT host('192.168.1.5/24') AS RESULT;
result

192.168.1.5
(1 row)
```
  - **hostmask(inet)**  
Description: Constructs the host mask for a network.  
Return type: inet  
Example:  

```
gaussdb=# SELECT hostmask('192.168.23.20/30') AS RESULT;
result

0.0.0.3
(1 row)
```
  - **masklen(inet)**  
Description: Extracts subnet mask length.  
Return type: int  
Example:  

```
gaussdb=# SELECT masklen('192.168.1.5/24') AS RESULT;
result

24
(1 row)
```
  - **netmask(inet)**  
Description: Constructs the subnet mask for a network.  
Return type: inet

Example:

```
gaussdb=# SELECT netmask('192.168.1.5/24') AS RESULT;
 result

255.255.255.0
(1 row)
```

- `network(inet)`

Description: Extracts the network part of an address.

Return type: `cidr`

Example:

```
gaussdb=# SELECT network('192.168.1.5/24') AS RESULT;
 result

192.168.1.0/24
(1 row)
```

- `set_masklen(inet, int)`

Description: Sets subnet mask length for the **inet** value.

Return type: `inet`

Example:

```
gaussdb=# SELECT set_masklen('192.168.1.5/24', 16) AS RESULT;
 result

192.168.1.5/16
(1 row)
```

- `set_masklen(cidr, int)`

Description: Sets subnet mask length for the **cidr** value.

Return type: `cidr`

Example:

```
gaussdb=# SELECT set_masklen('192.168.1.0/24::cidr', 16) AS RESULT;
 result

192.168.0.0/16
(1 row)
```

- `text(inet)`

Description: Extracts IP addresses and subnet mask length as text.

Return type: `text`

Example:

```
gaussdb=# SELECT text(inet '192.168.1.5') AS RESULT;
 result

192.168.1.5/32
(1 row)
```

Any **cidr** value can be cast to **inet** implicitly or explicitly; therefore, the functions shown above as operating on **inet** also work on **cidr** values. An **inet** value can be cast to **cidr**. After the conversion, any bits to the right of the subnet mask are silently zeroed to create a valid **cidr** value. In addition, you can cast a text string to **inet** or **cidr** using normal casting syntax. For example, **inet(expression)** or **colname::cidr**.

## macaddr Functions

The function **trunc(macaddr)** returns a MAC address with the last 3 bytes set to zero.

trunc(macaddr)

Description: Sets last 3 bytes to zero.

Return type: macaddr

Example:

```
gaussdb=# SELECT trunc(macaddr '12:34:56:78:90:ab') AS RESULT;
result

12:34:56:00:00:00
(1 row)
```

The **macaddr** type also supports the standard relational operators (such as > and <=) for lexicographical ordering, and the bitwise arithmetic operators (~, & and |) for NOT, AND and OR.

## 7.5.12 Text Search Functions and Operators

### Text Search Operators

- @@

Description: Specifies whether the tsvector-typed words match the tsquery-typed words.

Example:

```
gaussdb=# SELECT to_tsvector('fat cats ate rats') @@ to_tsquery('cat & rat') AS RESULT;
result

t
(1 row)
```

- @@@

Description: Synonym for @@

Example:

```
gaussdb=# SELECT to_tsvector('fat cats ate rats') @@@ to_tsquery('cat & rat') AS RESULT;
result

t
(1 row)
```

- ||

Description: Connects two tsvector-typed words.

Example:

```
gaussdb=# SELECT 'a:1 b:2'::tsvector || 'c:1 d:2 b:3'::tsvector AS RESULT;
result

'a:1 'b':2,5 'c':3 'd':4
(1 row)
```

- &&

Description: Performs the AND operation on two tsquery-typed words.

Example:

```
gaussdb=# SELECT 'fat | rat'::tsquery && 'cat'::tsquery AS RESULT;
result

('fat' | 'rat') & 'cat'
(1 row)
```

- ||  
Description: Performs the OR operation on two tsquery-typed words.

Example:

```
gaussdb=# SELECT 'fat | rat'::tsquery || 'cat'::tsquery AS RESULT;
result

('fat' | 'rat') | 'cat'
(1 row)
```

- !!  
Description: Not a tsquery-typed word.

Example:

```
gaussdb=# SELECT !! 'cat'::tsquery AS RESULT;
result

!'cat'
(1 row)
```

- @>  
Description: Specifies whether a tsquery-typed word contains another tsquery-typed word.

Example:

```
gaussdb=# SELECT 'cat'::tsquery @> 'cat & rat'::tsquery AS RESULT;
result

f
(1 row)
```

- <@  
Description: Specifies whether a tsquery-typed word is contained in another tsquery-typed word.

Example:

```
gaussdb=# SELECT 'cat'::tsquery <@ 'cat & rat'::tsquery AS RESULT;
result

t
(1 row)
```

In addition to the preceding operators, the ordinary B-tree comparison operators (including = and <) are defined for types **tsvector** and **tsquery**.

## Text Search Functions

- get\_current\_ts\_config()  
Description: Obtains default text search configurations.  
Return type: regconfig

Example:

```
gaussdb=# SELECT get_current_ts_config();
get_current_ts_config

english
(1 row)
```

- length(tsvector)**  
Description: Specifies the number of lexemes in a **tsvector**-typed word.  
Return type: integer  
Example:  

```
gaussdb=# SELECT length('fat:2,4 cat:3 rat:5A'::tsvector);
length

 3
(1 row)
```
- numnode(tsquery)**  
Description: Specifies the number of lexemes plus **tsquery** operators.  
Return type: integer  
Example:  

```
gaussdb=# SELECT numnode('(fat & rat) | cat'::tsquery);
numnode

 5
(1 row)
```
- plainto\_tsquery([ config regconfig , ] query text)**  
Description: Generates **tsquery** lexemes without punctuation.  
Return type: tsquery  
Example:  

```
gaussdb=# SELECT plainto_tsquery('english', 'The Fat Rats');
plainto_tsquery

'fat' & 'rat'
(1 row)
```
- querytree(query tsquery)**  
Description: Obtains the indexable part of a **tsquery**.  
Return type: text  
Example:  

```
gaussdb=# SELECT querytree('foo & ! bar'::tsquery);
querytree

'foo'
(1 row)
```
- setweight(tsvector, "char")**  
Description: Assigns weight to each element of tsvector.  
Return type: tsvector  
Example:  

```
gaussdb=# SELECT setweight('fat:2,4 cat:3 rat:5B'::tsvector, 'A');
setweight

'cat':3A 'fat':2A,4A 'rat':5A
(1 row)
```
- strip(tsvector)**  
Description: Removes positions and weights from **tsvector**.  
Return type: tsvector  
Example:  

```
gaussdb=# SELECT strip('fat:2,4 cat:3 rat:5A'::tsvector);
strip
```

- ```
-----
'cat' 'fat' 'rat'
(1 row)
```
- `to_tsquery([config regconfig ,] query text)`
 Description: Normalizes words and converts them to **tsquery**.
 Return type: **tsquery**
 Example:

```
gaussdb=# SELECT to_tsquery('english', 'The & Fat & Rats');
to_tsquery
-----
'fat' & 'rat'
(1 row)
```
 - `to_tsvector([config regconfig ,] document text)`
 Description: Reduces document text to **tsvector**.
 Return type: **tsvector**
 Example:

```
gaussdb=# SELECT to_tsvector('english', 'The Fat Rats');
to_tsvector
-----
'fat':2 'rat':3
(1 row)
```
 - `to_tsvector_for_batch([config regconfig ,] document text)`
 Description: Reduces document text to **tsvector**.
 Return type: **tsvector**
 Example:

```
gaussdb=# SELECT to_tsvector_for_batch('english', 'The Fat Rats');
to_tsvector
-----
'fat':2 'rat':3
(1 row)
```
 - `ts_headline([config regconfig,] document text, query tsquery [, options text])`
 Description: Highlights a query match.
 Return type: **text**
 Example:

```
gaussdb=# SELECT ts_headline('x y z', 'z!::tsquery');
ts_headline
-----
x y <b>z</b>
(1 row)
```
 - `ts_rank([weights float4[],] vector tsvector, query tsquery [, normalization integer])`
 Description: Ranks document for query.
 Return type: **float4**
 Example:

```
gaussdb=# SELECT ts_rank('hello world'::tsvector, 'world'::tsquery);
ts_rank
-----
.0607927
(1 row)
```
 - `ts_rank_cd([weights float4[],] vector tsvector, query tsquery [, normalization integer])`

Description: Ranks document for query using cover density.

Return type: float4

Example:

```
gaussdb=# SELECT ts_rank_cd('hello world':tsvector, 'world':tsquery);
ts_rank_cd
-----
.0
(1 row)
```

- `ts_rewrite(query tsquery, target tsquery, substitute tsquery)`

Description: Replaces **tsquery**-typed word.

Return type: tsquery

Example:

```
gaussdb=# SELECT ts_rewrite('a & b':tsquery, 'a':tsquery, 'foo|bar':tsquery);
ts_rewrite
-----
'b' & ( 'foo' | 'bar' )
(1 row)
```

- `ts_rewrite(query tsquery, select text)`

Description: Replaces **tsquery** data in the target with the result of a **SELECT** command.

Return type: tsquery

Example:

```
gaussdb=# SELECT ts_rewrite('world':tsquery, 'select "world":tsquery, "hello":tsquery');
ts_rewrite
-----
'hello'
(1 row)
```

Text Search Debugging Functions

- `ts_debug([config regconfig,] document text, OUT alias text, OUT description text, OUT token text, OUT dictionaries regdictionary[], OUT dictionary regdictionary, OUT lexemes text[])`

Description: Tests a configuration.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_debug('english', 'The Brightest supernovaes');
ts_debug
-----
(asciiword,"Word, all ASCII",The,{english_stem},english_stem,{})
(blank,"Space symbols"," ",{},{,})
(asciiword,"Word, all ASCII",Brightest,{english_stem},english_stem,{brightest})
(blank,"Space symbols"," ",{},{,})
(asciiword,"Word, all ASCII",supernovaes,{english_stem},english_stem,{supernova})
(5 rows)
```

- `ts_lexize(dict regdictionary, token text)`

Description: Tests a data dictionary.

Return type: text[]

Example:

```
gaussdb=# SELECT ts_lexize('english_stem', 'stars');
ts_lexize
-----
{star}
(1 row)
```

- `ts_parse(parser_name text, document text, OUT tokid integer, OUT token text)`

Description: Tests a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_parse('default', 'foo - bar');
ts_parse
-----
(1,foo)
(12," ")
(12,"- ")
(1,bar)
(4 rows)
```

- `ts_parse(parser_oid oid, document text, OUT tokid integer, OUT token text)`

Description: Tests a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_parse(3722, 'foo - bar');
ts_parse
-----
(1,foo)
(12," ")
(12,"- ")
(1,bar)
(4 rows)
```

- `ts_token_type(parser_name text, OUT tokid integer, OUT alias text, OUT description text)`

Description: Obtains token types defined by a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_token_type('default');
ts_token_type
-----
(1,asciword,"Word, all ASCII")
(2,word,"Word, all letters")
(3,numword,"Word, letters and digits")
(4,email,"Email address")
(5,url,URL)
(6,host,Host)
(7,sfloat,"Scientific notation")
(8,version,"Version number")
(9,hword_numpart,"Hyphenated word part, letters and digits")
(10,hword_part,"Hyphenated word part, all letters")
(11,hword_asciipart,"Hyphenated word part, all ASCII")
(12,blank,"Space symbols")
(13,tag,"XML tag")
(14,protocol,"Protocol head")
(15,numhword,"Hyphenated word, letters and digits")
(16,asciihword,"Hyphenated word, all ASCII")
(17,hword,"Hyphenated word, all letters")
(18,url_path,"URL path")
(19,file,"File or path name")
(20,float,"Decimal notation")
(21,int,"Signed integer")
(22,uint,"Unsigned integer")
(23,entity,"XML entity")
(23 rows)
```

- `ts_token_type(parser_oid oid, OUT tokid integer, OUT alias text, OUT description text)`

Description: Obtains token types defined by a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_token_type(3722);
          ts_token_type
-----
(1,asciiword,"Word, all ASCII")
(2,word,"Word, all letters")
(3,numword,"Word, letters and digits")
(4,email,"Email address")
(5,url,URL)
(6,host,Host)
(7,sfloat,"Scientific notation")
(8,version,"Version number")
(9,hword_numpart,"Hyphenated word part, letters and digits")
(10,hword_part,"Hyphenated word part, all letters")
(11,hword_asciipart,"Hyphenated word part, all ASCII")
(12,blank,"Space symbols")
(13,tag,"XML tag")
(14,protocol,"Protocol head")
(15,numhword,"Hyphenated word, letters and digits")
(16,asciihword,"Hyphenated word, all ASCII")
(17,hword,"Hyphenated word, all letters")
(18,url_path,"URL path")
(19,file,"File or path name")
(20,float,"Decimal notation")
(21,int,"Signed integer")
(22,uint,"Unsigned integer")
(23,entity,"XML entity")
(23 rows)
```

- `ts_stat(sqlquery text, [weights text,] OUT word text, OUT ndoc integer, OUT nentry integer)`

Description: Obtains statistics of a **tsvector** column.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_stat('select "hello world"::tsvector');
          ts_stat
-----
(world,1,1)
(hello,1,1)
(2 rows)
```

7.5.13 JSON/JSONB Functions and Operators

For details about the JSON/JSONB data type, see [JSON/JSONB Types](#). For details about operators, see [Table 7-38](#) and [Table 7-39](#).

Table 7-38 JSON/JSONB common operators

Operator	Left Operand Type	Right Operand Type	Return Type	Description	Example
->	Array- json(b)	int	json(b)	Obtains the array-json element. If the index does not exist, NULL is returned.	SELECT '["a":"foo"],["b":"bar"], {"c":"baz"}::json->2; ?column? ----- {"c":"baz"} (1 row)
->	object- json(b)	text	json(b)	Obtains the value by a key. If no record is found, NULL is returned.	SELECT '{"a": {"b":"foo"}}::json->'a'; ?column? ----- {"b":"foo"} (1 row)
->>	Array- json(b)	int	text	Obtains the JSON array element. If the subscript does not exist, NULL is returned.	SELECT '[1,2,3]::json->>2; ?column? ----- 3 (1 row)
->>	object- json(b)	text	text	Obtains the value by a key. If no record is found, NULL is returned.	SELECT '{"a":1,"b":2}::json->>'b'; ?column? ----- 2 (1 row)
#>	container- json(b)	text[]	json(b)	Obtains the JSON object in the specified path. If the path does not exist, NULL is returned.	SELECT '{"a": {"b":{"c": "foo"}}}::json #>'a,b'; ?column? ----- {"c": "foo"} (1 row)
#>>	container- json(b)	text[]	text	Obtains the JSON object in the specified path. If the path does not exist, NULL is returned.	SELECT '{"a":[1,2,3],"b":[4,5,6]}::json #>>'a,2'; ?column? ----- 3 (1 row)

 **CAUTION**

For the #> and #>> operators, if no data can be found in the specified path, no error is reported and a **NULL** value is returned.

Table 7-39 Additional JSONB support for operators

Operators	Right Operand Type	Description	Example
@>	jsonb	Specifies whether the top layer of the JSON on the left contains all items of the top layer of the JSON on the right.	'{"a":1, "b":2}'::jsonb @> '{"b":2}'::jsonb
<@	jsonb	Specifies whether all items in the JSON file on the left exist at the top layer of the JSON file on the right.	'{"b":2}'::jsonb <@ '{"a":1, "b":2}'::jsonb
?	text	Specifies whether the string of the key or element exists at the top layer of the JSON value.	'{"a":1, "b":2}'::jsonb ? 'b'
?	text[]	Specifies whether any of these array strings exists as top-layer keys.	'{"a":1, "b":2, "c":3}'::jsonb ? array['b', 'c']
?&	text[]	Specifies whether all these array strings exist as top-layer keys.	'["a", "b"]'::jsonb ? & array['a', 'b']
=	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_eq function.	/
<>	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_ne function.	/

Operators	Right Operand Type	Description	Example
<	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_lt function.	/
>	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_gt function.	/
<=	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_le function.	/
>=	jsonb	Determines the size between two JSONB files, which is the same as the jsonb_ge function.	/

Functions Supported by JSON/JSONB

- array_to_json(anyarray [, pretty_bool])**

Description: Returns the array as JSON. It combines a multi-dimensional array into a JSON array. Line feeds will be added between one-dimensional elements if **pretty_bool** is **true**.

Return type: json

Example:

```
gaussdb=# SELECT array_to_json('{{1,5},{99,100}}':int[]);
array_to_json
-----
[[1,5],[99,100]]
(1 row)
```
- json_array_element(array-json, integer), jsonb_array_element(array-jsonb, integer)**

Description: Same as the operator ``->``, which returns the element with the specified index in the array.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_array_element('[1,true,[1,[2,3]],null]',2);
```

```
json_array_element
```

```
-----  
[1,[2,3]]  
(1 row)
```

- `json_array_element_text(array-json, integer)`, `jsonb_array_element_text(array-jsonb, integer)`

Description: Same as the operator ``->>``, which returns the element with the specified index in the array.

Return type: text, text

Example:

```
gaussdb=# SELECT json_array_element_text('[1,true,[1,[2,3]],null]',2);  
json_array_element_text
```

```
-----  
[1,[2,3]]  
(1 row)
```

- `json_object_field(object-json, text)`, `jsonb_object_field(object-jsonb, text)`

Description: Same as the operator ``->``, which returns the value of a specified key in an object.

Return type: json, json

Example:

```
gaussdb=# SELECT json_object_field('{\"a\": {\"b\":\"foo\"}}', 'a');  
json_object_field
```

```
-----  
{\"b\":\"foo\"}  
(1 row)
```

- `json_object_field_text(object-json, text)`, `jsonb_object_field_text(object-jsonb, text)`

Description: Same as the operator ``->``, which returns the value of a specified key in an object.

Return type: text, text

Example:

```
gaussdb=# SELECT json_object_field_text('{\"a\": {\"b\":\"foo\"}}', 'a');  
json_object_field_text
```

```
-----  
{\"b\":\"foo\"}  
(1 row)
```

- `json_extract_path(json, VARIADIC text[])`, `jsonb_extract_path((jsonb, VARIADIC text[])`

Description: Equivalent to the operator ``#>`` searches for JSON based on the path specified by `$2` and returns the result.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_extract_path('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}', 'f4','f6');  
json_extract_path
```

```
-----  
\"stringy\"  
(1 row)
```

- `json_extract_path_op(json, text[])`, `jsonb_extract_path_op(jsonb, text[])`

Description: It is equivalent to the operator ``#>`` and searches for JSON based on the path specified by `$2` and returns the result.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_extract_path_op('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}', ARRAY['f4','f6']);
json_extract_path_op
-----
"stringy"
(1 row)
```

- `json_extract_path_text(json, VARIADIC text[]), jsonb_extract_path_text((jsonb, VARIADIC text[])`

Description: It is equivalent to the operator ``#>`` and searches for JSON based on the path specified by `$2` and returns the result.

Return type: text, text

Example:

```
gaussdb=# SELECT json_extract_path_text('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}', 'f4','f6');
json_extract_path_text
-----
"stringy"
(1 row)
```

- `json_extract_path_text_op(json, text[]), jsonb_extract_path_text_op(jsonb, text[])`

Description: It is equivalent to the operator ``#>>`` and searches for JSON based on the path specified by `$2` and returns the result.

Return type: text, text

Example:

```
gaussdb=# SELECT json_extract_path_text_op('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}',
ARRAY['f4','f6']);
json_extract_path_text_op
-----
"stringy"
(1 row)
```

- `json_array_elements(array-json), jsonb_array_elements(array-jsonb)`

Description: Splits an array. Each element returns a row.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_array_elements('[1,true,[1,[2,3]],null]');
json_array_elements
-----
1
true
[1,[2,3]]
null
(4 rows)
```

- `json_array_elements_text(array-json), jsonb_array_elements_text(array-jsonb)`

Description: Splits an array. Each element returns a row.

Return type: text, text

Example:

```
gaussdb=# SELECT * FROM json_array_elements_text('[1,true,[1,[2,3]],null]');
value
-----
1
true
[1,[2,3]]
(4 rows)
```

- `json_array_length(array-json), jsonb_array_length(array-jsonb)`

Description: Returns the array length.

Return type: integer

Example:

```
gaussdb=# SELECT json_array_length('[1,2,3,{"f1":1,"f2":[5,6]},4,null]');
 json_array_length
-----
                6
(1 row)
```

- `json_each(object-json), jsonb_each(object-jsonb)`

Description: Splits each key-value pair of an object into one row and two columns.

Return type: `setof(key text, value json), setof(key text, value jsonb)`

Example:

```
gaussdb=# SELECT * FROM json_each('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
 key | value
-----+-----
 f1  | [1,2,3]
 f2  | {"f3":1}
 f4  | null
(3 rows)
```

- `json_each_text(object-json), jsonb_each_text(object-jsonb)`

Description: Splits each key-value pair of an object into one row and two columns.

Return type: `setof(key text, value text), setof(key text, value text)`

Example:

```
gaussdb=# SELECT * FROM json_each_text('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
 key | value
-----+-----
 f1  | [1,2,3]
 f2  | {"f3":1}
 f4  |
(3 rows)
```

- `json_object_keys(object-json), jsonb_object_keys(object-jsonb)`

Description: Returns all keys at the top layer of the object.

Return type: `SETOF text`

Example:

```
gaussdb=# SELECT json_object_keys('{"f1":"abc","f2":{"f3":"a"}, "f4":"b"}, {"f1":"abcd"}');
 json_object_keys
-----
 f1
 f2
 f1
(3 rows)
```

- **JSONB deduplication operations:**

```
gaussdb=# SELECT jsonb_object_keys('{"f1":"abc","f2":{"f3":"a"}, "f4":"b"}, {"f1":"abcd"}');
 jsonb_object_keys
-----
 f1
 f2
(2 rows)
```

- `json_typeof(json), jsonb_typeof(jsonb)`

Description: Checks the JSON type.

Return type: `text, text`

Example:

```
gaussdb=# SELECT value, json_typeof(value) FROM (values (json '123.4'), (json "'foo'"), (json 'true'),
(json 'null'), (json '[1, 2, 3]'), (json '{"x":"foo", "y":123}'), (NULL::json)) AS data(value);
 value | json_typeof
-----+-----
 123.4 | number
```

```
"foo"          | string
true           | boolean
null          | null
[1, 2, 3]      | array
{"x":"foo", "y":123} | object
|
(7 rows)
```

- `json_build_array([VARIADIC "any"])`

Description: Constructs a JSON array from a variable parameter list.

Return type: array-json

Example:

```
gaussdb=# SELECT json_build_array('a',1,'b',1.2,'c',true,'d',null,'e',json '{"x": 3, "y": [1,2,3]}', '');
           json_build_array
-----
["a", 1, "b", 1.2, "c", true, "d", null, "e", {"x": 3, "y": [1,2,3]}, ""]
(1 row)
```

- `json_build_object([VARIADIC "any"])`

Description: Constructs a JSON object from a variable parameter list. The number of input parameters must be an even number. Every two input parameters form a key-value pair. Note that the value of a key cannot be null.

Return type: object-json

Example:

```
gaussdb=# SELECT json_build_object(1,2);
           json_build_object
-----
{"1" : 2}
(1 row)
```

- `json_object(text[]), json_object(text[], text[])`

Description: Constructs an object-json from a text array. This is an overloaded function. When the input parameter is a text array, the array length must be an even number, and members are considered as alternate key-value pairs. When two text arrays are used, the first array is considered as a key, and the second array a value. The lengths of the two arrays must be the same. Note that the value of a key cannot be null.

Return type: object-json

Example:

```
gaussdb=# SELECT json_object('{a,1,b,2,3,NULL,"d e f","a b c"}');
           json_object
-----
{"a" : "1", "b" : "2", "3" : null, "d e f" : "a b c"}
(1 row)
gaussdb=# SELECT json_object('{a,b,"a b c"}', '{a,1,1}');
           json_object
-----
{"a" : "a", "b" : "1", "a b c" : "1"}
(1 row)
```

- `json_agg(any)`

Description: Aggregates values into a JSON array.

Return type: array-json

Example:

```
gaussdb=# SELECT * FROM classes;
 name | score
-----+-----
 A    |    2
 A    |    3
 D    |    5
```

```
D |
(4 rows)
gaussdb=# SELECT name, json_agg(score) score FROM classes GROUP BY name ORDER BY name;
name | score
-----+-----
A | [2, 3]
D | [5, null]
| [null]
(3 rows)
```

- `json_object_agg(any, any)`

Description: Aggregates values into a JSON object.

Return type: object-json

Example:

```
gaussdb=# SELECT * FROM classes;
name | score
-----+-----
A | 2
A | 3
D | 5
D |
(4 rows)
```

```
gaussdb=# SELECT json_object_agg(name, score) FROM classes GROUP BY name ORDER BY name;
json_object_agg
-----
{ "A" : 2, "A" : 3 }
{ "D" : 5, "D" : null }
(2 rows)
```

- `- jsonb_contained(jsonb, jsonb)`

Description: Same as the operator `<@``, determines whether all elements in `$1` exist at the top layer of `$2`.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_contained('[1,2,3]', '[1,2,3,4]');
jsonb_contained
-----
t
(1 row)
```

- `- jsonb_contains(jsonb, jsonb)`

Description: Same as the operator `@>``, checks whether all top-layer elements in `$1` are contained in `$2`.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_contains('[1,2,3,4]', '[1,2,3]');
jsonb_contains
-----
t
(1 row)
```

- `- jsonb_exists(jsonb, text)`

Description: Same as the operator ``?``, determines whether all elements in the string array `$2` exist at the top layer of `$1` in the form of `key\elem\scalar`.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_exists('["1",2,3]', '1');
jsonb_exists
-----
t
(1 row)
```

- - `jsonb_exists_all(jsonb, text[])`

Description: Same as the operator `?&`, checks whether all elements in the string array `$2` exist at the top layer of `$1` in the form of **key\elem\scalar**.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_exists_all('["1","2",3]', '{1, 2}');
 jsonb_exists_all
-----
t
(1 row)
```
- - `jsonb_exists_any(jsonb, text[])`

Description: Same as the operator `?|`, checks whether all elements in the string array `$2` exist at the top layer of `$1` in the form of **key\elem\scalar**.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_exists_any('["1","2",3]', '{1, 2, 4}');
 jsonb_exists_any
-----
t
(1 row)
```
- - `jsonb_cmp(jsonb, jsonb)`

Description: Compares values. A positive value indicates greater than, a negative value indicates less than, and **0** indicates equal.

Return type: integer

Example:

```
gaussdb=# SELECT jsonb_cmp('["a", "b"]', '{"a":1, "b":2}');
 jsonb_cmp
-----
-1
(1 row)
```
- - `jsonb_eq(jsonb, jsonb)`

Description: Same as the operator `=`, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_eq('["a", "b"]', '{"a":1, "b":2}');
 jsonb_eq
-----
f
(1 row)
```
- - `jsonb_ne(jsonb, jsonb)`

Description: Same as the operator `<>`, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_ne('["a", "b"]', '{"a":1, "b":2}');
 jsonb_ne
-----
t
(1 row)
```
- - `jsonb_gt(jsonb, jsonb)`

Description: Same as the operator `>`, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_gt('["a", "b"]', '{"a":1, "b":2}');
 jsonb_gt
-----
 f
(1 row)
```

- - jsonb_ge(jsonb, jsonb)

Description: Same as the operator `>=`, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_ge('["a", "b"]', '{"a":1, "b":2}');
 jsonb_ge
-----
 f
(1 row)
```

- - jsonb_lt(jsonb, jsonb)

Description: Same as the operator `<`, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_lt('["a", "b"]', '{"a":1, "b":2}');
 jsonb_lt
-----
 t
(1 row)
```

- - jsonb_le(jsonb, jsonb)

Description: Same as the operator `<=`, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_le('["a", "b"]', '{"a":1, "b":2}');
 jsonb_le
-----
 t
(1 row)
```

- - to_json(anyelement)

Description: Converts parameters to `json`.

Return type: json

Example:

```
gaussdb=# SELECT to_json('{1,5}::text[]');
 to_json
-----
 ["1","5"]
(1 row)
```

- - jsonb_hash(jsonb)

Description: Performs the hash operation on JSONB.

Return type: integer

Example:

```
gaussdb=# SELECT jsonb_hash('[1,2,3]');
 jsonb_hash
-----
 -559968547
(1 row)
```

- Other functions

```
json_agg_transfn
json_agg_finalfn
```

```
json_object_agg_transfn  
json_object_agg_finalfn
```

7.5.14 HLL Functions and Operators

Hash Functions

- `hll_hash_boolean(bool)`

Description: Hashes data of the bool type.

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_boolean(FALSE);  
hll_hash_boolean  
-----  
-5451962507482445012  
(1 row)
```

- `hll_hash_boolean(bool, int32)`

Description: Configures a hash seed (that is, change the hash policy) and hashes data of the bool type.

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_boolean(FALSE, 10);  
hll_hash_boolean  
-----  
-1169037589280886076  
(1 row)
```

- `hll_hash_smallint(smallint)`

Description: Hashes data of the smallint type.

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_smallint(100::smallint);  
hll_hash_smallint  
-----  
962727970174027904  
(1 row)
```

NOTE

If parameters with the same numeric value are hashed using different data types, the data will differ, because hash functions select different calculation policies for each type.

- `hll_hash_smallint(smallint, int32)`

Description: Configures a hash seed (that is, change the hash policy) and hashes data of the smallint type.

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_smallint(100::smallint, 10);  
hll_hash_smallint  
-----  
-9056177146160443041  
(1 row)
```

- `hll_hash_integer(integer)`

Description: Hashes data of the integer type.

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_integer(0);
 hll_hash_integer
-----
5156626420896634997
(1 row)
```

- `hll_hash_integer(integer, int32)`

Description: Hashes data of the integer type and configures a hash seed (that is, change the hash policy).

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_integer(0, 10);
 hll_hash_integer
-----
-5035020264353794276
(1 row)
```

- `hll_hash_bigint(bigint)`

Description: Hashes data of the bigint type.

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_bigint(100::bigint);
 hll_hash_bigint
-----
-2401963681423227794
(1 row)
```

- `hll_hash_bigint(bigint, int32)`

Description: Hashes data of the bigint type and configures a hash seed (that is, change the hash policy).

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_bigint(100::bigint, 10);
 hll_hash_bigint
-----
-2305749404374433531
(1 row)
```

- `hll_hash_bytea(bytea)`

Description: Hashes data of the bytea type.

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_bytea(E'\x');
 hll_hash_bytea
-----
0
(1 row)
```

- `hll_hash_bytea(bytea, int32)`

Description: Hashes data of the bytea type and configures a hash seed (that is, change the hash policy).

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_bytea(E'\x', 10);
 hll_hash_bytea
-----
```

```
7233188113542599437
(1 row)
```

- **hll_hash_text(text)**

Description: Hashes data of the text type.

Return type: hll_hashval

Example:

```
gaussdb=# SELECT hll_hash_text('AB');
 hll_hash_text
-----
-5666002586880275174
(1 row)
```

- **hll_hash_text(text, int32)**

Description: Hashes data of the text type and configures a hash seed (that is, change the hash policy).

Return type: hll_hashval

Example:

```
gaussdb=# SELECT hll_hash_text('AB', 10);
 hll_hash_text
-----
-2215507121143724132
(1 row)
```

- **hll_hash_any(anytype)**

Description: Hashes data of any type.

Return type: hll_hashval

Example:

```
gaussdb=# SELECT hll_hash_any(1);
 hll_hash_any
-----
-1316670585935156930
(1 row)

gaussdb=# SELECT hll_hash_any('08:00:2b:01:02:03::macaddr');
 hll_hash_any
-----
-3719950434455589360
(1 row)
```

- **hll_hash_any(anytype, int32)**

Description: Hashes data of any type and configures a hash seed (that is, change the hash policy).

Return type: hll_hashval

Example:

```
gaussdb=# SELECT hll_hash_any(1, 10);
 hll_hash_any
-----
7048553517657992351
(1 row)
```

- **hll_hashval_eq(hll_hashval, hll_hashval)**

Description: Compares two pieces of data of the hll_hashval type to check whether they are the same.

Return type: Boolean

Example:

```
gaussdb=# SELECT hll_hashval_eq(hll_hash_integer(1), hll_hash_integer(1));
 hll_hashval_eq
```

```
-----
t
(1 row)
```

- `hll_hashval_ne(hll_hashval, hll_hashval)`

Description: Compares two pieces of data of the `hll_hashval` type to check whether they are different.

Return type: Boolean

Example:

```
gaussdb=# SELECT hll_hashval_ne(hll_hash_integer(1), hll_hash_integer(1));
hll_hashval_ne
-----
f
(1 row)
```

HLL Functions

There are three HLL modes: explicit, sparse, and full. When the data size is small, the explicit mode is used. In this mode, distinct values are calculated without errors. As the number of distinct values increases, the HLL mode is switched to the sparse and full modes in sequence. The two modes have no difference in the calculation result, but vary in the calculation efficiency of HLL functions and the storage space of HLL objects. The following functions can be used to view some HLL parameters:

- `hll_print(hll)`

Description: Prints some debugging parameters of an HLL.

Example:

```
gaussdb=# SELECT hll_print(hll_empty());
hll_print
-----
type=1(HLL_EMPTY), log2m=14, log2explicit=10, log2sparse=12, duplicatecheck=0
(1 row)
```

- `hll_type(hll)`

Description: Checks the type of the current HLL. The return values are described as follows: **0** indicates **HLL_UNINIT**, an HLL object that is not initialized. **1** indicates **HLL_EMPTY**, an empty HLL object. **2** indicates **HLL_EXPLICIT**, an HLL object in explicit mode. **3** indicates **HLL_SPARSE**, an HLL object in sparse mode. **4** indicates **HLL_FULL**, an HLL object in full mode. **5** indicates **HLL_UNDEFINED**, an invalid HLL object.

Example:

```
gaussdb=# SELECT hll_type(hll_empty());
hll_type
-----
1
(1 row)
```

- `hll_log2m(hll)`

Description: Checks the value of **log2m** in the current HLL data structure. **log2m** is the logarithm of the number of buckets. This value affects the error rate of calculating distinct values by HLL. The error rate = $\pm 1.04/\sqrt{2^{\log 2m}}$. If the value of **log2m** ranges from 10 to 16, HLL sets the number of buckets to $2^{\log 2m}$. When the value of **log2explicit** is explicitly set to **-1**, the built-in default value is used.

Example:

```

gaussdb=# SELECT hll_log2m(hll_empty());
hll_log2m
-----
      14
(1 row)

gaussdb=# SELECT hll_log2m(hll_empty(10));
hll_log2m
-----
      10
(1 row)

gaussdb=# SELECT hll_log2m(hll_empty(-1));
hll_log2m
-----
      14
(1 row)

```

- **hll_log2explicit(hll)**

Description: Queries the value of **log2explicit** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can change the value of **log2explicit** to change the policy. For example, if the value of **log2explicit** is **0**, the HLL will skip the **explicit** mode and directly enter the **sparse** mode. When the value of **log2explicit** is explicitly set to a value ranging from 1 to 12, the HLL will switch to the sparse mode when the length of the data segment exceeds $2^{\text{log2explicit}}$. When the value of **log2explicit** is explicitly set to **-1**, the built-in default value is used.

Example:

```

gaussdb=# SELECT hll_log2explicit(hll_empty());
hll_log2explicit
-----
          10
(1 row)

gaussdb=# SELECT hll_log2explicit(hll_empty(12, 8));
hll_log2explicit
-----
           8
(1 row)

gaussdb=# SELECT hll_log2explicit(hll_empty(12, -1));
hll_log2explicit
-----
          10
(1 row)

```

- **hll_log2sparse(hll)**

Description: Queries the value of **log2sparse** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can adjust the value of **log2sparse** to change the policy. For example, if the value of **log2sparse** is **0**, the system skips the sparse mode and directly enters the full mode. If the value of **log2sparse** is explicitly set to a value ranging from 1 to 14, the HLL will switch to the full mode when the length of the data segment exceeds $2^{\text{log2sparse}}$. When the value of **log2sparse** is explicitly set to **-1**, the built-in default value is used.

Example:

```

gaussdb=# SELECT hll_log2sparse(hll_empty());
hll_log2sparse

```

Example:

```
gaussdb=# SELECT hll_cardinality(hll_empty() || hll_hash_integer(1));
hll_cardinality
-----
          1
(1 row)
```

- `hll_union(hll, hll)`

Description: Performs the UNION operation on two HLL data structures to obtain one HLL.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_union(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
          hll_union
-----
\x484c4c10002000002b0900000000000000004000000000000000b3ccc49320cca1ae3e2921ff133fba
ed00
(1 row)
```

Aggregate Functions

- `hll_add_agg(hll_hashval)`

Description: Groups hashed data into HLL.

Return type: HLL

Example:

```
-- Prepare data:
gaussdb=# CREATE TABLE t_id(id int);
gaussdb=# INSERT INTO t_id VALUES(generate_series(1,500));
gaussdb=# CREATE TABLE t_data(a int, c text);
gaussdb=# INSERT INTO t_data SELECT mod(id,2), id FROM t_id;

-- Create a table and specify an HLL column:
gaussdb=# CREATE TABLE t_a_c_hll(a int, c hll);

-- Use GROUP BY on column a to group data, and insert the data to the HLL.
gaussdb=# INSERT INTO t_a_c_hll SELECT a, hll_add_agg(hll_hash_text(c)) FROM t_data GROUP BY a;

-- Calculate the number of distinct values for each group in the HLL:
gaussdb=# SELECT a, #c AS cardinality FROM t_a_c_hll ORDER BY a;
a | cardinality
--+-----
0 | 247.862354346299
1 | 250.908710610377
(2 rows)
```

- `hll_add_agg(hll_hashval, int32 log2m)`

Description: Groups hashed data into HLL and specifies the **log2m** parameter. The value ranges from 10 to 16. If the input is **-1** or **NULL**, the built-in default value is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), 12)) FROM t_data;
hll_cardinality
-----
497.965240179228
(1 row)
```

- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit)`
Description: Groups hashed data into HLL and specifies the **log2m** and **log2explicit** parameters in sequence. The value of **log2explicit** ranges from 0 to 12. The value **0** indicates that the explicit mode is skipped. This parameter is used to set the threshold of the explicit mode. When the length of the data segment reaches $2^{\text{log2explicit}}$, the mode is switched to the sparse or full mode. If the input is **-1** or **NULL**, the built-in default value of **log2explicit** is used.
Return type: HLL
Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 1)) FROM t_data;
hll_cardinality
-----
498.496062953313
(1 row)
```
- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse)`
Description: Groups hashed data into HLL and sets the **log2m**, **log2explicit**, and **log2sparse** parameters in sequence. The value of **log2sparse** ranges from 0 to 14. The value **0** indicates that the sparse mode is skipped. This parameter is used to set the threshold of the sparse mode. When the length of the data segment reaches $2^{\text{log2sparse}}$, the mode is switched to the full mode. If the input is **-1** or **NULL**, the built-in default value of **log2sparse** is used.
Return type: HLL
Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10)) FROM t_data;
hll_cardinality
-----
498.496062953313
(1 row)
```
- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse, int32 duplicatecheck)`
Description: Groups hashed data into HLL and sets the **log2m**, **log2explicit**, **log2sparse**, and **duplicatecheck** parameters. The value of **duplicatecheck** can be **0** or **1**, indicating whether to enable this mode. By default, this mode is disabled. If the input is **-1** or **NULL**, the built-in default value of **duplicatecheck** is used.
Return type: HLL
Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10, -1)) FROM t_data;
hll_cardinality
-----
498.496062953313
(1 row)
```
- `hll_union_agg(hll)`
Description: Performs the UNION operation on multiple pieces of data of the HLL type to obtain one HLL.
Return type: HLL
Example:

```
-- Perform the UNION operation on data of the HLL type in each group to obtain one HLL, and
calculate the number of distinct values:
gaussdb=# SELECT #hll_union_agg(c) AS cardinality FROM t_a_c_hll;
cardinality
-----
```

498.496062953313
(1 row)

 **NOTE**

To perform the UNION operation on data in multiple HLLs, ensure that the HLLs have the same precision. Otherwise, **UNION** cannot be performed. This constraint also applies to the **hll_union(hll, hll)** function.

Obsolete Functions

Some old HLL functions are discarded due to version upgrade. You can replace them with similar functions.

- **hll_schema_version(hll)**
Description: Checks the schema version in the current HLL. In earlier versions, the schema version is fixed at **1**, which is used to verify the header of the HLL field. After refactoring, the HLL field is added to the header for verification. The schema version is no longer used.
- **hll_regwidth(hll)**
Description: Queries the bucket size in the HLL data structure. In earlier versions, the value of **regwidth** ranges from 1 to 5, which has a large error and limits the upper limit of the cardinality estimation. After refactoring, the value of *regwidth* is fixed at **6** and the variable is not used.
- **hll_expthresh(hll)**
Description: Obtains the value of **expthresh** in the current HLL. The **hll_log2explicit(hll)** function is used to replace similar functions.
- **hll_sparseon(hll)**
Description: Specifies whether the sparse mode is enabled. Use **hll_log2sparse(hll)** to replace similar functions. The value **0** indicates that the sparse mode is disabled.

Built-In Functions

HLL has a series of built-in functions for internal data processing. Generally, users do not need to know how to use these functions. For details, see [Table 7-40](#).

Table 7-40 Built-in functions

Function	Description
hll_in	Receives hll data in string format.
hll_out	Sends hll data in string format.
hll_recv	Receives hll data in bytea format.
hll_send	Sends hll data in bytea format.
hll_trans_in	Receives hll_trans_type data in string format.
hll_trans_out	Sends hll_trans_type data in string format.
hll_trans_recv	Receives hll_trans_type data in bytea format.

Function	Description
hll_trans_send	Sends hll_trans_type data in bytea format.
hll_typmod_in	Receives typmod data.
hll_typmod_out	Sends typmod data.
hll_hashval_in	Receives hll_hashval data.
hll_hashval_out	Sends hll_hashval data.
hll_add_trans0	Works similar to hll_add . No input parameter is specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.
hll_add_trans1	Works similar to hll_add . An input parameter is specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.
hll_add_trans2	Works similar to hll_add . Two input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.
hll_add_trans3	Works similar to hll_add . Three input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.
hll_add_trans4	Works similar to hll_add . Four input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.
hll_union_trans	Works similar to hll_union and is used on the first phase of DNs in distributed aggregation operations.
hll_union_collect	Works similar to hll_union and is used on the second phase of CNs in distributed aggregation operations to summarize the results of each DN.
hll_pack	Is used on the third phase of CNs in distributed aggregation operations to convert a user-defined type hll_trans_type to the hll type.
hll	Converts a hll type to another hll type. Input parameters can be specified.
hll_hashval	Converts the bigint type to the hll_hashval type.
hll_hashval_int4	Converts the int4 type to the hll_hashval type.

Operators

- =
Description: Compares the values of the hll or hll_hashval type to check whether they are the same.
Return type: Boolean

Example:

```
--hll
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) = (hll_empty() || hll_hash_integer(1));
column
-----
t
(1 row)

--hll_hashval
gaussdb=# SELECT hll_hash_integer(1) = hll_hash_integer(1);
?column?
-----
t
(1 row)
```

- <> or !=

Description: Compares the values of the hll or hll_hashval type to check whether they are different.

Return type: Boolean

Example:

```
--hll
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) <> (hll_empty() || hll_hash_integer(2));
?column?
-----
t
(1 row)

--hll_hashval
gaussdb=# SELECT hll_hash_integer(1) <> hll_hash_integer(2);
?column?
-----
t
(1 row)
```

- ||

Description: Represents the functions of **hll_add**, **hll_union**, and **hll_add_rev**.

Return type: HLL

Example:

```
--hll_add
gaussdb=# SELECT hll_empty() || hll_hash_integer(1);
?column?
-----
\x484c4c08000002002b090000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_add_rev
gaussdb=# SELECT hll_hash_integer(1) || hll_empty();
?column?
-----
\x484c4c08000002002b090000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_union
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) || (hll_empty() || hll_hash_integer(2));
?column?
-----
\x484c4c10002000002b0900000000000000400000000000000b3ccc49320cca1ae3e2921ff133fbaed00
(1 row)
```

- #

Description: Calculates the number of distinct values of an HLL. It works the same as the hll_cardinality function.

Return type: int

Example:

```
gaussdb=# SELECT #(hll_empty() || hll_hash_integer(1));
?column?
-----
      1
(1 row)
```

7.5.15 SEQUENCE Functions

The sequence functions provide a simple method to ensure security of multiple users for users to obtain sequence values from sequence objects.

- `nextval(regclass)`

Description: Specifies an increasing sequence and returns a new value.

NOTE

- To avoid blocking of concurrent transactions that obtain numbers from the same sequence, a `nextval` operation is never rolled back; that is, once a value is fetched, it is considered used, even if the transaction that did the `nextval` later aborts. This means that aborted transactions may leave unused "holes" in the sequence of assigned values. Therefore, sequences in GaussDB cannot be used to obtain sequence without gaps.
- If the `nextval` function is pushed to DNs, each DN will automatically connect to the GTM and requests the next value. For example, in the **INSERT INTO t1 SELECT xxx** statement, a column in table **t1** needs to call the `nextval` function. If maximum number of connections on the GTM is 8192, this type of pushed statements occupies too many GTM connections. Therefore, the number of concurrent connections for these statements is limited to 7000 divided by the number of cluster DNs. The other 1192 connections are reserved for other statements.

Return type: numeric

The `nextval` function can be called in either of the following ways: (In example 2, the ORA syntax is supported. Currently, the sequence name cannot contain a dot.)

Example 1:

```
gaussdb=# SELECT nextval('seqDemo');
nextval
-----
      2
(1 row)
```

Example 2:

```
gaussdb=# SELECT seqDemo.nextval;
nextval
-----
      2
(1 row)
```

- `currval(regclass)`

Description: Returns the last value returned by `nextval` in the current session. If `nextval` has not been called for the specified sequence in the current session, an error is reported when `currval` is called. By default, this function is disabled. To enable it, set **enable_beta_features** to **true**. After **enable_beta_features** is set to **true**, the `nextval()` function will not be pushed down.

Return type: numeric

The currval function can be called in either of the following ways: (In example 2, the ORA syntax is supported. Currently, the sequence name cannot contain a dot.)

Example 1:

```
gaussdb=# SELECT currval('seq1');
currval
-----
      2
(1 row)
```

Example 2:

```
gaussdb=# SELECT seq1.currval seq1;
currval
-----
      2
(1 row)
```

- lastval()

Description: Returns the last value returned by nextval in the current session. This function is equivalent to currval, except that it does not use sequence names as parameters. It fetches the sequence used by nextval last time in the current session. If nextval has not been called in the current session, an error is reported when lastval is called.

By default, this function is disabled. To enable it, set **enable_beta_features** or **lastval_supported** to **true**. After this function is enabled, nextval() will not be pushed down.

Return type: numeric

Example:

```
gaussdb=# SELECT lastval();
lastval
-----
      2
(1 row)
```

- setval(regclass, bigint)

Sets the current value of a sequence.

Return type: numeric

Example:

```
gaussdb=# SELECT setval('seqDemo',1);
setval
-----
      1
(1 row)
```

- setval(regclass, numeric, Boolean)

Sets the current value of a sequence and the is_called sign.

Return type: numeric

Example:

```
gaussdb=# SELECT setval('seqDemo',1,true);
setval
-----
      1
(1 row)
```

 **NOTE**

The current session and GTM will take effect immediately after **setval** is performed. If other sessions have buffered sequence values, **setval** will take effect only after the values are used up. Therefore, to prevent sequence value conflicts, you are advised to use **setval** with caution.

Because the sequence is non-transactional, changes made by **setval** will not be canceled when a transaction rolled back.

- `pg_sequence_last_value(sequence_oid oid, OUT cache_value int16, OUT last_value int16)`

Description: Obtains the parameters of a specified sequence, including the cache value and current value.

Return type: int16, int16

7.5.16 Array Functions and Operators

Array Operators

- =

Description: Specifies whether two arrays are equal.

Example:

```
gaussdb=# SELECT ARRAY[1.1,2.1,3.1]::int[] = ARRAY[1,2,3] AS RESULT ;
result
-----
t
(1 row)
```

- <>

Description: Specifies whether two arrays are not equal.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] <> ARRAY[1,2,4] AS RESULT;
result
-----
t
(1 row)
```

- <

Description: Specifies whether an array is less than another.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] < ARRAY[1,2,4] AS RESULT;
result
-----
t
(1 row)
```

- >

Description: Specifies whether an array is greater than another.

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] > ARRAY[1,2,4] AS RESULT;
result
-----
t
(1 row)
```

- <=

Description: Specifies whether an array is less than another.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] <= ARRAY[1,2,3] AS RESULT;
result
-----
t
(1 row)
```

- >=

Description: Specifies whether an array is greater than or equal to another.

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] >= ARRAY[1,4,3] AS RESULT;
result
-----
t
(1 row)
```

- @>

Description: Specifies whether an array contains another.

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] @> ARRAY[3,1] AS RESULT;
result
-----
t
(1 row)
```

- <@

Description: Specifies whether an array is contained in another.

Example:

```
gaussdb=# SELECT ARRAY[2,7] <@ ARRAY[1,7,4,2,6] AS RESULT;
result
-----
t
(1 row)
```

- &&

Description: Specifies whether an array overlaps another (have common elements).

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] && ARRAY[2,1] AS RESULT;
result
-----
t
(1 row)
```

- ||

Description: Array-to-array concatenation.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] || ARRAY[4,5,6] AS RESULT;
result
-----
{1,2,3,4,5,6}
(1 row)
gaussdb=# SELECT ARRAY[1,2,3] || ARRAY[[4,5,6],[7,8,9]] AS RESULT;
result
-----
{{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

- ||

Description: Element-to-array concatenation.

Example:

```
gaussdb=# SELECT 3 || ARRAY[4,5,6] AS RESULT;  
result  
-----  
{3,4,5,6}  
(1 row)
```

- ||

Description: Array-to-element concatenation.

Example:

```
gaussdb=# SELECT ARRAY[4,5,6] || 7 AS RESULT;  
result  
-----  
{4,5,6,7}  
(1 row)
```

Array comparisons compare the array contents element-by-element, using the default B-tree comparison function for the element data type. In multidimensional arrays, the elements are accessed in row-major order. If the contents of two arrays are equal but the dimensionality is different, the first difference in the dimensionality information determines the sort order.

Array Functions

- `array_append(anyarray, anyelement)`

Description: Appends an element to the end of an array, and only supports dimension-1 arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_append(ARRAY[1,2], 3) AS RESULT;  
result  
-----  
{1,2,3}  
(1 row)
```

- `array_prepend(anyelement, anyarray)`

Description: Appends an element to the beginning of an array, and only supports dimension-1 arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_prepend(1, ARRAY[2,3]) AS RESULT;  
result  
-----  
{1,2,3}  
(1 row)
```

- `array_cat(anyarray, anyarray)`

Description: Concatenates two arrays, and supports multi-dimensional arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_cat(ARRAY[1,2,3], ARRAY[4,5]) AS RESULT;  
result  
-----  
{1,2,3,4,5}  
(1 row)  
  
gaussdb=# SELECT array_cat(ARRAY[[1,2],[4,5]], ARRAY[6,7]) AS RESULT;
```

```

      result
-----
{{1,2},{4,5},{6,7}}
(1 row)

```

- `array_union(anyarray, anyarray)`

Description: Concatenates two arrays. Only one-dimensional arrays are supported. If an input parameter is **NULL**, another input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_union(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
```

```

      result
-----
{1,2,3,3,4,5}
(1 row)

```

```
gaussdb=# SELECT array_union(ARRAY[1,2,3], NULL) AS RESULT;
```

```

      result
-----
{1,2,3}
(1 row)

```

- `array_union_distinct(anyarray, anyarray)`

Description: Concatenates two arrays and deduplicates them. Only one-dimensional arrays are supported. If an input parameter is **NULL**, another input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_union_distinct(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
```

```

      result
-----
{1,2,3,4,5}
(1 row)

```

```
gaussdb=# SELECT array_union_distinct(ARRAY[1,2,3], NULL) AS RESULT;
```

```

      result
-----
{1,2,3}
(1 row)

```

- `array_intersect(anyarray, anyarray)`

Description: Intersects two arrays. Only one-dimensional arrays are supported. If any input parameter is **NULL**, **NULL** is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_intersect(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
```

```

      result
-----
{3}
(1 row)

```

```
gaussdb=# SELECT array_intersect(ARRAY[1,2,3], NULL) AS RESULT;
```

```

      result
-----
(1 row)

```

- `array_intersect_distinct(anyarray, anyarray)`

Description: Intersects two arrays and deduplicates them. Only one-dimensional arrays are supported. If any input parameter is **NULL**, **NULL** is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_intersect_distinct(ARRAY[1,2,2], ARRAY[2,2,4,5]) AS RESULT;
result
-----
{2}
(1 row)

gaussdb=# SELECT array_intersect_distinct(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
(1 row)
```

- `array_except(anyarray, anyarray)`

Description: Calculates the difference between two arrays. Only one-dimensional arrays are supported. If the first input parameter is **NULL**, **NULL** is returned. If the second input parameter is **NULL**, the first input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_except(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
result
-----
{1,2}
(1 row)

gaussdb=# SELECT array_except(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
{1,2,3}
(1 row)

gaussdb=# SELECT array_except(NULL, ARRAY[3,4,5]) AS RESULT;
result
-----
(1 row)
```

- `array_except_distinct(anyarray, anyarray)`

Description: Calculates the difference between two arrays and deduplicates them. Only one-dimensional arrays are supported. If the first input parameter is **NULL**, **NULL** is returned. If the second input parameter is **NULL**, the first input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_except_distinct(ARRAY[1,2,2,3], ARRAY[3,4,5]) AS RESULT;
result
-----
{1,2}
(1 row)

gaussdb=# SELECT array_except_distinct(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
{1,2,3}
(1 row)
```

```
gaussdb=# SELECT array_except_distinct(NULL, ARRAY[3,4,5]) AS RESULT;  
result  
-----  
(1 row)
```

- `array_ndims(anyarray)`

Description: Returns the number of dimensions of an array.

Return type: int

Example:

```
gaussdb=# SELECT array_ndims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;  
result  
-----  
2  
(1 row)
```

- `array_dims(anyarray)`

Description: Returns a text representation of array's dimensions.

Return type: text

Example:

```
gaussdb=# SELECT array_dims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;  
result  
-----  
[1:2][1:3]  
(1 row)
```

- `array_length(anyarray, int)`

Description: Returns the length of the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_length(array[1,2,3], 1) AS RESULT;  
result  
-----  
3  
(1 row)
```

- `array_lower(anyarray, int)`

Description: Returns lower bound of the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_lower('[0:2]={1,2,3}::int[], 1) AS RESULT;  
result  
-----  
0  
(1 row)
```

- `array_sort(anyarray)`

Description: Returns an array in ascending order.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_sort(ARRAY[5,1,3,6,2,7]) AS RESULT;  
result  
-----  
{1,2,3,5,6,7}  
(1 row)
```

- `array_upper(anyarray, int)`

Description: Returns upper bound of the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_upper(ARRAY[1,8,3,7], 1) AS RESULT;
result
-----
      4
(1 row)
```

- `array_to_string(anyarray, text [, text])`

Description: Uses the first **text** as the new delimiter and the second **text** to replace **NULL** values.

Return type: text

Example:

```
gaussdb=# SELECT array_to_string(ARRAY[1, 2, 3, NULL, 5], ',', '*') AS RESULT;
result
-----
1,2,3*,5
(1 row)
```

- `array_delete(anyarray)`

Description: Clears elements in an array and returns an empty array of the same type.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_delete(ARRAY[1,8,3,7]) AS RESULT;
result
-----
{}
(1 row)
```

- `array_deleteidx(anyarray, int)`

Description: Deletes specified index elements from an array and returns an array consisting of the remaining elements.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_deleteidx(ARRAY[1,2,3,4,5], 1) AS RESULT;
result
-----
{2,3,4,5}
(1 row)
```

NOTE

`array_deleteidx(anyarray, int)`: This function is disabled when the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s1** in the ORA-compatible database.

- `array_extendnull(anyarray, int)`

Description: Adds a specified number of null elements to the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_extendnull(ARRAY[1,8,3,7],1) AS RESULT;
result
-----
{1,8,3,7,null}
(1 row)
```

- `array_extendnull(anyarray, int, int)`

Description: Adds a specified number of elements with a specified index to the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_extendnull(ARRAY[1,8,3,7],2,2) AS RESULT;
result
-----
{1,8,3,7,8,8}
(1 row)
```

 **NOTE**

array_extendnull(anyarray, int, int): This function takes effect when the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s1** in an ORA-compatible database.

- array_trim(anyarray, int)

Description: Deletes a specified number of elements from the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_trim(ARRAY[1,8,3,7],1) AS RESULT;
result
-----
{1,8,3}
(1 row)
```

- array_exists(anyarray, int)

Description: Checks whether the second parameter is a valid index of an array.

Return type: Boolean

Example:

```
gaussdb=# SELECT array_exists(ARRAY[1,8,3,7],1) AS RESULT;
result
-----
t
(1 row)
```

- array_next(anyarray, int)

Description: Returns the index of the element following a specified index in an array based on the second input parameter.

Return type: int

Example:

```
gaussdb=# SELECT array_next(ARRAY[1,8,3,7],1) AS RESULT;
result
-----
2
(1 row)
```

- array_prior(anyarray, int)

Description: Returns the index of the element followed by a specified index in an array based on the second input parameter.

Return type: int

Example:

```
gaussdb=# SELECT array_prior(ARRAY[1,8,3,7],2) AS RESULT;
result
-----
1
(1 row)
```

- `string_to_array(text, text [, text])`

Description: Uses the second **text** as the new delimiter and the third **text** as the substring to be replaced by **NULL** values. A substring can be replaced by **NULL** values only when it is the same as the third **text**.

Return type: `text[]`

Example:

```
gaussdb=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'yy') AS RESULT;
 result
-----
{xx,NULL,zz}
(1 row)
gaussdb=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'y') AS RESULT;
 result
-----
{xx,y,zz}
(1 row)
```

- `unnest(anyarray)`

Description: Expands an array to a set of rows.

Return type: `setof anyelement`

Example:

```
gaussdb=# SELECT unnest(ARRAY[1,2]) AS RESULT;
 result
-----
 1
 2
(2 rows)
```

In **string_to_array**, if the delimiter parameter is **NULL**, each character in the input string will become a separate element in the resulting array. If the delimiter is an empty string, then the entire input string is returned as a one-element array. Otherwise the input string is split at each occurrence of the delimiter string.

In **string_to_array**, if the null-string parameter is omitted or **NULL**, none of the substrings of the input will be replaced by **NULL**.

In **array_to_string**, if the null-string parameter is omitted or **NULL**, any null elements in the array are simply skipped and not represented in the output string.

- `_pg_keysequal`

Description: Checks whether two smallint arrays are the same.

Parameter: `smallint[]`, `smallint[]`

Return type: Boolean

 **NOTE**

This function exists in the `information_schema` namespace.

7.5.17 Range Functions and Operators

Range Operators

- `=`

Description: Equals

Example:

```
gaussdb=# SELECT int4range(1,5) = '[1,4]':int4range AS RESULT;  
result  
-----  
t  
(1 row)
```

- <>

Description: Does not equal

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) <> numrange(1.1,2.3) AS RESULT;  
result  
-----  
t  
(1 row)
```

- <

Description: Is less than

Example:

```
gaussdb=# SELECT int4range(1,10) < int4range(2,3) AS RESULT;  
result  
-----  
t  
(1 row)
```

- >

Description: Is greater than

Example:

```
gaussdb=# SELECT int4range(1,10) > int4range(1,5) AS RESULT;  
result  
-----  
t  
(1 row)
```

- <=

Description: Is less than or equals

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) <= numrange(1.1,2.2) AS RESULT;  
result  
-----  
t  
(1 row)
```

- >=

Description: Is greater than or equals

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) >= numrange(1.1,2.0) AS RESULT;  
result  
-----  
t  
(1 row)
```

- @>

Description: Contains range

Example:

```
gaussdb=# SELECT int4range(2,4) @> int4range(2,3) AS RESULT;  
result  
-----  
t  
(1 row)
```

- **@>**
Description: Contains element
Example:

```
gaussdb=# SELECT '[2011-01-01,2011-03-01]':tsrange @> '2011-01-10':timestamp AS RESULT;  
result  
-----  
t  
(1 row)
```
- **<@**
Description: Range is contained by
Example:

```
gaussdb=# SELECT int4range(2,4) <@ int4range(1,7) AS RESULT;  
result  
-----  
t  
(1 row)
```
- **<@**
Description: Element is contained by
Example:

```
gaussdb=# SELECT 42 <@ int4range(1,7) AS RESULT;  
result  
-----  
f  
(1 row)
```
- **&&**
Description: Overlaps (has points in common)
Example:

```
gaussdb=# SELECT int8range(3,7) && int8range(4,12) AS RESULT;  
result  
-----  
t  
(1 row)
```
- **<<**
Description: Strictly left of
Example:

```
gaussdb=# SELECT int8range(1,10) << int8range(100,110) AS RESULT;  
result  
-----  
t  
(1 row)
```
- **>>**
Description: Strictly right of
Example:

```
gaussdb=# SELECT int8range(50,60) >> int8range(20,30) AS RESULT;  
result  
-----  
t  
(1 row)
```
- **&<**
Description: Does not extend to the right of
Example:

```
gaussdb=# SELECT int8range(1,20) &< int8range(18,20) AS RESULT;  
result
```

- ```

t
(1 row)
```

• **&>**  
Description: Does not extend to the left of  
Example:  

```
gaussdb=# SELECT int8range(7,20) &> int8range(5,10) AS RESULT;
result

t
(1 row)
```
- **-|-**  
Description: Is adjacent to  
Example:  

```
gaussdb=# SELECT numrange(1.1,2.2) -|- numrange(2.2,3.3) AS RESULT;
result

t
(1 row)
```
- **+**  
Description: Union  
Example:  

```
gaussdb=# SELECT numrange(5,15) + numrange(10,20) AS RESULT;
result

[5,20)
(1 row)
```
- **\***  
Description: Intersection  
Example:  

```
gaussdb=# SELECT int8range(5,15) * int8range(10,20) AS RESULT;
result

[10,15)
(1 row)
```
- **-**  
Description: Difference  
Example:  

```
gaussdb=# SELECT int8range(5,15) - int8range(10,20) AS RESULT;
result

[5,10)
(1 row)
```

The simple comparison operators `<`, `>`, `<=`, and `>=` compare the lower bounds first, and only if those are equal, compare the upper bounds.

The `<<`, `>>`, and `-|-` operators always return false when an empty range is involved; that is, an empty range is not considered to be either before or after any other range.

The union and difference operators will fail if the resulting range would need to contain two disjoint sub-ranges.

## Range Functions

The lower and upper functions return null if the range is empty or the requested bound is infinite. The lower\_inc, upper\_inc, lower\_inf, and upper\_inf functions all return false for an empty range.

- numrange(numeric, numeric, [text])

Description: Specifies a range.

Return type: Range's element type

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) AS RESULT;
result

[1.1,2.2)
(1 row)
gaussdb=# SELECT numrange(1.1,2.2, '()') AS RESULT;
result

(1.1,2.2)
(1 row)
```

- lower(anyrange)

Description: Lower bound of range

Return type: Range's element type

Example:

```
gaussdb=# SELECT lower(numrange(1.1,2.2)) AS RESULT;
result

1.1
(1 row)
```

- upper(anyrange)

Description: Upper bound of range

Return type: range's element type

Example:

```
gaussdb=# SELECT upper(numrange(1.1,2.2)) AS RESULT;
result

2.2
(1 row)
```

- isempty(anyrange)

Description: Is the range empty?

Return type: Boolean

Example:

```
gaussdb=# SELECT isempty(numrange(1.1,2.2)) AS RESULT;
result

f
(1 row)
```

- lower\_inc(anyrange)

Description: Is the lower bound inclusive?

Return type: Boolean

Example:

```
gaussdb=# SELECT lower_inc(numrange(1.1,2.2)) AS RESULT;
result
```

- ```
-----
t
(1 row)
```
- upper_inc(anyrange)**
Description: Is the upper bound inclusive?
Return type: Boolean
Example:
gaussdb=# SELECT upper_inc(numrange(1.1,2.2)) AS RESULT;
result

f
(1 row)
 - lower_inf(anyrange)**
Description: Is the lower bound infinite?
Return type: Boolean
Example:
gaussdb=# SELECT lower_inf('()::daterange) AS RESULT;
result

t
(1 row)
 - upper_inf(anyrange)**
Description: Is the upper bound infinite?
Return type: Boolean
Example:
gaussdb=# SELECT upper_inf('()::daterange) AS RESULT;
result

t
(1 row)
 - elem_contained_by_range(anelement, anyrange)**
Description: Determines whether an element is within the range.
Return type: Boolean
Example:
gaussdb=# SELECT elem_contained_by_range('2', numrange(1.1,2.2));
elem_contained_by_range

t
(1 row)

7.5.18 Aggregate Functions

Aggregate Functions

- sum(expression)**
Description: Specifies the sum of expressions across all input values.
Return type:
Generally, same as the argument data type. In the following cases, type conversion occurs:

 - **BIGINT** for **SMALLINT** or **INT** arguments

- **NUMBER** for **BIGINT** arguments
- **DOUBLE PRECISION** for floating-point arguments

Example:

```
gaussdb=# CREATE TABLE tab(a int);
CREATE TABLE
gaussdb=# INSERT INTO tab values(1);
INSERT 0 1
gaussdb=# INSERT INTO tab values(2);
INSERT 0 1
gaussdb=# SELECT sum(a) FROM tab;
sum
-----
 3
(1 row)
```

- **max(expression)**

Description: Specifies the maximum value of expression across all input values.

Parameter type: any array, numeric, string, or date/time type

Return type: same as the argument type

Example:

```
gaussdb=# CREATE TABLE max_t1(a int, b int);
gaussdb=# INSERT INTO max_t1 VALUES(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT MAX(a) FROM max_t1;
max
-----
 4
(1 row)
gaussdb=# DROP TABLE max_t1;
```

- **min(expression)**

Description: Specifies the minimum value of expression across all input values.

Parameter type: any array, numeric, string, or date/time type

Return type: same as the argument type

Example:

```
gaussdb=# CREATE TABLE min_t1(a int, b int);
gaussdb=# INSERT INTO min_t1 VALUES(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT MIN(a) FROM min_t1;
min
-----
 1
(1 row)
gaussdb=# DROP TABLE min_t1;
```

- **avg(expression)**

Description: Specifies the average (arithmetic mean) of all input values.

Return type:

NUMBER for any integer-type argument.

DOUBLE PRECISION for floating-point arguments.

otherwise the same as the argument data type.

Example:

```
gaussdb=# CREATE TABLE avg_t1(a int, b int);
gaussdb=# INSERT INTO avg_t1 VALUES(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT AVG(a) FROM avg_t1;
      avg
-----
2.5000000000000000
(1 row)
gaussdb=# DROP TABLE avg_t1;
```

- **count(expression)**

Description: Specifies the number of input rows for which the value of the expression is not null.

Return type: bigint

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE count_t1(a int, b int);
gaussdb=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT COUNT(a) FROM count_t1;
      count
-----
4
(1 row)
gaussdb=# DROP TABLE count_t1;
```

- **count(*)**

Description: Returns the number of input rows.

Return type: bigint

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE count_t1(a int, b int);
gaussdb=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT COUNT(*) FROM count_t1;
      count
-----
5
(1 row)
gaussdb=# DROP TABLE count_t1;
```

- **array_agg(expression)**

Description: Concatenates input values, including nulls, into an array.

Return type: array of the argument type

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE array_agg_t1(a int, b int);
gaussdb=# INSERT INTO array_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT ARRAY_AGG(a) FROM array_agg_t1;
      array_agg
-----
{NULL,1,2,3,4}
```

(1 row)

```
gaussdb=# DROP TABLE array_agg_t1;
```

- **string_agg(expression, delimiter)**

Description: Concatenates input values into a string, separated by delimiter.

Return type: same as the argument type

Operations on XML data that is explicitly converted to the character type are supported.

Example:

```
gaussdb=# CREATE TABLE string_agg_t1(a int, b int);
```

```
gaussdb=# INSERT INTO string_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
```

```
gaussdb=# SELECT STRING_AGG(a,;) FROM string_agg_t1;
```

```
string_agg
```

```
-----
```

```
1;2;3;4
```

```
(1 row)
```

```
gaussdb=# DROP TABLE string_agg_t1;
```

- **listagg(expression [, delimiter]) WITHIN GROUP(ORDER BY order-list)**

Description: Sorts aggregation column data according to the mode specified by **WITHIN GROUP** and concatenates the data to a string using the specified delimiter.

- **expression:** Mandatory. It specifies an aggregation column name or a column-based valid expression. It does not support the **DISTINCT** keyword and the **VARIADIC** parameter.
- **delimiter:** Optional. It specifies a delimiter, which can be a string constant or a deterministic expression based on a group of columns. The default value is empty.
- **order-list:** Mandatory. It specifies the sorting mode in a group.

Return type: text

NOTE

listagg is a column-to-row aggregation function, compatible with Oracle Database 11g Release 2. You can specify the **OVER** clause as a window function. When **listagg** is used as a window function, the **OVER** clause does not support the window sorting or framework of **ORDER BY**, to avoid ambiguity in **listagg** and **ORDER BY** of the **WITHIN GROUP** clause.

Example:

The aggregation column is of the text character set type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b text);
```

```
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'a1'),(1,'b2'),(1,'c3'),(2,'d4'),(2,'e5'),(3,'f6');
```

```
gaussdb=# SELECT a,LISTAGG(b,;) WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
```

```
a | listagg
```

```
---+-----
```

```
1 | b2;c3
```

```
2 | d4;e5
```

```
3 | f6
```

```
 | a1
```

```
(4 rows)
```

```
gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the integer type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b int);

gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
---+-----
1 | 2;3
2 | 4;5
3 | 6
   | 1
(4 rows)

gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the floating point type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b float);

gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,1.111),(1,2.222),(1,3.333),(2,4.444),(2,5.555),
(3,6.666);

gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
---+-----
1 | 2.222000;3.333000
2 | 4.444000;5.555000
3 | 6.666000
   | 1.111000
(4 rows)

gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the time type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b timestamp);

gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'2000-01-01'),(1,'2000-02-02'),(1,'2000-03-03'),
(2,'2000-04-04'),(2,'2000-05-05'),(3,'2000-06-06');

gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
---+-----
1 | 2000-02-02 00:00:00;2000-03-03 00:00:00
2 | 2000-04-04 00:00:00;2000-05-05 00:00:00
3 | 2000-06-06 00:00:00
   | 2000-01-01 00:00:00
(4 rows)

gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the time interval type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b interval);

gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');

gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
---+-----
1 | 2 days;3 days
2 | 4 days;5 days
3 | 6 days
   | 1 day
(4 rows)

gaussdb=# DROP TABLE listagg_t1;
```

By default, the delimiter is empty.

```

gaussdb=# CREATE TABLE listagg_t1(a int, b interval);

gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');

gaussdb=# SELECT a,LISTAGG(b) WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
-----+-----
1 | 2 days3 days
2 | 4 days5 days
3 | 6 days
   | 1 day
(4 rows)

gaussdb=# DROP TABLE listagg_t1;

```

When listagg is used as a window function, the OVER clause does not support the window sorting of ORDER BY, and the listagg column is an ordered aggregation of the corresponding groups.

```

gaussdb=# CREATE TABLE listagg_t1(a int, b interval);

gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');

gaussdb=# SELECT a,LISTAGG(b) WITHIN GROUP(ORDER BY b) OVER(PARTITION BY a) FROM
listagg_t1;
a | listagg
-----+-----
1 | 2 days3 days
1 | 2 days3 days
2 | 4 days5 days
2 | 4 days5 days
3 | 6 days
   | 1 day
(6 rows)

gaussdb=# DROP TABLE listagg_t1;

```

- **wm_concat(expression)**

Description: Concatenates column data into a string separated by commas (,).

Return type: same as the argument type

 **NOTE**

wm_concat is an ORA compatibility requirement. Currently, this function has been canceled in the latest ORA version and replaced by the listagg function. You can also use the string_agg function. For details, see the description of the two functions.

- **covar_pop(Y, X)**

Description: Specifies the overall covariance.

Return type: double precision

Example:

```

gaussdb=# CREATE TABLE covar_pop_t1(a int, b int);

gaussdb=# INSERT INTO covar_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);

gaussdb=# SELECT COVAR_POP(a,b) FROM covar_pop_t1;
covar_pop
-----
100
(1 row)

gaussdb=# DROP TABLE covar_pop_t1;

```

- **covar_samp(Y, X)**

Description: Specifies the sample covariance.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE covar_samp_t1(a int, b int);
gaussdb=# INSERT INTO covar_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT COVAR_SAMP(a,b) FROM covar_samp_t1;
 covar_samp
-----
          125
(1 row)
gaussdb=# DROP TABLE covar_samp_t1;
```

- **stddev_pop(expression)**

Description: Specifies the overall standard deviation.

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
gaussdb=# CREATE TABLE stddev_pop_t1(a int, b int);
gaussdb=# INSERT INTO stddev_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT STDDEV_POP(a) FROM stddev_pop_t1;
 stddev_pop
-----
7.4833147735478828
(1 row)
gaussdb=# DROP TABLE stddev_pop_t1;
```

- **stddev_samp(expression)**

Description: Specifies the sample standard deviation of the input values.

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
gaussdb=# CREATE TABLE stddev_samp_t1(a int, b int);
gaussdb=# INSERT INTO stddev_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT STDDEV_SAMP(a) FROM stddev_samp_t1;
 stddev_samp
-----
8.3666002653407555
(1 row)
gaussdb=# DROP TABLE stddev_samp_t1;
```

- **var_pop(expression)**

Description: Specifies the population variance of the input values (square of the population standard deviation).

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE var_pop_t1(a int, b int);
gaussdb=# INSERT INTO var_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT VAR_POP(a) FROM var_pop_t1;
```

```

var_pop
-----
56.0000000000000000
(1 row)

```

```
gaussdb=# DROP TABLE var_pop_t1;
```

- **var_samp(expression)**

Description: Specifies the sample variance of the input values (square of the sample standard deviation).

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE var_samp_t1(a int, b int);
```

```
gaussdb=# INSERT INTO var_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
```

```
gaussdb=# SELECT VAR_SAMP(a) FROM var_samp_t1;
var_samp
```

```

-----
70.0000000000000000
(1 row)

```

```
gaussdb=# DROP TABLE var_samp_t1;
```

- **bit_and(expression)**

Description: bitwise AND of all non-null input values, or null if none

Return type: same as the argument type

Example:

```
gaussdb=# CREATE TABLE bit_and_t1(a int, b int);
```

```
gaussdb=# INSERT INTO bit_and_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT BIT_AND(a) FROM bit_and_t1;
bit_and
```

```

-----
0
(1 row)

```

```
gaussdb=# DROP TABLE bit_and_t1;
```

- **bit_or(expression)**

Description: bitwise OR of all non-null input values, or null if none

Return type: same as the argument type

Example:

```
gaussdb=# CREATE TABLE bit_or_t1(a int, b int);
```

```
gaussdb=# INSERT INTO bit_or_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT BIT_OR(a) FROM bit_or_t1;
bit_or
```

```

-----
3
(1 row)

```

```
gaussdb=# DROP TABLE bit_or_t1;
```

- **bool_and(expression)**

Description: Its value is **true** if all input values are **true**, otherwise **false**.

Return type: Boolean

Example:

```
gaussdb=# SELECT bool_and(100 <2500);
bool_and
-----
t
(1 row)
```

- **bool_or(expression)**

Description: Its value is **true** if at least one input value is **true**, otherwise **false**.

Return type: Boolean

Example:

```
gaussdb=# SELECT bool_or(100 <2500);
bool_or
-----
t
(1 row)
```

- **corr(Y, X)**

Description: Specifies the correlation coefficient.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE corr_t1(a int, b int);
gaussdb=# INSERT INTO corr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CORR(a,b) FROM corr_t1;
corr
-----
.944911182523068
(1 row)
gaussdb=# DROP TABLE corr_t1;
```

- **every(expression)**

Description: Equivalent to **bool_and**

Return type: Boolean

Example:

```
gaussdb=# SELECT every(100 <2500);
every
-----
t
(1 row)
```

- **rank(expression)**

Description: The tuples in different groups are sorted non-consecutively by **expression**.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE rank_t1(a int, b int);
gaussdb=# INSERT INTO rank_t1 VALUES(NULL,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,RANK() OVER(PARTITION BY a ORDER BY b) FROM rank_t1;
a | b | rank
---+---+-----
1 | 2 | 1
1 | 3 | 2
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
```

```
| 1 | 1
(6 rows)
```

```
gaussdb=# DROP TABLE regr_t1;
```

- **regr_avgx(Y, X)**

Description: Specifies the average of the independent variable (**sum(X)/N**).

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_t1(a int, b int);
```

```
gaussdb=# INSERT INTO regr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT REGR_AVGX(a,b) FROM regr_t1;
```

```
regr_avgx
```

```
-----
```

```
4
(1 row)
```

```
gaussdb=# DROP TABLE regr_t1;
```

- **regr_avgy(Y, X)**

Description: Specifies the average of the dependent variable (**sum(Y)/N**).

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_avgy_t1(a int, b int);
```

```
gaussdb=# INSERT INTO regr_avgy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT REGR_AVGY(a,b) FROM regr_avgy_t1;
```

```
regr_avgy
```

```
-----
```

```
1.8
(1 row)
```

```
gaussdb=# DROP TABLE regr_avgy_t1;
```

- **regr_count(Y, X)**

Description: Specifies the number of input rows in which both expressions are non-null.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE regr_count_t1(a int, b int);
```

```
gaussdb=# INSERT INTO regr_count_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT REGR_COUNT(a,b) FROM regr_count_t1;
```

```
regr_count
```

```
-----
```

```
5
(1 row)
```

```
gaussdb=# DROP TABLE regr_count_t1;
```

- **regr_intercept(Y, X)**

Description: Specifies the y-intercept of the least-squares-fit linear equation determined by the (X, Y) pairs.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_intercept_t1(a int, b int);
```

```
gaussdb=# INSERT INTO regr_intercept_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_INTERCEPT(b,a) FROM regr_intercept_t1;
regr_intercept
-----
.785714285714286
(1 row)

gaussdb=# DROP TABLE regr_intercept_t1;
```

- **regr_r2(Y, X)**

Description: Specifies the square of the correlation coefficient.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_r2_t1(a int, b int);

gaussdb=# INSERT INTO regr_r2_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_R2(b,a) FROM regr_r2_t1;
regr_r2
-----
.892857142857143
(1 row)

gaussdb=# DROP TABLE regr_r2_t1;
```

- **regr_slope(Y, X)**

Description: Specifies the slope of the least-squares-fit linear equation determined by the (X, Y) pairs.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_slope_t1(a int, b int);

gaussdb=# INSERT INTO regr_slope_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_SLOPE(b,a) FROM regr_slope_t1;
regr_slope
-----
1.78571428571429
(1 row)

gaussdb=# DROP TABLE regr_slope_t1;
```

- **regr_sxx(Y, X)**

Description: $\text{sum}(X^2) - \text{sum}(X)^2/N$ (sum of squares of the independent variables)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_sxx_t1(a int, b int);

gaussdb=# INSERT INTO regr_sxx_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_SXX(b,a) FROM regr_sxx_t1;
regr_sxx
-----
2.8
(1 row)

gaussdb=# DROP TABLE regr_sxx_t1;
```

- **regr_sxy(Y, X)**

Description: $\text{sum}(X*Y) - \text{sum}(X) * \text{sum}(Y)/N$ (sum of products of independent times dependent variable)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_sxy_t1(a int, b int);
gaussdb=# INSERT INTO regr_sxy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_SXY(b,a) FROM regr_sxy_t1;
regr_sxy
-----
      5
(1 row)
gaussdb=# DROP TABLE regr_sxy_t1;
```

- `regr_syy(Y, X)`

Description: $\text{sum}(Y^2) - \text{sum}(Y)^2/N$ (sum of squares of the dependent variable)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_syy_t1(a int, b int);
gaussdb=# INSERT INTO regr_syy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_SYY(b,a) FROM regr_syy_t1;
regr_syy
-----
      10
(1 row)
gaussdb=# DROP TABLE regr_syy_t1;
```

- `stddev(expression)`

Description: Specifies the alias of **stddev_samp**.

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
gaussdb=# CREATE TABLE stddev_t1(a int, b int);
gaussdb=# INSERT INTO stddev_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT STDDEV(a) FROM stddev_t1;
stddev
-----
.83666002653407554798
(1 row)
gaussdb=# DROP TABLE stddev_t1;
```

- `variance(expression,ression)`

Description: Specifies the alias of **var_samp**.

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
gaussdb=# CREATE TABLE variance_t1(a int, b int);
gaussdb=# INSERT INTO variance_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT VARIANCE(a) FROM variance_t1;
```

- If the **CHECKSUM** value of all columns is calculated, set *expression* to *Table name::TEXT*.

The following types of data can be converted into the TEXT type by default: char, name, int8, int2, int1, int4, raw, pg_node_tree, float4, float8, bpchar, varchar, nvarchar2, date, timestamp, timestampz, numeric, and smalldatetime. Other types (for example, XML) need to be forcibly converted to TEXT.

Return type: numeric

Example:

The following shows the CHECKSUM value of a column that can be converted to the TEXT type by default:

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(a) FROM checksum_t1;
checksum
-----
18126842830
(1 row)
gaussdb=# DROP TABLE checksum_t1;
```

The following shows the CHECKSUM value of a column that cannot be converted to the TEXT type by default. Note that the CHECKSUM parameter is set to *Column name::TEXT*.

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(a::TEXT) FROM checksum_t1;
checksum
-----
18126842830
(1 row)
gaussdb=# DROP TABLE checksum_t1;
```

The following shows the CHECKSUM value of all columns in a table. Note that the CHECKSUM parameter is set to *Table name::TEXT*. The table name is not modified by its schema.

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(checksum_t1::TEXT) FROM checksum_t1;
checksum
-----
11160522226
(1 row)
gaussdb=# DROP TABLE checksum_t1;
```

7.5.19 Window Functions

Window Functions

This statement is used together with the window function. The OVER clause is used for grouping data and sorting the elements in a group. Window functions are used for generating sequence numbers for the values in the group.

 NOTE

ORDER BY in a window function must be followed by a column name. If it is followed by a number, the number is processed as a constant value and the target column is not ranked.

• RANK()

Description: The RANK function is used for generating non-consecutive sequence numbers for the values in each group. The same values have the same sequence number.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE rank_t1(a int, b int);

gaussdb=# INSERT INTO rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,RANK() OVER(PARTITION BY a ORDER BY b) FROM rank_t1;
 a | b | rank
-----+-----
 1 | 1 |   1
 1 | 1 |   1
 1 | 2 |   3
 1 | 3 |   4
 2 | 4 |   1
 2 | 5 |   2
 3 | 6 |   1
(7 rows)

gaussdb=# DROP TABLE rank_t1;
```

• ROW_NUMBER()

Description: The ROW_NUMBER function is used for generating consecutive sequence numbers for the values in each group. The same values have different sequence numbers.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE row_number_t1(a int, b int);

gaussdb=# INSERT INTO row_number_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,ROW_NUMBER() OVER(PARTITION BY a ORDER BY b) FROM row_number_t1;
 a | b | row_number
-----+-----
 1 | 1 |         1
 1 | 1 |         2
 1 | 2 |         3
 1 | 3 |         4
 2 | 4 |         1
 2 | 5 |         2
 3 | 6 |         1
(7 rows)

gaussdb=# DROP TABLE row_number_t1;
```

• DENSE_RANK()

Description: The DENSE_RANK function is used for generating consecutive sequence numbers for the values in each group. The same values have the same sequence number.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE dense_rank_t1(a int, b int);
```

```
gaussdb=# INSERT INTO dense_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,DENSE_RANK() OVER(PARTITION BY a ORDER BY b) FROM dense_rank_t1;
a | b | dense_rank
-----+-----
1 | 1 |          1
1 | 1 |          1
1 | 2 |          2
1 | 3 |          3
2 | 4 |          1
2 | 5 |          2
3 | 6 |          1
(7 rows)

gaussdb=# DROP TABLE dense_rank_t1;
```

- **PERCENT_RANK()**

Description: The PERCENT_RANK function is used for generating corresponding sequence numbers for the values in each group. That is, the function calculates the value according to the formula: Sequence number = **(rank - 1) / (totalrows - 1)**. **rank** is the corresponding sequence number generated based on the RANK function for the value and **totalrows** is the total number of elements in a group.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE percent_rank_t1(a int, b int);

gaussdb=# INSERT INTO percent_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,PERCENT_RANK() OVER(PARTITION BY a ORDER BY b) FROM percent_rank_t1;
a | b | percent_rank
-----+-----
1 | 1 |          0
1 | 1 |          0
1 | 2 | .6666666666666667
1 | 3 |          1
2 | 4 |          0
2 | 5 |          1
3 | 6 |          0
(7 rows)

gaussdb=# DROP TABLE percent_rank_t1;
```

- **CUME_DIST()**

Description: The CUME_DIST function is used for generating accumulative distribution sequence numbers for the values in each group. That is, the function calculates the value according to the following formula: Sequence number = Number of rows preceding or peer with current row/Total rows.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE cume_dist_t1(a int, b int);

gaussdb=# INSERT INTO cume_dist_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,CUME_DIST() OVER(PARTITION BY a ORDER BY b) FROM cume_dist_t1;
a | b | cume_dist
-----+-----
1 | 1 |          .5
1 | 1 |          .5
1 | 2 |          .75
1 | 3 |          1
2 | 4 |          .5
2 | 5 |          1
```

```
3 | 6 | 1
(7 rows)

gaussdb=# DROP TABLE cume_dist_t1;
```

- **NTILE(num_buckets integer)**

Description: The NTILE function is used for equally allocating sequential data sets to the buckets whose quantity is specified by **num_buckets** according to **num_buckets integer** and allocating the bucket number to each row. Divide the partition as evenly as possible.

Return type: integer

Example:

```
gaussdb=# CREATE TABLE ntile_t1(a int, b int);

gaussdb=# INSERT INTO ntile_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,NTILE(2) OVER(PARTITION BY a ORDER BY b) FROM ntile_t1;
a | b | ntile
-----+-----
1 | 1 | 1
1 | 1 | 1
1 | 2 | 2
1 | 3 | 2
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
(7 rows)

gaussdb=# DROP TABLE ntile_t1;
```

- **LAG(value any [, offset integer [, default any]])**

Description: The LAG function is used for generating lag values for the corresponding values in each group. That is, the value of the row obtained by moving forward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row does not exist after the moving, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **NULL**. The type of the **default** value must be the same as that of the **value** value.

Return type: same as the parameter type

Example:

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE ta1 (hire_date date, last_name varchar(20), department_id int);
CREATE TABLE
gaussdb=# INSERT INTO ta1 VALUES('07-DEC-02', 'Raphaely', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 VALUES('24-JUL-05', 'Tobias', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 VALUES('24-DEC-05', 'Baida', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 VALUES('18-MAY-03', 'Khoo', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('15-NOV-06', 'Himuro', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-AUG-07', 'Colmenares', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-07', 'yq', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-08', 'zi', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('', 'yq1', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, 'yq2', 30);
INSERT 0 1
```

```

gaussdb=# INSERT INTO ta1 values('10-DEC-07', 'yq3', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1

-- Call LAG and set offset to 3 and default to null.
gaussdb=# SELECT hire_date, last_name, department_id, lag(hire_date, 3, null) OVER (PARTITION BY
department_id ORDER BY last_name) AS "NextHired" FROM ta1 ORDER BY department_id;
  hire_date   | last_name | department_id | NextHired
-----+-----+-----+-----
2007-05-10 00:00:00 | yq       |          11 |
2008-05-10 00:00:00 | zi       |          11 |
                |          |          11 | 2007-05-10 00:00:00
2005-12-24 00:00:00 | Baida    |          30 |
2007-08-10 00:00:00 | Colmenares |          30 |
2006-11-15 00:00:00 | Himuro   |          30 |
2003-05-18 00:00:00 | Khoo     |          30 | 2005-12-24 00:00:00
2002-12-07 00:00:00 | Raphaely |          30 | 2007-08-10 00:00:00
2005-07-24 00:00:00 | Tobias    |          30 | 2006-11-15 00:00:00
                | yq1     |          30 | 2003-05-18 00:00:00

2007-12-10 00:00:00 | yq3     |          30 | 2005-07-24 00:00:00
(13 rows)

```

- LEAD(value any [, offset integer [, default any]])

Description: The LEAD function is used for generating leading values for the corresponding values in each group. That is, the value of the row obtained by moving backward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row after the moving exceeds the total number of rows for the current group, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **NULL**. The type of the **default** value must be the same as that of the **value** value.

Return type: same as the parameter type

Example:

```

-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE ta1 (hire_date date, last_name varchar(20), department_id int);
CREATE TABLE
gaussdb=# INSERT INTO ta1 values('07-DEC-02', 'Raphaely', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-JUL-05', 'Tobias', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-DEC-05', 'Baida', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('18-MAY-03', 'Khoo', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('15-NOV-06', 'Himuro', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-AUG-07', 'Colmenares', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-07', 'yq', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-08', 'zi', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('', 'yq1', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, 'yq2', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-DEC-07', 'yq3', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1

```

```
-- Call LEAD and set offset to 2.
gaussdb=# SELECT hire_date, last_name, department_id, lead(hire_date, 2) OVER (PARTITION BY
department_id ORDER BY last_name) AS "NextHired" FROM ta1 ORDER BY department_id;
 hire_date | last_name | department_id | NextHired
-----+-----+-----+-----
2007-05-10 00:00:00 | yq | 11 |
2008-05-10 00:00:00 | zi | 11 |
| | | 11 |
| | | 11 |
2005-12-24 00:00:00 | Baida | 30 | 2006-11-15 00:00:00
2007-08-10 00:00:00 | Colmenares | 30 | 2003-05-18 00:00:00
2006-11-15 00:00:00 | Himuro | 30 | 2002-12-07 00:00:00

| yq2 | 30 |
2007-12-10 00:00:00 | yq3 | 30 |
(13 rows)
```

- **FIRST_VALUE(value any)**

Description: Returns the first value of each group.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE first_value_t1(a int, b int);
gaussdb=# INSERT INTO first_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,FIRST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM first_value_t1;
 a | b | first_value
-----+-----+-----
1 | 1 | 1
1 | 1 | 1
1 | 2 | 1
1 | 3 | 1
2 | 4 | 4
2 | 5 | 4
3 | 6 | 6
(7 rows)
gaussdb=# DROP TABLE first_value_t1;
```

- **LAST_VALUE(value any)**

Description: Returns the last value of each group.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE last_value_t1(a int, b int);
gaussdb=# INSERT INTO last_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,LAST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM last_value_t1;
 a | b | last_value
-----+-----+-----
1 | 1 | 1
1 | 1 | 1
1 | 2 | 2
1 | 3 | 3
2 | 4 | 4
2 | 5 | 5
3 | 6 | 6
(7 rows)
gaussdb=# DROP TABLE last_value_t1;
```

- NTH_VALUE**(value any, nth integer)

Description: The *n*th row for a group is the returned value. If the row does not exist, **NULL** is returned by default.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE nth_value_t1(a int, b int);
gaussdb=# INSERT INTO nth_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,NTH_VALUE(b, 2) OVER(PARTITION BY a order by b) FROM nth_value_t1;
a | b | nth_value
-----+-----
1 | 1 | 1
1 | 1 | 1
1 | 2 | 1
1 | 3 | 1
2 | 4 |
2 | 5 | 5
3 | 6 |
(7 rows)
gaussdb=# DROP TABLE nth_value_t1;
```
- delta**

Description: Returns the difference between the current row and the previous row.

Parameter: numeric

Return type: numeric
- spread**

Description: Calculates the difference between the maximum value and minimum value in a certain period.

Parameter: real

Return type: real

7.5.20 Security Functions

Security Functions

- gs_encrypt_aes128**(encryptstr,keyststr)

Description: Encrypts **encryptstr** strings using the key derived from **keyststr** and returns encrypted strings. The value of **keyststr** ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters. Currently, the following types of data can be encrypted: numerals supported in the database; character type; RAW in binary type; and DATE, TIMESTAMP, and SMALLDATETIME in date/time type.

Return type: text

Length of the return value: At least 92 bytes and no more than $(4 * [Len / 3] + 68)$ bytes, where *Len* indicates the length of the data before encryption (unit: byte).

Example:

```
gaussdb=# SELECT gs_encrypt_aes128('MPPDB','1234@abc');
gs_encrypt_aes128
-----
```

```
OF1g3+70oeqFfyKiWlpxfYxPnpeitNc6+7nAe02Ttt37fZF8Q+bbEYhdw/YG+0c9tHKRWM6OcTzLB3HnqvX+1d8Bflo=
(1 row)
```

NOTE

A password is required during the execution of this function. For security purposes, the `gsql` tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in `gsql` by paging up and down.

- `gs_decrypt_aes128(decryptstr,keyst)`

Description: Decrypts **decrypt** strings using the key derived from **keyst** and returns decrypted strings. The **keyst** used for decryption must be consistent with that used for encryption. **keyst** cannot be empty.

NOTE

This function needs to be used with the `gs_encrypt_aes128` encryption function.

Return type: text

Example:

```
gaussdb=# SELECT gs_decrypt_aes128('OF1g3+70oeqFfyKiWlpxfYxPnpeitNc6+7nAe02Ttt37fZF8Q+bbEYhdw/YG+0c9tHKRWM6OcTzLB3HnqvX+1d8Bflo=', '1234@abc');
gs_decrypt_aes128
```

```
-----
MPPDB
(1 row)
```

NOTE

A password is required during the execution of this function. For security purposes, the `gsql` tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in `gsql` by paging up and down.

- `aes_encrypt(str, key_str, init_vector)`

Description: Encrypts the string **str** using the key string **key_str** and initialization vector **init_vector** based on the AES algorithm.

Parameters in the command above are as follows:

- **str**: character string to be encrypted. If **str** is set to **NULL**, the function returns **NULL**.
- **key_str**: key character string. If **key_str** is set to **NULL**, the function returns **NULL**. For security purposes, you are advised to use a 128-bit, 192-bit, or 256-bit secure random number as the key character string if the key length is 128 bits, 192 bits, or 256 bits (determined by the value of **block_encryption_mode**).
- **init_vector**: An initialization variable is provided for the required block encryption mode. The length is greater than or equal to 16 bytes. Bytes greater than 16 bytes are automatically ignored. If neither **str** nor **key_str** is **NULL**, this parameter cannot be **NULL**. Otherwise, an error is reported. For security purposes, you are advised to ensure that the IV value for each encryption is unique in OFB mode and that the IV value for each encryption is unpredictable in CBC or CFB mode.

Return type: text

Example:

```
gaussdb=# SELECT aes_encrypt('huwei123','123456vfhex4dyu,vdaladhjsadad','1234567890123456');
aes_encrypt
```

```
-----  
u*8\x05c?0  
(1 row)
```

NOTE

- This function is valid only when GaussDB is compatible with MySQL (that is, **sql_compatibility** is set to 'MYSQL').
 - A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.
 - Do not call this function during operations related to stored procedures, preventing the risk of sensitive information disclosure. In addition, when using the stored procedure that contains the function, you are advised to filter the parameter information of the function before providing the information for external maintenance personnel to locate the fault. Delete the logs after using them.
 - Do not call the function when **debug_print_plan** is set to **on**, preventing the risk of sensitive information disclosure. You are advised to filter parameter information of the function in the log files generated when **debug_print_plan** is set to **on** before providing the log files to external maintenance engineers for fault locating. After you finish using the logs, delete them as soon as possible.
 - The SQL_ASCII setting performs quite differently from other settings. If the character set of the server is SQL_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL_ASCII, no code conversion occurs. When this function calls the third-party OpenSSL library, the returned data is non-ASCII data. Therefore, when the character set of the database server is set to SQL_ASCII, the encoding of the client must also be set to SQL_ASCII. Otherwise, an error is reported. The database does not convert or verify non-ASCII characters.
- **aes_decrypt(pass_str, key_str, init_vector)**

Description: Decrypts the string **str** using the key string **key_str** and initialization vector **init_vector** based on the AES algorithm.

Parameters in the command above are as follows:

- **pass_str**: character string to be decrypted. If **pass_str** is set to **NULL**, the function returns **NULL**.
- **key_str**: key character string. If **key_str** is set to **NULL**, the function returns **NULL**. For security purposes, you are advised to use a 128-bit, 192-bit, or 256-bit secure random number as the key character string if the key length is 128 bits, 192 bits, or 256 bits (determined by the value of **block_encryption_mode**).
- **init_vector**: An initialization variable is provided for the required block decryption mode. The length is greater than or equal to 16 bytes. Bytes greater than 16 bytes are automatically ignored. If neither **pass_str** nor **key_str** is **NULL**, this parameter cannot be **NULL**. Otherwise, an error is reported. For security purposes, you are advised to ensure that the IV value for each encryption is unique in OFB mode and that the IV value for each encryption is unpredictable in CBC or CFB mode.

Return type: text

Example:

```
gaussdb=# SELECT  
aes_decrypt(aes_encrypt('huwei123','123456vfhex4dyu,vdaladhjsadad','1234567890123456'),'123456vf  
hex4dyu,vdaladhjsadad','1234567890123456');  
aes_decrypt
```

```
-----
huwei123
(1 row)
```

 **NOTE**

- This function is valid only when GaussDB is compatible with MySQL (that is, **sql_compatibility** is set to 'MYSQL').
- A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.
- Do not call this function during operations related to stored procedures, preventing the risk of sensitive information disclosure. In addition, when using the stored procedure that contains the function, you are advised to filter the parameter information of the function before providing the information for external maintenance personnel to locate the fault. Delete the logs after using them.
- Do not call the function when **debug_print_plan** is set to **on**, preventing the risk of sensitive information disclosure. You are advised to filter parameter information of the function in the log files generated when **debug_print_plan** is set to **on** before providing the log files to external maintenance engineers for fault locating. After you finish using the logs, delete them as soon as possible.
- To ensure successful decryption, ensure that the values of **block_encryption_mode**, **key_str** and IV are the same as those during encryption.
- Due to encoding differences, encrypted data cannot be directly copied from the gsql client for decryption. In this scenario, the decryption result may not be the character string before encryption.
- The SQL_ASCII setting performs quite differently from other settings. If the character set of the server is SQL_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL_ASCII, no code conversion occurs. When this function calls the third-party OpenSSL library, the returned data is non-ASCII data. Therefore, when the character set of the database server is set to SQL_ASCII, the encoding of the client must also be set to SQL_ASCII. Otherwise, an error is reported. The database does not convert or verify non-ASCII characters.

- **gs_digest(input_string, hash_algorithm)**

Description: Hashes the input string using the specified hash algorithm and returns a hexadecimal number.

Parameters in the command above are as follows:

- **input_string**: character string to be hashed. The value cannot be **NULL**.
- **hash_algorithm**: specifies the hash algorithm. Currently, SHA-256, SHA-384, SHA-512, and SM3 are supported. Both uppercase and lowercase letters are supported. If an unsupported hash algorithm is used, an error is reported.

Return type: text

Example:

```
gaussdb=# SELECT pg_catalog.gs_digest('gaussdb', 'sha256');
           gs_digest
-----
4dc50d746f4e04f9b446986b34a0050e358fbfb8bc1fba314c54b52a417b0b8e
(1 row)
```

- **gs_password_deadline**

Description: Indicates the number of remaining days before the password of the current user expires.

Return type: interval

Example:

```
gaussdb=# SELECT gs_password_deadline();
gs_password_deadline
-----
83 days 17:44:32.196094
(1 row)
```

- `gs_password_notifytime()`

Description: Specifies the number of days prior to password expiration that a user will receive a reminder.

Return type: int32

- `login_audit_messages(BOOLEAN)`

Description: Queries login information about a login user.

Return type: tuple

Example:

- Check the date, time, and IP address of the last successful login.

```
gaussdb=> SELECT * FROM login_audit_messages(true);
username | database | logintime      | mytype | result | client_conninfo
-----+-----+-----+-----+-----+-----
omm      | postgres | 2020-06-29 21:56:40+08 | login_success | ok | gsql@[local]
(1 row)
```

- Check the number, date, and time of failed attempts since the previous successful login.

```
gaussdb=> SELECT * FROM login_audit_messages(false);
username | database | logintime      | mytype | result | client_conninfo
-----+-----+-----+-----+-----+-----
omm      | postgres | 2020-06-29 21:57:55+08 | login_failed | failed | [unknown]@[local]
omm      | postgres | 2020-06-29 21:57:53+08 | login_failed | failed | [unknown]@[local]
(2 rows)
```

- `login_audit_messages_pid`

Description: Queries login information about a login user. Different from **login_audit_messages**, this function queries login information based on **backendid**. Information about subsequent logins of the same user does not alter the query result of previous logins and cannot be found using this function.

Return type: tuple

 **NOTE**

When the thread pool is enabled, the **backendid** obtained in the same session may change due to thread switchover. As a result, the return values are different when the function is called for multiple times. You are advised not to call this function when the thread pool is enabled.

Example:

- Check the date, time, and IP address of the last successful login.

```
gaussdb=> SELECT * FROM login_audit_messages_pid(true);
username | database | logintime      | mytype | result | client_conninfo | backendid
-----+-----+-----+-----+-----+-----+-----
omm      | postgres | 2020-06-29 21:56:40+08 | login_success | ok | gsql@[local] | 139823109633792
(1 row)
```

- Check the number, date, and time of failed attempts since the previous successful login.

```
gaussdb=> SELECT * FROM login_audit_messages_pid(false);
username | database | logintime      | mytype | result | client_conninfo | backendid
```

Name	Type	Description
database	text	Database name
client_conninfo	text	Client connection information
object_name	text	Object name
detail_info	text	Operation details
node_name	text	Node name
thread_id	text	Thread ID
local_port	text	Local port
remote_port	text	Remote port

- pgxc_query_audit**
 Description: Displays audit logs of all CNs.
 Return type: record
 The return fields of this function are the same as those of the `pg_query_audit` function.
- pg_delete_audit**
 Description: Deletes audit logs in a specified period.
 Return type: void
- alldigitsmasking**
 Description: Specifies the internal function of the masking policy, which is used to anonymize all characters.
 Parameter: col text, letter character default '0'
 Return type: text
- creditcardmasking**
 Description: Specifies the internal function of the masking policy, which is used to anonymize all credit card information.
 Parameter: col text, letter character default 'x'
 Return type: text
- randommasking**
 Description: Specifies the internal function of the masking policy. The random policy is used.
 Parameter: col text
 Return type: text
- fullemailmasking**
 Description: Specifies the internal function of the masking policy, which is used to anonymize the text (except @) before the last period (.).
 Parameter: col text, letter character default 'x'
 Return type: text

- **basicemailmasking**
Description: Specifies the internal function of the masking policy, which is used to anonymize the text before the first at sign (@).
Parameter: col text, letter character default 'x'
Return type: text
- **shufflemasking**
Description: Specifies the internal function of the masking policy, which is used to sort characters out of order.
Parameter: col text
Return type: text
- **regexprmasking**
Description: Specifies the internal function of the masking policy, which is used to replace characters using a regular expression.
Parameter: col text, reg text, replace_text text, pos INTEGER default 0, reg_len INTEGER default -1
Return type: text
- **gs_encrypt(encryptstr,keystr, encrypttype)**
Description: Encrypts **encryptstr** strings using **keystr** as the encryption password and returns encrypted strings based on **encrypttype**. The value of **keystr** contains 8 to 16 bytes and at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters. The value of **encrypttype** can be **aes128** or **sm4**.
Return type: text

Example:

```
gaussdb=# SELECT gs_encrypt('MPPDB','Asdf1234','sm4');
gs_encrypt
-----
ZBzOmaGA4Bb+coyucJOB8AkIshqc
(1 row)
```

NOTE

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in **gsql** by paging up and down.

- **gs_decrypt(decryptstr,keystr,decrypttype)**
Description: Decrypts **decrypt** strings using **keystr** as the decryption password and returns decrypted strings based on **decrypttype**. The **decrypttype** and **keystr** used for decryption must be consistent with **encrypttype** and **keystr** used for encryption. The value of **keystr** cannot be empty. The value of **decrypttype** can be **aes128** or **sm4**.
This function needs to be used with the **gs_encrypt** encryption function.
Return type: text

Example:

```
gaussdb=# SELECT gs_decrypt('ZBzOmaGA4Bb+coyucJOB8AkIshqc','Asdf1234','sm4');
gs_decrypt
-----
MPPDB
(1 row)
```

 NOTE

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

7.5.21 Encrypted Functions and Operators

- `byteawithoutorderwithequalcolin(cstring)`
Description: Converts input data to the internal `byteawithoutorderwithequalcol` format.
Parameter type: `cstring`
Return type: `byteawithoutorderwithequalcol`
- `byteawithoutorderwithequalcolout(byteawithoutorderwithequalcol)`
Description: Converts internal data of the `byteawithoutorderwithequalcol` type to data of the `cstring` type.
Parameter type: `byteawithoutorderwithequalcol`
Return type: `cstring`
- `byteawithoutorderwithequalcolsend(byteawithoutorderwithequalcol)`
Description: Converts data of the `byteawithoutorderwithequalcol` type to data of the `bytea` type.
Parameter type: `byteawithoutorderwithequalcol`
Return type: `bytea`
- `byteawithoutorderwithequalcolrecv(internal)`
Description: Converts data of the internal type to data of the `byteawithoutorderwithequalcol` type.
Parameter type: `internal`
Return type: `byteawithoutorderwithequalcol`
- `byteawithoutorderwithequalcoltypmodin(cstring[])`
Description: Converts data of the `cstring[]` type to data of the `byteawithoutorderwithequalcol` type.
Parameter type: `cstring[]`
Return type: `int4`
- `byteawithoutorderwithequalcoltypmodout(int4)`
Description: Converts data of the `int4` type into data of the `cstring` type.
Parameter type: `int4`
Return type: `cstring`
- `byteawithoutordercolin(cstring)`
Description: Converts input data to the internal `byteawithoutordercolin` format.
Parameter type: `cstring`
Return type: `byteawithoutordercol`
- `byteawithoutordercolout(byteawithoutordercol)`

Description: Converts internal data of the `byteawithoutordercol` type to data of the `cstring` type.

Parameter type: `byteawithoutordercol`

Return type: `cstring`

- `byteawithoutordercolsend(byteawithoutordercol)`

Description: Converts data of the `byteawithoutordercol` type to data of the `bytea` type.

Parameter type: `byteawithoutordercol`

Return type: `bytea`

- `byteawithoutordercolrecv(internal)`

Description: Converts data of the `internal` type to data of the `byteawithoutordercol` type.

Parameter type: `internal`

Return type: `byteawithoutordercol`

- `byteawithoutorderwithequalcolcmp(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`

Description: Compares two `byteawithoutorderwithequalcol` data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`

Return type: `int4`

- `byteawithoutorderwithequalcolcmpbytear(byteawithoutorderwithequalcol, bytea)`

Description: Compares the `byteawithoutorderwithequalcol` and `bytea` data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: `byteawithoutorderwithequalcol` or `bytea`

Return type: `int4`

- `byteawithoutorderwithequalcolcmpbyteal(bytea, byteawithoutorderwithequalcol)`

Description: Compares the `bytea` and `byteawithoutorderwithequalcol` data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: `bytea`, `byteawithoutorderwithequalcol`

Return type: `int4`

- `byteawithoutorderwithequalcoleq(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`

Description: Compares two `byteawithoutorderwithequalcol` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`

- Return type: Boolean
- `byteawithoutorderwithequalcoleqbyteal(bytea, byteawithoutorderwithequalcol)`
Description: Compares the `bytea` and `byteawithoutorderwithequalcol` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.
Parameter type: `bytea`, `byteawithoutorderwithequalcol`
Return type: Boolean
- `byteawithoutorderwithequalcoleqbytear(byteawithoutorderwithequalcol, bytea)`
Description: Compares the `byteawithoutorderwithequalcol` and `bytea` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.
Parameter type: `byteawithoutorderwithequalcol`, `bytea`
Return type: Boolean
- `byteawithoutorderwithequalcolne(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`
Description: Compares two `byteawithoutorderwithequalcol` data records. If they are different, **true** is returned. Otherwise, **false** is returned.
Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`
Return type: Boolean
- `byteawithoutorderwithequalcolnebyteal(bytea, byteawithoutorderwithequalcol)`
Description: Compares the `bytea` and `byteawithoutorderwithequalcol` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.
Parameter type: `bytea`, `byteawithoutorderwithequalcol`
Return type: Boolean
- `byteawithoutorderwithequalcolnebytear(byteawithoutorderwithequalcol, bytea)`
Description: Compares the `byteawithoutorderwithequalcol` and `bytea` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.
Parameter type: `byteawithoutorderwithequalcol`, `bytea`
Return type: Boolean
- `hll_hash_byteawithoutorderwithequalcol(byteawithoutorderwithequalcol)`
Description: Returns the hll hash value of `byteawithoutorderwithequalcol`.
Parameter type: `byteawithoutorderwithequalcol`
Return type: `hll_hashval`

Example

Encrypted equality functions such as `byteawithoutorderwithequalcolin` and `byteawithoutorderwithequalcolout` are read/write format conversion functions such as `in`, `out`, `send`, and `recv` specified by the data type `byteawithoutorderwithequalcol` in the database kernel. For details, see the `byteain` and `byteaout` functions of the `bytea` type. However, the local CEK is verified, and the function can be successfully executed only when the encrypted column contains a `cekoid` that exists on the local host.

- `generate_series(start, stop, step)`
Description: Generates a series of values, from **start** to **stop** with a step size of **step**.
Parameter type: int, bigint, numeric
Return type: setof int, setof bigint, setof numeric (same as the parameter type)
- `generate_series(start, stop, step interval)`
Description: Generates a series of values, from **start** to **stop** with a step size of **step**.
Parameter type: timestamp or timestamp with time zone
Return type: setof timestamp or setof timestamp with time zone (same as parameter type)

When **step** is positive, zero rows are returned if **start** is greater than **stop**. Conversely, when **step** is negative, zero rows are returned if **start** is less than **stop**. Zero rows are also returned for **NULL** inputs. It is an error for **step** to be zero.

Example:

```
gaussdb=# SELECT * FROM generate_series(2,4);
generate_series
-----
         2
         3
         4
(3 rows)

gaussdb=# SELECT * FROM generate_series(5,1,-2);
generate_series
-----
         5
         3
         1
(3 rows)

gaussdb=# SELECT * FROM generate_series(4,3);
generate_series
-----
(0 rows)

-- This example applies to the date-plus-integer operator.
gaussdb=# SELECT current_date + s.a AS dates FROM generate_series(0,14,7) AS s(a);
dates
-----
2017-06-02
2017-06-09
2017-06-16
(3 rows)

gaussdb=# SELECT * FROM generate_series('2008-03-01 00:00'::timestamp, '2008-03-04 12:00', '10 hours');
generate_series
-----
2008-03-01 00:00:00
2008-03-01 10:00:00
2008-03-01 20:00:00
2008-03-02 06:00:00
2008-03-02 16:00:00
2008-03-03 02:00:00
2008-03-03 12:00:00
2008-03-03 22:00:00
2008-03-04 08:00:00
(9 rows)
```

Subscript Generating Functions

- `generate_subscripts(array anyarray, dim int)`
Description: Generates a series comprising the given array's subscripts.
Return type: setof int
- `generate_subscripts(array anyarray, dim int, reverse boolean)`
Description: Generates a series comprising the given array's subscripts. When **reverse** is true, the series is returned in reverse order.
Return type: setof int

generate_subscripts is a function that generates the set of valid subscripts for the specified dimension of the given array. Zero rows are returned for arrays that do not have the requested dimension, or for NULL arrays (but valid subscripts are returned for NULL array elements). Example:

```
-- Basic usage
gaussdb=# SELECT generate_subscripts('{NULL,1,NULL,2}'::int[], 1) AS s;
s
-----
1
2
3
4
(4 rows)
-- Unnest a 2D array.
gaussdb=# CREATE OR REPLACE FUNCTION unnest2(anyarray)
RETURNS SETOF anyelement AS $$
SELECT $1[i][j]
FROM generate_subscripts($1,1) g1(i),
generate_subscripts($1,2) g2(j);
$$ LANGUAGE sql IMMUTABLE;

gaussdb=# SELECT * FROM unnest2(ARRAY[[1,2],[3,4]]);
unnest2
-----
1
2
3
4
(4 rows)

-- Delete the function.
gaussdb=# DROP FUNCTION unnest2;
```

7.5.23 Conditional Expression Functions

Conditional Expression Functions

- `coalesce(expr1, expr2, ..., exprn)`
Description:
Returns the first of its arguments that are not null.
COALESCE(expr1, expr2) is equivalent to **CASE WHEN expr1 IS NOT NULL THEN expr1 ELSE expr2 END**.
Example:

```
gaussdb=# SELECT coalesce(NULL,'hello');
coalesce
-----
hello
(1 row)
```

Note:

- Null is returned only if all parameters are null.
- This value is replaced by the default value when data is displayed.
- Like a **CASE** expression, **COALESCE** only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first non-NULL parameter are not evaluated.

- decode(base_expr, compare1, value1, Compare2,value2, ... default)

Description: Compares **base_expr** with each **compare(n)** and returns **value(n)** if they are matched. If **base_expr** does not match each **compare(n)**, the default value is returned.

Example:

```
gaussdb=# SELECT decode('A','A',1,'B',2,0);
case
-----
1
(1 row)
```

Note: Operations on the XML data are not supported.

- nullif(expr1, expr2)

Description: Returns **NULL** only when **expr1** is equal to **expr2**. Otherwise, **expr1** is returned.

nullif(expr1, expr2) is equivalent to **CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END**.

Example:

```
gaussdb=# SELECT nullif('hello','world');
nullif
-----
hello
(1 row)
```

Note: Operations on the XML data are not supported.

Assume the two parameter data types are different:

- If implicit conversion exists between the two data types, implicitly convert the parameter of lower priority to this data type using the data type of higher priority. If the conversion succeeds, computation is performed.

Otherwise, an error is reported. Example:

```
gaussdb=# SELECT nullif('1234'::VARCHAR,123::INT4);
nullif
-----
1234
(1 row)
gaussdb=# SELECT nullif('1234'::VARCHAR,'2012-12-24'::DATE);
ERROR:  invalid input syntax for type timestamp: "1234"
```

- If implicit conversion is not applied between two data types, an error is displayed. Example:

```
gaussdb=# SELECT nullif(TRUE::BOOLEAN,'2012-12-24'::DATE);
ERROR:  operator does not exist: boolean = timestamp without time zone
LINE 1: SELECT nullif(TRUE::BOOLEAN,'2012-12-24'::DATE) FROM sys_dummy,
^
HINT:  No operator matches the given name and argument type(s). You might need to add explicit type casts.
```

- nvl(expr1 , expr2)

Description:

- If the value of **expr1** is **NULL**, the value of **expr2** is returned.

- If the value of **expr1** is not **NULL**, the value of **expr1** is returned.

Example:

```
gaussdb=# SELECT nvl('hello','world');
nvl
-----
hello
(1 row)
```

Parameters **expr1** and **expr2** can be of any data type. If **expr1** and **expr2** are of different data types, NVL checks whether **expr2** can be implicitly converted to **expr1**. If it can, the **expr1** data type is returned. If **expr2** cannot be implicitly converted to **expr1** but **expr1** can be implicitly converted to **expr2**, the **expr2** data type is returned. If no implicit type conversion exists between the two parameters and the parameters are different data types, an error is reported.

- `nvl2(expr1, expr2, expr3)`

Description:

- If *expr1* is **NULL**, *expr3* is returned.
- If *expr1* is not **NULL**, *expr2* is returned.

 **NOTE**

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database.

Example:

```
gaussdb=# SELECT nvl2('hello','world','other');
case
-----
world
(1 row)
```

Note: The *expr2* and *expr3* parameters can be of any type. If the last two parameters of NVL2 are of different types, check whether *expr3* can be implicitly converted to *expr2*. If *expr3* cannot be implicitly converted to *expr2*, an error is returned. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- `greatest(expr1 [, ...])`

Description: Selects the largest value from a list of any number of expressions.

Return type:

Example:

```
gaussdb=# SELECT greatest(1*2,2-3,4-1);
greatest
-----
3
(1 row)
gaussdb=# SELECT greatest('HARRY', 'HARRIOT', 'HAROLD');
greatest
-----
HARRY
(1 row)
```

Note: Operations on the XML data are not supported.

 NOTE

In the scenario where this function is in an ORA-compatible database, the value of **a_format_version** is **10c**, and that of **a_format_dev_version** is **s1**:

1. If the value of any parameter is null, the function returns null.
2. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- **least(expr1 [, ...])**

Description: Selects the smallest value from a list of any number of expressions.

Example:

```
gaussdb=# SELECT least(1*2,2-3,4-1);
least
-----
-1
(1 row)
gaussdb=# SELECT least('HARRY','HARRIOT','HAROLD');
least
-----
HAROLD
(1 row)
```

Note: Operations on the XML data are not supported.

 NOTE

In the scenario where this function is in an ORA-compatible database, the value of **a_format_version** is **10c**, and that of **a_format_dev_version** is **s1**:

1. If the value of any parameter is null, the function returns null.
2. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- **EMPTY_BLOB()**

Description: Initiates a BLOB variable in an **INSERT** or an **UPDATE** statement to a **NULL** value.

Return type: BLOB

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE blob_tb(b blob,id int) DISTRIBUTE BY REPLICATION;
-- Insert data.
gaussdb=# INSERT INTO blob_tb VALUES (empty_blob(),1);
-- Drop the table.
gaussdb=# DROP TABLE blob_tb;
```

Note: The length is 0 obtained using **DBE_LOB.GET_LENGTH**.

- **EMPTY_CLOB()**

Description: Initiates a CLOB variable in an **INSERT** or **UPDATE** statement to a null value.

 NOTE

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database.

Return type: CLOB

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE clob_tb(c clob,id int);
-- Insert data.
gaussdb=# INSERT INTO clob_tb VALUES (empty_clob(),1);
-- Drop the table.
gaussdb=# DROP TABLE clob_tb;
```

Note: The length is 0 obtained using **DBE_LOB.GET_LENGTH**.

- **lnvl(condition)**

Description: Checks the condition in the WHERE clause of a query statement. If the condition is true, **false** is returned. If the condition is unknown or false, **true** is returned.

condition: The value must be a logical expression. However, it cannot be used in composite conditions with keywords such as AND, OR, and BETWEEN.

Return type: Boolean

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE student_demo (name VARCHAR2(20), grade NUMBER(10,2));
CREATE TABLE

-- Insert data.
gaussdb=# INSERT INTO student_demo VALUES ('name0',0);
INSERT 0 1
gaussdb=# INSERT INTO student_demo VALUES ('name1',1);
INSERT 0 1
gaussdb=# INSERT INTO student_demo VALUES ('name2',2);
INSERT 0 1

-- Call lnvl.
gaussdb=# SELECT * FROM student_demo WHERE LNNVL(name = 'name1');
 name | grade
-----+-----
name0 | 0.00
name2 | 2.00
(2 rows)
```

 NOTE

The **lnvl** function is supported only when the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s2** in an ORA-compatible database.

7.5.24 System Information Functions

Session Information Functions

- **SYS_CONTEXT()**

Description: Returns the value of the parameter associated with the context namespace at the current time.

Return type: text

Example:

```
select SYS_CONTEXT('userenv','NLS_CURRENCY');
sys_context
```

```

-----
$
(1 row)

select SYS_CONTEXT('userenv','NLS_DATE_FORMAT');
sys_context
-----
ISO, MDY
(1 row)

select SYS_CONTEXT('userenv','NLS_DATE_LANGUAGE');
sys_context
-----
en_US.UTF-8
(1 row)

```

- **current_catalog**
Description: Name of the current database (called "catalog" in the SQL standard)

Return type: name

Example:

```

testdb=# SELECT current_catalog;
current_database
-----
testdb
(1 row)

```

- **current_database()**
Description: Name of the current database

Return type: name

Example:

```

testdb=# SELECT current_database();
current_database
-----
testdb
(1 row)

```

- **current_query()**
Description: Text of the currently executing query committed by the client (which might contain more than one statement)

Return type: text

Example:

```

gaussdb=# SELECT current_query();
current_query
-----
SELECT current_query();
(1 row)

```

- **current_schema[()]**
Description: Name of the current schema

Return type: name

Example:

```

gaussdb=# SELECT current_schema();
current_schema
-----
public
(1 row)

```

Note: **current_schema** returns the first valid schema name in the search path. (If the search path is empty or contains no valid schema name, **NULL** is

returned.) This is the schema that will be used for any tables or other named objects that are created without specifying a target schema.

- `current_schemas(Boolean)`

Description: Name of a schema in the search path

Return type: `name[]`

Example:

```
gaussdb=# SELECT current_schemas(true);
current_schemas
-----
{pg_catalog,public}
(1 row)
```

Note:

current_schemas(Boolean) returns an array of the names of all schemas in the search path. The Boolean option specifies whether implicitly included system schemas such as **pg_catalog** are included in the returned search path.

NOTE

The search path can be altered at the run time. The command is as follows:

```
SET search_path TO schema [, schema, ...]
```

- `current_user`

Description: Username of current execution context

Return type: `name`

Example:

```
gaussdb=# SELECT current_user;
current_user
-----
omm
(1 row)
```

Note: **current_user** is the user identifier used for permission check. Normally it is equal to the session user, but it can be changed by using **SET ROLE**. It also changes during the execution of functions with the **SECURITY DEFINER** attribute.

- `definer_current_user`

Description: Username in the current execution environment

Return type: `name`

Example:

```
gaussdb=# SELECT definer_current_user();
definer_current_user
-----
omm
(1 row)
```

Note: In most cases, the results of **definer_current_user** and **current_user** are the same. However, when this function is executed in a stored procedure, the name of user who defines the current stored procedure is returned.

- `pg_current_sessionid()`

Description: Session ID of the current execution context

Return type: `text`

Example:

```
gaussdb=# SELECT pg_current_sessionid();
pg_current_sessionid
```

```
-----
1579228402.140190434944768
(1 row)
```

Note: **pg_current_sessionid()** is used to obtain the session ID in the current execution environment. The format of the value is *Timestamp.Session ID*. When **enable_thread_pool** is set to **off**, the actual session ID is the thread ID.

- **pg_current_sessid**

Description: Session ID in the current execution environment

Return type: text

Example:

```
gaussdb=# select pg_current_sessid();
pg_current_sessid
-----
140308875015936
(1 row)
```

Note: In thread pool mode, the session ID of the current session is obtained. In non-thread pool mode, the backend thread ID of the current session is obtained.

- **pg_current_userid**

Description: Current user ID

Return type: text

Example:

```
gaussdb=# SELECT pg_current_userid();
pg_current_userid
-----
10
(1 row)
```

- **tablespace_oid_name()**

Description: Queries the tablespace name based on the tablespace OID.

Return type: text

Example:

```
gaussdb=# select tablespace_oid_name(1663);
tablespace_oid_name
-----
pg_default
(1 row)
```

- **inet_client_addr()**

Description: Remote connection address. **inet_client_addr** returns the IP address of the current client.

NOTE

It is available only in remote connection mode.

Return type: inet

Example:

```
gaussdb=# SELECT inet_client_addr();
inet_client_addr
-----
10.10.0.50
(1 row)
```

- **inet_client_port()**

Description: Remote connection port. **inet_client_port** returns the port number of the current client.

 **NOTE**

This function is valid only in remote connection mode.

Return type: int

Example:

```
gaussdb=# SELECT inet_client_port();
inet_client_port
-----
          33143
(1 row)
```

- **inet_server_addr()**

Description: Local connection address. **inet_server_addr** returns the IP address on which the server accepts the current connection.

 **NOTE**

It is available only in remote connection mode.

Return type: inet

Example:

```
gaussdb=# SELECT inet_server_addr();
inet_server_addr
-----
10.10.0.13
(1 row)
```

- **inet_server_port()**

Description: Local connection port. **inet_server_port** returns the number of the port receiving the current connection. All these functions return **NULL** if the current connection is via a Unix-domain socket.

 **NOTE**

This function is valid only in remote connection mode.

Return type: int

Example:

```
gaussdb=# SELECT inet_server_port();
inet_server_port
-----
          8000
(1 row)
```

- **pg_backend_pid()**

Description: Process ID of the service process attached to the current session.

Return type: int

Example:

```
gaussdb=# SELECT pg_backend_pid();
pg_backend_pid
-----
140229352617744
(1 row)
```

- **pg_conf_load_time()**

Description: Configures load time. **pg_conf_load_time** returns the timestamp when the server configuration files were last loaded.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_conf_load_time();
 pg_conf_load_time
-----
2017-09-01 16:05:23.89868+08
(1 row)
```

- `pg_my_temp_schema()`

Description: OID of the temporary schema of a session. The value is **0** if the OID does not exist.

Return type: oid

Example:

```
gaussdb=# SELECT pg_my_temp_schema();
 pg_my_temp_schema
-----
0
(1 row)
```

Note: **pg_my_temp_schema** returns the OID of the current session's temporary schema, or **0** if it has no temporary schemas (because no temporary tables are created). **pg_is_other_temp_schema** returns **true** if the given OID is the OID of another session's temporary schema.

- `pg_is_other_temp_schema(oid)`

Description: Specifies whether the schema is the temporary schema of another session.

Return type: Boolean

Example:

```
gaussdb=# SELECT pg_is_other_temp_schema(25356);
 pg_is_other_temp_schema
-----
f
(1 row)
```

- `pg_listening_channels()`

Description: Name of the channel that the session is currently listening to.

Return type: setof text

Example:

```
gaussdb=# SELECT pg_listening_channels();
 pg_listening_channels
-----
(0 rows)
```

Note: **pg_listening_channels** returns a set of names of channels that the current session is currently listening to.

- `pg_postmaster_start_time()`

Description: Server start time. **pg_postmaster_start_time** returns the **timestamp with time zone** when the server is started.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_postmaster_start_time();
 pg_postmaster_start_time
-----
2017-08-30 16:02:54.99854+08
(1 row)
```

- `sessionid2pid()`
Description: Obtains PID information from a session ID (for example, the **sessid** column in **pv_session_stat**).
Return type: int8
Example:

```
gaussdb=# select sessionid2pid(sessid::cstring) from pv_session_stat limit 2;
 sessionid2pid
-----
139973107902208
139973107902208
(2 rows)
```
- `session_context('namespace' , 'parameter')`
Description: Obtains and returns the parameter values of a specified namespace.
Return type: VARCHAR
Example:

```
gaussdb=# SELECT session_context('USERENV', 'CURRENT_SCHEMA');
 session_context
-----
public
(1 row)
```

The result varies according to the current actual schema.
Note: Currently, only the `SESSION_CONTEXT('USERENV', 'CURRENT_SCHEMA')` and `SESSION_CONTEXT('USERENV', 'CURRENT_USER')` formats are supported.
- `pg_trigger_depth()`
Description: Nesting level of triggers.
Return type: int
Example:

```
gaussdb=# SELECT pg_trigger_depth();
 pg_trigger_depth
-----
0
(1 row)
```
- `opengauss_version()`
Description: openGauss version information.
Return type: text
The following is an example. Replace *x.x.x* in the query result with the actual value.

```
gaussdb=# SELECT opengauss_version();
 opengauss_version
-----
x.x.x
(1 row)
```
- `gs_deployment()`
Description: Deployment mode of the current system. For a distributed system, **Distribute** is returned.
Return type: text
Example:

```
gaussdb=# select gs_deployment();
 gs_deployment
```

- ```

Distribute
(1 row)
```
- `session_user`  
Description: Session username.  
Return type: name  
Example:  

```
gaussdb=# SELECT session_user;
session_user

omm
(1 row)
```

Note: **session\_user** usually specifies the initial user connected to the current database, but the system administrator can change this setting by using **SET SESSION AUTHORIZATION**.
  - `user`  
Description: Equivalent to `current_user`.  
Return type: name  
Example:  

```
gaussdb=# SELECT user;
current_user

omm
(1 row)
```
  - `get_shard_oids_byname`  
Description: Returns the OID of the node when the node name is entered.  
Return type: oid  
Example:  

```
gaussdb=# select get_shard_oids_byname('datanode1');
get_shard_oids_byname

{16385}
(1 row)
```
  - `getpgusername()`  
Description: Obtains the database username.  
Return type: name  
Example:  

```
gaussdb=# select getpgusername();
getpgusername

GaussDB_userna
(1 row)
```
  - `getdatabaseencoding()`  
Description: Obtains the database encoding mode.  
Return type: name  
Example:  

```
gaussdb=# select getdatabaseencoding();
getdatabaseencoding

SQL_ASCII
(1 row)
```

- version()**

Description: version information. **version** returns a string describing a server's version.

Return type: text

Example:

```
gaussdb=# SELECT version();
```

| version                                                                                                     |
|-------------------------------------------------------------------------------------------------------------|
| gaussdb (GaussDB 503.1.XXX build f521c606) compiled at 2021-09-16 14:55:22 commit 2935 last mr 6385 release |

(1 row)
- working\_version\_num()**

Description: version number. It returns a version number related to system compatibility.

Return type: int

Example:

```
gaussdb=# SELECT working_version_num();
```

| working_version_num |
|---------------------|
| 92231               |

(1 row)
- get\_hostname()**

Description: Returns the host name of the current node.

Return type: text

Example:

```
gaussdb=# SELECT get_hostname();
```

| get_hostname |
|--------------|
| linux-user   |

(1 row)
- get\_nodename()**

Description: Returns the name of the current node.

Return type: text

Example:

```
gaussdb=# SELECT get_nodename();
```

| get_nodename |
|--------------|
| coordinator1 |

(1 row)
- get\_schema\_oid(cstring)**

Description: Returns the OID of the queried schema.

Return type: oid

Example:

```
gaussdb=# SELECT get_schema_oid('public');
```

| get_schema_oid |
|----------------|
| 2200           |

(1 row)
- pgxc\_parse\_clog(OUT xid int8, OUT nodename text, OUT status text)**

Description: Returns the status of all transactions in the current cluster.

Return type: SETOF record

Example:

```
gaussdb=# SELECT pgxc_parse_clog();
pgxc_parse_clog

(0,dn_6004_6005_6006,INPROGRESS)
(1,dn_6004_6005_6006,COMMITTED)
(2,dn_6004_6005_6006,INPROGRESS)
(3 row)
```

- `pgxc_prepared_xact( )`

Description: Returns the list of transaction GIDs at the prepared stage in the cluster.

Return type: set of text

Example:

```
gaussdb=# SELECT pgxc_prepared_xact();
pgxc_prepared_xact

(0 row)
```

- `pgxc_xacts_iscommitted()`

Description: Returns the status of the transaction with the specified XID in the cluster. **t** indicates the committed state, **f** indicates the aborted state, and **null** indicates other states. To execute this function, you must have the **sysadmin** or **monadmin** permission.

Return type: set of record

Example:

```
gaussdb=# SELECT pgxc_xacts_iscommitted(1);
pgxc_xacts_iscommitted

(dn_6004_6005_6006,t)
(cn_5001,t)
(cn_5002,t)
(dn_6001_6002_6003,t)
(4 row)
```

- `pgxc_total_memory_detail()`

Description: Displays the memory usage in the cluster. To execute this function, you must have the **sysadmin** or **monadmin** permission.

#### NOTE

If the GUC parameter **enable\_memory\_limit** is set to **off**, this function cannot be used.

Return type: set of `pv_total_memory_detail`

Example:

```
gaussdb=# SELECT pgxc_total_memory_detail();
pgxc_total_memory_detail

(dn_6004_6005_6006,max_process_memory,81920)
(dn_6004_6005_6006,process_used_memory,72747)
(dn_6004_6005_6006,max_dynamic_memory,12096)
(dn_6004_6005_6006,dynamic_used_memory,1530)
(4 row)
```

- `pv_total_memory_detail`

Description: Collects statistics on memory usage of the current database node in the unit of MB.

 NOTE

If the GUC parameter **enable\_memory\_limit** is set to **off**, this function cannot be used.

Return type: record

**Table 7-41** Return value description

| Name        | Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- `get_client_info()`  
Description: Returns client information.  
Return type: record

## Access Permission Query Functions

The DDL permissions, including ALTER, DROP, COMMENT, INDEX, and VACUUM, are inherent permissions implicitly owned by the owner.

The following access permission query functions only specify whether a user has a certain permission on an object (that is, a permission on an object recorded in the **acl** column of a system catalog is returned):

- `has_any_column_privilege(user, table, privilege)`

Description: Queries whether a specified user has permissions on any column of a table.

**Table 7-42** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| privilege | text                       | Permissions | <ul style="list-style-type: none"> <li>• <b>SELECT</b>: allows the <b>SELECT</b> statement to be executed on any column of a specified table.</li> <li>• <b>INSERT</b>: allows the <b>INSERT</b> statement to be executed on any column of a specified table.</li> <li>• <b>UPDATE</b>: allows the <b>UPDATE</b> statement to be executed on any column of a specified table.</li> <li>• <b>REFERENCES</b>: allows a foreign key constraint (not supported in distributed mode).</li> <li>• <b>COMMENT</b>: allows the <b>COMMENT</b> statement to be executed on any column of a specified table.</li> </ul> |

Return type: Boolean

- `has_any_column_privilege(table, privilege)`

Description: Queries whether the current user has the permission to access any column of a table. For details about the valid parameter types, see [Table 7-42](#).

Return type: Boolean

Note: **has\_any\_column\_privilege** checks whether a user can access any column of a table in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**, except that the desired access permission

type must be some combination of **SELECT**, **INSERT**, **UPDATE**, or **REFERENCES**.

 **NOTE**

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table. Therefore, **has\_any\_column\_privilege** always returns **true** if **has\_table\_privilege** has the same parameters. A success message is also returned if a column-level permission is granted for at least one column.

- `has_column_privilege(user, table, column, privilege)`

Description: Specifies whether a specified user has the permission to access columns.

**Table 7-43** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| column    | text, smallint             | Column name | Name or attribute number of a column                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| privilege | text                       | Permissions | <ul style="list-style-type: none"> <li>• <b>SELECT</b>: allows the <b>SELECT</b> statement to be executed on specified columns of a table.</li> <li>• <b>INSERT</b>: allows the <b>INSERT</b> statement to be executed on specified columns of a table.</li> <li>• <b>UPDATE</b>: allows the <b>UPDATE</b> statement to be executed on specified columns of a table.</li> <li>• <b>REFERENCES</b>: allows a foreign key constraint (not supported in distributed mode).</li> <li>• <b>COMMENT</b>: allows the <b>COMMENT</b> statement to be executed on specified columns of a table.</li> </ul> |

Return type: Boolean

- `has_column_privilege(table, column, privilege)`

Description: Specifies whether the current user has the permission to access columns. For details about the valid parameter types, see [Table 7-43](#).

Return type: Boolean

**has\_column\_privilege** checks whether a user can access a column in a particular way. Its parameter possibilities are analogous to those of

**has\_table\_privilege.** Columns can be added either by name or by attribute number. The desired access permission type must be some combination of **SELECT**, **INSERT**, **UPDATE**, or **REFERENCES**.

 **NOTE**

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table.

- `has_cek_privilege(user, cek, privilege)`  
Description: Specifies whether a specified user has permissions on CEKs.

**Table 7-44** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range                                                                                                                                                                |
|-----------|----------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| user      | name, oid                  | Users       | Username or ID                                                                                                                                                             |
| cek       | text, oid                  | CEK         | Name or ID of a CEK                                                                                                                                                        |
| privilege | text                       | Permission  | <ul style="list-style-type: none"> <li>• <b>USAGE:</b> allows users to use the specified CEK.</li> <li>• <b>DROP:</b> allows users to delete the specified CEK.</li> </ul> |

Return type: Boolean

- `has_cmk_privilege(user, cmk, privilege)`  
Description: Specifies whether a specified user has permissions on CMKs.

**Table 7-45** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range                                                                                                                                                                |

| database  | text, oid                  | Database    | Database name or ID                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| privilege | text                       | Permission  | <ul style="list-style-type: none"> <li>• <b>CREATE</b>: For databases, allows new schemas to be created within the database.</li> <li>• <b>TEMPORARY</b>: allows users to create temporary tables when the database is used.</li> <li>• <b>TEMP</b>: allows users to create temporary tables when the database is used.</li> <li>• <b>CONNECT</b>: allows users to access specified databases.</li> <li>• <b>ALTER</b>: allows users to modify the attributes of a specified object.</li> <li>• <b>DROP</b>: allows users to delete a specified object.</li> <li>• <b>COMMENT</b>: allows users to define or modify comments of a specified object.</li> </ul> |

Return type: Boolean

- `has_database_privilege(database, privilege)`

Description: Queries whether the current user has the permission to access a database. For details about the valid parameter types, see [Table 7-46](#).

Return type: Boolean

Note: **has\_database\_privilege** checks whether a user can access a database in a particular way. Its argument possibilities are analogous to **has\_table\_privilege**. The desired access permission type must be some combination of **CREATE**, **CONNECT**, **TEMPORARY**, or **TEMP** (which is equivalent to **TEMPORARY**).

- `has_directory_privilege(user, directory, privilege)`

**Table 7-47** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range                                                                                                                                                                  |
|-----------|----------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| user      | name, oid                  | Users       | Username or ID                                                                                                                                                               |
| directory | text, oid                  | Directory   | Directory name or OID                                                                                                                                                        |
| privilege | text                       | Permission  | <ul style="list-style-type: none"> <li>• <b>READ</b>: allows read operations on the directory.</li> <li>• <b>WRITE</b>: allows write operations on the directory.</li> </ul> |

Description: Specifies whether a specified user has permissions on directories.

Return type: Boolean

- `has_directory_privilege(directory, privilege)`

Description: Queries whether the current user has the permission to access a directory. For details about the valid parameter types, see [Table 7-47](#).

Return type: Boolean

- `has_foreign_data_wrapper_privilege(user, fdw, privilege)`

**Table 7-48** Parameter type description

| Parameter | Valid Input Parameter Type | Description          | Value Range                                               |
|-----------|----------------------------|----------------------|-----------------------------------------------------------|
| user      | name, oid                  | Users                | Username or ID                                            |
| fdw       | text, oid                  | Foreign data wrapper | Name or ID of the foreign data wrapper                    |
| privilege | text                       | Permission           | <b>USAGE</b> : allows access to the foreign data wrapper. |

Description: Specifies whether a specified user has permissions on foreign data wrappers.

Return type: Boolean

- `has_foreign_data_wrapper_privilege(fdw, privilege)`

Description: Queries whether the current user has permissions on foreign data wrappers. For details about the valid parameter types, see [Table 7-48](#).

Return type: Boolean

Note: **has\_foreign\_data\_wrapper\_privilege** checks whether a user can access a foreign data wrapper in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The desired access permission type must evaluate to **USAGE**.

- `has_function_privilege(user, function, privilege)`

**Table 7-49** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| user      | name, oid                  | Users       | Username or ID                                                                                                                                                                                                                                                                                                                                                                                                     |
| function  | text, oid                  | Function    | Function name or ID                                                                                                                                                                                                                                                                                                                                                                                                |
| privilege | text                       | Permission  | <p><b>EXECUTE</b>: allows users to use specified functions and the operators that are realized by the functions.</p> <ul style="list-style-type: none"> <li>• <b>ALTER</b>: allows users to modify the attributes of a specified object.</li> <li>• <b>DROP</b>: allows users to delete a specified object.</li> <li>• <b>COMMENT</b>: allows users to define or modify comments of a specified object.</li> </ul> |

Description: Specifies whether a specified user has permissions on functions.

Return type: Boolean

- `has_function_privilege(function, privilege)`

Description: Specifies whether the current user has permissions on functions. For details about valid parameter types, see [Table 7-49](#).

Return type: Boolean

Note: **has\_function\_privilege** checks whether a user can access a function in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. When a function is specified by a text string rather than by an OID, the allowed input is the same as that for the **regprocedure** data type (see [Object Identifier Types](#)). The desired access permission type must be **EXECUTE**.

- `has_language_privilege(user, language, privilege)`

**Table 7-50** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range    |
|-----------|----------------------------|-------------|----------------|
| user      | name, oid                  | Users       | Username or ID |

| Parameter | Valid Input Parameter Type | Description | Value Range                                                                          |
|-----------|----------------------------|-------------|--------------------------------------------------------------------------------------|
| language  | text, oid                  | Language    | Language name or ID                                                                  |
| privilege | text                       | Permission  | <b>USAG:</b> allows users to specify a procedural language when creating a function. |

Description: Specifies whether a specified user has permissions on languages.

Return type: Boolean

- `has_language_privilege(language, privilege)`

Description: Specifies whether the current user has permissions on languages. For details about valid parameter types, see [Table 7-50](#).

Return type: Boolean

Note: **has\_language\_privilege** checks whether a user can access a procedural language in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The desired access permission type must be **USAGE**.

- `has_nodegroup_privilege(user, nodegroup, privilege)`

Description: Checks whether a user has permission to access a cluster node.

Return type: Boolean

**Table 7-51** Parameter type description

| Parameter | Valid Input Parameter Type | Description  | Value Range             |
|-----------|----------------------------|--------------|-------------------------|
| user      | name, oid                  | Users        | Existing username or ID |
| nodegroup | text, oid                  | Cluster node | Existing cluster node   |

| Parameter | Valid Input Parameter Type | Description | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|----------------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| privilege | text                       | Permission  | <ul style="list-style-type: none"> <li>• <b>USAGE</b>: For sub-clusters, allows users who can access objects contained in the schema to access tables in the sub-cluster.</li> <li>• <b>CREATE</b>: For sub-clusters, allows users to create tables within the sub-cluster.</li> <li>• <b>COMPUTE</b>: allows elastic computing in the sub-cluster.</li> <li>• <b>ALTER</b>: allows users to modify the attributes of a specified object.</li> <li>• <b>DROP</b>: allows users to delete a specified object.</li> </ul> |

- `has_nodegroup_privilege(nodegroup, privilege)`  
Description: Checks whether a user has permission to access a cluster node.  
Return type: Boolean
- `has_schema_privilege(user, schema, privilege)`  
Description: Specifies whether a specified user has permissions on schemas.  
Return type: Boolean
- `has_schema_privilege(schema, privilege)`  
Description: Specifies whether the current user has permissions on schemas.  
Return type: Boolean  
Note: **has\_schema\_privilege** checks whether a user can access a schema in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The desired access permission type must be **CREATE**, **USAGE**, **ALTER**, **DROP**, or **COMMENT**.
- `has_sequence_privilege(user, sequence, privilege)`  
Description: Queries whether a specified user has permissions on sequences.  
Return type: Boolean

**Table 7-52** Parameter type description

| Parameter | Valid Input Parameter Type | Description | Value Range                  |
|-----------|----------------------------|-------------|------------------------------|
| user      | name, oid                  | Users       | Existing username or ID      |
| sequence  | text, oid                  | Sequence    | Existing sequence name or ID |

| Parameter | Valid Input Parameter Type | Description | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| privilege | text                       | Permission  | <ul style="list-style-type: none"> <li>• <b>USAGE</b>: For sequences, allows users to use the <b>nextval</b> function.</li> <li>• <b>SELECT</b>: allows users to create a sequence.</li> <li>• <b>UPDATE</b>: allows users to execute the <b>UPDATE</b> statement.</li> <li>• <b>ALTER</b>: allows users to modify the attributes of a specified object.</li> <li>• <b>DROP</b>: allows users to delete a specified object.</li> <li>• <b>COMMENT</b>: allows users to define or modify comments of a specified object.</li> </ul> |

- `has_sequence_privilege(sequence, privilege)`  
Description: Queries whether the current user has permissions on sequences.  
Return type: Boolean
- `has_server_privilege(user, server, privilege)`  
Description: Specifies whether a specified user has permissions on foreign servers.  
Return type: Boolean
- `has_server_privilege(server, privilege)`  
Description: Specifies whether the current user has permissions on foreign servers.  
Return type: Boolean  
Note: **has\_server\_privilege** checks whether a user can access a foreign server in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The access permission type must be **USAGE**, **ALTER**, **DROP**, or **COMMENT**.
- `has_table_privilege(user, table, privilege)`  
Description: Specifies whether a specified user has permissions on tables.  
Return type: Boolean
- `has_table_privilege(table, privilege)`  
Description: Specifies whether the current user has permissions on tables.  
Return type: Boolean  
Note: **has\_table\_privilege** checks whether a user can access a table in a particular way. The user can be specified by name or by OID (**pg\_authid.oid**), or be set to **public** which indicates public pseudo roles. If this parameter is omitted, **current\_user** is used. The table can be specified by name or by OID.

When it is specified by name, the name can be schema-qualified if necessary. If the desired access permission type is specified by a text string, the text string must be one of the values **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE**, **REFERENCETRIGGER**, **ALTER**, **DROP**, **COMMENT**, **INDEX**, or **VACUUM**. Optionally, **WITH GRANT OPTION** can be added to a permission type to test whether the permission is held with the grant option. Also, multiple permission types can be listed separated by commas, in which case the result will be **true** if any of the listed permissions is held.

Example:

```
gaussdb=# SELECT has_table_privilege('tpcds.web_site', 'select');
has_table_privilege

t
(1 row)

gaussdb=# SELECT has_table_privilege('omm', 'tpcds.web_site', 'select,INSERT WITH GRANT OPTION ');
has_table_privilege

t
(1 row)
```

- `has_tablespace_privilege(user, tablespace, privilege)`  
Description: Specifies whether a specified user has permissions on tablespaces.  
Return type: Boolean
- `has_tablespace_privilege(tablespace, privilege)`  
Description: Specifies whether the current user has permissions on tablespaces.  
Return type: Boolean  
Note: **has\_tablespace\_privilege** checks whether a user can access a tablespace in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The access permission type must be **CREATE**, **ALTER**, **DROP**, or **COMMENT**.
- `pg_has_role(user, role, privilege)`  
Description: Specifies whether a specified user has permissions on roles.  
Return type: Boolean
- `pg_has_role(role, privilege)`  
Description: Specifies whether the current user has permissions on roles.  
Return type: Boolean  
Note: **pg\_has\_role** checks whether a user can access a role in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**, except that **public** cannot be used as a username. The desired access permission type must be some combination of **MEMBER** or **USAGE**. **MEMBER** denotes direct or indirect membership in the role (that is, permission **SET ROLE**), while **USAGE** denotes the usage permission on the role that is available without the **SET ROLE** permission.
- `has_any_privilege(user, privilege)`  
Description: Queries whether a specified user has certain ANY permission. If multiple permissions are queried at the same time, **true** is returned as long as one permission is obtained.  
Return type: Boolean

**Table 7-53** Parameter type description

| Parameter | Valid Input Parameter Type | Description    | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|----------------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| user      | name                       | Users          | Existing username                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| privilege | text                       | ANY permission | Available values: <ul style="list-style-type: none"> <li>• CREATE ANY TABLE [WITH ADMIN OPTION]</li> <li>• ALTER ANY TABLE [WITH ADMIN OPTION]</li> <li>• DROP ANY TABLE [WITH ADMIN OPTION]</li> <li>• SELECT ANY TABLE [WITH ADMIN OPTION]</li> <li>• INSERT ANY TABLE [WITH ADMIN OPTION]</li> <li>• UPDATE ANY TABLE [WITH ADMIN OPTION]</li> <li>• DELETE ANY TABLE [WITH ADMIN OPTION]</li> <li>• CREATE ANY SEQUENCE [WITH ADMIN OPTION]</li> <li>• CREATE ANY INDEX [WITH ADMIN OPTION]</li> <li>• CREATE ANY FUNCTION [WITH ADMIN OPTION]</li> <li>• EXECUTE ANY FUNCTION [WITH ADMIN OPTION]</li> <li>• CREATE ANY TYPE [WITH ADMIN OPTION]</li> </ul> |

## Schema Visibility Query Functions

Each function performs the visibility check on one type of database objects. For functions and operators, an object in the search path is visible if there is no object of the same name and parameter data type earlier in the path. For operator classes, both name and associated index access methods are considered.

All these functions require OIDs to identify the objects to be checked. If you want to test an object by name, it is convenient to use the OID alias type (**regclass**, **regtype**, **regprocedure**, **regoperator**, **regconfig**, or **regdictionary**).

For example, a table is said to be visible if the schema where the table is located is in the search path and no table of the same name appears earlier in the search path. This is equivalent to the statement that the table can be referenced by name

without explicit schema qualification. To list the names of all visible tables, run the following command:

```
gaussdb=# SELECT relname FROM pg_class WHERE pg_table_is_visible(oid);
```

- `pg_collation_is_visible(collation_oid)`  
Description: Specifies whether the collation is visible in the search path.  
Return type: Boolean
- `pg_conversion_is_visible(conversion_oid)`  
Description: Specifies whether the conversion is visible in the search path.  
Return type: Boolean
- `pg_function_is_visible(function_oid)`  
Description: Specifies whether the function is visible in the search path.  
Return type: Boolean
- `pg_opclass_is_visible(opclass_oid)`  
Description: Specifies whether the operator class is visible in the search path.  
Return type: Boolean
- `pg_operator_is_visible(operator_oid)`  
Description: Specifies whether the operator is visible in the search path.  
Return type: Boolean
- `pg_opfamily_is_visible(opfamily_oid)`  
Description: Specifies whether the operator family is visible in the search path.  
Return type: Boolean
- `pg_table_is_visible(table_oid)`  
Description: Specifies whether the table is visible in the search path.  
Return type: Boolean
- `pg_ts_config_is_visible(config_oid)`  
Description: Specifies whether the text search configuration is visible in the search path.  
Return type: Boolean
- `pg_ts_dict_is_visible(dict_oid)`  
Description: Specifies whether the text search dictionary is visible in the search path.  
Return type: Boolean
- `pg_ts_parser_is_visible(parser_oid)`  
Description: Specifies whether the text search parser is visible in the search path.  
Return type: Boolean
- `pg_ts_template_is_visible(template_oid)`  
Description: Specifies whether the text search template is visible in the search path.  
Return type: Boolean
- `pg_type_is_visible(type_oid)`

Description: Specifies whether the type (or domain) is visible in the search path.

Return type: Boolean

## System Catalog Information Functions

- `format_type(type_oid, typemod)`

Description: Obtains the SQL name of a data type.

Return type: text

Note: **format\_type** returns the SQL name of a data type based on the OID of the data type and possible modifiers. If the specific modifier is unknown, pass **NULL** at the position of the modifier. Modifiers are generally meaningful only for data types with length restrictions. The SQL name returned by **format\_type** contains the length of the data type, which can be calculated by taking `sizeof(int32)` from actual storage length [actual storage len - `sizeof(int32)`] in the unit of bytes. 32-bit space is required to store the customized length set by users. Therefore, the actual storage length contains 4 bytes more than the customized length. In the following example, the SQL name returned by **format\_type** is `character varying(6)`, indicating the length of the `varchar` type is 6 bytes. Therefore, the actual storage length of the `varchar` type is 10 bytes.

```
gaussdb=# SELECT format_type((SELECT oid FROM pg_type WHERE typename='varchar'), 10);
format_type

character varying(6)
(1 row)
```

- `pg_check_authid(role_oid)`

Description: Checks whether a role name with given OID exists.

Return type: Boolean

```
gaussdb=# select pg_check_authid(1);
pg_check_authid

f
(1 row)
```

- `pg_describe_object(catalog_id, object_id, object_sub_id)`

Description: Obtains the description of a database object.

Return type: text

Note: **pg\_describe\_object** returns the description of a database object specified by a catalog OID, an object OID, and a (possibly zero) sub-object ID. This is useful to determine the identity of an object stored in the **pg\_depend** catalog.

- `pg_get_constraintdef(constraint_oid)`

Description: Obtains definition of a constraint.

Return type: text

- `pg_get_constraintdef(constraint_oid, pretty_bool)`

Description: Obtains definition of a constraint.

Return type: text

Note: **pg\_get\_constraintdef** and **pg\_get\_indexdef** respectively reconstruct the creation command for a constraint and an index.

- `pg_get_expr(pg_node_tree, relation_oid)`  
 Description: Decompiles the internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.  
 Return type: text
- `pg_get_expr(pg_node_tree, relation_oid, pretty_bool)`  
 Description: Decompiles the internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.  
 Return type: text  
 Note: **pg\_get\_expr** decompiles the internal form of an individual expression, such as the default value of a column, which helps to check the contents of system catalogs. If the expression might contain keywords, specify the OID of the relationship they refer to as the second parameter; if no keywords are expected, zero is sufficient.
- `pg_get_functiondef(func_oid)`  
 Description: Obtains the definition of a function.  
 Return type: text  
 Example:  

```
gaussdb=# SELECT * FROM pg_get_functiondef(598);
headerlines | definition
-----+-----
4 | CREATE OR REPLACE FUNCTION pg_catalog.abbrev(inet)+
| RETURNS text +
| LANGUAGE internal +
| IMMUTABLE STRICT NOT FENCED NOT SHIPPABLE +
| AS $function$inet_abbrev$function$ +
(1 row)
```
- `pg_get_function_arguments(func_oid)`  
 Description: Obtains argument list of function's definition (with default values).  
 Return type: text  
 Note: **pg\_get\_function\_arguments** returns the parameter list of a function, in the form it would need to appear in CREATE FUNCTION.
- `pg_get_function_identity_arguments(func_oid)`  
 Description: Obtains the parameter list to identify a function (without default values).  
 Return type: text  
 Note: **pg\_get\_function\_identity\_arguments** returns the parameter list necessary to identify a function, in the form it would need to appear in within ALTER FUNCTION. This form omits default values.
- `pg_get_function_result(func_oid)`  
 Description: Obtains the RETURNS clause for a function.  
 Return type: text  
 Note: **pg\_get\_function\_result** returns the appropriate **RETURNS** clause for the function.
- `pg_get_indexdef(index_oid)`  
 Description: Obtains the **CREATE INDEX** command for an index.  
 Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_indexdef(16416);
 pg_get_indexdef

CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
```

- `pg_get_indexdef(index_oid, dump_schema_only)`

Description: Obtains the **CREATE INDEX** command for indexes in dump scenarios. In the current version, the value of **dump\_schema\_only** does not affect the function output.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_indexdef(16416, true);
 pg_get_indexdef

CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
```

- `pg_get_indexdef(index_oid, column_no, pretty_bool)`

Description: Obtains the **CREATE INDEX** command for an index, or definition of just one index column when the value of **column\_no** is not zero.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_indexdef(16416, 0, false);
 pg_get_indexdef

CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
gaussdb=# SELECT * FROM pg_get_indexdef(16416, 1, false);
 pg_get_indexdef

b
(1 row)
```

Note: **pg\_get\_functiondef** returns a complete **CREATE OR REPLACE FUNCTION** statement for a function.

- `pg_get_keywords()`

Description: Obtains the list of SQL keywords and their categories.

Return type: SETOF record

Note: **pg\_get\_keywords** returns a set of records describing the SQL keywords recognized by the server. The **word** column contains the keywords. The **catcode** column contains a category code: **U** for unreserved, **C** for column name, **T** for type or function name, or **R** for reserved. The **catdesc** column contains a possibly-localized string describing the category.

- `pg_get_ruledef(rule_oid)`

Description: Obtains the **CREATE RULE** command for a rule.

Return type: text

- `pg_get_ruledef(rule_oid, pretty_bool)`

Description: Obtains the **CREATE RULE** command for a rule.

Return type: text

- `pg_get_userbyid(role_oid)`

Description: Obtains the role name with a given OID.

Return type: name

Note: **pg\_get\_userbyid** extracts a role's name given its OID.

- **pg\_check\_authid(role\_id)**

Description: Checks whether a user exists based on **role\_id**.

Return type: text

```
gaussdb=# SELECT pg_check_authid(20);
pg_check_authid

f
(1 row)
```

- **pg\_get\_viewdef(view\_name)**

Description: Obtains the underlying **SELECT** command for a view.

Return type: text

- **pg\_get\_viewdef(view\_name, pretty\_bool)**

Description: Obtains the underlying **SELECT** command for a view, lines with columns are wrapped to 80 columns if **pretty\_bool** is set to **true**.

Return type: text

Note: **pg\_get\_viewdef** reconstructs the **SELECT** query that defines a view. Most of these functions come in two forms. When the function has the **pretty\_bool** parameter and the value is **true**, it can optionally "pretty-print" the result. The pretty-printed format is more readable. The other one is the default format which is more likely to be interpreted in the same way by future versions. Avoid using pretty-printed output for dump purposes. Passing **false** to the pretty-print parameter generates the same result as a variant without this parameter.

- **pg\_get\_viewdef(view\_oid)**

Description: Obtains the underlying **SELECT** command for a view.

Return type: text

- **pg\_get\_viewdef(view\_oid, pretty\_bool)**

Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to 80 columns if **pretty\_bool** is set to **true**.

Return type: text

- **pg\_get\_viewdef(view\_oid, wrap\_column\_int)**

Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to the specified number of columns and printing is implicit.

Return type: text

- **pg\_get\_tabledef(table\_oid)**

Description: Obtains the definition of a table based on **table\_oid**.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_tabledef(16384);
pg_get_tabledef

SET search_path = public; +
CREATE TABLE t1 (+
 c1 bigint DEFAULT nextval('serial'::regclass)+
) +
WITH (orientation=row,compression=no) +
DISTRIBUTE BY HASH(c1) +
```

```
TO GROUP group1;
(1 row)
```

- `pg_get_tabledef(table_name)`

Description: Obtains the definition of a table based on **table\_name**.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_tabledef('t1');
pg_get_tabledef
```

```

SET search_path = public; +
CREATE TABLE t1 (+
 c1 bigint DEFAULT nextval('serial'::regclass)+
) +
WITH (orientation=row, compression=no) +
DISTRIBUTE BY HASH(c1) +
TO GROUP group1;
(1 row)
```

Note: **pg\_get\_tabledef** reconstructs the **CREATE** statement of the definition of the table, including the table definition, index information, and comments. Users need to create the dependent objects of the table, such as groups, schemas, tablespaces, and servers. The table definition does not include the statements for creating these dependent objects.

- `pg_options_to_table(reloptions)`

Description: Obtains the set of storage option name/value pairs.

Return type: SETOF record

Note: **pg\_options\_to\_table** returns the set of storage option name/value pairs (**option\_name/option\_value**) when **pg\_class.reloptions** or **pg\_attribute.attoptions** is passed.

- `pg_tablespace_databases(tablespace_oid)`

Description: Obtains the set of database OIDs that have objects in the specified tablespace.

Return type: setof oid

Note: **pg\_tablespace\_databases** allows a tablespace to be checked. It returns the set of OIDs of databases that have objects stored in the tablespace. If this function returns any rows of data, the tablespace is not empty and cannot be dropped. To display the specific objects in the tablespace, you need to connect to the databases identified by **pg\_tablespace\_databases** and query their **pg\_class** catalogs.

- `pg_tablespace_location(tablespace_oid)`

Description: Obtains the path in the file system that this tablespace is located in.

Return type: text

- `pg_typeof(any)`

Description: Obtains the data type of any value.

Return type: regtype

Note: **pg\_typeof** returns the OID of the data type of the value that is passed to it. This can be helpful for troubleshooting or dynamically constructing SQL queries. It is declared that the function returns **regtype**, which is an OID alias type (see [Object Identifier Types](#)). This means that it is the same as an OID for comparison purposes but displays as a type name.

Example:

```
gaussdb=# SELECT pg_typeof(33);
pg_typeof

integer
(1 row)

gaussdb=# SELECT typlen FROM pg_type WHERE oid = pg_typeof(33);
typlen

4
(1 row)
```

- `collation for (any)`

Description: Obtains the collation of the parameter.

Return type: text

Note: The expression **collation for** returns the collation of the value that is passed to it. Example:

```
gaussdb=# SELECT collation for (description) FROM pg_description LIMIT 1;
pg_collation_for

"default"
(1 row)
```

The value might be quoted and schema-qualified. If no collation is derived for the parameter expression, then a null value is returned. If the argument is not of a collatable data type, then an error is raised.

- `getdistributekey(table_name)`

Description: Gets a distribution key for a hash table.

Return type: text

Example:

```
gaussdb=# SELECT getdistributekey('item');
getdistributekey

i_item_sk
(1 row)
```

- `pg_extension_update_paths(name)`

Description: Returns the version update path of the specified extension. This function can be called only by the system administrator.

Return type: text (source text), text (target text), text (path text)

- `pg_get_serial_sequence(tablename, colname)`

Description: Obtains the sequence of the corresponding table name and column name.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_serial_sequence('t1', 'c1');
pg_get_serial_sequence

public.serial
(1 row)
```

- `pg_sequence_parameters(sequence_oid)`

Description: Obtains the parameters of a specified sequence, including the start value, minimum value, maximum value, and incremental value.

Return type: int16, int16, int16, int16, Boolean

Example:

```
gaussdb=# SELECT * FROM pg_sequence_parameters(16420);
 start_value | minimum_value | maximum_value | increment | cycle_option
-----+-----+-----+-----+-----
 101 | 1 | 9223372036854775807 | 1 | f
(1 row)
```

- `pgxc_get_variable_info( )`

Description: Obtains variable values on the node, including **nodeName**, **nextOid**, **nextXid**, **oldestXid**, **xidVacLimit**, **oldestXidDB**, **lastExtendCSNLogpage**, **startExtendCSNLogpage**, **nextCommitSeqNo**, **latestCompleteXid**, and **startupMaxXid**.

Return type: set of `pg_variable_info`

Example:

```
gaussdb=# SELECT pgxc_get_variable_info();
 pgxc_get_variable_info

(dn_6004_6005_6006,25617,141396349,2073,20000002073,15808,138111,0,127154152,141396348,104433004)
(1 row)
```

- `gs_get_index_status(schema_name, index_name)`

Description: Obtains the index status information on all nodes, including whether an index can be inserted and whether an index is available. This function is mainly used to check the index status during online index creation or when the index creation fails. The return values include **node\_name**, **indisready**, and **indisvalid**. Only when **indisready** and **indisvalid** of indexes on all nodes are set to **true** and the index state is not changed to unusable, the current index is available.

Return type: text, Boolean, Boolean

Example:

```
gaussdb=# SELECT * FROM gs_get_index_status('public', 'index1');
 node_name | indisready | indisvalid
-----+-----+-----
 datanode1 | t | t
 datanode2 | t | t
 coordinator1 | t | t
(3 row)
```

## Comment Information Functions

- `col_description(table_oid, column_number)`

Description: Obtains the comment for a table column.

Return type: text

Note: **col\_description** returns the comment for a table column, which is specified by the OID of its table and its column number.

- `obj_description(object_oid, catalog_name)`

Description: Obtains the comment for a database object.

Return type: text

Note: The two-parameter form of **obj\_description** returns the comment for a database object specified by its OID and the name of the system catalog to which it belongs. For example, **obj\_description(123456,'pg\_class')** would retrieve the comment for the table with OID 123456. The one-parameter form of **obj\_description** requires only the OID.

**obj\_description** cannot be used for table columns since columns do not have OIDs of their own.

- **obj\_description(object\_oid)**  
Description: Obtains the comment for a database object.  
Return type: text
- **shobj\_description(object\_oid, catalog\_name)**  
Description: Obtains the comment for a shared database object.  
Return type: text

Note: **shobj\_description** is used just like **obj\_description**, except that the former is used for shared objects. Some system catalogs are global to all databases in the cluster, and the comments for objects in them are stored globally as well.

## XIDs and Snapshots

Internal XIDs are 64 bits. **txid\_snapshot**, data type used by these functions, stores information about XID visibility at a particular moment in time. [Table 7-54](#) describes its components.

**Table 7-54** Snapshot components

| Name     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| xmin     | Earliest XID ( <b>txid</b> ) that is still active. All earlier transactions will either be committed and visible, or rolled back.                                                                                                                                                                                                                                                                                                                                                                         |
| xmax     | First as-yet-unassigned <b>txid</b> . All txids greater than or equal to this are not yet started as of the time of the snapshot, so they are invisible.                                                                                                                                                                                                                                                                                                                                                  |
| xip_list | Active <b>txids</b> at the time of the snapshot. The list includes only those active <b>txids</b> between <b>xmin</b> and <b>xmax</b> ; there might be active <b>txids</b> higher than <b>xmax</b> . A <b>txid</b> that is greater than or equal to <b>xmin</b> and less than <b>xmax</b> and that is not in this list was already completed at the time of the snapshot, and is either visible or rolled back according to its commit status. The list does not include <b>txids</b> of subtransactions. |

The textual representation of **txid\_snapshot** is **xmin:xmax:xip\_list**.

For example, **10:20:10,14,15** means **xmin=10, xmax=20, xip\_list=10, 14, 15**.

The following functions provide server transaction information in an exportable form. These functions are mainly used to determine which transactions were committed between two snapshots.

- **pgxc\_is\_committed(transaction\_id)**  
Description: Specifies whether the given XID is committed or ignored. **NULL** indicates the unknown status (it can be running, ready, frozen, or other status).  
Return type: Boolean

- `txid_current()`  
Description: Obtains the current XID.  
Return type: `bigint`
- `gs_txid_oldestxmin()`  
Description: Obtains the minimum XID (specified by **oldestxmin**).  
Return type: `bigint`
- `txid_current_snapshot()`  
Description: Obtains the current snapshot.  
Return type: `txid_snapshot`
- `txid_snapshot_xip(txid_snapshot)`  
Description: Obtains in-progress XIDs in a snapshot.  
Return type: `setof bigint`
- `txid_snapshot_xmax(txid_snapshot)`  
Description: Obtains **xmax** of snapshots.  
Return type: `bigint`
- `txid_snapshot_xmin(txid_snapshot)`  
Description: Obtains **xmin** of snapshots.  
Return type: `bigint`
- `txid_visible_in_snapshot(bigint, txid_snapshot)`  
Description: Specifies whether the XID is visible in a snapshot (do not use subtransaction IDs).  
Return type: `Boolean`
- `get_local_prepared_xact()`  
Description: Obtains the two-phase residual transaction information of the current node, including the XID, GID of the two-phase transaction, prepared time, owner OID, database OID, and node name of the current node.  
Return type: `xid, text, timestamptz, oid, oid, text`
- `get_remote_prepared_xacts()`  
Description: Obtains the two-phase residual transaction information of all remote nodes, including the XID, GID of the two-phase transaction, prepared time, owner name, database name, and node name.  
Return type: `xid, text, timestamptz, name, name, text`
- `global_clean_prepared_xacts(text, text)`  
Description: Concurrently cleans two-phase residual transactions. Only the `gs_clean` tool can call this function for cleaning. In other situations, **false** is returned.  
Return type: `Boolean`
- `pgxc_stat_get_wal_senders()`  
Description: Returns the sent logs of all primary DN's and the received logs of their corresponding standby DN's in the cluster. Only users with the **system admin** or **monitor admin** permission can use this function.  
The output is as follows:

**Table 7-55** pgxc\_stat\_get\_wal\_senders parameter description

| Field                      | Description                                                                                                                                                                                       |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nodename                   | Instance name                                                                                                                                                                                     |
| sender_pid                 | PID of the thread for sending logs                                                                                                                                                                |
| local_role                 | Instance role                                                                                                                                                                                     |
| peer_role                  | Role of the instance on the receiver                                                                                                                                                              |
| peer_state                 | Status of the instance on the receiver                                                                                                                                                            |
| state                      | Synchronization status between instances                                                                                                                                                          |
| sender_sent_location       | Location where the sender sends logs                                                                                                                                                              |
| sender_write_location      | Location where the sender writes logs                                                                                                                                                             |
| sender_flush_location      | Location where the sender flushes logs to disks                                                                                                                                                   |
| sender_replay_location     | Location of the instance logs. If the DN is a primary DN, the location is the value of <b>sender_flush_location</b> . Otherwise, the location where the current instance log is replayed is used. |
| receiver_received_location | Location where the receiver receives logs                                                                                                                                                         |
| receiver_write_location    | Location where the receiver writes logs                                                                                                                                                           |
| receiver_flush_location    | Location where the receiver flushes logs to disks                                                                                                                                                 |
| receiver_replay_location   | Location where the receiver replays logs                                                                                                                                                          |

- `pgxc_stat_get_wal_senders_status()`  
Description: Returns the receiving status of transaction logs on all nodes. Only users with the **system admin** or **monitor admin** permission can use this function.

The return values are as follows:

**Table 7-56** pgxc\_stat\_get\_wal\_senders\_status parameter description

| Field     | Description                    |
|-----------|--------------------------------|
| nodename  | Name of the primary node       |
| source_ip | IP address of the primary node |

| Field                      | Description                            |
|----------------------------|----------------------------------------|
| source_port                | Port of the primary node               |
| dest_ip                    | IP address of the standby node         |
| dest_port                  | Port of the standby node               |
| sender_pid                 | PID of the sending thread              |
| local_role                 | Type of the primary node               |
| peer_role                  | Type of the standby node               |
| peer_state                 | Status of the standby node             |
| state                      | WAL sender status                      |
| sender_sent_location       | Sending position of the primary node   |
| sender_write_location      | Writing position of the primary node   |
| sender_replay_location     | Redo position of the primary node      |
| receiver_received_location | Receiving position of the standby node |
| receiver_write_location    | Writing position of the standby node   |
| receiver_flush_location    | Flushing location of the standby node  |
| receiver_replay_location   | Redo location of the standby node      |

- `gs_get_next_xid_csn()`  
Description: Returns the values of **next\_xid** and **next\_csn** on all nodes globally.  
The return values are as follows:

**Table 7-57** `gs_get_next_xid_csn` parameter description

| Field    | Description                                     |
|----------|-------------------------------------------------|
| nodename | Node name                                       |
| next_xid | ID of the next transaction on the current node. |
| next_csn | Next CSN of the current node.                   |

- `pg_control_system()`  
Description: Returns the status of the system control file.  
Return type: SETOF record
- `pg_control_checkpoint()`  
Description: Returns the system checkpoint status.  
Return type: SETOF record

- `get_prepared_pending_xid`  
Description: Returns **nextxid** when restoration is complete.  
Parameter: nan  
Return type: text
- `pg_clean_region_info`  
Description: Clears the region map.  
Parameter: nan  
Return type: character varying
- `pg_get_replication_slot_name`  
Description: Obtains the slot name.  
Parameter: nan  
Return type: text
- `pg_get_running_xacts`  
Description: Obtains running **xact**.  
Parameter: nan  
Return type: handle integer, gxid xid, state tinyint, node text, xmin xid, vacuum boolean, timeline bigint, prepare\_xid xid, pid bigint, next\_xid xid
- `pg_get_variable_info`  
Description: Obtains the shared memory variable cache.  
Parameter: nan  
Return type: node\_name text, nextOid oid, nextXid xid, oldestXid xid, xidVacLimit xid, oldestXidDB oid, lastExtendCSNLogpage xid, startExtendCSNLogpage xid, nextCommitSeqNo xid, latestCompletedXid xid, and startupMaxXid xid
- `pg_get_xidlimit`  
Description: Obtains XID information from the shared memory.  
Parameter: nan  
Return type: nextXid xid, oldestXid xid, xidVacLimit xid, xidWarnLimit xid, xidStopLimit xid, xidWrapLimit xid, oldestXidDB oid
- `pg_relation_compression_ratio`  
Description: Queries the compression rate of a table. By default, **1.0** is returned.  
Parameter: text  
Return type: real
- `pg_relation_with_compression`  
Description: Specifies whether a table is compressed.  
Parameter: text  
Return type: Boolean
- `pg_stat_file_recursive`  
Description: Lists all files in a path.  
Parameter: location text  
Return type: path text, filename text, size bigint, isdir boolean

- `pg_stat_get_activity_for temptable`  
Description: Returns records of backend processes related to the temporary table.  
Parameter: nan  
Return type: `datid oid`, `timelineid integer`, `tempid integer`, and `sessionid bigint`
- `pg_stat_get_activity_ng`  
Description: Returns records of background processes related to the node group.  
Parameter: `pid bigint`  
Return type: `datid oid`, `pid bigint`, `sessionid bigint`, and `node_group text`
- `pg_stat_get_cgroup_info`  
Description: Returns Cgroup information.  
Parameter: nan  
Return type: `cgroup_name text`, `percent integer`, `usage_percent integer`, `shares bigint`, `usage bigint`, `cpuset text`, `relpath text`, `valid text`, `node_group text`
- `pg_stat_get_realtime_info_internal`  
Description: Returns real-time information. Currently, this API is unavailable. **FailedToGetSessionInfo** is returned.  
Parameter: `oid, oid, bigint, cstring, oid`  
Return type: `text`
- `pg_stat_get_session_wlmstat`  
Description: Returns the load information of the current session.  
Parameter: `pid integer`  
Return type: `datid oid`, `threadid bigint`, `sessionid bigint`, `threadpid integer`, `usesysid oid`, `appname text`, `query text`, `priority bigint`, `block_time bigint`, `elapsed_time bigint`, `total_cpu_time bigint`, `skew_percent integer`, `statement_mem integer`, `active_points integer`, `dop_value integer`, `current_cgroup text`, `current_status text`, `enqueue_state text`, `attribute text`, `is_plana boolean`, `node_group text`, `srespool name`
- `pg_stat_get_wlm_instance_info`  
Description: Returns the load information of the current instance.  
Parameter: nan  
Return type: `instancename text`, `timestamp`, `timestamp with time zone`, `used_cpu integer`, `free_memory integer`, `used_memory integer`, `io_await double precision`, `io_util double precision`, `disk_read double precision`, `disk_write double precision`, `process_read bigint`, `process_write bigint`, `logical_read bigint`, `logical_write bigint`, `read_counts bigint`, `write_counts bigint`
- `pg_stat_get_wlm_instance_info_with_cleanup`  
Description: Returns the load information of the current instance and saves the information to the system catalog.  
Parameter: nan  
Return type: `instancename text`, `timestamp`, `timestamp with time zone`, `used_cpu integer`, `free_memory integer`, `used_memory integer`, `io_await double precision`, `io_util double precision`, `disk_read double precision`, `disk_write`

double precision, process\_read bigint, process\_write bigint, logical\_read bigint, logical\_write bigint, read\_counts bigint, write\_counts bigint

- pg\_stat\_get\_wlm\_node\_resource\_info

Description: Obtains the resource information of the current node.

Parameter: nan

Return type: min\_mem\_util integer, max\_mem\_util integer, min\_cpu\_util integer, max\_cpu\_util integer, min\_io\_util integer, max\_io\_util integer, used\_mem\_rate integer

- pg\_stat\_get\_wlm\_operator\_info

Description: Obtains the operator information of the execution plan from the internal hash table.

Parameter: nan

Return type: queryid bigint, pid bigint, plan\_node\_id integer, plan\_node\_name text, start\_time timestamp with time zone, duration bigint, query\_dop integer, estimated\_rows bigint, tuple\_processed bigint, min\_peak\_memory integer, max\_peak\_memory integer, average\_peak\_memory integer, memory\_skew\_percent integer, min\_spill\_size integer, max\_spill\_size integer, average\_spill\_size integer, spill\_skew\_percent integer, min\_cpu\_time bigint, max\_cpu\_time bigint, total\_cpu\_time bigint, cpu\_skew\_percent integer, warning text

- pg\_stat\_get\_wlm\_realtime\_operator\_info

Description: Obtains the operator information of the real-time execution plan from the internal hash table.

Parameter: nan

Return type: queryid bigint, pid bigint, plan\_node\_id integer, plan\_node\_name text, start\_time timestamp with time zone, duration bigint, status text, query\_dop integer, estimated\_rows bigint, tuple\_processed bigint, min\_peak\_memory integer, max\_peak\_memory integer, average\_peak\_memory integer, memory\_skew\_percent integer, min\_spill\_size integer, max\_spill\_size integer, average\_spill\_size integer, spill\_skew\_percent integer, min\_cpu\_time bigint, max\_cpu\_time bigint, total\_cpu\_time bigint, cpu\_skew\_percent integer, warning text

- pg\_stat\_get\_wlm\_realtime\_session\_info

Description: Returns the load information of the real-time session.

Parameter: nan

Return type: nodename text, threadid bigint, block\_time bigint, duration bigint, estimate\_total\_time bigint, estimate\_left\_time bigint, schemaname text, query\_band text, spill\_info text, control\_group text, estimate\_memory integer, min\_peak\_memory integer, max\_peak\_memory integer, average\_peak\_memory integer, memory\_skew\_percent integer, min\_spill\_size integer, max\_spill\_size integer, average\_spill\_size integer, spill\_skew\_percent integer, min\_dn\_time bigint, max\_dn\_time bigint, average\_dn\_time bigint, dntime\_skew\_percent integer, min\_cpu\_time bigint, max\_cpu\_time bigint, total\_cpu\_time bigint, cpu\_skew\_percent integer, min\_peak\_iops integer, max\_peak\_iops integer, average\_peak\_iops integer, iops\_skew\_percent integer, warning text, query text, query\_plan text, cpu\_top1\_node\_name text, cpu\_top2\_node\_name text, cpu\_top3\_node\_name text, cpu\_top4\_node\_name text, cpu\_top5\_node\_name text, mem\_top1\_node\_name text,

mem\_top2\_node\_name text, mem\_top3\_node\_name text,  
mem\_top4\_node\_name text, mem\_top5\_node\_name text, cpu\_top1\_value  
bigint, cpu\_top2\_value bigint, cpu\_top3\_value bigint, cpu\_top4\_value bigint,  
cpu\_top5\_value bigint, mem\_top1\_value bigint, mem\_top2\_value bigint,  
mem\_top3\_value bigint, mem\_top4\_value bigint, mem\_top5\_value bigint,  
top\_mem\_dn text, top\_cpu\_dn text

- `pg_stat_get_wlm_session_info_internal`  
Description: Returns the session load information.  
Parameter: oid, bigint, bigint, oid  
Return type: SETOF text
- `pg_stat_get_wlm_session_iodstat_info`  
Description: Returns the session load I/O information.  
Parameter: nan  
Return type: threadid bigint, maxcurr\_iops integer, mincurr\_iops integer,  
maxpeak\_iops integer, minpeak\_iops integer, iops\_limits integer, io\_priority  
integerw, and curr\_io\_limits integer
- `pg_stat_get_wlm_statistics`  
Description: Returns session load statistics.  
Parameter: nan  
Return type: statement text, block\_time bigint, elapsed\_time bigint,  
total\_cpu\_time bigint, qualification\_time bigint, skew\_percent integer,  
control\_group text, status text, action text
- `pg_test_err_contain_err`  
Description: Tests the error type and return information.  
Parameter: integer  
Return type: void
- `pv_session_memory_detail_tp`  
Description: Returns the memory usage of the session. For details, see  
**pv\_session\_memory\_detail**.  
Parameter: nan  
Return type: sessid text, sesstype text, contextname text, level smallint, parent  
text, totalsize bigint, freesize bigint, usedsize bigint
- `gs_get_table_distribution`  
Description: Returns the distribution of table data on each DN.  
Parameter: table\_name text, schema\_name text  
Return type: text
- `pv_builtin_functions`  
Description: Displays information about all built-in system functions.  
Parameter: nan  
Return type: proname name, pronamespace oid, proowner oid, prolang oid,  
procost real, prorows real, provariadic oid, protransform regproc, proisagg  
boolean, proiswindow boolean, proscdef boolean, proleakproof boolean,  
proisstrict boolean, proretset boolean, provolatile "char", pronargs smallint,  
pronargdefaults smallint, prorettype oid, proargtypes oidvector, proallargtypes

integer[], proargmodes "char"[], proargnames text[], proargdefaults pg\_node\_tree, prosrc text, probin text, proconfig text[], proacl aclitem[], prodefaultargpos int2vector, fencedmode boolean, proshippable boolean, propackage boolean, oid oid

- `pv_thread_memory_detail`

Description: Returns the memory information of each thread.

Parameter: nan

Return type: threadid text, tid bigint, thrdtype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint

- `pg_shared_memory_detail`

Description: Returns usage information about all generated shared memory contexts. For details about each column, see [SHARED\\_MEMORY\\_DETAIL](#).

Parameter: nan

Return type: contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint

- `pgxc_get_running_xacts`

Description: Returns information about running transactions on each node in the cluster. The field content is the same as that in [PGXC\\_RUNNING\\_XACTS](#). Only users with the system admin or monitor admin permission can view the information.

Parameter: nan

Return type: SETOF record

- `pgxc_snapshot_status()`

Description: Returns the status of key memory information in the GTM in GTM mode for fault locating. GTM-Free and GTM-Lite do not support this function.

Parameter: nan

Return type: xmin xid, xmax xid, xcnt int, oldestxmin xid, next\_xid xid, timeline int, active\_thread\_num int, max\_active\_thread\_num int, snapshot\_num int, snapshot\_totalsize bigint

The return values are described as follows:

**Table 7-58** `get_gtm_lite_status` return parameters

| Field      | Description                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------|
| xmin       | Minimum active XID in the GTM.                                                                                      |
| xmax       | Largest XID committed in the GTM plus 1. Transactions whose IDs are greater than or equal to this value are active. |
| xcnt       | Number of active transactions in the GTM.                                                                           |
| oldestxmin | ID of the earliest accessed transaction in the GTM.                                                                 |
| next_xid   | ID of the next transaction allocated by the GTM.                                                                    |

| Field                 | Description                                                     |
|-----------------------|-----------------------------------------------------------------|
| timeline              | Current time line in the GTM.                                   |
| active_thread_num     | Number of active worker threads in the GTM.                     |
| max_active_thread_num | Peak number of worker threads in the GTM within one minute.     |
| snapshot_num          | Number of snapshots delivered by the GTM within one minute.     |
| snapshot_totalsize    | Total size of snapshots delivered by the GTM within one minute. |

- get\_gtm\_lite\_status()**  
 Description: Returns the backup XID and CSN in the GTM for fault locating. This system function is not supported in GTM-Free mode.  
 The return values are as follows:

**Table 7-59** get\_gtm\_lite\_status parameter description

| Field      | Description                   |
|------------|-------------------------------|
| backup_xid | Backup XID in the GTM.        |
| csn        | Latest CSN issued by the GTM. |

- adm\_hist\_snapshot\_func()**  
 Description: Returns information about the snapshot execution time. To access this function, set the **enable\_wdr\_snapshot** parameter to **on** and obtain the permission to access the **snapshot schema**, **snapshot table**, and **tables\_snap\_timestamp** tables.  
 Parameter: nan  
 Return type: snap\_id bigint, dbid oid, begin\_interval\_time timestamp(3), end\_interval\_time timestamp(3), flush\_elapsed interval day(5) to second(1), begin\_interval\_time\_tz timestamp(3) with time zone, end\_interval\_time\_tz timestamp(3) with time zone
- global\_sql\_patch\_func()**  
 Description: SQL patch information on each global node, which is used to return the result of the global\_sql\_patch view.  
 The output is as follows:

**Table 7-60** global\_sql\_patch\_func return parameters

| Name       | Type | Description                                      |
|------------|------|--------------------------------------------------|
| node_name  | text | Name of the node where the SQL patch is located. |
| patch_name | name | Patch name.                                      |

| Name                 | Type    | Description                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| unique_sql_id        | bigint  | Global unique query ID.                                                                                                                                                                                                                                                                                                                 |
| owner                | oid     | ID of the user who creates the patch.                                                                                                                                                                                                                                                                                                   |
| enable               | boolean | Determines whether the patch takes effect.                                                                                                                                                                                                                                                                                              |
| status               | "char"  | Patch status (reserved field).                                                                                                                                                                                                                                                                                                          |
| abort                | boolean | Determines whether the value is <b>AbortHint</b> .                                                                                                                                                                                                                                                                                      |
| hint_string          | text    | Hint text.                                                                                                                                                                                                                                                                                                                              |
| description          | text    | Patch description.                                                                                                                                                                                                                                                                                                                      |
| parent_unique_sql_id | bigint  | Globally unique ID of the outer statement of the SQL statement for which the patch takes effect. The value of this parameter is <b>0</b> for statements outside a stored procedure. For statements inside the stored procedure, the value of this parameter is the globally unique ID of the statement that calls the stored procedure. |

- gs\_get\_current\_version()**  
 Description: Returns the current compilation mode based on the current compilation macro. **'M'** is returned.  
 Parameter: nan  
 Return type: char
- gs\_get\_kernel\_info()**  
 Description: Global transaction information on each primary CN and DN.  
 The return values are as follows:

**Table 7-61** gs\_get\_kernel\_info parameter description

| Name      | Type | Description |
|-----------|------|-------------|
| node_name | text | Node name.  |

| Name   | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## 7.5.25 System Administration Functions

### 7.5.25.1 Configuration Settings Functions

Configuration setting functions are used for querying and modifying configuration parameters during running.

- `current_setting(setting_name)`

Description: Specifies the current setting.

Return type: text

Note: **current\_setting** obtains the current setting of **setting\_name** by query. It is equivalent to the **SHOW** statement. For example:

```
gaussdb=# SELECT current_setting('datestyle');
```

```
current_setting

ISO, MDY
(1 row)
```

- `set_working_grand_version_num_manually(tmp_version)`

Description: Upgrades new features of GaussDB by switching the authorization version.

Return type: void

- `shell_in(type)`

Description: Inputs a route for the shell type that has not yet been filled.

Return type: void

- `shell_out(type)`

Description: Outputs a route for the shell type that has not yet been filled.

Return type: void

- `set_config(setting_name, new_value, is_local)`

Description: Sets the parameter and returns a new value.

Return type: text

Note: **set\_config** sets the parameter **setting\_name** to **new\_value**. If **is\_local** is **true**, **new\_value** will only apply to the current transaction. If you want **new\_value** to apply to the current session, use **false** instead. This function is equivalent to the SQL statement SET.

Example:

```
gaussdb=# SELECT set_config('log_statement_stats', 'off', false);

 set_config

 off
(1 row)
```

## 7.5.25.2 Universal File Access Functions

Universal file access functions provide local access APIs for files on a database server. Only files in the database cluster directory and the **log\_directory** directory can be accessed. A relative path is used for files in the cluster directory, and a path matching the **log\_directory** configuration is used for log files. Only database initialization users can use these functions.

- **pg\_ls\_dir**(dirname text)

Description: Lists files in a directory.

Return type: setof text

Note: **pg\_ls\_dir** returns all the names in the specified directory, except the special entries "." and "..".

Example:

```
gaussdb=# SELECT pg_ls_dir('./');
 pg_ls_dir

 .postgresql.conf.swp
 postgresql.conf
 pg_tblspc
 PG_VERSION
 pg_ident.conf
 core
 server.crt
 pg_serial
 pg_twophase
 postgresql.conf.lock
 pg_stat_tmp
 pg_notify
 pg_subtrans
 pg_ctl.lock
 pg_xlog
 pg_clog
 base
 pg_snapshots
 postmaster.opts
 postmaster.pid
 server.key.rand
 server.key.cipher
 pg_multixact
 pg_errorinfo
 server.key
 pg_hba.conf
 pg_replslot
 .pg_hba.conf.swp
 cacert.pem
 pg_hba.conf.lock
 global
 gaussdb.state
(32 rows)
```

- `pg_read_file(filename text, offset bigint, length bigint)`

Description: Returns the content of a text file.

Return type: text

Note: `pg_read_file` returns part of a text file. It can return a maximum of *length* bytes from *offset*. The actual size of fetched data is less than *length* if the end of the file is reached first. If *offset* is negative, it is the length rolled back from the file end. If *offset* and *length* are omitted, the entire file is returned.

Example:

```
gaussdb=# SELECT pg_read_file('postmaster.pid',0,100);
 pg_read_file
```

```

53078 +
/srv/BigData/testdir/data1/coordinator+
1500022474 +
8000 +
/var/run/FusionInsight +
localhost +
2
(1 row)
```

- `pg_read_binary_file(filename text [, offset bigint, length bigint,missing_ok boolean])`

Description: Returns the content of a binary file.

Return type: bytea

Note: `pg_read_binary_file` is similar to `pg_read_file`, except that the result is a **bytea** value; accordingly, no encoding checks are performed. In combination with the `convert_from` function, this function can be used to read a file in a specified encoding.

```
gaussdb=# SELECT convert_from(pg_read_binary_file('filename'), 'UTF8');
```

- `pg_stat_file(filename text)`

Description: Returns status information about a file.

Return type: record

Note: `pg_stat_file` returns a record containing the file size, last access timestamp, last modification timestamp, last file status change timestamp, and a **Boolean** value indicating if it is a directory. Typical usages are as follows:

```
gaussdb=# SELECT * FROM pg_stat_file('filename');
gaussdb=# SELECT (pg_stat_file('filename')).modification;
```

Example:

```
gaussdb=# SELECT convert_from(pg_read_binary_file('postmaster.pid'), 'UTF8');
 convert_from
```

```

4881 +
/srv/BigData/gaussdb/data1/coordinator+
1496308688 +
25108 +
/opt/huawei/Bigdata/gaussdb/gaussdb_tmp +
* +
25108001 43352069 +
```

(1 row)

```
gaussdb=# SELECT * FROM pg_stat_file('postmaster.pid');
```

```
size | access | modification | change
| creation | isdir
```

when **redirect\_stderr** is used for log output. Otherwise, no log file manager subprocess is generated.

- `pg_terminate_session(pid bigint, sessionid bigint)`

Description: Terminates a backend session in thread pool mode.

Return type: Boolean

Note: The input parameters of this function can be queried using the **pid** and **sessionid** fields in **pg\_stat\_activity**. A user with the SYSADMIN permission, the owner of the database connected to the session, the owner of the session, or a user who inherits the built-in role permission `gs_role_signal_backend` has the permission to use this function. If the target session fails to be terminated after this function is executed, the socket connection between the session and the client is forcibly closed.

---

#### NOTICE

When the input parameters **pid** and **sessionid** are the same and both are thread IDs, this function can terminate non-thread pool threads and active thread pool threads.

When the input parameters **pid** and **sessionid** are different, this function can terminate active sessions or close inactive sessions and the socket connection of the client.

- 
- `pg_terminate_active_session_socket(pid int64, sessionid int64)`

Description: Closes the socket connection between an active session and the client.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the SYSADMIN permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits the built-in role permission `gs_role_signal_backend` has the permission to use this function.

- `pg_terminate_backend(pid int)`

Description: Terminates a backend thread.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the SYSADMIN permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits the built-in role permission `gs_role_signal_backend` can use this function. If the target session fails to be terminated after this function is executed, the socket connection between the session and the client is forcibly closed.

---

#### NOTICE

This function can terminate non-thread pool threads and active thread pool threads, but cannot terminate inactive thread pool threads.

---

Example:

```
gaussdb=# SELECT pid from pg_stat_activity;
 pid

140657876268816
(1 rows)

## 7.5.25.4 Backup and Restoration Control Functions

### Backup Control Functions

Backup control functions help with online backup.

- `pg_create_restore_point(name text)`

Description: Creates a named point for performing the restoration operation (restricted to the system administrator).

Return type: text

Note: **pg\_create\_restore\_point** creates a named transaction log record that can be used as a restoration target, and returns the corresponding transaction log location. The given name can then be used with **recovery\_target\_name** to specify the point up to which restoration will proceed. Avoid creating multiple restoration points with the same name, since restoration will stop at the first one whose name matches the restoration target.

- `pg_current_xlog_location()`

Description: Obtains the write position of the current transaction log.

Return type: text

Note: **pg\_current\_xlog\_location** displays the write position of the current transaction log in the same format as those of the previous functions. Read-only operations do not require permissions of the system administrator.

- `pg_current_xlog_insert_location()`

Description: Obtains the insert position of the current transaction log.

Return type: text

Note: **pg\_current\_xlog\_insert\_location** displays the insert position of the current transaction log. The insertion point is the logical end of the transaction log at any instant, while the write location is the end of what has been written out from the server's internal buffers. The write position is the end that can be detected externally from the server. This operation can be performed to archive only some of completed transaction log files. The insert position is mainly used for commissioning the server. Read-only operations do not require permissions of the system administrator.

- `gs_current_xlog_insert_end_location()`

Description: Obtains the insert position of the current transaction log.

Return type: text

Note: **gs\_current\_xlog\_insert\_end\_location** displays the insert position of the current transaction log.

- pg\_start\_backup(label text[, fast boolean ])**

Description: Starts to perform online backup. (An administrator, replication role, or O&M administrator must enable **operation\_mode**.) Label strings starting with **gs\_roach** are reserved and can be used only by the internal backup tool GaussRoach.

Return type: text

Note: **pg\_start\_backup** receives a user-defined backup label (usually the name of the position where the backup dump file is stored). This function writes a backup label file to the data directory of the database cluster and then returns the starting position of backed up transaction logs in text mode.

```
gaussdb=# SELECT pg_start_backup('label_goes_here',true);
pg_start_backup

0/3000020
(1 row)
```
- pg\_stop\_backup()**

Description: Completes online backup An administrator, replication role, or O&M administrator must enable **operation\_mode**.

Return type: text

Note: **pg\_stop\_backup** deletes the label file created by **pg\_start\_backup** and creates a backup history file in the transaction log archive area. The history file includes the label given to **pg\_start\_backup**, the start and end transaction log locations for the backup, and the start and end time of the backup. The return value is the backup's ending transaction log location. After the end position is calculated, the insert position of the current transaction log automatically goes ahead to the next transaction log file. The ended transaction log file can be immediately archived so that backup is complete.
- pg\_switch\_xlog()**

Description: Switches to a new transaction log file An administrator or O&M administrator must enable **operation\_mode**.

Return type: text

Note: **pg\_switch\_xlog** moves to the next transaction log file so that the current log file can be archived (if continuous archive is used). The return value is the ending transaction log location + 1 within the just-completed transaction log file. If there has been no transaction log activity since the last transaction log switchover, **pg\_switch\_xlog** does not move but returns the start location of the transaction log file currently in use.
- pg\_xlogfile\_name(location text)**

Description: Converts the position string in a transaction log to a file name.

Return type: text

Note: **pg\_xlogfile\_name** extracts only the transaction log file name. If the given transaction log position is the transaction log file border, a transaction log file name will be returned for both the two functions. This is usually the desired behavior for managing transaction log archiving, since the preceding file is the last one that currently needs to be archived.
- pg\_xlogfile\_name\_offset(location text)**

Description: Converts the position string in a transaction log to a file name and returns the byte offset in the file.

Return type: text, integer

Note: **pg\_xlogfile\_name\_offset** can extract transaction log file names and byte offsets from the returned results of the preceding functions. Example:

```
gaussdb=# SELECT * FROM pg_xlogfile_name_offset(pg_stop_backup());
NOTICE: pg_stop_backup cleanup done, waiting for required WAL segments to be archived
NOTICE: pg_stop_backup complete, all required WAL segments have been archived
 file_name | file_offset
-----+-----
000000010000000000000003 | 272
(1 row)
```

- **pg\_xlog\_location\_diff**(location text, location text)  
Description: Calculates the difference in bytes between two transaction log locations.  
Return type: numeric
- **pg\_cbm\_start\_tracked\_location**()  
Description: Queries the start LSN parsed by CBM.  
Return type: text
- **pg\_cbm\_tracked\_location**()  
Description: Queries the LSN location parsed by CBM.  
Return type: text
- **pg\_cbm\_get\_merged\_file**(startLSNArg text, endLSNArg text)  
Description: Combines CBM files within the specified LSN range into one and returns the name of the combined file.  
Return type: text  
Note: Only the system administrator or O&M administrator can obtain the CBM combination file.
- **pg\_cbm\_get\_changed\_block**(startLSNArg text, endLSNArg text)  
Description: Combines CBM files within the specified LSN range into a table and return records of this table.  
Return type: record  
Note: The table columns returned by **pg\_cbm\_get\_changed\_block** include the start LSN, end LSN, tablespace OID, database OID, table relfilenode, table fork number, whether the table is a system catalog, whether the table is deleted, whether the table is created, whether the table is truncated, number of pages in the truncated table, number of modified pages, and list of modified page numbers.
- **pg\_cbm\_recycle\_file**(targetLSNArg text)  
Description: Deletes the CBM files that are no longer used and returns the first LSN after the deletion.  
Return type: text
- **pg\_cbm\_force\_track**(targetLSNArg text, timeOut int)  
Description: Forcibly executes the CBM trace to the specified Xlog position and returns the Xlog position of the actual trace end point.  
Return type: text
- **pg\_enable\_delay\_ddl\_recycle**()  
Description: Enables DDL delay and returns the Xlog position of the enabling point. An administrator or O&M administrator must enable **operation\_mode**.  
Return type: text

- `pg_disable_delay_ddl_recycle(barrierLSNArg text, isForce bool)`  
Description: Disables DDL delay and returns the Xlog range where DDL delay takes effect. An administrator or O&M administrator must enable **operation\_mode**.  
Return type: record
- `pg_enable_delay_xlog_recycle()`  
Description: Enables the Xlog recycling delay function for CN recovery. An administrator or O&M administrator must enable **operation\_mode**.  
Return type: void
- `pg_disable_delay_xlog_recycle()`  
Description: Disables the Xlog recycling delay function for CN recovery. An administrator or O&M administrator must enable **operation\_mode**.  
Return type: void
- `pg_cbm_rotate_file(rotate_lsn text)`  
Description: Forcibly switches the file after the CBM parses **rotate\_lsn**. This function is called during the build process.  
Return type: void
- `gs_roach_stop_backup(backupid text)`  
Description: Stops a backup started by the internal backup tool GaussRoach. It is similar to the **pg\_stop\_backup system** function but is more lightweight.  
Return type: text. The content is the insertion position of the current log.
- `gs_roach_enable_delay_ddl_recycle(backupid name)`  
Description: Enables DDL delay and returns the log location of the enabling point. It is similar to the **pg\_enable\_delay\_ddl\_recycle** system function but is more lightweight. In addition, different **backupid** values can be used to concurrently open DDL statements with delay.  
Return type: text. The content is the log location of the start point.
- `gs_roach_disable_delay_ddl_recycle(backupid text)`  
Description: Disables DDL delay, returns the range of logs on which DDL delay takes effect. It is similar to the **pg\_enable\_delay\_ddl\_recycle** system function but is more lightweight. In addition, the DDL delay function can be disabled concurrently by specifying different backupid values.  
Return type: record. The content is the range of logs for which DDL is delayed to take effect.
- `gs_roach_switch_xlog(request_ckpt bool)`  
Description: Switches the currently used log segment file and triggers a full checkpoint if **request\_ckpt** is set to **true**.  
Return type: text. The content is the location of the segment log.
- `gs_block_dw_io(timeout int, identifier text)`  
Description: Blocks doublewrite page flushing.  
Parameter description:
  - `timeout`  
Block duration.  
Value range: [0,3600], in seconds. The value **0** indicates that the block duration is 0s.

- identifier  
ID of the operation.  
Value range: a string, supporting only uppercase letters, lowercase letters, digits, and underscores (\_).

Return type: Boolean

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**.

- `gs_is_dw_io_blocked()`

Description: Checks whether disk flushing on the current doublewrite page is blocked. If disk flushing is blocked, **true** is returned.

Return type: Boolean

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**.

- `gs_pitr_advance_last_updated_barrier()`

Description: In PITR mode, forcibly pushes the global maximum archived recovery point uploaded to OBS/NAS last time to the current point. No input parameter is required.

Return type: text

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**. This parameter is valid only on the first normal CN in a distributed system. The return value is the latest local maximum archived recovery point.

- `gs_pitr_clean_local_barrier_files('delete_timestamp')`

Description: Clears locally cached barrier record files.

Value range: The **delete\_timestamp** parameter is of the text type. It is a Linux timestamp and contains 10 characters.

Return type: text

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**. The returned result is the start timestamp of the earliest barrier file on the local host after the deletion.

- `gs_get_barrier_lsn(barrier_name text)`

Description: Obtains the LSN corresponding to the barrier created using a backup.

Return type: text

Note: Currently, only **gs\_roach\_full** and **gs\_roach\_inc** are supported. To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**.

- `gs_gbr_relation_associated_filenode(schemaName name, tableName name)`

Description: Returns the relfilenode of all indexes, sequences, partitions, TOASTs, and TOAST indexes related to the input table.

Return type: record

Note: The table columns returned by `gs_gbr_relation_associated_filenode` include the file type relkind, namespace where the file is located, relation name corresponding to the file, OID of the database where the file is located, OID of the tablespace where the file is located, and relfilenode of the file.

- `pg_create_physical_replication_slot_extern(slotname text, dummy_standby bool, extra_content text, need_recycle_xlog bool)`

### NOTICE

Value range of **slotname**: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name. You are advised to use an alphabetic character string as the archive slot name, and the length cannot exceed 64 characters.

Description: Creates an OBS or a NAS archive slot. **slotname** indicates the name of the archive slot or recovery slot. The primary and standby slots must use the same slot name. **dummy\_standby** is a reserved parameter.

**extra\_content** contains some information about the archive slot. For an OBS archive slot, the format is

**OBS;obs\_server\_ip;obs\_bucket\_name;obs\_ak;obs\_sk;archive\_path;is\_recovery;is\_vote\_replicate**, in which **OBS** indicates the archive media of the archive slot, **obs\_server\_ip** indicates the IP address of OBS, **obs\_bucket\_name** indicates the bucket name, **obs\_ak** indicates the AK of OBS, **obs\_sk** indicates the SK of OBS, **archive\_path** indicates the archive path, and **is\_recovery** specifies whether the slot is an archive slot or a recovery slot (**0**: archive slot; **1**: recovery slot). **is\_vote\_replicate** specifies whether the voting copy is archived first. The value **0** indicates that the synchronous standby server is archived first, and the value **1** indicates that the voting copy is archived first.

This column is reserved in the current version and is not adapted yet. For a NAS archive slot, the format is

**NAS;archive\_path;is\_recovery;is\_vote\_replicate**. Compared with the OBS archive slot, the NAS archive slot does not have the OBS configuration information, while the meanings of other fields are the same.

If the media is not OBS or NAS, the OBS archive slot is used by default. The **extra\_content** format is

**obs\_server\_ip;obs\_bucket\_name;obs\_ak;obs\_sk;archive\_path;is\_recovery;is\_vote\_replicate**.

**need\_recycle\_xlog** specifies whether to recycle old archived logs when creating an archive slot. The value **true** indicates that old archived logs are recycled, and the value **false** indicates that old archive logs are not recycled.

Return type: record contains slotname and xlog\_position

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role. Currently, multiple archive slots cannot be created.

Examples:

Create an OBS archive slot.

```
gaussdb=# SELECT * FROM pg_create_physical_replication_slot_extern('uuid', false, 'OBS;obs.cn-north-7.ulanqab.huawei.com;dyk;19D772JBCACXX3KWS51D;*****;gaussdb_uuid/dn1;0;0', false);
 slotname | xlog_position
```

```
-----+-----
 uuid |
(1 row)
```

Create a NAS archive slot.

```
gaussdb=# SELECT * FROM pg_create_physical_replication_slot_extern('uuid', false, 'NAS:/data/nas/
media/gaussdb_uuid/dn1;0;0', false);
 slotname | xlog_position
-----+-----
 uuid |
```

- `gs_set_obs_delete_location(delete_location text)`

Description: Sets the location where OBS archive logs can be deleted. The value of **delete\_location** is an LSN. The logs before this location have been replayed and flushed to disks and can be deleted on OBS.

Return type: `xlog_file_name` text, indicating the file name of the logs that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

```
gaussdb=# SELECT gs_set_obs_delete_location('0/54000000');
 gs_set_obs_delete_location

0000000100000000000000054_00
(1 row)
```

- `gs_set_obs_delete_location_with_slotname(cstring, cstring )`

Description: Sets the location where OBS archive logs in a specified archive slot can be deleted. The first parameter indicates the LSN. The logs before this location have been replayed and flushed to disks and can be deleted on OBS. The second parameter indicates the name of the archive slot.

Return type: `xlog_file_name` text, indicating the file name of the logs that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

- `gs_get_global_barrier_status()`

Description: `gs_get_global_barrier_status` is used to query the latest global barrier archived in OBS by the primary cluster.

Return type: text

**global\_barrier\_id**: globally latest barrier ID.

**global\_archive\_barrier\_id**: globally latest archived barrier ID.

- `gs_get_global_barriers_status()`

Description: `gs_get_global_barriers_status` is used to query the latest global barrier archived in OBS by the primary cluster.

Return type: text

**slot\_name**: slot name.

**global\_barrier\_id**: globally latest barrier ID.

**global\_archive\_barrier\_id**: globally latest archived barrier ID.

## Restoration Control Functions

Restoration control functions provide information about the status of standby nodes. These functions may be executed both during restoration and in normal running.

- `pg_is_in_recovery()`

Description: Returns **true** if restoration is still in progress.

Return type: Boolean

- `pg_last_xlog_receive_location()`

Description: Obtains the last transaction log location received and synchronized to disk by streaming replication. While streaming replication is in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received and synchronized to disk during restoration. If streaming replication is disabled or if it has not yet started, the function returns a null value.

Return type: text

- `pg_last_xlog_replay_location()`

Description: Obtains last transaction log location replayed during restoration. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. When the server has been started normally without restoration, the function returns a null value.

Return type: text

- `pg_last_xact_replay_timestamp()`

Description: Obtains the timestamp of last transaction replayed during restoration. This is the time to commit a transaction or abort a WAL record on the primary node. If no transactions have been replayed during restoration, this function will return a null value. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. If the server normally starts without manual intervention, this function will return a null value.

Return type: timestamp with time zone

Restoration control functions control restoration processes. These functions may be executed only during restoration.

- `pg_is_xlog_replay_paused()`

Description: Returns **true** if restoration is paused.

Return type: Boolean

- `pg_xlog_replay_pause()`

Description: Pauses restoration immediately.

Return type: void

- `pg_xlog_replay_resume()`

Description: Restarts restoration if it was paused.

Return type: void

- `gs_get_active_archiving_standby()`

Description: Queries information about archive standby nodes in the same shard. The standby node name, archive location, and number of archived logs are returned.

Return type: text, int

- `gs_pitr_get_warning_for_xlog_force_recycle()`

Description: Checks whether logs are recycled because a large number of logs are stacked in the archive slot after archiving is enabled.

Return type: Boolean

- `gs_pitr_clean_history_global_barriers(stop_barrier_timestamp cstring)`  
 Description: Clears all barrier records generated before the specified time. The earliest barrier record is returned. The input parameter is of the cstring type and is a Linux timestamp. You need to perform this operation as an administrator or O&M administrator.  
 Return type: text
- `gs_pitr_archive_slot_force_advance(stop_barrier_timestamp cstring)`  
 Description: Forcibly pushes the archive slot and clears unnecessary barrier records. The new archive slot location is returned. The input parameter is of the cstring type and is a Linux timestamp. You need to perform this operation as an administrator or O&M administrator.  
 Return type: text

While restoration is paused, no further database changes are applied. In hot standby mode, all new queries will see the same consistent snapshot of the database, and no further query conflicts will be generated until restoration is resumed.

If streaming replication is disabled, the paused state may continue indefinitely without problem. While streaming replication is in progress, WAL records will continue to be received, which will eventually fill available disk space. This progress depends on the duration of the pause, the rate of WAL generation, and available disk space.

- `gs_recent_barrier_buffer_info(start_time text, end_time text)`  
 Description: Queries barrier information based on the time range entered by the user to obtain time\_stamp, CSN, LSN, and standard\_time.  
 Return type: record

Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. The input parameters **start\_time** and **end\_time** are in the format of year-month-day time, where the time is in the clock format. The maximum query time span is one day. If the time span exceeds the limit, the end time is automatically converted to the limit boundary based on the query start time.

Example:

```
gaussdb=# SELECT * FROM gs_recent_barrier_buffer_info('2024-01-15 23:27:50', '2024-01-15 23:28:00');
```

| timestamp  | lsn               | csn      | standard_time       |
|------------|-------------------|----------|---------------------|
| 1705332470 | 00000000/15FFBBA0 | 41020421 | 2024-01-15 23:27:50 |
| 1705332471 | 00000000/15FFBDF0 | 41020422 | 2024-01-15 23:27:51 |
| 1705332472 | 00000000/15FFC058 | 41020423 | 2024-01-15 23:27:52 |
| 1705332472 | 00000000/15FFC0F8 | 41020424 | 2024-01-15 23:27:52 |
| 1705332473 | 00000000/15FFC348 | 41020425 | 2024-01-15 23:27:53 |
| 1705332474 | 00000000/15FFC598 | 41020426 | 2024-01-15 23:27:54 |
| 1705332475 | 00000000/15FFC638 | 41020427 | 2024-01-15 23:27:55 |
| 1705332476 | 00000000/15FFC888 | 41020428 | 2024-01-15 23:27:56 |
| 1705332476 | 00000000/15FFDC80 | 41020433 | 2024-01-15 23:27:56 |
| 1705332477 | 00000000/15FFDD20 | 41020434 | 2024-01-15 23:27:57 |
| 1705332478 | 00000000/15FFDF70 | 41020435 | 2024-01-15 23:27:58 |
| 1705332479 | 00000000/15FFE1D8 | 41020436 | 2024-01-15 23:27:59 |
| 1705332480 | 00000000/15FFE278 | 41020437 | 2024-01-15 23:28:00 |
| 1705332480 | 00000000/15FFE4C8 | 41020438 | 2024-01-15 23:28:00 |

(14 rows)

- `gs_show_obs_media_files(slot_name cstring, src cstring, offset int32, limit int32)`

Description: Queries the OBS file list based on the archive slot (**slot\_name**) and OBS directory address (**src**) entered by the user.

Return type: record

Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. **offset** indicates the query result offset, and **limit** indicates the maximum number of output lines. All files in **src** are queried. Example:

```
gaussdb=# SELECT gs_show_obs_archive_files('ssh','cn_5001/pg_xlog',1, 5);
 gs_show_obs_archive_files
```

```

(wstdist_ssh/archive/cn_5001/pg_xlog/
0000000100000000000000010_01_01_00000000_00000000_00000003)
(wstdist_ssh/archive/cn_5001/pg_xlog/
0000000100000000000000010_02_01_00000000_00000000_00000003)
(wstdist_ssh/archive/cn_5001/pg_xlog/
0000000100000000000000010_03_01_00000000_00000000_00000003)
(wstdist_ssh/archive/cn_5001/pg_xlog/
0000000100000000000000011_00_01_00000000_00000000_00000003)
(wstdist_ssh/archive/cn_5001/pg_xlog/
0000000100000000000000011_01_01_00000000_00000000_00000003)
(5 rows)
```

- **gs\_upload\_obs\_media\_file(slot\_name cstring, src cstring, dest cstring, is\_forced bool)**

Description: Uploads OBS files based on the archive slot (**slot\_name**), source address (**src**), OBS address (**dest**), and whether to forcibly upload files (**is\_forced**).

Return type: void

Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. The original file directory must be the directory specified by **\$GAUSSLOG**. Example:

```
gaussdb=# SELECT * FROM gs_upload_obs_archive_file('ssh', '/data/gauss/log/stwang/test/
0000000100000000000000019_02_01_00000000_00000000_00000003', 'cn_5001/pg_xlog/
0000000100000000000000019_02_01_00000000_00000000_00000003', true);
 gs_upload_obs_archive_file
```

```

(1 row)
```

- **gs\_download\_obs\_media\_file(slot\_name cstring, src cstring, dest cstring)**

Description: Downloads OBS files based on the archive slot (**slot\_name**), download source address (**src**), and local destination address (**dest**).

Return type: void

Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. The download directory must be the directory specified by **\$GAUSSLOG**. Example:

```
gaussdb=# SELECT * FROM gs_download_obs_archive_file('ssh','cn_5001/pg_xlog/
0000000100000000000000019_02_01_00000000_00000000_00000003','/data/gauss/log/stwang/test');
 gs_download_obs_archive_file
```

```

(1 row)
```

### 7.5.25.5 Dual-Cluster DR Control Functions

- **gs\_hadr\_do\_switchover()**

Description: Truncates services during a planned switchover in the primary cluster in the remote DR scenario.

Return type: Boolean, indicating whether the service truncation is successful and whether the switchover process can be performed normally.

- `gs_streaming_dr_in_switchover()`

Description: Truncates services during a planned switchover in the primary cluster in streaming replication-based remote DR solutions.

Return type: Boolean, indicating whether the service truncation is successful and whether the switchover process can be performed normally.

### 7.5.25.6 Dual-Cluster DR Query Functions

- `gs_get_local_barrier_status()`

Description: If two-city 3DC DR is enabled, the primary cluster and DR cluster synchronize logs. The barrier log is flushed to disks in the primary cluster, and replayed in the DR cluster to determine the archive log progress of the primary cluster and the log replay progress of the DR cluster.

`gs_get_local_barrier_status` is used to query the current log replay status of each node in the DR cluster.

Return type: text

**barrier\_id**: latest barrier ID of a node in the DR cluster.

**barrier\_lsn**: LSN of the latest barrier ID returned by a node in the DR cluster.

**archive\_lsn**: location of archived logs obtained by a node in the DR cluster. This parameter does not take effect currently.

**flush\_lsn**: location of logs that have been flushed to disks on a node in the DR cluster.

- `gs_hadr_in_recovery()`

Description: Checks whether the current node is in barrier-based log restoration if two-city 3DC DR is enabled. If yes, **true** is returned. Only after the log restoration is complete, can the DR cluster be promoted to the production cluster during the switchover process. This operation must be performed by the system administrator.

Return type: Boolean

#### NOTE

This function is used only when a planned switchover is performed in the DR cluster.

- `gs_streaming_dr_get_switchover_barrier()`

Description: Checks whether the CN and first standby DN in the DR cluster have received the switchover barrier logs and replayed the logs in the streaming replication-based two-city 3DC DR solution. If it has, **true** is returned. In the DR cluster, the procedure for promoting the DR database instance to the production database instance in the switchover process can be started only after the switchover barrier logs of all DNs are replayed (restricted to the system administrator).

Return type: Boolean

Note: This function is used only when a planned switchover is performed in the DR database instance in streaming DR solutions.

- `gs_streaming_dr_service_truncation_check()`

Description: Checks whether the CN and primary DN in the primary cluster has sent the switchover barrier logs in the streaming replication-based two-

city 3DC DR solution. If it has, **true** is returned. The procedure for demoting the production database instance to the DR database instance in the switchover process can be started only after the logs are sent (restricted to the system administrator).

Return type: Boolean

Note: This function is used only when a planned switchover is performed in the DR database instance.

- `gs_hadr_local_rto_and_rpo_stat()`

Description: Displays the log flow control information of the local database instance and DR database instance for streaming DR. (If this command is executed on a node that does not participate in streaming DR, for example, a standby DN or a CN, no information may be returned.)

The return value type is record. The types and meanings of the columns are as described in [Table 7-62](#).

**Table 7-62** Parameters of `gs_hadr_local_rto_and_rpo_stat`

| Parameter                            | Type | Description                                                                                                           |
|--------------------------------------|------|-----------------------------------------------------------------------------------------------------------------------|
| <code>hadr_sender_node_name</code>   | text | Node name, including the primary database instance and the first standby node of the standby database instance.       |
| <code>hadr_receiver_node_name</code> | text | Name of the first standby node of the standby database instance.                                                      |
| <code>source_ip</code>               | text | IP address of the primary DN of the primary database instance.                                                        |
| <code>source_port</code>             | int  | Communication port of the primary DN of the primary database instance.                                                |
| <code>dest_ip</code>                 | text | IP address of the first standby DN of the standby database instance.                                                  |
| <code>dest_port</code>               | int  | Communication port of the first standby DN of the standby database instance.                                          |
| <code>current_rto</code>             | int  | Flow control information, that is, log RTO time of the current primary and standby database instances (unit: second). |
| <code>target_rto</code>              | int  | Flow control information, that is, RTO time between the target primary and standby database instances (unit: second). |
| <code>current_rpo</code>             | int  | Flow control information, that is, log RPO time of the current primary and standby database instances (unit: second). |
| <code>target_rpo</code>              | int  | Flow control information, that is, RPO time between the target primary and standby database instances (unit: second). |

| Parameter      | Type | Description                                                                                                                                   |
|----------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| rto_sleep_time | int  | RTO flow control information, that is, expected sleep time (unit: $\mu$ s) required by walsender on the host to reach the specified RTO.      |
| rpo_sleep_time | int  | RPO flow control information, that is, the expected sleep time (unit: $\mu$ s) required by xlogInsert on the host to reach the specified RPO. |

- gs\_hadr\_remote\_rto\_and\_rpo\_stat()**  
 Description: Displays the log flow control information of all other shards or CN database instances and DR database instances for streaming DR. (Generally, this command is executed on CNs. If this command is executed on DNs, no information may be returned.)  
 The return value type is record. The types and meanings of the columns are as described in [Table 7-63](#).

**Table 7-63** gs\_hadr\_remote\_rto\_and\_rpo\_stat

| Parameter               | Type | Description                                                                                                           |
|-------------------------|------|-----------------------------------------------------------------------------------------------------------------------|
| hadr_sender_node_name   | text | Node name, including the primary database instance and the first standby node of the standby database instance.       |
| hadr_receiver_node_name | text | Name of the first standby node of the standby database instance.                                                      |
| source_ip               | text | IP address of the primary DN of the primary database instance.                                                        |
| source_port             | int  | Communication port of the primary DN of the primary database instance.                                                |
| dest_ip                 | text | IP address of the first standby DN of the standby database instance.                                                  |
| dest_port               | int  | Communication port of the first standby DN of the standby database instance.                                          |
| current_rto             | int  | Flow control information, that is, log RTO time of the current primary and standby database instances (unit: second). |
| target_rto              | int  | Flow control information, that is, RTO time between the target primary and standby database instances (unit: second). |
| current_rpo             | int  | Flow control information, that is, log RPO time of the current primary and standby database instances (unit: second). |

| Parameter      | Type | Description                                                                                                                                   |
|----------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| target_rpo     | int  | Flow control information, that is, RPO time between the target primary and standby database instances (unit: second).                         |
| rto_sleep_time | int  | RTO flow control information, that is, expected sleep time (unit: $\mu$ s) required by walsender on the host to reach the specified RTO.      |
| rpo_sleep_time | int  | RPO flow control information, that is, the expected sleep time (unit: $\mu$ s) required by xlogInsert on the host to reach the specified RPO. |

### 7.5.25.7 Snapshot Synchronization Functions

Snapshot synchronization functions save the current snapshot and return its identifier.

- `pg_export_snapshot()`

Description: Saves the current snapshot and returns its identifier.

Return type: text

Note: **pg\_export\_snapshot** saves the current snapshot and returns a text string identifying the snapshot. This string must be passed to clients that want to import the snapshot. A snapshot can be imported when the **set transaction snapshot snapshot\_id;** command is executed. Doing so is possible only when the transaction is set to the **SERIALIZABLE** or **REPEATABLE READ** isolation level. GaussDB does not support these two isolation levels currently. The output of the function cannot be used as the input of **set transaction snapshot**.

- `pg_export_snapshot_and_csn()`

Description: Saves the current snapshot and returns its identifier. Compared with **pg\_export\_snapshot()**, **pg\_export\_snapshot()** returns a CSN, indicating the CSN of the current snapshot.

Return type: text

### 7.5.25.8 Database Object Functions

#### Database Object Size Functions

Database object size functions calculate the actual disk space used by database objects.

- `pg_column_size(any)`

Description: Specifies the number of bytes used to store a particular value (possibly compressed)

Return type: int

Note: `pg_column_size` displays the space for storing an independent data value.

```
gaussdb=# SELECT pg_column_size(1);
pg_column_size

 4
(1 row)
```

- **pg\_database\_size(oid)**  
Description: Specifies the disk space used by the database with the specified OID.  
Return type: bigint
- **pg\_database\_size(name)**  
Description: Specifies the disk space used by the database with the specified name.  
Return type: bigint  
Note: `pg_database_size` receives the OID or name of a database and returns the disk space used by the corresponding object.

Example:

```
gaussdb=# SELECT pg_database_size('testdb');
pg_database_size

 51590112
(1 row)
```

- **pg\_relation\_size(oid)**  
Description: Specifies the disk space used by the table with a specified OID or index.  
Return type: bigint
- **get\_db\_source\_datasize()**  
Description: Estimates the total size of non-compressed data in the current database.  
Return type: bigint  
Note: Perform an analysis before this function is called.

Example:

```
gaussdb=# analyze;
ANALYZE
gaussdb=# SELECT get_db_source_datasize();
get_db_source_datasize

 35384925667
(1 row)
```

- **pg\_relation\_size(text)**  
Description: Specifies the disk space used by the table with a specified name or index. The table name can be schema-qualified.  
Return type: bigint
- **pg\_relation\_size(relation regclass, fork text)**  
Description: Specifies the disk space used by the specified bifurcating tree ('main', 'fsm', or 'vm') of a certain table or index.  
Return type: bigint
- **pg\_relation\_size(relation regclass)**  
Description: Is an abbreviation of **pg\_relation\_size(..., 'main')**.  
Return type: bigint

Note: `pg_relation_size` receives the OID or name of a table, an index, or a compressed table, and returns the size.

- `pg_partition_size(oid, oid)`  
Description: Specifies the disk space used by the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.  
Return type: `bigint`
- `pg_partition_size(text, text)`  
Description: Specifies the disk space used by the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.  
Return type: `bigint`
- `pg_partition_indexes_size(oid, oid)`  
Description: Specifies the disk space used by the index of the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.  
Return type: `bigint`
- `pg_partition_indexes_size(text, text)`  
Description: Specifies the disk space used by the index of the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.  
Return type: `bigint`
- `pg_indexes_size(regclass)`  
Description: Specifies the total disk space used by the index appended to the specified table.  
Return type: `bigint`
- `pg_size_pretty(bigint)`  
Description: Converts a size in bytes expressed as a 64-bit integer into a human-readable format with size units.  
Return type: `text`
- `pg_size_pretty(numeric)`  
Description: Converts a size in bytes expressed as a numeric value into a human-readable format with size units.  
Return type: `text`  
Note: `pg_size_pretty` formats the results of other functions into a human-readable format. KB, MB, GB, and TB can be used.
- `pg_table_size(regclass)`  
Description: Specifies the disk space used by the specified table, excluding indexes (but including TOAST, free space mapping, and visibility mapping).  
Return type: `bigint`
- `pg_tablespace_size(oid)`  
Description: Specifies the disk space used by the tablespace with a specified OID.  
Return type: `bigint`

- pg\_tablespace\_size(name)**  
 Description: Specifies the disk space used by the tablespace with a specified name.  
 Return type: bigint  
 Note:  
 pg\_tablespace\_size receives the OID or name of a database and returns the disk space used by the corresponding object.
- pg\_total\_relation\_size(oid)**  
 Description: Specifies the disk space used by the table with a specified OID, including the index and the compressed data.  
 Return type: bigint
- pg\_total\_relation\_size(regclass)**  
 Description: Specifies the total disk space used by the specified table, including all indexes and TOAST data.  
 Return type: bigint
- pg\_total\_relation\_size(text)**  
 Description: Specifies the disk space used by the table with a specified name, including the index and the compressed data. The table name can be schema-qualified.  
 Return type: bigint  
 Note: pg\_total\_relation\_size receives the OID or name of a table or a compressed table, and returns the sizes of the data, related indexes, and the compressed table in bytes.
- datalength(any)**  
 Description: Specifies the number of bytes used by an expression of a specified data type (data management space, data compression, or data type conversion is not considered).  
 Return type: int  
 Note: datalength calculates the space of an independent data value.

Example:

```
gaussdb=# SELECT datalength(1);
datalength

4
(1 row)
```

The following table lists the supported data types and calculation methods.

| Data Type          |               | Storage Space  |   |
|--------------------|---------------|----------------|---|
| Numeric data types | Integer types | TINYINT        | 1 |
|                    |               | SMALLINT       | 2 |
|                    |               | INTEGER        | 4 |
|                    |               | BINARY_INTEGER | 4 |
|                    |               | BIGINT         | 8 |

| Data Type          |                           | Storage Space    |                                                                                                                      |
|--------------------|---------------------------|------------------|----------------------------------------------------------------------------------------------------------------------|
|                    | Arbitrary precision types | DECIMAL          | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
|                    |                           | NUMERIC          | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
|                    |                           | NUMBER           | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
|                    | Sequence integer          | SMALLSERIAL      | 2                                                                                                                    |
|                    |                           | SERIAL           | 4                                                                                                                    |
|                    |                           | BIGSERIAL        | 8                                                                                                                    |
|                    | Floating point types      | FLOAT4           | 4                                                                                                                    |
|                    |                           | DOUBLE PRECISION | 8                                                                                                                    |
|                    |                           | FLOAT8           | 8                                                                                                                    |
|                    |                           | BINARY_DOUBLE    | 8                                                                                                                    |
|                    |                           | FLOAT[(p)]       | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
|                    |                           | DEC[(p,s)]       | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
|                    |                           | INTEGER[(p,s)]   | Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately. |
| Boolean data types | Boolean type              | BOOLEAN          | 1                                                                                                                    |

| Data Type            |                                        | Storage Space          |                                        |
|----------------------|----------------------------------------|------------------------|----------------------------------------|
| Character data types | Character types                        | CHAR                   | n                                      |
|                      |                                        | CHAR(n)                | n                                      |
|                      |                                        | CHARACTER(n)           | n                                      |
|                      |                                        | NCHAR(n)               | n                                      |
|                      |                                        | VARCHAR(n)             | n                                      |
|                      |                                        | CHARACTER              | Actual number of bytes of a character. |
|                      |                                        | VARYING(n)             | Actual number of bytes of a character. |
|                      |                                        | VARCHAR2(n)            | Actual number of bytes of a character. |
|                      |                                        | NVARCHAR2(n)           | Actual number of bytes of a character. |
|                      |                                        | TEXT                   | Actual number of bytes of a character. |
| CLOB                 | Actual number of bytes of a character. |                        |                                        |
| Time data types      | Time types                             | DATE                   | 8                                      |
|                      |                                        | TIME                   | 8                                      |
|                      |                                        | TIMEZ                  | 12                                     |
|                      |                                        | TIMESTAMP              | 8                                      |
|                      |                                        | TIMESTAMPZ             | 8                                      |

## Database Object Position Functions

- pg\_relation\_filenode(relation regclass)**  
 Description: Specifies the ID of a filenode with the specified relationship.  
 Return type: oid

Note: **pg\_relation\_filenode** receives the OID or name of a table, an index, a sequence, or a compressed table, and returns the ID of **filenode** allocated to it. **filenode** is the basic component of the file name used by the relationship. For most tables, the result is the same as that of **pg\_class.relfilenode**. For the specified system directory, **relfilenode** is **0** and this function must be used to obtain the correct value. If a relationship that is not stored is transmitted, such as a view, this function returns a null value.

- **pg\_relation\_filepath**(relation regclass)  
Description: Specifies the name of a file path with the specified relationship.  
Return type: text  
Description: **pg\_relation\_filepath** is similar to **pg\_relation\_filenode**, except that **pg\_relation\_filepath** returns the whole file path name for the relationship (relative to the data directory **PGDATA** of the database cluster).
- **get\_large\_table\_name**(relfile\_node text, threshold\_size\_gb int8)  
Description: Queries whether the table size (in GB) exceeds the threshold (**threshold\_size\_gb**) based on the table file code (**relfile\_node**). If yes, the schema name and table name (in *schemaname.tablename* format) are returned; otherwise, **null** is returned.  
Return type: text
- **pg\_filenode\_relation**(tablespacename, relname)  
Description: Obtains the table names corresponding to the **tablespace** and **relfilenode**.  
Return type: regclass
- **pg\_partition\_filenode**(partition\_oid)  
Description: Obtains **filenode** corresponding to the OID lock of a specified partitioned table.  
Return type: oid
- **pg\_partition\_filepath**(partition\_oid)  
Description: Specifies the file path name of a partition.  
Return type: text

## Recycle Bin Object Functions

- **gs\_is\_recycle\_object**(classid, objid, objname)  
Description: Determines whether an object is in the recycle bin. This function is not supported in distributed mode.  
Return type: Boolean

### 7.5.25.9 Advisory Lock Functions

Advisory lock functions manage advisory locks.

- **pg\_advisory\_lock**(key bigint)  
Description: Obtains an exclusive session-level advisory lock.  
Return type: void  
Note: **pg\_advisory\_lock** locks resources defined by an application. The resources can be identified using a 64-bit or two nonoverlapped 32-bit key

values. If another session locks the resources, the function blocks the resources until they can be used. The lock is exclusive. Multiple locking requests are pushed into the stack. Therefore, if the same resource is locked three times, it must be unlocked three times so that it is released to another session.

- `pg_advisory_lock(key1 int, key2 int)`  
Description: Obtains an exclusive session-level advisory lock.  
Return type: void  
Note: Only users with the `sysadmin` permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).
- `pg_advisory_lock(lock_id int4, lock_id int4, database_name Name)`  
Description: Obtains the exclusive advisory lock of a specified database by inputting the lock ID and database name.  
Return type: void
- `pg_advisory_lock_shared(key bigint)`  
Description: Obtains a shared session-level advisory lock.  
Return type: void
- `pg_advisory_lock_shared(key1 int, key2 int)`  
Description: Obtains a shared session-level advisory lock.  
Return type: void  
Note: **pg\_advisory\_lock\_shared** works in the same way as **pg\_advisory\_lock**, except that **pg\_advisory\_lock\_shared** obtains an advisory lock shared with other sessions requesting the lock, while **pg\_advisory\_lock** obtains an exclusive advisory lock.
- `pg_advisory_unlock(key bigint)`  
Description: Releases an exclusive session-level advisory lock.  
Return type: Boolean
- `pg_advisory_unlock(key1 int, key2 int)`  
Description: Releases an exclusive session-level advisory lock.  
Return type: Boolean  
Note: **pg\_advisory\_unlock** releases the obtained exclusive advisory lock. If the release is successful, the function returns **true**. If the lock was not held, it will return **false**. In addition, a SQL warning will be reported by the server.
- `pg_advisory_unlock(lock_id int4, lock_id int4, database_name Name)`  
Description: Releases an exclusive advisory lock of a specified database by inputting the lock ID and database name.  
Return type: Boolean  
Note: If the release is successful, **true** is returned. If no lock is held, **false** is returned.
- `pg_advisory_unlock_shared(key bigint)`  
Description: Releases a shared session-level advisory lock.  
Return type: Boolean
- `pg_advisory_unlock_shared(key1 int, key2 int)`  
Description: Releases a shared session-level advisory lock.

Return type: Boolean

Note: **pg\_advisory\_unlock\_shared** works in the same way as **pg\_advisory\_unlock**, except it releases a shared session-level advisory lock.

- **pg\_advisory\_unlock\_all()**

Description: Releases all advisory locks owned by the current session.

Return type: void

Note: **pg\_advisory\_unlock\_all** releases all advisory locks owned by the current session. The function is implicitly invoked when the session ends even if the client is abnormally disconnected.

- **pg\_advisory\_xact\_lock(key bigint)**

Description: Obtains an exclusive transaction-level advisory lock.

Return type: void

- **pg\_advisory\_xact\_lock(key1 int, key2 int)**

Description: Obtains an exclusive transaction-level advisory lock.

Return type: void

Note: **pg\_advisory\_xact\_lock** works in the same way as **pg\_advisory\_lock**, except that the lock is automatically released at the end of the current transaction and cannot be released explicitly. Only users with the sysadmin permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).

- **pg\_advisory\_xact\_lock\_shared(key bigint)**

Description: Obtains a shared transaction-level advisory lock.

Return type: void

- **pg\_advisory\_xact\_lock\_shared(key1 int, key2 int)**

Description: Obtains a shared transaction-level advisory lock.

Return type: void

Note: **pg\_advisory\_xact\_lock\_shared** works in the same way as **pg\_advisory\_lock\_shared**, except the lock is automatically released at the end of the current transaction and cannot be released explicitly.

- **pg\_try\_advisory\_lock(key bigint)**

Description: Obtains an exclusive session-level advisory lock if available.

Return type: Boolean

Note: **pg\_try\_advisory\_lock** is similar to **pg\_advisory\_lock**, except **pg\_try\_advisory\_lock** does not block the resource until the resource is released. It either immediately obtains the lock and returns **true** or returns **false**, which indicates the lock cannot be performed currently.

- **pg\_try\_advisory\_lock(key1 int, key2 int)**

Description: Obtains an exclusive session-level advisory lock if available.

Return type: Boolean

Note: Only users with the sysadmin permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).

- **pg\_try\_advisory\_lock\_shared(key bigint)**

Description: Obtains a shared session-level advisory lock if available.

Return type: Boolean

- `pg_try_advisory_lock_shared(key1 int, key2 int)`  
Description: Obtains a shared session-level advisory lock if available.  
Return type: Boolean  
Note: **`pg_try_advisory_lock_shared`** works in the same way as **`pg_try_advisory_lock`**, except that **`pg_try_advisory_lock_shared`** attempts to obtain a shared lock instead of an exclusive lock.
- `pg_try_advisory_xact_lock(key bigint)`  
Description: Obtains an exclusive transaction-level advisory lock if available.  
Return type: Boolean
- `pg_try_advisory_xact_lock(key1 int, key2 int)`  
Description: Obtains an exclusive transaction-level advisory lock if available.  
Return type: Boolean  
Note: **`pg_try_advisory_xact_lock`** works in the same way as **`pg_try_advisory_lock`**, except that the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly. Only users with the `sysadmin` permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).
- `pg_try_advisory_xact_lock_shared(key bigint)`  
Description: Obtains a shared transaction-level advisory lock if available.  
Return type: Boolean
- `pg_try_advisory_xact_lock_shared(key1 int, key2 int)`  
Description: Obtains a shared transaction-level advisory lock if available.  
Return type: Boolean  
Note: **`pg_try_advisory_xact_lock_shared`** works in the same way as **`pg_try_advisory_lock_shared`**, except the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly.
- `lock_cluster_ddl()`  
Description: Attempts to obtain a session-level exclusive advisory lock for all active CNs in the cluster.  
Return type: Boolean  
Note: Only users with the **`sysadmin`** permission can call this function.
- `unlock_cluster_ddl()`  
Description: Attempts to add a session-level exclusive advisory lock on a CN.  
Return type: Boolean

## 7.5.25.10 Logical Replication Functions

### NOTE

When using the logical replication functions, set the GUC parameter **`wal_level`** to **`logical`**. For details about the configuration, see "Logical Replication > Logical Decoding > Logical Decoding by SQL Function Interfaces" in *Feature Guide*.

- `pg_create_logical_replication_slot('slot_name', 'plugin_name', 'output_order')`  
Description: Creates a logical replication slot.  
Parameter description:

- slot\_name  
Indicates the name of the streaming replication slot.  
Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.
- plugin\_name  
Indicates the name of the plug-in.  
Value range: a string, supporting **mppdb\_decoding**
- output\_order  
Indicates the output sequence of the replication slot decoding results.  
This parameter is optional.  
Valid value: **0** or **1**. The default value is **0** on DNs and **1** on CNs.
  - **0**: The replication slot decoding results are sorted by transaction COMMIT LSN. In this case, the value of **confirmed\_csn** of the replication slot is **0**. This replication slot is called an LSN-based replication slot.
  - **1**: The replication slot decoding results are sorted by transaction CSN. In this case, the value of **confirmed\_csn** of the replication slot is not **0**. This replication slot is called a CSN-based replication slot. In this case, the **confirmed\_flush** value is meaningless.

Return type: name, text

Example:

```
gaussdb=# SELECT * FROM pg_create_logical_replication_slot('slot_lsn','mppdb_decoding',0);
 slotname | xlog_position
-----+-----
 slot_lsn | 0/6D08B58
(1 row)

gaussdb=# SELECT * FROM pg_create_logical_replication_slot('slot_csn','mppdb_decoding',1);
 slotname | xlog_position
-----+-----
 slot_csn | 0/59AD800
(1 row)
```

Note: The first return value is the slot name, and the second one has different meanings in LSN-based replication slots and CSN-based replication slots. For an LSN-based replication slot, the value is **confirmed\_flush** of the replication slot, indicating that transactions whose commit LSN is less than or equal to the value will not be decoded and output. For a CSN-based replication slot, the value is **confirmed\_csn** of the replication slot, indicating that transactions whose CSN is less than or equal to the value will not be decoded and output. Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role. Currently, this function can be called only on the CN or primary DNs.

---

 **CAUTION**

When this function is executed on a CN, if **output\_order** is set to **1**, a replication slot with the same name will be created on all CNs and primary DNs. If a replication slot with the same name already exists on some DNs, a CSN-based logical replication slot will be created on other CNs and primary DNs that do not have a replication slot with the same name. In addition, an error message is displayed, indicating that the replication slot already exists. In this case, you need to delete the existing replication slot with the same name on the DN (if the replication slot is an LSN-based logical replication slot, you need to manually delete it on the corresponding node) and create a replication slot on the CN. If you set **output\_order** to **0** when creating a replication slot on a CN, no replication slot will be created on DNs. Replication slots created on CNs are only used to identify whether related replication slots exist on DNs.

---

- `pg_create_physical_replication_slot('slot_name', 'isDummyStandby')`

Description: Creates a physical replication slot.

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `isDummyStandby`

Reserved parameter.

Type: Boolean

Return type: name, text

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the `gs_role_replication` permission of the built-in role. The physical replication slot created by this function does not have **restart\_lsn**. Therefore, the slot is considered invalid and will be automatically deleted when the checkpoint is performed.

- `pg_drop_replication_slot('slot_name')`

Description: Deletes a streaming replication slot.

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

Return type: void

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the `gs_role_replication` permission of the built-in role.

 **CAUTION**

- When a logical replication slot is deleted from a CN, if the logical replication slot is an LSN-based logical replication slot, only the replication slot of the current node is deleted. Replication slots with the same name on other nodes are not affected. When a CSN-based logical replication slot with the same name exists on other nodes, no error is reported because some nodes do not have replication slots. In addition, replication slots with the same name on all nodes are successfully deleted. If no replication slot exists on any node, an error is reported.
- If an LSN-based logical replication slot remains on the current CN and a CSN-based logical replication slot with the same name remains on other nodes, deleting the replication slot on the current CN will delete only the local LSN-based logical replication slot. After the deletion is complete, perform the deletion operation again to delete the CSN-based logical replication slots with the same name on other nodes.

- `pg_logical_slot_peek_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding on the decoding DN but does not go to the next streaming replication slot. (The decoded result will be returned again during the next decoding.)

Parameter:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `upto_lsn`

For the CSN-based logical replication slot, the decoding is complete until the transaction whose CSN is less than or equal to the value is decoded (a transaction whose CSN is greater than the specified CSN may be decoded). For the LSN-based replication slot, the decoding is complete until the first transaction whose COMMIT LSN is greater than or equal to the value is decoded.

Value range: a string, for example, `'1/2AAFC60'`, `'0/A060'`, or `'3A/0'` (a hexadecimal uint64 value containing two uint32 values separated by a slash (/); if any uint32 value is **0**, **0** is displayed.) **NULL** indicates that the end position of decoding is not specified.

- `upto_nchanges`

Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto\_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto\_nchanges** after decoding in the first two transactions is finished.

Value range: a non-negative integer

 NOTE

If any of the **upto\_lsn** and **upto\_nchanges** values is reached, decoding ends.

- **options**: Specifies optional parameters, consisting of **options\_name** and **options\_value**.

- **include-xids**

Specifies whether the decoded **data** column contains XID information.

Valid value: **0** and **1**. The default value is **1**.

- **0**: The decoded **data** column does not contain XID information.
- **1**: The decoded **data** column contains XID information.

- **skip-empty-xacts**

Specifies whether to ignore empty transaction information during decoding.

Value range: **0** and **1**. The default value is **0**.

- **0**: The empty transaction information is not ignored during decoding.
- **1**: The empty transaction information is ignored during decoding.

- **include-timestamp**

Specifies whether decoded information contains the **commit** timestamp.

Value range: **0** and **1**. The default value is **0**.

- **0**: The decoded information does not contain the **commit** timestamp.
- **1**: The decoded information contains the **commit** timestamp.

- **only-local**

Specifies whether to decode only local logs.

Value range: **0** and **1**. The default value is **1**.

- **0**: Non-local logs and local logs are decoded.
- **1**: Only local logs are decoded.

- **force-binary**

Specifies whether to output the decoding result in binary format.

Value range: **0**

- **0**: The decoding result is output in text format.

- **white-table-list**

Whitelist parameter, including the schema and table name to be decoded.

Value range: a string that contains table names in the whitelist. Different tables are separated by commas (.). An asterisk (\*) is used to fuzzily match all tables. Schema names and table names are

separated by periods (.). No space character is allowed. The following is an example:

```
SELECT * FROM pg_logical_slot_peek_changes('slot1', NULL, 4096, 'white-table-list', 'public.t1,public.t2');
```

- **max-txn-in-memory**  
Memory control parameter. The unit is MB. If the memory occupied by a single transaction is greater than the value of this parameter, data is flushed to disks.  
Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.
- **max-reorderbuffer-in-memory**  
Memory control parameter. The unit is GB. If the total memory (including the cache) of transactions being concatenated in the sender thread is greater than the value of this parameter, the current decoding transaction is flushed to disks.  
Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.
- **include-user**  
Specifies whether the BEGIN logical log of a transaction records the username of the transaction.  
Value range: **0** and **1**. The default value is **0**.
  - **0**: The BEGIN logical log of a transaction does not contain the username of the transaction.
  - **1**: The BEGIN logical log of a transaction records the username of the transaction.
- **exclude-userids**  
Specifies the OID of a blacklisted user.  
Value range: OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not check whether the OIDs exist.
- **exclude-users**  
Specifies the name of a blacklisted user.  
Value range: names of blacklisted users. Multiple names are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.
- **dynamic-resolution**  
Specifies whether to dynamically parse the names of blacklisted users.  
Value range: **0** and **1**. The default value is **1**.

- **0**: If the parameter is set to **0**, an error is reported and the logical decoding exits when the decoding detects that the user does not exist in blacklist **exclude-users**.
- **1**: If the parameter is set to **1**, decoding continues when it detects that the user does not exist in blacklist **exclude-users**.

 **NOTE**

For details about other configuration options, see "Logical Replication > Logical Decoding > Logical Decoding Options" in *Feature Guide*.

Return type: text, xid, text

(9 rows)
```

Note: The decoding result returned by the function contains three columns, corresponding to the preceding return value types, which are the LSN (for an LSN-based replication slot) or CSN (for a CSN-based replication slot), XID, and decoded content, respectively. If the **location** column indicates the CSN, the value of the **location** column is updated only when the commit logs are decoded. Users who call this function must have the SYSADMIN permission,

the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role.

 NOTE

On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed\_csn** is not 0).

- `pg_logical_slot_get_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding on the decoding DN and updates the streaming replication slot.

Parameter: This function has the same parameters as **pg\_logical\_slot\_peek\_changes**. For details, see [pg\\_logical\\_slot\\_peek\\_ch...](#)

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role.

 NOTE

On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed\_csn** is not 0). When this function is called on the standby DN, the corresponding logical replication slot on the primary DN is updated synchronously. If this function is executed on the standby DN, a WAL sender of the primary DN is occupied when the replication slot number on the primary DN is updated. The logical decoding function reserves a WAL sender for each logical replication slot. Therefore, if this function is executed in normal scenarios, the logical replication slot number on the primary DN is updated normally. If this function is executed continuously in a short period of time, the primary DN fails to update the slot number and no error is reported.

- `pg_logical_slot_peek_binary_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding in binary format on the decoding DN and does not update the streaming replication slot. (The decoded data can be obtained again during the next decoding.)

Parameter:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `upto_lsn`

For the CSN-based logical replication slot, the decoding is complete until the transaction whose CSN is less than or equal to the value is decoded (a transaction whose CSN is greater than the specified CSN may be decoded). For the LSN-based replication slot, the decoding is complete until the first transaction whose COMMIT LSN is greater than or equal to the value is decoded.

Value range: a string, for example, '1/2AAFC60', '0/A060', or '3A/0' (a hexadecimal uint64 value containing two uint32 values separated by a slash (/); if any uint32 value is 0, 0 is displayed.) **NULL** indicates that the end position of decoding is not specified.

- upto\_nchanges
  - Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto\_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto\_nchanges** after decoding in the first two transactions is finished.
  - Value range: a non-negative integer
  -  **NOTE**
    - If any of the **upto\_lsn** and **upto\_nchanges** values is reached, decoding ends.
- **options**: Specifies optional parameters, consisting of **options\_name** and **options\_value**.
  - include-xids
    - Specifies whether the decoded **data** column contains XID information.
    - Valid value: **0** and **1**. The default value is **1**.
    - **0**: The decoded **data** column does not contain XID information.
    - **1**: The decoded **data** column contains XID information.
  - skip-empty-xacts
    - Specifies whether to ignore empty transaction information during decoding.
    - Value range: **0** and **1**. The default value is **0**.
    - **0**: The empty transaction information is not ignored during decoding.
    - **1**: The empty transaction information is ignored during decoding.
  - include-timestamp
    - Specifies whether decoded information contains the **commit** timestamp.
    - Value range: **0** and **1**. The default value is **0**.
    - **0**: The decoded information does not contain the **commit** timestamp.
    - **1**: The decoded information contains the **commit** timestamp.
  - only-local
    - Specifies whether to decode only local logs.
    - Value range: **0** and **1**. The default value is **1**.
    - **0**: Non-local logs and local logs are decoded.
    - **1**: Only local logs are decoded.
  - force-binary
    - Specifies whether to output the decoding result in binary format.

Value range: **0** or **1**. The default value is **0**. The result is output in binary format.

- `white-table-list`

Whitelist parameter, including the schema and table name to be decoded.

Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (\*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed. Example:  
**select \* from pg\_logical\_slot\_peek\_binary\_changes('slot1', NULL, 4096, 'white-table-list', 'public.t1,public.t2');**

- `max-txn-in-memory`

Memory control parameter. The unit is MB. If the memory occupied by a single transaction is greater than the value of this parameter, data is flushed to disks.

Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.

- `max-reorderbuffer-in-memory`

Memory control parameter. The unit is GB. If the total memory (including the cache) of transactions being concatenated in the sender thread is greater than the value of this parameter, the current decoding transaction is flushed to disks.

Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.

- `include-user`

Specifies whether the BEGIN logical log of a transaction records the username of the transaction.

Value range: **0** and **1**. The default value is **0**.

- **0**: The BEGIN logical log of a transaction does not contain the username of the transaction.
- **1**: The BEGIN logical log of a transaction records the username of the transaction.

- `exclude-userids`

Specifies the OID of a blacklisted user.

Value range: OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not check whether the OIDs exist.

- `exclude-users`

Specifies the name of a blacklisted user.

Value range: names of blacklisted users. Multiple names are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username

from the blacklist to start decoding and continue to obtain logical logs.

- **dynamic-resolution**

Specifies whether to dynamically parse the names of blacklisted users.

Value range: **0** and **1**. The default value is **1**.

- **0**: If the parameter is set to **0**, an error is reported and the logical decoding exits when the decoding detects that the user does not exist in blacklist **exclude-users**.
- **1**: If the parameter is set to **1**, decoding continues when it detects that the user does not exist in blacklist **exclude-users**.

 **NOTE**

Some configuration options do not take effect even if they are configured in functions. For details, see "Logical Replication > Logical Decoding > Logical Decoding Options" in *Feature Guide*.

Return type: text, xid, bytea

Note: The function returns the decoding result. Each decoding result contains three columns, corresponding to the above return types and indicating the LSN position, XID, and decoded content in binary format, respectively. Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role.

 **NOTE**

On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed\_csn** is not **0**).

- `pg_logical_slot_get_binary_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding in binary format on the decoding DN and updates the streaming replication slot.

Parameter: This function has the same parameters as **pg\_logical\_slot\_peek\_binary\_changes**. For details, see [•pg\\_logical\\_slot\\_peek\\_bi...](#)

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role.

 **NOTE**

On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed\_csn** is not **0**). This function cannot be executed on the standby DN.

- `pg_replication_slot_advance ('slot_name', 'upto_lsn')`

Description: Directly updates the streaming replication slot to a specified LSN on the decoding DN, without outputting any decoded result.

Parameter:

- `slot_name`

Indicates the name of the streaming replication slot.

 NOTE

The constraints are as follows:

- The current network and hardware environment are normal.
- It is recommended that the size of a single tuple be less than or equal to 500 MB. If the size ranges from 500 MB to 1 GB, an error is reported.
- Data page replication is not supported for data retrieval that does not fall into Xlogs.
- When an API is called, the log level parameter **wal\_level** must be set to **logical**, and only the log files generated when **wal\_level** is set to **logical** can be parsed. If the used Xlog file is not at the logical level, the decoded content does not have the corresponding value or type. There is no other impact. If **wal\_level** is not set to **logical**, an error is reported and decoding is not performed.
- The Xlog file can be parsed only by a copy of a completely homogeneous DN, and no DDL operation or VACUUM FULL occurs in the database to ensure that the metadata corresponding to the data can be found.
- Do not read too many Xlog files at a time. If no file is specified for decoding within a specified range, you are advised to read one Xlog file each time. Generally, the memory occupied by an Xlog file during decoding is about two to three times the size of the Xlog file.
- Data before VACUUM FULL cannot be retrieved.
- The Xlog file before scale-out cannot be decoded.
- To decode the UPDATE statement, the table must have a primary key. Otherwise, the WHERE clause in the UPDATE statement is empty.
- In this decoding mode, the content that can be decoded is decoded based on the Xlog text record data, and the decoding is not performed based on transactions. Therefore, data that is not in the Xlog cannot be decoded.
- If no decoding file is specified from the decoding point, the system checks whether DDL occurs between the decoding start point and the latest redo value. If DDL occurs, the system does not decode all data. If a decoding file is specified, the system checks whether DDL occurs between the start point of the decoding file and the last readable content of the file and between the start point of the Xlog in the data directory and the latest redo value. If a DDL operation is detected, the system does not decode all tables.

Note: When separation-of-duties is enabled, only the initial database user can call the function. When separation-of-duties is disabled, the system administrator permission is required.

Parameter description:

- LSN\_start  
Specifies the LSN at the start of decoding.  
Value range: a string, in the format of *xlogid/xrecoff*, for example, '1/2AAFC60'. **NULL** indicates that the end position of decoding is not specified.
- LSN\_end  
Specifies the LSN at the end of decoding.  
Value range: a string, in the format of *xlogid/xrecoff*, for example, '1/2AAFC60'. **NULL** indicates that the end position of decoding is not specified.
- upto\_nchanges  
Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which

involve 3, 5, and 7 records, respectively. If **upto\_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto\_nchanges** after decoding in the first two transactions is finished.

Value range: a non-negative integer

 **NOTE**

If any of the **LSN** and **upto\_nchanges** values are reached, decoding ends.

- **decoding\_plugin**

Decoding plug-in, which is a .so plug-in that specifies the output format of the decoded content.

Value range: **mppdb\_decoding** and **sql\_decoding**.

- **xlog\_path**

Decoding plug-in, which specifies the Xlog absolute path and file level of the decoding file.

Value range: **NULL** or a character string of the absolute path of the Xlog file.

- **options**: This parameter is optional and consists of multiple pairs of **options\_name** and **options\_value**. You can retain the default values. For details, see [pg\\_logical\\_slot\\_peek\\_changes](#).

Example:

```
gaussdb=# execute direct on (datanode1) 'select * from pg_logical_get_area_changes("0/502E418", NULL, NULL, "sql_decoding", NULL);'
```

```
location | xid | data
-----+-----+-----
0/502E448 | 17365 | insert into public.t1 values (1, 1);
0/502E5A0 | 17365 | COMMIT 17365 (at 2023-11-01 11:28:43.92526+08) 2010016
0/502E5D0 | 17366 | delete from public.t1 where a = 1;insert into public.t1 values (1, 2);
0/502E6D8 | 17366 | COMMIT 17366 (at 2023-11-01 11:28:45.889283+08) 2010017
0/502E7B8 | 17367 | delete from public.t1 where a = 1;
0/502E8B0 | 17367 | COMMIT 17367 (at 2023-11-01 11:28:48.301307+08) 2010018
(6 rows)
```

- **gs\_get\_parallel\_decode\_status()**

Description: Monitors the length of the read log queue and decoding result queue of each decoder thread on the DN where parallel decoding is performed to locate the concurrent decoding performance bottleneck.

Return type: text, int, text, text, text, int64, int64, TimestampTz

Example:

```
gaussdb=# execute direct on (datanode1) 'select * from gs_get_parallel_decode_status();'
```

```
slot_name | parallel_decode_num | read_change_queue_length | decode_change_queue_length | reader_lsn | working_txn_cnt | working_txn_memory | decoded_time
```

```
-----+-----+-----+-----+-----+-----+-----+-----
slot1 | 2 | queue0: 1005, queue1: 320 | queue0: 63, queue1: 748 | 0/1DCE2578 | 42 | 192927504 | 2023-01-10 11:18:22+08
(1 row)
```

Note: In the return values, **slot\_name** indicates the replication slot name, **parallel\_decode\_num** indicates the number of parallel decoder threads in the replication slot, **read\_change\_queue\_length** indicates the current length of the log queue read by each decoder thread, **decode\_change\_queue\_length** indicates the current length of the decoding result queue of each decoder thread, **reader\_lsn** indicates the log location read by the reader thread,

**working\_txn\_cnt** indicates the number of transactions being concatenated in the current sender thread, **working\_txn\_memory** indicates the total memory (in bytes) occupied by the concatenation transactions in the sender thread, and **decoded\_time** indicates the time of the latest WAL decoded by the replication slot.

---

#### NOTICE

The value of **decoded\_time** comes from checkpoint logs and transaction commit logs, which has a certain error. If no log containing the time is decoded, "2000-01-01 08:00:00+08" (depending on the time zone set in the database) is displayed.

- 
- `gs_get_slot_decoded_wal_time(slot_name)`

Description: Queries the latest decoded WAL time of an active replication slot on the DN where parallel decoding is performed.

Parameter:

- `slot_name`

Specifies the name of the replication slot to be queried.

Value range: a string, supporting only letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`).

Example:

```
gaussdb=# execute direct on (datanode1) 'select * from
gs_get_slot_decoded_wal_time("replication_slot");'
gs_get_slot_decoded_wal_time

2023-01-10 11:25:22+08
(1 row)
```

Note: The returned values indicate the time of the latest WAL decoded by the replication slot.

---

#### NOTICE

The returned time comes from checkpoint logs and transaction commit logs, which has a certain error. If no log containing the time is decoded, "2000-01-01 08:00:00+08" (depending on the time zone set in the database) is displayed. When you query the latest decoded WAL log time of a logical replication slot that does not exist, **NULL** is returned. In GSQL, the display of **NULL** is related to the setting, which can be set using `\pset null 'null'`.

- 
- `gs_logical_parallel_decode_status('slot_name')`

Description: Obtains the decoding statistics of an active replication slot for parallel logical decoding on the DN where parallel decoding is performed, including 26 rows of indicators.

The descriptions of the statistical items are listed in the following table.

Record - (stat\_id int, stat\_name TEXT, value TEXT)

**Table 7-64** Statistical items

| Statistical Item             | Description                                                                                               |
|------------------------------|-----------------------------------------------------------------------------------------------------------|
| slot_name                    | Name of the logical replication slot.                                                                     |
| reader_lsn                   | Location of the logic logs to be decoded.                                                                 |
| wal_read_total_time          | Time required for loading the log module.                                                                 |
| wal_wait_total_time          | Time required for waiting for log decoding.                                                               |
| parser_total_time            | Processing duration of the reader thread.                                                                 |
| decoder_total_time           | Processing duration of all decoder threads.                                                               |
| sender_total_time            | Processing duration of the sender thread.                                                                 |
| net_send_total_time          | Time required for the network to send logical logs.                                                       |
| net_wait_total_time          | Time required for the network to wait for sending logical logs.                                           |
| net_send_total_bytes         | Number of logical log bytes sent by the network.                                                          |
| transaction_count            | Number of transactions.                                                                                   |
| big_transaction_count        | Number of large transactions.                                                                             |
| max_transaction_tuples       | Maximum number of transaction operation tuples.                                                           |
| sent_transaction_count       | Number of transactions sent (by the local database).                                                      |
| spill_disk_transaction_count | Number of flushed transactions.                                                                           |
| spill_disk_bytes             | Total number of bytes flushed to disks.                                                                   |
| spill_disk_count             | Number of disk flushing times.                                                                            |
| input_queue_full_count       | Total number of times that the input queues of all decoder threads are full.                              |
| output_queue_full_count      | Total number of times that the output queues of all decoder threads are full.                             |
| dml_count                    | Total number of DML statements in WALs decoded by each decoder thread in the local database.              |
| dml_filtered_count           | Total number of DML statements in WALs decoded and filtered by each decoder thread in the local database. |
| toast_count                  | Number of modified TOAST table rows.                                                                      |

| Statistical Item        | Description                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------|
| candidate_catalog_xmin  | Indicates the <b>catalog_xmin</b> candidate point of the current logical replication slot. |
| candidate_xmin_lsn      | Updates the log confirmation receiving point required by <b>catalog_xmin</b> .             |
| candidate_restart_valid | Updates the log confirmation receiving point required by <b>restart_lsn</b> .              |
| candidate_restart_lsn   | Indicates the <b>restart_lsn</b> candidate point of the current logical replication slot.  |

Parameter description:

- slot\_name

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

Return type: int, text, text

Example:

```
gaussdb=# execute direct on (datanode1) 'select * from
gs_logical_parallel_decode_status("replication_slot");'
```

```
stat_id | stat_name | value
-----+-----+-----
 1 | slot_name | replication_slot
 2 | reader_lsn | 0/357E180
 3 | wal_read_total_time | 266694599
 4 | wal_wait_total_time | 266691307
 5 | parser_total_time | 39971
 6 | decoder_total_time | 81216
 7 | sender_total_time | 48193
 8 | net_send_total_time | 19388
 9 | net_wait_total_time | 0
10 | net_send_total_bytes | 266897
11 | transaction_count | 7
12 | big_transaction_count | 1
13 | max_transaction_tuples | 4096
14 | sent_transaction_count | 7
15 | spill_disk_transaction_count | 1
16 | spill_disk_bytes | 244653
17 | spill_disk_count | 4096
18 | input_queue_full_count | 0
19 | output_queue_full_count | 0
20 | dml_count | 4097
21 | dml_filtered_count | 0
22 | toast_count | 0
23 | candidate_catalog_xmin | 17152
24 | candidate_xmin_lsn | 0/420A598
25 | candidate_restart_valid | 0/420A598
26 | candidate_restart_lsn | 0/420A598
```

(26 rows)

Note: According to the definitions of statistical items, they must meet the following requirements:

wal\_read\_total\_time >= wal\_wait\_total\_time;

transaction\_count >= big\_transaction\_count;

```
transaction_count >= sent_transaction_count;
transaction_count >= spill_disk_transaction_count;
dml_count >= dml_filtered_count;
dml_count >= toast_count;
```

If spill\_transaction\_count == 0, then spill\_disk\_bytes == 0;

However, frequent locking and unlocking are required, which greatly affects the performance. As a result, the preceding constraints may not be met in extreme cases.

**transaction\_count** indicates the number of transactions in all databases.

**sent\_transaction\_count** indicates the number of transactions sent by the local database because transactions that are not in the local database will not be sent.

If the value of **slot\_name** does not exist, the function does not report an error and the return value is empty.

- gs\_logical\_parallel\_decode\_reset\_status('slot\_name')

Description: Resets indicators in gs\_logical\_parallel\_decode\_status('slot\_name') on the DN where parallel decoding is performed.

Parameter:

- slot\_name

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

Return type: text

Example:

```
gaussdb=# execute direct on (datanode1) 'select * from
gs_logical_parallel_decode_reset_status("replication_slot");';
gs_logical_parallel_decode_reset_status
```

```

OK
(1 row)
```

```
gaussdb=# execute direct on (datanode1) 'select * from
gs_logical_parallel_decode_status("replication_slot");';
```

| stat_id | stat_name                    | value            |
|---------|------------------------------|------------------|
| 1       | slot_name                    | replication_slot |
| 2       | reader_lsn                   | 0/357E420        |
| 3       | wal_read_total_time          | 0                |
| 4       | wal_wait_total_time          | 0                |
| 5       | parser_total_time            | 0                |
| 6       | decoder_total_time           | 0                |
| 7       | sender_total_time            | 0                |
| 8       | net_send_total_time          | 0                |
| 9       | net_wait_total_time          | 0                |
| 10      | net_send_total_bytes         | 0                |
| 11      | transaction_count            | 0                |
| 12      | big_transaction_count        | 0                |
| 13      | max_transaction_tuples       | 0                |
| 14      | sent_transaction_count       | 0                |
| 15      | spill_disk_transaction_count | 0                |
| 16      | spill_disk_bytes             | 0                |
| 17      | spill_disk_count             | 0                |
| 18      | input_queue_full_count       | 0                |

```

19 | output_queue_full_count | 0
20 | dml_count | 0
21 | dml_filtered_count | 0
22 | toast_count | 0
23 | candidate_catalog_xmin | 0
24 | candidate_xmin_lsn | 0/0
25 | candidate_restart_valid | 0/420A598
26 | candidate_restart_lsn | 0/420A598
(26 rows)

```

Note: If the value of **slot\_name** does not exist, the function does not report an error and the return value is **invalid slot name**.

Do not reset a replication slot that is being observed. The error information is as follows:

- a. If **slot\_name** is empty, the following error is reported: "ERROR: inputString should not be NULL is displayed".
- b. If **slot\_name** is not empty but does not exist, no error is reported but "invalid slot name" is displayed.
- c. If **slot\_name** is not empty but the replication slot corresponding to **slot\_name** is being observed, no error is reported but "can't reset during observing! use gs\_logical\_decode\_stop\_observe to stop." is displayed.

- **gs\_get\_parallel\_decode\_thread\_info()**

Description: Returns the thread information of the active replication slot on the current DN where parallel decoding is performed.

Return type: int64, text, text, int

Example:

```

gaussdb=# execute direct on (decode_datanode1) 'select * from gs_get_parallel_decode_thread_info();'
 thread_id | slot_name | thread_type | seq_number
-----+-----+-----+-----
140335364699904 | slot1 | sender | 1
140335214098176 | slot1 | reader | 1
140335325312768 | slot1 | decoder | 1
140335291750144 | slot1 | decoder | 2
140335274968832 | slot1 | decoder | 3
140335258187520 | slot1 | decoder | 4
140335165404928 | slot2 | sender | 1
140335022864128 | slot2 | reader | 1
140335129818880 | slot2 | decoder | 1
140335113037568 | slot2 | decoder | 2
(10 rows)

```

Note: In the return values, **thread\_id** indicates the thread ID, **slot\_name** indicates the replication slot name, and **thread\_type** indicates the thread type (including the sender, reader and decoder), **seq\_number** indicates the sequence number of each thread with same type in the current replication slot. Each parallel decoding connection only has one sender and reader. Therefore, the sequence numbers of the sender and reader are both 1. The sequence numbers of the decoder are arranged from 1 to the decoding degree of parallelism (DOP) of the current replication slot.

- **gs\_get\_distribute\_decode\_status()**

Description: Obtains the distributed decoding status details (by replication slot) on the current node. This command must be executed on CNs. If it is executed on DNs, null is returned.

Return type: text, int, int, int64, xid, xid, text, text, text

```

gaussdb=# SELECT * FROM gs_get_distribute_decode_status();
 slot_name | logical_receiver_num | slice_num | walsender_thread_id | last_sent_csn |

```

```

last_confirmed_csn | receiver_queue_length | connect_times |
csn_receive_array
+-----+-----+-----+-----+
slot1 | 1 | 3 | 139958481843968 | 2012169 | 2010107 | queue0: 1,
queue1: 1, queue2: 0 | slice0: 2, slice1: 2, slice2: 2 | slice0: 2012244, slice1: 2012244, slice2: 2012244
(1 row)

```

**Table 7-65** Description

| Statistical Item      | Type  | Description                                                                                                 |
|-----------------------|-------|-------------------------------------------------------------------------------------------------------------|
| slot_name             | text  | Replication slot name.                                                                                      |
| logical_receiver_num  | int   | Number of receiver threads started for distributed decoding.                                                |
| slice_num             | int   | Number of shards in a cluster.                                                                              |
| walsender_thread_id   | int64 | WAL sender thread ID.                                                                                       |
| last_sent_csn         | xid   | CSN that is sent recently.                                                                                  |
| last_confirmed_csn    | xid   | The last CSN returned from the client that has been confirmed for reception.                                |
| receiver_queue_length | text  | Length of the log queue received on each DN (displayed in the character string format after concatenation). |
| connect_times         | text  | Number of times that each DN is connected (displayed in the character string format after concatenation).   |
| csn_receive_array     | text  | Latest CSN obtained by each DN (displayed in the character string format after concatenation).              |

- gs\_get\_distribute\_decode\_status\_detail()**  
 Description: Obtains the distributed decoding status details (by DN) on the current node. This command must be executed on CNs. If it is executed on DNs, null is returned.

Return type: text, int, int64, int, int, xid

```

gaussdb=# SELECT * FROM gs_get_distribute_decode_status_detail();
slot_name | slice_id | thread_id | queue_len | connect_times | received_csn
+-----+-----+-----+-----+-----+-----+
slot1 | 0 | 139959895848704 | 1 | 2 | 2012244
slot1 | 1 | 139959895848704 | 1 | 2 | 2012244
slot1 | 2 | 139959895848704 | 0 | 2 | 2012244
(3 rows)

```

**Table 7-66** Description

| Statistical Item | Type  | Description                                                 |
|------------------|-------|-------------------------------------------------------------|
| slot_name        | text  | Replication slot name.                                      |
| slice_id         | int   | Shard ID (starting from 0).                                 |
| thread_id        | int64 | ID of the receiver thread started for distributed decoding. |
| queue_len        | int   | Length of the log queue received on the current DN.         |
| connect_times    | int   | Number of times that each DN is connected.                  |
| received_csn     | xid   | Latest CSN obtained from the current DN.                    |

### 7.5.25.11 Undo System Functions

#### NOTE

The Undo system function can be executed only on DNs.

- `gs_undo_meta(type, zoneld, location)`

Description: Specifies metadata of a module in the undo system.

Parameter description:

- **type** (metadata type)
  - **0**: indicates metadata corresponding to an undo zone (record).
  - **1**: indicates metadata corresponding to an undo zone(transaction slot).
  - **2**: indicates metadata corresponding to an undo space (record).
  - **3**: indicates metadata corresponding to an undo space(transaction slot).
- **zoneld** (undo zone ID)
  - **-1**: indicates metadata of all undo zones.
  - **0** to  $1024 \times 1024 - 1$ : indicates the meta information of the corresponding zone ID.
- **location** (read location)
  - **0**: indicates that data is read from the current memory.
  - **1**: indicates that data is read from a physical file.

Return type: record

**Table 7-67** gs\_undo\_meta parameters

| Category         | Parameter   | Type | Description                                                                                                                                        |
|------------------|-------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Output parameter | zoneld      | oid  | ID of an undo zone.                                                                                                                                |
| Output parameter | persistType | oid  | Persistence level.                                                                                                                                 |
| Output parameter | insert      | text | Position of the next undo record to be inserted.                                                                                                   |
| Output parameter | discard     | text | Position of the undo record that is recycled in common mode.                                                                                       |
| Output parameter | end         | text | Position of the undo record that is forcibly recycled. Values smaller than the value of this parameter indicate that the record has been recycled. |
| Output parameter | used        | text | Undo space that has been used.                                                                                                                     |
| Output parameter | lsn         | text | Modifies the LSN of an undo zone.                                                                                                                  |
| Output parameter | pid         | oid  | ID of a process bound to an undo zone.                                                                                                             |

- gs\_undo\_translot(location, zoneld)  
Description: Specifies transaction slot information of the undo system.  
Parameter description:
  - **location** (read location)
    - **0**: indicates that data is read from the current memory.
    - **1**: indicates that data is read from a physical file.
  - **zoneld** (undo zone ID)
    - **-1**: indicates metadata of all undo zones.
    - **0** to 1024 x 1024 – 1: indicates the meta information of the corresponding zone ID.

Return type: record

**Table 7-68** gs\_undo\_translot parameters

| Category         | Parameter    | Type | Description                                                                                                                                                             |
|------------------|--------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output parameter | groupId      | oid  | Undo zone ID that is used.                                                                                                                                              |
| Output parameter | xactId       | text | Transaction ID.                                                                                                                                                         |
| Output parameter | startUndoPtr | text | Position where an undo record is inserted at the start of a transaction corresponding to a transaction slot.                                                            |
| Output parameter | endUndoPtr   | text | Position where an undo record is inserted at the end of a transaction corresponding to a transaction slot.                                                              |
| Output parameter | lsn          | text | Transaction slot pointer.                                                                                                                                               |
| Output parameter | slot_states  | oid  | Transaction status. <ul style="list-style-type: none"> <li>0: committed.</li> <li>1: being executed.</li> <li>2: being rolled back.</li> <li>3: rolled back.</li> </ul> |

- gs\_stat\_undo([bool init])  
Description: Collects undo statistics.  
Return type: record

**Table 7-69** gs\_stat\_undo parameters

| Category         | Parameter            | Type   | Description                                                                         |
|------------------|----------------------|--------|-------------------------------------------------------------------------------------|
| Input parameter  | init                 | bool   | (Optional) Specifies whether to clear statistics and restart statistics collection. |
| Output parameter | curr_used_zone_count | uint32 | Number of used undo zones.                                                          |

| Category         | Parameter               | Type   | Description                                                                                                                                                                                                                                                                                    |
|------------------|-------------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output parameter | top_used_zones          | text   | Information about the first three undo zones with the maximum usage. The output format is as follows: <ul style="list-style-type: none"> <li>• <b>zone1d1</b>: used size of zone 1.</li> <li>• <b>zone1d2</b>: used size of zone 2.</li> <li>• <b>zone1d3</b>: used size of zone 3.</li> </ul> |
| Output parameter | curr_used_undo_size     | uint32 | Total size of the undo tablespace that is being used. The unit is MB.                                                                                                                                                                                                                          |
| Output parameter | undo_threshold          | uint32 | Calculation result of the value of the GUC parameter <b>undo_space_limit_size</b> x 80%. The unit is MB.                                                                                                                                                                                       |
| Output parameter | global_recycle_xid      | uint64 | XID of the transaction recycled to the undo space. The undo records generated by the transaction whose XID is smaller than the value of XID are recycled.                                                                                                                                      |
| Output parameter | oldest_xmin             | uint64 | Oldest active transaction.                                                                                                                                                                                                                                                                     |
| Output parameter | total_undo_chain_len    | int64  | Total length of all accessed undo chains.                                                                                                                                                                                                                                                      |
| Output parameter | max_undo_chain_len      | int64  | Maximum length of the accessed undo chain.                                                                                                                                                                                                                                                     |
| Output parameter | create_undo_file_count  | uint32 | Number of created undo files.                                                                                                                                                                                                                                                                  |
| Output parameter | discard_undo_file_count | uint32 | Number of deleted undo files.                                                                                                                                                                                                                                                                  |

Description: Parses the page header information of the disk page in the Ustore table, header information of each tuple, flag bit information, and all historical undo version information that can be queried.

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.

 **NOTE**

Currently, this API supports only Ustore tables.

**Table 7-70** gs\_undo\_dump\_parsepage\_mv parameters

| Category         | Parameter | Type    | Description                                                                                                                                                                                                                                         |
|------------------|-----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | relpath   | text    | Relative path of the Ustore table data file, in the format of <i>Tablespace name/Database OID/relfilenode</i> , for example, <b>base/16603/16384</b> . You can run the <b>pg_relation_filepath('tablename')</b> command to query the relative path. |
| Input parameter  | blkno     | bigint  | <ul style="list-style-type: none"> <li>• <b>-1</b>: All block pages are parsed.</li> <li>• <b>0–MaxBlocNumber</b>: A specified block page is parsed.</li> </ul>                                                                                     |
| Input parameter  | reltype   | text    | Table type. Currently, only the Ustore table is supported. The value is <b>uheap</b> .                                                                                                                                                              |
| Input parameter  | rmem      | Boolean | <ul style="list-style-type: none"> <li>• <b>false</b></li> <li>• <b>true</b></li> </ul> Currently, the value can only be <b>false</b> , indicating that the corresponding page is parsed from the disk file.                                        |
| Output parameter | output    | text    | Absolute path of the parsing result file.                                                                                                                                                                                                           |

- gs\_undo\_meta\_dump\_zone(zone\_id int, read\_memory boolean)

Description: Parses undo zone metadata in an undo module.

Return type: record

**Table 7-71** gs\_undo\_meta\_dump\_zone parameters

| Category         | Parameter    | Type    | Description                                                                                                                                                                                      |
|------------------|--------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | zone_id      | int     | Undo zone ID.<br><ul style="list-style-type: none"> <li>• <b>-1</b>: All undo zones are queried.</li> <li>• <b>0-1048575</b>: The undo zone metadata is queried based on the zone ID.</li> </ul> |
| Input parameter  | read_memory  | Boolean | <ul style="list-style-type: none"> <li>• <b>true</b>: Data is read from the current memory.</li> <li>• <b>false</b>: Data is read from the physical file.</li> </ul>                             |
| Output parameter | zone_id      | int     | Undo zone ID.                                                                                                                                                                                    |
| Output parameter | persist_type | int     | Persistence level.<br><ul style="list-style-type: none"> <li>• <b>0</b>: ordinary table</li> <li>• <b>1</b>: unlogged table</li> <li>• <b>2</b>: temporary table</li> </ul>                      |
| Output parameter | insert       | text    | Position of the next undo record to be inserted.                                                                                                                                                 |
| Output parameter | discard      | text    | Position of the undo record that is recycled in common mode.                                                                                                                                     |
| Output parameter | forcediscard | text    | Position of the undo record that is forcibly recycled. Values smaller than the value of this parameter indicate that the record has been recycled.                                               |
| Output parameter | lsn          | text    | Modifies the LSN of a zone.                                                                                                                                                                      |

- `gs_undo_meta_dump_spaces(zone_id int, read_memory boolean)`  
 Description: Parses metadata of an undo record space and a transaction slot space in an undo module.  
 Return type: record

**Table 7-72** gs\_undo\_meta\_dump\_spaces parameters

| Category         | Parameter             | Type    | Description                                                                                                                                                                                      |
|------------------|-----------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | zone_id               | int     | Undo zone ID.<br><ul style="list-style-type: none"> <li>• <b>-1</b>: All undo zones are queried.</li> <li>• <b>0-1048575</b>: The undo zone metadata is queried based on the zone ID.</li> </ul> |
| Input parameter  | read_memory           | Boolean | <ul style="list-style-type: none"> <li>• <b>true</b>: Data is read from the current memory.</li> <li>• <b>false</b>: Data is read from the physical file.</li> </ul>                             |
| Output parameter | zone_id               | int     | Undo zone ID.                                                                                                                                                                                    |
| Output parameter | undorecord_space_tail | text    | End position of the undo record space.                                                                                                                                                           |
| Output parameter | undorecord_space_head | text    | Start position of the undo record space.                                                                                                                                                         |
| Output parameter | undorecord_space_lsn  | text    | Modifies the LSN of an undo record space.                                                                                                                                                        |
| Output parameter | undoslot_space_tail   | text    | End position of a transaction slot space.                                                                                                                                                        |
| Output parameter | undoslot_space_head   | text    | Start position of a transaction slot space.                                                                                                                                                      |
| Output parameter | undoreslot_space_lsn  | text    | Modifies the LSN of an undo slot space.                                                                                                                                                          |

- gs\_undo\_meta\_dump\_slot(zone\_id int, read\_memory boolean)  
Description: Parses transaction slot metadata in an undo module.  
Return type: record

- gs\_undo\_translot\_dump\_xid(slot\_xid xid, read\_memory boolean)  
Description: Parses a transaction slot in an undo zone based on the XID.  
Return type: record

**Table 7-75** gs\_undo\_translot\_dump\_xid parameters

| Category         | Parameter      | Type    | Description                                                                                                                                                                                           |
|------------------|----------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | slot_xid       | xid     | Transaction ID to be queried.                                                                                                                                                                         |
| Input parameter  | read_memory    | Boolean | <ul style="list-style-type: none"> <li>• <b>true</b>: Data is read from the current memory.</li> <li>• <b>false</b>: Data is read from the physical file.</li> </ul>                                  |
| Output parameter | zone_id        | text    | Undo zone ID.                                                                                                                                                                                         |
| Output parameter | slot_xid       | text    | Transaction ID.                                                                                                                                                                                       |
| Output parameter | start_undo_ptr | text    | Position where an undo record is inserted at the start of a transaction corresponding to a transaction slot.                                                                                          |
| Output parameter | end_undoptr    | text    | Position where an undo record is inserted at the end of a transaction corresponding to a transaction slot.                                                                                            |
| Output parameter | slot_ptr       | text    | Position of a transaction slot.                                                                                                                                                                       |
| Output parameter | slot_states    | oid     | Transaction state <ul style="list-style-type: none"> <li>• <b>0</b>: committed</li> <li>• <b>1</b>: being executed</li> <li>• <b>2</b>: being rolled back</li> <li>• <b>3</b>: rolled back</li> </ul> |

- gs\_undo\_dump\_record(undoptr bigint)  
Description: Parses undo records.  
Return type: record

**Table 7-76** gs\_undo\_dump\_record parameters

| Category        | Parameter | Type   | Description                                     |
|-----------------|-----------|--------|-------------------------------------------------|
| Input parameter | undoptr   | bigint | Start position of the undo record to be parsed. |

| Category         | Parameter    | Type   | Description                                             |
|------------------|--------------|--------|---------------------------------------------------------|
| Output parameter | undoptr      | bigint | Start position of the undo record to be parsed.         |
| Output parameter | xactid       | text   | Transaction ID.                                         |
| Output parameter | cid          | text   | Command ID.                                             |
| Output parameter | reloid       | text   | Relation OID.                                           |
| Output parameter | relfilenode  | text   | Relfinode of the file.                                  |
| Output parameter | utype        | text   | Undo record type.                                       |
| Output parameter | blkprev      | text   | Position of the previous undo record in the same block. |
| Output parameter | blockno      | text   | Block number.                                           |
| Output parameter | uoffset      | text   | Undo record offset.                                     |
| Output parameter | prevurp      | text   | Position of the previous undo record.                   |
| Output parameter | payloadlen   | text   | Length of the undo record data.                         |
| Output parameter | oldxactid    | text   | Previous transaction ID.                                |
| Output parameter | partitionoid | text   | Partition OID.                                          |

**Table 7-77** gs\_undo\_dump\_xid parameters

| Category         | Parameter   | Type | Description                                             |
|------------------|-------------|------|---------------------------------------------------------|
| Input parameter  | undo_xid    | xid  | Transaction ID.                                         |
| Output parameter | undoptr     | xid  | Start position of the undo record to be parsed.         |
| Output parameter | xactid      | text | Transaction ID.                                         |
| Output parameter | cid         | text | Command ID.                                             |
| Output parameter | reloid      | text | Relation OID.                                           |
| Output parameter | relfilenode | text | Relfinode of the file.                                  |
| Output parameter | utype       | text | Undo record type.                                       |
| Output parameter | blkprev     | text | Position of the previous undo record in the same block. |
| Output parameter | blockno     | text | Block number.                                           |
| Output parameter | uoffset     | text | Undo record offset.                                     |
| Output parameter | prevurp     | text | Position of the previous undo record.                   |
| Output parameter | payloadlen  | text | Length of the undo record data.                         |
| Output parameter | oldxactid   | text | Previous transaction ID.                                |

| Category         | Parameter         | Type | Description                                                      |
|------------------|-------------------|------|------------------------------------------------------------------|
| Output parameter | partitionoid      | text | Partition OID.                                                   |
| Output parameter | tablespace        | text | Tablespace.                                                      |
| Output parameter | alreadyread_bytes | text | Length of the read undo record.                                  |
| Output parameter | prev_undo_rec_len | text | Length of the previous undo record.                              |
| Output parameter | td_id             | text | ID of the transaction directory.                                 |
| Output parameter | reserved          | text | Reserved flag of the old version tuple stored in an undo record. |
| Output parameter | flag              | text | Status flag of the old version tuple stored in an undo record.   |
| Output parameter | flag2             | text | Number of old version tuple columns stored in an undo record.    |
| Output parameter | t_hoff            | text | Length of the undo record data header.                           |

- `gs_verify_undo_record(type, start_idx, end_idx, location)`

Description: Verifies undo records. Currently, only the disk verification mode is supported. Offline verification can be performed only when services are not running. Before the verification, you need to manually perform checkpoint flushing.

Return type: record

**Table 7-78** gs\_verify\_undo\_record parameters

| Category         | Parameter | Type  | Description                                                                                                                                                                                                                                             |
|------------------|-----------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | type      | text  | Verification type. <ul style="list-style-type: none"> <li>'urp': verifies all undo records in a specified URP range.</li> <li>'zone': verifies all undo records of all zones in a specified zone range.</li> </ul>                                      |
| Input parameter  | start_idx | int64 | Start position. <ul style="list-style-type: none"> <li>When <b>type</b> is set to 'urp', this parameter indicates the start position of undo records.</li> <li>When type is set to 'zone', this parameter indicates the start undo zone ID.</li> </ul>  |
| Input parameter  | end_idx   | int64 | End position. <ul style="list-style-type: none"> <li>When <b>type</b> is set to 'urp', this parameter indicates the end position of undo records.</li> <li>When <b>type</b> is set to 'zone', this parameter indicates the end undo zone ID.</li> </ul> |
| Input parameter  | location  | bool  | <ul style="list-style-type: none"> <li>0: memory verification</li> <li>1: disk verification</li> </ul> Currently, this parameter can only be set to 1.                                                                                                  |
| Output parameter | zone_id   | int64 | Undo zone ID.                                                                                                                                                                                                                                           |
| Output parameter | detail    | text  | Verification error information.                                                                                                                                                                                                                         |

Example 1: Verify the undo record whose URP is 24.

```
gaussdb=# select * from gs_verify_undo_record('urp', 24, 24, 1);
zone_id | detail
-----+-----
(0 rows)
```

Example 2: If the entered value of **urp** is incorrect, that is, the value is not the start position of the undo record, the system may return a message indicating that the verification result is empty or the verification fails.

```
gaussdb=# select * from gs_verify_undo_record('urp', 35184372173095, 35184372173095, 1);
zone_id | detail
-----+-----
```

```
2 | verification failed: xid is invalid, urp:35184372173095.
(1 row)
```

Example 3: Verify all undo records from zone 0 to zone 2 on the disk.

```
gaussdb=# select * from gs_verify_undo_record('zone', 0, 2, 1);
zone_id | detail
-----+-----
(0 rows)
```

 **NOTE**

If an error is reported when this view is called, contact Huawei technical support.

- `gs_verify_undo_slot(type, start_idx, end_idx, location)`

Description: Verifies undo transaction slots. Currently, only the disk verification mode is supported. Offline verification can be performed only when services are not running. Before the verification, you need to manually perform checkpoint flushing.

Return type: record

**Table 7-79** gs\_verify\_undo\_slot parameters

| Category         | Parameter | Type  | Description                                                                                                                                            |

| Category         | Parameter | Type  | Description                                                                                                                                                                                            |
|------------------|-----------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | type      | text  | Verification type. The value of <b>type</b> can only be set to 'all'. <ul style="list-style-type: none"> <li>• 'all': verifies all meta information of all zones in a specified zone range.</li> </ul> |
| Input parameter  | start_idx | int64 | Start undo zone ID.                                                                                                                                                                                    |
| Input parameter  | end_idx   | int64 | End undo zone ID.                                                                                                                                                                                      |
| Input parameter  | location  | bool  | <ul style="list-style-type: none"> <li>• 0: memory verification</li> <li>• 1: disk verification</li> </ul> Currently, this parameter can only be set to 1.                                             |
| Output parameter | zone_id   | int64 | Undo zone ID.                                                                                                                                                                                          |
| Output parameter | detail    | text  | Verification error information.                                                                                                                                                                        |

Example 1: Verify all meta information records from zone 0 to zone 2 on the disk.

```
gaussdb=# select * from gs_verify_undo_meta('all', 0, 2, 1);
zone_id | detail
-----+-----
(0 rows)
```

 **NOTE**

If an error is reported when this view is called, contact Huawei technical support.

- `gs_async_rollback_worker_status()`  
Description: Monitors the status of active asynchronous rollback threads.

Return type: record

**Table 7-81** gs\_async\_rollback\_worker\_status parameters

| Category         | Parameter           | Type        | Description                                                                                                                           |
|------------------|---------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Output parameter | datid               | oid         | Database ID.                                                                                                                          |
| Output parameter | pid                 | int64       | Process ID.                                                                                                                           |
| Output parameter | sessionid           | int64       | Session ID.                                                                                                                           |
| Output parameter | usesysid            | oid         | ID of the user who initiates the thread.                                                                                              |
| Output parameter | state               | int32       | Thread status.<br><b>0</b> : undefined<br><b>1</b> : idle<br><b>2</b> : running                                                       |
| Output parameter | rollback_start_time | timestamptz | Timestamp when a thread is started.                                                                                                   |
| Output parameter | idx                 | uint32      | Index of an asynchronous rollback thread in the array.                                                                                |
| Output parameter | xid                 | uint64      | XID of the transaction that is being rolled back.                                                                                     |
| Output parameter | progress            | text        | Rollback progress of the transaction (number of undo records that have been rolled back/total number of undo records, in percentage). |

- gs\_async\_rollback\_xact\_status()  
Description: Monitors the hash table of asynchronous rollback tasks.  
Return type: record

**Table 7-82** gs\_async\_rollback\_xact\_status parameters

| Category         | Parameter     | Type   | Description                                                       |
|------------------|---------------|--------|-------------------------------------------------------------------|
| Output parameter | xid           | xid    | XID of the transaction that requires asynchronous rollback.       |
| Output parameter | start_undoptr | uint64 | Pointer to the start undo record of the transaction.              |
| Output parameter | end_undoptr   | uint64 | Pointer to the end undo record of the transaction.                |
| Output parameter | dbid          | uint32 | ID of the database where the transaction is located.              |
| Output parameter | slot_ptr      | uint64 | Pointer to the transaction slot corresponding to the transaction. |
| Output parameter | launched      | bool   | Checks whether there is an active asynchronous rollback thread.   |

- gs\_undo\_recycler\_status()  
Description: Monitors the status of asynchronous recycling threads.  
Return type: record

**Table 7-83** gs\_undo\_recycler\_status parameters

| Category         | Parameter     | Type       | Description                                                                     |
|------------------|---------------|------------|---------------------------------------------------------------------------------|
| Output parameter | datid         | oid        | Database ID.                                                                    |
| Output parameter | pid           | int64      | Process ID.                                                                     |
| Output parameter | sessionid     | int64      | Session ID.                                                                     |
| Output parameter | usesysid      | oid        | ID of the user who initiates the thread.                                        |
| Output parameter | state         | int32      | Thread status.<br><b>0</b> : undefined<br><b>1</b> : idle<br><b>2</b> : running |
| Output parameter | backend_start | timestampz | Timestamp when a thread is started.                                             |

| Category         | Parameter                                | Type   | Description                                         |
|------------------|------------------------------------------|--------|-----------------------------------------------------|
| Output parameter | total_recycle_time                       | uint64 | Total recycling time.                               |
| Output parameter | max_recycle_time                         | uint64 | Maximum recycling time.                             |
| Output parameter | total_recycle_size                       | uint64 | Total recycled space.                               |
| Output parameter | total_recycle_count                      | uint64 | Total number of recycling times.                    |
| Output parameter | recycle_sleep_count                      | uint64 | Number of sleep times.                              |
| Output parameter | recycle_sleep_time                       | uint64 | Total sleep time.                                   |
| Output parameter | max_recycle_sleep_time                   | uint64 | Maximum sleep time.                                 |
| Output parameter | last_recycle_timestamp                   | uint64 | Timestamp of the last successful recycling.         |
| Output parameter | last_update_global_recycle_xid_timestamp | uint64 | Timestamp of the last global recycling transaction. |

- gs\_undo\_launcher\_status()**  
 Description: Monitors the status of asynchronous rollback launcher threads.  
 Return type: record

**Table 7-84** gs\_undo\_launcher\_status parameters

| Category         | Parameter | Type  | Description                                                                  |
|------------------|-----------|-------|------------------------------------------------------------------------------|
| Output parameter | datid     | oid   | Database ID.                                                                 |
| Output parameter | pid       | int64 | Process ID.                                                                  |
| Output parameter | sessionid | int64 | Session ID.                                                                  |
| Output parameter | usesysid  | oid   | ID of the user who initiates the thread.                                     |
| Output parameter | state     | int32 | Thread status.<br><b>0:</b> undefined<br><b>1:</b> idle<br><b>2:</b> running |

| Category         | Parameter                               | Type        | Description                                                                                            |
|------------------|-----------------------------------------|-------------|--------------------------------------------------------------------------------------------------------|
| Output parameter | backend_start                           | timestamptz | Timestamp when a thread is started.                                                                    |
| Output parameter | total_async_roll<br>back_task_coun<br>t | uint64      | Total number of asynchronous rollback tasks initiated after the database on the local node is started. |
| Output parameter | average_async_<br>rollback_time         | uint64      | Average duration of an asynchronous rollback task.                                                     |
| Output parameter | max_async_roll<br>back_time             | uint64      | Maximum duration of an asynchronous rollback task.                                                     |
| Output parameter | min_async_rollb<br>ack_time             | uint64      | Minimum duration of an asynchronous rollback task.                                                     |

### 7.5.25.12 Other Functions

- pgxc\_pool\_check()**  
Description: Checks whether the connection data buffered in the pool is consistent with **pgxc\_node**.  
Return type: Boolean
- pgxc\_pool\_reload()**  
Description: Updates the connection information buffered in the pool.  
Return type: Boolean
- reload\_active\_coordinator()**  
Description: Updates the connection information buffered in the pool for all active CNs.  
Return type: void
- pgxc\_lock\_for\_backup()**  
Description: Locks a cluster for taking backup that would be restored on the new node to be added.  
Return type: Boolean

#### NOTE

- pgxc\_lock\_for\_backup** locks a cluster before **gs\_dump** or **gs\_dumpall** is used to back up the cluster. After a cluster is locked, operations changing the system structure are not allowed. This function does not affect DML statements.
- pg\_pool\_validate(clear bool, node\_name text)**  
Description: Displays invalid connections in the pooler between the CN and node\_name. When the value of **clear** is **true**, invalid connections are cleared.  
Return type: record

- `gs_validate_node_conn(validate_type cstring, validate_node_name cstring)`  
Description: Displays or clears the connections received by the current node from a specified node.  
Return type: record

**Table 7-85** `gs_validate_node_conn` parameters

| Category         | Parameter                       | Type                 | Description                                                                                                                                                                                                                                                                               |
|------------------|---------------------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input parameter  | <code>validate_type</code>      | <code>cstring</code> | Specifies an input parameter type. <ul style="list-style-type: none"> <li>• <b>'check'</b>: displays the connections received by the current node from a specified node.</li> <li>• <b>'clear'</b>: clears the connections received by the current node from a specified node.</li> </ul> |
| Input parameter  | <code>validate_node_name</code> | <code>cstring</code> | Specifies a node name.                                                                                                                                                                                                                                                                    |
| Output parameter | <code>pid</code>                | <code>bigint</code>  | Displays the ID of a thread where the current node receives connections from the specified node. If the thread is from a thread pool, the value is <b>0</b> .                                                                                                                             |
| Output parameter | <code>sessionid</code>          | <code>bigint</code>  | Displays the ID of a session where the current node receives connections from the specified node. If the thread is not from a thread pool, the value is <b>0</b> .                                                                                                                        |
| Output parameter | <code>node_name</code>          | <code>text</code>    | Displays the name of a node from which the current node receives connections.                                                                                                                                                                                                             |

- `pgxc_pool_connection_status()`  
Description: Checks whether the pooler connection status is **normal**.  
Return type: Boolean
- `pg_nodes_memory()`  
Description: Queries the memory usage of all nodes.  
Return type: record
- `table_skewness(text)`  
Description: Queries the percentage of table data among all nodes.  
Parameter: Indicates that the type of the name of the to-be-queried table is text.  
Return type: record

- table\_skewness(text, text, text)**

Description: Queries the percentage of a specified column in the table data among all nodes.

Parameters: name of the table to be queried, specified column name, and number of records in the specified table. The default value is **0**, indicating that all records are queried. All parameters are of the text type.

Return type: record

Return value description: Node ID, number of data rows in a specified column, and percentage of the data volume of the current node to the total data volume

Example:

Return the distribution of the first five rows of data in the **a** column of the **t** table on a node.

```
gaussdb=# select table_skewness('t', 'a',5);
table_skewness

(1,3,60.000%)
(2,2,40.000%)
(2 rows)
```

Return the distribution of all data in the **a** column of the **t** table on a node.

```
gaussdb=# select table_skewness('t', 'a');
table_skewness

(1,7,70.000%)
(2,2,20.000%)
(0,1,10.000%)
(3 rows)
```
- table\_skewness\_with\_schema(text, text)**

Description: Checks the proportion of table data on all nodes. The function is the same as that of **table\_skewness(text)**.

**text** indicates that the types of the schema name and table name for the table to be queried are both text.

Return type: record
- table\_data\_skewness(colrecord, type)**

Description: Queries the node where the table data is located.

Parameter description:

**colrecord**: column name record of the table to be queried. The value is of the record type.

**type**: hash distribution type

Return type: smallint

Example:

```
-- Return the node where the index column data of the 'test1' table is located.
gaussdb=# select table_data_skewness(row(index), 'R') from test1;
table_data_skewness

4
3
1
2
(4 rows)
```
- table\_distribution(schemaname text, tablename text)**

Description: Queries the storage space occupied by a specified table on each node.

**text** indicates that the types of the schema name and table name for the table to be queried are both text.

Return type: record

 **NOTE**

- To query the storage distribution of a specified table by using this function, you must have the SELECT permission for the table.
- The performance of **table\_distribution** is better than that of **table\_skewness**. In the scenario with a large amount of data, **table\_distribution** is recommended.
- When you use **table\_distribution** and want to view the space usage, you can use **dnsize** or **(sum(dnsize) over ())** to view the percentage.

- **table\_distribution()**

Description: Queries the storage distribution of all tables in the current database.

Return type: record

 **NOTE**

- This function involves the query for information about all tables in the database. To execute this function, you must have the administrator rights.
- Based on the **table\_distribution()** function, GaussDB provides the **PGXC\_GET\_TABLE\_SKEWNESS** view as an alternative way to query data skew. You are advised to use this view when the number of tables in the database is less than 10000.

- **plan\_seed()**

Description: Obtains the seed value of the previous query statement (internal use).

Return type: int

- **pg\_stat\_get\_env()**

Description: Obtains the environment variable information of the current node. Only users with the sysadmin or monitor admin permission can access the environment variable information.

Return type: record

Example:

```
gaussdb=# select pg_stat_get_env();
 pg_stat_get_env

(coordinator1,localhost,144773,49100,/data1/GaussDB_Kernel_TRUNK/install,/data1/
GaussDB_Kernel_TRUNK/install/data/coordinator1,pg_log)
(1 row)
```

- **pg\_catalog.plancache\_clean()**

Description: Clears the global plan cache that is not used on nodes.

Return type: Boolean

- **pg\_stat\_get\_thread()**

Description: Provides thread status information on the current node. Users with the sysadmin or monitor admin permission can view information about all threads. Common users can view only their own thread information.

Return type: record

- `pgxc_get_os_threads()`  
Description: Provides thread status information about all normal nodes in the entire cluster.  
Return type: record
  - `pg_stat_get_sql_count()`  
Description: Provides the counts of the SELECT, UPDATE, INSERT, DELETE, and MERGE INTO statements executed on the current node. Users with the `sysadmin` or `monitor admin` permission can view information about all users. Common users can view only their own statistics.  
Return type: record
  - `pgxc_get_sql_count()`  
Description: Provides the counts of the SELECT, UPDATE, INSERT, DELETE, and MERGE INTO statements executed on all the nodes in the entire cluster.  
Return type: record
  - `pgxc_get_node_env()`  
Description: Provides the environment variable information about all nodes in a cluster.  
Return type: record
  - `pgxc_disaster_read_set(text)`  
Description: Configures node information about the DR cluster on ETCD. Only the DR cluster is available and can be called only by initial users.  
Return type: Boolean
  - `pgxc_disaster_read_init()`  
Description: Initializes readable DR resources and status information. Only the DR cluster is available and can be called only by initial users.  
Return type: Boolean
  - `pgxc_disaster_read_clear()`  
Description: Clears readable DR resources and status information. Only the DR cluster is available and can be called only by initial users.  
Return type: Boolean
  - `pgxc_disaster_read_status()`  
Description: Provides node information about the DR cluster. This function is available only for the DR cluster.  
Return type: record
  - `gs_switch_relfilenode()`  
Description: Exchanges meta information of two tables or partitions. (This is only used for the redistribution tool. An error message is displayed when the function is directly used by users).  
Return type: int
-  **NOTE**
- This function may cause clearing of statistics. You are advised to collect statistics again after this function is called.
- `pg_catalog.plancache_clean()`  
Description: Clears the global plan cache that is not used on the current node.

Return type: Boolean

- DBE\_PERF.global\_plancache\_clean()

Description: Clears the global plan cache that is not used on all nodes.

Return type: Boolean

- copy\_error\_log\_create()

Description: Creates the error table (**public.pgxc\_copy\_error\_log**) required for creating the **COPY FROM** error tolerance mechanism.

Return type: Boolean

 NOTE

- This function attempts to create the **public.pgxc\_copy\_error\_log** table. For details about the table, see [Table 7-86](#).
- In addition, it creates a B-tree index on the **relname** column and executes **REVOKE ALL on public.pgxc\_copy\_error\_log FROM public** to manage permissions on the error table (the permissions are the same as those of the **COPY** statement).
- **public.pgxc\_copy\_error\_log** is a row-store table. Therefore, this function can be executed and **COPY** error tolerance is available only when row-store tables can be created in the cluster. Row-store tables cannot be created in the cluster if the GUC parameter **enable\_hadoop\_env** is set to **on** (by default, this parameter set to **off** for GaussDB).
- Same as the error table and the **COPY** statement, the function requires **sysadmin** or higher permissions.
- If the **public.pgxc\_copy\_error\_log** table or the **copy\_error\_log\_relname\_idx** index exists before the function creates it, the function will report an error and roll back.

**Table 7-86** Error table public.pgxc\_copy\_error\_log

| Column        | Type                     | Description                                                              |
|---------------|--------------------------|--------------------------------------------------------------------------|
| relname       | character varying        | Table name in the form of <i>Schema name.Table name</i>                  |
| begintime     | timestamp with time zone | Time when a data format error was reported                               |
| filename      | character varying        | Name of the source data file where a data format error occurs            |
| lineno        | bigint                   | Number of the row where a data format error occurs in a source data file |
| rawrecord     | text                     | Raw record of a data format error in the source data file                |
| <b>detail</b> | text                     | Error details                                                            |

- pg\_stat\_get\_data\_senders()

Description: Provides detailed information about the data-copy sender thread active at the moment.

Return type: record

- `textlen()`  
Description: Provides the method of querying the logical length of text.  
Return type: int
- `threadpool_status()`  
Description: Displays the status of worker threads and sessions in the thread pool.  
Return type: record
- `get_local_active_session()`  
Description: Provides sampling records of historical active sessions stored in the memory by current node. Users with the **sysadmin** or **monitor admin** permission can view all historical active session records of the current node. Common users can view the historical active session records of the current session.  
Return type: record
- `dbe_perf.get_global_active_session()`  
Description: Provides sampling records of the historical active sessions stored in the memory of all nodes.  
Return type: record
- `dbe_perf.get_global_gs_asp(timestamp, timestamp)`  
Description: Provides sampling records of the historical active sessions stored in the `gs_asp` system catalog of all nodes.  
Return type: record
- `get_wait_event_info()`  
Description: Provides detailed information about the wait event.  
Return type: record
- `dbe_perf.get_datanode_active_session(text)`  
Description: Provides sampling records of historical active sessions stored in the memory of DN, which is queried from CN.  
Return type: record  
Note: This function queries the records in the `local_active_session` view on the target DN and matches the records with those in the `local_active_session` view on all CNs to obtain the query string. Therefore, a large amount of memory is occupied.
- `dbe_perf.get_datanode_active_session_hist(text, timestamp, timestamp)`  
Description: Provides sampling records of historical active sessions stored in the `gs_asp` system catalog of DN, which is queried from CN.  
Return type: record  
Note: This function queries the **gs\_asp** records of a specified period on the target DN. If the period is specified too long, too many records will be queried, which takes a long time.
- `generate_wdr_report(bigint, bigint, cstring, cstring, cstring)`  
Description: Generates a system diagnosis report based on two snapshots. By default, the initial user or monitor administrator can access the report. The result can be queried only in the system database but cannot be queried in the user database.

Return type: text

**Table 7-87** generate\_wdr\_report parameter description

| Parameter     | Description                                                                                                                                                                                                                                                                    | Range                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| begin_snap_id | Snapshot ID that starts the diagnosis report period.                                                                                                                                                                                                                           | N/A                                                                                                                                                                          |
| end_snap_id   | Snapshot ID that ends the diagnosis report period. By default, the value of <b>end_snap_id</b> is greater than that of <b>begin_snap_id</b> .                                                                                                                                  | N/A                                                                                                                                                                          |
| report_type   | Specifies the type of the generated report.                                                                                                                                                                                                                                    | <ul style="list-style-type: none"> <li>• <b>summary</b></li> <li>• <b>detail</b></li> <li>• <b>all</b>: Both <b>summary</b> and <b>detail</b> types are included.</li> </ul> |
| report_scope  | Specifies the scope for a report to be generated.                                                                                                                                                                                                                              | <ul style="list-style-type: none"> <li>• <b>cluster</b>: database-level information</li> <li>• <b>node</b>: node-level information.</li> </ul>                               |
| node_name     | <ul style="list-style-type: none"> <li>• When <b>report_scope</b> is set to <b>node</b>, set this parameter to the name of the corresponding node.</li> <li>• If <b>report_scope</b> is set to <b>cluster</b>, this parameter can be omitted or set to <b>NULL</b>.</li> </ul> | <ul style="list-style-type: none"> <li>• <b>node</b>: node name in GaussDB.</li> <li>• <b>cluster</b>: This value is omitted, left blank or set to <b>NULL</b>.</li> </ul>   |

- **create\_wdr\_snapshot()**  
Description: Manually generates system diagnosis snapshots. This function requires the **sysadmin** permission and can be executed only on the CCN.  
Return type: text
- **kill\_snapshot()**  
Description: Kills the WDR snapshot backend thread. Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role.  
Return type: void
- **capture\_view\_to\_json(text, integer)**  
Description: Saves the view result to the directory specified by GUC: **perf\_directory**. If **is\_crossdb** is set to **1**, the view is accessed once for all databases. If the value of **is\_crossdb** is **0**, the current database is accessed only once. Only users with the sysadmin or monitor admin permission can execute this function.

- Return type: int
- `reset_unique_sql(text, text, bigint)`  
Description: Clears the Unique SQL statements in the memory of CN/DN. (The `sysadmin` or `monitor admin` permission is required.)  
Return type: Boolean

**Table 7-88** `reset_unique_sql` parameter description

| Parameter                | Type | Description                                                                                                                                                                                                             |
|--------------------------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>scope</code>       | text | Clearance scope type. The options are as follows:<br><b>'GLOBAL'</b> : Clears all CNs/DNs. If the value is <b>'GLOBAL'</b> , this function can be executed only on the CN.<br><b>'LOCAL'</b> : Clears the current node. |
| <code>clean_type</code>  | text | <b>'BY_USERID'</b> : Unique SQL statements are cleared based on user IDs.<br><b>'BY_CNID'</b> : Unique SQL statements are cleared based on CN IDs.<br><b>'ALL'</b> : All data is cleared.                               |
| <code>clean_value</code> | int8 | Clearance value corresponding to the clearance type. If the second parameter is set to <b>ALL</b> , the third parameter does not take effect and can be set to any value.                                               |

- `wdr_xdb_query(db_name_str text, query text)`  
Description: Provides the capability of executing local cross-database queries. For example, when connecting to the **testdb** database, access tables in the **test** database. Only the initial user has the permission to run this command.  

```
select col1 from wdr_xdb_query('dbname=test','select col1 from t1') as dd(col1 int);
```

  
Return type: record
- `pg_wlm_jump_queue(pid int)`  
Description: Moves a task to the top of the queue of CN.  
Return type: Boolean
  - **true**: success
  - **false**: failure
- `gs_wlm_switch_cgroup(pid int, cgroup text)`  
Description: Moves a job to another Cgroup to change the job priority.  
Return type: Boolean
  - **true**: success
  - **false**: failure
- `pv_session_memctx_detail(threadid tid, MemoryContextName text)`  
Description: Records information about the memory context **MemoryContextName** of the thread **tid** into the `threadid_timestamp.log` file

in the `$GAUSSLOG/pg_log/${node_name}/dumpmem` directory. `threadid` can be obtained from `sessid` in the `PV_SESSION_MEMORY_DETAIL` table. In the officially released version, only the `MemoryContextName` that is an empty string (two single quotation marks indicate that the input is an empty string) is accepted. In this case, all memory context information is recorded. Otherwise, no operation is performed. This function can be executed only by the administrator.

Return type: Boolean

- **true**: success
- **false**: failure

- `pg_shared_memctx_detail(MemoryContextName text)`

Description: Records information about the memory context `MemoryContextName` into the `threadid_timestamp.log` file in the `$GAUSSLOG/pg_log/${node_name}/dumpmem` directory. Calling this function in the officially released version does not involve any operation. Only the administrator can execute this function.

Return type: Boolean

- **true**: success
- **false**: failure

- `local_bgwriter_stat()`

Description: Displays the information about pages flushed by the bgwriter thread of this instance, number of pages in the candidate buffer chain, and buffer elimination information.

Return type: record

- `local_candidate_stat()`

Description: Displays the number of pages in the candidate buffer chain of this instance and buffer elimination information, including the normal buffer pool and segment buffer pool.

Return type: record

- `local_ckpt_stat()`

Description: Displays the information about checkpoints and flushing pages of the current instance.

Return type: record

- `local_double_write_stat()`

Description: Displays the doublewrite file status of the current instance.

Return type: record

**Table 7-89** `local_double_write_stat` parameters

| Parameter                    | Type | Description                                   |
|------------------------------|------|-----------------------------------------------|
| <code>node_name</code>       | text | Instance name                                 |
| <code>curr_dwn</code>        | int8 | Sequence number of the doublewrite file       |
| <code>curr_start_page</code> | int8 | Start page for restoring the doublewrite file |

| Parameter             | Type | Description                                                                                                                     |
|-----------------------|------|---------------------------------------------------------------------------------------------------------------------------------|
| file_trunc_num        | int8 | Number of times that the doublewrite file is reused                                                                             |
| file_reset_num        | int8 | Number of reset times after the doublewrite file is full                                                                        |
| total_writes          | int8 | Total number of I/Os of the doublewrite file                                                                                    |
| low_threshold_writes  | int8 | Number of I/Os for writing doublewrite files with low efficiency (the number of I/O flushing pages at a time is less than 16)   |
| high_threshold_writes | int8 | Number of I/Os for writing doublewrite files with high efficiency (the number of I/O flushing pages at a time is more than 421) |
| total_pages           | int8 | Total number of pages that are flushed to the doublewrite file area                                                             |
| low_threshold_pages   | int8 | Number of pages that are flushed with low efficiency                                                                            |
| high_threshold_pages  | int8 | Number of pages that are flushed with high efficiency                                                                           |
| file_id               | int8 | ID of the current doublewrite file.                                                                                             |

- local\_single\_flush\_dw\_stat()**

Description: Displays the elimination of dual-write files on a single page in the instance.

Return type: record
- local\_pagewriter\_stat()**

Description: Displays the page flushing information and checkpoint information of the current instance.

Return type: record
- local\_redo\_stat()**

Description: Displays the replay status of the current standby instance.

Return type: record

Note: The returned replay status includes the current replay position and the replay position of the minimum restoration point.
- local\_recovery\_status()**

Description: Displays log flow control information about the primary and standby nodes.

Return type: record
- local\_rto\_status()**

Description: Displays log flow control information about the primary and standby nodes.

Return type: record

- `gs_wlm_switch_cgroup(sess_id int8, cgroup name)`  
Description: Switches the Cgroup of a specified session.  
Return type: record
- `comm_client_info()`  
Description: Queries active client connections of a single node. For details about the returned result, see [COMM\\_CLIENT\\_INFO](#).  
Return type: SETOF record
- `pg_get_flush_lsn()`  
Description: Returns the position of the Xlog flushed from the current node.  
Return type: text
- `pg_get_sync_flush_lsn()`  
Description: Returns the position of the Xlog flushed by the majority on the current node.  
Return type: text
- `pgxc_wlm_rebuild_user_resource_pool()`  
Description: Rebuilds user and resource pool cache information. Only the system administrator can execute this function.  
Return type: Boolean
- `locktag_decode(locktag text)`  
Description: Parses lock details from **locktag**.  
Example:  

```
gaussdb=# select locktag_decode('271b:0:0:0:6');
locktag_decode

locktype:transactionid, transactionid:10011
(1 row)
```

Return type: text
- `disable_conn(disconn_mode text, host text, port integer)`  
Description: Specifies that the CM Agent processes commands delivered by the CM Server. When a DN is selected as the primary DN, it is configured to reject connections to all DNs, forcibly connect to a DN, or connect to all DNs in polling mode. Only the initial user and system administrator can call this function.  
Return type: void

**Table 7-90** disable\_conn parameter description

| Parameter    | Type | Description                                                                                                                                                                                                                                                                          |
|--------------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| disconn_mode | text | DN connection mode: <ul style="list-style-type: none"> <li>• <b>'prohibit_connection'</b>: rejects to connect to all DNs.</li> <li>• <b>'specify_connection'</b>: forcibly connects to a DN.</li> <li>• <b>'polling_connection'</b>: connects to all DNs in polling mode.</li> </ul> |

| Parameter | Type    | Description           |
|-----------|---------|-----------------------|
| host      | text    | IP address of the DN  |
| port      | integer | Port number of the DN |

- `db_perf.get_global_full_sql_by_timestamp(start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)`

Description: Obtains full SQL information about a cluster. The result can be queried only in the system database but cannot be queried in the user database.

Return type: record

**Table 7-91** `db_perf.get_global_full_sql_by_timestamp` parameter description

| Parameter       | Type                     | Description                              |
|-----------------|--------------------------|------------------------------------------|
| start_timestamp | timestamp with time zone | Start point of the SQL start time range. |
| end_timestamp   | timestamp with time zone | End point of the SQL start time range.   |

- `db_perf.get_global_slow_sql_by_timestamp(start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)`

Description: Obtains cluster-level slow SQL information. The result can be queried only in the system database but cannot be queried in the user database.

Return type: record

**Table 7-92** `db_perf.get_global_slow_sql_by_timestamp` parameter description

| Parameter       | Type                     | Description                              |
|-----------------|--------------------------|------------------------------------------|
| start_timestamp | timestamp with time zone | Start point of the SQL start time range. |
| end_timestamp   | timestamp with time zone | End point of the SQL start time range.   |

- `statement_detail_decode(detail text, format text, pretty boolean)`

Description: Parses the **details** column in a full or slow SQL statement. The result can be queried only in the system database but cannot be queried in the user database.

Return type: text

**Table 7-93** statement\_detail\_decode parameter description

| Parameter | Type    | Description                                                                                                                                                                                                                                                                                                                                              |
|-----------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| detail    | text    | Set of events generated by the SQL statement (unreadable).                                                                                                                                                                                                                                                                                               |
| format    | text    | Parsing output format. The value is <b>plaintext</b> .                                                                                                                                                                                                                                                                                                   |
| pretty    | Boolean | Specifies whether to display the text in pretty format when <b>format</b> is set to <b>plaintext</b> . The options are as follows: <ul style="list-style-type: none"> <li>The value <b>true</b> indicates that <code>\n</code> is used to separate events.</li> <li>The value <b>false</b> indicates that events are separated by commas (,).</li> </ul> |

- `pgxc_get_csn(tid)`  
 Description: Returns the transaction submission sequence number (CSN) corresponding to a given transaction ID.  
 Return type: int8
- `get_global_user_transaction()`  
 Description: Returns transaction information about each user on all nodes.  
 Return type: node\_name name, username name, commit\_counter bigint, rollback\_counter bigint, resp\_min bigint, resp\_max bigint, resp\_avg bigint, resp\_total bigint, bg\_commit\_counter bigint, bg\_rollback\_counter bigint, bg\_resp\_min bigint, bg\_resp\_max bigint, bg\_resp\_avg bigint, and bg\_resp\_total bigint
- `pg_collation_for()`  
 Description: Returns the sorting rule corresponding to the input parameter string.  
 Parameter: any (Explicit type conversion is required for constants.)  
 Return type: text
- `pgxc_unlock_for_sp_database(name Name)`  
 Description: Releases a specified database lock.  
 Parameter: database name  
 Return type: Boolean
- `pgxc_lock_for_sp_database(name Name)`  
 Description: Locks a specified database.  
 Parameter: database name  
 Return type: Boolean
- `pgxc_unlock_for_transfer(name Name)`  
 Description: Releases the lock used for data transmission (data redistribution).  
 Parameter: database name  
 Return type: Boolean

- `pgxc_lock_for_transfer(name Name)`  
 Description: Locks the database for data transmission (data redistribution).  
 Parameter: database name  
 Return type: Boolean
- `gs_comm_proxy_thread_status()`  
 Description: Collects statistics on data packets sent and received by the proxy communications library **comm\_proxy** when a user-mode network is configured for the cluster. This function is not supported in the current version.  
 Parameter: nan  
 Return type: record
- `gs_catalog_attribute_records()`  
 Description: Returns the definition of each field in a specified system catalog. Only common system catalogs whose OIDs are less than 10000 are supported. Indexes and TOAST tables are not supported.  
 Parameter: OID of the system catalog  
 Return type: record
- `dynamic_func_control(scope text, function_name text, action text, "{params}" text[])`  
 Description: Dynamically enables built-in functions. Currently, only full SQL statements can be dynamically enabled.  
 Return type: record

**Table 7-94** Parameter description of `dynamic_func_control`

| Parameter     | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scope         | text | Scope where the function is to be dynamically enabled. Currently, only <b>GLOBAL</b> and <b>LOCAL</b> are supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| function_name | text | Function name. Currently, only <b>STMT</b> is supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| action        | text | When <b>function_name</b> is set to <b>STMT</b> , the value of <b>action</b> can only be <b>TRACK</b> , <b>UNTRACK</b> , <b>LIST</b> , or <b>CLEAN</b> . <ul style="list-style-type: none"> <li>• <b>TRACK</b>: records the full SQL information of normalized SQL statements.</li> <li>• <b>UNTRACK</b>: cancels the recording of full SQL information of normalized SQL statements.</li> <li>• <b>LIST</b>: lists normalized SQL information that is recorded in the current track.</li> <li>• <b>CLEAN</b>: cleans normalized SQL information that is recorded in the current track.</li> </ul> |

| Parameter | Type   | Description                                                                                                                                                                                                                                                                                                                                     |
|-----------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| params    | text[] | <p>When <b>function_name</b> is set to <b>STMT</b>, the parameters corresponding to different actions are set as follows:</p> <ul style="list-style-type: none"> <li>• <b>TRACK:</b> '{"Normalized SQLID", "L0/L1/L2"}'</li> <li>• <b>UNTRACK:</b> '{"Normalized SQLID"}'</li> <li>• <b>LIST:</b> '{}'</li> <li>• <b>CLEAN:</b> '{}'</li> </ul> |

- `gs_parse_page_bypath(path text, blocknum bigint, relation_type text, read_memory boolean)`

Description: Parses a specified table page and returns the path for storing the parsed content.

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.

**Table 7-95** gs\_parse\_page\_bypath parameters

| Parameter | Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path      | text | <ul style="list-style-type: none"> <li>For an ordinary table, the relative path is <i>Tablespace name/Database OID/Relfilenode of the table (physical file name)</i>, for example, <b>base/16603/16394</b>.</li> <li>For the visibility map of an ordinary table, the relative path is <i>Tablespace name/Database OID/Visibility map of the ordinary table</i>. For example, <b>base/16603/16394_vm</b>.</li> <li>For clog files, the parsed content is stored in the <b>pg_clog</b> directory. For example: 000000000000.</li> <li>For csnlog files, the parsed content is stored in the <b>pg_csnlog</b> directory. For example: 000000000000.</li> <li>For undo record files, the relative path is <b>undo/UNDOPERSISTENCE/zondid.segno</b> in the <b>undo</b> directory. Example: undo/permanent/00000.0000009.</li> <li>For undo meta files, the relative path is <b>undo/UNDOPERSISTENCE/zondid.meta.segno</b> in the <b>undo</b> directory. Example: undo/permanent/00000.meta.0000004.</li> <li>You can run the <b>pg_relation_filepath(table_name text)</b> command to query the relative path of the table file. To obtain the path of the partitioned table, view the <b>pg_partition</b> system catalog and call <b>pg_partition_filepath(partition_oid)</b>.</li> <li>Valid path formats are as follows: <ul style="list-style-type: none"> <li>global/relNode</li> <li>base/dbNode/relNode</li> <li>pg_tblspc/spcNode/version_dir/dbNode/relNode</li> </ul> </li> </ul> |

| Parameter     | Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| read_memory   | Boolean | <ul style="list-style-type: none"> <li>• <b>false</b>: The system parses the page from the disk file.</li> <li>• <b>true</b>: The system attempts to parse the page from the shared buffer. If the page does not exist in the shared buffer, the system parses the page from the disk file.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                      |

Example:

```
Parse the information of all pages in the B-tree index file.
Before calling the function, ensure that the file path exists based on the parameter description.
gaussdb=# select gs_parse_page_bypath('base/16603/16394', -1, 'btree', false);
 gs_parse_page_bypath

/data_dir/1663_16603_16394_-1.page
(1 row)

Parse the visibility result of all blocks in the visibility map file.
```

```
gaussdb=# select gs_parse_page_bypath('base/12828/16771_vm', -1, 'vm', false);
gs_parse_page_bypath

/data_dir/1663_12828_16771_-1_vm.page
(1 row)

Parse the commit log of block 0 in the Clog file.
gaussdb=# select gs_parse_page_bypath('000000000000', 0, 'clog', false);
gs_parse_page_bypath

/data_dir/000000000000.clog
(1 row)
```

The following is an example of an exception error:

```
An error is reported when the value of the block number exceeds the value range.
gaussdb=# select gs_parse_page_bypath('base/12828/16777', -10, 'heap', false);
ERROR: Blocknum should be between -1 and 4294967294.
CONTEXT: referenced column: gs_parse_page_bypath
```

- gs\_xlogdump\_lsn(start\_lsn text, end\_lsn text)**

Description: Parses Xlogs within the specified LSN range and returns the path for storing the parsed content. You can use `pg_current_xlog_location()` to obtain the current Xlog position.

Parameters: LSN start position and LSN end position

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.
- gs\_xlogdump\_xid(c\_xid xid)**

Description: Parses Xlogs of a specified XID and returns the path for storing the parsed content. You can use **`txid_current()`** to obtain the current XID.

Parameter: XID

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.
- gs\_xlogdump\_tablepath(path text, blocknum bigint, relation\_type text)**

Description: Parses logs corresponding to a specified table page and returns the path for storing the parsed content.

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.

- gs\_xlogdump\_parsepage\_tablepath(path text, blocknum bigint, relation\_type text, read\_memory boolean)

Description: Parses the specified table page and logs corresponding to the table page and returns the path for storing the parsed content. It can be regarded as one execution of **gs\_parse\_page\_bypath** and **gs\_xlogdump\_tablepath**. The prerequisite for executing this function is that the table file exists. To view logs of deleted tables, call **gs\_xlogdump\_tablepath**.

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.

**Table 7-97** gs\_xlogdump\_parsepage\_tablepath parameters

| Parameter     | Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
