<b>1 Database System Overview</b>	<b>1</b>
1.1 Database Logical Architecture	1
1.2 Query Request Handling Process	2
1.3 Managing Transactions	2
1.4 Concepts	6
<b>2 Database Security</b>	<b>8</b>
2.1 Users and Permissions	8
2.1.1 Default Permission Mechanism	8
2.1.2 Administrators	9
2.1.3 Separation of Duties	11
2.1.4 Users	13
2.1.5 Roles	14
2.1.6 Schemas	16
2.1.7 User Permissions	17
2.1.8 Row-Level Security Policy	18
2.2 Database Audit	20
<b>3 Database Quick Start</b>	<b>23</b>
3.1 Operating a Database	23
3.1.1 Creating a Database Account	23
3.1.2 Creating and Managing Databases	23
3.1.3 Creating and Managing Tablespaces	26
3.1.4 Creating and Managing Tables	28
3.1.4.1 Creating a Table	28
3.1.4.2 Inserting Data to Tables	29
3.1.4.3 Updating Data in a Table	33
3.1.4.4 Viewing Data	34
3.1.4.5 Deleting Data from a Table	35
3.1.5 Querying System Catalogs	35
3.1.6 Other Operations	37
3.1.6.1 Creating and Managing Schemas	37
3.1.6.2 Creating and Managing Partitioned Tables	40
3.1.6.3 Creating and Managing Indexes	44

3.1.6.4 Creating and Managing Views.....	48
3.1.6.5 Creating and Managing Sequences.....	49
3.1.6.6 Creating and Managing Scheduled Jobs.....	51
<b>4 Development and Design Proposal.....</b>	<b>55</b>
4.1 Overview.....	55
4.2 Database Object Naming Conventions.....	55
4.3 Database Object Design.....	56
4.3.1 Database and Schema Design.....	56
4.3.2 Table Design.....	57
4.3.3 Column Design.....	61
4.3.4 Constraint Design.....	62
4.3.5 View and Joined Table Design.....	62
4.4 Tool Interconnection.....	62
4.4.1 JDBC Configuration.....	63
4.5 SQL Compilation.....	64
<b>5 Application Development Guide.....</b>	<b>69</b>
5.1 Development Specifications.....	69
5.2 Obtaining the Driver Package.....	70
5.3 Development Based on JDBC.....	70
5.3.1 JDBC Packages, Driver Classes, and Environment Classes.....	70
5.3.2 Development Process.....	73
5.3.3 Loading a Driver.....	73
5.3.4 Connecting to a Database.....	73
5.3.5 Connecting to a Database (Using SSL).....	95
5.3.6 Connecting to a Database (Using UDS).....	97
5.3.7 Running SQL Statements.....	98
5.3.8 Processing Data in a Result Set.....	102
5.3.9 Closing a Database Connection.....	105
5.3.10 Log Management.....	105
5.3.11 Examples: Common Operations.....	109
5.3.12 Example: Retrying SQL Queries for Applications.....	115
5.3.13 Example: Logic Replication Code.....	118
5.3.14 Example: Parameters for Connecting to the Database in Different Scenarios.....	126
5.3.15 JDBC Interface Reference.....	127
5.3.15.1 java.sql.Connection.....	128
5.3.15.2 java.sql.CallableStatement.....	136
5.3.15.3 java.sql.DatabaseMetaData.....	138
5.3.15.4 java.sql.Driver.....	146
5.3.15.5 java.sql.PreparedStatement.....	147
5.3.15.6 java.sql.ResultSet.....	150
5.3.15.7 java.sql.ResultSetMetaData.....	158
5.3.15.8 java.sql.Statement.....	159

5.3.15.9 javax.sql.ConnectionPoolDataSource.....	161
5.3.15.10 javax.sql.DataSource.....	162
5.3.15.11 javax.sql.PooledConnection.....	162
5.3.15.12 javax.naming.Context.....	163
5.3.15.13 javax.naming.spi.InitialContextFactory.....	163
5.3.15.14 CopyManager.....	164
5.3.15.15 PGReplicationConnection.....	165
5.3.15.16 PGReplicationStream.....	168
5.3.15.17 ChainedStreamBuilder.....	170
5.3.15.18 ChainedCommonStreamBuilder.....	171
5.3.16 Common JDBC Parameters.....	171
5.3.17 FAQs.....	176
5.3.17.1 Incorrect batchSize Settings.....	176
5.3.18 JDBC Data Type Mapping.....	176
5.4 Development Based on ODBC.....	178
5.4.1 ODBC Packages, Dependent Libraries, and Header Files.....	179
5.4.2 Development Process.....	180
5.4.3 Configuring a Data Source in the Linux OS.....	181
5.4.4 Configuring a Data Source in the Windows OS.....	194
5.4.5 Example: Common Functions and Batch Binding.....	199
5.4.6 Typical Application Scenarios and Configurations.....	209
5.4.7 ODBC Interface Reference.....	221
5.4.7.1 SQLAllocEnv.....	221
5.4.7.2 SQLAllocConnect.....	221
5.4.7.3 SQLAllocHandle.....	221
5.4.7.4 SQLAllocStmt.....	222
5.4.7.5 SQLBindCol.....	223
5.4.7.6 SQLBindParameter.....	224
5.4.7.7 SQLColAttribute.....	225
5.4.7.8 SQLConnect.....	227
5.4.7.9 SQLDisconnect.....	228
5.4.7.10 SQLExecDirect.....	229
5.4.7.11 SQLExecute.....	230
5.4.7.12 SQLFetch.....	231
5.4.7.13 SQLFreeStmt.....	232
5.4.7.14 SQLFreeConnect.....	232
5.4.7.15 SQLFreeHandle.....	232
5.4.7.16 SQLFreeEnv.....	233
5.4.7.17 SQLPrepare.....	233
5.4.7.18 SQLGetData.....	234
5.4.7.19 SQLGetDiagRec.....	235
5.4.7.20 SQLSetConnectAttr.....	238

5.4.7.21 SQLSetEnvAttr.....	239
5.4.7.22 SQLSetStmtAttr.....	240
5.5 Development Based on libpq.....	241
5.5.1 libpq Package, Dependent Library, and Header Files.....	241
5.5.2 Development Process.....	241
5.5.3 Examples.....	242
5.5.4 libpq Interface Reference.....	248
5.5.4.1 Database Connection Control Functions.....	248
5.5.4.1.1 PQconnectdbParams.....	248
5.5.4.1.2 PQconnectdb.....	249
5.5.4.1.3 PQbackendPID.....	250
5.5.4.1.4 PQsetdbLogin.....	250
5.5.4.1.5 PQfinish.....	251
5.5.4.1.6 PQreset.....	252
5.5.4.1.7 PQstatus.....	252
5.5.4.2 Database Statement Execution Functions.....	253
5.5.4.2.1 PQexec.....	253
5.5.4.2.2 PQprepare.....	254
5.5.4.2.3 PQresultStatus.....	256
5.5.4.2.4 PQclear.....	257
5.5.4.2.5 PQfnnumberEx.....	257
5.5.4.3 Functions for Asynchronous Command Processing.....	258
5.5.4.3.1 PQsendQuery.....	258
5.5.4.3.2 PQsendQueryParams.....	259
5.5.4.3.3 PQsendPrepare.....	260
5.5.4.3.4 PQsendQueryPrepared.....	261
5.5.4.3.5 PQflush.....	262
5.5.4.4 Functions for Canceling Queries in Progress.....	262
5.5.4.4.1 PQgetCancel.....	263
5.5.4.4.2 PQfreeCancel.....	263
5.5.4.4.3 PQcancel.....	264
5.5.5 Connection Parameters.....	265
5.6 Psycopg-based Development.....	270
5.6.1 Development Process.....	272
5.6.2 Psycopg Package.....	272
5.6.3 Examples: Common Operations.....	275
5.6.4 Psycopg API Reference.....	277
5.6.4.1 psycopg2.connect().....	277
5.6.4.2 connection.cursor().....	279
5.6.4.3 cursor.execute(query,vars_list).....	280
5.6.4.4 curosr.executemany(query,vars_list).....	280
5.6.4.5 connection.commit().....	281

5.6.4.6 connection.rollback()	282
5.6.4.7 cursor.fetchone()	282
5.6.4.8 cursor.fetchall()	283
5.6.4.9 cursor.close()	283
5.6.4.10 connection.close()	283
5.7 ECPG-based Development	284
5.7.1 Development Process	285
5.7.2 ECPG Components	286
5.7.3 ECPG Preprocessing and Compiling	287
5.7.4 Managing Database Connections	288
5.7.4.1 Connecting to a Database	288
5.7.4.2 Managing Connections	289
5.7.5 Running SQL Commands	290
5.7.5.1 Running SQL Statements	290
5.7.5.2 Using Cursors	291
5.7.5.3 Transaction	292
5.7.5.4 Prepared Statements	292
5.7.5.5 Embedded SQL Commands	293
5.7.5.5.1 ALLOCATE DESCRIPTOR	293
5.7.5.5.2 CONNECT	293
5.7.5.5.3 DEALLOCATE DESCRIPTOR	296
5.7.5.5.4 DECLARE	296
5.7.5.5.5 DESCRIBE	297
5.7.5.5.6 DISCONNECT	298
5.7.5.5.7 EXECUTE IMMEDIATE	299
5.7.5.5.8 GET DESCRIPTOR	299
5.7.5.5.9 OPEN	301
5.7.5.5.10 PREPARE	301
5.7.5.5.11 SET AUTOCOMMIT	302
5.7.5.5.12 SET CONNECTION	302
5.7.5.5.13 SET DESCRIPTOR	303
5.7.5.5.14 TYPE	304
5.7.5.5.15 VAR	305
5.7.5.5.16 WHENEVER	306
5.7.6 Querying the Result Set	307
5.7.7 Closing a Database Connection	307
5.7.8 Host Variables	308
5.7.8.1 Overview	308
5.7.8.2 DECLARE Section	308
5.7.8.3 Retrieving Query Results	309
5.7.8.4 Type Mapping	309
5.7.8.5 Handling Character Strings	310

5.7.8.6 Host Variables with Non-primitive Types.....	311
5.7.8.7 Accessing Special Data Types.....	313
5.7.8.8 Handling Non-primitive SQL Data Types.....	315
5.7.9 Executing Dynamic SQL Statements.....	318
5.7.9.1 Executing Statements Without a Result Set.....	318
5.7.9.2 Executing a Statement with Input Parameters.....	318
5.7.9.3 Executing a Statement with a Result Set.....	318
5.7.10 Error Handling.....	319
5.7.10.1 Setting Callbacks.....	319
5.7.10.2 sqlca.....	321
5.7.10.3 SQLSTATE and SQLCODE.....	322
5.7.11 Preprocessor Directives.....	326
5.7.11.1 Including Files.....	326
5.7.11.2 Directives: ifdef, ifndef, else, elif, and endif.....	326
5.7.11.3 Directives define and undef.....	327
5.7.12 Using Library Functions.....	327
5.7.13 SQL Descriptor Area.....	329
5.7.13.1 Named SQLDA.....	329
5.7.13.2 SQLDA.....	331
5.7.14 Examples.....	334
5.7.15 ecpg and Pro*C Compatibility Comparison.....	342
5.7.16 ECPG API Reference.....	342
5.7.16.1 Interval Type.....	342
5.7.16.2 Numeric Types.....	343
5.7.16.3 Date Type.....	348
5.7.16.4 Timestamp Type.....	352
5.8 Development Based on the Go Driver.....	355
5.8.1 Setting Up the Go Driver Environment.....	355
5.8.2 Development Process.....	356
5.8.3 Connecting to the Database.....	358
5.8.4 Connecting to the Database (Using SSL).....	363
5.8.5 Go APIs.....	365
5.8.5.1 sql.Open.....	365
5.8.5.2 type DB.....	365
5.8.5.3 type Stmt.....	368
5.8.5.4 type Tx.....	372
5.8.5.5 type Rows.....	374
5.8.5.6 type Row.....	375
5.8.5.7 type ColumnType.....	375
5.8.5.8 type Result.....	376
5.9 Compatibility Reference.....	376
5.10 Commissioning.....	377

<b>6 SQL Optimization.....</b>	<b>382</b>
6.1 Query Execution Process.....	382
6.2 Introduction to the SQL Execution Plan.....	384
6.2.1 Overview.....	385
6.2.2 Description.....	386
6.3 Optimization Process.....	395
6.4 Updating Statistics.....	396
6.5 Reviewing and Modifying a Table Definition.....	397
6.5.1 Overview.....	397
6.5.2 Selecting a Distribution Mode.....	398
6.5.3 Selecting Distribution Keys.....	399
6.5.4 Using Partitioned Tables.....	400
6.5.5 Selecting a Data Type.....	401
6.6 Typical SQL Optimization Methods.....	401
6.6.1 Optimizing SQL Self-diagnosis.....	401
6.6.2 Optimizing Statement Pushdown.....	403
6.6.3 Optimizing Subqueries.....	415
6.6.4 Optimizing Statistics.....	423
6.6.5 Optimizing Operators.....	429
6.6.6 Optimizing Data Skew.....	431
6.7 Experience in Rewriting SQL Statements.....	437
6.8 Configuring Key Parameters for SQL Tuning.....	439
6.9 Hint-based Optimization.....	441
6.9.1 Plan Hint Optimization.....	441
6.9.2 Hint Specifying the Query Block Where the Hint Is Located.....	447
6.9.3 Hint Specifying the Query Block and Schema of a Table.....	450
6.9.4 Join Order Hints.....	451
6.9.5 Join Operation Hints.....	452
6.9.6 Rows Hints.....	453
6.9.7 Stream Operation Hints.....	455
6.9.8 Scan Hints.....	457
6.9.9 Sublink Name Hints.....	459
6.9.10 Skew Hints.....	460
6.9.11 Parameterized Path Hint.....	462
6.9.12 Hint Errors, Conflicts, and Other Warnings.....	464
6.9.13 GUC Parameter Hints.....	466
6.9.14 Hints for Selecting the Custom Plan or Generic Plan.....	467
6.9.15 Hints Specifying Not to Expand Subqueries.....	468
6.9.16 Hints Specifying Not to Use Global Plan Cache.....	469
6.9.17 Hints of Parameterized Paths at the Same Level.....	470
6.9.18 Hints for Setting Slow SQL Control Rules.....	472
6.9.19 Bitmap Scan Hints.....	473

6.9.20 Hint for Inner Table Materialization During Join.....	473
6.9.21 AGG Hint.....	474
6.9.22 Query Rewriting Hints.....	475
6.9.23 Hints for Specifying ANY Sublink Pullup.....	495
6.9.24 Hints for Specifying the Degree of Parallelism for Scans.....	496
6.9.25 Hints for Specifying Whether to Use Semi-Join.....	497
6.9.26 Hints for Specifying Whether to Use Minmax Optimization.....	498
6.10 Checking the Implicit Conversion Performance.....	499
6.11 Performing Optimization with SQL Patches.....	501
6.12 Optimization Cases.....	508
6.12.1 Case: Selecting an Appropriate Distribution Key.....	508
6.12.2 Case: Creating an Appropriate Index.....	509
6.12.3 Case: Adjusting Distribution Keys.....	511
6.12.4 Case: Adjusting the GUC Parameter best_agg_plan.....	511
6.12.5 Case: Rewriting SQL Statements to Eliminate Subqueries.....	513
6.12.6 Case: Rewriting SQL Statements to Eliminate Pruning Interference.....	514
6.12.7 Case: Rewriting SQL Statements and Deleting in-clause.....	515
6.12.8 Case: Modifying the GUC Parameter rewrite_rule.....	516
6.12.9 Using DN Gather to Reduce Stream Nodes in the Plan.....	523
<b>7 SQL Reference.....</b>	<b>532</b>
7.1 GaussDB SQL.....	532
7.2 Keywords.....	533
7.3 Data Types.....	573
7.3.1 Numeric Types.....	573
7.3.2 Monetary Types.....	586
7.3.3 Boolean Types.....	586
7.3.4 Character Types.....	587
7.3.5 Binary Types.....	593
7.3.6 Date/Time Types.....	596
7.3.7 Geometric Types.....	618
7.3.8 Network Address Types.....	620
7.3.9 Bit String Types.....	622
7.3.10 UUID Type.....	623
7.3.11 JSON/JSONB Types.....	624
7.3.12 HLL Type.....	628
7.3.13 Range Types.....	632
7.3.14 Object Identifier Types.....	636
7.3.15 Pseudo-Types.....	638
7.3.16 Data Types Used by the Ledger Database.....	640
7.3.17 XML Type.....	640
7.3.18 XMLType.....	643
7.3.19 ACLItem Type.....	644

7.3.20 Array Types.....	645
7.4 Character Sets and Collations.....	650
7.4.1 Character Sets and Collations of the Client Connection.....	651
7.4.2 Database-level Character Sets and Collations.....	652
7.4.3 Schema-level Character Sets and Collations.....	653
7.4.4 Table-level Character Sets and Collations.....	654
7.4.5 Column-level Character Sets and Collations.....	655
7.4.6 Character Sets and Collations of Expressions of the String Type.....	656
7.4.7 Rules for Combining Character Sets and Collations.....	657
7.5 Constant and Macro.....	659
7.6 Functions and Operators.....	660
7.6.1 Logical Operators.....	660
7.6.2 Comparison Operators.....	661
7.6.3 Character Processing Functions and Operators.....	662
7.6.4 Binary String Functions and Operators.....	725
7.6.5 Bit String Functions and Operators.....	728
7.6.6 Pattern Matching Operators.....	730
7.6.7 Arithmetic Functions and Operators.....	739
7.6.8 Date and Time Processing Functions and Operators.....	760
7.6.9 Type Conversion Functions.....	828
7.6.10 Geometric Functions and Operators.....	860
7.6.11 Network Address Functions and Operators.....	870
7.6.12 Text Search Functions and Operators.....	876
7.6.13 JSON/JSONB Functions and Operators.....	882
7.6.14 HLL Functions and Operators.....	908
7.6.15 SEQUENCE Functions.....	922
7.6.16 Array Functions and Operators.....	924
7.6.17 Range Functions and Operators.....	933
7.6.18 Aggregate Functions.....	938
7.6.19 Window Functions.....	956
7.6.20 Security Functions.....	965
7.6.21 Ledger Database Functions.....	975
7.6.22 Encrypted Functions and Operators.....	977
7.6.23 Set Returning Functions.....	990
7.6.24 Conditional Expression Functions.....	992
7.6.25 System Information Functions.....	1000
7.6.26 System Administration Functions.....	1041
7.6.26.1 Configuration Setting Functions.....	1041
7.6.26.2 Universal File Access Functions.....	1042
7.6.26.3 Server Signal Functions.....	1044
7.6.26.4 Backup and Restoration Control Functions.....	1046
7.6.26.5 Dual-Cluster DR Control Functions.....	1055

7.6.26.6 Dual-Cluster DR Query Functions.....	1056
7.6.26.7 Snapshot Synchronization Functions.....	1059
7.6.26.8 Database Object Functions.....	1059
7.6.26.9 Advisory Lock Functions.....	1066
7.6.26.10 Logical Replication Functions.....	1069
7.6.26.11 Segment-Page Storage Functions.....	1094
7.6.26.12 Hash Bucket System Functions.....	1118
7.6.26.13 Undo System Functions.....	1127
7.6.26.14 Other Functions.....	1151
7.6.27 SPM Functions.....	1191
7.6.28 Statistics Information Functions.....	1195
7.6.29 Trigger Functions.....	1283
7.6.30 Hash Functions.....	1284
7.6.31 Prompt Message Function.....	1292
7.6.32 Fault Injection System Function.....	1292
7.6.33 Redistribution Functions.....	1293
7.6.34 Distribution Key Recommendation Functions.....	1293
7.6.35 Other System Functions.....	1298
7.6.36 Internal Functions.....	1353
7.6.37 AI Feature Functions.....	1360
7.6.38 Sensitive Data Discovery Function.....	1363
7.6.39 Dynamic Data Masking Functions.....	1364
7.6.40 Hotkey Feature Functions.....	1365
7.6.41 Global SysCache Functions.....	1365
7.6.42 Data Damage Detection and Repair Functions.....	1367
7.6.43 Functions of the XML Type.....	1385
7.6.44 Functions of the XMLType Type.....	1403
7.6.45 Pivot Table Functions.....	1413
7.6.46 UUID Functions.....	1414
7.6.47 SQL Statement Concurrency Control Function.....	1415
7.6.48 Obsolete Functions.....	1420
7.7 Expressions.....	1422
7.7.1 Simple Expressions.....	1422
7.7.2 Condition Expressions.....	1424
7.7.3 Subquery Expressions.....	1429
7.7.4 Array Expressions.....	1431
7.7.5 Row Expressions.....	1433
7.7.6 Time Interval Expressions.....	1435
7.8 Pseudocolumn.....	1437
7.9 Type Conversion.....	1440
7.9.1 Overview.....	1441
7.9.2 Operators.....	1442

7.9.3 Functions.....	1444
7.9.4 Value Storage.....	1447
7.9.5 UNION, CASE, and Related Constructs.....	1447
7.10 System Operation.....	1452
7.11 Controlling Transactions.....	1452
7.12 SQL Syntax.....	1453
7.12.1 SQL Syntax.....	1453
7.12.2 DCL Syntax Overview.....	1454
7.12.3 DDL Syntax Overview.....	1454
7.12.4 DML Syntax Overview.....	1468
7.12.5 Other Syntax List.....	1470
7.12.6 A.....	1472
7.12.6.1 ABORT.....	1472
7.12.6.2 ALTER AGGREGATE.....	1473
7.12.6.3 ALTER AUDIT POLICY.....	1475
7.12.6.4 ALTER COLUMN ENCRYPTION KEY.....	1477
7.12.6.5 ALTER COORDINATOR.....	1478
7.12.6.6 ALTER DATABASE.....	1480
7.12.6.7 ALTER DATABASE LINK.....	1484
7.12.6.8 ALTER DEFAULT PRIVILEGES.....	1486
7.12.6.9 ALTER DIRECTORY.....	1488
7.12.6.10 ALTER FOREIGN DATA WRAPPER.....	1489

# 1 Database System Overview

## 1.1 Database Logical Architecture

Each DN in a cluster stores data on disks. This section describes the objects on each DN from the logical view and the relationship between these objects, and how data is distributed on different nodes. [Figure 1-1](#) shows the database logical structure.

**Figure 1-1** Database logical architecture

**NOTE**

- A tablespace is a directory. A database contains one or more tablespaces to store physical files of the database. Each tablespace can contain files belonging to different databases.
- A database manages various data objects and is isolated from each other. Objects managed by a database can be distributed to multiple tablespaces.
- A datafile segment stores data of only one table. A table containing more than 1 GB of data is stored in multiple datafile segments.
- One table belongs to only one database and one tablespace. The data file segments storing the data of the same table must be in the same tablespace.
- Block: Basic unit of database management. Its default size is 8 KB.
- Data can be distributed on DN in replication, hash, range, or list mode. You can specify a mode when creating a table.

## 1.2 Query Request Handling Process

Figure 1-2 GaussDB service response process

## 1.3 Managing Transactions

A transaction is a customized sequence of database operations, which form an integral unit of work. In GaussDB, you can start, set, commit, and roll back transactions. GaussDB supports the following transaction isolation levels: READ

COMMITTED, REPEATABLE READ, and SERIALIZABLE. SERIALIZABLE is equivalent to REPEATABLE READ.

## Controlling Transactions

The following describes transaction operations supported by the database:

- Starting transactions  
You can use the `START TRANSACTION` or `BEGIN` syntax to start a transaction. For details, see [START TRANSACTION](#) and [BEGIN](#).
- Setting transactions  
You can use the `SET TRANSACTION` or `SET LOCAL TRANSACTION` syntax to set transactions. For details, see [SET TRANSACTION](#).
- Committing transactions  
You can commit all operations of a transaction using `COMMIT` or `END`. For details, see [COMMIT | END](#).
- Rolling back transactions  
Rollback indicates that the system cancels all changes that a transaction has made to a database if the transaction fails to be executed due to a fault. For details, see [ROLLBACK](#).

## Transaction Isolation Levels

A transaction isolation level specifies how concurrent transactions process the same object.

### NOTE

The isolation level cannot be changed after the first data manipulation statement (`SELECT`, `INSERT`, `DELETE`, `UPDATE`, `FETCH`, or `COPY`) in a transaction is executed.

- **READ COMMITTED:** At this level, a transaction can access only committed data. This is the default level.  
The `SELECT` statement accesses the snapshot of the database taken when the query begins. The `SELECT` statement can also access the data modifications in its transaction, regardless of whether they have been committed. Note that different database snapshots may be available to two consecutive `SELECT` statements for the same transaction, because data may be committed for other transactions while the first `SELECT` statement is executed.  
At the **READ COMMITTED** level, the execution of each statement begins with a new snapshot, which contains all the transactions that have been committed by the execution time. Therefore, during a transaction, a statement can access the result of other committed transactions. Check whether a single statement always accesses absolutely consistent data in a database.  
Transaction isolation at this level meets the requirements of many applications, and is fast and easy to use. However, applications performing complicated queries and updates may require data that is more consistent than this level can provide.
- **REPEATABLE READ:** At this level, a transaction can only read data committed before it starts. Uncommitted data or data committed in other concurrent transactions cannot be read. However, a query can read earlier data

modifications in its transaction, regardless of whether they have been committed. **READ COMMITTED** differs from this level in that a transaction reads the snapshot taken at the start of the transaction, not at the beginning of the current query within the transaction. Therefore, the **SELECT** statement within a transaction always reads the same data, and cannot read data committed by other concurrent transactions after the transaction starts. Applications at this level must be able to retry transactions, because serialization failures may occur.

- **SERIALIZABLE**: Currently, GaussDB does not support this isolation level. Setting this isolation level is equivalent to **REPEATABLE READ**.

 NOTE

**REPEATABLE READ is implemented based on multi-version snapshots and write skew may occur. To avoid this scenario, perform the SELECT FOR UPDATE operation on the rows involved in the transaction. An example of write skew is as follows:**

Scenario 1: Table **a** has the **id** and **value** columns of the int type. Two data records are inserted. Assume that the sum of the values of the two data records must be less than or equal to 10 in the service logic of table **a**. Two transactions are concurrently started. The values are updated and modified based on the read values. After the modification, the sum of values is less than or equal to 10 in the transactions. After the modification is committed, the sum of values is 12, which violates the assumed service logic of table **a**.

```
gaussdb=# create table a(id int, value int);
CREATE TABLE
gaussdb=# insert into a values(1,4);
INSERT 0 1
gaussdb=# insert into a values(2,4);
INSERT 0 1
session1 :
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# select * from a;
id | value
----+-----
1 | 4
2 | 4
(2 rows)
gaussdb=# update a set value = 6 where id = 1;
UPDATE 1
gaussdb=# select * from a;
id | value
----+-----
1 | 6
2 | 4
(2 rows)
session2:
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# select * from a;
id | value
----+-----
1 | 4
2 | 4
(2 rows)
gaussdb=# update a set value = 6 where id = 2;
UPDATE 1
gaussdb=# select * from a;
id | value
----+-----
1 | 4
2 | 6
(2 rows)
session1:
gaussdb=# commit;
COMMIT
session2:
gaussdb=# commit;
COMMIT
gaussdb=# select * from a;
id | value
----+-----
1 | 6
2 | 6
(2 rows)
```

Scenario 2: Table **a** has the **id** and **value** columns of the int type. The **id** is the primary key. When the primary key is deleted and inserted concurrently, the values of two primary keys may be read in the transaction, violating the primary key constraint.

```
gaussdb=# create table a(id int primary key, value int);
NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "a_pkey" for table "a"
CREATE TABLE
gaussdb=# insert into a values(1,10);
INSERT 0 1
session1:
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# delete a where id = 1;
DELETE 1
session2:
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# select * from a;
id | value
----+-----
 1 |   10
(1 row)
session1:
gaussdb=# commit;
COMMIT
session2:
gaussdb=# insert into a values(1, 100);
INSERT 0 1
gaussdb=# select * from a;
id | value
----+-----
 1 |   10
 1 |  100
(2 rows)
```

## 1.4 Concepts

### Database

Databases manage various data objects and are isolated from each other. While creating a database, you can specify a tablespace. If you do not specify it, the object will be saved to the PG\_DEFAULT tablespace by default. Objects managed by a database can be distributed to multiple tablespaces.

### Tablespace

In GaussDB, a tablespace is a directory storing physical files of the databases. Multiple tablespaces can coexist. Files are physically isolated using tablespaces and managed by a file system.

### Schemas

GaussDB schemas logically separate databases. All database objects are created under certain schemas. In GaussDB, schemas and users are loosely bound. When you create a user, a schema with the same name as the user will be created automatically. You can also create a schema or specify another schema.

### Users and Roles

GaussDB uses users and roles to control the access to databases. A role can be a database user or a group of database users, depending on role settings. Each user

can have only one role. In GaussDB, the difference between roles and users is that a role does not have the LOGIN permission by default. In GaussDB, you can put a user's role under a parent role for flexible management.

## Transactions

In GaussDB, transactions are managed by multi-version concurrency control (MVCC) and two-phase locking (2PL). It enables smooth data reads and writes. In GaussDB, an Astore stores historical version data together with the current tuple version. The GaussDB Astore uses a VACUUM thread instead of rollback segments to periodically delete historical version data. Generally, you do not need to pay special attention to the VACUUM thread unless you need to optimize the performance. The GaussDB Ustore stores historical version data to the undo rollback segments. The thread for purging undo deletes historical version data in a unified manner. In addition, GaussDB automatically commits transactions for single-statement queries (without using statements such as BEGIN to explicitly start a transaction block).

# 2 Database Security

---

## 2.1 Users and Permissions

### 2.1.1 Default Permission Mechanism

A user who creates an object is the owner of this object. By default, [separation of duties](#) is disabled after cluster installation. A database system administrator has the same permissions as object owners. After an object is created, only the object owner or system administrators can query, modify, and delete the object, and grant permissions for the object to other users through [GRANT](#) by default.

To enable another user to use the object, grant required permissions to the user or the role that contains the user.

GaussDB supports the following permissions: SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, CREATE, CONNECT, EXECUTE, USAGE, ALTER, DROP, COMMENT, INDEX, and VACUUM. Permission types are associated with object types. For permission details, see [GRANT](#).

To revoke a permission that has been granted, see [REVOKE](#). Object owners have implicit permissions (such as ALTER, DROP, COMMENT, INDEX, VACUUM, GRANT, and REVOKE) on objects. That is, once becoming the owner of an object, the owner is immediately granted the implicit permissions on the object. Object owners can remove their own common permissions (SELECT, INSERT, UPDATE, and DELETE), for example, making tables read-only to themselves or others, except system administrators.

System catalogs and views are visible to either system administrators or all users. System catalogs and views that require system administrator permissions can be queried only by system administrators. For details, see [System Catalogs and System Views](#).

The database provides the object isolation feature. If this feature is enabled, users can view only the objects (tables, views, columns, and functions) that they have the permission to access. System administrators are not affected by this feature. For details, see [ALTER DATABASE](#).

It is not recommended to modify the permissions on system catalogs and system views.

## 2.1.2 Administrators

### Initial User

The account automatically generated during the cluster installation is called the initial user. The initial user is also a system administrator, security administrator, audit administrator, monitor administrator, O&M administrator, and security policy administrator. It has the highest permissions in the system and can perform all operations. If the initial username is not set during the installation, the username is the same as the name of the OS user who installs the cluster. If the password of the initial user is not set during the cluster installation, the password is empty after the installation. In this case, you need to change the password of the initial user on the gsql client before performing other operations. If the initial user password is empty, you cannot perform other SQL operations, such as upgrade, capacity expansion, and node replacement, except changing the password.

#### NOTE

- The OID of the initial user is 10, which can be queried in the pg\_roles view.
- An initial user bypasses all permission checks. It is recommended that this user be used only as a database administrator for database management instead of service applications.

### System Administrator

A system administrator is an account with the **SYSADMIN** attribute. By default, a system administrator has the same permissions as the object owner but does not have the object permissions in the dbe\_perf schema.

To create a database administrator, connect to the database as the initial user or a system administrator and use the **CREATE USER** or **ALTER USER** statement with the **SYSADMIN** option.

```
gaussdb=# CREATE USER sysadmin WITH SYSADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe SYSADMIN;
```

When ALTER USER is executed, the user must exist.

### Security Administrator

A security administrator is an account with the **CREATEROLE** attribute. It has the permission to create, modify, and delete users or roles, and grant or revoke the permission of any non-system administrator, built-in role, permanent user, or O&M administrator.

If you want to create a security administrator and separation of duties is disabled, connect to the database as a system administrator or security administrator. If separation of duties is enabled, connect to the database as a security administrator and use the **CREATE USER** or **ALTER USER** statement with the **CREATEROLE** option.

```
gaussdb=# CREATE USER createrole WITH CREATEROLE password '*****';
```

Or

```
gaussdb=# ALTER USER joe CREATEROLE;
```

When ALTER USER is executed, the user must exist.

## Audit Administrator

An audit administrator is an account with the **AUDITADMIN** attribute, which has the permission to view and delete audit logs.

If you want to create an audit administrator and separation of duties is disabled, connect to the database as a system administrator or security administrator. If separation of duties is enabled, connect to the database only as the initial user and use the **CREATE USER** or **ALTER USER** statement with the **AUDITADMIN** option.

```
gaussdb=# CREATE USER auditadmin WITH AUDITADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe AUDITADMIN;
```

When ALTER USER is executed, the user must exist.

## Monitor Administrator

A monitor administrator is an account with the **MONADMIN** attribute and has the permission to view views and functions in the `dbe_perf` schema. The monitor administrator can also grant or revoke object permissions in the `dbe_perf` schema.

To create a monitor administrator, connect to the database as a system administrator and use the **CREATE USER** or **ALTER USER** statement with **MONADMIN** specified.

```
gaussdb=# CREATE USER monadmin WITH MONADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe MONADMIN;
```

When ALTER USER is executed, the user must exist.

## O&M Administrator

An O&M administrator is an account with the **OPRADMIN** attribute and has the permission to use Roach to perform backup and restoration.

To create an O&M administrator, connect to the database as an initial user and use the **CREATE USER** or **ALTER USER** statement with **OPRADMIN** specified.

```
gaussdb=# CREATE USER opradmin WITH OPRADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe OPRADMIN;
```

When ALTER USER is executed, the user must exist.

## Security Policy Administrator

A security policy administrator is an account with the **POLADMIN** attribute and has the permission to create resource tags, masking policies, and unified audit policies.

To create a security policy administrator, connect to the database as an administrator and use the **CREATE USER** or **ALTER USER** statement with **POLADMIN** specified.

```
gaussdb=# CREATE USER poladmin WITH POLADMIN password "*****";
```

Or

```
gaussdb=# ALTER USER joe POLADMIN;
```

When ALTER USER is executed, the user must exist.

### 2.1.3 Separation of Duties

Descriptions in **Default Permission Mechanism** and **Administrators** are about the initial situation after a cluster is created. By default, the system administrator with the SYSADMIN attribute has the highest permission in the system.

To avoid risks caused by centralized permissions, you can enable separation of duties to assign the system administrator's user management permission to security administrators and audit management permission to audit administrators.

After separation of duties, the system administrator does not have the CREATEROLE attribute (security administrator) or the AUDITADMIN attribute (audit administrator). That is, a system administrator can neither create roles or users, nor view or maintain database audit logs. For details about the CREATEROLE and AUDITADMIN attributes, see **CREATE ROLE**.

Separation of duties does not take effect for an initial user. Therefore, it is recommended that this user be used only as a database administrator for database management instead of service applications.

Contact Huawei technical support.

---

#### WARNING

If you need to use the separation of duties model, specify it during database initialization. You are advised not to switch the permission management model back and forth. In particular, if you want to switch from a non-separation-of-duties permission management model to the separation-of-duties permission management model, you need to review the permission set of existing users. If a user has the system administrator permission and audit administrator permission, the permissions need to be tailored.

---

After separation of duties, the system administrator does not have permissions for non-system schemas of other users. Therefore, the system administrator cannot access the objects in other users' schemas before being granted the permissions. For details about permission changes before and after enabling separation of duties, see **Table 2-1** and **Table 2-2**.

**Table 2-1** Default user permissions

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
Tablespaces	Has all permissions.	Can create, modify, delete, access, or grant permissions for tablespaces.	Cannot create, modify, delete, or grant permissions for tablespaces and can access tablespaces if the access permission is granted.		
Schemas		Has all permissions for all schemas except db_perf.	Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users.		
User-defined function		Has all permissions for all user-defined functions.	Has all permissions for their own functions, and has only the call permission for other users' functions.		
User-defined table or view		Has all permissions for all user-defined tables or views.	Has all permissions for their own tables or views, but does not have permissions for other users' tables or views.		

**Table 2-2** Changes in permissions after separation of duties

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
Tablespace	No change.	No change.	No change.		
Schema	Has all permissions.	Permissions reduced Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users.	No change.		
User-defined function		Cannot access functions in non-system schemas of other users before being granted the permissions.	No change.		

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
User-defined table or view		Cannot access tables or views in non-system schemas of other users before being granted the permissions.	No change.		

**NOTICE**

PG\_STATISTIC and PG\_STATISTIC\_EXT store sensitive information about statistical objects, such as high-frequency MCVs. After separation of duties is enabled, the system administrator can still access the two system catalogs to obtain sensitive information in the statistics.

## 2.1.4 Users

You can use CREATE USER and ALTER USER to create and manage database users, respectively. A database cluster can have one or more databases. Users and roles are shared within the entire cluster, but their data is not shared. That is, a user can connect to any database, but after the connection is successful, any user can access only the database declared in the connection request.

In modes other than **separation of duties**, GaussDB user accounts can be created and deleted only by a system administrator or a security administrator with the CREATEROLE attribute. In separation-of-duties scenarios, a user account can be created only by an initial user or a security administrator.

When a user logs in, GaussDB authenticates the user. A user can own databases and database objects (such as tables), and grant permissions of these objects to other users and roles. In addition to system administrators, users with the CREATEDB attribute can create databases and grant permissions on these databases.

### Adding, Modifying, and Deleting Users

- To create a user, use the SQL statement **CREATE USER**.  
For example, create user **joe** and set the CREATEDB attribute for the user.  
gaussdb=# **CREATE USER joe WITH CREATEDB PASSWORD '\*\*\*\*\*';**  
CREATE ROLE
- To create a system administrator, use the **CREATE USER** statement with the SYSADMIN option.
- To delete an existing user, use **DROP USER**.
- To change a user account (for example, rename the user or change the password), use **ALTER USER**.

- To view a user list, query the **PG\_USER** view.  
`gaussdb=# SELECT * FROM pg_user;`
- To view user attributes, query the **PG\_AUTHID** system catalog.  
`gaussdb=# SELECT * FROM pg_authid;`

## Permanent User

GaussDB provides a permanent user solution. You can create a permanent user with the **PERSISTENCE** attribute, which can use the `service_reserved_connections` channel to connect to the database.

### NOTE

**service\_reserved\_connections** indicates the minimum number of connections reserved with the **PERSISTENCE** attribute. You are advised not to set this parameter to a large value.

```
gaussdb=# CREATE USER user_persistence WITH PERSISTENCE IDENTIFIED BY "*****";
```

Only the initial user is allowed to create, modify, and delete permanent users with the **PERSISTENCE** attribute.

## 2.1.5 Roles

After a role is granted to a user through **GRANT**, the user will have all the permissions of the role. It is recommended that roles be used to efficiently grant permissions. For example, you can create different roles of design, development, and maintenance personnel, grant the roles to users, and then grant specific data permissions required by different users. When permissions are granted or revoked at the role level, these changes take effect on all members of the role.

GaussDB provides an implicitly defined group **PUBLIC** that contains all roles. By default, all new users and roles have the permissions of **PUBLIC**. For details about the default permissions of **PUBLIC**, see **GRANT**. To revoke permissions of **PUBLIC** from a user or role, or re-grant these permissions to them, add the **PUBLIC** keyword in the **REVOKE** or **GRANT** statement.

To view all roles, query the system catalog **PG\_ROLES**.

```
SELECT * FROM PG_ROLES;
```

## Adding, Modifying, and Deleting Roles

In scenarios other than separation of duties, a role can be created, modified, and deleted only by a system administrator or a user with the **CREATEROLE** attribute. In **separation-of-duties** scenarios, a role can be created, modified, and deleted only by an initial user or a user with the **CREATEROLE** attribute.

- To create a role, use **CREATE ROLE**.
- To add or delete users in an existing role, use **ALTER ROLE**.
- To delete a role, use **DROP ROLE**. **DROP ROLE** deletes only a role, rather than member users in the role.

## Built-in Roles

GaussDB provides a group of default roles whose names start with **gs\_role\_**. These roles are provided to access to specific, typically high-privileged operations. You

can grant these roles to other users or roles within the database so that they can use specific functions. These roles should be given with great care to ensure that they are used where they are needed. [Table 2-3](#) describes the permissions of built-in roles.

**Table 2-3** Permission description of built-in roles

Roles	Permission
gs_role_signal_backend	Permission to call the pg_cancel_backend, pg_terminate_backend, and pg_terminate_session functions to cancel or terminate other sessions. However, this role cannot perform operations on sessions of the initial user or <b>PERSISTENCE</b> user.
gs_role_tablespace	Permission to create a tablespace.
gs_role_replication	Permission to call logical replication functions, such as kill_snapshot, pg_create_logical_replication_slot, pg_create_physical_replication_slot, pg_drop_replication_slot, pg_replication_slot_advance, pg_create_physical_replication_slot_extern, pg_logical_slot_get_changes, pg_logical_slot_peek_changes, pg_logical_slot_get_binary_changes, and pg_logical_slot_peek_binary_changes.
gs_role_account_lock	Permission to lock and unlock users. However, this role cannot lock or unlock the initial user or users with the <b>PERSISTENCE</b> attribute.
gs_role_pldebugger	Permission to debug functions in <b>dbe_pldebugger</b> .
gs_role_public_dblink_drop	Permission to delete public database links.
gs_role_public_dblink_alter	Permission to modify public database links.
gs_role_seclabel	Permission to create, delete, and apply security labels.
gs_role_public_synonym_create	Permission to create public synonyms.
gs_role_public_synonym_drop	Permission to delete public synonyms.

The restrictions on built-in roles are as follows:

- The role names starting with **gs\_role\_** are reserved for built-in roles in the database. Do not create users, roles, or schemas starting with **gs\_role\_** or rename existing users, roles, or schemas to names starting with **gs\_role\_**.
- Do not perform ALTER or DROP operations on built-in roles.

- By default, built-in roles do not have the LOGIN permission and do not have preset passwords.
- The `gsql` meta-commands `\du` and `\dg` do not display information about built-in roles. However, if `pattern` is set to a specific built-in role, the information is displayed.
- When separation of duties is disabled, the initial user, users with the SYSADMIN permission, and users with the ADMIN OPTION built-in role permission have the permission to perform GRANT and REVOKE operations on built-in roles. When separation-of-duties is enabled, the initial user and users with the ADMIN OPTION built-in role permission have the permission to perform GRANT and REVOKE operations on built-in roles. For example:

```
GRANT gs_role_signal_backend TO user1;  
REVOKE gs_role_signal_backend FROM user1;
```

## 2.1.6 Schemas

Schemas allow multiple users to use the same database without interference. In this way, database objects can be organized into logical groups that are easy to manage, and third-party applications can be added to corresponding schemas without causing conflicts.

Each database has one or more schemas. Each schema contains tables and other types of objects. When a database is created, a public schema named **public** is created by default, and all users have the USAGE permission on this schema. In addition, each database has a `pg_catalog` schema, which contains system catalogs and all built-in data types, functions, and operators. Only a system administrator and initial user can create functions, stored procedures, and synonyms under the public and `pg_catalog` schemas. Other users cannot create these objects even if they are granted with the CREATE permission on the public and `pg_catalog` schemas. You can group database objects by schema. A schema is similar to an OS directory but cannot be nested. By default, only the initial user can create objects under the `pg_catalog` schema.

The same database object name can be used in different schemas of the same database without causing conflicts. For example, both `a_schema` and `b_schema` can contain a table named **mytable**. Users with required permissions can access objects across multiple schemas of the same database.

When you run the **CREATE USER** command to create a user, the system creates a schema with the same name as the user in the database where the command is executed.

Database objects are generally created in the first schema in a database search path. For details about the first schema and how to change the schema order, see [Search Path](#).

### Creating, Modifying, and Deleting Schemas

- To create a schema, use **CREATE SCHEMA**. By default, the initial user and system administrators can create schemas. Other users can create schemas in the database only when they have the CREATE permission on the database. For details about how to grant the permission, see the syntax in **GRANT**.
- To change the name or owner of a schema, use **ALTER SCHEMA**. The schema owner can change a schema.

- To delete a schema and its objects, use **DROP SCHEMA**. The schema owner can delete a schema.
- To create a table in a schema, use the *schema\_name.table\_name* format to specify the table. If *schema\_name* is not specified, the table will be created in the first schema in **search path**.
- To view the owner of a schema, perform the join query on the system catalogs PG\_NAMESPACE and PG\_USER. Replace *schema\_name* in the statement with the name of the schema to be queried.

```
gaussdb=# SELECT s.nspname,u.username AS nspowner FROM pg_namespace s, pg_user u WHERE nspname='schema_name' AND s.nspowner = u.usesysid;
```
- To view a list of all schemas, query the system catalog PG\_NAMESPACE.

```
gaussdb=# SELECT * FROM pg_namespace;
```
- To view a list of tables in a schema, query the system catalog PG\_TABLES. For example, the following query will return a table list from PG\_CATALOG in the schema:

```
gaussdb=# SELECT distinct(tablename),schemaname from pg_tables where schemaname = 'pg_catalog';
```

## Search Path

A search path is defined in the GUC parameter **search\_path**. The parameter value is a list of schema names separated by commas (,). If no target schema is specified during object creation, the object will be added to the first schema listed in the search path. If there are objects with the same name across different schemas and no schema is specified for an object query, the object will be returned from the first schema containing the object in the search path.

- To view the current search path, use **SHOW**.

```
gaussdb=# SHOW SEARCH_PATH;
search_path
-----
"$user",public
(1 row)
```

The default value of **search\_path** is "*\$user*",**public**. *\$user* indicates the name of the schema with the same name as the current session user. If the schema does not exist, *\$user* will be ignored. By default, after a user connects to a database that has schemas with the same name, objects will be added to all the schemas. If there are no such schemas, objects will be added only to the public schema.

- To change the default schema of the current session, run the **SET** command.

Set the search path to **myschema, public** (**myschema** will be searched first).

```
gaussdb=# SET SEARCH_PATH TO myschema, public;
SET
```

## 2.1.7 User Permissions

- To grant permissions for an object to a user, use **GRANT**.

When permissions for a table or view in a schema are granted to a user or role, the USAGE permission of the schema must be granted together. Otherwise, the user or role can only see these objects but cannot access them.

In the following example, permissions for the schema **tpcds** are first granted to user **joe**, and then the SELECT permission for the **tpcds.web\_returns** table is also granted:

```
gaussdb=# GRANT USAGE ON SCHEMA tpcds TO joe;  
gaussdb=# GRANT SELECT ON TABLE tpcds.web_returns to joe;
```

- Grant a role to a user to allow the user to inherit the object permissions of the role.

- a. Create a role.

Create a role **lily** and grant the system permission **CREATEDB** to the role.

```
gaussdb=# CREATE ROLE lily WITH CREATEDB PASSWORD '*****';
```

- b. To grant object permissions to a role, use **GRANT**.

For example, first grant permissions for the schema **tpcds** to the role **lily**, and then grant the **SELECT** permission of the **tpcds.web\_returns** table to **lily**.

```
gaussdb=# GRANT USAGE ON SCHEMA tpcds TO lily;  
gaussdb=# GRANT SELECT ON TABLE tpcds.web_returns to lily;
```

- c. Grant the role permissions to a user.

```
gaussdb=# GRANT lily to joe;
```

#### NOTE

When the permissions of a role are granted to a user, the attributes of the role are not transferred together.

- To revoke user permissions, use **REVOKE**.

## 2.1.8 Row-Level Security Policy

The row-level security feature enables database access control to be accurate to each row of data tables. In this way, the same SQL query may return different results for different users.

You can create a row-level security policy for a data table. The policy defines an expression that takes effect only for specific database users and SQL operations. When a database user accesses the data table, if an SQL statement meets the specified row-level security policies of the data table, the expressions that meet the specified condition will be combined by using **AND** or **OR** based on the attribute type (**PERMISSIVE** | **RESTRICTIVE**) and applied to the execution plan in the query optimization phase.

Row-level security policy is used to control the visibility of row-level data in tables. By predefining filters for data tables, the expressions that meet the specified condition can be applied to execution plans in the query optimization phase, which will affect the final execution result. Currently, the SQL statements that can be affected include **SELECT**, **UPDATE**, and **DELETE**.

Scenario 1: A table summarizes the data of different users. Users can view only their own data.

```
-- Create users alice, bob, and peter.  
gaussdb=# CREATE USER alice PASSWORD '*****';  
gaussdb=# CREATE USER bob PASSWORD '*****';  
gaussdb=# CREATE USER peter PASSWORD '*****';  
  
-- Create the all_data table that contains user information.  
gaussdb=# CREATE TABLE all_data(id int, role varchar(100), data varchar(100));  
  
-- Insert data into the data table.  
gaussdb=# INSERT INTO all_data VALUES(1, 'alice', 'alice data');  
gaussdb=# INSERT INTO all_data VALUES(2, 'bob', 'bob data');  
gaussdb=# INSERT INTO all_data VALUES(3, 'peter', 'peter data');
```

```
-- Grant the read permission for the all_data table to users alice, bob, and peter.
gaussdb=# GRANT SELECT ON all_data TO alice, bob, peter;

-- Enable row-level security policy.
gaussdb=# ALTER TABLE all_data ENABLE ROW LEVEL SECURITY;

-- Create a row-level security policy to specify that the current user can view only their own data.
gaussdb=# CREATE ROW LEVEL SECURITY POLICY all_data_ri ON all_data USING(role = CURRENT_USER);

-- View table details.
gaussdb=# \d+ all_data
          Table "public.all_data"
Column |      Type      | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
 id    | integer        |           |         |              |
 role  | character varying(100) |           | extended |              |
 data  | character varying(100) |           | extended |              |
Row Level Security Policies:
  POLICY "all_data_ri" FOR ALL
  TO public
  USING (((role)::name = "current_user"()))
Has OIDs: no
Distribute By: HASH(id)
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no, enable_rowsecurity=true

-- Switch to user alice and run SELECT * FROM public.all_data.
gaussdb=# SELECT * FROM public.all_data;
 id | role | data
---+---+---
  1 | alice | alice data
(1 row)

gaussdb=# EXPLAIN(COSTS OFF) SELECT * FROM public.all_data;
          QUERY PLAN
-----
Streaming (type: GATHER)
 Node/s: All datanodes
  -> Seq Scan on all_data
       Filter: ((role)::name = 'alice'::name)
 Notice: This query is influenced by row level security feature
(5 rows)

-- Switch to user peter and run SELECT * FROM public.all_data.
gaussdb=# SELECT * FROM public.all_data;
 id | role | data
---+---+---
  3 | peter | peter data
(1 row)

gaussdb=# EXPLAIN(COSTS OFF) SELECT * FROM public.all_data;
          QUERY PLAN
-----
Streaming (type: GATHER)
 Node/s: All datanodes
  -> Seq Scan on all_data
       Filter: ((role)::name = 'peter'::name)
 Notice: This query is influenced by row level security feature
(5 rows)
```

### NOTICE

PG\_STATISTIC and PG\_STATISTIC\_EXT store sensitive information about statistical objects, such as high-frequency MCVs. If the permission to query the two system catalogs is granted to a common user after the row-level security policy is created, the common user can still access the two system catalogs to obtain sensitive information in the statistical objects.

PG\_STATS, PG\_EXT\_STATS, and PG\_GTT\_STATS are statistics query views and are used to verify users' SELECT permission on columns. If a common user has the SELECT permission and row-level security exists in the table, the common user may query some data that cannot be queried but appears frequently in the statistics. (The data is not the entire row but only a value of a column. The statistics are collected and calculated by column.)

## 2.2 Database Audit

### Context

Database audit is critical to the security of the database system. Database audit administrators can use the audit logs to reproduce a series of events that cause faults in the database and identify unauthorized users, unauthorized operations, and the time when these operations are performed.

You need to know the following about the audit function:

- The GUC parameter **audit\_enabled** is used to enable or disable the audit function. Its value can be dynamically loaded. After you change the switch status when the database is running, the change takes effect immediately and you do not need to restart the database. Its default value is **on**, indicating that the audit function is enabled.
- In addition to the overall audit switch, each audit item has an independent switch. An audit item is available only after its own switch is turned on.
- The switch of each audit supports dynamic loading. After changing the audit switch status when the database is running, the modification takes effect immediately without restarting the database.

**Table 2-4** describes the audit items supported by GaussDB. If you need to modify a specific audit configuration item, contact the administrator. For details about parameter types and value ranges, see "Configuring Running Parameters > GUC Parameters > Auditing" in *Administrator Guide*.

**Table 2-4** Audit items

Configuration Item	Description
User login and logout audit	Parameter: <b>audit_login_logout</b> Its default value is <b>7</b> , which indicates that the function of user login and logout audit is enabled. <b>0</b> indicates that the function of user login and logout audit is disabled. Other values are not recommended.
Database startup, stop, recovery, and switchover audit	Parameter: <b>audit_database_process</b> Its default value is <b>1</b> , which indicates that the audit of database startup, stop, recovery, and switchover is enabled.
User locking and unlocking audit	Parameter: <b>audit_user_locked</b> Its default value is <b>1</b> , which indicates that the audit of user locking and unlocking is enabled.
Unauthorized access audit	Parameter: <b>audit_user_violation</b> Its default value is <b>0</b> , which indicates that the audit of unauthorized access disabled.
Permission granting and revoking audit	Parameter: <b>audit_grant_revoke</b> Its default value is <b>1</b> , which indicates that the audit of permission granting and revoking is enabled.
Full audit of user operations	Parameter: <b>full_audit_users</b> Its default value is an empty string, indicating that the default configuration is used and no full audit of user operations is configured.
Names and IP addresses of clients that do not need to be audited	Parameter: <b>no_audit_client</b> Its default value is an empty string, indicating that the default configuration is used and no clients and IP addresses are added to the audit blacklist.
Audit of CREATE, ALTER, and DROP operations on database objects	Parameter: <b>audit_system_object</b> Its default value is <b>67121159</b> , which indicates that the CREATE, ALTER, and DROP operations only on databases, schemas, users, and node groups are audited.
Audit of INSERT, UPDATE, and DELETE operations on a specific table	Parameter: <b>audit_dml_state</b> Its default value is <b>0</b> , which indicates that the audit of DML operations (except SELECT) on a specific table is disabled.
SELECT operation audit	Parameter: <b>audit_dml_state_select</b> Its default value is <b>0</b> , which indicates that the audit of the SELECT operation is disabled.

Configuration Item	Description
COPY operation audit	Parameter: <b>audit_copy_exec</b> Its default value is <b>1</b> , which indicates that the audit of COPY operations is enabled.
Audit of execution of stored procedures and user-defined functions	Parameter: <b>audit_function_exec</b> Its default value is <b>0</b> , which indicates that no execution audit logs of stored procedures and user-defined functions are recorded.
Audit of system functions in the whitelist	Parameter: <b>audit_system_function_exec</b> Its default value is <b>0</b> , which indicates that audit logs of system function execution are not recorded.
SET operation audit	Parameter: <b>audit_set_parameter</b> Its default value is <b>0</b> , which indicates that the audit of the SET operation is disabled.
Transaction ID record	Parameter: <b>audit_xid_info</b> Its default value is <b>0</b> , which indicates that the function of recording transaction IDs in audit logs is disabled.
Audit of internal tool connections and operations, and audit of logins and logouts from CNs on DNs	Parameter: <b>audit_internal_event</b> The default value is <b>off</b> , which indicates that the logins, logouts, and operations of internal tools CM Agent, gs_clean, and WDRXdb are not audited. In addition, the logins and logouts from CNs are not audited on DNs.

# 3 Database Quick Start

---

## 3.1 Operating a Database

This section explains how to use databases, including creating database accounts, databases, and tables, inserting data to tables, and querying data in tables.

### 3.1.1 Creating a Database Account

Only administrators that are created during the cluster installation can access the initial database by default. You can also create other database users.

```
gaussdb=# CREATE USER joe WITH PASSWORD "*****";
```

If the following information is displayed, the creation is successful:

```
CREATE ROLE
```

In this case, you have created a user account named **joe**, and the user password is **\*\*\*\*\***. Set user **joe** as a system administrator.

```
gaussdb=# GRANT ALL PRIVILEGES TO joe;
```

Run the **GRANT** command to set related permissions. For details, see [GRANT](#).

#### NOTE

For more information about database users, see [Users and Permissions](#).

### 3.1.2 Creating and Managing Databases

#### Prerequisites

Only database system administrators or users granted with database creation permissions can create a database. For details about how to grant database creation permissions to a user, see [Users and Permissions](#).

#### Context

- GaussDB has two default template databases **template0** and **template1** and a default user database **postgres**.

- `CREATE DATABASE` creates a database by copying a template database. Only **template0** can be copied. Do not use a client or any other tools to connect to or to perform operations on the template databases.

 **NOTE**

- The template database does not contain any user table. You can view the attributes of the template database in the `PG_DATABASE` system catalog.
- The **template0** template database does not allow user connections. Only the initial user and the system administrator of the database can connect to **template1**.
- A database system consists of multiple databases. A client can connect to only one database at a time. Currently, cross-database query or cross-database transaction is not supported.
- If multiple databases exist in the database cluster, you can use the `-d` parameter of the client tool to specify the target database for login. Alternatively, you can run the `\c` command to switch the database after the client program logs in to the database.

## Precautions

Assume that the database encoding is `SQL_ASCII`. (You can run the **show server\_encoding** command to query the encoding used for storing data in the current database.) If the database object name contains multi-byte characters (such as Chinese) or if the object name length exceeds the allowed maximum (63 bytes), the database truncates the last byte (not the last character) of the object name. In this case, half characters may appear.

To resolve this problem, you need to:

- Ensure that the name of the data object does not exceed the maximum length.
- Use UTF-8 as the default database storage code set (`server_encoding`).
- Exclude multi-byte characters from object names.
- If you fail to delete an object whose name is truncated mistakenly, specify its original name to delete it, or manually delete it from the corresponding system catalog on each node.

## Procedure

### Step 1 Create a database named **db\_tpcds**.

```
gaussdb=# CREATE DATABASE db_tpcds;  
CREATE DATABASE
```

 NOTE

- Database names must comply with the general naming convention rules of SQL identifiers. The current role automatically becomes the owner of this new database.
- If a database system is used to support independent users and projects, store them in different databases.
- If the projects or users are associated with each other and share resources, store them in one database. However, you can divide them into different schemas. A schema is a logical structure, and the access permission for a schema is controlled by the permission system module.
- A database name contains a maximum of 63 bytes and the excessive bytes at the end of the name will be truncated by the server. You are advised to specify a database name no longer than 63 bytes when you create a database.

- New databases are created in the `pg_default` tablespace by default. Specify another tablespace.

```
gaussdb=# CREATE DATABASE db_tpcds WITH TABLESPACE = hr_local;  
CREATE DATABASE
```

*hr\_local* indicates the tablespace name. For details about how to create a tablespace, see [Creating and Managing Tablespaces](#).

- After creating the `db_tpcds` database, you can perform other operations in the default `postgres` database. Alternatively, you can perform the following operations to exit the `postgres` database, connect to the `db_tpcds` database as a new user, and perform operations such as creating tables:

```
gaussdb=# \q  
gsq! -d db_tpcds -p 8000 -U joe  
Password for user joe:  
gsq!((GaussDB Kernel XXX.XXX.XXX build f521c606) compiled at 2021-09-16 14:55:22 commit  
2935 last mr 6385 release)  
Non-SSL connection (SSL connection is recommended when requiring high-security)  
Type "help" for help.
```

```
db_tpcds=>
```

**Step 2** View databases.

- Run the `\l` meta-command to view the database list of the database system.  
gaussdb=# \l
- Query the database list in the `pg_database` system catalog.  
gaussdb=# **SELECT datname FROM pg\_database;**

**Step 3** Modify the database.

You can modify database configuration such as the database owner, name, and default settings.

- Rename the database.  
gaussdb=# **ALTER DATABASE db\_tpcds RENAME TO human\_tpcds;**  
ALTER DATABASE

 NOTE

After setting the parameters, you need to manually run the **CLEAN CONNECTION** command to clear the old connections. Otherwise, the parameter values between nodes may be inconsistent.

**Step 4** Delete the database.

You can run the **DROP DATABASE** command to delete a database. This command deletes the system directory in the database, as well as the database directory on the disk that stores data. Only the database owner or system administrator can delete a database. A database accessed by users cannot be deleted. You need to connect to another database before deleting this database.

```
Delete the database.  
gaussdb=# DROP DATABASE human_tpcds;  
DROP DATABASE
```

----End

## 3.1.3 Creating and Managing Tablespaces

### Context

An administrator can use tablespaces to control the layout of disks where a database is installed. The advantages are as follows:

- If the disk partition or tablespace initially allocated to the database is full and the space cannot be logically extended, you can create and use tablespaces in other partitions until the disk space is reconfigured.
- Tablespaces allow the administrator to distribute data based on a schema of database objects, improving system performance.
  - A frequently used index can be stored in a disk having stable performance and high computing speed, such as a solid-state device.
  - A table that stores archived data and is rarely used or has low performance requirements can be placed in a disk with a slow computing speed.
- An administrator can use tablespaces to limit the disk space of databases. If a tablespace shares a partition with other tablespaces, the tablespace will never occupy the space allocated to other tablespaces.
- Tablespaces are used to manage the disk space occupied by a database. The database will switch to the read-only mode when the usage of the disk occupied by the database reaches 90%. Once the disk usage drops below 90%, the database will be switched to the read-write mode. The automatic disk check function of the CM component is enabled by default. If the function is disabled, contact the administrator to enable it.
- Each tablespace corresponds to a file system directory. You can run the following command to create a tablespace corresponding to **/pg\_location/mount1/path1** and specify the maximum available space to 500 GB:

```
-- Create a tablespace.  
gaussdb=# CREATE TABLESPACE ds_location1 LOCATION '/pg_location/mount1/path1' MAXSIZE  
'500G';
```

If **MAXSIZE** is used to manage tablespace quotas, the concurrent insertion performance may deteriorate by about 30%. **MAXSIZE** specifies the maximum quota for each DN. The difference between the actual tablespace capacity of each DN and the specified quota should be within 500 MB. You can determine whether to set a tablespace to its maximum size as required.

GaussDB provides two tablespaces: **pg\_default** and **pg\_global**.

- Default tablespace **pg\_default**: stores non-shared system catalogs, user tables, user table indexes, temporary tables, temporary table indexes, and internal temporary tables. The corresponding storage directory is the **base** directory in the instance data directory.
- Shared tablespace **pg\_global**: stores shared system catalogs. The corresponding storage directory is the **global** directory in the instance data directory.

**Precautions:**

- You are advised not to use user-defined tablespaces in the Huawei Cloud scenario.

This is because user-defined tablespaces are usually used with storage media other than the main storage (storage device where the default tablespace is located, such as a disk) to isolate I/O resources that can be used by different services. However, in the Huawei Cloud scenario, storage devices use standard configurations and do not have other available storage media. If the user-defined tablespaces are not properly used, the system cannot run stably for a long time and the overall performance is affected. Therefore, you are advised to use the default tablespace.

**Procedure**

- Create a tablespace.
  - Create user **jack** and set the password to **\*\*\*\*\***.

```
gaussdb=# CREATE USER jack IDENTIFIED BY *****;
```

If the following information is displayed, the creation is successful:

```
CREATE ROLE
```
  - Create a tablespace.

```
gaussdb=# CREATE TABLESPACE fastspace RELATIVE LOCATION 'my_tablespace/tablesace1';
```

If the following information is displayed, the creation is successful:

```
CREATE TABLESPACE
```

**fastspace** is the new tablespace, and *CN or DN data directory* **pg\_location/my\_tablespace/tablesace1** is an empty directory on which users have read and write permissions.
  - Grant the permission of accessing the **fastspace** tablespace to user **jack** as a database system administrator.

```
gaussdb=# GRANT CREATE ON TABLESPACE fastspace TO jack;
```

If the following information is displayed, the grant operation is successful:

```
GRANT
```
- Create an object in a tablespace.

If you have the CREATE permission on the tablespace, you can create database objects in the tablespace, such as tables and indexes.

Take creating a table as an example:

  - Method 1: Create a table in a specified tablespace.

```
gaussdb=# CREATE TABLE foo(i int) TABLESPACE fastspace;
```

If the following information is displayed, the creation is successful:

```
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'i' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
```
  - Method 2: Run **set default\_tablespace** to set the default tablespace and then create a table.

```
gaussdb=# SET default_tablespace = 'fastspace';
SET
gaussdb=# CREATE TABLE foo2(i int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'i' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
```

In this example, **fastspace** is the default tablespace, and **foo2** is the created table.

- Query tablespaces.
  - Method 1: Check the `pg_tablespace` system catalog. View all tablespaces defined by the system and users.  
`gaussdb=# SELECT spcname FROM pg_tablespace;`
  - Method 2: Run a `gsql` meta-command to query tablespaces.  
`gaussdb=# \db`

- Query the tablespace usage.

- a. Query the current usage of a tablespace.  
`gaussdb=# SELECT PG_TABLESPACE_SIZE('fastspace');`

The following information is displayed:

```
pg_tablespace_size
-----
                2146304
(1 row)
```

**2146304** is the size of the tablespace, and its unit is byte.

- b. Calculate the tablespace usage.

Tablespace usage = Value of `PG_TABLESPACE_SIZE`/Size of the disk where the tablespace resides

- Modify a tablespace.

Rename tablespace **fastspace** to **fspace**.

```
gaussdb=# ALTER TABLESPACE fastspace RENAME TO fspace;
ALTER TABLESPACE
```

- Delete a tablespace and related data.

- Delete user **jack**.

```
gaussdb=# DROP USER jack CASCADE;
DROP ROLE
```

- Delete tables **foo** and **foo2**.

```
gaussdb=# DROP TABLE foo;
gaussdb=# DROP TABLE foo2;
```

If the following information is displayed, the deletion is successful:

```
DROP TABLE
```

- Delete tablespace **fspace**.

```
gaussdb=# DROP TABLESPACE fspace;
DROP TABLESPACE
```

#### NOTE

Only the tablespace owner or system administrators can delete a tablespace.

## 3.1.4 Creating and Managing Tables

### 3.1.4.1 Creating a Table

#### Context

A table is created in a database and can be stored in different databases. Tables under different schemas in a database can have the same name.

For details about how to design a table suitable for services, see [Best Practices of Table Design](#).

## Creating a Table

Create a table.

```
gaussdb=# CREATE TABLE customer_t1
(
  c_customer_sk      integer,
  c_customer_id      char(5),
  c_first_name       char(6),
  c_last_name        char(8)
)
distribute by hash (c_last_name);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

**c\_customer\_sk**, **c\_customer\_id**, **c\_first\_name**, and **c\_last\_name** are the column names of the table. **integer**, **char(5)**, **char(6)**, and **char(8)** are column name types.

### NOTE

- By default, new database objects are created in the \$user schema. For more details about schemas, see [Creating and Managing Schemas](#).
- In addition to the created tables, a database contains many system catalogs. These system catalogs contain cluster installation information and information about various queries and processes in GaussDB. You can collect information about the database by querying system catalogs. For details, see [Querying System Catalogs](#).
- For more details about how to create a table, see [CREATE TABLE](#).

### 3.1.4.2 Inserting Data to Tables

A new table contains no data. You need to insert data to the table before using it. This section describes how to insert a row or multiple rows of data by running the **INSERT** command and to insert data from a specified table. Contact the administrator if a large amount of data needs to be imported.

## Context

In case of different character sets used on the client and server, the length of a character on both ends may differ. A string entered on the client will be processed on the server based on the server's character set, and therefore the result may differ from the expected result.

**Table 3-1** Comparison of outputs varying depending on character sets on the client and server

Procedure	Same Encoding on the Server and Client	Different Encoding on the Server and Client
No operations are performed on the string while it is saved and read.	Your expected result is returned.	Your expected result is returned (only if the encoding on the client remains unchanged).

Procedure	Same Encoding on the Server and Client	Different Encoding on the Server and Client
Operations (such as executing string functions) are performed on the string while it is saved and read.	Your expected result is returned.	The result may differ from the expected result, depending on the operations performed on the string.
An ultra long string is truncated while it is saved.	Your expected result is returned.	If the character sets used on the client and server have different character length, the result may differ from the expected result.

More than one of the preceding operations may be performed on a string. For example, if the character sets of the client and server are different and the string is truncated after being processed, the result will also be unexpected. For details, see [Table 3-2](#).

 **NOTE**

Ultra long strings are truncated only if **DBCOMPATIBILITY** is set to **TD** (compatible with Teradata) and the GUC parameter **td\_compatible\_truncation** is set to **on**.

Create **table1** and **table2** to be used in the examples.

```
gaussdb=# CREATE TABLE table1(id int, a char(6), b varchar(6),c varchar(6));
gaussdb=# CREATE TABLE table2(id int, a char(20), b varchar(20),c varchar(20));
```

**Table 3-2** Examples

No.	Character Set on the Server	Character Set on the Client	Automatic Truncation Enabled	Example	Result	Description
1	SQL_ASCII	UTF8	Yes	gaussdb=# INSERT INTO table1 VALUES(1,reverse('123AA78'),reverse('123AA78'),reverse('123AA78'));	id  a b c ----+----- +-----+----- 1   87  87  87	A string is reversed on the server and then truncated. Because character sets used by the server and client are different, character A is displayed in multiple bytes on the server and the result is unexpected.
2	SQL_ASCII	UTF8	Yes	gaussdb=# INSERT INTO table1 VALUES(2,reverse('123A78'),reverse('123A78'),reverse('123A78'));	id  a b c ----+----- +-----+----- 2   873  873  873	A string is reversed and then automatically truncated. Therefore, the result is unexpected.
3	SQL_ASCII	UTF8	Yes	gaussdb=# INSERT INTO table1 VALUES(3,'87A123','87A123','87A123');	id   a   b   c ----+----- +-----+----- 3   87A1   87A1   87A1	The column length in the string type is an integer multiple of the length in client character encoding. Therefore, the result is as expected after truncation.

No.	Character Set on the Server	Character Set on the Client	Automatic Truncation Enabled	Example	Result	Description
4	SQL_ASCII	UTF8	No	<pre>gaussdb=# INSERT INTO table2 VALUES(1,reverse('123AA78'),reverse('123AA78'),reverse('123AA78')); gaussdb=# INSERT INTO table2 VALUES(2,reverse('123A78'),reverse('123A78'),reverse('123A78'));</pre>	<pre>id  a b c ---- +-----+ --+----- +----- 1   87 321  87 321   87 321 2   87321  87321  87321</pre>	Similar to the first example, multi-byte characters are different from the original characters after being reversed.

## Procedure

You need to create a table before inserting data to it. For details about how to create a table, see [Creating and Managing Tables](#).

- Insert a row to table **customer\_t1**.

Data values are arranged in the same order as the columns in the table and are separated by commas (.). Generally, column values are text values (constants), but scalar expressions are also allowed.

```
gaussdb=# INSERT INTO customer_t1(c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', 'Grace');
```

If you know the sequence of the columns in the table, you can obtain the same result without listing these columns. For example, the following command generates the same result as the preceding command:

```
gaussdb=# INSERT INTO customer_t1 VALUES (3769, 'hello', 'Grace');
```

If you do not know some of the column values, you can omit them. In the INSERT statement, if the column name of the specified target table is not displayed, the values to be inserted in the VALUES clause correspond to the columns of the target table based on the column number. That is, the first value in the VALUES clause corresponds to the first column of the target table, the second value of the VALUES clause corresponds to the second column of the target table, and so on. Columns that do not have corresponding values in the VALUES clause are automatically filled with default values or NULL. If no value is specified for a column, the column is set to the default value. For example:

```
gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_first_name) VALUES (3769, 'Grace');
```

```
gaussdb=# INSERT INTO customer_t1 VALUES (3769, 'hello');
```

You can also specify the default value of a column or row.

```
gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', DEFAULT);
```

```
gaussdb=# INSERT INTO customer_t1 DEFAULT VALUES;
```

- Insert multiple rows to a table.

```
gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES
(6885, 'maps', 'Joes'),
(4321, 'tpcds', 'Lily'),
(9527, 'world', 'James');
```

You can also insert multiple rows by running the command for inserting one row for multiple times. However, you are advised to run this command to improve efficiency.

- Assume that you have created a backup table **customer\_t2** for table **customer\_t1**. To insert data from **customer\_t1** to **customer\_t2**, run the following commands:

```
gaussdb=# CREATE TABLE customer_t2
(
  c_customer_sk      integer,
  c_customer_id      char(5),
  c_first_name       char(6),
  c_last_name        char(8)
);
gaussdb=# INSERT INTO customer_t2 SELECT * FROM customer_t1;
```

#### NOTE

If implicit conversion is not implemented between the column data types of the specified table and those of the current table, the two tables must have the same column data types when data is inserted from the specified table to the current table.

- Use a table alias without AS to insert data into the table.

```
gaussdb=# CREATE TABLE table_name(a int,b text,c timestamp,d float);
gaussdb=# INSERT INTO table_name alias_name VALUES(1,'ha','1997-01-01
10:00:00'::timestamp,1.234);
gaussdb=# INSERT INTO table_name alias_name(b,c,d) VALUES('ha','1997-01-01
10:00:00'::timestamp,1.234);
```

#### NOTE

1. When the INSERT statement is used without AS, the table alias cannot be a keyword (such as SELECT or VALUE) or an expression. The alias must comply with the identifier naming rule.
  2. When the INSERT statement is used without AS, the table alias does not support this format: INSERT INTO table\_name alias\_name(alias\_name.col1,...,alias\_name.coln) VALUES(xxx).
  3. When the INSERT statement is used without AS, data cannot be inserted to the specified partition.
- Delete a backup table.

```
gaussdb=# DROP TABLE customer_t2 CASCADE;
```

#### NOTE

If the table to be deleted is dependent on other tables, you need to delete the corresponding tables first.

### 3.1.4.3 Updating Data in a Table

Existing data in a database can be updated. You can update one row, all rows, or specified rows of data, or update data in a single column without affecting the data in the other columns.

The following information is required when the UPDATE statement is used to update rows:

- Table name and column name of the data to be updated

- New column value
- Rows to be updated

Generally, in SQL, no unique ID is specified for a row of data. Therefore, it is impossible to directly specify the rows of the data to be updated. However, you can specify the conditions that must be met by the rows to be updated. If a table contains primary keys, you can specify a row using the primary keys.

For details about how to create a table and insert data to it, see [Creating a Table](#) and [Inserting Data to Tables](#).

The value of **c\_customer\_sk** in the table **customer\_t1** must be changed from **9527** to **9876**.

```
gaussdb=# UPDATE customer_t1 SET c_customer_sk = 9876 WHERE c_customer_sk = 9527;
```

You can use a schema to modify the table name. If no such modifier is specified, the table is located based on the default schema path. SET is followed by the column and the new column value. The new value can be a constant or an expression.

For example, increase all the values in the **c\_customer\_sk** column by 100.

```
gaussdb=# UPDATE customer_t1 SET c_customer_sk = c_customer_sk + 100;
```

This statement does not contain the WHERE clause, and therefore all rows are updated. If the statement contains the WHERE clause, only the rows matching the clause are updated.

In the SET clause, the equal sign (=) indicates value setting. In the WHERE clause, the equal sign indicates comparison. A WHERE condition does not have to be an equality comparison, and can be another operator.

You can use an UPDATE statement to update multiple columns by specifying multiple values in the SET clause, for example:

```
gaussdb=# UPDATE customer_t1 SET c_customer_id = 'Admin', c_first_name = 'Local' WHERE c_customer_sk = 4421;
```

After data has been updated or deleted in batches, a large number of deletion markers are generated in the data file. During query, data with these deletion markers needs to be scanned as well. In this case, a large amount of data with deletion marks may greatly affect the query performance after batch updates or deletions. If data needs to be updated or deleted in batches frequently, you are advised to periodically run **VACUUM FULL** so as to ensure the query performance.

### 3.1.4.4 Viewing Data

- Run the following command to query information about all tables in a database in the system catalog **pg\_tables**:  

```
gaussdb=# SELECT * FROM pg_tables;
```
- Run the **\d+** command of the **gsql** tool to query table attributes:  

```
gaussdb=# \d+ customer_t1;
```
- Run the following command to query the data volume of table **customer\_t1**:  

```
gaussdb=# SELECT count(*) FROM customer_t1;
```
- Run the following command to query all data in the table **customer\_t1**:  

```
gaussdb=# SELECT * FROM customer_t1;
```
- Run the following command to query only the data in the column **c\_customer\_sk**:

```
gaussdb=# SELECT c_customer_sk FROM customer_t1;
```

- Run the following command to filter repeated data in the column **c\_customer\_sk**:  
gaussdb=# SELECT DISTINCT( c\_customer\_sk ) FROM customer\_t1;
- Run the following command to query all data whose column **c\_customer\_sk** is **3869**:  
gaussdb=# SELECT \* FROM customer\_t1 WHERE c\_customer\_sk = 3869;
- Run the following command to collate data based on the column **c\_customer\_sk**:  
gaussdb=# SELECT \* FROM customer\_t1 ORDER BY c\_customer\_sk;

### 3.1.4.5 Deleting Data from a Table

Outdated data may need to be deleted when tables are used. Data can be deleted from tables only by row.

In SQL, you can only access and delete an independent row by declaring conditions. If a table has a primary key, you can use it to specify a row. You can delete several rows that match the specified condition or delete all the rows from a table.

For example, delete all the rows whose **c\_customer\_sk** column is **3869** from the table **customer\_t1**.

```
gaussdb=# DELETE FROM customer_t1 WHERE c_customer_sk = 3869;
```

To delete all rows from the table, run either of the following commands:

```
gaussdb=# DELETE FROM customer_t1;
```

Or

```
gaussdb=# TRUNCATE TABLE customer_t1;
```

#### NOTE

If you need to delete an entire table, you are advised to use the TRUNCATE statement rather than DELETE.

Delete the created table.

```
gaussdb=# DROP TABLE customer_t1;
```

## 3.1.5 Querying System Catalogs

In addition to the created tables, a database contains many system catalogs. These system catalogs contain cluster installation information and information about various queries and processes in GaussDB. You can collect information about the database by querying system catalogs.

In [System Catalogs and System Views](#), the description about each table specifies whether the table is visible to all users or only the initial user. To query tables that are visible only to the initial user, log in as the initial user.

GaussDB provides the following types of system catalogs and views:

- PG-compatible system catalogs and views  
These system catalogs and views have the prefix **PG**.

**Step 2** View the running query statements. View the database names, users performing queries, query status, and the corresponding PID which are connected to the running query statements.

```
SELECT datname, username, state, pid FROM pg_stat_activity;
 datname | username | state | pid
-----+-----+-----+-----
 testdb | Ruby    | active | 140298793514752
 testdb | Ruby    | active | 140298718004992
 testdb | Ruby    | idle   | 140298650908416
 testdb | Ruby    | idle   | 140298625742592
 testdb | omm     | active | 140298575406848
(5 rows)
```

If the **state** column is **idle**, the connection is idle and requires a user to enter a command.

View the query statements that are not in the idle state.

```
SELECT datname, username, state, pid FROM pg_stat_activity WHERE state != 'idle';
```

**Step 3** To cancel queries that have been running for a long time, use the `PG_TERMINATE_BACKEND` function to end sessions based on the thread ID (corresponding to the PID in [Step 2](#)).

```
SELECT PG_TERMINATE_BACKEND(140298793514752);
```

If information similar to the following is displayed, the session is successfully terminated:

```
PG_TERMINATE_BACKEND
-----
t
(1 row)
```

If information similar to the following is displayed, a user has terminated the current session:

```
FATAL: terminating connection due to administrator command
FATAL: terminating connection due to administrator command
```

#### NOTE

1. When an initial user uses the `PG_TERMINATE_BACKEND` function to terminate the background threads of active sessions, the `gsql` client is reconnected automatically rather than be logged out. The message "The connection to the server was lost. Attempting reset: Succeeded." is returned. If non-initial users do this operation, the message "The connection to the server was lost. Attempting reset: Failed." is returned. This is because only initial users can log in to the system in password-free mode.
2. If the `PG_TERMINATE_BACKEND` function is used to end inactive background threads, and the thread pool is enabled, idle sessions do not have thread IDs and cannot be terminated. In non-thread pool mode, terminated sessions are not automatically reconnected.

----End

## 3.1.6 Other Operations

### 3.1.6.1 Creating and Managing Schemas

#### Context

Schemas function as models. Schemas allow multiple users to use the same database without interference. In this way, database objects can be organized into

logical groups that are easy to manage, and third-party applications can be added to corresponding schemas without causing conflicts. Schema management involves creating a schema, using a schema, deleting a schema, setting a search path for a schema, and setting schema permissions.

## Precautions

- A database cluster can have one or more databases. Users and user groups are shared within the entire cluster, but their data is not shared. Any user who has connected to a server can access only the database specified in the connection request.
- A database can have one or more schemas, and a schema can contain tables and other data objects, such as data types, functions, and operators. One object name can be used in different schemas. For example, both schema1 and schema2 can have a table named **mytable**.
- Different from databases, schemas are not isolated. You can access the objects in a schema of the connected database if you have schema permissions. To manage schema permissions, you need to have knowledge about database permissions.
- Schema names prefixed with **PG\_** cannot be created. Such schema names are reserved for the database system.
- Each time a new user is created, the system creates a schema with the same name for the new user in the current database. In other databases, such a schema needs to be manually created.
- To reference a table that is not modified with a schema name, the system uses **search\_path** to find the schema that the table belongs to. `pg_temp` and `pg_catalog` are always the first two schemas to be searched no matter whether or how they are specified in **search\_path**. **search\_path** is a schema name list, and the first table detected in it is the target table. If no target table is found, an error will be reported. (If a table exists but the schema it belongs to is not listed in **search\_path**, the search fails as well.) The first schema in **search\_path** is called "current schema." This schema is the first one to be searched. If no schema name is declared, newly created database objects are saved in this schema by default.
- Each database has a `pg_catalog` schema, which contains system catalogs and all built-in data types, functions, and operators. `pg_catalog` is a part of the search path and has the second highest search priority. It is searched after the schema of temporary tables and before other schemas specified in **search\_path**. This search order ensures that database built-in objects can be found. To use a custom object that has the same name as a built-in object, you can specify the schema of the custom object.

## Procedure

- Create a schema.

- Create a schema.  
`gaussdb=# CREATE SCHEMA myschema;`

If the following information is displayed, the schema named **myschema** is successfully created:

```
CREATE SCHEMA
```

To create or access an object in the schema, specify the complete object name, which consists of the schema name and the object names separated by periods (.). Example: **myschema.table**.

- Create a schema and specify the owner.

```
gaussdb=# CREATE SCHEMA myschema AUTHORIZATION omm;
```

If the following information is displayed, the **myschema** schema that belongs to the **omm** user is created successfully:

```
CREATE SCHEMA
```

- Use a schema.

If you want to create or access an object in a specified schema, the object name must contain the schema name. To be specific, the name consists of a schema name and an object name, which are separated by a dot (.).

- Create the **mytable** table in **myschema**.

```
gaussdb=# CREATE TABLE myschema.mytable(id int, name varchar(20));  
CREATE TABLE
```

To specify the location of an object, the object name must contain the schema name.

- Query all data of the **mytable** table in **myschema**.

```
gaussdb=# SELECT * FROM myschema.mytable;  
id | name  
----+-----  
(0 rows)
```

- View the search path of a schema.

You can set **search\_path** to specify the sequence of schemas in which objects are searched. The first schema listed in the search path will become the default schema. If no schema is specified during object creation, the object will be created in the default schema.

- View the search path.

```
gaussdb=# SHOW SEARCH_PATH;  
search_path  
-----  
"$user",public  
(1 row)
```

- Set the search path to **myschema, public** (**myschema** will be searched first).

```
gaussdb=# SET SEARCH_PATH TO myschema, public;  
SET
```

- Set permissions for a schema.

By default, a user can only access database objects in their own schema. Only after a user is granted with the usage permission for a schema by the schema owner, the user can access the objects in the schema.

By granting the CREATE permission for a schema to a user, the user can create objects in this schema. By default, all roles have the USAGE permission in the public schema, but common users do not have the CREATE permission in the public schema. It is insecure for a common user to connect to a specified database and create objects in its public schema. If the common user has the CREATE permission on the public schema, it is advised to:

- Revoke **PUBLIC**'s permission to create objects in the public schema. In the following command, **public** indicates the schema and **PUBLIC** indicates all roles:

```
gaussdb=# REVOKE CREATE ON SCHEMA public FROM PUBLIC;  
REVOKE
```

- View the current schema.

```
gaussdb=# SELECT current_schema();
current_schema
-----
myschema
(1 row)
```
- Create user **jack** and grant the usage permission for **myschema** to the user.

```
gaussdb=# CREATE USER jack IDENTIFIED BY '*****';
CREATE ROLE
gaussdb=# GRANT USAGE ON schema myschema TO jack;
GRANT
```
- Revoke the usage permission for **myschema** from **jack**.

```
gaussdb=# REVOKE USAGE ON schema myschema FROM jack;
REVOKE
```
- Drop a schema.
  - If a schema is empty, that is, it contains no database objects, you can run the **DROP SCHEMA** command. For example, drop an empty schema named **nullschema**.

```
gaussdb=# DROP SCHEMA IF EXISTS nullschema;
DROP SCHEMA
```
  - To drop a schema that is not null, use the keyword **CASCADE** to drop it and all its objects. For example, drop **myschema** and all its objects.

```
gaussdb=# DROP SCHEMA myschema CASCADE;
DROP SCHEMA
```
  - Drop user **jack**.

```
gaussdb=# DROP USER jack;
DROP ROLE
```

### 3.1.6.2 Creating and Managing Partitioned Tables

#### Context

GaussDB supports range partitioned tables, list partitioned tables, and hash partitioned tables.

- Range partitioned table: Data within a certain range is mapped to each partition. The range is determined by the partition key specified when the partitioned table is created. This partitioning mode is most commonly used. The partition key is usually a date. For example, sales data is partitioned by month.
- List partitioned table: Key values contained in the data are stored in different partitions, and the data is mapped to each partition in sequence. The key values contained in the partitions are specified when the partitioned table is created.
- Hash partitioned table: Data is mapped to each partition based on the internal hash algorithm. The number of partitions is specified when the partitioned table is created.

A partitioned table has the following advantages over an ordinary table:

- High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
- High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.

- Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.
- Balanced I/O: Partitions can be mapped to different disks to balance I/O and improve the overall system performance.

To convert an ordinary table to a partitioned table, you need to create a partitioned table and import data to it from the ordinary table. When you design tables, plan whether to use partitioned tables based on service requirements.

## Procedure

Example 1: Use the default tablespace.

- Create a partitioned table (assuming that the **tpcds** schema has been created).

```
gaussdb=# CREATE TABLE tpcds.customer_address
(
  ca_address_sk integer NOT NULL ,
  ca_address_id character(16) NOT NULL ,
  ca_street_number character(10) ,
  ca_street_name character varying(60) ,
  ca_street_type character(15) ,
  ca_suite_number character(10) ,
  ca_city character varying(60) ,
  ca_county character varying(30) ,
  ca_state character(2) ,
  ca_zip character(10) ,
  ca_country character varying(20) ,
  ca_gmt_offset numeric(5,2) ,
  ca_location_type character(20)
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
  PARTITION P1 VALUES LESS THAN(5000),
  PARTITION P2 VALUES LESS THAN(10000),
  PARTITION P3 VALUES LESS THAN(15000),
  PARTITION P4 VALUES LESS THAN(20000),
  PARTITION P5 VALUES LESS THAN(25000),
  PARTITION P6 VALUES LESS THAN(30000),
  PARTITION P7 VALUES LESS THAN(40000),
  PARTITION P8 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Insert data.

Insert data from the **tpcds.customer\_address** table to the **tpcds.web\_returns\_p2** table.

Suppose that the backup table **tpcds.web\_returns\_p2** of the **tpcds.customer\_address** table has been created in the database. You can insert the data of the **tpcds.customer\_address** table into the backup table **tpcds.web\_returns\_p2**.

```
gaussdb=# CREATE TABLE tpcds.web_returns_p2
(
  ca_address_sk integer NOT NULL ,
  ca_address_id character(16) NOT NULL ,
  ca_street_number character(10) ,
  ca_street_name character varying(60) ,
  ca_street_type character(15) ,
  ca_suite_number character(10) ,
  ca_city character varying(60) ,
```

```

ca_county    character varying(30)
ca_state     character(2)
ca_zip       character(10)
ca_country   character varying(20)
ca_gmt_offset numeric(5,2)
ca_location_type character(20)
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
PARTITION P1 VALUES LESS THAN(5000),
PARTITION P2 VALUES LESS THAN(10000),
PARTITION P3 VALUES LESS THAN(15000),
PARTITION P4 VALUES LESS THAN(20000),
PARTITION P5 VALUES LESS THAN(25000),
PARTITION P6 VALUES LESS THAN(30000),
PARTITION P7 VALUES LESS THAN(40000),
PARTITION P8 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;
CREATE TABLE
gaussdb=# INSERT INTO tpceds.web_returns_p2 SELECT * FROM tpceds.customer_address,
INSERT 0 0

```

- Modify the row movement attributes of the partitioned table.

```

gaussdb=# ALTER TABLE tpceds.web_returns_p2 DISABLE ROW MOVEMENT;
ALTER TABLE

```

- Delete a partition.

Delete partition **P8**.

```

gaussdb=# ALTER TABLE tpceds.web_returns_p2 DROP PARTITION P8;
ALTER TABLE

```

- Add a partition.

Add partition **P8** and set its range to [40000,MAXVALUE).

```

gaussdb=# ALTER TABLE tpceds.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN
(MAXVALUE);
ALTER TABLE

```

- Rename a partition.

– Rename partition **P8** to **P\_9**.

```

gaussdb=# ALTER TABLE tpceds.web_returns_p2 RENAME PARTITION P8 TO P_9;
ALTER TABLE

```

– Rename partition **P\_9** to **P8**.

```

gaussdb=# ALTER TABLE tpceds.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;
ALTER TABLE

```

- Query a partition.

Query partition **P6**.

```

gaussdb=# SELECT * FROM tpceds.web_returns_p2 PARTITION (P6);
gaussdb=# SELECT * FROM tpceds.web_returns_p2 PARTITION FOR (35888);

```

- Delete a partitioned table and its tablespaces.

```

gaussdb=# DROP TABLE tpceds.customer_address;
DROP TABLE
gaussdb=# DROP TABLE tpceds.web_returns_p2;
DROP TABLE

```

Example 2: Use a user-defined tablespace (assuming that the **tpceds** schema has been created).

Perform the following operations on a range partitioned table:

- Create a tablespace.

```

gaussdb=# CREATE TABLESPACE example1 RELATIVE LOCATION 'tablespace1/tablespace_1';
gaussdb=# CREATE TABLESPACE example2 RELATIVE LOCATION 'tablespace2/tablespace_2';
gaussdb=# CREATE TABLESPACE example3 RELATIVE LOCATION 'tablespace3/tablespace_3';
gaussdb=# CREATE TABLESPACE example4 RELATIVE LOCATION 'tablespace4/tablespace_4';

```

If the following information is displayed, the creation is successful:

```
CREATE TABLESPACE
```

- Create a partitioned table.

```
gaussdb=# CREATE TABLE tpcds.customer_address
(
  ca_address_sk integer NOT NULL ,
  ca_address_id character(16) NOT NULL ,
  ca_street_number character(10) ,
  ca_street_name character varying(60) ,
  ca_street_type character(15) ,
  ca_suite_number character(10) ,
  ca_city character varying(60) ,
  ca_county character varying(30) ,
  ca_state character(2) ,
  ca_zip character(10) ,
  ca_country character varying(20) ,
  ca_gmt_offset numeric(5,2) ,
  ca_location_type character(20)
)
TABLESPACE example1
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
  PARTITION P1 VALUES LESS THAN(5000),
  PARTITION P2 VALUES LESS THAN(10000),
  PARTITION P3 VALUES LESS THAN(15000),
  PARTITION P4 VALUES LESS THAN(20000),
  PARTITION P5 VALUES LESS THAN(25000),
  PARTITION P6 VALUES LESS THAN(30000),
  PARTITION P7 VALUES LESS THAN(40000),
  PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
)
ENABLE ROW MOVEMENT;
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Insert data.

Insert data from the **tpcds.customer\_address** table to the **tpcds.web\_returns\_p2** table.

Suppose that the backup table **tpcds.web\_returns\_p2** of the **tpcds.customer\_address** table has been created in the database. You can insert the data of the **tpcds.customer\_address** table into the backup table **tpcds.web\_returns\_p2**.

```
gaussdb=# CREATE TABLE tpcds.web_returns_p2
(
  ca_address_sk integer NOT NULL ,
  ca_address_id character(16) NOT NULL ,
  ca_street_number character(10) ,
  ca_street_name character varying(60) ,
  ca_street_type character(15) ,
  ca_suite_number character(10) ,
  ca_city character varying(60) ,
  ca_county character varying(30) ,
  ca_state character(2) ,
  ca_zip character(10) ,
  ca_country character varying(20) ,
  ca_gmt_offset numeric(5,2) ,
  ca_location_type character(20)
)
TABLESPACE example1
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
  PARTITION P1 VALUES LESS THAN(5000),
  PARTITION P2 VALUES LESS THAN(10000),
```

```

PARTITION P3 VALUES LESS THAN( 15000),
PARTITION P4 VALUES LESS THAN(20000),
PARTITION P5 VALUES LESS THAN(25000),
PARTITION P6 VALUES LESS THAN(30000),
PARTITION P7 VALUES LESS THAN(40000),
PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
)
ENABLE ROW MOVEMENT;
CREATE TABLE
gaussdb=# INSERT INTO tpcds.web_returns_p2 SELECT * FROM tpcds.customer_address;
INSERT 0 0

```

- Modify the row movement attributes of the partitioned table.

```

gaussdb=# ALTER TABLE tpcds.web_returns_p2 DISABLE ROW MOVEMENT;
ALTER TABLE

```

- Delete a partition.

Delete partition **P8**.

```

gaussdb=# ALTER TABLE tpcds.web_returns_p2 DROP PARTITION P8;
ALTER TABLE

```

- Add a partition.

Add partition **P8** and set its range to [40000,MAXVALUE).

```

gaussdb=# ALTER TABLE tpcds.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN
(MAXVALUE);
ALTER TABLE

```

- Rename a partition.

- Rename partition **P8** to **P\_9**.

```

gaussdb=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION P8 TO P_9;
ALTER TABLE

```

- Rename partition **P\_9** to **P8**.

```

gaussdb=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;
ALTER TABLE

```

- Change the tablespace of a partition.

- Change the tablespace of partition **P6** to **example3**.

```

gaussdb=# ALTER TABLE tpcds.web_returns_p2 MOVE PARTITION P6 TABLESPACE example3;
ALTER TABLE

```

- Change the tablespace of partition **P4** to **example4**:

```

gaussdb=# ALTER TABLE tpcds.web_returns_p2 MOVE PARTITION P4 TABLESPACE example4;
ALTER TABLE

```

- Query a partition.

Query partition **P6**.

```

gaussdb=# SELECT * FROM tpcds.web_returns_p2 PARTITION (P6);
gaussdb=# SELECT * FROM tpcds.web_returns_p2 PARTITION FOR (35888);

```

- Delete a partitioned table and its tablespaces.

```

gaussdb=# DROP TABLE tpcds.customer_address;
DROP TABLE
gaussdb=# DROP TABLE tpcds.web_returns_p2;
DROP TABLE
gaussdb=# DROP TABLESPACE example1;
gaussdb=# DROP TABLESPACE example2;
gaussdb=# DROP TABLESPACE example3;
gaussdb=# DROP TABLESPACE example4;
DROP TABLESPACE

```

### 3.1.6.3 Creating and Managing Indexes

#### Context

Indexes accelerate data access but increase the processing time of insertion, update, and deletion operations. Therefore, before creating an index, consider

whether it is necessary and select the columns where indexes are to be created. You can determine whether to create an index for a table by analyzing the service processing and data use of applications, as well as columns that are frequently used as search criteria or need to be collated.

Indexes are created based on columns in database tables. Therefore, you must correctly identify which columns require indexes. You are advised to create indexes for any of the following columns:

- Columns that are often searched and queried. This speeds up searches.
- Columns that function as primary keys. This enforces the uniqueness of the columns and the data collation structures in organized tables.
- Columns that are often joined. This increases the join efficiency.
- Columns that are often searched by range. The index helps collate data, and therefore the specified ranges are contiguous.
- Columns that often need to be collated. The index helps collate data, reducing the time for a collation query.
- Columns where the WHERE clause is executed frequently. This speeds up condition judgment.
- Columns that often appear after the keywords ORDER BY, GROUP BY, and DISTINCT.

 **NOTE**

- After an index is created, the system automatically determines when to reference it. If the system determines that indexing is faster than sequential scan, the index will be used.
- After an index is successfully created, it must be synchronized with the associated table to ensure new data can be accurately located, which increases the data operation load. Therefore, delete unnecessary indexes periodically.
- Partitioned table indexes are classified into local indexes and global indexes. A local index corresponds to a specific partition, and a global index corresponds to the entire partitioned table.
- When logical replication is enabled, if you need to create a primary key index that contains system columns, you must set the **REPLICA IDENTITY** attribute of the table to **FULL** or use **USING INDEX** to specify a unique, non-local, non-deferrable index that does not contain system columns and contains only columns marked **NOT NULL**.

## Procedure

To create a partitioned table, see [Creating and Managing Partitioned Tables](#).

- Create an index.
  - Create the partitioned table index **tpcds\_web\_returns\_p2\_index1** without specifying the partition name.

```
gaussdb=# CREATE INDEX tpcds_web_returns_p2_index1 ON tpcds.web_returns_p2 (ca_address_id) LOCAL;
```

If the following information is displayed, the creation is successful:

```
CREATE INDEX
```
  - Create the partitioned table index **tpcds\_web\_returns\_p2\_index2** with the partition name specified.

```
gaussdb=# CREATE INDEX tpcds_web_returns_p2_index2 ON tpcds.web_returns_p2
(ca_address_sk) LOCAL
(
PARTITION web_returns_p2_P1_index,
PARTITION web_returns_p2_P2_index TABLESPACE example3,
PARTITION web_returns_p2_P3_index TABLESPACE example4,
PARTITION web_returns_p2_P4_index,
PARTITION web_returns_p2_P5_index,
PARTITION web_returns_p2_P6_index,
PARTITION web_returns_p2_P7_index,
PARTITION web_returns_p2_P8_index
) TABLESPACE example2;
```

If the following information is displayed, the creation is successful:

```
CREATE INDEX
```

- Change the tablespace of an index partition.
  - Change the tablespace of index partition **web\_returns\_p2\_P2\_index** to **example1**.

```
gaussdb=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 MOVE PARTITION
web_returns_p2_P2_index TABLESPACE example1;
```

If the following information is displayed, the modification is successful:

```
ALTER INDEX
```

- Change the tablespace of index partition **web\_returns\_p2\_P3\_index** to **example2**.

```
gaussdb=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 MOVE PARTITION
web_returns_p2_P3_index TABLESPACE example2;
```

If the following information is displayed, the modification is successful:

```
ALTER INDEX
```

- Rename an index partition.

Rename the index partition **web\_returns\_p2\_P8\_index** to **web\_returns\_p2\_P8\_index\_new**.

```
gaussdb=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 RENAME PARTITION
web_returns_p2_P8_index TO web_returns_p2_P8_index_new;
```

If the following information is displayed, the rename operation is successful:

```
ALTER INDEX
```

- Query indexes.
  - Query all indexes defined by the system and users.

```
gaussdb=# SELECT RELNAME FROM PG_CLASS WHERE RELKIND='i';
```
  - Query information about a specified index.

```
gaussdb=# \di+ tpcds.tpcds_web_returns_p2_index2
```

- Delete indexes.

```
gaussdb=# DROP INDEX tpcds.tpcds_web_returns_p2_index1;
gaussdb=# DROP INDEX tpcds.tpcds_web_returns_p2_index2;
```

If the following information is displayed, the deletion is successful:

```
DROP INDEX
```

GaussDB supports four methods for creating indexes. For details, see [Table 3-3](#).

**Table 3-3** Indexing methods

Indexing Method	Description
Unique index	An index that requires the uniqueness of an index attribute or an attribute group. If a table declares unique constraints or primary keys, GaussDB automatically creates unique indexes (or composite indexes) for columns that form the primary keys or unique constraints. Currently, unique indexes can be created only for the B-tree and UB-tree in GaussDB.
Composite index	An index that can be defined for multiple attributes of a table. Currently, composite indexes can be created only for B-tree in GaussDB and up to 32 columns can share a composite index.
Partial index	An index that can be created for subsets of a table. This indexing method contains only tuples that meet condition expressions.
Expression index	An index that is built on a function or expression calculated based on one or more attributes of a table. An expression index works only when the queried expression is the same as the created expression.

- Create an ordinary table.

```
gaussdb=# CREATE TABLE tpcds.customer_address_bak AS TABLE tpcds.customer_address;
INSERT 0 0
```

- Create an ordinary index.

For the **tpcds.customer\_address\_bak** table, you need to perform the following operations frequently:

```
gaussdb=# SELECT ca_address_sk FROM tpcds.customer_address_bak WHERE ca_address_sk=14888;
```

Generally, the database system needs to scan the

**tpcds.customer\_address\_bak** table row by row to find all matched tuples. If the size of the **tpcds.customer\_address\_bak** table is large but only a few (possibly zero or one) of the WHERE conditions are met, the performance of this sequential scan is low. If the database system uses an index to maintain the **ca\_address\_sk** attribute, the database system only needs to search a few tree layers for the matched tuples. This greatly improves data query performance. Furthermore, indexes can improve the update and deletion operation performance in the database.

Create an index.

```
gaussdb=# CREATE INDEX index_wr_returned_date_sk ON tpcds.customer_address_bak
(ca_address_sk);
CREATE INDEX
```

- Create a unique index.

Create a unique index on the **SM\_SHIP\_MODE\_SK** column in the **tpcds.ship\_mode\_t1** table.

```
gaussdb=# CREATE UNIQUE INDEX ds_ship_mode_t1_index1 ON
tpcds.ship_mode_t1(SM_SHIP_MODE_SK);
```

- Create a composite index.

Assume that you need to frequently query records with **ca\_address\_sk** being **5050** and **ca\_street\_number** smaller than **1000** in the

**tpcds.customer\_address\_bak** table. Run the following commands:

```
gaussdb=# SELECT ca_address_sk,ca_address_id FROM tpcds.customer_address_bak WHERE  
ca_address_sk = 5050 AND ca_street_number < 1000;
```

Define a composite index on the **ca\_address\_sk** and **ca\_street\_number** columns.

```
gaussdb=# CREATE INDEX more_column_index ON  
tpcds.customer_address_bak(ca_address_sk ,ca_street_number);  
CREATE INDEX
```

- Create a partial index.

If you only want to find records with **ca\_address\_sk** being **5050**, you can create a partial index to facilitate your query.

```
gaussdb=# CREATE INDEX part_index ON tpcds.customer_address_bak(ca_address_sk) WHERE  
ca_address_sk = 5050;  
CREATE INDEX
```

- Create an expression index.

Assume that you need to frequently query records with **ca\_street\_number** smaller than **1000**. Run the following command:

```
gaussdb=# SELECT * FROM tpcds.customer_address_bak WHERE trunc(ca_street_number) < 1000;
```

The following expression index can be created for this query task:

```
gaussdb=# CREATE INDEX para_index ON tpcds.customer_address_bak (trunc(ca_street_number));  
CREATE INDEX
```

- Delete the **tpcds.customer\_address\_bak** table.

```
gaussdb=# DROP TABLE tpcds.customer_address_bak;  
DROP TABLE
```

### 3.1.6.4 Creating and Managing Views

#### Context

If some columns in one or more tables in a database are frequently searched for, an administrator can define a view for these columns, and then users can directly access these columns in the view without entering search criteria.

A view is different from a base table. It is only a virtual object rather than a physical one. Only view definition is stored in the database and view data is not. The data is stored in a base table. If data in the base table changes, the data in the view changes accordingly. In this sense, a view is like a window through which users can know their interested data and data changes in the database. A view is triggered every time it is referenced.

#### Managing Views

- Creating a view

Create the **MyView** view. In the command, **tpcds.web\_returns** indicates the created user table that contains the **wr\_refunded\_cash** integer column.

```
gaussdb=# CREATE OR REPLACE VIEW MyView AS SELECT * FROM tpcds.web_returns WHERE  
trunc(wr_refunded_cash) > 10000;  
CREATE VIEW
```

#### NOTE

The **OR REPLACE** parameter in this command is optional. It indicates that if the view exists, the new view will replace the existing view.

- Query a view.  
Query **MyView**.  
gaussdb=# `SELECT * FROM MyView;`
- Querying views of the current user  
gaussdb=# `SELECT * FROM my_views;`
- Querying all views  
gaussdb=# `SELECT * FROM adm_views;`
- Viewing details about a specified view

View details about **MyView**.

```
gaussdb=# \d+ MyView
View "PG_CATALOG.MyView"
Column | Type | Modifiers | Storage | Description
-----+-----+-----+-----+-----
USERNAME | CHARACTER VARYING(64) | | extended |
View definition:
SELECT PG_AUTHID.ROLNAME::CHARACTER VARYING(64) AS USERNAME
FROM PG_AUTHID;
```

- Deleting a view  
Delete **MyView**.  
gaussdb=# `DROP VIEW MyView;`  
DROP VIEW

### 3.1.6.5 Creating and Managing Sequences

#### Context

A sequence is a database object that generates unique integers. Sequence numbers are generated according to a certain rule. Sequences are unique because they increase automatically. This is why they are often used as primary keys.

You can create a sequence for a column in either of the following methods:

- Set the data type of a column to **sequence integer**. A sequence will be automatically created by the database for this column.
- Use the **CREATE SEQUENCE** statement to create a sequence. Set the initial value of the `nextval('sequence_name')` function to the default value of a column.

#### Procedure

Method 1: Set the data type of a column to a sequence integer. For example:

```
gaussdb=# CREATE TABLE T1
(
  id serial,
  name text
);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

Method 2: Create a sequence and set the initial value of the `nextval('sequence_name')` function to the default value of a column. You can cache a specific number of sequence values to reduce the requests to the GTM, improving the performance.

1. Create a sequence.

```
gaussdb=# CREATE SEQUENCE seq1 cache 100;
```

If the following information is displayed, the creation is successful:

```
CREATE SEQUENCE
```

2. Set the default value of a column so that the column has a unique identification attribute.

```
gaussdb=# CREATE TABLE T2
(
  id int not null default nextval('seq1'),
  name text
);
```

If the following information is displayed, the default value has been specified:

```
CREATE TABLE
```

3. Associate a sequence with a column.

Associate a sequence with a specified column included in a table. In this way, the sequence will be deleted when you delete its associated column or the table where the column belongs to.

```
gaussdb=# ALTER SEQUENCE seq1 OWNED BY T2.id;
```

If the following information is displayed, the operation is successful:

```
ALTER SEQUENCE
```

#### NOTE

The preceding methods are similar, except that the second method specifies cache for the sequence. A sequence having cache defined has inconsecutive values (such as 1, 4, and 5) and cannot maintain the order of its values. After the dependent column of a sequence has been specified, once the sequence is deleted, the sequence of the dependent will be deleted. A sequence shared by multiple columns is not forbidden in a database, but you are advised not to do that.

In the current version, you can specify the auto-increment column or set the default value of a column to **nextval('seqname')** when defining a table. You cannot add an auto-increment column or a column whose default value is **nextval('seqname')** to an existing table.

## Precautions

Sequence values are generated by the GTM. By default, each request for a sequence value is sent to the GTM. The GTM calculates the result of the current value plus the step and then returns the result. The GTM is a globally unique node and is the performance bottleneck. Therefore, you are advised not to generate sequence values frequently and numerously, such as to use BulkLoad to import data. For example, the INSERT INTO SELECT FROM statement has poor performance in the following scenario:

```
gaussdb=# CREATE SEQUENCE newSeq1;
gaussdb=# CREATE TABLE newT1
(
  id int not null default nextval('newSeq1'),
  name text
);
gaussdb=# INSERT INTO newT1(name) SELECT name FROM T1;
```

Assume that data imported from table **T1** to table **newT1** has 10,000 rows. The following statements achieve better performance:

```
gaussdb=# INSERT INTO newT1(id, name) SELECT id,name FROM T1;
gaussdb=# SELECT SETVAL('newSeq1',10000);
```

 NOTE

Rollback is not supported by sequence functions, including `nextval()` and `setval()`. The value of the `setval` function immediately takes effect on `nextval` in the current session in any cases and take effect in other sessions only when no cache is specified for them. If cache is specified for a session, it takes effect only after all the cached values have been used. To avoid duplicate values, use `setval` only when necessary. Do not set it to an existing sequence value or a cached sequence value.

To generate the default sequence value using BulkLoad, set sufficient cache for **newSeq1** and do not set **Maxvalue** or **Minvalue**. The database will push down the calling of `nextval('sequence_name')` to DNs to improve performance. Currently, the concurrent connection requests that can be processed by the GTM are limited. If there are too many DNs, a large number of concurrent connection requests will be sent to the GTM. In this case, you need to limit the bulk loading concurrency, so that DNs do not fully occupy GTM connections. If the target table is a replication table (DISTRIBUTE BY REPLICATION), pushdown cannot be performed. When the data volume is large, the performance is affected and the space may bloat sharply. After the import is complete, you need to run the **vacuum full** command to restore the data. The best way is not to use BulkLoad to generate the default sequence value.

After a sequence is created, one single-row table is maintained on each node to store the sequence definition and value, which is obtained from the last interaction with the GTM rather than updated in real time. The single-row table on a node does not update when other nodes request a new value from the GTM or when the sequence is modified using `setval`.

### 3.1.6.6 Creating and Managing Scheduled Jobs

#### Context

Time-consuming jobs, such as summarizing statistics or synchronizing data from another database, affect service performance if they are performed during the daytime and incur overtime hours if performed at night. To solve this problem, the GaussDB Kernel database is compatible with the scheduled job function in the ORA database. You can create scheduled jobs that are automatically triggered to reduce O&M workload.

This function calls APIs provided by the **DBE\_SCHEDULER** and **DBE\_TASK** packages to create scheduled jobs, execute jobs automatically, delete jobs, and modify job attributes (including job ID, the enabled/disabled status of a job, job triggering time, triggering interval, and job content). The **DBE\_SCHEDULER** API is recommended to ensure high availability and reliability and support more flexible job scheduling. For details about the API description and migration guide examples, see [DBE\\_SCHEDULER](#).

#### Managing Scheduled Jobs

**Step 1** Create a test table.

```
gaussdb=# CREATE TABLE test(id int, time date);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

**Step 2** Create a user-defined stored procedure.

```
gaussdb=# CREATE OR REPLACE PROCEDURE PRC_JOB_1()
AS
N_NUM integer :=1;
BEGIN
FOR I IN 1..1000 LOOP
INSERT INTO test VALUES(I,SYSDATE);
END LOOP;
END;
/
```

If the following information is displayed, the creation is successful:

```
CREATE PROCEDURE
```

**Step 3** Create a job.

- Create a job with unspecified **job\_id** and execute the **PRC\_JOB\_1** stored procedure every minute.

```
gaussdb=# call db_task.submit('call public.prc_job_1(); ', sysdate, 'interval "1 minute"', :a);
id
-----
1
(1 row)
```

- Specify **job\_id** to create a job. The value of **job\_id** ranges from 1 to 32767.

```
gaussdb=# call db_task.id_submit(1,'call public.prc_job_1(); ', sysdate, 'interval "1 minute"');
id_submit
-----
1
(1 row)
```

**Step 4** View details of jobs created by the current user.

```
gaussdb=# select job,dbname,start_date,last_date,this_date,next_date,broken,status,interval,failures,what
from my_jobs;
job | dbname | start_date | last_date | this_date | next_date | broken | status | interval | failures | what
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
1 | testdb | 2017-07-18 11:38:03 | 2017-07-18 13:53:03.607838 | 2017-07-18 13:53:03.607838 | 2017-07-18 13:54:03 | n | s | interval '1 minute' | 0 | call public.prc_job_1();
(1 row)
```

**Step 5** Stop a job.

```
gaussdb=# call db_task.finish(1,true);
finish
-----
1
(1 row)
```

**Step 6** Start a job.

```
gaussdb=# call db_task.finish(1,false);
finish
-----
1
(1 row)
```

**Step 7** Modify job attributes.

- Modify the **Next\_date** parameter information about a job.

```
-- Set Next_date of Job1 to 1 hour so that Job1 will be executed in one hour.
gaussdb=# call db_task.next_date(1, sysdate+1.0/24);
next_date
-----
1
(1 row)
```

- Modify the **Interval** parameter of a job.

```
-- Set Interval of Job1 to 1 hour so that Job1 will be executed every one hour.  
gaussdb=# call dbe_task.interval(1,'sysdate + 1.0/24');  
interval  
-----
```

```
(1 row)
```

- Modify the **What** parameter of a job.

```
-- Set What to the SQL statement insert into public.test values(333, sysdate+5); for Job1.  
gaussdb=# call dbe_task.content(1,'insert into public.test values(333, sysdate+5);');  
content  
-----
```

```
(1 row)
```

- Modify **Next\_date**, **Interval**, and **What** parameters of a job.

```
gaussdb=# call dbe_task.update(1, 'call public.prc_job_1();', sysdate, 'interval "1 minute");  
update  
-----
```

```
(1 row)
```

### Step 8 Delete a job.

```
gaussdb=# call dbe_task.cancel(1);  
cancel  
-----
```

```
(1 row)
```

### Step 9 View the job execution status.

If a job fails to be automatically executed (that is, the value of **job\_status** is 'f'), contact the administrator to view the **gs\_log** run log to view the failure information of the job.

From **detail error msg**, you can see the failure causes.

```
LOG: Execute Job Detail:  
job_id: 1  
what: call public.test();  
start_date: 2017-07-19 23:30:47.401818  
job_status: failed  
detail error msg: relation "test" does not exist  
end_date: 2017-07-19 23:30:47.401818  
next_run_date: 2017-07-19 23:30:56.855827
```

### Step 10 Set job permissions.

- During the creation of a job, the job is bound to the user and database that created the job. Accordingly, the user and database are added to **dbname** and **log\_user** columns in the **pg\_job** system catalog, respectively.
- If the current user is a database administrator, system administrator, or the user (**log\_user** of **pg\_job**) who created the job, the user has permissions to delete or modify job parameters using the **remove**, **change**, **next\_data**, **what**, or **interval** parameter. Otherwise, the system displays a message indicating that the user has no permissions to perform operations on this job.
- If the current database is the one that created a job (that is, **dbname** in **pg\_job**), you can delete or modify parameter settings of the job using the **cancel**, **update**, **next\_data**, **content**, or **interval** parameter.
- When deleting the database that created a job (that is, **dbname** in **pg\_job**), the system automatically deletes the job records of the database.
- When deleting the user who created a job (that is, **log\_user** in **pg\_job**), the system automatically deletes the job records of the user.

**Step 11** Manage job concurrency.

You can configure the GUC parameter **job\_queue\_processes** to adjust the number of jobs running at the same time.

- Setting **job\_queue\_processes** to **0** indicates that the scheduled job function is disabled and all jobs will not be executed.
- Setting **job\_queue\_processes** to a value that is greater than **0** indicates that the scheduled job function is enabled and this value is the maximum number of jobs that can be concurrently processed.

Too many concurrent jobs consume many system resources, so you need to set the number of concurrent jobs to be processed. If the current number of concurrent jobs reaches the value of **job\_queue\_processes** and some of them expire, these jobs will be postponed to the next polling period. Therefore, you are advised to set the polling interval (the **Interval** parameter of the submit API) based on the execution duration of each job to avoid the problem that jobs in the next polling period cannot be properly processed because of overlong job execution time.

Note: For clusters that do not use jobs, set **job\_queue\_processes** to **0** to disable job functions to reduce the resource consumption.

----End

# 4 Development and Design Proposal

---

## 4.1 Overview

This section describes the design specifications for database modeling and application development. Modeling based on these specifications fits the distributed processing architecture of GaussDB and outputs efficient SQL code.

The meaning of "Proposal" and "Notice" in this section is as follows:

- **Proposal:** Design rules. Services compliant with the rules can run efficiently, and those violating the rules may have low performance or logic errors.
- **Notice:** Details requiring attention during service development. This term identifies SQL behavior that complies with SQL standards but users may have misconceptions about, and default behavior that users may be unaware of in a program.

## 4.2 Database Object Naming Conventions

Database object names must meet the following requirements:

- The name length of a table or an identifier cannot exceed 63 bytes. If you need to copy a table with a global secondary index (GSI) or import GDS data to the table, the length of the table name cannot exceed 38 bytes.
- An identifier starts with a letter or underscore (\_) and can contain letters, digits, underscores (\_), dollar signs (\$), and number signs (#).
- If an identifier is enclosed in backquotes (`) in MySQL-compatible mode or double quotation marks (""), any combination of valid characters can be used, for example, "123gs\_column".
- Identifiers are case-insensitive. They are case-sensitive only when they are enclosed in backquotes (`) in MySQL-compatible mode or double quotation marks ("").
- The gsql shortcut commands (except \sf) cannot be used to query the object names enclosed in backquotes.
- Do not use reserved or non-reserved keywords to name database objects.

 NOTE

To query the GaussDB keywords, run `select * from pg_get_keywords()` or refer to [Keywords](#).

- Do not use a string enclosed in double quotation marks (") to define the database object name, unless you need to specify its capitalization. Case sensitivity of database object names makes problem location difficult.
- Use the same naming format for database objects.
  - In a system undergoing incremental development or service migration, you are advised to comply with its historical naming conventions.
  - You are advised to use multiple words separated with underscores (\_).
  - You are advised to use intelligible names and common acronyms or abbreviations for database objects. Acronyms or abbreviations that are generally understood are recommended. For example, you can use English words or Chinese pinyin indicating actual business terms. The naming format should be consistent within a cluster.
  - A variable name must be descriptive and meaningful. It must have a prefix indicating its type.
- The name of a table object should indicate its main characteristics, for example, whether it is an ordinary, temporary, or unlogged table.
  - An ordinary table name should indicate the business relevant to a dataset.
  - Temporary tables are named in the format of **tmp\_Suffix**.
  - Unlogged tables are named in the format of **ul\_Suffix**.
  - Foreign tables are named in the format of **f\_Suffix**.
  - Do not create database objects whose names start with **redis\_**.
  - Do not create database objects named **pgxc\_redistb**.
  - Do not create database objects whose names start with **mlog\_** or **matviewmap\_**.
  - Do not create database objects whose names start with **gs\_role\_**.
- The name of a table object shall not exceed 63 bytes. If the length of a table name exceeds this value, the kernel truncates the table name. As a result, the actual name is inconsistent with the configured value. In addition, characters may be truncated in different character sets and unexpected characters may appear.
- If you need to copy a table with a global secondary index (GSI) or import GDS data to the table, the length of the table name cannot exceed 38 bytes. If the length exceeds the maximum, the temporary table name created during COPY or GDS import may be truncated. As a result, the data import process is interrupted and unexpected characters are generated.

## 4.3 Database Object Design

### 4.3.1 Database and Schema Design

In GaussDB, services can be isolated by databases and schemas. Databases share little resources and cannot directly access each other. Connections to and

permissions on them are also isolated. Schemas share more resources than databases do. User permissions on schemas and subordinate objects can be controlled using the GRANT and REVOKE syntax.

- You are advised to use schemas to isolate services for convenience and resource sharing.
- It is recommended that system administrators create schemas and databases and then assign required permissions to users.

## Database Design

- Create databases as required by your business. Do not use the default **postgres** database of a cluster.
- In a cluster, the recommended number of user-defined databases is 3. It is recommended that the number of user-defined databases be less than or equal to 10. If there are too many user-defined databases, O&M operations, such as upgrade and backup, will be inefficient.
- To make your database compatible with most characters, you are advised to use the UTF-8 encoding when creating a database.
- When you create a database, exercise caution when you set **ENCODING** and **DBCMPATIBILITY** configuration items. GaussDB supports the TD-, ORA-, MySQL-, and PG-compatible modes which are compatible with the Teradata syntax, Oracle syntax, MySQL syntax, and PostgreSQL syntax, respectively. The syntax behavior varies according to the compatibility mode. By default, the MySQL-compatible mode is used.
- By default, a database owner has all permissions for all objects in the database, including the deletion permission. Exercise caution when deleting a permission.

## Schema Design

- It is recommended that the number of schemas in the actual user environment be no more than 100. If there are too many schemas in a database, operations that depend on the number of schemas, such as `gs_dump`, becomes slow.
- To let a user access an object in a schema, assign the usage permission and the permissions for the object to the user, unless the user has the `sysadmin` permission or is the schema owner.
- To let a user create an object in the schema, grant the CREATE permission for the schema to the user.
- By default, a schema owner has all permissions for all objects in the schema, including the deletion permission. Exercise caution when deleting a permission.

### 4.3.2 Table Design

GaussDB uses a distributed architecture. Data is distributed on DNs. Generally, well-designed table must comply with the following rules:

- Evenly distribute data on each DN to prevent data skew. If most data is stored on several DNs, the effective capacity of a cluster decreases. Select a proper distribution key to avoid data skew.

- Evenly scan each DN when querying tables. Otherwise, DNs most frequently scanned will become the performance bottleneck. For example, when you use equivalent filter conditions on a fact table, the nodes are not evenly scanned.
- Reduce the amount of data to be scanned. You can use the pruning mechanism of a partitioned table.
- Minimize random I/Os. Through clustering, you can sequentially store hot data, converting random I/O to sequential I/O to reduce the cost of I/O scanning.
- Avoid data shuffle. To shuffle data is to physically transfer it from one node to another. This unnecessarily occupies many network resources. To reduce network pressure, locally process data, and to improve cluster performance and concurrency, you can minimize data shuffling by using proper association and grouping conditions.

## Selecting a Distribution Mode

**Table 2 Table distribution modes and scenarios** shows how to select a table distribution mode.

**Table 4-1** Table distribution modes and scenarios

Distribution Mode	Description	Application Scenario
Hash	Table data is distributed on all DNs in a cluster by hash.	Fact tables containing a large amount of data
Replication	Full data in a table is stored on every DN in the cluster.	Dimension tables and fact tables containing a small amount of data
Range	Table data is mapped to specified columns based on the range and distributed to the corresponding DNs.	Users need to customize distribution rules.
List	Table data is mapped to specified columns based on specific values and distributed to corresponding DNs.	Users need to customize distribution rules.

The example of defining a distributed table is as follows:

```
-- Define a table with each row stored in all DNs.
CREATE TABLE warehouse_d1
(
  W_WAREHOUSE_SK      INTEGER      NOT NULL,
  W_WAREHOUSE_ID      CHAR(16)      NOT NULL,
  W_WAREHOUSE_NAME    VARCHAR(20)
  W_WAREHOUSE_SQ_FT   INTEGER
  W_STREET_NUMBER     CHAR(10)
  W_STREET_NAME       VARCHAR(60)
  W_STREET_TYPE       CHAR(15)
  W_SUITE_NUMBER      CHAR(10)
```

```
W_CITY          VARCHAR(60)
W_COUNTY        VARCHAR(30)
W_STATE         CHAR(2)
W_ZIP           CHAR(10)
W_COUNTRY       VARCHAR(20)
W_GMT_OFFSET    DECIMAL(5,2)
)DISTRIBUTE BY REPLICATION;

-- Define a hash table.
CREATE TABLE warehouse_d2
(
  W_WAREHOUSE_SK      INTEGER          NOT NULL,
  W_WAREHOUSE_ID      CHAR(16)         NOT NULL,
  W_WAREHOUSE_NAME    VARCHAR(20)
  W_WAREHOUSE_SQ_FT   INTEGER
  W_STREET_NUMBER     CHAR(10)
  W_STREET_NAME       VARCHAR(60)
  W_STREET_TYPE       CHAR(15)
  W_SUITE_NUMBER      CHAR(10)
  W_CITY              VARCHAR(60)
  W_COUNTY            VARCHAR(30)
  W_STATE             CHAR(2)
  W_ZIP               CHAR(10)
  W_COUNTRY           VARCHAR(20)
  W_GMT_OFFSET        DECIMAL(5,2),
  CONSTRAINT W_CONSTR_KEY3 UNIQUE(W_WAREHOUSE_SK)
)DISTRIBUTE BY HASH(W_WAREHOUSE_SK);

-- Define a table using RANGE distribution.
CREATE TABLE warehouse_d3
(
  W_WAREHOUSE_SK      INTEGER          NOT NULL,
  W_WAREHOUSE_ID      CHAR(16)         NOT NULL,
  W_WAREHOUSE_NAME    VARCHAR(20)
  W_WAREHOUSE_SQ_FT   INTEGER
  W_STREET_NUMBER     CHAR(10)
  W_STREET_NAME       VARCHAR(60)
  W_STREET_TYPE       CHAR(15)
  W_SUITE_NUMBER      CHAR(10)
  W_CITY              VARCHAR(60)
  W_COUNTY            VARCHAR(30)
  W_STATE             CHAR(2)
  W_ZIP               CHAR(10)
  W_COUNTRY           VARCHAR(20)
  W_GMT_OFFSET        DECIMAL(5,2)
)DISTRIBUTE BY RANGE(W_WAREHOUSE_ID)
(
  SLICE s1 VALUES LESS THAN (10) DATANODE dn1,
  SLICE s2 VALUES LESS THAN (20) DATANODE dn2,
  SLICE s3 VALUES LESS THAN (30) DATANODE dn3,
  SLICE s4 VALUES LESS THAN (MAXVALUE) DATANODE dn4
);

-- Define a table using LIST distribution.
CREATE TABLE warehouse_d4
(
  W_WAREHOUSE_SK      INTEGER          NOT NULL,
  W_WAREHOUSE_ID      CHAR(16)         NOT NULL,
  W_WAREHOUSE_NAME    VARCHAR(20)
  W_WAREHOUSE_SQ_FT   INTEGER
  W_STREET_NUMBER     CHAR(10)
  W_STREET_NAME       VARCHAR(60)
  W_STREET_TYPE       CHAR(15)
  W_SUITE_NUMBER      CHAR(10)
  W_CITY              VARCHAR(60)
  W_COUNTY            VARCHAR(30)
  W_STATE             CHAR(2)
  W_ZIP               CHAR(10)
  W_COUNTRY           VARCHAR(20)
```

```
W_GMT_OFFSET      DECIMAL(5,2)
)DISTRIBUTE BY LIST(W_COUNTRY)
(
  SLICE s1 VALUES ('USA') DATANODE dn1,
  SLICE s2 VALUES ('CANADA') DATANODE dn2,
  SLICE s3 VALUES ('UK') DATANODE dn3,
  SLICE s4 VALUES (DEFAULT) DATANODE dn4
);
```

For details about the table distribution syntax, see [CREATE TABLE](#).

## Selecting a Distribution Key

A distribution key is important for a distributed table. An improper distribution key may cause data skew. As a result, the I/O load is heavy on several DNs, affecting the overall query performance. Therefore, after determining the distribution policy of a distributed table, you need to check the table data skew to ensure that data is evenly distributed. Comply with the following rules to select a distribution key:

- Select a column containing discrete data as the distribution key, so that data can be evenly distributed on each DN. If the data in a single column is not discrete enough, consider using multiple columns as distribution keys. You can select the primary key of a table as the distribution key. For example, in an employee information table, select the certificate number column as the distribution key.
- If the first rule is met, do not select a column having constant filter conditions as the distribution key. For example, in a query on the **dwcjck** table, if the **zqdh** column contains the constant filter condition **zqdh='000001'**, avoid selecting the **zqdh** column as the distribution key.
- If the first and second rules are met, select the join conditions in a query as distribution keys. If a join condition is used as a distribution key, the data involved in a join task is locally distributed on DNs, which greatly reduces the data flow cost among DNs.

## Selecting a Partitioning Mode

Comply with the following rules to partition a table containing a large amount of data:

- Create partitions on columns that indicate certain ranges, such as dates and regions.
- A partition name should show the data characteristics of a partition. For example, its format can be *Keyword+Range* characteristics.
- Set the upper limit of a partition to **MAXVALUE** to prevent data overflow.

**Table 4-2** Table partitioning modes and scenarios

Partitioning Mode	Description
Range	Table data is partitioned by range.
List	Table data is partitioned by a specified column based on a specific value.
Hash	Table data is partitioned by hash.

The example of defining a partitioned table is as follows:

```
-- Create a range partitioned table.
CREATE TABLE staffS_p1
(
  staff_ID      NUMBER(6) not null,
  FIRST_NAME   VARCHAR2(20),
  LAST_NAME    VARCHAR2(25),
  EMAIL        VARCHAR2(25),
  PHONE_NUMBER VARCHAR2(20),
  HIRE_DATE     DATE,
  employment_ID VARCHAR2(10),
  SALARY        NUMBER(8,2),
  COMMISSION_PCT NUMBER(4,2),
  MANAGER_ID    NUMBER(6),
  section_ID    NUMBER(4)
)
PARTITION BY RANGE (HIRE_DATE)
(
  PARTITION HIRE_19950501 VALUES LESS THAN ('1995-05-01 00:00:00'),
  PARTITION HIRE_19950502 VALUES LESS THAN ('1995-05-02 00:00:00'),
  PARTITION HIRE_maxvalue VALUES LESS THAN (MAXVALUE)
);

-- Create a list partitioned table.
CREATE TABLE test_list (col1 int, col2 int)
partition by list(col1)
(
  partition p1 values (2000),
  partition p2 values (3000),
  partition p3 values (4000),
  partition p4 values (5000)
);

-- Create a hash partitioned table.
CREATE TABLE test_hash (col1 int, col2 int)
partition by hash(col1)
(
  partition p1,
  partition p2
);
```

For details about the table partition syntax, see [CREATE TABLE PARTITION](#).

## 4.3.3 Column Design

### Selecting a Data Type

To improve query efficiency, comply with the following rules when designing columns:

- Use the most efficient data types allowed.  
If all of the following number types provide the required service precision, they are recommended in descending order of priority: integer, floating point, and numeric.
- In tables that are logically related, columns having the same meaning should use the same data type.
- For string data, you are advised to use variable-length strings and specify the maximum length. Ensure that the specified maximum length is greater than the maximum number of characters to be stored. Otherwise, an error is reported, causing service interruption. You are advised not to use CHAR(n),

BPCHAR(n), NCHAR(n), or CHARACTER(n), unless you know that the string length is fixed.

For details about string types, see [Common String Types](#).

## Common String Types

Every column requires a data type suitable for its data characteristics. [Character Types](#) lists common string types in GaussDB.

### 4.3.4 Constraint Design

#### DEFAULT and NULL Constraints

- If all the column values can be obtained from services, you are advised not to use the DEFAULT constraint. Otherwise, unexpected results will be generated during data loading.
- Add NOT NULL constraints to columns that never have NULL values. The optimizer automatically optimizes the columns in certain scenarios.
- Explicitly name all constraints excluding **NOT NULL** and **DEFAULT**.

#### Unique Constraints

- The constraint name should indicate that it is a unique constraint, for example, *UNIColumn name*.

#### Primary Key Constraints

- The constraint name should indicate that it is a primary key constraint, for example, *PKColumn name*.

#### Check Constraints

- The constraint name should indicate that it is a check constraint, for example, *CKColumn name*.

### 4.3.5 View and Joined Table Design

#### View Design

- Do not nest views unless they have strong dependency on each other.
- Try to avoid collation operations in a view definition.

#### Joined Table Design

- Minimize joined columns across tables.
- Use the same data type for joined columns.
- The names of joined columns should indicate their relationship. For example, they can use the same name.

## 4.4 Tool Interconnection

## 4.4.1 JDBC Configuration

Currently, third-party tools are connected to GaussDB through JDBC. This section describes the precautions for configuring the tool.

### Connection Parameters

- When a third-party tool connects to GaussDB through JDBC, JDBC sends a connection request to GaussDB. By default, the following configuration parameters are added. For details, see the implementation of the `ConnectionFactoryImpl` class in the JDBC code.

```
params = {  
    { "user", user },  
    { "database", database },  
    { "client_encoding", "UTF8" },  
    { "DateStyle", "ISO" },  
    { "extra_float_digits", "3" },  
    { "TimeZone", createPostgresTimeZone() },  
};
```

These parameters may cause the JDBC and `gsqL` clients to display inconsistent data, for example, date data display mode, floating point precision representation, and timezone.

If the result is not as expected, you are advised to explicitly set these parameters in the Java connection setting.

When the database is connected through JDBC, **extra\_float\_digits** is set to **3**. When the database is connected using `gsqL`, **extra\_float\_digits** is set to **0**. As a result, the precision of the same data displayed in JDBC clients may be different from that displayed in `gsqL` clients.

- In precision-sensitive scenarios, the numeric type is recommended.
- When JDBC connects to the database, ensure that the following three time zones are the same:
  - Time zone of the host where the JDBC client is located
  - Time zone of the host where the GaussDB cluster is located
  - Time zone during GaussDB cluster configuration

#### NOTE

For details about how to set the time zone, contact the administrator.

### fetchsize

To use **fetchsize** in applications, disable **autocommit**. Enabling the **autocommit** switch makes the **fetchsize** configuration invalid.

### autocommit

You are advised to enable **autocommit** in the code for connecting to GaussDB by the JDBC. If **autocommit** needs to be disabled to improve performance or for other purposes, applications need to ensure that transactions are committed. For example, explicitly commit transactions after specifying service SQL statements. Particularly, ensure that all transactions are committed before the client exits.

## Connection Releasing

- You are advised to use connection pools to limit the number of connections from applications. You are advised not to connect to a database each time an SQL statement is executed.
- After an application completes its jobs, disconnect it from GaussDB to release occupied resources. You are advised to set the session timeout interval in the jobs.
- Reset the session environment before releasing connections to the JDBC connection pool. Otherwise, historical session information may cause object conflicts.
  - If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
  - If a temporary table is used, delete the temporary table before you return the connection to the connection pool.

## CopyManager

In the scenario where the ETL tool is not used and real-time data import is required, it is recommended that you use the CopyManager API driven by the GaussDB JDBC to import data in batches during application development.

## 4.5 SQL Compilation

### DDL

- In GaussDB, you are advised to perform DDL operations (such as table creation and COMMENT) in a unified manner. Prevent DDL operations in batch processing jobs so that performance is not affected.
- Perform the TRUNCATE operation immediately after the unlogged table is used. GaussDB cannot ensure the security of unlogged tables in abnormal scenarios.
- Suggestions on the storage mode of temporary and unlogged tables are the same as those on base tables.
- The total length of an index column cannot exceed 50 bytes. Otherwise, the index size will increase greatly, resulting in large storage cost and low index performance.
- Do not delete objects using DROP..CASCADE, unless the dependency between objects is specified. Otherwise, the objects may be deleted by mistake.

### Data Loading and Unloading

- Explicitly set the inserted column list in the INSERT statement. Example:  
`INSERT INTO task(name,id,comment) VALUES ('task1','100','100th task');`
- After data is imported to the database in batches or the data increment reaches the threshold, you are advised to analyze tables to prevent the execution plan from being degraded due to inaccurate statistics.

- To clear all data in a table, you are advised to use TRUNCATE TABLE instead of DELETE TABLE. DELETE TABLE is not efficient and cannot release disk space occupied by the deleted data.

## Type Conversion

- Convert data types explicitly. If you perform implicit conversion, the result may differ from expected.
- During data query, explicitly specify the data type for constants, and do not attempt to perform any implicit data type conversion.
- If **sql\_compatibility** is set to **ORA**, null strings will be automatically converted to NULL during data import. If null strings need to be reserved, set **sql\_compatibility** to **TD**.

## Query Operation

- Do not return a large number of result sets to a client except the ETL program. If a large result set is returned, consider modifying your service design.
- Perform DDL and DML operations encapsulated in transactions. For example, operations such as TRUNCATE TABLE, UPDATE TABLE, DELETE TABLE, and DROP TABLE cannot be restored once they are committed. You are advised to encapsulate such operations in transactions so that you can roll back the operations if necessary.
- During query compilation, you are advised to list all columns to be queried and avoid using SELECT \*. Doing so reduces output columns, improves query performance, and avoids the impact of adding or deleting columns on front-end service compatibility.
- During table object access, add the schema prefix to the table object to avoid accessing an unexpected table due to schema switchover.
- The cost of joining more than three tables or views, especially full joins, is difficult to be estimated. You are advised to use the WITH TABLE AS statement to create interim tables to improve the readability of SQL statements.
- Avoid using Cartesian products or full joins. Cartesian products and full joins will result in a sharp expansion of result sets and poor performance.
- Only IS NULL and IS NOT NULL can be used to determine NULL value comparison results. If any other method is used, NULL is returned. For example, NULL instead of expected Boolean values is returned for NULL<>NULL, NULL=NULL, and NULL<>1.
- Do not use count(col) instead of count(\*) to count the total number of records in a table. count(\*) counts the NULL value (actual rows) while count(col) does not.
- While executing count(col), the number of NULL record rows is counted as 0. While executing sum(col), NULL is returned if all records are NULL. If not all the records are NULL, the number of NULL record rows is counted as 0.
- To count multiple columns using count(), column names must be enclosed in parentheses. For example, count ((col1, col2, col3)). Note: When multiple columns are used to count the number of NULL record rows, a row is counted even if all the selected columns are NULL. The result is the same as that when count(\*) is executed.

- NULL records are not counted when count(distinct col) is used to calculate the number of non-NULL columns that are not repeated.
- If all statistical columns are NULL when count(distinct (col1,col2,...)) is used to count the number of unique values in multiple columns, Null records are also counted, and the records are considered the same.
- Use the connection operator || to replace the concat function for string connection, because the output of the concat function depends on the data type of the strings to be connected. When the execution plan is generated, the value cannot be calculated in advance. As a result, the query performance deteriorates severely.
- Use the time-related macros listed in [Table 1](#) to replace the now function and obtain the current time, because the execution plan generated by the now function cannot be pushed down to disks. As a result, the query performance severely deteriorates.

**Table 4-3** Time-related macros

Macro Name	Description	Example
CURRENT_DATE	Obtains the current date, excluding the hour, minute, and second details.	gaussdb=# SELECT CURRENT_DATE; date ----- 2018-02-02 (1 row)
CURRENT_TIME	Obtains the current time, excluding the year, month, and day.	gaussdb=# SELECT CURRENT_TIME; timetz ----- 00:39:34.633938+08 (1 row)
CURRENT_TIMESTAMP( n)	Obtains the current date and time, including the year, month, day, hour, minute, second, and time zone.  <b>NOTE</b> <i>n</i> indicates the number of digits after the decimal point in the time string.	gaussdb=# SELECT CURRENT_TIMESTAMP(6); timestampz ----- 2018-02-02 00:39:55.231689+08 (1 row)

- Do not use scalar subquery statements. A scalar subquery is a subquery in the output list of the SELECT statement. In the following example, "SELECT COUNT(\*) FROM films f WHERE f.did = s.id" is a scalar subquery statement:  
SELECT id, (SELECT COUNT(\*) FROM films f WHERE f.did = s.id) FROM staffs\_p1 s;  
Scalar subqueries often result in query performance deterioration. During application development, scalar subqueries need to be converted into equivalent table associations based on the service logic.
- In WHERE clauses, the filter conditions should be collated. The condition that few records are selected for reading (the number of filtered records is small) is listed at the beginning.

- Filter conditions in WHERE clauses should comply with unilateral rules, that is, to place the column name on one side of a comparison operator. In this way, the optimizer automatically performs pruning optimization in some scenarios. The format is *col op expression*, where *col* indicates a table column, *op* indicates a comparison operator, such as = and >, and *expression* indicates an expression that does not contain a column name. For example:

```
SELECT id, from_image_id, from_person_id, from_video_id FROM face_data WHERE
current_timestamp(6) - time < '1 days'::interval;
```

The modification is as follows:

```
SELECT id, from_image_id, from_person_id, from_video_id FROM face_data where time >
current_timestamp(6) - '1 days'::interval;
```

- Do not perform unnecessary collation operations. Collation requires a large amount of memory and CPU. If service logic permits, ORDER BY and LIMIT can be combined to reduce resource overhead. By default, GaussDB performs collation by ASC & NULL LAST.
- When the ORDER BY clause is used for collation, specify collation modes (**ASC** or **DESC**), and use NULL FIRST or NULL LAST for NULL record sorting.
- Do not rely on only the LIMIT clause to return the result set displayed in a specific sequence. Combine ORDER BY and LIMIT clauses if some specific result sets are returned, and use OFFSET to skip specific results if necessary.
- If the service logic is accurate, you are advised to use UNION ALL instead of UNION.
- If a filter condition contains only an OR expression, convert the OR expression to UNION ALL to improve performance. SQL statements that use OR expressions cannot be optimized, resulting in slow execution. For example, the conversion of the following statements:

```
SELECT * FROM scdc.pub_menu
WHERE (cdp= 300 AND inline=301) OR (cdp= 301 AND inline=302) OR (cdp= 302 AND inline=301);
```

Convert the statement to the following:

```
SELECT * FROM scdc.pub_menu
WHERE (cdp= 300 AND inline=301)
union all
SELECT * FROM scdc.pub_menu
WHERE (cdp= 301 AND inline=302)
union all
SELECT * FROM tablename
WHERE (cdp= 302 AND inline=301)
```

- If an IN(val1, val2, val3...) expression contains a large number of columns, you are advised to replace it with the IN (VALUES (val1), (val2),(val3)...) statement. The optimizer will automatically convert the IN constraint into a non-correlated subquery to improve the query performance.
- Use (NOT) EXIST instead of (NOT) IN when associated columns do not contain null values. For example, in a query statement, if the **T1.C1** column does not contain any **NULL** value, add the **NOT NULL** constraint to the **T1.C1** column, and then rewrite the statements.

```
SELECT * FROM T1 WHERE T1.C1 NOT IN (SELECT T2.C2 FROM T2);
```

Rewrite the statement as follows:

```
SELECT * FROM T1 WHERE NOT EXISTS (SELECT * FROM T2 WHERE T1.C1=T2.C2);
```

 **NOTE**

- If the value of the **T1.C1** column is not **NOT NULL**, the preceding rewriting cannot be performed.
- If the **T1.C1** column is the output of a subquery, check whether the output is **NOT NULL** based on the service logic.
- Use cursors instead of the **LIMIT OFFSET** syntax to perform pagination queries to avoid resource overheads caused by multiple executions. A cursor must be used in a transaction, and you must disable the cursor and commit the transaction once the query is finished.

# 5 Application Development Guide

## 5.1 Development Specifications

If the connection pool mechanism is used during application development, comply with the following specifications:

- If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
- If a temporary table is used, delete the temporary table before you return the connection to the connection pool.

If you do not do so, the connection state in the connection pool will remain, which affects subsequent operations using the connection pool.

[Table 5-1](#) describes the compatibility of application development drivers.

**Table 5-1** Compatibility description

Driver	Compatibility Description
JDBC, Go, ODBC, libpq, Psycopg, and ecpg	The new drivers are forward compatible with the database. To use the new features added to the driver and database, you must upgrade the database.

### NOTICE

- In principle, you need to set the compatibility parameter after the database creation, instead of switching the parameters when using the database.
- The JDBC driver must be upgraded to that maps to GaussDB Kernel 503.1.0 or later if the following features are used:
  - The s2 compatibility parameter is enabled and the validity check of **sessiontimezone** is set.

If the driver is used in a multi-thread environment:

The JDBC driver is not thread-safe and does not guarantee that the connection methods are synchronized. The caller synchronizes the calls to the driver.

## 5.2 Obtaining the Driver Package

### Obtaining the Driver Package

Download particular packages listed in [Table 5-2](#) based on the version of your instance.

**Table 5-2** Driver package download list

Version	Download Address
8.x	<a href="#">Driver package</a> <a href="#">Verification package for the driver package</a>

To prevent a software package from being tampered with during transmission or storage, download the corresponding verification package and perform the following steps to verify the software package:

1. Upload the software package and verification package to the same directory on a Linux VM.
2. Run the following command to verify the integrity of the software package:

```
cat GaussDB_driver.zip.sha256 | sha256sum --check
```

If **OK** is displayed in the command output, the verification is successful.

```
GaussDB_driver.zip: OK
```

## 5.3 Development Based on JDBC

Java Database Connectivity (JDBC) is a Java API for running SQL statements. It provides unified access APIs for different relational databases, based on which applications process data. GaussDB supports JDBC 4.2 and requires JDK 1.8 for code compiling. It does not support JDBC-ODBC bridge.

### 5.3.1 JDBC Packages, Driver Classes, and Environment Classes

#### JDBC Packages

Obtain the `GaussDB-Kernel_Database version number_OS version number_64bit_Jdbc.tar.gz` package from the release package. After the decompression, you will obtain the following JDBC packages in .jar format:

- `gaussdbjdbc.jar`: The main class name is `com.huawei.gaussdb.jdbc.Driver`. The URL prefix of the database connection is `jdbc:gaussdb`. This driver

package is recommended. The Java code examples in this section use the **gaussdbjdbc.jar** package by default.

- **gscejdbc.jar**: The main class name is **com.huawei.gaussdb.jdbc.Driver**. The URL prefix of the database connection is **jdbc:gaussdb**. This driver package contains the dependent libraries related to encryption and decryption that need to be loaded to the encrypted database. You are advised to use this driver package in encrypted scenarios. Currently, only EulerOS is supported.
- **gaussdbjdbc-JRE7.jar**: The main class name is **com.huawei.gaussdb.jdbc.Driver**. The URL prefix of the database connection is **jdbc:gaussdb**. The **gaussdbjdbc-JRE7.jar** package is used in the JDK 1.7 environment.

---

 **CAUTION**

- Before using the **gscejdbc.jar** driver package, you need to set the environment variable **LD\_LIBRARY\_PATH**. For details, see section "Setting Encrypted Equality Queries > Using JDBC to Operate an Encrypted Database" in *Feature Guide*.
  - In JDK 1.8, you are advised to use **gaussdbjdbc.jar** instead of **gaussdbjdbc-JRE7.jar**.
  - The JAR packages of the JDBC release package are classified by architecture. Except **gscejdbc.jar**, the deployment environment of the JAR packages can be different from that of the JAR packages.
  - For details about other JAR packages, see [JDBC Compatibility Package](#).
- 

## Driver Class

Before establishing a database connection, load the **com.huawei.gaussdb.jdbc.Driver** database driver class.

 **NOTE**

1. GaussDB is compatible with PostgreSQL in the use of JDBC. Therefore, when two JDBC drivers are used in the same process, class names may conflict.
2. JDBC of this version does not support identity & access management suite (IAM) for authentication.
3. The GaussDB JDBC driver has the following enhanced features:
  1. The SHA256 encryption mode is supported for login.
  2. The third-party log framework that implements the sf4j API can be connected.
  3. Distributed load balancing at the connection level is supported.
  4. DR failover is supported.

## Environment Class

The JDK1.8 must be configured on the client. JDK supports multiple platforms such as Windows and Linux. The following uses Windows as an example to describe how to configure JDK:

- Step 1** Enter **java -version** in the MS-DOS window (command prompt in Windows) to check the JDK version. Ensure that the JDK version is JDK1.8. If the JDK is not installed, download the installation package and install it.

- Step 2** On the Windows desktop, right-click **This PC** and choose **Properties** from the shortcut menu.
- Step 3** In the **System** window, click **Advanced system settings** in the navigation pane.
- Step 4** In the **System Properties** dialog box, click **Environment Variables** in the lower right corner.
- Step 5** In the **System variables** area of the **Environment Variables** dialog box, click **New** or **Edit** to configure system variables. For details about the variables, see [Table 5-3](#).

**Table 5-3** Variables

Variable	Operation	Variable Value
JAVA_HOME	<ul style="list-style-type: none"> <li>• If the variable exists, click <b>Edit</b>.</li> <li>• If the variable does not exist, click <b>New</b>.</li> </ul>	Specifies the Java installation directory. Example: <b>C:\Program Files\Java\jdk1.8.0_131</b>
Path	Click <b>Edit</b> .	<ul style="list-style-type: none"> <li>• If <i>JAVA_HOME</i> is configured, add <i>%JAVA_HOME%\bin</i> before the variable value.</li> <li>• If <i>JAVA_HOME</i> is not configured, add the full Java installation path before the variable value:  <b>C:\Program Files\Java\jdk1.8.0_131\bin</b> </li> </ul>
CLASSPATH	Click <b>New</b> .	<b>%JAVA_HOME%\lib;%JAVA_HOME%\lib\tools.jar</b>

- Step 6** Click **OK** and close the windows one by one.
- End

## 5.3.2 Development Process

Figure 5-1 Application development process based on JDBC

## 5.3.3 Loading a Driver

Load the database driver before creating a database connection.

You can load the driver in the following ways:

- Implicit loading at any position before a connection is created in the code:  
`Class.forName("com.huawei.gaussdb.jdbc.Driver")`
- Parameter transfer during JVM startup: `java -Djdbc.drivers=com.huawei.gaussdb.jdbc.Driver jdbctest`

### NOTE

`jdbctest` is the name of a test application.

## 5.3.4 Connecting to a Database

After a database is connected, it can be used to run SQL statements to operate data.

## Function Prototype

JDBC provides three database connection methods.

- `DriverManager.getConnection(String url)`
- `DriverManager.getConnection(String url, Properties info)`
- `DriverManager.getConnection(String url, String user, String password)`

## Parameters

**Table 5-4** Database connection parameters

Parameter	Description
url	<p><b>gaussdbjdbc.jar</b> database connection descriptor.</p> <p>If <b>host</b> is set to a server name or an IPv4 address, formats are as follows:</p> <ul style="list-style-type: none"> <li>● jdbc:gaussdb: (If the database name is left empty, the username is used.)</li> <li>● jdbc:gaussdb:database</li> <li>● jdbc:gaussdb://host/database</li> <li>● jdbc:gaussdb://host:port/database</li> <li>● jdbc:gaussdb://host:port/database?param1=value1&amp;param2=value2</li> <li>● jdbc:gaussdb://host1:port1,host2:port2/database?param1=value1&amp;param2=value2</li> </ul> <p>If <b>host</b> is set to an IPv6 address, formats are as follows:</p> <ul style="list-style-type: none"> <li>● jdbc:gaussdb: (If the database name is left empty, the username is used.)</li> <li>● jdbc:gaussdb:database</li> <li>● jdbc:gaussdb://host/database or jdbc:gaussdb://[host]/database</li> <li>● jdbc:gaussdb://[host]:port/database</li> <li>● jdbc:gaussdb://[host]:port/database?param1=value1&amp;param2=value2</li> <li>● jdbc:gaussdb://[host1]:port1,[host2]:port2/database?param1=value1&amp;param2=value2</li> </ul>

Parameter	Description
	<p><b>NOTE</b></p> <ul style="list-style-type: none"> <li>• <b>database</b> indicates the name of the database to connect.</li> <li>• <b>host</b> indicates the name or IP address of the database server. Both IPv4 and IPv6 addresses are supported. For security purposes, the database CN forbids access from other nodes in the cluster without authentication. To access the CN from inside the cluster, deploy the JDBC program on the host where the CN is located and set <b>host</b> to <b>127.0.0.1</b>. Otherwise, the error message "FATAL: Forbid remote connection with trust method!" may be displayed. It is recommended that the service system be deployed outside the cluster. If it is deployed inside, database performance may be affected. By default, the local host is used to connect to the server.</li> <li>• <b>port</b> indicates the port number of the database server. By default, the database on port 5432 of the local host is connected.</li> <li>• If <b>host</b> is set to an IPv6 address and the port number is specified in the URL, use square brackets ([]) to enclose the IP address. The format is [IP address]:Port number.</li> <li>• <b>param</b> indicates a database connection attribute. The parameter can be configured in the URL. The URL starts with a question mark (?), uses an equal sign (=) to assign a value to the parameter, and uses an ampersand (&amp;) to separate parameters. You can also use the attributes of the info object for configuration. For details, see <a href="#">Examples</a>.</li> <li>• <b>value</b> indicates the database connection attribute values.</li> <li>• The <b>connectTimeout</b> and <b>socketTimeout</b> parameters must be set for connection. If they are not set, the default value <b>0</b> is used, indicating that the connection will not time out. When the network between the DN and client is faulty, the client does not receive the ACK packet from the DN. In this case, the client starts the timeout retransmission mechanism to continuously retransmit packets. A timeout error is reported only when the timeout interval reaches the default value <b>600s</b>. As a result, the RTO is high.</li> <li>• You are advised to ensure the validity of the URL when using the standard JDBC API to establish a connection. An invalid URL may cause an exception, and the exception contains the original URL character string, which may cause sensitive information leakage.</li> </ul>

Parameter	Description
info	<p>Database connection attributes (all attributes are case sensitive). Common attributes are described as follows:</p> <ul style="list-style-type: none"> <li>● <b>PGDBNAME</b>: string type. This parameter specifies the database name. You do not need to set this parameter in the URL because the database name is automatically parsed from the URL.</li> <li>● <b>PGHOST</b>: string type. It specifies the host IP address. Both IPv4 and IPv6 addresses are supported. Use colons (:) to separate IP addresses and port numbers, and use commas (,) to separate multiple CNs. (This parameter does not need to be set in the URL. The system automatically parses the URL to obtain its value.) For details, see <a href="#">Examples</a>.</li> <li>● <b>PGPORT</b>: integer type. It specifies the host port number. Use colons (:) to separate IP addresses and port numbers, and use commas (,) to separate multiple CNs. (This parameter does not need to be set in the URL. The system automatically parses the URL to obtain its value.) For details, see <a href="#">Examples</a>.</li> <li>● <b>user</b>: string type. It specifies the database user who creates the connection.</li> <li>● <b>password</b>: string type. It specifies the password of the database user.</li> <li>● <b>enable_ce</b>: string type. <b>enable_ce=1</b> indicates that JDBC supports the basic capability of encrypted equality query. <b>enable_ce=3</b> indicates that software and hardware integration is supported based on the encrypted equality query capability.</li> <li>● <b>key_info</b>: string type. This parameter is used together with <b>enable_ce</b> to set parameters for accessing an external key manager in an encrypted database.</li> <li>● <b>refreshClientEncryption</b>: string type. The default value is <b>NULL</b>. If <b>refreshClientEncryption</b> is set to <b>1</b> (default value), the encrypted database supports cache update on the client.</li> <li>● <b>loggerLevel</b>: string type. The default value is <b>NULL</b> (disabled). The following log levels are supported: <b>OFF</b>, <b>INFO</b>, <b>DEBUG</b>, and <b>TRACE</b>. <b>OFF</b> indicates that the log function is disabled. <b>INFO</b>, <b>DEBUG</b>, and <b>TRACE</b> logs record information of different levels.</li> <li>● <b>loggerFile</b>: string type. It specifies the log output path (directory and file name). You need to specify the log directory and file name. If no directory is specified, log files are generated in the directory where the client program is running. If the path is not configured or the configured path does not exist, logs are output through streams by default. This parameter has been discarded and does not take effect any more. It is used to specify the path for exporting monitoring logs only when the connection monitoring function is enabled. To export JDBC logs to a specified path, configure it in the <b>java.util.logging</b> attribute file or system attributes.</li> <li>● <b>logger</b>: string type. It indicates the log output framework used by the JDBC driver. The JDBC driver supports the log output framework</li> </ul>

Parameter	Description
	<p>used for interconnecting with user applications. Currently, only the Slf4j-API-based third-party log output framework is supported. For details, see <a href="#">6.2.9 Log Management</a>.</p> <ol style="list-style-type: none"> <li>1. If it is left empty or is set to <b>JDK LOGGER</b>, JDK LOGGER is used.</li> <li>2. Otherwise, the slf4j-API-based third-party log framework must be used.</li> </ol> <ul style="list-style-type: none"> <li>• <b>allowEncodingChanges</b>: Boolean type. The default value is <b>false</b>. If this parameter is set to <b>true</b>, the character set type can be changed. This parameter is used together with <b>characterEncoding</b> to set the character set. The two parameters are separated by ampersands (&amp;). The value of <b>characterEncoding</b> can be <b>UTF8</b>, <b>GBK</b>, <b>LATIN1</b>, <b>GB18030</b>, <b>GB18030_2022</b>, or <b>ZHS16GBK</b>. Example: <b>allowEncodingChanges=true&amp;characterEncoding=UTF8</b>.</li> <li>• <b>currentSchema</b>: string type. You need to specify a schema in <b>search-path</b>. If the schema name contains special characters except letters, digits, and underscores (_), you are advised to enclose the schema name in quotation marks. Note that the schema name is case sensitive after quotation marks are added. If multiple schemas need to be configured, separate them with commas (,). Schemas containing special characters also need to be enclosed in quotation marks. Example: <b>currentSchema=schema_a,"schema-b","schema/c"</b>.</li> <li>• <b>loadBalanceHosts</b>: Boolean type. In the default mode (disabled), multiple hosts specified in the URL are connected in sequence. If load balancing is enabled, the shuffle algorithm is used to randomly select a host from the candidate hosts to establish a connection.</li> <li>• <b>autoBalance</b>: string type. <ol style="list-style-type: none"> <li>1. If this parameter is set to <b>true</b>, <b>balance</b>, or <b>roundrobin</b>, the JDBC load balancing function is enabled to balance multiple connections of an application to each CN available in the database cluster. Example: <b>jdbc:gaussdb://host1:port1,host2:port2/database?autoBalance=true</b>. JDBC periodically obtains the list of available CNs in the entire cluster, for example, the obtained list is <b>host1:port1,host2:port2,host3:port3,host4:port4</b>. The <b>refreshCNipListTime</b> parameter specifies the interval for obtaining the list, and the default interval is 10 seconds. Hosts obtained from the CN list are data IP addresses. When <b>autoBalance</b> is enabled on <b>host1</b> and <b>host2</b>, HA is implemented only for the first connection. The driver will select available CNs from <b>host1</b>, <b>host2</b>, <b>host3</b>, and <b>host4</b> in sequence to update the available CN list and new connections will be established on <b>host1</b>, <b>host2</b>, <b>host3</b>, and <b>host4</b> using the RoundRobin algorithm.</li> </ol> </li> </ul>

Parameter	Description
	<p>2. <b>priority</b><math>n</math> indicates that the JDBC-based load balancing function is enabled. Multiple connections of an application are balanced to the first <math>n</math> available CNs configured in the URL. When the first <math>n</math> CNs are unavailable, connections are randomly allocated to other available CNs in the database cluster. <math>n</math> is a number not less than 0 and less than the number of CNs configured in the URL. When <b>parseCandidatesByDomain</b> is set to <b>true</b>, the priority configuration of <b>priority</b><math>n</math> does not take effect. In this scenario, the priority is specified by <b>priorityDomains</b>. When <b>priority</b><math>n</math> is used for load balancing, the value of <b>host</b> cannot be IPv6.</p> <p>Example: <b>jdbc:gaussdb://host1:port1,host2:port2,host3:port3,host4:port4/database?autoBalance=priority2.</b></p> <p>JDBC periodically obtains the list of available CNs in the entire cluster (defined by <b>refreshCNIPListTime</b>). For example, the obtained list is <b>host1:port1,host2:port2,host3:port3,host4:port4,host5:port5,host6:port6</b>, where <b>host1</b> and <b>host2</b> are in AZ1, and <b>host3</b> and <b>host4</b> are in AZ2.</p> <p>The driver preferentially selects <b>host1</b> and <b>host2</b> for load balancing. If both <b>host1</b> and <b>host2</b> are unavailable, the driver randomly selects a CN from <b>host3</b>, <b>host4</b>, <b>host5</b>, and <b>host6</b> for connection.</p> <p>3. If this parameter is set to <b>shuffle</b>, JDBC random load balancing is enabled to randomly and evenly distribute multiple connections of the application to available CNs in the database cluster.</p> <p>Example: <b>jdbc:gaussdb://host1:port1,host2:port2,host3:port3/database?autoBalance=shuffle.</b></p> <p>JDBC periodically obtains the list of available CNs in the entire cluster. For example, the obtained list is <b>host1:port1,host2:port2,host3:port3,host4:port4</b>. The <b>refreshCNIPListTime</b> parameter specifies the interval for obtaining the list, and the default interval is 10 seconds.</p> <p>For the first connection, <b>host1:port1,host2:port2,host3:port3</b> is used for HA. For subsequent connections, the shuffle algorithm is used to randomly select a CN from the refreshed CN list.</p> <p>4. If this parameter is set to <b>specified</b>, the JDBC load balancing function is enabled and connections are established only on nodes specified in the user URL.</p> <p>Example: <b>jdbc:postgresql://host1:port1,host2:port2,host3:port3,host4:port4/database?autoBalance=specified&amp;priorityServers=2.</b></p> <p>JDBC identifies <b>host1</b> and <b>host2</b> as the connection nodes in the primary cluster, and <b>host3</b> and <b>host4</b> as the connection nodes in</p>

Parameter	Description
	<p>the standby cluster. First, connections are evenly established on <b>host1</b> and <b>host2</b>. If all nodes are faulty, connections are not established on the remaining nodes in the cluster. After the standby node becomes the primary node, connections are evenly established on <b>host3</b> and <b>host4</b>. If all nodes are faulty, connections are not established on the remaining nodes in the cluster.</p> <p>5. If this parameter is set to <b>false</b>, the JDBC load balancing and priority-based load balancing functions are disabled. The default value is <b>false</b>.</p> <p><b>CAUTION</b></p> <ol style="list-style-type: none"> <li>1. Load balancing is based on the connection level rather than the transaction level. If the connection is persistent and the load on the connection is unbalanced, the load on the CN may be unbalanced.</li> <li>2. Load balancing can be used only in distributed scenarios and cannot be used in centralized scenarios.</li> <li>3. If the load balancing function is enabled when the DR cluster is connected, query requests are sent to the primary cluster. As a result, the query performance is affected.</li> <li>4. When load balancing is enabled, the floating IP address or data IP address can be configured in the URL. If the floating IP address is configured, the system obtains the corresponding data IP address based on the floating IP address and performs load balancing based on the obtained data IP address. Therefore, when configuring the floating IP address or data IP address in the URL, ensure that the network connection of the data IP address is normal. Otherwise, the load balancing function is abnormal.</li> </ol> <ul style="list-style-type: none"> <li>● <b>refreshCNIpListTime</b>: integer type. This parameter specifies the interval at which JDBC periodically checks the status of CNs in the database cluster and obtains the IP address list of available CNs. The default value is 10 seconds.</li> <li>● <b>hostRecheckSeconds</b>: integer type. After JDBC attempts to connect to a host, the host status is saved: connection success or connection failure. This status is trusted within the duration specified by <b>hostRecheckSeconds</b>. After the duration expires, the status becomes invalid. The default value is 10 seconds.</li> <li>● <b>ssl</b>: Boolean type. It specifies a connection in SSL mode. When <b>ssl</b> is set to <b>true</b>, the NonValidatingFactory channel and certificate mode are supported. <ol style="list-style-type: none"> <li>1. For the NonValidatingFactory channel, configure the username and password and set <b>SSL</b> to <b>true</b>.</li> <li>2. In certification mode, configure the client certificate, key, and root certificate, and set <b>SSL</b> to <b>true</b>.</li> </ol> </li> <li>● <b>sslmode</b>: string type. It specifies the SSL authentication mode. The value can be <b>disable</b>, <b>allow</b>, <b>prefer</b>, <b>require</b>, <b>verify-ca</b>, or <b>verify-full</b>. <ul style="list-style-type: none"> <li>– <b>disable</b>: SSL connection is disabled.</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>- <b>allow</b>: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.</li> <li>- <b>prefer</b>: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.</li> <li>- <b>require</b>: The system only attempts to set up an SSL connection. It neither checks whether the server certificate is issued by a trusted CA, nor checks whether the host name of the server is the same as that in the certificate.</li> <li>- <b>verify-ca</b>: attempts to set up an SSL connection and checks whether the server certificate is issued by a trusted CA.</li> <li>- <b>verify-full</b>: The system attempts to set up an SSL connection, checks whether the server certificate is issued by a trusted CA, and checks whether the host name of the server is the same as that in the certificate.</li> </ul> <ul style="list-style-type: none"> <li>● <b>sslcert</b>: string type. It specifies the complete path of the certificate file. The type of the client and server certificates is <b>End Entity</b>.</li> <li>● <b>sslkey</b>: string type. It specifies the complete path of the key file. You need to convert the client certificate to the DER format. For details, see <a href="#">Connecting to a Database (Using SSL)</a>.</li> <li>● <b>sslrootcert</b>: string type. It specifies the name of the SSL root certificate. The root certificate type is CA.</li> <li>● <b>sslpassword</b>: string type. It is provided for ConsoleCallbackHandler.</li> <li>● <b>sslpasswordcallback</b>: string type. It specifies the class name of the SSL password provider. Default value: <b>com.huawei.gaussdb.jdbc.ssl.jdbc4.LibPQFactory.ConsoleCallbackHandler</b>.</li> <li>● <b>sslfactory</b>: string type. It specifies the class name used by SSLSocketFactory to establish an SSL connection.</li> <li>● <b>sslprivatekeyfactory</b>: string type. The provided value is the fully qualified name of the implementation class of the com.huawei.gaussdb.jdbc.ssl.PrivateKeyFactory API that implements the private key decryption method. If it is not provided, try the default JDK private key decryption algorithm. If the decryption fails, use com.huawei.gaussdb.jdbc.ssl.BouncyCastlePrivateKeyFactory. You need to provide the <b>bcpkix-jdk15on.jar</b> package. The recommended version is 1.65 or later.</li> <li>● <b>sslfactoryarg</b>: string type. The value is an optional parameter of the constructor function of the sslfactory class. (This parameter is not recommended.)</li> <li>● <b>sslhostnameverifier</b>: string type. It specifies the class name of the host name verifier. The API must implement javax.net.ssl.HostnameVerifier. The default value is <b>com.huawei.gaussdb.jdbc.ssl.PGjdbcHostnameVerifier</b>.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>● <b>loginTimeout</b>: integer type. It specifies the waiting time for establishing the database connection, in seconds. When multiple IP addresses are configured in the URL, if the time for obtaining the connection exceeds this value, the connection fails and the subsequent IP addresses are not tried. The default value is <b>0</b> (disabled).</li> <li>● <b>connectTimeout</b>: integer type. It specifies the timeout interval for connecting to a server. If the time taken to connect to a server exceeds the value specified, the connection is interrupted. The unit of the timeout interval is second. The value <b>0</b> indicates that the timeout mechanism does not take effect. When multiple IP addresses are configured in the URL, this parameter indicates the timeout interval for connecting to a single IP address. The default value is <b>0</b>.</li> <li>● <b>socketTimeout</b>: integer type. It specifies the timeout interval for a socket read operation. If the time taken to read data from a server exceeds the value specified, the connection is closed. The unit of the timeout interval is second. The value <b>0</b> indicates that the timeout mechanism does not take effect. The default value is <b>0</b>. If this parameter is not set, the client waits for a long time when the database process is abnormal. You are advised to set this parameter based on the SQL execution time acceptable to services. When the timeout is triggered on the JDBC and the connection is closed, the running services delivered by the JDBC to the database are forcibly terminated. This capability is controlled by the GUC parameter <b>check_disconnect_query</b>. If this parameter is set to <b>on</b>, the capability is supported. If this parameter is set to <b>off</b>, the capability is not supported.</li> <li>● <b>socketTimeoutInConnecting</b>: integer type. It specifies the timeout interval for a socket read operation during the connection establishment. If the time taken to read data from the server exceeds this value, it searches for the next node for connection. The unit of the timeout interval is second. The default value is <b>5s</b>.</li> <li>● <b>statementTimeout</b>: integer type. It specifies the timeout interval for executing a statement in a connection. If the execution time of a statement exceeds this value, the statement execution is canceled. The unit of the timeout interval is millisecond. The default value <b>0</b> indicates that the timeout mechanism is disabled.</li> <li>● <b>cancelSignalTimeout</b>: integer type. A cancel message may cause a block. This attribute controls "connect timeout" and "socket timeout" in a cancel command. If the cancel command does not respond within the specified time, the connection is interrupted to reduce the occupation of client resources. The unit of the timeout interval is second. The default value is 10 seconds.</li> <li>● <b>tcpKeepAlive</b>: Boolean type. It is used to enable or disable TCP keepalive detection. The default value is <b>false</b>.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>● <b>logUnclosedConnections</b>: Boolean type. The default value is <b>false</b>. The client may leak a connection object because it does not call the connection object's close() method. These objects will be collected as garbage and finalized using the finalize() method. After it is set to <b>true</b>, if the caller ignores this operation, this method closes the connection.</li> <li>● <b>assumeMinServerVersion</b> (discarded): string type. This parameter indicates the version of the server to connect.</li> <li>● <b>ApplicationName</b>: string type. This parameter specifies the name of the application that is being connected. You can query the <b>pgxc_stat_activity</b> table on the CN to view information about the client that is being connected. The name is displayed in the <b>application_name</b> column. The default value is <b>GaussDB JDBC Driver</b>.</li> <li>● <b>connectionExtraInfo</b>: Boolean type. It specifies whether the driver reports the driver deployment path, process owner, and URL connection configuration information to the database. The value can be <b>true</b> or <b>false</b>. The default value is <b>false</b>. If <b>connectionExtraInfo</b> is set to <b>true</b>, the JDBC driver reports the driver deployment path, process owner, and URL connection configuration information to the database and displays the information in the <b>connection_info</b> parameter. In this case, you can query the information from PG_STAT_ACTIVITY or PGXC_STAT_ACTIVITY.</li> <li>● <b>autosave</b>: string type. The value can be <b>always</b>, <b>never</b>, or <b>conservative</b>. It specifies the action that the driver should perform upon a query failure. If <b>autosave</b> is set to <b>always</b>, the JDBC driver sets a savepoint before each query and rolls back to the savepoint if the query fails. If <b>autosave</b> is set to <b>never</b>, there is no savepoint. If <b>autosave</b> is set to <b>conservative</b>, a savepoint is set for each query. However, the system rolls back and retries only when there is an invalid statement. The default value is <b>never</b>.</li> <li>● <b>protocolVersion</b>: integer type. It specifies the connection protocol version. Only versions 1 and 3 are supported. If it is set to <b>1</b>, only the V1 server is connected. If it is set to <b>3</b>, MD5 encryption is used. You must need to set the GUC parameter <b>password_encryption_type</b> to <b>1</b> to change the database encryption mode. After the cluster is restarted, create a user who uses MD5 encryption to encrypt passwords. You must also change the client connection mode to <b>md5</b> in the <b>gs_hba.conf</b> file. Log in to the system as a new user. (You are advised not to set this value because the MD5 encryption algorithm has lower security and poses security risks.) <b>NOTE</b> The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.</li> <li>● <b>prepareThreshold</b>: integer type. It specifies the number of times that the PreparedStatement object is executed before the prepared</li> </ul>

Parameter	Description
	<p>statement on the server is used. The default value is <b>5</b>, indicating that when the same PreparedStatement object is executed for five or more times, the parse message is not sent to the server to parse the statement. Instead, the statement that has been parsed on the server is used.</p> <ul style="list-style-type: none"> <li>● <b>preparedStatementCacheQueries</b>: integer type. This parameter specifies the maximum number of queries generated by the cache statement object of each connection. The default value is <b>256</b>. If the number of queries generated by the statement object is greater than 256, the least recently used queries will be discarded from the cache. The value <b>0</b> indicates that the cache function is disabled.</li> <li>● <b>preparedStatementCacheSizeMiB</b>: integer type. This parameter indicates the maximum size of queries generated by the cache statement object of each connection, in MB. The default value is <b>5</b>. If the size of the cached queries exceeds 5 MB, the least recently used query cache will be discarded. The value <b>0</b> indicates that the cache function is disabled.</li> <li>● <b>databaseMetadataCacheFields</b>: integer type. The default value is <b>65536</b>. It specifies the maximum number of columns that can be cached in each connection. The value <b>0</b> indicates that the cache function is disabled.</li> <li>● <b>databaseMetadataCacheFieldsMiB</b>: integer type. The default value is <b>5</b>. This parameter indicates the maximum size of columns that can be cached in each connection, in MB. The value <b>0</b> indicates that the cache function is disabled.</li> <li>● <b>stringtype</b>: string type. The options are <b>unspecified</b> and <b>varchar</b>. It specifies the type of the <b>PreparedStatement</b> parameter used by the <code>setString()</code> method. If <b>stringtype</b> is set to <b>VARCHAR</b> (default value), these parameters are sent to the server as varchar parameters. If <b>stringtype</b> is set to <b>unspecified</b>, these parameters are sent to the server as an untyped value, and the server attempts to infer their appropriate type.</li> <li>● <b>batchMode</b>: string type. It specifies whether to connect the database in batch mode. The default value is <b>on</b>, indicating that the batch mode is enabled. If <b>batchMode</b> is set to <b>on</b>, the returned result is <code>[count, 0, 0...0]</code>. The first element in the array is the total number of records affected in batches. If <b>batchMode</b> is set to <b>off</b>, the returned result is <code>[1, 1, 1...1]</code>. Each element in the array corresponds to the number of affected records in a single modification.</li> <li>● <b>fetchsize</b>: integer type. It specifies the default <b>fetchsize</b> for statements in the created connection. The default value is <b>0</b>, indicating that all results are obtained at a time. It has the same function as <b>defaultRowFetchSize</b>. If they are set at the same time, <b>fetchsize</b> prevails.</li> <li>● <b>rewriteBatchedInserts</b>: Boolean type. The default value is <b>false</b>. During batch import, set this parameter to <b>true</b> to combine <i>N</i></li> </ul>

Parameter	Description
	<p>insert statements into one: insert into TABLE_NAME values(values1, ..., valuesN), ..., (values1, ..., valuesN). To use this parameter, set <b>batchMode</b> to <b>off</b>.</p> <ul style="list-style-type: none"> <li>● <b>unknownLength</b>: integer type. The default value is <b>Integer.MAX_VALUE</b>. This parameter specifies the length of the unknown length type when the data of some GaussDB types (such as TEXT) is returned by functions such as ResultSetMetaData.getColumnDisplaySize and ResultSetMetaData.getPrecision.</li> <li>● <b>defaultRowFetchSize</b>: integer type. It specifies the number of rows read by fetch in ResultSet at a time. Limiting the number of rows read each time in a database access request can avoid unnecessary memory consumption, thereby avoiding out of memory exception. The default value is <b>0</b>, indicating that all rows are obtained at a time in ResultSet. This parameter cannot be set to a negative value.</li> <li>● <b>binaryTransfer</b>: Boolean type. It specifies whether data is sent and received in binary format. The default value is <b>false</b>.</li> <li>● <b>binaryTransferEnable</b>: string type. It specifies types for which binary transmission is enabled. Every two types are separated by commas (,). You can select either the OID or name, for example, <b>binaryTransferEnable=INT4_ARRAY,INT8_ARRAY</b>. For example, if the name is BLOB and the OID is 88, set <b>binaryTransferEnable</b> to <b>BLOB</b> or <b>88</b>.</li> <li>● <b>binaryTransferDisable</b>: string type. It specifies types for which binary transmission is disabled. Every two types are separated by commas (,). You can select either the OID or name. It overwrites the setting of <b>binaryTransferEnable</b>.</li> <li>● <b>blobMode</b>: string type. It is used to set the data type of parameters bound to the setBinaryStream method. If the value is <b>on</b>, the data type is blob. If the value is <b>off</b>, the data type is bytea. The default value is <b>on</b>. You are advised to set this parameter to <b>on</b> for systems migrated from ORA and MySQL and to <b>off</b> for systems migrated from PG.</li> <li>● <b>socketFactory</b>: string type. It specifies the name of the class used to create a socket connection with the server. This class must implement the javax.net.SocketFactory API and define a constructor with no parameter or a single string parameter.</li> <li>● <b>socketFactoryArg</b>: string type. The value is an optional parameter of the constructor function of the socketFactory class and is not recommended.</li> <li>● <b>receiveBufferSize</b>: integer type. It is used to set <b>SO_RCVBUF</b> on the connection stream.</li> <li>● <b>sendBufferSize</b>: integer type. It is used to set <b>SO_SNDBUF</b> on the connection stream.</li> <li>● <b>preferQueryMode</b>: string type. The value can be <b>"extended"</b>, <b>"extendedForPrepared"</b>, <b>"extendedCacheEverything"</b>, or <b>"simple"</b>. This parameter specifies the query mode. The default</li> </ul>

Parameter	Description
	<p>value is <b>extended</b>. In <b>simple</b> mode, only the Q message in text mode can be sent. The parse and bind messages are not supported. In <b>extended</b> mode, parse, bind, and execute messages are used. In <b>extendedForPrepared</b> mode, only the prepared statement object uses extended query, and the statement object uses only simple query. The <b>extendedCacheEverything</b> mode caches the query generated by each statement object.</p> <ul style="list-style-type: none"> <li>• <b>ApplicationType</b>: string type. The value can be "<b>not_perfect_sharding_type</b>" or "<b>perfect_sharding_type</b>". It specifies whether to enable distributed write and query. The default value is <b>not_perfect_sharding_type</b>. Distributed write and query are enabled if this parameter is set to <b>not_perfect_sharding_type</b>. If it is set to <b>perfect_sharding_type</b>, distributed write and query are disabled by default. Distributed write and query can be performed only when <b>/* multinode */</b> is added to the SQL statement. This parameter is valid only when the database is in the GTM-free scenario.</li> <li>• <b>priorityServers</b>: integer type. This value is used to specify the first <i>n</i> nodes configured in the URL as the primary cluster to be connected preferentially. The default value is <b>NULL</b>. The value is a number greater than 0 and less than the number of CNs configured in the URL. It is used in streaming DR scenarios. Example: <b>jdbc:gaussdb://host1:port1,host2:port2,host3:port3,host4:port4,/database?priorityServers=2</b>. That is, <b>host1</b> and <b>host2</b> are primary cluster nodes, and <b>host3</b> and <b>host4</b> are DR cluster nodes.</li> <li>• <b>usingEip</b>: Boolean type. This value specifies whether to use an elastic IP address for load balancing. The default value is <b>true</b>, indicating that an elastic IP address is used for load balancing. The value <b>false</b> indicates that a data IP address is used for load balancing. If <b>usingEip</b> is set to <b>true</b> or left blank, the host in the URL must use an EIP. If <b>usingEip</b> is set to <b>false</b>, the host in the URL must use a data IP address. Otherwise, the priority load balancing policy will become invalid.</li> <li>• <b>traceInterfaceClass</b>: string type. The default value is <b>NULL</b>, which is used to obtain the implementation class of <b>traced</b>. The value is the fully qualified name of the implementation class of the <code>com.huawei.gaussdb.jdbc.log.Tracer</code> API that implements the method for obtaining <b>traced</b>.</li> <li>• <b>use_boolean</b>: Boolean type. It is used to set the OID type bound to the <code>setBoolean</code> method in extended mode. The default value is <b>false</b>, indicating that the <code>int2</code> type is bound. The value <b>true</b> indicates that the Boolean type is bound.</li> <li>• <b>allowReadOnly</b>: Boolean type. It specifies whether to enable the read-only mode for a connection. The default value is <b>true</b>, indicating that the read-only mode is enabled. If it is set to <b>false</b>, the read-only mode is disabled. In this case, calling</li> </ul>

Parameter	Description
	<p>connection.setReadOnly(true) does not take effect, and data can still be modified.</p> <ul style="list-style-type: none"> <li> <b>TLSCiphersSupported</b>: string type. It is used to set the supported TLS encryption suite. The default value is <code>TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,TLS_DHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384</code>.         </li> <li> <b>stripTrailingZeros</b>: Boolean type. The default value is <b>false</b>. If the value is <b>true</b>, trailing 0s of the numeric type are removed. It is valid only for <code>ResultSet.getObject(int columnIndex)</code>.         </li> <li> <b>enableTimeZone</b>: Boolean type. The default value is <b>true</b>. It specifies whether to enable the time zone setting on the server. The value <b>true</b> indicates that the JVM time zone is obtained to specify the database time zone. The value <b>false</b> indicates that the database time zone is used.         </li> <li> <b>enableStandbyRead</b>: Boolean type. It specifies whether to enable the read on standby mode. The default value is <b>false</b>. The value <b>true</b> indicates that the mode is enabled, and the value <b>false</b> indicates that the mode is disabled.         </li> <li> <b>compatibilityTags</b>: string type. The default value is <b>NULL</b>. It is used to restore some features of the driver to an earlier version to ensure forward compatibility. You can configure one or more tags. Each tag indicates that the corresponding forward compatibility feature is enabled. Different tags are separated by commas (,). Generally, this parameter is not recommended unless there is an obvious forward compatibility issue. Currently, the following tag is supported:           <p><b>typeMapInitNull</b>: After this tag is used, the behavior of earlier driver versions is compatible. The initial value of <b>typeMap</b> in <code>java.sql.Connection</code> is <b>NULL</b>. If this tag is not used, the initial value is an empty map.</p> </li> <li> <b>parseCandidatesByDomain</b>: Boolean type. It specifies whether to obtain candidate nodes based on domain names. The default value is <b>false</b>. The value is <b>true</b> (enabled) or <b>false</b> (disabled). After this function is enabled, you need to configure the host information in the URL in the format of domain name plus port number. The driver obtains the IP address based on the domain name, generates a standby node set, and works with the <b>autoBalance</b> parameter for load balancing.         </li> <li> <b>primaryDomains</b>: integer type. Specifies the first <i>n</i> domain names configured in the URL as the primary cluster to be preferentially connected. The default value is <b>0</b> (disabled). It takes effect only when <b>parseCandidatesByDomain</b> is set to <b>true</b>. A value greater than <b>0</b> and less than the number of domain names configured in the URL indicates that the function is enabled. The domain names         </li> </ul>

Parameter	Description
	<p>in the URL are divided into two groups. The first group is the primary cluster, and the second group is the standby cluster. After a primary/standby switchover, the two groups switch their positions. The first group is the primary cluster, and the second group is the standby cluster. This mode applies to streaming DR and Dorado dual-cluster scenarios.</p> <p>Example: <b>jdbc:gaussdb://domain1:port1,domain2:port2,domain3:port3,domain4:port4/database?parseCandidatesByDomain=true&amp;primaryDomains=2</b>, in which <b>domain1</b> and <b>domain2</b> correspond to the primary cluster and the IP addresses corresponding to <b>domain1</b> and <b>domain2</b> are preferentially connected. If a primary/standby switchover occurs, <b>domain3</b> and <b>domain4</b> are marked as the primary cluster, and connections are preferentially established to <b>domain3</b> and <b>domain4</b>.</p> <ul style="list-style-type: none"> <li> <p><b>priorityDomains</b>: integer type. It specifies the first <i>n</i> domain names configured in the URL as the domain names to be preferentially connected. The default value is <b>0</b> (disabled). The function takes effect only when <b>parseCandidatesByDomain</b> is set to <b>true</b>. A value greater than <b>0</b> and less than the number of domain names configured in the URL indicates that the function is enabled. If <b>primaryDomains</b> is configured, the value must be less than the value of <b>primaryDomains</b>.</p> <p>Example: <b>jdbc:gaussdb://domain1:port1,domain2:port2,domain3:port3,domain4:port4/database?parseCandidatesByDomain=true&amp;primaryDomains=2&amp;priorityDomains=1</b>, in which <b>domain1</b> and <b>domain2</b> correspond to the primary cluster but the IP address corresponding to <b>domain1</b> is preferentially connected. <b>domain2</b> is the standby domain name. The system attempts to connect to <b>domain2</b> only when <b>domain1</b> cannot be connected. If a primary/standby switchover occurs, <b>domain3</b> and <b>domain4</b> are marked as the primary cluster. However, the IP address corresponding to <b>domain3</b> is preferentially connected. If <b>domain3</b> cannot be connected, the IP address corresponding to <b>domain4</b> is connected.</p> </li> <li> <p><b>refreshDomainResolveTime</b>: integer type. The default value is <b>10</b>, in seconds. The minimum value is <b>1</b> and the maximum value is <b>2147483647</b>. It specifies the interval for updating the domain name resolution result and takes effect only when <b>parseCandidatesByDomain</b> is set to <b>true</b>. After it takes effect, the domain name resolution update time involved in the URL is set to a specified value and the domain name resolution result is periodically updated in the asynchronous thread. Driver obtains domain name resolution results only from the DNS service in the environment where the application is located. To ensure that domain name binding changes can be detected by Driver in a timely manner, the DNS service in the environment where the application is located</p> </li> </ul>

Parameter	Description
	<p>must ensure that the domain name binding changes take effect in a timely manner.</p> <ul style="list-style-type: none"> <li>● <b>oracleCompatible</b>: string type. The default value is <b>false</b>. This is used to set the ORA-compatible features of driver APIs. The options are as follows:               <ol style="list-style-type: none"> <li>1. <b>true</b> or <b>on</b>: All ORA-compatible features of drivers are enabled.</li> <li>2. <b>false</b> or <b>off</b>: All ORA-compatible features of drivers are disabled.</li> <li>3. <b>"tag1,tag2,tag3"</b>: Some ORA-compatible features of drivers are enabled. You can configure one or more tags separated by commas (,). Each tag corresponds to an ORA-compatible feature. Currently, the following tags are supported:                   <ul style="list-style-type: none"> <li>- <b>getProcedureColumns</b>: The behavior of the DatabaseMetaData#getProcedureColumns API is compatible with behavior ORA.</li> <li>- <b>getCallableStatementResults</b>: The database is compatible with ORA when the getLong, getInt, getShort, and getByte APIs of CallableStatement are called. When the registered output parameter type is java.sql.Types#NUMERIC, you can call the getLong, getInt, getShort, and getByte APIs of CallableStatement to receive the value of <b>out</b>. The SQLException message is displayed only when the value of <b>out</b> exceeds the value range of the Java numeric data type.</li> <li>- <b>batchInsertAffectedRows</b>: After reWriteBatchedInserts is enabled, the result returned by the Statement#executeBatch API is compatible with behavior ORA.</li> </ul> </li> </ol> </li> <li>● <b>printSqlInLog</b>: Boolean type. It specifies whether to output SQL statements in exception information or logs. The value is <b>true</b> (enabled) or <b>false</b> (disabled). The default value is <b>true</b>.</li> <li>● <b>useGsClobBlobClass</b>: Boolean type. The default value is false, which means that speculative execution for Reduce tasks is disabled.               <ul style="list-style-type: none"> <li>- If this parameter is set to <b>true</b>, an object of the PGClob type is returned when the java.sql.ResultSet#getObject API is used to obtain the CLOB column. An object of the PGBlob type is returned when the blob field is obtained. When the metadata API java.sql.ResultSetMetaData#getColumnName is used to obtain the type name of a CLOB column, java.sql.Clob is returned. When the metadata API java.sql.ResultSetMetaData#getColumnName is used to obtain the type name of a BLOB column, java.sql.Blob is returned.</li> <li>- If this parameter is set to <b>false</b>, an object of the PGClob type is returned when the java.sql.ResultSet#getObject API is used to obtain the CLOB column. An object of the byte[] type is returned when the blob field is obtained. When the metadata API</li> </ul> </li> </ul>

Parameter	Description
	<p>java.sql.ResultSetMetaData#getColumnName is used to obtain the type name of a CLOB column, java.sql.CLOB is returned. When the metadata API java.sql.ResultSetMetaData#getColumnName is used to obtain the type name of a BLOB column, java.sql.BLOB is returned.</p> <ul style="list-style-type: none"> <li>● <b>sessionType</b>: string type. It specifies the type of the current session. An execution plan is generated based on the actual value. The value can be <b>singleNode</b>, <b>globalReadOnly</b>, or <b>normal</b>. The default value is <b>normal</b>. <ul style="list-style-type: none"> <li>– <b>normal</b>: default value, indicating a normal session. The plan is executed based on the original logic of the database.</li> <li>– <b>singleNode</b>: indicates a single-node session. The read and write operations of the session can be pushed down. In single-node session mode, a CN sends a one-to-one session to a specified target DN. This parameter must be used together with <b>execTargetNode</b>. Set <b>execTargetNode</b> to the name of the target DN. JDBC preferentially connects to the local CN corresponding to the target DN.</li> <li>– <b>globalReadOnly</b>: indicates a cross-node read-only session. In this mode, distributed plans are generated normally, but distributed write operations are prohibited.</li> </ul> </li> <li>● <b>execTargetNode</b>: string type. It must be used together with <b>sessionType</b>. This parameter is valid only when <b>sessionType</b> is set to <b>singleNode</b>. It indicates a DN in single-node session. The value range is the names of all DNs in the current cluster. If <b>sessionType</b> is set to <b>singleNode</b> and <b>execTargetNode</b> is not specified (the default value is <b>NULL</b>), the effect is the same as that when <b>sessionType</b> is set to <b>normal</b>.</li> <li>● <b>executeUpdateQueryable</b>: Boolean type. It specifies whether to enable the executeUpdate method to execute DQL statements. The value is <b>true</b> (enabled) or <b>false</b> (disabled). The default value is <b>false</b>. After this method is enabled, <b>-1</b> is returned when the executeUpdate method executes DQL statements, and a result set can be obtained. You are advised not to enable this parameter.</li> <li>● <b>dbMonitor</b>: Boolean type. It specifies whether to enable the connection monitoring function for JDBC. The default value is <b>false</b>. The value is <b>true</b> (enabled) or <b>false</b> (disabled). <ul style="list-style-type: none"> <li>– The connection monitoring function can monitor the following JDBC metrics: number of connections enabled by applications, number of connections disabled by applications, number of abnormal disconnections, database access volume, client CPU usage, memory usage, uplink and downlink transmission rates, and network delay, jitter, and packet loss rate between applications and databases.</li> <li>– If <b>dbMonitor</b> is set to <b>true</b>, <b>loggerLevel</b> is set to <b>debug</b>, and <b>loggerFile</b> is set to <b>filePath</b>, the client connection monitoring</li> </ul> </li> </ul>

Parameter	Description
	<p>information is recorded in the <b>filePath</b> log file. For details, see <a href="#">Example 4: Using the Database Connection Monitoring Function</a>.</p> <ul style="list-style-type: none"> <li> <b>enableStreamingQuery</b>: Boolean type. It specifies whether to enable the streaming read function. The default value is <b>false</b>. The value is <b>true</b> (enabled) or <b>false</b> (disabled). If this parameter is set to <b>true</b> and <code>statement.setFetchSize(Integer.MIN_VALUE)</code> or <code>statement.enableStreamingResults()</code> is used, the streaming read function is enabled.                     <p>Streaming read: All data is read at a time and sent to the socket buffer of a client until the buffer is full. If there is free space, the data continues to be sent to the buffer. At the same time, a JVM reads data from the buffer row by row. The advantage of streaming read is that the result is processed fast and no JVM memory overflow occurs. The disadvantage is that only backward traversal is supported. Before the data processing is complete or the statement is closed, other operations cannot be performed on the current connection. For details, see example 2 in <a href="#">Examples</a>.</p> </li> <li> <b>yearIsDateType</b>: Boolean type. The default value is <b>true</b> (enabled).                     <ul style="list-style-type: none"> <li><b>true</b>: An object of the date type is returned when the <code>java.sql.ResultSet#getObject</code> API is used to obtain columns of the year type. A date character string in the <code>yyyy-mm-dd</code> format is returned when the <code>java.sql.ResultSet#getString</code> API is used to obtain data. A year value is returned when the <code>java.sql.ResultSet#getInt/getLong/getShort</code> API is used to obtain data.</li> <li><b>false</b>: An object of the integer type is returned when the <code>java.sql.ResultSet#getObject</code> API is used to obtain columns of the year data type. A year character string is returned when the <code>java.sql.ResultSet#getString</code> API is used to obtain data. A year value is returned when the <code>java.sql.ResultSet#getInt/getLong/getShort</code> API is used to obtain data.</li> </ul> </li> <li> <b>setFloat</b>: Boolean type, indicating whether the OID transferred to the kernel is the OID of float4 when <code>setFloat</code> is called or <b>setObject</b> is set to <b>float</b>. The value <b>true</b> (enabled) indicates that the OID transferred to the kernel is float8. The value <b>false</b> (disabled) indicates that the OID transferred to the kernel is float4. The default value is <b>false</b>.                     </li> <li> <b>disasterToleranceCluster</b>: Boolean type. The default value is <b>false</b>. When the load balancing function is enabled and only DR cluster nodes are configured in the URL for the JDBC to connect to the database, it determines whether to connect to the primary cluster or the DR cluster. The value <b>true</b> indicates that load balancing is performed on DR cluster nodes. The value <b>false</b> indicates that load balancing is performed between primary cluster nodes.                     </li> </ul>
user	Database user.

Parameter	Description
password	Password of the database user.

## Examples

### Example 1: Connect to a database.

```
// gaussdbjdbc.jar is used as an example.
// The following code encapsulates database connection operations into an API. The database can then be
// connected using an authorized username and a password.
public static Connection getConnect(String username, String passwd)
{
    // Driver class.
    String driver = "com.huawei.gaussdb.jdbc.Driver";
    // Database connection descriptor.
    String sourceURL = "jdbc:gaussdb://$ip:$port/database";
    Connection conn = null;

    try
    {
        // Load the driver.
        Class.forName(driver);
    }
    catch( Exception e )
    {
        e.printStackTrace();
        return null;
    }

    try
    {
        // Create a connection.
        conn = DriverManager.getConnection(sourceURL, username, passwd);
        System.out.println("Connection succeed!");
    }
    catch(Exception e)
    {
        e.printStackTrace();
        return null;
    }

    return conn;
}
```

### Example 2: Use the Properties object as a parameter to create a connection.

```
// The following code uses the Properties object as a parameter to establish a connection:
public static Connection getConnectUseProp(String username, String passwd)
{
    // Driver class.
    String driver = "com.huawei.gaussdb.jdbc.Driver";
    // Database connection descriptor.
    String sourceURL = "jdbc:gaussdb://$ip:$port/database?autoBalance=true";
    Connection conn = null;
    Properties info = new Properties();

    try
    {
        // Load the driver.
        Class.forName(driver);
    }
    catch( Exception e )
```

```
{
    e.printStackTrace();
    return null;
}

try
{
    info.setProperty("user", username);
    info.setProperty("password", passwd);
    // Create a connection.
    conn = DriverManager.getConnection(sourceURL, info);
    System.out.println("Connection succeed!");
}
catch(Exception e)
{
    e.printStackTrace();
    return null;
}

return conn;
}
```

For details about common parameters, see [Common JDBC Parameters](#).

Example 3: Use the streaming read function.

```
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
// Establish a connection.
public static Connection getConnection(String username, String passwd) {
    String driver = "com.huawei.gaussdb.jdbc.Driver";
    String sourceURL = "jdbc:gaussdb://$ip.$port/database?enableStreamingQuery=true";
    Connection conn = null;
    try {
        // Load the driver.
        Class.forName(driver);
    } catch (Exception e) {
        e.printStackTrace();
        return null;
    }
    try {
        // Create a connection.
        conn = DriverManager.getConnection(sourceURL, username, passwd);
        System.out.println("Connection succeed!");
    } catch (Exception e) {
        e.printStackTrace();
        return null;
    }
    return conn;
}

// Execute common SQL statements to create table t_user.
public static void CreateTable(Connection conn) {
    Statement stmt = null;
    try {
        stmt = conn.createStatement();

        // Execute common SQL statements.
        stmt.executeUpdate("DROP TABLE IF EXISTS t_user");
        stmt.executeUpdate("CREATE TABLE t_user(id int, name VARCHAR(20));");
        stmt.close();
    } catch (SQLException e) {
        if (stmt != null) {
            try {
                stmt.close();
            }
        }
    }
}
```

```
        } catch (SQLException e1) {
            e1.printStackTrace();
        }
    }
    e.printStackTrace();
}

// Execute a prepared statement to insert data in batches.
public static void BatchInsertData(Connection conn) {
    PreparedStatement pst = null;

    try {
        // Generate a prepared statement.
        pst = conn.prepareStatement("INSERT INTO t_user VALUES (?,?)");
        for (int i = 0; i < 20; i++) {
            // Add parameters.
            pst.setInt(1, i + 1);
            pst.setString(2, "name " + (i + 1));
            pst.addBatch();
        }
        // Perform batch processing.
        pst.executeBatch();
        pst.close();
    } catch (SQLException e) {
        if (pst != null) {
            try {
                pst.close();
            } catch (SQLException e1) {
                e1.printStackTrace();
            }
        }
        e.printStackTrace();
    }
}

// Enable streaming read and query the content in the t_user table.
public static void StreamingQuery(Connection conn) {
    PreparedStatement pst = null;
    ResultSet resultSet = null;

    try {
        // Query all values in the t_user table.
        pst = conn.prepareStatement("SELECT * FROM t_user");
        pst.setFetchSize(Integer.MIN_VALUE); // Functions the same as
        ((PgStatement)statement).enableStreamingResults();
        resultSet = pst.executeQuery();
        while (resultSet.next()) {
            System.out.println(resultSet.getInt(1));
        }
    } catch (SQLException e) {
        throw new RuntimeException(e);
    } finally {
        if (resultSet != null) {
            try {
                resultSet.close();
            } catch (SQLException e) {
                throw new RuntimeException(e);
            }
        }
    }

    if (pst != null) {
        try {
            pst.close();
        } catch (SQLException e) {
            throw new RuntimeException(e);
        }
    }
}
}
```

```
}  
  
public static void main(String[] args) throws Exception {  
    String userName = System.getenv("EXAMPLE_USERNAME_ENV");  
    String password = System.getenv("EXAMPLE_PASSWORD_ENV");  
    Connection conn = getConnection(userName , password);  
  
    CreateTable(conn);  
  
    BatchInsertData(conn);  
  
    StreamingQuery(conn);  
  
    // Close the database connection.  
    try {  
        conn.close();  
    } catch (SQLException e) {  
        e.printStackTrace();  
    }  
}
```

#### NOTICE

When the streaming read function is used, you need to perform the `resultSet.close()` or `statement.close()` operation after the result set is used. Otherwise, the current connection is unavailable.

## 5.3.5 Connecting to a Database (Using SSL)

When establishing connections to the GaussDB server using JDBC, you can enable SSL connections to encrypt client and server communications for security of sensitive data transmission on the Internet.

This section describes how applications configure the client in SSL mode through JDBC. For details about how to configure the server, contact the administrator.

To use the method described in this section, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

### Configuring the Client

Upload the certificate files **client.key.pk8**, **client.crt**, and **cacert.pem** generated in section "Configuring the Server" to the client.

### Examples

Note: Select either example 1 or example 2.

```
// There will be security risks if the username and password used for authentication are directly written into  
// code. It is recommended that the username and password be stored in the configuration file or  
// environment variables (the password must be stored in ciphertext and decrypted when being used) to  
// ensure security.  
// In this example, the username and password are stored in environment variables. Before running this  
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local  
// environment (set the environment variable names based on the actual situation).  
import java.sql.Connection;  
import java.sql.DriverManager;  
import java.util.Properties;
```

```
public class SSL{
    public static void main(String[] args) {
        Properties urlProps = new Properties();
        String urls = "jdbc:gaussdb://$ip:$port/database";
        String userName = System.getenv("EXAMPLE_USERNAME_ENV");
        String password = System.getenv("EXAMPLE_PASSWORD_ENV");

        /**
         * ===== Example 1: Use the NonValidatingFactory channel.
         */
        urlProps.setProperty("sslfactory", "com.huawei.gaussdb.jdbc.ssl.NonValidatingFactory");
        urlProps.setProperty("user", userName);
        urlProps.setProperty("password", password);
        urlProps.setProperty("ssl", "true");
        /**
         * ===== Examples 2: Use a certificate.
         */
        urlProps.setProperty("sslcert", "client.crt");
        urlProps.setProperty("sslkey", "client.key.pk8");
        urlProps.setProperty("sslrootcert", "cacert.pem");
        urlProps.setProperty("user", userName);
        urlProps.setProperty("password", password);
        urlProps.setProperty("ssl", "true");
        /* sslmode can be set to require, verify-ca, or verify-full. Select one from the following three
examples.*/
        /* ===== Example 2.1: Set sslmode to require to use the certificate for authentication.
        */
        urlProps.setProperty("sslmode", "require");
        /* ===== Example 2.2: Set sslmode to verify-ca to use the certificate for
authentication. */
        urlProps.setProperty("sslmode", "verify-ca");
        /* ===== Example 2.3: Set sslmode to verify-full to use the certificate (in the Linux
OS) for authentication. */
        urls = "jdbc:gaussdb://world:8000/database";
        urlProps.setProperty("sslmode", "verify-full");

        try {
            Class.forName("com.huawei.gaussdb.jdbc.Driver").newInstance();
        } catch (Exception e) {
            e.printStackTrace();
        }
        try {
            Connection conn;
            conn = DriverManager.getConnection(urls,urlProps);
            conn.close();
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
/**
 * Note: Convert the client key to the DER format.
 * openssl pkcs8 -topk8 -outform DER -in client.key -out client.key.pk8 -nocrypt
 * openssl pkcs8 -topk8 -inform PEM -in client.key -outform DER -out client.key.der -v1 PBE-MD5-DES
 * openssl pkcs8 -topk8 -inform PEM -in client.key -outform DER -out client.key.der -v1 PBE-SHA1-3DES
 * The preceding algorithms are not recommended due to their low security.
 * If the customer needs to use a higher-level private key encryption algorithm, the following private key
encryption algorithms can be used after the BouncyCastle or a third-party private key is used to decrypt the
password package:
 * openssl pkcs8 -in client.key -topk8 -outform DER -out client.key.der -v2 AES128
 * openssl pkcs8 -in client.key -topk8 -outform DER -out client.key.der -v2 aes-256-cbc -iter 1000000
 * openssl pkcs8 -in client.key -topk8 -out client.key.der -outform Der -v2 aes-256-cbc -v2prf
hmacWithSHA512
 * Enable BouncyCastle: Introduce the bcpkix-jdk15on.jar package for projects that use JDBC. The
recommended version is 1.65 or later.
 */
}
```

## 5.3.6 Connecting to a Database (Using UDS)

The Unix domain socket (UDS) is used for data exchange between different processes on the same host. You can add **unixsocket** to obtain the socket factory.

The **unixsocket-core-XXX.jar**, **unixsocket-common-XXX.jar**, and **unixsocket-native-common-XXX.jar** JAR packages need to be referenced. In addition, you need to add **socketFactory=org.newsclub.net.unix.AFUNIXSocketFactory \$FactoryArg&socketFactoryArg= [path-to-the-unix-socket]** to the URL connection string.

Example:

```
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.util.Properties;

public class Test {
    public static void main(String[] args) {
        String driver = "com.huawei.gaussdb.jdbc.Driver";
        String userName = System.getenv("EXAMPLE_USERNAME_ENV");
        String password = System.getenv("EXAMPLE_PASSWORD_ENV");
        Connection conn;
        try {
            Class.forName(driver).newInstance();
            Properties properties = new Properties();
            properties.setProperty("user", userName);
            properties.setProperty("password", password);
            conn = DriverManager.getConnection("jdbc:gaussdb://$ip:$port/database?
socketFactory=org.newsclub.net.unix.AFUNIXSocketFactory$FactoryArg&socketFactoryArg=/data/tmp/s.PGSQL.8000",
properties);
            System.out.println("Connection Successful!");
            Statement statement = conn.createStatement();
            statement.executeQuery("select 1");
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

### NOTICE

- Set the **socketFactoryArg** parameter based on the actual path. The value must be the same as that of the GUC parameter **unix\_socket\_directory**.
- The connection host name must be set to **localhost**.

## 5.3.7 Running SQL Statements

### Running a Common SQL Statement

To enable an application to operate data in the database by running SQL statements (statements that do not need to transfer parameters), perform the following operations:

Operations such as SELECT, UPDATE, INSERT, and DELETE can be performed on XML data.

**Step 1** Create a statement object by calling the `createStatement` method in `Connection`.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Connection conn = DriverManager.getConnection("url",userName,password);
Statement stmt = conn.createStatement();
```

**Step 2** Run the SQL statement by calling the `executeUpdate` method in `Statement`.

```
int rc = stmt.executeUpdate("CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name VARCHAR(32));");
```

#### NOTE

- If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. The VACUUM operation is not supported in a transaction block. If one of the statements fails, the entire request will be rolled back.
- Use semicolons (;) to separate statements. Stored procedures, functions, and anonymous blocks do not support multi-statement execution. When `preferQueryMode` is set to **simple**, the statement does not execute the parsing logic, and the semicolons (;) cannot be used to separate statements in this scenario.
- The slash (/) can be used as the terminator for creating a single stored procedure, function, anonymous block, or package body. When `preferQueryMode` is set to **simple**, the statement does not execute the parsing logic, and the slash (/) cannot be used as the terminator in this scenario.
- When `prepareThreshold` is set to **1**, each SQL statement executed by the statement is cached because cached statements are not evicted by default (default value of `preferQueryMode`). As a result, memory bloat may occur. In this case, set `preferQueryMode` to **extendedCacheEverything** to evict cached statements.

**Step 3** Close the statement object.

```
stmt.close();
```

----End

### Running a Prepared SQL Statement

Prepared statements are compiled and optimized once but can be used in different scenarios by assigning multiple values. Using prepared statements improves execution efficiency. If you want to run a statement for several times, use a prepared statement. Perform the following operations:

**Step 1** Create a prepared statement object by calling the `prepareStatement` method in `Connection`.

```
PreparedStatement pstmt = con.prepareStatement("UPDATE customer_t1 SET c_customer_name = ?  
WHERE c_customer_sk = 1");
```

**Step 2** Set parameters by calling the `setShort` method in `PreparedStatement`.

```
pstmt.setShort(1, (short)2);
```

---

**CAUTION**

After binding parameters are set in `PreparedStatement`, a B packet or U packet is constructed and sent to the server when the SQL statement is executed. However, the maximum length of a B packet or U packet cannot exceed 1023 MB. If the data bound at a time is too large, an exception may occur because the packet is too long. Therefore, when setting binding parameters in `PreparedStatement`, you need to evaluate and control the size of the bound data to avoid exceeding the upper limit of the packet.

---

**Step 3** Run the prepared statement by calling the `executeUpdate` method in `PreparedStatement`.

```
int rowcount = pstmt.executeUpdate();
```

**Step 4** Close the prepared statement object by calling the `close` method in `PreparedStatement`.

```
pstmt.close();
```

----End

## Calling a Stored Procedure

To call an existing stored procedure by using JDBC in GaussDB, perform the following operations:

**Step 1** Create a call statement object by calling the `prepareCall` method in `Connection`.

```
// There will be security risks if the username and password used for authentication are directly written into  
// code. It is recommended that the username and password be stored in the configuration file or  
// environment variables (the password must be stored in ciphertext and decrypted when being used) to  
// ensure security.
```

```
// In this example, the username and password are stored in environment variables. Before running this  
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local  
// environment (set the environment variable names based on the actual situation).
```

```
String userName = System.getenv("EXAMPLE_USERNAME_ENV");  
String password = System.getenv("EXAMPLE_PASSWORD_ENV");  
Connection myConn = DriverManager.getConnection("url",userName,password);  
CallableStatement cstmt = myConn.prepareCall("{? = CALL TESTPROC(?,?,?)}");
```

**Step 2** Set parameters by calling the `setInt` method in `CallableStatement`.

```
cstmt.setInt(2, 50);  
cstmt.setInt(1, 20);  
cstmt.setInt(3, 90);
```

**Step 3** Register an output parameter by calling the `registerOutParameter` method in `CallableStatement`.

```
cstmt.registerOutParameter(4, Types.INTEGER); // Register an OUT parameter of the integer type.
```

**Step 4** Call the stored procedure by calling the `execute` method in `CallableStatement`.

```
cstmt.execute();
```

**Step 5** Obtain the output parameter by calling the `getInt` method in `CallableStatement`.

```
int out = cstmt.getInt(4); // Obtain the OUT parameter.
```

Example:

```
// The following stored procedure (containing the OUT parameter) has been created:  
create or replace procedure testproc  
(  
    psv_in1 in integer,  
    psv_in2 in integer,  
    psv_inout inout integer  
)  
as  
begin  
    psv_inout := psv_in1 + psv_in2 + psv_inout;  
end;  
/
```

**Step 6** Close the call statement by calling the `close` method in `CallableStatement`.

```
cstmt.close();
```

 **NOTE**

- Many database classes such as `Connection`, `Statement`, and `ResultSet` have a `close()` method. Close these classes after using their objects. Closing `Connection` will close all the related `Statements`, and closing a `Statement` will close its `ResultSet`.
- Some JDBC drivers support named parameters, which can be used to set parameters by name rather than sequence. If a parameter has the default value, you do not need to specify any parameter value but can use the default value directly. Even though the parameter sequence changes during a stored procedure, the application does not need to be modified. Currently, the GaussDB JDBC driver does not support this method.
- GaussDB does not support functions containing OUT parameters, or stored procedures and function parameters containing default values.
- When you bind parameters in `myConn.prepareStatement("{? = CALL TESTPROC(?,?,?)}")` during a stored procedure calling, you can bind parameters and register the first parameter as the output parameter according to the placeholder sequence or the fourth parameter as the output parameter according to the parameter sequence in the stored procedure. The preceding example registers the fourth parameter.

**NOTICE**

- If JDBC is used to call a stored procedure whose returned value is a cursor, the returned cursor cannot be used.
- A stored procedure and an SQL statement must be run separately.
- Output parameters must be registered for parameters of the `inout` type in the stored procedure.

----End

## Batch Processing

When a prepared statement processes multiple pieces of similar data, the database creates only one execution plan. This improves compilation and optimization efficiency. Perform the following operations:

**Step 1** Create a prepared statement object by calling the `prepareStatement` method in `Connection`.

```
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Connection conn = DriverManager.getConnection("url",userName,password);
PreparedStatement pstmt = conn.prepareStatement("INSERT INTO customer_t1 VALUES (?)");
```

**Step 2** Call `setShort` to set parameters for each piece of data, and call `addBatch` to confirm that the setting is complete.

```
pstmt.setShort(1, (short)2);
pstmt.addBatch();
```

**Step 3** Perform batch processing by calling the `executeBatch` method in `PreparedStatement`.

```
int[] rowcount = pstmt.executeBatch();
```

**Step 4** Close the prepared statement object by calling the `close` method in `PreparedStatement`.

```
pstmt.close();
```

#### NOTE

Do not terminate a batch processing action when it is ongoing; otherwise, database performance will deteriorate. Therefore, disable automatic commit during batch processing. Manually commit several rows at a time. The statement for disabling automatic commit is `conn.setAutoCommit(false)`.

----End

## Adding Single-Shard Execution Syntaxes to Statements

**Step 1** Set the `nodeName` parameter by calling `setClientInfo("nodeName","dnx")` in `Connection`.

```
Connection conn = getConnection();
conn.setClientInfo("nodeName","datanode1");
```

**Step 2** Execute the SQL statements by using the `executeQuery(String sql)` and `execute(String sql)` methods in `Statement` and the `executeQuery()` and `execute()` methods in `PreparedStatement`.

```
PreparedStatement pstmt = conn.prepareStatement("select * from test");
pstmt.execute();
pstmt.executeQuery();
Statement stmt=conn.createStatement();
stmt.execute("select * from test");
stmt.executeQuery("select * from test");
```

**Step 3** Set the parameter to an empty string to disable it.

```
conn.setClientInfo("nodeName","");
```

#### NOTICE

1. This function is adapted based on the single-shard execution function of the kernel. Therefore, before using this function, check whether the database kernel supports single-shard execution.
2. After the parameter is enabled, you must manually disable it. Otherwise, the execution of other query statements will be affected.
3. Once this parameter is enabled, all statements of the current connection will be executed on a specified DN.
4. After the parameter is enabled, the cache mechanism of PreparedStatement will be affected, cached statements will be cleared, and subsequent statements executed for single-shard queries will not be cached until the parameter is disabled.
5. The parameter is a connection parameter. Therefore, the parameter value takes effect once. The API cannot be used to execute the statements on different shards at the same time.

----End

## 5.3.8 Processing Data in a Result Set

### Setting a Result Set Type

Different types of result sets apply to different application scenarios. Applications select proper types of result sets based on the actual situation. Before running an SQL statement, you must create a statement object. Some methods of creating statement objects can set the type of a result set. [Table 5-5](#) lists result set parameters. The related Connection methods are as follows:

```
// Create a Statement object that will generate a ResultSet object with a specified type and concurrency.  
createStatement(int resultSetType, int resultSetConcurrency);  
  
// Create a PreparedStatement object. This object will generate a ResultSet object with a specified type and  
concurrency.  
prepareStatement(String sql, int resultSetType, int resultSetConcurrency);  
  
// Create a CallableStatement object. This object will generate a ResultSet object with a specified type and  
concurrency.  
prepareCall(String sql, int resultSetType, int resultSetConcurrency);
```

**Table 5-5** Result set types

Parameter	Description
resultSetType	<p>Type of a result set. There are three types of result sets:</p> <ul style="list-style-type: none"><li>• <b>ResultSet.TYPE_FORWARD_ONLY</b>: The ResultSet object can only be navigated forward. It is the default value.</li><li>• <b>ResultSet.TYPE_SCROLL_SENSITIVE</b>: You can view the modified result by scrolling to the modified row.</li><li>• <b>ResultSet.TYPE_SCROLL_INSENSITIVE</b>: The ResultSet object is insensitive to changes in the underlying data source.</li></ul> <p><b>NOTE</b> After a result set has obtained data from the database, the result set is insensitive to data changes made by other transactions, even if the result set type is <b>ResultSet.TYPE_SCROLL_SENSITIVE</b>. To obtain up-to-date data of the record pointed by the cursor from the database, call the <code>refreshRow()</code> method in a ResultSet object.</p>
resultSetConcurrency	<p>Concurrency type of a result set. There are two types of concurrency.</p> <ul style="list-style-type: none"><li>• <b>ResultSet.CONCUR_READ_ONLY</b>: Data in a result set cannot be updated except that an updated statement has been created in the result set data.</li><li>• <b>ResultSet.CONCUR_UPDATEABLE</b>: changeable result set. The concurrency type for a result set object can be updated if the result set is scrollable.</li></ul>

## Positioning a Cursor in a Result Set

ResultSet objects include a cursor pointing to the current data row. The cursor is initially positioned before the first row. The `next()` method moves the cursor to the next row from its current position. When a ResultSet object does not have a next row, a call to this method returns **false**. Therefore, this method is used in the while loop for result set iteration. However, the JDBC driver provides more cursor positioning methods for scrollable result sets, which allows positioning cursor in the specified row. [Table 5-6](#) describes these methods.

**Table 5-6** Methods for positioning in a result set

Method	Description
<code>next()</code>	Moves cursor to the next row from its current position.
<code>previous()</code>	Moves cursor to the previous row from its current position.
<code>beforeFirst()</code>	Places cursor before the first row.

Method	Description
afterLast()	Places cursor after the last row.
first()	Places cursor to the first row.
last()	Places cursor to the last row.
absolute(int)	Places cursor to a specified row.
relative(int)	Moves the row specified by the forward parameter (that is, the value is <b>1</b> , which is equivalent to next()) or backward parameter (that is, the value is <b>-1</b> , which is equivalent to previous()).

## Obtaining the Cursor Position from a Result Set

This cursor positioning method can be used to change the cursor position for a scrollable result set. The JDBC driver provides a method to obtain the cursor position in a result set. [Table 5-7](#) describes these methods.

**Table 5-7** Methods for obtaining a cursor position in a result set

Method	Description
isFirst()	Checks whether it is in the first row.
isLast()	Checks whether it is in the last row.
isBeforeFirst()	Checks whether it is before the first row.
isAfterLast()	Checks whether it is after the last row.
getRow()	Obtains its current row number.

## Obtaining Data from a Result Set

ResultSet objects provide a variety of methods to obtain data from a result set. [Table 5-8](#) describes the common methods for obtaining data. If you want to know more about other methods, see JDK official documents.

**Table 5-8** Common methods for obtaining data from a result set

Method	Description
int getInt(int columnIndex)	Retrieves the value of the column designated by a column index in the current row as an integer.

Method	Description
<code>int getInt(String columnLabel)</code>	Retrieves the value of the column designated by a column label in the current row as an integer.
<code>String getString(int columnIndex)</code>	Retrieves the value of the column designated by a column index in the current row as a string.
<code>String getString(String columnLabel)</code>	Retrieves the value of the column designated by a column label in the current row as a string.
<code>Date getDate(int columnIndex)</code>	Obtains date data by column index.
<code>Date getDate(String columnLabel)</code>	Retrieves the value of the column designated by a column name in the current row as a date.

### 5.3.9 Closing a Database Connection

After you complete required data operations in a database, close the database connection.

Call the close method to close the connection.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.  
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).  
String userName = System.getenv("EXAMPLE_USERNAME_ENV");  
String password = System.getenv("EXAMPLE_PASSWORD_ENV");  
Connection conn = DriverManager.getConnection(sourceURL, userName, password);  
conn.close();
```

### 5.3.10 Log Management

The GaussDB JDBC driver uses log records to help solve problems when the GaussDB JDBC driver is used in applications. GaussDB JDBC supports the following log management methods:

1. Use the SLF4J log framework for interconnecting with applications.
2. Use the JdkLogger log framework for interconnecting with applications.

SLF4J and JdkLogger are mainstream frameworks for Java application log management in the industry. For details about how to use these frameworks, see the official documents (SLF4J: <http://www.slf4j.org/manual.html>; JdkLogger: <https://docs.oracle.com/javase/8/docs/technotes/guides/logging/overview.html>).

Method 1: Use the SLF4J log framework for interconnecting with applications.

When a connection is set up, **logger=Slf4JLogger** is configured in the URL.

The SLF4J may be implemented by using Log4j or Log4j2. When the Log4j is used to implement the SLF4J, the following JAR packages need to be added: **log4j-\*.jar**, **slf4j-api-\*.jar**, and **slf4j-log4j12-\*.jar** (\* varies according to versions), and configuration file **log4j.properties**. In addition, the code for reading the configuration file must be added to the main program. If the Log4j2 is used to implement the SLF4J, you need to add the following JAR packages: **log4j-api-\*.jar**, **log4j-core-\*.jar**, **log4j-slf4j18-impl-\*.jar**, and **slf4j-api-1.7.25-alpha1.jar** (\* varies according to versions), and configuration file **log4j2.xml**.

This method supports log management and control. The SLF4J can implement powerful log management and control functions through related configurations in files. This method is recommended.

Example:

```
// Note: The location of the log4j.properties or log4j2.xml file must be specified during calling.
// Specify the location of log4j.properties.
//PropertyConfigurator.configure("log4j.properties");

// Specify log4j2.xml.
//ConfigurationSource source = new ConfigurationSource(new FileInputStream("log4j2.xml"));
//Configurator.initialize(null, source);

public static Connection GetConnection(String username, String passwd){

    String sourceURL = "jdbc:gaussdb://$ip:$port/database?logger=Slf4JLogger";
    Connection conn = null;

    try{
        // Create a connection.
        conn = DriverManager.getConnection(sourceURL,username,passwd);
        System.out.println("Connection succeed!");
    }catch (Exception e){
        e.printStackTrace();
        return null;
    }
    return conn;
}
```

The following is an example of the **log4j.properties** file:

```
log4j.logger.com.huawei.gaussdb.jdbc=ALL, log_gsjdbc

# Default file output configuration
log4j.appender.log_gsjdbc=org.apache.log4j.RollingFileAppender
log4j.appender.log_gsjdbc.Append=true
log4j.appender.log_gsjdbc.File=gsjdbc.log
log4j.appender.log_gsjdbc.Threshold=TRACE
log4j.appender.log_gsjdbc.MaxFileSize=10MB
log4j.appender.log_gsjdbc.MaxBackupIndex=5
log4j.appender.log_gsjdbc.layout=org.apache.log4j.PatternLayout
log4j.appender.log_gsjdbc.layout.ConversionPattern=%d %p %t %c - %m%n
log4j.appender.log_gsjdbc.File.Encoding = UTF-8
```

The following is an example of the **log4j2.xml** file:

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration status="OFF">
  <appenders>
    <Console name="Console" target="SYSTEM_OUT">
      <PatternLayout pattern="%d %p %t %c - %m%n"/>
    </Console>
    <File name="FileTest" fileName="test.log">
      <PatternLayout pattern="%d %p %t %c - %m%n"/>
    </File>
    <!-- JDBC driver log file output configuration. Log rewinding is supported. When the log size exceeds
    10 MB, a new file is created. The new file is named in the format of yyyy-mm-dd-file ID. -->
```

```
<RollingFile name="RollingFileJdbc" fileName="gsjdbc.log" filePattern="%d{yyyy-MM-dd}-%i.log">
  <PatternLayout pattern="%d %p %t %c - %m%n"/>
  <Policies>
    <SizeBasedTriggeringPolicy size="10 MB"/>
  </Policies>
</RollingFile>
</appenders>
<loggers>
  <root level="all">
    <appender-ref ref="Console"/>
    <appender-ref ref="FileTest"/>
  </root>
  <!-- JDBC driver logs. The log level is all. All logs can be viewed and exported to the gsjdbc.log file. -->
  <logger name="com.huawei.gaussdb.jdbc.Driver" level="all" additivity="false">
    <appender-ref ref="RollingFileJdbc"/>
  </logger>
</loggers>
</configuration>
```

Method 2: Use the JdkLogger log framework for interconnecting with applications.

The default Java logging framework stores its configurations in a file named **logging.properties**. Java installs the global configuration file in the folder in the Java installation directory. The **logging.properties** file can also be created and stored with a single project.

Configuration example of **logging.properties**:

```
# Specify the processing program as a file.
handlers= java.util.logging.FileHandler

# Specify the default global log level.
.level= ALL

# Specify the log output control standard.
java.util.logging.FileHandler.level=ALL
java.util.logging.FileHandler.pattern = gsjdbc.log
java.util.logging.FileHandler.limit = 500000
java.util.logging.FileHandler.count = 30
java.util.logging.FileHandler.formatter = java.util.logging.SimpleFormatter
java.util.logging.FileHandler.append=false
```

The following is a code example:

```
System.setProperty("java.util.logging.FileHandler.pattern","jdbc.log");
FileHandler fileHandler = new FileHandler(System.getProperty("java.util.logging.FileHandler.pattern"));
Formatter formatter = new SimpleFormatter();
fileHandler.setFormatter(formatter);
Logger logger = Logger.getLogger("com.huawei.gaussdb.jdbc");
logger.addHandler(fileHandler);
logger.setLevel(Level.ALL);
logger.setUseParentHandlers(false);
```

### Link trace function

The GaussDB JDBC driver provides the application-to-database link trace function to associate discrete SQL statements on the database side with application requests. This function requires application developers to implement the `com.huawei.gaussdb.jdbc.log.Tracer` API class and specify the permission name of the API implementation class in the URL.

URL example:

```
String URL = "jdbc:gaussdb://$ip:$port/database?traceInterfaceClass=xxx.xxx.xxx.OpenGaussTraceImpl";
```

The `com.huawei.gaussdb.jdbc.log.Tracer` API class is defined as follows:

```
public interface Tracer {
  // Retrieves the value of traceId.
```

```
String getTraceld();  
}
```

The following is an example of the `com.huawei.gaussdb.jdbc.log.Tracer` API implementation class:

```
import com.huawei.gaussdb.jdbc.log.Tracer;  
  
public class OpenGaussTraceImpl implements Tracer {  
    private static MDC mdc = new MDC();  
  
    private final String TRACE_ID_KEY = "traceld";  
  
    public void set(String traceld) {  
        mdc.put(TRACE_ID_KEY, traceld);  
    }  
  
    public void reset() {  
        mdc.clear();  
    }  
  
    @Override  
    public String getTraceld() {  
        return mdc.get(TRACE_ID_KEY);  
    }  
}
```

The following is an example of context mapping which is used to store **traceld** generated for different requests:

```
import java.util.HashMap;  
  
public class MDC {  
    static final private ThreadLocal<HashMap<String, String>> threadLocal = new ThreadLocal<>();  
  
    public void put(String key, String val) {  
        if (key == null || val == null) {  
            throw new IllegalArgumentException("key or val cannot be null");  
        } else {  
            if (threadLocal.get() == null) {  
                threadLocal.set(new HashMap<>());  
            }  
            threadLocal.get().put(key, val);  
        }  
    }  
  
    public String get(String key) {  
        if (key == null) {  
            throw new IllegalArgumentException("key cannot be null");  
        } else if (threadLocal.get() == null) {  
            return null;  
        } else {  
            return threadLocal.get().get(key);  
        }  
    }  
  
    public void clear() {  
        if (threadLocal.get() == null) {  
            return;  
        } else {  
            threadLocal.get().clear();  
        }  
    }  
}
```

Take the service **traceld** as an example. The prerequisite is that the table **test\_trace\_id (id int,name varchar(20))** is created.

```
String traceld = UUID.randomUUID().toString().replaceAll("-", "");  
OpenGaussTraceImpl openGaussTrace = new OpenGaussTraceImpl();
```

```
openGaussTrace.set(traceld);
Connection con = DriverManager.getConnection(url, user, password);
pstmt = con.prepareStatement("select * from test_trace_id where id = ?");
pstmt.setInt(1, 1);
pstmt.execute();
pstmt = con.prepareStatement("insert into test_trace_id values(?,?)");
pstmt.setInt(1, 2);
pstmt.setString(2, "test");
pstmt.execute();
openGaussTrace.reset();
```

#### NOTE

- When the link trace function is used, the link function at the application layer is guaranteed by services.
- The application must expose the API for obtaining **traceld** to the JDBC and configure the API implementation class to the JDBC connection string.
- SQL statements of the same request must use the same **traceld**.
- The value of **traceld** transferred by the application cannot exceed 32 bytes. Otherwise, the extra bytes will be truncated.

## 5.3.11 Examples: Common Operations

### Example 1: Creating a Database Connection, Creating a Table, and Inserting Data

This example illustrates how to develop applications based on the JDBC API provided by GaussDB. Before executing the example, load the driver. For details about how to obtain and load the driver, see [JDBC Packages, Driver Classes, and Environment Classes](#).

```
// DBTest.java
/* gaussdbjdbc.jar is used as an example. */
// This example illustrates the main processes of JDBC-based development, covering database connection
// creation, table creation, and data insertion.
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.CallableStatement;
import java.sql.Types;

public class DBTest {

    // Create a database connection.
    public static Connection GetConnection(String username, String passwd) {
        String driver = "com.huawei.gaussdb.jdbc.Driver";
        String sourceURL = "jdbc:gaussdb://$ip:$port/database";
        Connection conn = null;
        try {
            // Load the database driver.
            Class.forName(driver).newInstance();
        } catch (Exception e) {
            e.printStackTrace();
            return null;
        }
    }

    try {
        stmt = conn.createStatement();
        // Create a function to return the sum of the three input values.
        stmt.execute("create or replace procedure testproc \n" +
            "\n" +
            "    psv_in1 in integer,\n" +
            "    psv_in2 in integer,\n" +
            "    psv_inout inout integer\n" +
            ")\n" +
            "as\n" +
            "begin\n" +
            "    psv_inout := psv_in1 + psv_in2 + psv_inout;\n" +
            "end;\n" +
            "/");
    } catch (SQLException e) {
        throw new RuntimeException(e);
    } finally {
        if (stmt != null) {
            try {
                stmt.close();
            } catch (SQLException e) {
                throw new RuntimeException(e);
            }
        }
    }
}

// Run a stored procedure.
public static void ExecCallableSQL(Connection conn) {
    CallableStatement cstmt = null;
    try {
        // The stored procedure TESTPROC must be created in advance.
        cstmt=conn.prepareCall("{? = CALL TESTPROC(?,?,?)}");
        cstmt.setInt(2, 50);
        cstmt.setInt(1, 20);
        cstmt.setInt(3, 90);
        cstmt.registerOutParameter(4, Types.INTEGER); // Register an OUT parameter of the integer type.
        cstmt.execute();
        int out = cstmt.getInt(4); // Obtain the OUT parameter.
        System.out.println("The CallableStatment TESTPROC returns:"+out);
        cstmt.close();
    } catch (SQLException e) {
        if (cstmt != null) {
            try {
                cstmt.close();
            } catch (SQLException e1) {
                e1.printStackTrace();
            }
        }
    }
}
```

```
    }
    e.printStackTrace();
  }
}

/**
 * Main process. Call static methods one by one.
 * @param args
 */
public static void main(String[] args) {
    // Create a database connection.
    String userName = System.getenv("EXAMPLE_USERNAME_ENV");
    String password = System.getenv("EXAMPLE_PASSWORD_ENV");
    Connection conn = GetConnection(userName, password);

    // Create a table.
    CreateTable(conn);

    // Insert data in batches.
    BatchInsertData(conn);

    // Run a prepared statement to update data.
    ExecPreparedSQL(conn);

    // Create a stored procedure.
    CreateCallable(conn);

    // Run a stored procedure.
    ExecCallableSQL(conn);

    // Close the database connection.
    try {
        conn.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
}
```

## Example 2: High Client Memory Usage

In this example, **setFetchSize** adjusts the memory usage of the client by using the database cursor to obtain server data in batches. It may increase network interaction and damage some performance.

The cursor is valid within a transaction. Therefore, disable automatic commit and then manually commit the code.

```
// Disable automatic commit.
conn.setAutoCommit(false);

// Create a table.
Statement st = conn.createStatement();
st.execute("create table mytable (cal1 int);");

// Insert 200 rows of data into the table.
PreparedStatement pstmt = conn.prepareStatement("insert into mytable values (?)");
for (int i = 0; i < 200; i++) {
    pstmt.setInt(1, i + 1);
    pstmt.addBatch();
}
pstmt.executeBatch();
conn.commit();
pstmt.close();
```

```
// Open the cursor and obtain 50 rows of data each time.
st.setFetchSize(50);
ResultSet rs = st.executeQuery("SELECT * FROM mytable");
while (rs.next()){
    System.out.println("a row was returned.");
}
conn.commit();
rs.close();

// Disable the server cursor.
st.setFetchSize(0);
rs = st.executeQuery("SELECT * FROM mytable");
while (rs.next()){
    System.out.println("many rows were returned.");
}
conn.commit();
rs.close();

// Close the statement.
st.close();
conn.close();
```

Enable automatic commit.

```
conn.setAutoCommit(true);
```

### Example 3: Using Common Data Types

```
// Prerequisites
String createsql = "create table if not exists t_bit(col_bit bit, col_bit1 int)";
Statement stmt = conn.createStatement();
stmt.execute(createsql);
stmt.close();
// Example of using the bit type. Note that the value range of the bit type is [0,1].
Statement st = conn.createStatement();
String sqlstr = "create or replace function fun_1()\n" +
    "returns bit AS $$\n" +
    "select col_bit from t_bit limit 1;\n" +
    "$$\n" +
    "LANGUAGE SQL;";
st.execute(sqlstr);
CallableStatement c = conn.prepareCall("{ ? = call fun_1() }");
// Register the output type, which is a bit string.
c.registerOutParameter(1, Types.BIT);
c.execute();
// Use the Boolean type to obtain the result.
System.out.println(c.getBoolean(1));

// Example of using the float8 type
st.execute("create table if not exists t_float(col1 float8,col2 int)");
PreparedStatement pstmt = conn.prepareStatement("insert into t_float values(?)");
pstmt.setDouble(1,123456.123);
pstmt.execute();
pstmt.close();

// Example of using the function whose return value is of the float8 type.
st.execute("create or replace function func_float() " +
    "return float8 " +
    "as declare " +
    "var1 float8; " +
    "begin " +
    " select col1 into var1 from t_float limit 1; " +
    " return var1; " +
    "end;");
CallableStatement cs = conn.prepareCall("{? = call func_float()}");
cs.registerOutParameter(1,Types.DOUBLE);
cs.execute();
System.out.println(cs.getDouble(1));
st.close();
```

## Example 4: Using the Database Connection Monitoring Function

This example demonstrates how to use the connection monitoring function of the JDBC driver.

```
// gaussdbjdbc.jar is used as an example.
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;

public class DBMonitorTest {
    // Create a database connection.
    public static void main(String[] args){
        String driver = "com.huawei.gaussdb.jdbc.Driver";
        String username = System.getenv("EXAMPLE_USERNAME_ENV");
        String passwd = System.getenv("EXAMPLE_PASSWORD_ENV");
        String sourceURL
            = "jdbc:gaussdb://$ip:$port/database?
dbMonitor=true&loggerLevel=debug&loggerFile=dbMonitor.log";
        try {
            // Load the database driver.
            Class.forName(driver).newInstance();
        } catch (Exception e) {
            e.printStackTrace();
        }

        Connection conn = null;
        Statement statement = null;
        try {
            // Create a database connection.
            conn = DriverManager.getConnection(sourceURL, username, passwd);

            // Create a table.
            statement = conn.createStatement();
            String createTableQuery = "CREATE TABLE IF NOT EXISTS mytable (id INT PRIMARY KEY, name
VARCHAR(50))";
            statement.executeUpdate(createTableQuery);

            // Insert data.
            String insertQuery = "INSERT INTO mytable (id, name) VALUES (1, 'John')";
            statement.executeUpdate(insertQuery);

            // Query data.
            String selectQuery = "SELECT * FROM mytable ";
            ResultSet resultSet = statement.executeQuery(selectQuery);
            while (resultSet.next()) {
                int id = resultSet.getInt("id");
                String name = resultSet.getString("name");
                System.out.println("id: " + id + ", name: " + name);
            }

            // Delete the table.
            String dropTableQuery = "DROP TABLE IF EXISTS mytable";
            statement.executeUpdate(dropTableQuery);
        } catch (SQLException e) {
            e.printStackTrace();
        } finally {
            try {
                if (statement != null) {
                    statement.close();
                }
            }
        }
    }
}
```

```
    }
    if (conn != null) {
        conn.close();
    }
} catch (SQLException e) {
    e.printStackTrace();
}
}

try {
    Thread.sleep(10000);
} catch (InterruptedException e) {
    throw new RuntimeException(e);
}
}
```

You can view the following connection monitoring information in the **dbMonitor.log** file:

```
Nov 23, 2023 10:30:54 AM com.huawei.gaussdb.jdbc.qos.DataProcess saveQosResult

## Example 5: Obtaining the Driver Version

```
Driver.getGSVersion();
```

### 5.3.12 Example: Retrying SQL Queries for Applications

If the primary DN is faulty and cannot be restored within 10s, the standby DN is automatically promoted to primary to ensure the normal running of the GaussDB cluster. Jobs running during the failover will fail and those started after the failover will not be affected. To prevent upper-layer services from being affected by the DN failover, refer to the following example to construct an SQL retry mechanism at the service layer. Before executing the example, load the driver. For details about how to obtain and load the driver, see [JDBC Packages, Driver Classes, and Environment Classes](#).

```
// gaussdbjdbc.jar is used as an example.
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;
```

```
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;

class ExitHandler extends Thread {
    private Statement cancel_stmt = null;

    public ExitHandler(Statement stmt) {
        super("Exit Handler");
        this.cancel_stmt = stmt;
    }
    public void run() {
        System.out.println("exit handle");
        try {
            this.cancel_stmt.cancel();
        } catch (SQLException e) {
            System.out.println("cancel query failed.");
            e.printStackTrace();
        }
    }
}

public class SQLRetry {
    // Create a database connection.
    public static Connection GetConnection(String username, String passwd) {
        String driver = "com.huawei.gaussdb.jdbc.Driver";
        String sourceURL = "jdbc:gaussdb://$p:$port/database";
        Connection conn = null;
        try {
            // Load the database driver.
            Class.forName(driver).newInstance();
        } catch (Exception e) {
            e.printStackTrace();
            return null;
        }

        try {
            // Create a database connection.
            conn = DriverManager.getConnection(sourceURL, username, passwd);
            System.out.println("Connection succeed!");
        } catch (Exception e) {
            e.printStackTrace();
            return null;
        }

        return conn;
    }

    // Execute common SQL statements to create the jdbc_test1 table.
    public static void CreateTable(Connection conn) {
        Statement stmt = null;
        try {
            stmt = conn.createStatement();

            Runtime.getRuntime().addShutdownHook(new ExitHandler(stmt));

            // Execute common SQL statements.
            int rc2 = stmt
                .executeUpdate("DROP TABLE if exists jdbc_test1;");

            int rc1 = stmt
                .executeUpdate("CREATE TABLE jdbc_test1(col1 INTEGER, col2 VARCHAR(10));");

            stmt.close();
        } catch (SQLException e) {
            if (stmt != null) {
                try {
                    stmt.close();
                }
            }
        }
    }
}
```

}
```

### 5.3.13 Example: Logic Replication Code

The example demonstrates how to use the logical replication function through the JDBC APIs. Before executing the example, load the driver. For details about how to obtain and load the driver, see [JDBC Packages, Driver Classes, and Environment Classes](#).

For details about the configuration options of logical replication, see section "Logical Replication > Logical Decoding" in *Feature Guide*. In addition, the following configuration items are added for streaming decoding tools such as JDBC:

1. Decoding thread concurrency

Set **parallel-decode-num** to specify the number of decoder threads for parallel decoding. The value is an integer ranging from 1 to 20. The value **1** indicates that decoding is performed based on the original serial logic. Other values indicate that parallel decoding is enabled. The default value is **1**. When this parameter is set to **1**, do not configure the following options: **decode-style**, **sending-batch**, and **parallel-queue-size**.

2. Decoding format

Configure **decode-style** to specify the decoding format. The value can be 'j', 't' or 'b' of the char type, indicating the JSON, text, or binary format, respectively. The default value is 'b', indicating binary decoding. This option is set only when parallel decoding is allowed and binary decoding is supported only in the parallel decoding scenario. For the JSON and text formats corresponding to the binary format, in the decoding result sent in batches, the uint32 consisting of the first four bytes of each decoding statement indicates the total number of bytes of the statement (the four bytes occupied by the uint32 are excluded, and **0** indicates that the decoding of this batch ends). The 8-byte uint64 indicates the corresponding LSN (**begin** corresponds to **first\_lsn**, **commit** corresponds to **end\_lsn**, and other values correspond to the LSN of the statement).

 NOTE

The binary encoding rules are as follows:

1. The first four bytes represent the total number of bytes of the decoding result of statements following the statement-level delimiter letter P (excluded) or the batch end character F (excluded). If the value is 0, the decoding of this batch ends.
2. The next eight bytes (uint64) indicate the corresponding LSN (**begin** corresponds to **first\_lsn**, **commit** corresponds to **end\_lsn**, and other values correspond to the LSN of the statement).
3. The next one-byte letter can be **B**, **C**, **I**, **U**, or **D**, representing BEGIN, COMMIT, INSERT, UPDATE, or DELETE.
4. If **B** is used in the step 3:
  1. The next eight bytes (uint64) indicate the CSN.
  2. The next eight bytes (uint64) indicate **first\_lsn**.
  3. (Optional) If the next one-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length for committing the transaction. The following characters with the same length are the timestamp character string.
  4. (Optional) If the next one-byte letter is **N**, the following four bytes (uint32) indicate the length of the transaction username. The following characters with the same length are the transaction username.
5. If **C** is used in the step 3:
  1. (Optional) If the next one-byte letter is **X**, the following eight bytes (uint64) indicate the XID.
  2. (Optional) If the next one-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length. The following characters with the same length are the timestamp character string.
  3. When logs are sent in batches, decoding results of other transactions may still exist after a COMMIT log is decoded. If the next 1-byte letter is **P**, the batch still needs to be decoded. If the letter is **F**, the batch decoding ends.
6. If **I**, **U**, or **D** is used in the step 3:
  1. The following two bytes (uint16) indicate the length of the schema name.
  2. The schema name is read based on the preceding length.
  3. The following two bytes (uint16) indicate the length of the table name.
  4. The table name is read based on the preceding length.
  5. (Optional) If the next one-byte letter is **N**, it indicates a new tuple. If the letter is **O**, it indicates an old tuple. In this case, the new tuple is sent first.
    1. The following two bytes (uint16) indicate the number of columns to be decoded for the tuple, which is recorded as **attrnum**.
    2. The following procedure is repeated for *attrnum* times.
      1. The next two bytes (uint16) indicate the length of the column name.
      2. The column name is read based on the preceding length.
      3. The following four bytes (uint32) indicate the OID of the current column type.
      4. The next four bytes (uint32) indicate the length of the value (stored in the character string format) in the current column. If the value is **0xFFFFFFFF**, it indicates null. If the value is 0, it indicates a character string whose length is 0.
      5. The column value is read based on the preceding length.
  6. Because there may still be a decoding statement after, if the next one-byte letter is **P**, it indicates that the batch still needs to be decoded, and if the next one-byte letter is **F**, it indicates that decoding of the batch ends.

3. Decoding only on the standby node  
Configure the **standby-connection** option to specify whether to perform decoding only on the standby node. The value is of the Boolean type (**0** or **1**). The value **true** (or **1**) indicates that only the standby node can be connected for decoding. When the primary node is connected for decoding, an error is reported and the system exits. The value **false** (or **0**) indicates that there is no restriction. The default value is **false** (or **0**).
4. Batch sending  
Configure **sending-batch** to specify whether to send results in batches. The value is an integer ranging from 0 to 1. The value **0** indicates that decoding results are sent one by one. The value **1** indicates that decoding results are sent in batches when the accumulated size of decoding results reaches 1 MB. The default value is **0**. This parameter can be set only during parallel decoding. In the scenario where batch sending is enabled, if the decoding format is 'j' or 't', before each original decoding statement, a uint32 type is added indicating the length of the decoding result (excluding the current uint32 type), and a uint64 type is added, indicating the LSN corresponding to the current decoding result.
5. Length of the parallel decoding queue  
Configure **parallel-queue-size** to specify the length of the queue for interaction among parallel logical decoding threads. The value ranges from 2 to 1024 and must be a power of 2. The default value is **128**. The queue length is positively correlated with the memory usage during decoding.
6. Memory threshold for logical decoding  
The **max-txn-in-memory** configuration item specifies the memory threshold for caching the intermediate decoding result of a single transaction, in MB. The value range is [0,100] for serial decoding. The default value is **0**, indicating that the memory usage is not controlled. For parallel decoding, the value range is [0,*max\_process\_memory* × 25%]. The default value is *max\_process\_memory*/4/1024, where **1024** indicates the conversion from KB to MB. The value **0** indicates that this memory control is disabled. The **max-reorderbuffer-in-memory** configuration item specifies the memory threshold for caching intermediate decoding results of all transactions, in GB. The value range is [0,100] for serial decoding. The default value is **0**, indicating that the memory usage is not controlled. For parallel decoding, the value range is [0, *max\_process\_memory* × 50%]. The default value is *max\_process\_memory*/2/1048576, where **1048576** indicates the conversion from KB to GB. The value **0** indicates that this memory control is disabled. When the memory usage exceeds the threshold, intermediate decoding results are written into a temporary file during decoding, affecting the logical decoding performance.
7. Logical decoding sending timeout threshold  
The **sender-timeout** configuration item specifies the heartbeat timeout threshold between the kernel and client. If no message is received from the client within the period, the logical decoding stops and disconnects from the client. The unit is ms, and the value range is [0,2147483647]. The default value depends on the value of the GUC parameter **logical\_sender\_timeout**.
8. User blacklist options for logical decoding

Use the user blacklist for logical decoding. The transaction operations of blacklisted users are filtered from the logical decoding result. The options are as follows:

- a. **exclude-userids**: specifies the OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not check whether the user OIDs exist. The OIDs of the same service user on different DNs may be different. Therefore, the OID of the service user on each DN needs to be transferred for logical decoding of directly connected DNs in distributed mode. Otherwise, the logical decoding results of some DNs may be filtered while those of some DNs are not filtered.
  - b. **exclude-users**: specifies blacklisted usernames. Multiple usernames are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.
  - c. **dynamic-resolution**: specifies whether to dynamically parse blacklisted usernames. The default value is **true**. If the parameter is set to **false**, an error is reported and the logical decoding exits when the decoding detects that the user does not exist in blacklist **exclude-users**. If the parameter is set to **true**, decoding continues when it detects that the user does not exist in blacklist **exclude-users**.
9. Output options for transaction logic logs
    - a. **include-xids**: specifies whether the BEGIN logical log of a transaction outputs the transaction ID. The default value is **true**.
    - b. **include-timestamp**: specifies whether the BEGIN logical log of a transaction outputs the time when the transaction is committed. The default value is **false**.
    - c. **include-user**: specifies whether the BEGIN logical log of a transaction outputs the username of the transaction. The default value is **false**. The username of a transaction refers to the authorized user, that is, the login user who executes the session corresponding to the transaction. The username does not change during the execution of the transaction.
  10. By default, **socketTimeout** of the logical decoding connection is set to **10s**. When the primary node is overloaded during decoding on the standby node, the connection may be closed due to timeout. You can set **withStatusInterval(10000,TimeUnit.MILLISECONDS)** to adjust the timeout interval.
  11. Heartbeat log output option

**enable-heartbeat**: specifies whether to generate heartbeat logs. The default value is **false**.

 NOTE

If the heartbeat log output option is enabled, heartbeat logs will be generated. The heartbeat logs can be parsed as follows: For a binary heartbeat log message, it starts with a character 'h' and then the heartbeat log content: an 8-byte uint64 string, an 8-byte uint64 string, and an 8-byte int64 string. For the first 8-byte uint64 string, in the decoding scenario where DNs are directly connected, this string is an LSN, indicating the end position of the WAL read when the heartbeat logical log is sent; in the decoding scenario where distributed strong consistency is required, this string is a CSN, indicating the decoding log transaction CSN that has been sent when the heartbeat logical log is sent. For the second 8-byte uint64 string, in the decoding scenario where DNs are directly connected, this string is an LSN, indicating the location of the WAL that has been flushed to disks when the heartbeat logical log is sent; in the decoding scenario where distributed strong consistency is required, this string is a CSN, indicating the CSN to be obtained by the next transaction committed by the cluster. The last 8-byte int64 string indicates the generation timestamp (starting from January 1, 1970) of the latest decoded transaction log or checkpoint log. Then, it ends with character 'F'. TEXT/JSON heartbeat log messages that are sent in batches end with '0'. There is no such terminator for each TEXT/JSON heartbeat log message. The message content is transmitted in big-endian mode. The following figure shows the format. (In consideration of forward compatibility, the LSN naming mode is retained. The actual meaning depends on the specific scenario.)

The decoding performance (Xlog consumption) is greater than or equal to 100 Mbps in the following standard parallel decoding scenario: 16-core CPU, 128 GB memory, network bandwidth > 200 Mbps, 10 to 100 columns in a table, 0.1 KB to 1 KB data in a single row, INSERT as main DML operations, less than 4096 statements in a single transaction, **parallel-decode-num** set to **8**, decoding format as 't', and batch sending function enabled. To ensure that the decoding performance meets the requirements and minimize the impact on services, you are advised to set up only one parallel decoding connection on a standby node to ensure that the CPU, memory, and bandwidth resources are sufficient.

 CAUTION

The logical replication class PGReplicationStream is a non-thread-safe class. Concurrent calls may cause data exceptions.

```
// gaussdbjdbc.jar is used as an example.
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
// Logical replication function example: file name, LogicalReplicationDemo.java
// Prerequisite: Add the IP address of the JDBC user machine to the database whitelist. Add the following content to gs_hba.conf:
// Assume that the IP address of the JDBC user machine is 10.10.10.10.
//host all all 10.10.10.10/32 sha256
//host replication all 10.10.10.10/32 sha256

## 5.3.14 Example: Parameters for Connecting to the Database in Different Scenarios

### NOTE

In the example, **host:port** represents a node, where **host** indicates the name or IP address of the server where the database resides, and **port** indicates the port number of the server where the database resides.

## DR

A customer has two database clusters. Cluster A is the production cluster, and cluster B is the DR cluster. When the customer performs a DR failover, cluster A becomes the DR cluster, and cluster B becomes the production cluster. In this case, to avoid application restart or re-release caused by configuration file modification, the customer can write clusters A and B to the connection string when initializing the configuration file. In this case, if the primary cluster cannot be connected, the driver attempts to connect to the DR cluster. Assume that cluster A is {node1,node2,node3} and cluster B is {node4,node5,node6}.

Take the dual-cluster Dorado as an example. To connect to the new primary cluster only after the primary/standby switchover, you can set the URL as follows:

```
jdbc:gaussdb://node1,node2,node3,node4,node5,node6/database
```

## Load Balancing

A customer has a database cluster that contains the following nodes: {node1,node2,node3,node4,node5,node6,node7,node8,node9,node10,node11,node12}.

1. The customer establishes 120 persistent connections in application A and expects that the connections on application A can be evenly distributed on each node in the current cluster. The URL can be configured as follows:  

```
jdbc:gaussdb://node1,node2,node3/database?autoBalance=true
```
2. The customer develops two applications B and C and wants the three applications to be evenly distributed on specified nodes. For example, the connections of application A are distributed on {node1,node2,node3,node4}. The connections of application B are distributed on {node5,node6,node7,node8}. The connections of application C are distributed on {node9,node10,node11,node12}. The URLs can be configured as follows (If the first four nodes in the URL cannot be connected, the application connects to the fifth node based on the information in the pgxc\_node system catalog. All available nodes in the cluster are connected in polling mode.):

Application A: **`jdbc:gaussdb://node1,node2,node3,node4,node5/database?autoBalance=priority4`**

Application B: **`jdbc:gaussdb://node5,node6,node7,node8,node9/database?autoBalance=priority4`**

Application C: **`jdbc:gaussdb://node9,node10,node11,node12,node1/database?autoBalance=priority4`**

3. The customer develops more applications, uses the same connection configuration string, and expects that the application connections can be evenly distributed on each node in the cluster. The URL can be configured as follows:

```
jdbc:gaussdb://node1,node2,node3,node4/database?autoBalance=shuffle
```

4. The customer has developed some applications and wants to establish connections in single-node session mode. The URL can be configured as follows:

```
jdbc:gaussdb://node1,node2,node3,node4/database?  
sessionType=singleNode&execTargetNode=your_dn_name
```

5. If the customer does not want to use the load balancing function, configure the URL as follows:

```
jdbc:gaussdb://node1/database
```

Or

```
jdbc:gaussdb://node1/database?autoBalance=false
```

#### NOTE

When the **autoBalance** parameter is enabled, the interval for the JDBC to refresh the available CN list is 10s by default. You can use **refreshCNIPListTime** to set the interval:

```
jdbc:gaussdb://node1,node2,node3,node4/database?autoBalance=true&refreshCNIPListTime=3
```

## Log Diagnosis

If you encounter slow data import or some errors that are difficult to analyze, the trace log function can be enabled for diagnosis. The URL can be configured as follows:

```
jdbc:gaussdb://node1/database?loggerLevel=trace
```

## High Performance

A customer may execute the same SQL statement for multiple times with different input parameters. To improve the execution efficiency, the **prepareThreshold** parameter can be enabled to avoid repeatedly generating execution plans. The URL can be configured as follows:

```
jdbc:gaussdb://node1/database?prepareThreshold=5
```

A customer queries 10 million data records at a time. To prevent memory overflow caused by simultaneous return of the data records, the **defaultRowFetchSize** parameter can be used. The URL can be configured as follows:

```
jdbc:gaussdb://node1/database?defaultRowFetchSize=50000
```

A customer needs to insert 10 million data records in batches. To improve efficiency, the **batchMode** parameter can be used. The URL can be configured as follows:

```
jdbc:gaussdb://node1/database?batchMode=on
```

### 5.3.15 JDBC Interface Reference

This section describes common JDBC interfaces. For more interfaces, check JDK1.8 (software package) and JDBC 4.2.

### 5.3.15.1 java.sql.Connection

java.sql.Connection is an API for connecting to a database.

**Table 5-9** Support status for java.sql.Connection

Method Name	Description	Return Type	throws	JDBC 4 Supported or Not
abort(Executor executor)	Aborts an open connection.	void	SQLException	Yes
clearWarnings()	Clears all warnings reported for this connection object.	void	SQLException	Yes
close()	Releases the database and JDBC resources of this connection object immediately instead of waiting for them to be automatically released.	void	SQLException	Yes
commit()	Makes all changes made since the last commit/rollback permanent and releases any database locks currently held by this connection object. This method should be used only when the autocommit mode is disabled.	void	SQLException	Yes
createArrayOf(String typeName, Object[] elements)	Creates an array object using this factory method.	Array	SQLException	Yes
createBlob()	Constructs an object that implements the BLOB API. The returned object does not contain data initially. The setBinaryStream and setBytes methods of the BLOB API can be used to add data to BLOBs.	Blob	SQLException	Yes
createClob()	Constructs an object that implements the CLOB API. The returned object does not contain data initially. The setAsciiStream, setCharacterStream, and setString methods of the CLOB API can be used to add data to CLOBs.	Clob	SQLException	Yes

Method Name	Description	Return Type	throws	JDBC 4 Supported or Not
createSQLXML() ( )	Constructs an object that implements the SQLXML API. The returned object does not contain data initially. You can use the createXmlStreamWriter object of the SQLXML API and the setString method to add data to an SQLXML object.	SQLXML	SQLException	Yes
createStatement()	Creates a statement object that sends SQL statements to a database.	Statement	SQLException	Yes
createStatement(int resultSetType, int resultSetConcurrency)	Creates a statement object that will generate a ResultSet object with a given type and concurrency.	Statement	SQLException	Yes
createStatement(int resultSetType, int resultSetConcurrency, int resultSetHoldability)	Creates a statement object that will generate a ResultSet object with a given type and concurrency.	Statement	SQLException	Yes
getAutoCommit()	Retrieves the current autocommit mode for this connection object.	boolean	SQLException	Yes
getCatalog()	Obtains the current directory name of this connection object.	String	SQLException	Yes
getClientInfo()	Returns a list containing the name and current value of each client information property supported by the driver. If the client information property has not been set and has no default value, the value of this attribute may be <b>NULL</b> .	Properties	SQLException	Yes

Method Name	Description	Return Type	throws	JDBC 4 Supported or Not
getClientInfo(String name)	Returns the value of the client information property specified by name. This method may return <b>NULL</b> if the specified client information property has not been set and there is no default value. This method also returns <b>NULL</b> if the driver does not support the specified client information property name.	String	SQLException	Yes
getHoldability()	Obtains the current holdability of the ResultSet object created using this connection object.	int	SQLException	Yes
getMetaData()	Retrieves the DatabaseMetaData object that contains metadata about the database to which this connection object represents the connection. Metadata includes information about database tables, supported SQL syntax, stored procedures, and functions of the connection.	DatabaseMetaData	SQLException	Yes
getNetworkTimeout()	Obtains the number of milliseconds the driver will wait for a database request to complete. If the limit is exceeded, SQLException is thrown.	int	SQLException	Yes
getSchema()	Retrieves the current schema name of this connection object.	String	SQLException	Yes
getTransactionIsolation()	Retrieves the current transaction isolation level of this connection object.	int	SQLException	Yes
getTypeMap()	Retrieves the map object associated with this connection object. Unless the application adds an entry, the returned type mapping will be empty.	Map<String,Class<?>>	SQLException	Yes

Method Name	Description	Return Type	throws	JDBC 4 Supported or Not
getWarnings()	Retrieves the first warning reported by calls on this connection object. If there are multiple warnings, subsequent warnings are linked to the first warning and can be retrieved by calling the <code>SQLWarning.getNextWarning</code> method on the previously retrieved warning.	SQLWarning	SQLException	Yes
isClosed()	Checks whether this connection object has been closed. If a method has been called to close the connection, or if some major error occurs, the connection is closed. Ensure that <b>true</b> is returned only when this method is called after the <code>connection.close</code> method is called.	boolean	SQLException	Yes
isReadOnly()	Checks whether this connection object is in read-only mode.	boolean	SQLException	Yes
isValid(int timeout)	Returns <b>true</b> if the connection has not been closed and is still valid. The driver should commit a query to the connection, or use other mechanisms to affirmatively verify that the connection is still valid when this method is called.	boolean	SQLException	Yes
nativeSQL(String sql)	Converts a given SQL statement to the native SQL syntax of the system. The driver can convert the JDBC SQL syntax to the native SQL syntax of its system before sending it. This method returns the native form of the statement that the driver should have sent.	String	SQLException	Yes

Method Name	Description	Return Type	throws	JDBC 4 Supported or Not
prepareCall(String sql)	Creates a CallableStatement object that calls a database stored procedure. The CallableStatement object provides methods for setting its IN and OUT parameters, as well as methods for executing calls to stored procedures.	CallableStatement	SQLException	Yes
prepareCall(String sql, int resultSetType, int resultSetConcurrency)	Creates a CallableStatement object. This object will generate a ResultSet object with the given type and concurrency. This method is the same as the preparation call method above, but it allows overwriting the default result set type and concurrency.	CallableStatement	SQLException	Yes
prepareCall(String sql, int resultSetType, int resultSetConcurrency, int resultSetHoldability)	Creates a CallableStatement object. This object will generate a ResultSet object with the given type and concurrency. This method is the same as the preparation call method above, but it allows overwriting the default result set type, result set concurrency type, and holdability.	CallableStatement	SQLException	Yes
prepareStatement(String sql)	Creates a prepared statement object for sending parameterized SQL statements to a database.	PreparedStatement	SQLException	Yes
prepareStatement(String sql, int autoGeneratedKeys)	Creates a default prepared statement object that can retrieve automatically generated keys. The given constant tells the driver whether it should make the automatically generated key available for retrieval. If the SQL statement is not an INSERT statement or an SQL statement that can return an automatically generated key, this parameter is ignored.	PreparedStatement	SQLException	Yes

Method Name	Description	Return Type	throws	JDBC 4 Supported or Not
prepareStatement(String sql, int[] columnIndexes)	Creates a default prepared statement object that can return an automatically generated key specified by a given array. This array contains the indexes of the columns in the target table that contain the automatically generated keys, which should be available. If the SQL statement is not an INSERT statement or an SQL statement that can return an automatically generated key, the driver ignores the array.	PreparedStatement	SQLException	Yes
prepareStatement(String sql, int resultSetType, int resultSetConcurrency)	Creates a prepared statement object that will generate a ResultSet object with a given type and concurrency. This method is the same as the prepared statement method above, but it allows overwriting the default result set type and concurrency.	PreparedStatement	SQLException	Yes
prepareStatement(String sql, int resultSetType, int resultSetConcurrency, int resultSetHoldability)	Creates a prepared statement object that will generate a ResultSet object with a given type, concurrency, and holdability.	PreparedStatement	SQLException	Yes
prepareStatement(String sql, String[] columnNames)	Creates a default prepared statement object that can return an automatically generated key specified by a given array. This array contains the names of the columns in the target table that contain the automatically generated keys, which should be returned. If the SQL statement is not an INSERT statement or an SQL statement that can return an automatically generated key, the driver ignores the array.	PreparedStatement	SQLException	Yes

Method Name	Description	Return Type	throws	JDBC 4 Supported or Not
releaseSavepoint(Savepoint savepoint)	Deletes the specified savepoint and subsequent savepoint objects from the current transaction. Any reference to the savepoint after it is deleted will cause an SQL exception to be thrown.	void	SQLException	Yes
rollback()	Undoes all changes made in the current transaction and releases any database locks currently held by this connection object. This method should be used only when the autocommit mode is disabled.	void	SQLException	Yes
rollback(Savepoint savepoint)	Undoes all changes made after a given savepoint object is set. This method should be used only when the autocommit mode is disabled.	void	SQLException	Yes
setAutoCommit(boolean autoCommit)	Sets the autocommit mode of this connection to the given state. If a connection is in autocommit mode, all its SQL statements are executed and committed as a single transaction. Otherwise, its SQL statements are grouped into transactions that are terminated by calls to method commits or method rollbacks. By default, new connections are in autocommit mode.	void	SQLException	Yes
setClientInfo(Properties properties)	Sets the client information property value of the connection. The properties object contains the names and values of the client information properties to be set. The client information property set contained in the attribute list replaces the current client information property set on the connection. If the property currently set on the connection is not in the property list, the property is cleared.	void	SQLClientInfoException	Yes

Method Name	Description	Return Type	throws	JDBC 4 Supported or Not
setClientInfo(String name,String value)	Sets the client information property value specified by name to that specified by value.	void	SQLClientInfoException	Yes
setHoldability(int holdability)	Changes the default holdability of the ResultSet object created with this connection object to the given holdability. The default holdability of the ResultSet object can be determined by calling DatabaseMetaData.getResultSetHoldability.	void	SQLException	Yes
setNetworkTimeout(Executor executor, int milliseconds)	Sets the maximum time that a connection or an object created from a connection waits for the database to reply to any request. If any request is still not answered, the waiting method returns SQLException, and the connection or object created from the connection is marked as closed. Any subsequent use of the object other than the Close, isCabled, or Connection.isValid method will result in SQLException.	void	SQLException	Yes
setReadOnly(boolean readOnly)	Sets this connection to read-only mode as a hint for the driver to enable database optimization.	void	SQLException	Yes
setSavepoint()	Creates an unnamed savepoint in the current transaction and returns a new savepoint object representing it.	Savepoint	SQLException	Yes
setSavepoint(String name)	Creates a savepoint with the given name in the current transaction and returns a new savepoint object representing it.	Savepoint	SQLException	Yes
setSchema(String schema)	Sets the given schema name to access.	void	SQLException	Yes

Method Name	Description	Return Type	throws	JDBC 4 Supported or Not
setTransactionIsolation(int level)	Attempts to change the transaction isolation level of this connection object to a given level. Constants defined in the connection API are possible transaction isolation levels.	void	SQLException	Yes
setTypeMap(Map<String,Class<?>> map)	Installs the given TypeMap object as the type mapping for this connection object. Type mappings will be used for SQL structured types and custom mappings for different types.	void	SQLException	Yes

**NOTICE**

1. The autocommit mode is used by default within the API. If you disable it by running **setAutoCommit(false)**, all the statements executed later will be packaged in explicit transactions, and you cannot execute statements that cannot be executed within transactions.
2. Fully-encrypted databases cannot use `setClientInfo("send_token", null)` to transmit keys or use `setClientInfo("clear_token", null)` to destroy keys.

### 5.3.15.2 java.sql.CallableStatement

java.sql.CallableStatement is an API for executing stored procedures.

**Table 5-10** Support status for java.sql.CallableStatement

Method Name	Return Type	JDBC4 Supported or Not
getArray(int parameterIndex)	Array	Yes
getBigDecimal(int parameterIndex)	BigDecimal	Yes
getBlob(int parameterIndex)	Blob	Yes
getBoolean(int parameterIndex)	boolean	Yes
getByte(int parameterIndex)	byte	Yes

Method Name	Return Type	JDBC4 Supported or Not
getBytes(int parameterIndex)	byte[]	Yes
getClob(int parameterIndex)	Clob	Yes
getDate(int parameterIndex)	Date	Yes
getDate(int parameterIndex, Calendar cal)	Date	Yes
getDouble(int parameterIndex)	double	Yes
getFloat(int parameterIndex)	float	Yes
getInt(int parameterIndex)	int	Yes
getLong(int parameterIndex)	long	Yes
getObject(int parameterIndex)	Object	Yes
getObject(int parameterIndex, Class<T> type)	Object	Yes
getShort(int parameterIndex)	short	Yes
getSQLXML(int parameterIndex)	SQLXML	Yes
getString(int parameterIndex)	String	Yes
getNString(int parameterIndex)	String	Yes
getTime(int parameterIndex)	Time	Yes
getTime(int parameterIndex, Calendar cal)	Time	Yes
getTimestamp(int parameterIndex)	Timestamp	Yes
getTimestamp(int parameterIndex, Calendar cal)	Timestamp	Yes
registerOutParameter(int parameterIndex, int type)	void	Yes
registerOutParameter(int parameterIndex, int sqlType, int type)	void	Yes
wasNull()	boolean	Yes

**NOTE**

- The batch operation of statements containing OUT parameter is not allowed.
- The following methods are inherited from `java.sql.Statement`: `close`, `execute`, `executeQuery`, `executeUpdate`, `getConnection`, `getResultSet`, `getUpdateCount`, `isClosed`, `setMaxRows`, and `setFetchSize`.
- The following methods are inherited from `java.sql.PreparedStatement`: `addBatch`, `clearParameters`, `execute`, `executeQuery`, `executeUpdate`, `getMetaData`, `setBigDecimal`, `setBoolean`, `setByte`, `setBytes`, `setDate`, `setDouble`, `setFloat`, `setInt`, `setLong`, `setNull`, `setObject`, `setString`, `setTime`, and `setTimestamp`.
- The `registerOutParameter(int parameterIndex, int sqlType, int type)` method is used only to register the composite data type.

### 5.3.15.3 `java.sql.DatabaseMetaData`

`java.sql.DatabaseMetaData` is an API for defining database objects.

**Table 5-11** Support status for `java.sql.DatabaseMetaData`

Method Name	Return Type	JDBC4 Supported or Not
<code>allProceduresAreCallable()</code>	Boolean	Yes
<code>allTablesAreSelectable()</code>	Boolean	Yes
<code>autoCommitFailureClosesAllResultSets()</code>	Boolean	Yes
<code>dataDefinitionCausesTransactionCommit()</code>	Boolean	Yes
<code>dataDefinitionIgnoredInTransactions()</code>	Boolean	Yes
<code>deletesAreDetected(int type)</code>	Boolean	Yes
<code>doesMaxRowSizeIncludeBlobs()</code>	Boolean	Yes
<code>generatedKeyAlwaysReturned()</code>	Boolean	Yes
<code>getBestRowIdentifier(String catalog, String schema, String table, int scope, boolean nullable)</code>	ResultSet	Yes
<code>getCatalogs()</code>	ResultSet	Yes
<code>getCatalogSeparator()</code>	String	Yes
<code>getCatalogTerm()</code>	String	Yes
<code>getClientInfoProperties()</code>	ResultSet	Yes

Method Name	Return Type	JDBC4 Supported or Not
getColumnPrivileges(String catalog, String schema, String table, String columnNamePattern)	ResultSet	Yes
getConnection()	Connection	Yes
getCrossReference(String parentCatalog, String parentSchema, String parentTable, String foreignCatalog, String foreignSchema, String foreignTable)	ResultSet	Yes
getDefaultTransactionIsolation()	int	Yes
getExportedKeys(String catalog, String schema, String table)	ResultSet	Yes
getExtraNameCharacters()	String	Yes
getFunctionColumns(String catalog, String schemaPattern, String functionNamePattern, String columnNamePattern)	ResultSet	Yes
getFunctions(String catalog, String schemaPattern, String functionNamePattern)	ResultSet	Yes
getIdentifierQuoteString()	String	Yes
getImportedKeys(String catalog, String schema, String table)	ResultSet	Yes
getIndexInfo(String catalog, String schema, String table, boolean unique, boolean approximate)	ResultSet	Yes
getMaxBinaryLiteralLength()	int	Yes
getMaxCatalogNameLength()	int	Yes
getMaxCharLiteralLength()	int	Yes
getMaxColumnNameLength()	int	Yes

Method Name	Return Type	JDBC4 Supported or Not
getMaxColumnsInGroupBy()	int	Yes
getMaxColumnsInIndex()	int	Yes
getMaxColumnsInOrderBy()	int	Yes
getMaxColumnsInSelect()	int	Yes
getMaxColumnsInTable()	int	Yes
getMaxConnections()	int	Yes
getMaxCursorNameLength()	int	Yes
getMaxIndexLength()	int	Yes
getMaxLogicalLobSize()	default long	Yes
getMaxProcedureName- Length()	int	Yes
getMaxRowSize()	int	Yes
getMaxSchemaName- Length()	int	Yes
getMaxStatementLength()	int	Yes
getMaxStatements()	int	Yes
getMaxTableNameLength()	int	Yes
getMaxTablesInSelect()	int	Yes
getMaxUserNameLength()	int	Yes
getNumericFunctions()	String	Yes
getPrimaryKeys(String catalog, String schema, String table)	ResultSet	Yes
getPartitionTablePrimary- Keys(String catalog, String schema, String table)	ResultSet	Yes
getProcedureColumns(String catalog, String schemaPattern, String procedureNamePattern, String columnNamePattern)	ResultSet	Yes
getProcedures(String catalog, String schemaPattern, String procedureNamePattern)	ResultSet	Yes

Method Name	Return Type	JDBC4 Supported or Not
getProcedureTerm()	String	Yes
getSchemas()	ResultSet	Yes
getSchemas(String catalog, String schemaPattern)	ResultSet	Yes
getSchemaTerm()	String	Yes
getSearchStringEscape()	String	Yes
getSQLKeywords()	String	Yes
getSQLStateType()	int	Yes
getStringFunctions()	String	Yes
getSystemFunctions()	String	Yes
getTablePrivileges(String catalog, String schemaPattern, String tableNamePattern)	ResultSet	Yes
getTimeDateFunctions()	String	Yes
getTypeInfo()	ResultSet	Yes
getUDTs(String catalog, String schemaPattern, String typeNamePattern, int[] types)	ResultSet	Yes
getURL()	String	Yes
getVersionColumns(String catalog, String schema, String table)	ResultSet	Yes
insertsAreDetected(int type)	Boolean	Yes
locatorsUpdateCopy()	Boolean	Yes
othersDeletesAreVisible(int type)	Boolean	Yes
othersInsertsAreVisible(int type)	Boolean	Yes
othersUpdatesAreVisible(int type)	Boolean	Yes
ownDeletesAreVisible(int type)	Boolean	Yes
ownInsertsAreVisible(int type)	Boolean	Yes

Method Name	Return Type	JDBC4 Supported or Not
ownUpdatesAreVisible(int type)	Boolean	Yes
storesLowerCaselIdentifiers()	Boolean	Yes
storesMixedCaselIdentifiers()	Boolean	Yes
storesUpperCaselIdentifiers()	Boolean	Yes
supportsBatchUpdates()	Boolean	Yes
supportsCatalogsInDataManipulation()	Boolean	Yes
supportsCatalogsInIndexDefinitions()	Boolean	Yes
supportsCatalogsInPrivilegeDefinitions()	Boolean	Yes
supportsCatalogsInProcedureCalls()	Boolean	Yes
supportsCatalogsInTableDefinitions()	Boolean	Yes
supportsCorrelatedSubqueries()	Boolean	Yes
supportsDataDefinitionAndDataManipulationTransactions()	Boolean	Yes
supportsDataManipulationTransactionsOnly()	Boolean	Yes
supportsGetGeneratedKeys()	Boolean	Yes
supportsMixedCaselIdentifiers()	Boolean	Yes
supportsMultipleOpenResults()	Boolean	Yes
supportsNamedParameters()	Boolean	Yes
supportsOpenCursorsAcrossCommit()	Boolean	Yes
supportsOpenCursorsAcrossRollback()	Boolean	Yes
supportsOpenStatementsAcrossCommit()	Boolean	Yes
supportsOpenStatementsAcrossRollback()	Boolean	Yes

Method Name	Return Type	JDBC4 Supported or Not
supportsPositionedDelete()	Boolean	Yes
supportsPositionedUpdate()	Boolean	Yes
supportsRefCursors()	Boolean	Yes
supportsResultSetConcurrency(int type, int concurrency)	Boolean	Yes
supportsResultSetType(int type)	Boolean	Yes
supportsSchemasInIndexDefinitions()	Boolean	Yes
supportsSchemasInPrivilegeDefinitions()	Boolean	Yes
supportsSchemasInProcedureCalls()	Boolean	Yes
supportsSchemasInTableDefinitions()	Boolean	Yes
supportsSelectForUpdate()	Boolean	Yes
supportsStatementPooling()	Boolean	Yes
supportsStoredFunctionsUsingCallSyntax()	Boolean	Yes
supportsStoredProcedures()	Boolean	Yes
supportsSubqueriesInComparisons()	Boolean	Yes
supportsSubqueriesInExists()	Boolean	Yes
supportsSubqueriesInIns()	Boolean	Yes
supportsSubqueriesInQuantifieds()	Boolean	Yes
supportsTransactionIsolationLevel(int level)	Boolean	Yes
supportsTransactions()	Boolean	Yes
supportsUnion()	Boolean	Yes
supportsUnionAll()	Boolean	Yes
updatesAreDetected(int type)	Boolean	Yes

Method Name	Return Type	JDBC4 Supported or Not
getTables(String catalog, String schemaPattern, String tableNamePattern, String[] types)	ResultSet	Yes
getColumns(String catalog, String schemaPattern, String tableNamePattern, String columnNamePattern)	ResultSet	Yes
getTableTypes()	ResultSet	Yes
getUserName()	String	Yes
isReadOnly()	Boolean	Yes
nullsAreSortedHigh()	Boolean	Yes
nullsAreSortedLow()	Boolean	Yes
nullsAreSortedAtStart()	Boolean	Yes
nullsAreSortedAtEnd()	Boolean	Yes
getDatabaseProductName()	String	Yes
getDatabaseProductVersion()	String	Yes
getDriverName()	String	Yes
getDriverVersion()	String	Yes
getDriverMajorVersion()	int	Yes
getDriverMinorVersion()	int	Yes
usesLocalFiles()	Boolean	Yes
usesLocalFilePerTable()	Boolean	Yes
supportsMixedCaseIdentifiers()	Boolean	Yes
storesUpperCaseIdentifiers()	Boolean	Yes
storesLowerCaseIdentifiers()	Boolean	Yes
supportsMixedCaseQuotedIdentifiers()	Boolean	Yes
storesUpperCaseQuotedIdentifiers()	Boolean	Yes
storesLowerCaseQuotedIdentifiers()	Boolean	Yes

Method Name	Return Type	JDBC4 Supported or Not
storesMixedCaseQuotedIdentifiers()	Boolean	Yes
supportsAlterTableWithAddColumn()	Boolean	Yes
supportsAlterTableWithDropColumn()	Boolean	Yes
supportsColumnAliasing()	Boolean	Yes
nullPlusNonNullIsNull()	Boolean	Yes
supportsConvert()	Boolean	Yes
supportsConvert(int fromType, int toType)	Boolean	Yes
supportsTableCorrelationNames()	Boolean	Yes
supportsDifferentTableCorrelationNames()	Boolean	Yes
supportsExpressionsInOrderBy()	Boolean	Yes
supportsOrderByUnrelated()	Boolean	Yes
supportsGroupBy()	Boolean	Yes
supportsGroupByUnrelated()	Boolean	Yes
supportsGroupByBeyondSelect()	Boolean	Yes
supportsLikeEscapeClause()	Boolean	Yes
supportsMultipleResultSets()	Boolean	Yes
supportsMultipleTransactions()	Boolean	Yes
supportsNonNullableColumns()	Boolean	Yes
supportsMinimumSQLGrammar()	Boolean	Yes
supportsCoreSQLGrammar()	Boolean	Yes
supportsExtendedSQLGrammar()	Boolean	Yes
supportsANSI92EntryLevelSQL()	Boolean	Yes

Method Name	Return Type	JDBC4 Supported or Not
supportsANSI92IntermediateSQL()	Boolean	Yes
supportsANSI92FullSQL()	Boolean	Yes
supportsIntegrityEnhancementFacility()	Boolean	Yes
supportsOuterJoins()	Boolean	Yes
supportsFullOuterJoins()	Boolean	Yes
supportsLimitedOuterJoins()	Boolean	Yes
isCatalogAtStart()	Boolean	Yes
supportsSchemasInDataManipulation()	Boolean	Yes
supportsSavepoints()	Boolean	Yes
supportsResultSetHoldability(int holdability)	Boolean	Yes
getResultSetHoldability()	int	Yes
getDatabaseMajorVersion()	int	Yes
getDatabaseMinorVersion()	int	Yes
getJDBCMinorVersion()	int	Yes
getJDBCMajorVersion()	int	Yes
getJDBCMinorVersion()	int	Yes

 **NOTE**

The `getPartitionTablePrimaryKeys(String catalog, String schema, String table)` method is used to obtain the primary key column of a partitioned table that contains global indexes. The following is an example:

```
PgDatabaseMetaData dbmd = (PgDatabaseMetaData)conn.getMetaData();
dbmd.getPartitionTablePrimaryKeys("catalogName", "schemaName", "tableName");
```

### 5.3.15.4 java.sql.Driver

This section describes **java.sql.Driver**, the database driver interface.

**Table 5-12** Support status for java.sql.Driver

Method Name	Return Type	Support JDBC4 (Yes/No)
acceptsURL(String url)	Boolean	Yes
connect(String url, Properties info)	Connection	Yes

Method Name	Return Type	Support JDBC4 (Yes/No)
jdbcCompliant()	Boolean	Yes
getMajorVersion()	int	Yes
getMinorVersion()	int	Yes
getParentLogger()	Logger	Yes
getPropertyInfo(String url, Properties info)	DriverPropertyInfo[]	Yes

### 5.3.15.5 java.sql.PreparedStatement

java.sql.PreparedStatement is a prepared statement API.

**Table 5-13** Support status for java.sql.PreparedStatement

Method Name	Return Type	JDBC4 Supported or Not
clearParameters()	void	Yes
execute()	Boolean	Yes
executeQuery()	ResultSet	Yes
executeUpdate()	int	Yes
executeLargeUpdate()	long	No
getMetaData()	ResultSetMetaData	Yes
getParameterMetaData()	ParameterMetaData	Yes
setArray(int parameterIndex, Array x)	void	Yes
setAsciiStream(int parameterIndex, InputStream x, int length)	void	Yes
setBinaryStream(int parameterIndex, InputStream x)	void	Yes
setBinaryStream(int parameterIndex, InputStream x, int length)	void	Yes

Method Name	Return Type	JDBC4 Supported or Not
setBinaryStream(int parameterIndex, InputStream x, long length)	void	Yes
setBlob(int parameterIndex, InputStream inputStream)	void	Yes
setBlob(int parameterIndex, InputStream inputStream, long length)	void	Yes
setBlob(int parameterIndex, Blob x)	void	Yes
setCharacterStream(int parameterIndex, Reader reader)	void	Yes
setCharacterStream(int parameterIndex, Reader reader, int length)	void	Yes
setClob(int parameterIndex, Reader reader)	void	Yes
setClob(int parameterIndex, Reader reader, long length)	void	Yes
setClob(int parameterIndex, Clob x)	void	Yes
setDate(int parameterIndex, Date x, Calendar cal)	void	Yes
setNull(int parameterIndex, int sqlType)	void	Yes
setNull(int parameterIndex, int sqlType, String typeName)	void	Yes

Method Name	Return Type	JDBC4 Supported or Not
setObject(int parameterIndex, Object x)	void	Yes
setObject(int parameterIndex, Object x, int targetSqlType)	void	Yes
setObject(int parameterIndex, Object x, int targetSqlType, int scaleOrLength)	void	Yes
setSQLXML(int parameterIndex, SQLXML xmlObject)	void	Yes
setTime(int parameterIndex, Time x)	void	Yes
setTime(int parameterIndex, Time x, Calendar cal)	void	Yes
setTimestamp(int parameterIndex, Timestamp x)	void	Yes
setTimestamp(int parameterIndex, Timestamp x, Calendar cal)	void	Yes
setUnicodeStream(int parameterIndex, InputStream x, int length)	void	Yes
setURL(int parameterIndex, URL x)	void	Yes
setBoolean(int parameterIndex, boolean x)	void	Yes
setBigDecimal(int parameterIndex, BigDecimal x)	void	Yes
setByte(int parameterIndex, byte x)	void	Yes

Method Name	Return Type	JDBC4 Supported or Not
setBytes(int parameterIndex, byte[] x)	void	Yes
setDate(int parameterIndex, Date x)	void	Yes
setDouble(int parameterIndex, double x)	void	Yes
setFloat(int parameterIndex, float x)	void	Yes
setInt(int parameterIndex, int x)	void	Yes
setLong(int parameterIndex, long x)	void	Yes
setShort(int parameterIndex, short x)	void	Yes
setString(int parameterIndex, String x)	void	Yes
setNString(int parameterIndex, String x)	void	Yes
addBatch()	void	Yes
executeBatch()	int[]	Yes

 **NOTE**

- Execute **addBatch()** and **execute()** only after running **clearBatch()**.
- Batch is not cleared by calling `executeBatch()`. Clear batch by explicitly calling `clearBatch()`.
- After bounded variables of a batch are added, if you want to reuse these values, you do not need to use `set*()` again. Instead, add a batch.
- The following methods are inherited from `java.sql.Statement`: `close`, `execute`, `executeQuery`, `executeUpdate`, `getConnection`, `getResultSet`, `getUpdateCount`, `isClosed`, `setMaxRows`, `setFetchSize`, and `enableStreamingResults`.
- The `executeLargeUpdate()` method can only be used in JDBC 4.2 or later.

### 5.3.15.6 java.sql.ResultSet

`java.sql.ResultSet` is an execution result set API.

**Table 5-14** Support status for java.sql.ResultSet

Method Name	Return Type	JDBC4 Supported or Not
absolute(int row)	Boolean	Yes
afterLast()	void	Yes
beforeFirst()	void	Yes
cancelRowUpdates()	void	Yes
clearWarnings()	void	Yes
close()	void	Yes
deleteRow()	void	Yes
findColumn(String columnLabel)	int	Yes
first()	Boolean	Yes
getArray(int columnIndex)	Array	Yes
getArray(String columnLabel)	Array	Yes
getAsciiStream(int columnIndex)	InputStream	Yes
getAsciiStream(String columnLabel)	InputStream	Yes
getBigDecimal(int columnIndex)	BigDecimal	Yes
getBigDecimal(String columnLabel)	BigDecimal	Yes
getBinaryStream(int columnIndex)	InputStream	Yes
getBinaryStream(String columnLabel)	InputStream	Yes
getBlob(int columnIndex)	Blob	Yes
getBlob(String columnLabel)	Blob	Yes
getBoolean(int columnIndex)	Boolean	Yes
getBoolean(String columnLabel)	Boolean	Yes
getByte(int columnIndex)	byte	Yes

Method Name	Return Type	JDBC4 Supported or Not
getBytes(int columnIndex)	byte[]	Yes
getBytes(String columnLabel)	byte	Yes
getBytes(String columnLabel)	byte[]	Yes
getCharacterStream(int columnIndex)	Reader	Yes
getCharacterStream(String columnLabel)	Reader	Yes
getClob(int columnIndex)	Clob	Yes
getClob(String columnLabel)	Clob	Yes
getConcurrency()	int	Yes
getCursorName()	String	Yes
getDate(int columnIndex)	Date	Yes
getDate(int columnIndex, Calendar cal)	Date	Yes
getDate(String columnLabel)	Date	Yes
getDate(String columnLabel, Calendar cal)	Date	Yes
getDouble(int columnIndex)	double	Yes
getDouble(String columnLabel)	double	Yes
getFetchDirection()	int	Yes
getFetchSize()	int	Yes
getFloat(int columnIndex)	float	Yes
getFloat(String columnLabel)	float	Yes
getInt(int columnIndex)	int	Yes
getInt(String columnLabel)	int	Yes

Method Name	Return Type	JDBC4 Supported or Not
getLong(int columnIndex)	long	Yes
getLong(String columnLabel)	long	Yes
getMetaData()	ResultSetMetaData	Yes
getObject(int columnIndex)	Object	Yes
getObject(int columnIndex, Class<T> type)	<T> T	Yes
getObject(int columnIndex, Map<String,Class<?>> map)	Object	Yes
getObject(String columnLabel)	Object	Yes
getObject(String columnLabel, Class<T> type)	<T> T	Yes
getObject(String columnLabel, Map<String,Class<?>> map)	Object	Yes
getRow()	int	Yes
getShort(int columnIndex)	short	Yes
getShort(String columnLabel)	short	Yes
getSQLXML(int columnIndex)	SQLXML	Yes
getSQLXML(String columnLabel)	SQLXML	Yes
getStatement()	Statement	Yes
getString(int columnIndex)	String	Yes
getString(String columnLabel)	String	Yes
getNString(int columnIndex)	String	Yes

Method Name	Return Type	JDBC4 Supported or Not
getNString(String columnLabel)	String	Yes
getTime(int columnIndex)	Time	Yes
getTime(int columnIndex, Calendar cal)	Time	Yes
getTime(String columnLabel)	Time	Yes
getTime(String columnLabel, Calendar cal)	Time	Yes
getTimestamp(int columnIndex)	Timestamp	Yes
getTimestamp(int columnIndex, Calendar cal)	Timestamp	Yes
getTimestamp(String columnLabel)	Timestamp	Yes
getTimestamp(String columnLabel, Calendar cal)	Timestamp	Yes
getType()	int	Yes
getWarnings()	SQLWarning	Yes
insertRow()	void	Yes
isAfterLast()	Boolean	Yes
isBeforeFirst()	Boolean	Yes
isClosed()	Boolean	Yes
isFirst()	Boolean	Yes
isLast()	Boolean	Yes
last()	Boolean	Yes
moveToCurrentRow()	void	Yes
moveToInsertRow()	void	Yes
next()	Boolean	Yes
previous()	Boolean	Yes
refreshRow()	void	Yes

Method Name	Return Type	JDBC4 Supported or Not
relative(int rows)	Boolean	Yes
rowDeleted()	Boolean	Yes
rowInserted()	Boolean	Yes
rowUpdated()	Boolean	Yes
setFetchDirection(int direction)	void	Yes
setFetchSize(int rows)	void	Yes
updateArray(int columnIndex, Array x)	void	Yes
updateArray(String columnLabel, Array x)	void	Yes
updateAsciiStream(int columnIndex, InputStream x, int length)	void	Yes
updateAsciiStream(String columnLabel, InputStream x, int length)	void	Yes
updateBigDecimal(int columnIndex, BigDecimal x)	void	Yes
updateBigDecimal(String columnLabel, BigDecimal x)	void	Yes
updateBinaryStream(int columnIndex, InputStream x, int length)	void	Yes
updateBinaryStream(String columnLabel, InputStream x, int length)	void	Yes
updateBoolean(int columnIndex, boolean x)	void	Yes
updateBoolean(String columnLabel, boolean x)	void	Yes
updateByte(int columnIndex, byte x)	void	Yes
updateByte(String columnLabel, byte x)	void	Yes

Method Name	Return Type	JDBC4 Supported or Not
updateBytes(int columnIndex, byte[] x)	void	Yes
updateBytes(String columnLabel, byte[] x)	void	Yes
updateCharacterStream(int columnIndex, Reader x, int length)	void	Yes
updateCharacterStream(String columnLabel, Reader reader, int length)	void	Yes
updateDate(int columnIndex, Date x)	void	Yes
updateDate(String columnLabel, Date x)	void	Yes
updateDouble(int columnIndex, double x)	void	Yes
updateDouble(String columnLabel, double x)	void	Yes
updateFloat(int columnIndex, float x)	void	Yes
updateFloat(String columnLabel, float x)	void	Yes
updateInt(int columnIndex, int x)	void	Yes
updateInt(String columnLabel, int x)	void	Yes
updateLong(int columnIndex, long x)	void	Yes
updateLong(String columnLabel, long x)	void	Yes
updateNull(int columnIndex)	void	Yes
updateNull(String columnLabel)	void	Yes
updateObject(int columnIndex, Object x)	void	Yes

Method Name	Return Type	JDBC4 Supported or Not
updateObject(int columnIndex, Object x, int scaleOrLength)	void	Yes
updateObject(String columnLabel, Object x)	void	Yes
updateObject(String columnLabel, Object x, int scaleOrLength)	void	Yes
updateRow()	void	Yes
updateShort(int columnIndex, short x)	void	Yes
updateShort(String columnLabel, short x)	void	Yes
updateSQLXML(int columnIndex, SQLXML xmlObject)	void	Yes
updateSQLXML(String columnLabel, SQLXML xmlObject)	void	Yes
updateString(int columnIndex, String x)	void	Yes
updateString(String columnLabel, String x)	void	Yes
updateTime(int columnIndex, Time x)	void	Yes
updateTime(String columnLabel, Time x)	void	Yes
updateTimestamp(int columnIndex, Timestamp x)	void	Yes
updateTimestamp(String columnLabel, Timestamp x)	void	Yes
wasNull()	Boolean	Yes

 NOTE

- One statement cannot have multiple open ResultSets.
- The cursor that is used for traversing the ResultSet cannot be open after being committed.

### 5.3.15.7 java.sql.ResultSetMetaData

This section describes **java.sql.ResultSetMetaData**, which provides details about ResultSet object information.

**Table 5-15** Support status for java.sql.ResultSetMetaData

Method Name	Return Type	Support JDBC4 (Yes/No)
getCatalogName(int column)	String	Yes
getColumnClassName(int column)	String	Yes
getColumnCount()	int	Yes
getColumnDisplaySize(int column)	int	Yes
getColumnLabel(int column)	String	Yes
getColumnName(int column)	String	Yes
getColumnType(int column)	int	Yes
getColumnTypeName(int column)	String	Yes
getPrecision(int column)	int	Yes
getScale(int column)	int	Yes
getSchemaName(int column)	String	Yes
getTableName(int column)	String	Yes
isAutoIncrement(int column)	boolean	Yes
isCaseSensitive(int column)	boolean	Yes
isCurrency(int column)	boolean	Yes
isDefinitelyWritable(int column)	boolean	Yes
isNullable(int column)	int	Yes
isReadOnly(int column)	boolean	Yes

Method Name	Return Type	Support JDBC4 (Yes/No)
isSearchable(int column)	boolean	Yes
isSigned(int column)	boolean	Yes
isWritable(int column)	boolean	Yes

### 5.3.15.8 java.sql.Statement

java.sql.Statement is an SQL statement API.

**Table 5-16** Support status for java.sql.Statement

Method Name	Return Type	JDBC4 Supported or Not
addBatch(String sql)	void	Yes
clearBatch()	void	Yes
clearWarnings()	void	Yes
close()	void	Yes
closeOnCompletion()	void	Yes
execute(String sql)	Boolean	Yes
execute(String sql, int autoGeneratedKeys)	Boolean	Yes
execute(String sql, int[] columnIndexes)	Boolean	Yes
execute(String sql, String[] columnNames)	Boolean	Yes
executeBatch()	Boolean	Yes
executeQuery(String sql)	ResultSet	Yes
executeUpdate(String sql)	int	Yes
executeUpdate(String sql, int autoGeneratedKeys)	int	Yes
executeUpdate(String sql, int[] columnIndexes)	int	Yes

Method Name	Return Type	JDBC4 Supported or Not
executeUpdate(String sql, String[] columnNames)	int	Yes
getConnection()	Connection	Yes
getFetchDirection()	int	Yes
getFetchSize()	int	Yes
getGeneratedKeys()	ResultSet	Yes
getMaxFieldSize()	int	Yes
getMaxRows()	int	Yes
getMoreResults()	Boolean	Yes
getMoreResults(int current)	Boolean	Yes
getResultSet()	ResultSet	Yes
getResultSetConcurrency()	int	Yes
getResultSetHoldability()	int	Yes
getResultSetType()	int	Yes
getQueryTimeout()	int	Yes
getUpdateCount()	int	Yes
getWarnings()	SQLWarning	Yes
isClosed()	Boolean	Yes
isCloseOnCompletion()	Boolean	Yes
isPoolable()	Boolean	Yes
setCursorName(String name)	void	Yes
setEscapeProcessing(boolean enable)	void	Yes
setFetchDirection(int direction)	void	Yes
setMaxFieldSize(int max)	void	Yes
setMaxRows(int max)	void	Yes

Method Name	Return Type	JDBC4 Supported or Not
setPoolable(boolean poolable)	void	Yes
setQueryTimeout(int seconds)	void	Yes
setFetchSize(int rows)	void	Yes
cancel()	void	Yes
executeLargeUpdate(String sql)	long	No
getLargeUpdateCount()	long	No
executeLargeBatch()	long	No
executeLargeUpdate(String sql, int autoGeneratedKeys)	long	No
executeLargeUpdate(String sql, int[] columnIndexes)	long	No
executeLargeUpdate(String sql, String[] columnNames)	long	No
enableStreamingResults()	void	Yes

 **NOTE**

- Using setFetchSize can reduce the memory occupied by result sets on the client. Result sets are packaged into cursors and segmented for processing, which will increase the communication traffic between the database and the client, affecting performance.
- Database cursors are valid only within their transactions. If **setFetchSize** is set, set **setAutoCommit(false)** and commit transactions on the connection to flush service data to a database.
- The LargeUpdate method can only be used in JDBC 4.2 or later.
- enableStreamingResults() is a customized API for enabling streaming read. This API indirectly calls setFetchSize(Integer.MIN\_VALUE). To enable the streaming read function, set **enableStreamingQuery** in the URL to **true** and call setFetchSize(Integer.MIN\_VALUE) or enableStreamingResults(). Except that the streaming read function is enabled, the input parameter of setFetchSize() can only be a positive number or 0.

### 5.3.15.9 javax.sql.ConnectionPoolDataSource

This section describes javax.sql.ConnectionPoolDataSource, the interface for data source connection pools.

**Table 5-17** Support status for javax.sql.ConnectionPoolDataSource

Method Name	Return Type	Support JDBC4 (Yes/No)
getPooledConnection()	PooledConnection	Yes
getPooledConnection(String user,String password)	PooledConnection	Yes

### 5.3.15.10 javax.sql.DataSource

This section describes javax.sql.DataSource, the interface for data sources.

**Table 5-18** Support status for javax.sql.DataSource

Method Name	Return Type	Support JDBC4 (Yes/No)
getConnection()	Connection	Yes
getConnection(String username,String password)	Connection	Yes
getLoginTimeout()	int	Yes
getLogWriter()	PrintWriter	Yes
setLoginTimeout(int seconds)	void	Yes
setLogWriter(PrintWriter out)	void	Yes

### 5.3.15.11 javax.sql.PooledConnection

This section describes javax.sql.PooledConnection, the connection interface created by a connection pool.

**Table 5-19** Support status for javax.sql.PooledConnection

Method Name	Return Type	Support JDBC4 (Yes/No)
addConnectionEventListener (ConnectionEventListener listener)	void	Yes
close()	void	Yes
getConnection()	Connection	Yes

Method Name	Return Type	Support JDBC4 (Yes/No)
removeConnectionEventListener (ConnectionEventListener listener)	void	Yes

### 5.3.15.12 javax.naming.Context

This section describes javax.naming.Context, the context interface for connection configuration.

**Table 5-20** Support status for javax.naming.Context

Method Name	Return Type	Support JDBC4 (Yes/No)
bind(Name name, Object obj)	void	Yes
bind(String name, Object obj)	void	Yes
lookup(Name name)	Object	Yes
lookup(String name)	Object	Yes
rebind(Name name, Object obj)	void	Yes
rebind(String name, Object obj)	void	Yes
rename(Name oldName, Name newName)	void	Yes
rename(String oldName, String newName)	void	Yes
unbind(Name name)	void	Yes
unbind(String name)	void	Yes

### 5.3.15.13 javax.naming.spi.InitialContextFactory

This section describes javax.naming.spi.InitialContextFactory, the initial context factory interface.

**Table 5-21** Support status for javax.naming.spi.InitialContextFactory

Method Name	Return Type	Support JDBC4 (Yes/No)
getInitialContext(Hashtable<?,?> environment)	Context	Yes

### 5.3.15.14 CopyManager

CopyManager is an API class provided by the JDBC driver in GaussDB. It is used to import data to GaussDB clusters in batches.

#### Inheritance Relationship of CopyManager

The CopyManager class is in the **com.huawei.gaussdb.jdbc.copy** package and inherits the java.lang.Object class. The declaration of the class is as follows:

```
public class CopyManager
extends Object
```

#### Constructor Method

```
public CopyManager(BaseConnection connection)
throws SQLException
```

#### Common Methods

**Table 5-22** Common methods of CopyManager

Return Value	Method	Description	throws	Support JDBC4 (Yes/No)
CopyIn	copyIn(String sql)	-	SQLException	Yes
long	copyIn(String sql, InputStream from)	Uses <b>COPY FROM STDIN</b> to quickly load data to tables in the database from InputStream.	SQLException, IOException	Yes

Return Value	Method	Description	throws	Support JDBC4 (Yes/No)
long	copyIn(String sql, InputStream from, int bufferSize)	Uses <b>COPY FROM STDIN</b> to quickly load data to tables in the database from InputStream.	SQLException, IOException	Yes
long	copyIn(String sql, Reader from)	Uses <b>COPY FROM STDIN</b> to quickly load data to tables in the database from Reader.	SQLException, IOException	Yes
long	copyIn(String sql, Reader from, int bufferSize)	Uses <b>COPY FROM STDIN</b> to quickly load data to tables in the database from Reader.	SQLException, IOException	Yes
CopyOutput	copyOut(String sql)	-	SQLException	Yes
long	copyOut(String sql, OutputStream to)	Sends the result set of <b>COPY TO STDOUT</b> from the database to the OutputStream class.	SQLException, IOException	Yes
long	copyOut(String sql, Writer to)	Sends the result set of <b>COPY TO STDOUT</b> from the database to the Writer class.	SQLException, IOException	Yes

### 5.3.15.15 PGReplicationConnection

PGReplicationConnection is an API class provided by the JDBC driver in GaussDB. It is used to implement functions related to logical replication.

### Inheritance Relationship of PGReplicationConnection

PGReplicationConnection is a logical replication API. Its implementation class is PGReplicationConnectionImpl, which is in the

**com.huawei.gaussdb.jdbc.replication** package. The declaration of the class is as follows:

```
public class PGReplicationConnection implements PGReplicationConnection
```

## Constructor

```
public PGReplicationConnection(BaseConnection connection)
```

## Common Methods

**Table 5-23** Common methods of PGReplicationConnection

Return Value	Method	Description	Throws
ChainedCreateReplicationSlotBuilder	createReplicationSlot()	Creates a logical replication slot. Only cluster-level (CSN-based) logical replication slots can be created for connecting to CNs, and replication slots with the same name can be created on other CNs and primary DNs. Only local (LSN-based) logical replication slots can be created for connecting to DNs. For details about how to create an LSN-based logical replication slot on a CN or a CSN-based logical replication slot on a DN, see the SQL function <code>pg_create_logical_replication_slot</code> for logical replication.	-

Return Value	Method	Description	Throws
void	dropReplication-Slot(String slotName)	<p>Deletes a logical replication slot.</p> <p>When you connect to a CN to delete a logical replication slot, if the logical replication slot is an LSN-based logical replication slot, only the replication slot of the current node is deleted. Replication slots with the same name on other nodes are not affected. When a CSN-based logical replication slot with the same name exists on other nodes, no error is reported because some nodes do not have replication slots. In addition, replication slots with the same name on all nodes are successfully deleted. If no replication slot exists on any node, an error is reported. If an LSN-based logical replication slot remains on the current CN and a CSN-based logical replication slot with the same name remains on other nodes, connecting to a CN to delete a</p>	SQLException,IOE xception

Return Value	Method	Description	Throws
		replication slot will delete only the local LSN-based logical replication slot. After the deletion is complete, perform the deletion operation again to delete the replication slots with the same name on other nodes.	
ChainedStreamBuilder	replicationStream()	Enables logical replication.	-

### 5.3.15.16 PGReplicationStream

PGReplicationStream is an API class provided by the GaussDB JDBC driver. It is used to operate logical replication streams.

### Inheritance Relationship of PGReplicationStream

PGReplicationStream is a logical replication API. Its implementation class is V3PGReplicationStream, which is in the **com.huawei.gaussdb.jdbc.core.v3.replication** package. The declaration of the class is as follows:

```
public class V3PGReplicationStream implements PGReplicationStream
```

### Constructor

```
public V3PGReplicationStream(CopyDual copyDual, LogSequenceNumber startLSN, long updateIntervalMs, ReplicationType replicationType)
```

### Common Methods

**Table 5-24** Common methods of PGReplicationStream

Return Value	Method	Description	throws
void	close()	Ends the logical replication and releases resources.	SQLException

Return Value	Method	Description	throws
void	forceUpdateStatus()	Forcibly sends the LSN status received, refreshed, and applied last time to the backend.	SQLException
LogSequenceNumber	getLastAppliedLSN()	Obtains the LSN when the primary node replays logs last time.	-
LogSequenceNumber	getLastFlushedLSN()	Obtains the LSN flushed by the primary node last time, that is, the LSN pushed by the current logic decoding.	-
LogSequenceNumber	getLastReceiveLSN()	Obtains the last received LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots).	-
boolean	isClosed()	Determines whether the replication stream is disabled.	-
ByteBuffer	read()	Reads the next WAL record from the backend. If the data cannot be read, this method blocks the I/O read.	SQLException
ByteBuffer	readPending()	Reads the next WAL record from the backend. If the data cannot be read, this method does not block the I/O read.	SQLException
void	setAppliedLSN(LogSequenceNumber applied)	Sets the applied LSN.	-

Return Value	Method	Description	throws
void	setFlushedLSN(LogSequenceNumber flushed)	Updates the LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots), which is sent to the backend at the next update to update the LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots) on the server.	-

### 5.3.15.17 ChainedStreamBuilder

ChainedStreamBuilder is an API class provided by the GaussDB JDBC driver. It is used to build replication streams.

#### Inheritance Relationship of ChainedStreamBuilder

ChainedStreamBuilder is a logical replication API. Its implementation class is ReplicationStreamBuilder, which is in the **com.huawei.gaussdb.jdbc.replication.fluent** package. The declaration of the class is as follows:

```
public class ReplicationStreamBuilder implements ChainedStreamBuilder
```

#### Constructor

```
public ReplicationStreamBuilder(final BaseConnection connection)
```

#### Common Methods

**Table 5-25** Common methods of ReplicationStreamBuilder

Return Value	Method	Description	throws
ChainedLogicalStreamBuilder	logical()	Creates a logical replication stream.	-
ChainedPhysicalStreamBuilder	physical()	Creates a physical replication stream.	-

### 5.3.15.18 ChainedCommonStreamBuilder

ChainedCommonStreamBuilder is an API class provided by the GaussDB JDBC driver. It is used to specify common parameters for logical and physical replication.

#### Inheritance Relationship of ChainedCommonStreamBuilder

ChainedCommonStreamBuilder is an API for logical replication. The implementation abstract class is AbstractCreateSlotBuilder. The inheritance class is LogicalCreateSlotBuilder which is in the **com.huawei.gaussdb.jdbc.replication.fluent.logical** package. The declaration of this class is as follows:

```
public class LogicalCreateSlotBuilder
    extends AbstractCreateSlotBuilder<ChainedLogicalCreateSlotBuilder>
    implements ChainedLogicalCreateSlotBuilder
```

#### Constructor

```
public LogicalCreateSlotBuilder(BaseConnection connection)
```

#### Common Methods

**Table 5-26** Common methods of LogicalCreateSlotBuilder

Return Value	Method	Description	throws
T	withSlotName(String slotName)	Specifies the name of a replication slot.	-
ChainedLogicalCreateSlotBuilder	withOutputPlugin(String outputPlugin)	Plug-in name. Currently, mppdb_decoding is supported.	-
void	make()	Creates a slot with the specified parameters in the database.	SQLException
ChainedLogicalCreateSlotBuilder	self()	Returns the implementation of ChainedLogicalCreateSlotBuilder.	-

### 5.3.16 Common JDBC Parameters

#### allowReadOnly

**Principle:** Checks whether the transaction access mode can be modified through **setReadOnly**. If the value is **true**, the transaction access mode can be modified. If

the value is **false**, the transaction access mode cannot be modified through this API. To modify the transaction access mode, execute the statements: SET SESSION CHARACTERISTICS AS TRANSACTION + READ ONLY / READ WRITE.

**Suggestion:** The default value **true** is recommended.

## autoBalance

**Principle:** If this parameter is set to **true**, **balance**, or **roundrobin**, the JDBC load balancing function is enabled to balance multiple connections of applications to available CNs in the database cluster. When a connection is established for the first time, the IP address configured in the JDBC connection string is used to establish the connection. As long as the connection can be established using one of the IP addresses, the internal available CN list is updated. Then, connections are established based on the CN list instead of the IP addresses in the JDBC connection string.

**Suggestion:** The recommended value is **true**.

## refreshCNIpListTime

**Principle:** When a new connection is established, the system checks whether the interval between the current time and the last update time is greater than the value of this parameter. If the interval is greater than this value, the system queries the available CN list in the database and updates the CN list of JDBC. If the interval exceeds the value of this parameter but no new connection is established, the system does not update the CN list.

**Suggestion:** The default value is **10s**. You are advised to adjust the value based on service requirements. This parameter must be used together with **autoBalance**.

## fetchsize

**Principle:** After **fetchsize** is set to  $n$  and the database server executes a query, JDBC communicates with the server when the caller executes `resultset.next()`, fetches  $n$  pieces of data to the JDBC client, and returns the first piece of data to the caller. When the caller fetches the  $(n+1)$ th data record, the caller fetches data from the database server again.

**Function:** Prevents the database from transmitting all results to the client at a time, which exhausts the memory resources of the client.

**Suggestion:** You are advised to set this parameter based on the amount of data queried by services and the memory of the client. When setting **fetchsize**, disable automatic commit (set **autocommit** to **false**). Otherwise, the setting of **fetchsize** does not take effect.

## defaultRowFetchSize

**Function:** The default value of **fetchsize** is **0**. Setting **defaultRowFetchSize** will change the default value of **fetchsize**.

## batchMode

**Function:** This parameter specifies whether to connect the database in batch mode. The default value is **on**. After the function is enabled, the batch update

performance is improved, and the return value is also batch updated. For example, if three data records are inserted in batches, the return value is **[3,0,0]** when the function is enabled, and the return value is **[1,1,1]** when the function is disabled.

**Suggestion:** If the service framework (such as hibernate) checks the return value during batch update, you can set this parameter to solve the problem.

## loginTimeout

**Function:** Controls the time for establishing a connection with the database. The time includes connectTimeout and socketTimeoutInConnecting. If the time elapsed exceeds the threshold, the connection exits. The calculation formula is as follows:

**loginTimeout** = (**connectTimeout** + Connection authentication time + Initialization statement execution time) x Number of nodes. The default value is **0**.

**Suggestion:** After the configuration, an asynchronous thread is started each time a connection is established. If there are a large number of connections, the pressure on the client may increase. You can adjust the value based on service requirements. You are advised to set it as follows:  $\max(\text{connectTimeout}, \text{socketTimeoutInConnecting}) \times \text{Number of nodes}$ .

---

### NOTICE

- This parameter sets the time for attempting to connect to all IP addresses in a list. If this parameter is set to a small value, the subsequent IP addresses in the list may fail to be connected. For example, if three IP addresses are set, **loginTimeout** is set to **5s**, and it takes 5s to connect to the first two IP addresses, the third IP address cannot be connected.
- When any of the CPU, memory, and I/O load approaches 100%, the connection is slow, which may cause the connection time to exceed the threshold. You can locate the fault as follows:
  1. Log in to a physical machine with slow connections or use a management tool to query the resource load. You can run the **top** command to check the CPU usage, run the **free** command to check the memory usage, and run the **iostat** command to check the I/O load. In addition, you can check the monitoring logs in the CM Agent and the monitoring records on the database O&M platform.
  2. For peak load scenarios caused by a large number of slow queries in a short period of time, you can use the port specified by [*Port number of the database server* + 1] to query the pg\_stat\_activity view. For slow queries, you can use the system function **pg\_terminate\_backend(pid int)** to kill sessions.
  3. If service overloading exists for a long time (that is, there is no obvious slow query, or new queries still become slow after slow queries are killed), reduce the service load and increase database resources.

---

## cancelSignalTimeout

**Function:** A cancel message may cause a block. This parameter controls connect timeout and socket timeout in a cancel command, in seconds. It is used to prevent

timeout detection from being performed when the connection is canceled due to timeout.

**Suggestion:** The default value is **10s**. You are advised to adjust the value based on service requirements.

## connectTimeout

**Function:** Controls the socket timeout threshold during connection setup. In this case, this timeout threshold is the time when the JDBC connects to the database through the socket, not the time when the connection object is returned. If the time elapsed exceeds the threshold, JDBC searches for the next IP address.

**Suggestion:** This parameter determines the maximum timeout interval for establishing a TCP connection on each node. If a network fault occurs on a node, it attempts to connect to the node until the time specified by **connectTimeout** elapses, and then attempts to connect to the next node. Considering the network jitter and delay, you are advised to set this parameter to **3s**.

## socketTimeout

**Function:** Controls the timeout threshold of socket operations. If the time of executing service statements or reading data streams from the network exceeds the threshold (that is, when the statement execution time exceeds the specified threshold and no data is returned), the connection is interrupted.

**Suggestion:** This parameter specifies the maximum execution time of a single SQL statement. If the execution time of a single SQL statement exceeds the value of this parameter, an error is reported and the statement exits. You are advised to set this parameter based on service characteristics. If this parameter is not set, the default value **0** is used, indicating that the execution of SQL statement does not time out. If this parameter is not set, the client waits for a long time when the database process is abnormal. You are advised to set this parameter based on the SQL execution time acceptable to services.

## socketTimeoutInConnecting

**Function:** Controls the socket operation timeout value during connection establishment. If the time of reading data streams from the network exceeds the threshold, it attempts to search for the next node for connection.

**Suggestion:** This parameter affects only the socket timeout value during the connection establishment. If this parameter is not set, the default value **5s** is used.

## autosave

**Function:** If the value is **always**, you can set a savepoint before each statement in a transaction. If an error is reported during statement execution in a transaction, the system returns to the latest savepoint. In this way, subsequent statements in the transaction can be properly executed and committed. If the value is **conservative**, a savepoint is set for each query. However, the system rolls back and retries only when there is an invalid statement. If the value is **never**, there is no savepoint.

**Suggestion:** You are advised not to set this parameter to avoid severe performance deterioration.

## currentSchema

**Function:** Specifies the schema of the current connection. If this parameter is not set, the default schema is the username used for the connection.

**Suggestion:** You are advised to set this parameter to the schema where the service data is located. If the schema name contains special characters except letters, digits, and underscores (\_), you are advised to enclose the schema name in quotation marks. Note that the schema name is case sensitive after quotation marks are added. If multiple schemas need to be configured, separate them with commas (,). Schemas containing special characters also need to be enclosed in quotation marks.

## prepareThreshold

**Function:** The default value is **5**. If an SQL statement is executed for multiple consecutive times in a session and the number of execution times specified by **prepareThreshold** is reached, JDBC does not send the PARSE command to the SQL statement but caches the SQL statement to improve the execution speed.

**Suggestion:** The default value is **5**. Adjust the value based on service requirements.

## preparedStatementCacheQueries

**Function:** Specifies the number of queries cached in each connection. The default value is **256**. If more than 256 different queries are used in the **prepareStatement()** call, the least recently used query cache will be discarded.

**Suggestion:** The default value is **256**. Adjust the value based on service requirements. This parameter is used together with **prepareThreshold**.

## blobMode

**Function:** Sets the **setBinaryStream** method to assign values to different types of data. The value **on** indicates that values are assigned to BLOB data. The value **off** indicates that values are assigned to bytea data. The default value is **on**. For example, you can assign values to parameters in the **preparestatement** and **callablestatement** objects.

**Suggestion:** The default value is **on**.

## setAutocommit

**Function:** If the value is **true**, a transaction is automatically started when each statement is executed. After the execution is complete, the transaction is automatically committed. That is, each statement is a transaction. If the value is **false**, a transaction is automatically started. However, you need to manually commit the transaction.

**Suggestion:** Adjust the value based on service characteristics. If autocommit needs to be disabled for performance or other purposes, the application must ensure

that transactions can be committed. For example, explicitly commit transactions after specifying service SQL statements. Particularly, ensure that all transactions are committed before the client exits.

## 5.3.17 FAQs

### 5.3.17.1 Incorrect batchMode Settings

#### Symptom

Set the URL parameters **batchMode** to **on** and **rewriteBatchedInserts** to **true**. After JDBC is used to insert data in batches, a message is displayed, indicating that the number of binding parameters is inconsistent with the number of parameters required by the statement.

```
bind message supplies * parameters, but prepared statement "" requires *
```

#### Example 1:

```
// conn is a created connection object. The URL parameters for creating the connection contain
// &batchMode=on&rewriteBatchedInserts=true.
// Bind parameters in batches and then execute the statement. The number of bound parameters does not
// match the number of columns in the rewritten INSERT statement. As a result, an exception is reported.
// java.sql.BatchUpdateException: bind message supplies 3 parameters, but prepared statement "" requires 6
PreparedStatement stmt = conn.prepareStatement("insert into test_tbl values (?, ?, ?)");

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.executeBatch();
```

#### Cause Analysis

When **rewriteBatchedInserts** is set to **true**, multiple SQL statements are combined into one. As a result, the number of reserved parameter columns in the statement changes. If **batchMode** is set to **on**, parameters are bound based on the SQL statements before combination. As a result, the number of bound parameters is inconsistent with the number of parameters required by the statement.

#### Solution

If **rewriteBatchedInserts** is set to **true**, set **batchMode** to **off**.

## 5.3.18 JDBC Data Type Mapping

The relationships among data types, Java variable types, and JDBC type indexes are as follows (ORA: Oracle-compatible; MYSQL: MySQL-compatible).

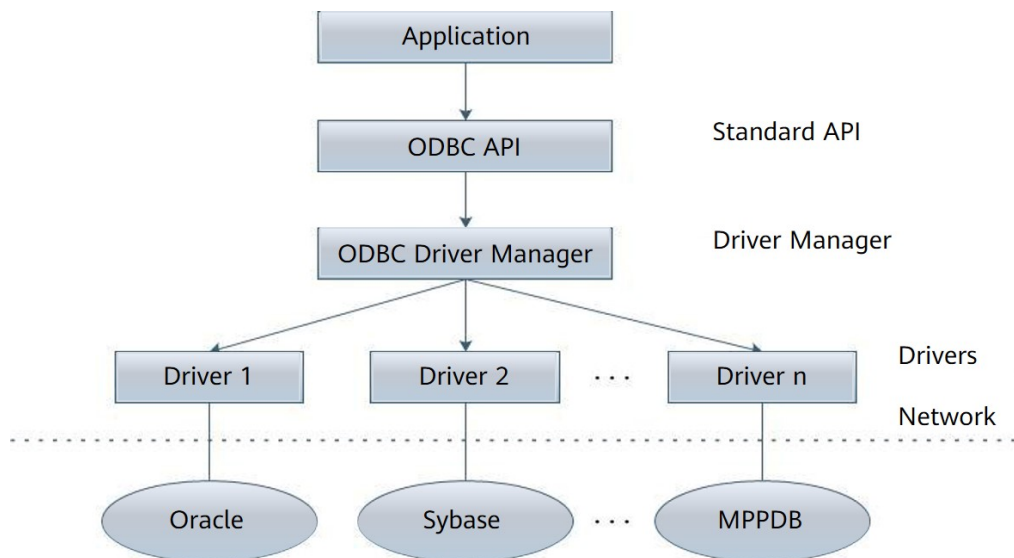

Compatibility Mode	GaussDB Data Type	Java Variable Type	JDBC Type Index
ORA/MYSQL	oid	java.lang.Long	java.sql.Types.BIGINT
ORA/MYSQL	numeric	java.math.BigDecimal	java.sql.Types.NUMERIC
ORA/MYSQL	tinyint	java.lang.Integer	java.sql.Types.TINYINT
ORA/MYSQL	smallint	java.lang.Integer	java.sql.Types.SMALLINT
ORA/MYSQL	bigint	java.lang.Long	java.sql.Types.BIGINT
ORA/MYSQL	float4	java.lang.Float	java.sql.Types.REAL
ORA/MYSQL	float8	java.lang.Double	java.sql.Types.DOUBLE
ORA/MYSQL	char	java.lang.String	java.sql.Types.CHAR
ORA/MYSQL	character	java.lang.String	java.sql.Types.CHAR
ORA/MYSQL	bpchar	java.lang.String	java.sql.Types.CHAR
ORA/MYSQL	character varying	java.lang.String	java.sql.Types.VARCHAR
ORA/MYSQL	varchar	java.lang.String	java.sql.Types.VARCHAR
ORA/MYSQL	text	java.lang.String	java.sql.Types.VARCHAR
ORA/MYSQL	name	java.lang.String	java.sql.Types.VARCHAR
ORA/MYSQL	bytea	byte[]	java.sql.Types.BINARY
ORA/MYSQL	blob	java.sql.Blob	java.sql.Types.BLOB
ORA/MYSQL	clob	java.sql.Clob	java.sql.Types.CLOB
ORA/MYSQL	boolean	java.lang.Boolean	java.sql.Types.BIT
MYSQL	date	java.sql.Date	java.sql.Types.DATE
ORA/MYSQL	time	java.sql.Time	java.sql.Types.TIME
ORA/MYSQL	timetz	java.sql.Time	java.sql.Types.TIME
ORA/MYSQL	timestamp	java.sql.Timestamp	java.sql.Types.TIMESTAMP
ORA/MYSQL	smalldatetime	java.sql.Timestamp	java.sql.Types.TIMESTAMP
ORA/MYSQL	timestampz	java.sql.Timestamp	java.sql.Types.TIMESTAMP
ORA/MYSQL	refcursor	java.sql.ResultSet	java.sql.Types.REF_CURSOR java.sql.Types.OTHER -10

## 5.4 Development Based on ODBC

Open Database Connectivity (ODBC) is a Microsoft API for accessing databases based on the X/OPEN CLI. ODBC APIs alleviate applications from directly operating in databases, and enhance the database portability, extensibility, and maintainability.

Figure 5-2 shows the system structure of ODBC.

Figure 5-2 ODBC system structure

GaussDB supports ODBC 3.5 in the following environments.

Table 5-27 OSs Supported by ODBC

OS	Platform
EulerOS V2.0SP5	x86_64
EulerOS V2.0SP9	Arm64
EulerOS V2.0SP10	x86_64
EulerOS V2.0SP10	Arm64
Windows 7	x86_32
Windows 7	x86_64
Windows Server 2008	x86_32
Windows Server 2008	x86_64
Kylin V10	x86_64
Kylin V10	Arm64

OS	Platform
UnionTech V20	x86_64
UnionTech V20	Arm64
Huawei Cloud EulerOS 2.0	x86_64
Huawei Cloud EulerOS 2.0	Arm64

The ODBC Driver Manager running on Unix or Linux can be unixODBC or iODBC. unixODBC-2.3.7 is used as the component for connecting to the database.

Windows has a native ODBC Driver Manager. You can locate **Data Sources (ODBC)** by choosing **Control Panel > Administrative Tools**.

#### NOTE

The current database ODBC driver is based on an open-source version and may be incompatible with Huawei-developed data types such as tinyint, smalldatetime, and nvarchar2.

## ODBC Constraints

- ODBC does not support DR switchover.
- When the **proc\_outparam\_override** parameter is enabled for the database, ODBC cannot properly call the stored procedure that contains the **out** parameter.

## 5.4.1 ODBC Packages, Dependent Libraries, and Header Files

### ODBC Packages for the Linux OS

Obtain the package **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Odbc.tar.gz** from the release package. In the Linux OS, header files (including **sql.h** and **sqlext.h**) and the library (**libodbc.so**) are required in application development. These header files and library can be obtained from the unixODBC-2.3.7 installation package.

### ODBC Packages for the Windows OS

Obtain the package **GaussDB-Kernel\_Database version number\_Windows\_X86\_Odbc.tar.gz** (32-bit) or **GaussDB-Kernel\_Database version number\_Windows\_X64\_Odbc.tar.gz** (64-bit) from the release package. In the Windows OS, the required header files and library files are system-resident.

## 5.4.2 Development Process

Figure 5-3 ODBC-based application development process

### APIs Involved in the Development Process

Table 5-28 API description

Function	API
Allocate a handle.	<b>SQLAllocHandle</b> is a generic function for allocating a handle. It can replace the following functions: <ul style="list-style-type: none"> <li>• <b>SQLAllocEnv</b>: allocates an environment handle.</li> <li>• <b>SQLAllocConnect</b>: allocates a connection handle.</li> <li>• <b>SQLAllocStmt</b>: allocates a statement handle.</li> </ul>
Set environment attributes.	<b>SQLSetEnvAttr</b>
Set connection attributes.	<b>SQLSetConnectAttr</b>
Set statement attributes.	<b>SQLSetStmtAttr</b>
Connect to a data source.	<b>SQLConnect</b>

Function	API
Bind a buffer to a column in the result set.	<a href="#">SQLBindCol</a>
Bind the parameter marker of an SQL statement to a buffer.	<a href="#">SQLBindParameter</a>
Return the error message of the last operation.	<a href="#">SQLGetDiagRec</a>
Prepare an SQL statement for execution.	<a href="#">SQLPrepare</a>
Run a prepared SQL statement.	<a href="#">SQLExecute</a>
Run an SQL statement directly.	<a href="#">SQLExecDirect</a>
Fetch the next row (or rows) from a result set.	<a href="#">SQLFetch</a>
Return data in a column of a result set.	<a href="#">SQLGetData</a>
Get the column information from a result set.	<a href="#">SQLColAttribute</a>
Disconnect from a data source.	<a href="#">SQLDisconnect</a>
Release a handle.	<p><a href="#">SQLFreeHandle</a> is a generic function for releasing a handle. It can replace the following functions:</p> <ul style="list-style-type: none"> <li>• <a href="#">SQLFreeEnv</a>: releases an environment handle.</li> <li>• <a href="#">SQLFreeConnect</a>: releases a connection handle.</li> <li>• <a href="#">SQLFreeStmt</a>: releases a statement handle.</li> </ul>

 NOTE

- ODBC connects applications to the database and delivers the SQL statements sent by an application to the database. It does not parse the SQL syntax. Therefore, when confidential information is written into the SQL statement sent by an application, the confidential information is exposed in the driver log.
- If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. If one of the statements fails, the entire request will be rolled back.

### 5.4.3 Configuring a Data Source in the Linux OS

The ODBC DRIVER ([gsqldbcs.so](#)) provided by GaussDB can be used after it has been configured in a data source. To configure a data source, you must configure

the **odbc.ini** and **odbcinst.ini** files on the server. The two files are generated during the unixODBC compilation and installation, and are saved in the **/usr/local/etc** directory by default.

## Procedure

**Step 1** Obtain the source code package of unixODBC by clicking the following link:

Download address: <https://www.unixodbc.org/unixODBC-2.3.7.tar.gz>.

After the download, verify the integrity based on the integrity verification algorithm provided by the community. Download <https://www.unixodbc.org/unixODBC-2.3.7.tar.gz.md5>, view the MD5 value, and check whether the MD5 value is the same as that in the source code package.

**Step 2** Install unixODBC. It does not matter if unixODBC of another version has been installed.

For example, install unixODBC-2.3.7.

```
tar zxvf unixODBC-2.3.7.tar.gz
cd unixODBC-2.3.7
```

```
./configure --enable-gui=no # To perform compilation on an Arm server, add the configure parameter --  
build=aarch64-unknown-linux-gnu.  
make  
# The installation may require root permissions.  
make install
```

### NOTE

- Currently, unixODBC-2.2.1 is not supported.
- It is installed in the **/usr/local** directory by default. The data source file is generated in the **/usr/local/etc** directory, and the library file is generated in the **/usr/local/lib** directory.
- You can compile unixODBC with the **--enable-fastvalidate=yes** option to achieve higher performance. However, this option may cause an application that passes an invalid handle to the ODBC API to fail instead of returning an SQL\_INVALID\_HANDLE error.

**Step 3** Replace the GaussDB client driver.

Decompress **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Odbc.tar.gz**. After the decompression, the **lib** and **odbc** folders are generated. The **odbc** folder contains another **lib** folder. Copy all dynamic libraries in the **/lib** and **/odbc/lib** folders to the **/usr/local/lib** directory.

**Step 4** Configure a data source.

1. Configure the ODBC driver file.

Add the following content to the **/usr/local/etc/odbcinst.ini** file:

```
[GaussMPP]  
Driver64=/usr/local/lib/gsqlodbcw.so  
setup=/usr/local/lib/gsqlodbcw.so
```

For descriptions of the parameters in the **odbcinst.ini** file, see [Table 5-29](#).

**Table 5-29** odbcinst.ini configuration parameters

Parameter	Description	Example
[DriverName]	Driver name, corresponding to Driver in DSN.	[DRIVER_N]
Driver64	Path of the dynamic driver library.	Driver64=/usr/local/lib/gsqlodbcw.so
setup	Driver installation path, which is the same as the dynamic library path in Driver64.	setup=/usr/local/lib/gsqlodbcw.so

2. Configure the data source file.

Add the following content to the `/usr/local/etc/odbc.ini` file:

```
[gaussdb]
Driver=GaussMPP
Servername=127.0.0.1 # Database server IP address
Database=db1 # Database name
Username=omm # Database username
Password= # Database user password
Port=8000 # Database listening port
Sslmode=allow
```

For descriptions of the parameters in the `odbc.ini` file, see [Table 5-30](#).

**Table 5-30** odbc.ini configuration parameters

Parameter	Description	Example
[DSN]	Data source name.	[gaussdb]
Driver	Driver name, corresponding to DriverName in <code>odbcinst.ini</code> .	Driver=DRIVER_N
Servername	Server IP address. Multiple IP addresses can be configured. Both IPv4 and IPv6 are supported.	Servername=127.0.0.1
Database	Name of the database to connect.	Database=db1
Username	Database username.	Username=omm

Parameter	Description	Example
Password	<p>Database user password.</p> <p><b>NOTE</b> After a user establishes a connection, the ODBC driver automatically clears their password stored in memory.</p> <p>However, if this parameter is configured, unixODBC will cache data source files, which may cause the password to be stored in the memory for a long time.</p> <p>When you connect to an application, you are advised to send your password through an API instead of writing it in a data source configuration file. After the connection has been established, immediately clear the memory segment where your password is stored.</p> <p><b>CAUTION</b> The password in the configuration file must comply with the following HTTP rules:</p> <ol style="list-style-type: none"> <li>1. Characters must comply with the URL encoding specifications. For example, the exclamation mark (!) must be written as %21, and the percent sign (%) must be written as %25. Therefore, pay attention to the characters.</li> <li>2. A plus sign (+) will be replaced by a space.</li> </ol>	Password=*****

Parameter	Description	Example
Port	Port number of the server. When load balancing is enabled, multiple port numbers can be configured and must correspond to multiple IP addresses. If multiple IP addresses are configured and only one port number is configured when load balancing is enabled, all IP addresses share the same port number by default, that is, the configured port number.	Port=8000
Sslmode	Specifies whether to enable SSL.	Sslmode=allow
Debug	If this parameter is set to <b>1</b> , the <b>mylog</b> file of the gsqlODBC driver will be printed. The directory generated for storing logs is <b>/tmp/</b> . If this parameter is set to <b>0</b> , no directory is generated.	Debug=1
UseServerSidePrepare	Specifies whether to enable the extended query protocol for the database.  The value can be <b>0</b> or <b>1</b> . The default value is <b>1</b> , indicating that the extended query protocol is enabled.	UseServerSidePrepare=1

Parameter	Description	Example
UseBatchProtocol	<p>Specifies whether to enable the batch query protocol. If it is enabled, DML performance can be improved. The value can be <b>0</b> or <b>1</b> (default).</p> <ul style="list-style-type: none"> <li>- If this parameter is set to <b>0</b>, the batch query protocol is disabled (mainly for communication with earlier database versions).</li> <li>- If this parameter is set to <b>1</b> and <b>support_batch_bind</b> is set to <b>on</b>, the batch query protocol is enabled.</li> </ul>	UseBatchProtocol=1
ForExtensionConnector	<p>This parameter specifies whether the savepoint is sent. The default value is <b>1</b>. If the value is <b>0</b>, the savepoint is sent. If the value is <b>1</b>, the savepoint is not sent.</p>	ForExtensionConnector=1
ConnectionExtraInfo	<p>Specifies whether to display the driver deployment path and process owner in the GUC parameter <b>connection_info</b>.</p> <p><b>NOTE</b> The default value is <b>0</b>. If this parameter is set to <b>1</b>, the ODBC driver reports the driver deployment path and process owner to the database and displays the information in the GUC parameter <b>connection_info</b>. In this case, you can query the information from <a href="#">PG_STAT_ACTIVITY</a> or <a href="#">PGXC_STAT_ACTIVITY</a>.</p>	ConnectionExtraInfo=1

Parameter	Description	Example
BoolAsChar	If this parameter is set to <b>Yes</b> , the Boolean value is mapped to the SQL_CHAR type. If this parameter is not set, the value is mapped to the SQL_BIT type. The default value is <b>Yes</b> .	BoolsAsChar = Yes
RowVersioning	When an attempt is made to update a row of data, setting this parameter to <b>Yes</b> allows the application to detect whether the data has been modified by other users. The default value is <b>No</b> .	RowVersioning=Yes
ShowSystemTables	If the value is <b>Yes</b> , the driver regards the system catalog as a common SQL table by default. The default value is <b>No</b> .	ShowSystemTables=Yes
AutoBalance	Specifies whether ODBC controls load balancing. The default value is <b>0</b> , indicating that the function is disabled. <b>1</b> indicates that the function is enabled. That is, all values except <b>1</b> do not take effect. IPv6 does not support load balancing.	AutoBalance=1
RefreshCNListTime	Specifies the interval for refreshing the CN list. The value is an integer and the default value is <b>10</b> , in seconds. This parameter can be configured when load balancing is enabled.	RefreshCNListTime=5

Parameter	Description	Example
Priority	<p>This parameter can be configured when load balancing is enabled. The default value is <b>0</b>, indicating that the function is disabled. <b>1</b> indicates that the function is enabled. That is, all values except <b>1</b> do not take effect. When <b>Priority</b> is enabled, all connections initiated by applications are preferentially sent to the CNs configured in the configuration file. If all the configured CNs are unavailable, the connections are sent to the remaining CNs.</p>	Priority=1
UsingEip	<p>This parameter can be configured when load balancing is enabled. The default value is <b>0</b>, indicating that the function is disabled. <b>1</b> indicates that the function is enabled. That is, all values except <b>1</b> do not take effect. This value specifies whether to use an elastic IP address for load balancing. If <b>UsingEip</b> is enabled, the elastic IP address is used for load balancing. If <b>UsingEip</b> is disabled, the data IP address is used for load balancing.</p>	UsingEip=1

Parameter	Description	Example
MaxCacheQueries	Controls the number of prepared statements cached for each connection. If this parameter is set to <b>0</b> , the prepared statement cache pool is disabled on the client. If this parameter is set to a value greater than 4096, the value <b>4096</b> is used. If the number of executed statements exceeds the upper limit specified by <b>MaxCacheQueries</b> , the least recently used statements are eliminated. The default value is <b>0</b> .	MaxCacheQueries=128
MaxCacheSizeMiB	Controls the total size of prepared statements cached for each connection. This parameter takes effect when the value of <b>MaxCacheQueries</b> is greater than 0. If the total size of cached statements is greater than the value of <b>MaxCacheSizeMiB</b> , the least recently used statements are eliminated. If this parameter is set to a value greater than 4096, the value <b>4096</b> is used. The unit is MB. The default value is <b>1</b> .	MaxCacheSizeMiB=10

Parameter	Description	Example
TcpUserTimeout	Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an OS that supports the <b>TCP_USER_TIMEOUT</b> socket option. <b>0</b> indicates that the default value is used. Ignore this parameter for UDS connections. The unit is millisecond. The default value is <b>0</b> .	TcpUserTimeout=5000
TextAsLongVarchar	If <b>TextAsLongVarchar</b> is set to <b>1</b> , the text type on the kernel side is mapped to the SQL_LONGVARCHAR type on the driver side. If <b>TextAsLongVarchar</b> is set to <b>0</b> , the text type on the kernel side is mapped to the SQL_VARCHAR type on the driver side. The default value is <b>1</b> .	TextAsLongVarchar=1
MaxLongVarcharSize	Maximum length of the SQL_LONGVARCHAR type on the driver side. The default value is <b>8190</b> .	MaxLongVarcharSize=8190
MaxVarcharSize	Maximum length of the SQL_VARCHAR type on the driver side. The default value is <b>255</b> .	MaxVarcharSize=255

**Table 3 sslmode options** describes the valid values of **Sslmode**.

**Table 5-31** sslmode options

sslmode	Whether SSL Encryption Is Enabled	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required and whether the database has a trusted certificate will be verified.
verify-full	Yes	SSL connection is required. In addition to the check scope specified by <b>verify-ca</b> , the system checks whether the name of the host where the database resides is the same as that in the certificate. If they are different, modify the <b>/etc/hosts</b> file as user <b>root</b> and add the IP address and host name of the connected database node to the file.  <b>NOTE</b> This mode does not support the default certificate of the product. Contact the administrator to generate a certificate.

**Step 5** Enable the SSL mode. For details, contact the database administrator.

**Step 6** Configure the database server. For details, contact the database administrator.

**Step 7** Configure the environment variables on the client.

```
vim ~/.bashrc
```

Add the following information to the configuration file:

```
export LD_LIBRARY_PATH=/usr/local/lib:$LD_LIBRARY_PATH
export ODBCYSINI=/usr/local/etc
export ODBCINI=/usr/local/etc/odbc.ini
```

**Step 8** Run the following command to validate the addition:

```
source ~/.bashrc
```

----End

## Verifying the Data Source Configuration

After the installation, the generated binary file is stored in the `/usr/bin` directory. You can run the `isql -v gaussdb` command (*gaussdb* is the data source name).

- If the following information is displayed, the configuration is correct and the connection succeeds:

```
+-----+
| Connected!          |
|                    |
| sql-statement      |
| help [tablename]  |
| quit              |
|                    |
+-----+
```

- If error information is displayed, the configuration is incorrect. Check the configuration.
- In a cluster environment, you need to copy and configure the unixODBC file on all nodes.

## FAQs

- [UnixODBC][Driver Manager]Can't open lib 'xxx/xxx/gsqlodbcw.so' : file not found.

Possible causes:

- The path configured in the `odbcinst.ini` file is incorrect.

Run `ls` to check the path in the error information, ensuring that the `gsqlodbcw.so` file exists and you have execution permissions on it.

- The dependent library of `gsqlodbcw.so` does not exist or is not in system environment variables.

Run the `ldd` command to check the path in the error information. If the unixODBC library such as `libodbc.so.1` is missing, reconfigure unixODBC according to the procedure, ensure that the `lib` directory in the installation path is added to `LD_LIBRARY_PATH`. If the problem persists after reinstallation, manually copy the content in the `unixodbc/lib` directory of the database installation package to the `lib` directory in the installation path of the unixODBC. If other libraries do not exist, add the `lib` directory under the ODBC driver package to `LD_LIBRARY_PATH`. If other standard libraries are missing, install them.

- [UnixODBC]connect to server failed: no such file or directory

Possible causes:

- An incorrect or unreachable database IP address or port was configured.

Check the **Servername** and **Port** configuration items in data sources.

- Server monitoring is improper.

If **Servername** and **Port** are correctly configured, ensure the proper network adapter and port are monitored by following the database server configurations in the procedure in this section.

- Firewall and network gatekeeper settings are improper.

Check firewall settings, and ensure that the database communication port is trusted.

Check to ensure network gatekeeper settings are proper (if any).

- [unixODBC]The password-stored method is not supported.  
Possible causes:  
The **sslmode** configuration item is not configured in the data sources.  
Solution:  
Set the configuration item to **allow** or a higher level. For details, see [Table 5-31](#).
- Server common name "xxxx" does not match host name "xxxxx"  
Possible causes:  
When **verify-full** is used for SSL encryption, the driver checks whether the host name in certificates is the same as the actual one.  
Solution:  
To solve this problem, use **verify-ca** to stop checking host names, or generate a set of server certificates containing the actual host names.
- Driver's SQLAllocHandle on SQL\_HANDLE\_DBC failed  
Possible causes:  
The executable file (such as the **isql** of unixODBC) and the database driver (**gsqldbcs.so**) depend on different library versions of ODBC, such as **libodbc.so.1** and **libodbc.so.2**. You can verify this problem by using the following method:

```
ldd `which isql` | grep odbc  
ldd gsqlodbcw.so | grep odbc
```

If the suffix digits of the outputs **libodbc.so** are different or indicate different physical disk files, this problem exists. Both **isql** and **gsqldbcs.so** require **libodbc.so** to be loaded. If they load different physical files, two sets of function lists with the same name are generated in a visible domain (the **libodbc.so.\*** function export lists of unixODBC are the same). This results in conflicts and the database driver cannot be loaded.  
Solution:  
Uninstall the unnecessary unixODBC, such as **libodbc.so.2**, and create a soft link with the same name and the **.so.2** suffix for the remaining **libodbc.so.1** library.
- FATAL: Forbid remote connection with trust method!  
For security purposes, the database CN forbids access from other nodes in the cluster without authentication.  
To access the CN from inside the cluster, deploy the ODBC program on the host where the CN is located and use 127.0.0.1 as the server address. It is recommended that the service system be deployed outside the cluster. If it is deployed inside, database performance may be affected.
- [unixODBC][Driver Manager]Invalid attribute value  
This problem occurs when you use SQL on other GaussDB. The possible cause is that the unixODBC version is not the recommended one. You are advised to run the **odbcinst --version** command to check the unixODBC version.
- authentication method 10 not supported.  
If this error occurs on an open-source client, the cause may be:  
The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

 NOTE

- The database stores the hashes of user passwords instead of actual passwords.
- If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
- An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the source version will only have SHA-256 hashes and not support MD5 authentication.
- The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

To solve this problem, you can update the user password (see [ALTER USER](#)) or create a user (see [CREATE USER](#)) having the same permissions as the faulty user.

- unsupported frontend protocol 3.51: server supports 1.0 to 3.0

The database version is too early or the database is an open-source database. Use the driver of the required version to connect to the database.

- FATAL: GSS authentication method is not allowed because XXXX user password is not disabled.

In **gs\_hba.conf** of the target CN, the authentication mode is set to **gss** for authenticating the IP address of the current client. However, this authentication algorithm cannot authenticate clients. Change the authentication algorithm to **sha256** and try again. For details, see [Step 6](#).

- isql: error while loading shared libraries:xxx

The dynamic library does not exist in the environment. You need to install the corresponding library.

## 5.4.4 Configuring a Data Source in the Windows OS

Configure an ODBC data source using the ODBC data source manager preinstalled in the Windows OS.

### Procedure

- Step 1** Replace the GaussDB client driver.

Decompress the **GaussDB-Kernel\_Database version number\_Windows\_X64\_Odbc.tar.gz** (64-bit) driver package or **GaussDB-Kernel\_Database version number\_Windows\_X86\_Odbc.tar.gz** (32-bit) driver package, and click **gsqlodbc.exe** to install the driver.

- Step 2** Open the driver manager.

When configuring the data source, use the ODBC driver manager corresponding to the ODBC version. If the 64-bit ODBC driver is used, the 64-bit ODBC driver manager must be used. Assume that the OS is installed on drive C (if the OS is installed on another drive, change the path accordingly):

- If you want to use 32-bit ODBC driver manager in a 64-bit OS, open **C:\Windows\SysWOW64\odbcad32.exe**. Do not choose **Control Panel > Administrative Tools > Data Sources (ODBC)**.

 **NOTE**

WoW64 is short for Windows 32-bit on Windows 64-bit. `C:\Windows\SysWOW64\` stores the 32-bit environment on a 64-bit system. `C:\Windows\System32\` stores the environment consistent with the current OS. For technical details, see Windows technical documents.

- For a 32-bit OS, open `C:\Windows\System32\odbcad32.exe` or choose **Computer > Control Panel > Administrative Tools > Data Sources (ODBC)** to open Driver Manager.
- For a 64-bit OS, choose **Control Panel > Administrative Tools > Data Sources (ODBC)** to enable driver management.

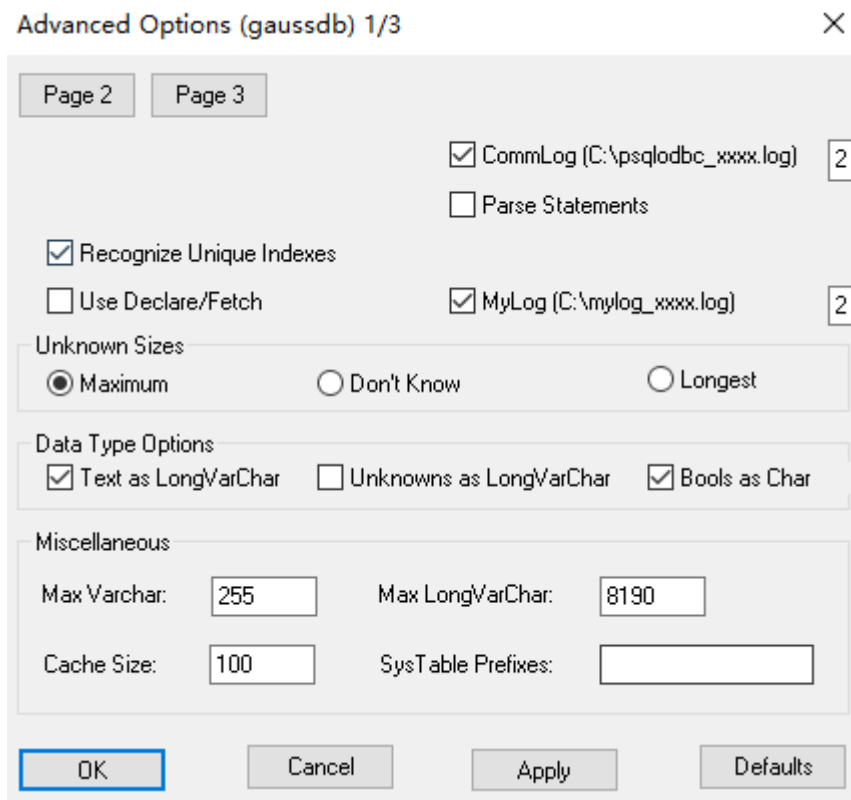

**Step 3** Configure a data source.

On the **User DSN** tab, click **Add** and choose **GaussDB Unicode** for setup.

For details about the parameters, see [Configuring a Data Source in the Linux OS](#).

You can click **Datasource** to configure whether to print logs.

**NOTICE**

The entered username and password will be recorded in the Windows registry and you do not need to enter them again when connecting to the database next time. For security purposes, you are advised to delete sensitive information before clicking **Save** and enter the required username and password again when using ODBC APIs to connect to the database.

**Step 4** Enable the SSL mode.

Change the value of **SSL Mode** in [step 3](#) to **require**.

**Table 5-32** sslmode options

sslmode	Whether SSL Encryption Is Enabled	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.

sslmode	Whether SSL Encryption Is Enabled	Description
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required and whether the database has a trusted certificate will be verified. Currently, Windows ODBC does not support the certificate-based authentication.
verify-full	Yes	SSL connection is required. In addition to the check scope specified by <b>verify-ca</b> , the system checks whether the name of the host where the database resides is the same as that on the certificate. Currently, Windows ODBC does not support the certificate-based authentication.

**Step 5** Configure a GaussDB server. For details, contact the administrator.

**Step 6** Restart the cluster.

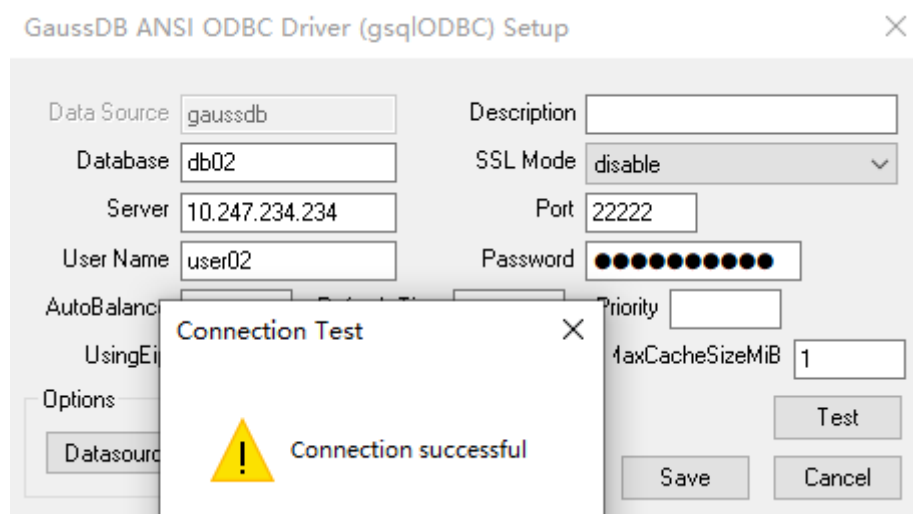

```
gs_om -t stop
gs_om -t start
```

----End

## Verifying the Data Source Configuration

Click **Test**.

- If the following information is displayed, the configuration is correct and the connection succeeds.

- If error information is displayed, the configuration is incorrect. Check the configuration.

## FAQs

- connect to server failed: no such file or directory

Possible causes:

- An incorrect or unreachable database IP address or port was configured. Check the **Server** and **Port** configuration items in data sources.

- Server monitoring is improper.

If **Server** and **Port** are correctly configured, ensure the proper NIC and port are monitored by following the database server configurations in the procedure in this section.

- Firewall and network gatekeeper settings are improper.

Check firewall settings, and ensure that the database communication port is trusted.

Check to ensure network gatekeeper settings are proper (if any).

- The password-stored method is not supported.

Possible causes:

**sslmode** is not configured for the data source. Set this configuration item to **allow** or a higher level to enable SSL connections. For details on **sslmode**, see [Table 5-32](#).

- authentication method 10 not supported.

If this error occurs on an open-source client, the cause may be:

The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

### NOTE

- The database stores the hashes of user passwords instead of actual passwords.
- If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
- An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the source version will only have SHA-256 hashes and not support MD5 authentication.
- The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

To solve this problem, you can update the user password (see [ALTER USER](#)) or create a user (see [CREATE USER](#)) having the same permissions as the faulty user.

- unsupported frontend protocol 3.51: server supports 1.0 to 3.0

The database version is too early or the database is an open-source database. Use the driver of the required version to connect to the database.

- FATAL: GSS authentication method is not allowed because XXXX user password is not disabled.

In **gs\_hba.conf** of the target CN, the authentication mode is set to **gss** for authenticating the IP address of the current client. However, this authentication algorithm cannot authenticate clients. Change the authentication algorithm to **sha256** and try again. For details, see [Step 5](#).

## 5.4.5 Example: Common Functions and Batch Binding

### NOTE

- The following is an example of the command for compiling ODBC application code in Windows:  
gcc odbctest.c -o odbctest -lodbc32  
Run the following command:  
./odbctest.exe
- The following is an example of the command for compiling ODBC application code in Linux:  
gcc odbctest.c -o odbctest -lodbc  
Run the following command:  
./odbctest
- If **sql.h** or API cannot be found during compilation, manually connect to the header file and dynamic library of unixODBC.  
gcc -I /home/omm/unixodbc/include -L /home/omm/unixodbc/lib odbctest.c -o odbctest -lodbc

### Code for Common Functions

```
// The example shows how to obtain data from GaussDB through ODBC.
// DBtest.c (compile with: libodbc.so)
#ifdef WIN32
#include <windows.h>
#else
#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqltext.h>
SQLHENV    V_OD_Env;    // Handle ODBC environment
SQLHSTMT   V_OD_hstmt;  // Handle statement
SQLHDBC    V_OD_hdbc;   // Handle connection
char        typename[100];
SQLINTEGER value = 100;
SQLINTEGER V_OD_erg,V_OD_buffer,V_OD_err,V_OD_id;
int main(int argc,char *argv[])
{
    // 1. Allocate an environment handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_ENV,SQL_NULL_HANDLE,&V_OD_Env);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        printf("Error AllocHandle\n");
        exit(0);
    }
    // 2. Set environment attributes (version information).
    SQLSetEnvAttr(V_OD_Env, SQL_ATTR_ODBC_VERSION, (void*)SQL_OV_ODBC3, 0);
    // 3. Allocate a connection handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_DBC, V_OD_Env, &V_OD_hdbc);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
        exit(0);
    }
    // In this example, the username and password are stored in environment variables. Before running this
    // example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
    // environment (set the environment variable names based on the actual situation).
    char *userName;
    userName = getenv("EXAMPLE_USERNAME_ENV");
    char *password;
    password = getenv("EXAMPLE_PASSWORD_ENV");
    // 4. Set connection attributes.
    SQLSetConnectAttr(V_OD_hdbc, SQL_ATTR_AUTOCOMMIT, (SQLPOINTER *)SQL_AUTOCOMMIT_ON,
0);
    // 5. Connect to the data source. userName and password indicate the username and password for
```

```
connecting to the database, respectively.
// If the username and password have been set in the odbc.ini file, you do not need to set userName or
password here, retaining "" for them. However, you are advised not to do so because the username and
password will be disclosed if the permission for odbc.ini is abused.
V_OD_erg = SQLConnect(V_OD_hdbc, (SQLCHAR*) "gaussdb", SQL_NTS,
                    (SQLCHAR*) userName, SQL_NTS, (SQLCHAR*) password, SQL_NTS);

return 0;  
}
```

## Connection Pool Scenario

A connection pool allows applications to reuse pre-established connections without re-establishing connections each time. Once a connection is created and put into the connection pool, applications can reuse the connection, avoiding repeated execution of the complete connection process.

The use of a connection pool can significantly improve performance, especially for middle-layer applications or applications requiring network connections that need to establish and close connections frequently.

In addition to the performance advantage, the connection pool architecture enables connections in the environment to be shared by multiple components in a single process. Therefore, different components in the same process can share connections in the connection pool without interfering with each other, further improving system efficiency and resource utilization.

### NOTE

In a connection pool, an open connection may be reused by multiple users. If an application script changes the database connection status, data leakage may occur. For security purposes, exercise caution when using a connection pool.

## Configurations on Linux

Enable an connection pool in the **odbcinst.ini** configuration file. The reference configuration of the connection pool is as follows:

```
[ODBC]  
Pooling=Yes # Enable an connection pool.  
[GaussMPP]  
CPOut=60 # Timeout for releasing a connection that is not reused in the connection pool. The default  
value is 0. To enable the connection pool, set this parameter to a value greater than 0.  
CPTimeToLive=60 # Lifetime of the connection pool under the driver.  
[GaussMPP2]  
CPOut=0 # Disable the connection pool.
```

## Configurations on Windows

On the **Connection Pool** tab, double-click **GaussDB Unicode**, and select **Pool Connections to this driver** (the default value is **60s**). This parameter is the same as **CPOutTimeout** configured on Linux.

#### NOTE

1. To configure the connection pool parameters in the application, you need to call `SQLSetEnvAttr` to set the connection pool parameters before creating the environment handle. The environment handle must be set to **null**. In this case, **SQL\_ATTR\_CONNECTION\_POOLING** becomes a process-level attribute.  
Currently, **SQL\_ATTR\_CONNECTION\_POOLING** can be set to either of the following values on Windows:
  - **SQL\_CP\_OFF** (Default): Disable a connection pool.
  - **SQL\_CP\_ONE\_PER\_DRIVER**: Enable a connection pool. Each driver supports a connection pool, and all connections in the driver share the same connection pool.
2. When an application calls `SQLConnect` or `SQLDriverConnect`, the connection is extracted from the connection pool. If the connection times out or no connection matches the request in the pool, a new connection is opened. The connection pool is transparent to the application.
3. When an application calls `SQLDisconnect`, the connection is not released but put back to the connection pool for the next use.
4. Before `SQLFreeHandle` is called in the environment to release the environment handle, all environment attributes that are successfully set by an application persist.
5. If a connection of an application is inactive (not used) for a period of time, the connection is deleted from the pool. The size of the connection pool is limited only by the memory and server.

#### Code examples

Enabling a connection pool on Linux or Windows can significantly improve the performance of middle-layer applications that need to establish and close connections frequently. The reference configurations are as described above. The sample code is as follows:

```
#ifndef WIN32
#include <windows.h>
#endif

#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
#include <string.h>
#include <sys/time.h>
#include <pthread.h>
#include <sqltypes.h>
#include <time.h>
SQLHENV env;
SQLHDBC conn;
struct timeval start, end;

#define CONN_COUNT 15000
#define CHECK_ERROR(retcode, str, handle, htype) \
({ \
    if (retcode != SQL_SUCCESS && retcode != SQL_SUCCESS_WITH_INFO) { \
        fprintf(stderr, "FAILED:\t"); \
        extract_error(str, handle, htype); \
        exit(-1); \
    } else { \
        printf("OK:\t%s\n", str); \
    } \
})
```

```
void print_diag(char *msg, SQLSMALLINT htype, SQLHANDLE handle)
{
    char sqlstate[32];
    char message[1000];
    SQLINTEGER nativeerror;
    SQLSMALLINT textlen;
    SQLRETURN ret;

    if (msg) {
        printf("%s\n", msg);
    }

    ret = SQLGetDiagRec(htype, handle, 1, sqlstate, &nativeerror, message, 256, &textlen);

    if (ret != SQL_ERROR) {
        printf("%s=%s\n", (CHAR *)sqlstate, (CHAR *)message);
    }
}

void extract_error(char *fn, SQLHANDLE handle, SQLSMALLINT type)
{
    SQLINTEGER i = 0;
    SQLINTEGER NativeError;
    SQLCHAR SQLState[7];
    SQLCHAR MessageText[256];
    SQLSMALLINT TextLength;
    SQLRETURN ret;

    fprintf(stderr, "The driver reported the following error %s\n", fn);
    if (NULL == handle)
        return;
    do {
        ret = SQLGetDiagRec(type, handle, ++i, SQLState, &NativeError, MessageText, sizeof(MessageText),
&TextLength);
        if (SQL_SUCCEEDED(ret)) {
            printf("[SQLState:%s]:[%ldth error]:[NativeError:%ld]: %s\n",
                SQLState,
                (long)i,
                (long)NativeError,
                MessageText);
        }
    } while (ret == SQL_SUCCESS);
}

void InitializeEnvironment()
{
    /* Enable a connection pool. Configure connection pool parameters on Windows before allocating an
environment handle. */
    SQLSetEnvAttr(env, SQL_ATTR_CONNECTION_POOLING, (SQLINTEGER *)SQL_CP_ONE_PER_DRIVER, 0);

    /* Disable the connection pool on Windows. */
    // SQLSetEnvAttr(env, SQL_ATTR_CONNECTION_POOLING, (SQLINTEGER*)SQL_CP_OFF, 0);

    // Allocate an environment handle.
    SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &env);
    // Configure the ODBC version.
    SQLSetEnvAttr(env, SQL_ATTR_ODBC_VERSION, (SQLPOINTER)SQL_OV_ODBC3, 0);
    // Configure the timeout interval for establishing a connection.
    SQLSetConnectAttr(conn, SQL_LOGIN_TIMEOUT, (SQLPOINTER *)5, 0);
}

void test_connect()
{
    SQLRETURN ret;
    SQLCHAR str[1024];
    SQLSMALLINT strl;
    SQLCHAR dsn[1024];
    SQLINTEGER ulntVal;
```

```
SQLAllocHandle(SQL_HANDLE_DBC, env, &conn);

/* Adjust the connection string based on the scenario. */
char *config = "Driver=GaussMPP;DSN=gaussdb;";
ret = SQLSetConnectAttr(conn, SQL_ATTR_AUTOCOMMIT, (SQLPOINTER)(1), 0);

ret = SQLDriverConnect(conn, 0, (SQLCHAR *)config, SQL_NTS, (SQLCHAR *)NULL, SQL_NTS, 0,
SQL_DRIVER_NOPROMPT);

if (SQL_SUCCEEDED(ret)) {
    // printf("Connected\n");
} else {
    print_diag("SQLDriverConnect failed.", SQL_HANDLE_DBC, conn);
    SQLFreeHandle(SQL_HANDLE_DBC, conn);
    SQLFreeHandle(SQL_HANDLE_ENV, env);
    exit(1);
}

/* Put the connection into the connection pool to reuse the connection. */
if (conn != SQL_NULL_HDBC) {
    SQLDisconnect(conn);
    SQLFreeHandle(SQL_HANDLE_DBC, conn);
    conn = SQL_NULL_HDBC;
}
}

int main()
{
    int count = 0;
    int timeuser;
    gettimeofday(&start, NULL);
    InitializeEnvironment();

    for (int i = 0; i < CONN_COUNT; i++) {
        test_connect();
        count++;
    }

    // Release an environment handle.
    SQLFreeHandle(SQL_HANDLE_ENV, env);
    printf("Connection count: %d\n", count);
    gettimeofday(&end, NULL);
    timeuser = 1000000 * (end.tv_sec - start.tv_sec) + end.tv_usec - start.tv_usec;
    printf("Connection time: %.3f s \n", (double)timeuser / 1000000);
    return 0;
}
```

The result varies with the environment. When the connection pool is enabled, the running result of this example is as follows:

```
Connection count: 15000
Connection time: 14.175 s
```

When the connection pool is disabled, the running result of this example is as follows:

```
Connection count: 15000
Connection time: 691.768 s
```

#### NOTE

The application code on Windows is the same as that on Linux. The connection string needs to be configured based on the scenario.

## 5.4.6 Typical Application Scenarios and Configurations

### Log Diagnosis

ODBC logs are classified into unixODBC driver manager logs and gsqlODBC driver logs. The former is used to trace whether the application API is successfully executed, and the latter is used to locate problems based on DFX logs generated during underlying implementation.

The unixODBC log needs to be configured in the **odbcinst.ini** file:

```
[ODBC]
Trace=Yes
TraceFile=/path/to/odbctrace.log

[GaussMPP]
Driver64=/usr/local/lib/gsqlodbcw.so
setup=/usr/local/lib/gsqlodbcw.so
```

For gsqlODBC logs, you only need to add the following content to **odbc.ini**:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 # Database server IP address
...
Debug=1 # Enable the debug log function of the driver.
```

#### NOTE

The unixODBC logs are generated in the path configured by **TraceFile**. The gsqlODBC generates the **mylog\_xxx.log** file in the **/tmp/** directory.

### High Performance

If a large amount of data needs to be inserted, you are advised to perform the following operations:

- You need to set **UseBatchProtocol** to **1** in the **odbc.ini** file and **support\_batch\_bind** to **on** in the database.
- The ODBC program binding type must be the same as that in the database.
- The character set of the client is the same as that of the database.
- The transaction is committed manually.

**odbc.ini** configuration file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 # Database server IP address
...
UseBatchProtocol=1 # Enabled by default
ConnSettings=set client_encoding=UTF8 # Set the character code on the client to be the same as that on the server.
```

Binding type case:

```
#ifdef WIN32
#include <windows.h>
#endif
#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
#include <string.h>
#include <sys/time.h>
```

```
#define MESSAGE_BUFFER_LEN 128
SQLHANDLE h_env = NULL;
SQLHANDLE h_conn = NULL;
SQLHANDLE h_stmt = NULL;
void print_error()
{
    SQLCHAR Sqlstate[SQL_SQLSTATE_SIZE+1];
    SQLINTEGER NativeError;
    SQLCHAR MessageText[MESSAGE_BUFFER_LEN];

}

RETURN_IF_NOT_SUCCESS(SQLRowCount(h_stmt, &RowCount));
RETURN_IF_NOT(i, RowCount);
SQLCloseCursor(h_stmt);
/* Final step. Delete the table and restore the environment. */
RETURN_IF_NOT_SUCCESS(execute_cmd(sql_drop));

end_unit_test();
}
```

#### NOTE

In the preceding example, the **number** column is defined. When the SQLBindParameter API is called, the performance of binding SQL\_NUMERIC is higher than that of SQL\_LONG. If char is used, the data type needs to be converted when data is inserted to the database server, causing a performance bottleneck.

## Load Balancing

Load balancing can be enabled when there are a large number of concurrent applications.

- Load balancing is to randomly distribute concurrent connections to all CNs to prevent a single CN from being overloaded and improve performance.
- Set **AutoBalance** to **1** to enable load balancing.
- Set **RefreshCNListTime** to **5** as required. The default refresh interval is 10s.
- Set **Priority** to **1** as required. In this case, concurrent connections are preferentially sent to the CNs configured in the configuration file. If all the

configured CNs are unavailable, the connections are distributed to the remaining CNs.

Example:

Six CNs, namely, CN1, CN2, CN3, CN4, CN5, and CN6, are configured in the cluster, and four CNs, namely, CN1, CN2, CN3, and CN4, are configured in the configuration file.

Example content of the **odbc.ini** file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.145.130.26,10.145.130.27,10.145.130.28,10.145.130.29 (IP address of the database server)
Database=db1 # Database name
Username=omm # Database username
Password= # Database user password
Port=8000 # Database listening port
Sslmode=allow
AutoBalance=1
RefreshCNListTime=3
Priority=1
```

If the configuration file and cluster environment are the same as those in the example, concurrent connections are randomly and evenly distributed to CN1, CN2, CN3, and CN4. When CN1, CN2, CN3, and CN4 are all unavailable, concurrent connections are randomly and evenly sent to CN5 and CN6. If any CN among CN1, CN2, CN3, and CN4 becomes available, the connections are not sent to CN5 and CN6 but to the available CN.

## Connection Pool Scenario

A connection pool allows applications to reuse pre-established connections without re-establishing connections each time. Once a connection is created and put into the connection pool, applications can reuse the connection, avoiding repeated execution of the complete connection process.

The use of a connection pool can significantly improve performance, especially for middle-layer applications or applications requiring network connections that need to establish and close connections frequently.

In addition to the performance advantage, the connection pool architecture enables connections in the environment to be shared by multiple components in a single process. Therefore, different components in the same process can share connections in the connection pool without interfering with each other, further improving system efficiency and resource utilization.

### NOTE

In a connection pool, an open connection may be reused by multiple users. If an application script changes the database connection status, data leakage may occur. For security purposes, exercise caution when using a connection pool.

## Configurations on Linux

Enable an connection pool in the **odbcinst.ini** configuration file. The reference configuration of the connection pool is as follows:

```
[ODBC]
Pooling=Yes # Enable an connection pool.
[GaussMPP]
```

```
CTimeout=60 # Timeout for releasing a connection that is not reused in the connection pool. The default value is 0. To enable the connection pool, set this parameter to a value greater than 0.
CTimeToLive=60 # Lifetime of the connection pool under the driver.
[GaussMPP2]
CTimeout=0 # Disable the connection pool.
```

## Configurations on Windows

On the **Connection Pool** tab, double-click **GaussDB Unicode**, and select **Pool Connections to this driver** (the default value is **60s**). This parameter is the same as **CTimeout** configured on Linux.

### NOTE

1. To configure the connection pool parameters in the application, you need to call `SQLSetEnvAttr` to set the connection pool parameters before creating the environment handle. The environment handle must be set to **null**. In this case, **SQL\_ATTR\_CONNECTION\_POOLING** becomes a process-level attribute. Currently, **SQL\_ATTR\_CONNECTION\_POOLING** can be set to either of the following values on Windows:
  - **SQL\_CP\_OFF** (Default): Disable a connection pool.
  - **SQL\_CP\_ONE\_PER\_DRIVER**: Enable a connection pool. Each driver supports a connection pool, and all connections in the driver share the same connection pool.
2. When an application calls `SQLConnect` or `SQLDriverConnect`, the connection is extracted from the connection pool. If the connection times out or no connection matches the request in the pool, a new connection is opened. The connection pool is transparent to the application.
3. When an application calls `SQLDisconnect`, the connection is not released but put back to the connection pool for the next use.
4. Before `SQLFreeHandle` is called in the environment to release the environment handle, all environment attributes that are successfully set by an application persist.
5. If a connection of an application is inactive (not used) for a period of time, the connection is deleted from the pool. The size of the connection pool is limited only by the memory and server.

## Code examples

Enabling a connection pool on Linux or Windows can significantly improve the performance of middle-layer applications that need to establish and close connections frequently. The reference configurations are as described above. The sample code is as follows:

```
#ifdef WIN32
#include <windows.h>
#endif

#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
#include <string.h>
#include <sys/time.h>
#include <pthread.h>
#include <sqltypes.h>
#include <time.h>
SQLHENV env;
SQLHDBC conn;
struct timeval start, end;

#define CONN_COUNT 15000
#define CHECK_ERROR(retcode, str, handle, htype) \
    ({ \
        if (retcode != SQL_SUCCESS && retcode != SQL_SUCCESS_WITH_INFO) { \
```

```
        fprintf(stderr, "FAILED:\t");
        extract_error(str, handle, htype);
        exit(-1);
    } else {
        printf("OK:\t%s\n", str);
    }
})

void print_diag(char *msg, SQLSMALLINT htype, SQLHANDLE handle)
{
    char sqlstate[32];
    char message[1000];
    SQLINTEGER nativeerror;
    SQLSMALLINT textlen;
    SQLRETURN ret;

    if (msg) {
        printf("%s\n", msg);
    }

    ret = SQLGetDiagRec(htype, handle, 1, sqlstate, &nativeerror, message, 256, &textlen);

    if (ret != SQL_ERROR) {
        printf("%s=%s\n", (CHAR *)sqlstate, (CHAR *)message);
    }
}

void extract_error(char *fn, SQLHANDLE handle, SQLSMALLINT type)
{
    SQLINTEGER i = 0;
    SQLINTEGER NativeError;
    SQLCHAR SQLState[7];
    SQLCHAR MessageText[256];
    SQLSMALLINT TextLength;
    SQLRETURN ret;

    fprintf(stderr, "The driver reported the following error %s\n", fn);
    if (NULL == handle)
        return;
    do {
        ret = SQLGetDiagRec(type, handle, ++i, SQLState, &NativeError, MessageText, sizeof(MessageText),
        &TextLength);
        if (SQL_SUCCEEDED(ret)) {
            printf("[SQLState:%s]:[%ldth error]:[NativeError:%ld]: %s\n",
                SQLState,
                (long)i,
                (long)NativeError,
                MessageText);
        }
    } while (ret == SQL_SUCCESS);
}

void InitializeEnvironment()
{
    /* Enable a connection pool. Configure connection pool parameters on Windows before allocating an
    environment handle. */
    SQLSetEnvAttr(env, SQL_ATTR_CONNECTION_POOLING, (SQLINTEGER *)SQL_CP_ONE_PER_DRIVER, 0);

    /* Disable the connection pool on Windows. */
    // SQLSetEnvAttr(env, SQL_ATTR_CONNECTION_POOLING, (SQLINTEGER*)SQL_CP_OFF, 0);

    // Allocate an environment handle.
    SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &env);
    // Configure the ODBC version.
    SQLSetEnvAttr(env, SQL_ATTR_ODBC_VERSION, (SQLPOINTER)SQL_OV_ODBC3, 0);
    // Configure the timeout interval for establishing a connection.
    SQLSetConnectAttr(conn, SQL_LOGIN_TIMEOUT, (SQLPOINTER *)5, 0);
}
```

```
void test_connect()
{
    SQLRETURN ret;
    SQLCHAR str[1024];
    SQLSMALLINT strl;
    SQLCHAR dsn[1024];
    SQLUIINTEGER ulntVal;

    SQLAllocHandle(SQL_HANDLE_DBC, env, &conn);

    /* Adjust the connection string based on the scenario. */
    char *config = "Driver=GaussMPP;DSN=gaussdb;";
    ret = SQLSetConnectAttr(conn, SQL_ATTR_AUTOCOMMIT, (SQLPOINTER)(1), 0);

    ret = SQLDriverConnect(conn, 0, (SQLCHAR *)config, SQL_NTS, (SQLCHAR *)NULL, SQL_NTS, 0,
SQL_DRIVER_NOPROMPT);

    if (SQL_SUCCEEDED(ret)) {
        // printf("Connected\n");
    } else {
        print_diag("SQLDriverConnect failed.", SQL_HANDLE_DBC, conn);
        SQLFreeHandle(SQL_HANDLE_DBC, conn);
        SQLFreeHandle(SQL_HANDLE_ENV, env);
        exit(1);
    }

    /* Put the connection into the connection pool to reuse the connection. */
    if (conn != SQL_NULL_HDBC) {
        SQLDisconnect(conn);
        SQLFreeHandle(SQL_HANDLE_DBC, conn);
        conn = SQL_NULL_HDBC;
    }
}

int main()
{
    int count = 0;
    int timeuser;
    gettimeofday(&start, NULL);
    InitializeEnvironment();

    for (int i = 0; i < CONN_COUNT; i++) {
        test_connect();
        count++;
    }

    // Release an environment handle.
    SQLFreeHandle(SQL_HANDLE_ENV, env);
    printf("Connection count: %d\n", count);
    gettimeofday(&end, NULL);
    timeuser = 1000000 * (end.tv_sec - start.tv_sec) + end.tv_usec - start.tv_usec;
    printf("Connection time: %.3f s \n", (double)timeuser / 1000000);
    return 0;
}
```

The result varies with the environment. When the connection pool is enabled, the running result of this example is as follows:

```
Connection count: 15000
Connection time: 14.175 s
```

When the connection pool is disabled, the running result of this example is as follows:

```
Connection count: 15000
Connection time: 691.768 s
```

 NOTE

The application code on Windows is the same as that on Linux. The connection string needs to be configured based on the scenario.

## 5.4.7 ODBC Interface Reference

The ODBC interface is a set of API functions provided to users. This chapter describes its common interfaces. For details on other interfaces, see "ODBC Programmer's Reference" at MSDN ([https://msdn.microsoft.com/en-us/library/windows/desktop/ms714177\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/windows/desktop/ms714177(v=vs.85).aspx)).

### 5.4.7.1 SQLAllocEnv

In ODBC 3.x, SQLAllocEnv (an ODBC 2.x function) was deprecated and replaced by SQLAllocHandle. For details, see [SQLAllocHandle](#).

### 5.4.7.2 SQLAllocConnect

In ODBC 3.x, SQLAllocConnect (an ODBC 2.x function) was deprecated and replaced by SQLAllocHandle. For details, see [SQLAllocHandle](#).

### 5.4.7.3 SQLAllocHandle

#### Description

Allocates environment, connection, statement, or descriptor handles. This function replaces the deprecated ODBC 2.x functions SQLAllocEnv, SQLAllocConnect, and SQLAllocStmt.

#### Prototype

```
SQLRETURN SQLAllocHandle(SQLSMALLINT HandleType,
                        SQLHANDLE InputHandle,
                        SQLHANDLE *OutputHandlePtr);
```

#### Parameter

**Table 5-33** SQLAllocHandle parameters

Keyword	Description
HandleType	<p>Type of handle to be allocated by SQLAllocHandle. The value must be one of the following:</p> <ul style="list-style-type: none"> <li>• <b>SQL_HANDLE_ENV</b> (environment handle)</li> <li>• <b>SQL_HANDLE_DBC</b> (connection handle)</li> <li>• <b>SQL_HANDLE_STMT</b> (statement handle)</li> <li>• <b>SQL_HANDLE_DESC</b> (descriptor handle)</li> </ul> <p>The handle allocation sequence is: environment handle &gt; connection handle &gt; statement handle. A later allocated handle depends on a previously allocated handle.</p>

Keyword	Description
InputHandle	<p>Existing handle to use as a context for the new handle being allocated. The <b>InputHandle</b> parameter specifies the parent handle of the handle to be created to establish the hierarchical relationship between handles. Handles of different types have different hierarchical relationships. The <b>InputHandle</b> parameter is used to specify the relationship.</p> <ul style="list-style-type: none"><li>• If <b>HandleType</b> is <b>SQL_HANDLE_ENV</b>, the value is <b>SQL_NULL_HANDLE</b>, indicating that there is no parent handle.</li><li>• If <b>HandleType</b> is <b>SQL_HANDLE_DBC</b>, this must be an environment handle, indicating that the connection handle is created in this environment.</li><li>• If <b>HandleType</b> is <b>SQL_HANDLE_STMT</b> or <b>SQL_HANDLE_DESC</b>, it must be a connection handle, indicating that the statement handle is created under the connection.</li></ul>
OutputHandlePtr	<p><b>Output parameter:</b> <b>OutputHandlePtr</b> is a pointer that points to the SQLHANDLE type and is used to return a new handle allocated.</p>

## Return Value

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If **SQLAllocHandle** returns **SQL\_ERROR** when it is used to allocate a non-environment handle, it sets **OutputHandlePtr** to **SQL\_NULL\_HDBC**, **SQL\_NULL\_HSTMT**, or **SQL\_NULL\_HDESC**. The application can then call **SQLGetDiagRec**, with **HandleType** and **Handle** set to the value of **InputHandle**, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.4 SQLAllocStmt

In ODBC 3.x, **SQLAllocStmt** was deprecated and replaced by **SQLAllocHandle**. For details, see [SQLAllocHandle](#).

### 5.4.7.5 SQLBindCol

#### Description

Binds application data buffers to columns in a result set.

#### Prototype

```
SQLRETURN SQLBindCol(SQLHSTMT StatementHandle,
                    SQLUSMALLINT ColumnNumber,
                    SQLSMALLINT TargetType,
                    SQLPOINTER TargetValuePtr,
                    SQLLEN BufferLength,
                    SQLLEN *StrLen_or_IndPtr);
```

#### Parameter

**Table 5-34** SQLBindCol parameters

Keyword	Description
StatementHandle	Statement handle.
ColumnNumber	Number of the column to be bound. The column number starts with 0 and increases in ascending order. Column 0 is the bookmark column. If no bookmark column is set, column numbers start with 1.
TargetType	C data type in the buffer.
TargetValuePtr	<b>Output parameter:</b> pointer to the buffer bound with the column. The SQLFetch function returns data in the buffer. If <b>TargetValuePtr</b> is null, <b>StrLen_or_IndPtr</b> is a valid value.
BufferLength	Size of the <b>TargetValuePtr</b> buffer in bytes.
StrLen_or_IndPtr	<b>Output parameter:</b> pointer to the length or indicator of the buffer. If the value is null, no length or indicator is used.

#### Return Value

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

#### Precautions

If SQLBindCol returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to

**SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.6 SQLBindParameter

#### Description

Binds parameter markers in an SQL statement to a buffer.

#### Prototype

```
SQLRETURN SQLBindParameter(SQLHSTMT StatementHandle,
    SQLUSMALLINT ParameterNumber,
    SQLSMALLINT InputOutputType,
    SQLSMALLINT ValueType,
    SQLSMALLINT ParameterType,
    SQLULEN ColumnSize,
    SQLSMALLINT DecimalDigits,
    SQLPOINTER ParameterValuePtr,
    SQLLEN BufferLength,
    SQLLEN *StrLen_or_IndPtr);
```

#### Parameter

**Table 5-35** SQLBindParameter parameters

Keyword	Description
StatementHandle	Statement handle.
ParameterNumber	Parameter marker number, starting with 1 and increasing in ascending order.
InputOutputType	Input/output type of the parameter. The value can be <b>SQL_PARAM_INPUT</b> , <b>SQL_PARAM_OUTPUT</b> or <b>SQL_PARAM_INPUT_OUTPUT</b> .
ValueType	C data type of the parameter. The value can be <b>SQL_C_CHAR</b> , <b>SQL_C_LONG</b> or <b>SQL_C_DOUBLE</b> .
ParameterType	SQL data type of the parameter. The value can be <b>SQL_CHAR</b> , <b>SQL_INTEGER</b> , or <b>SQL_DOUBLE</b> .
ColumnSize	Size of the column or expression marked by the corresponding parameter.
DecimalDigits	Decimal number of the column or expression marked by the corresponding parameter.
ParameterValuePtr	Pointer to the storage parameter buffer.

Keyword	Description
BufferLength	Size of the ParameterValuePtr buffer in bytes.
StrLen_or_IndPtr	Pointer to the length or indicator of the buffer. If the value is null, no length or indicator is used.

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If SQLBindParameter returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.7 SQLColAttribute

## Description

Returns the descriptor information about a column in the result set.

## Prototype

```
SQLRETURN SQLColAttribute(SQLHSTMT StatementHandle,
    SQLUSMALLINT ColumnNumber,
    SQLUSMALLINT FieldIdentifier,
    SQLPOINTER CharacterAttributePtr,
    SQLSMALLINT BufferLength,
    SQLSMALLINT *StringLengthPtr,
    SQLLEN *NumericAttributePtr);
```

## Parameter

**Table 5-36** SQLColAttribute parameters

Keyword	Description
StatementHandle	Statement handle.
ColumnNumber	Column number of the field to be queried, starting with 1 and increasing in ascending order.
FieldIdentifier	Field identifier of <b>ColumnNumber</b> in IRD.
CharacterAttributePtr	<b>Output parameter:</b> pointer to the buffer that returns the <b>FieldIdentifier</b> value.
BufferLength	<ul style="list-style-type: none"> <li>This parameter indicates the length of the buffer if <b>FieldIdentifier</b> is an ODBC-defined field and <b>CharacterAttributePtr</b> points to a string or a binary buffer.</li> <li>Ignore this parameter if <b>FieldIdentifier</b> is an ODBC-defined field and <b>CharacterAttributePtr</b> points to an integer.</li> </ul>
StringLengthPtr	<b>Output parameter:</b> pointer to a buffer in which the total number of valid bytes (for string data) is stored in <b>*CharacterAttributePtr</b> . Ignore the value of <b>BufferLength</b> if the data is not a string.
NumericAttributePtr	<b>Output parameter:</b> pointer to an integer buffer in which the value of the <b>FieldIdentifier</b> field in the <b>ColumnNumber</b> row of the IRD is returned.

## Return Value

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If SQLColAttribute returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.8 SQLConnect

#### Description

Establishes a connection between a driver and a data source. After the connection is established, the connection handle can be used to access all information about the data source, including its application operating status, transaction processing status, and error information.

#### Prototype

```
SQLRETURN SQLConnect(SQLHDBC ConnectionHandle,
                    SQLCHAR *ServerName,
                    SQLSMALLINT NameLength1,
                    SQLCHAR *UserName,
                    SQLSMALLINT NameLength2,
                    SQLCHAR *Authentication,
                    SQLSMALLINT NameLength3);
```

#### Parameters

**Table 5-37** SQLConnect parameters

Keyword	Description
ConnectionHandle	Connection handle, obtained from SQLAllocHandle.
ServerName	Name of the data source to connect.
NameLength1	Length of <b>ServerName</b> .
UserName	Username of the database in the data source.
NameLength2	Length of <b>UserName</b> .
Authentication	User password of the database in the data source.
NameLength3	Length of <b>Authentication</b> .

#### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.

## Precautions

If `SQLConnect` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.9 SQLDisconnect

#### Description

Closes the connection associated with a database connection handle.

#### Prototype

```
SQLRETURN SQLDisconnect(SQLHDBC ConnectionHandle);
```

#### Parameter

**Table 5-38** SQLDisconnect parameters

Keyword	Description
ConnectionHandle	Connection handle, obtained from <code>SQLAllocHandle</code> .

#### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If `SQLDisconnect` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.10 SQLExecDirect

#### Description

Executes a prepared statement specified in this parameter. This is the fastest method for executing only one SQL statement at a time.

#### Prototype

```
SQLRETURN SQLExecDirect(SQLHSTMT StatementHandle,  
                        SQLCHAR *StatementText,  
                        SQLINTEGER TextLength);
```

#### Parameters

**Table 5-39** SQLExecDirect parameters

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.
StatementText	SQL statement to be executed. Multiple statements cannot be executed at a time.
TextLength	Length of <b>StatementText</b> .

#### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_NEED\_DATA** indicates that parameters provided before executing the SQL statement are insufficient.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.
- **SQL\_NO\_DATA** indicates that the SQL statement does not return a result set.

#### Precautions

If SQLExecDirect returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the

**SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.11 SQLExecute

#### Description

If a statement contains a parameter marker, the `SQLExecute` function uses the current value of the parameter marker to execute a prepared SQL statement.

#### Prototype

```
SQLRETURN SQLExecute(SQLHSTMT StatementHandle);
```

#### Parameters

**Table 5-40** SQLExecute parameters

Keyword	Description
StatementHandle	Statement handle to be executed.

#### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_NEED\_DATA** indicates that parameters provided before executing the SQL statement are insufficient.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_NO\_DATA** indicates that the SQL statement does not return a result set.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.

#### Precautions

If `SQLExecute` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.12 SQLFetch

#### Description

Advances the cursor to the next row of the result set and retrieves any bound columns.

#### Prototype

```
SQLRETURN SQLFetch(SQLHSTMT StatementHandle);
```

#### Parameter

Table 5-41 SQLFetch parameters

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.

#### Return Value

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_NO\_DATA** indicates that the SQL statement does not return a result set.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.

#### Precautions

If SQLFetch returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.13 SQLFreeStmt

In ODBC 3.x, SQLFreeStmt (an ODBC 2.x function) was deprecated and replaced by SQLFreeHandle. For details, see [SQLFreeHandle](#).

### 5.4.7.14 SQLFreeConnect

In ODBC 3.x, SQLFreeConnect (an ODBC 2.x function) was deprecated and replaced by SQLFreeHandle. For details, see [SQLFreeHandle](#).

### 5.4.7.15 SQLFreeHandle

#### Description

Releases resources associated with a specific environment, connection, or statement handle. It replaces the ODBC 2.x functions: SQLFreeEnv, SQLFreeConnect, and SQLFreeStmt.

#### Prototype

```
SQLRETURN SQLFreeHandle(SQLSMALLINT HandleType,
                        SQLHANDLE Handle);
```

#### Parameter

Table 5-42 SQLFreeHandle parameters

Keyword	Description
HandleType	Type of handle to be freed by SQLFreeHandle. The value must be one of the following: <ul style="list-style-type: none"> <li>• <b>SQL_HANDLE_ENV</b></li> <li>• <b>SQL_HANDLE_DBC</b></li> <li>• <b>SQL_HANDLE_STMT</b></li> <li>• <b>SQL_HANDLE_DESC</b></li> </ul> If none of them is the value of <b>HandleType</b> , SQLFreeHandle returns <b>SQL_INVALID_HANDLE</b> .
Handle	Name of the handle to be freed.

#### Return Value

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If `SQLFreeHandle` returns **SQL\_ERROR**, the handle is still valid.

## Examples

See [Examples](#).

### 5.4.7.16 SQLFreeEnv

In ODBC 3.x, `SQLFreeEnv` (an ODBC 2.x function) was deprecated and replaced by `SQLFreeHandle`. For details, see [SQLFreeHandle](#).

### 5.4.7.17 SQLPrepare

## Description

Prepares an SQL statement to be executed.

Note that the prepared statements sent by ODBC do not support the kernel reuse plan. As a result, a new plan needs to be generated for each execution, causing high CPU usage. If services have requirements on plan reuse, you are advised to use the JDBC client.

## Prototype

```
SQLRETURN SQLPrepare(SQLHSTMT StatementHandle,  
SQLCHAR *StatementText,  
SQLINTEGER TextLength);
```

## Parameters

**Table 5-43** SQLPrepare parameters

Keyword	Description
StatementHandle	Statement handle.
StatementText	SQL text string.
TextLength	Length of <b>StatementText</b> .

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.

## Precautions

If `SQLPrepare` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.18 SQLGetData

## Description

`SQLGetData` is used to retrieve data for a single column in the result set. It can be called multiple times to partially retrieve variable-length data.

## Prototype

```
SQLRETURN SQLGetData(SQLHSTMT StatementHandle,
                    SQLUSMALLINT Col_or_Param_Num,
                    SQLSMALLINT TargetType,
                    SQLPOINTER TargetValuePtr,
                    SQLLEN BufferLength,
                    SQLLEN *StrLen_or_IndPtr);
```

## Parameters

**Table 5-44** `SQLGetData` parameters

Keyword	Description
StatementHandle	Statement handle, obtained from <code>SQLAllocHandle</code> .
Col_or_Param_Num	Column number for which the data retrieval is requested. The column number starts with 1 and increases in ascending order. The number of the bookmark column is 0.
TargetType	C data type in the <code>TargetValuePtr</code> buffer. If <b>TargetType</b> is <b>SQL_ARD_TYPE</b> , the driver uses the data type of the <b>SQL_DESC_CONCISE_TYPE</b> column in ARD. If it is <b>SQL_C_DEFAULT</b> , the driver selects a default data type according to the source SQL data type.
TargetValuePtr	<b>Output parameter:</b> pointer to the pointer that points to the buffer where the data is located.
BufferLength	Size of the buffer pointed to by <b>TargetValuePtr</b> .

Keyword	Description
StrLen_or_IndPtr	<b>Output parameter:</b> pointer to the buffer where the length or identifier value is returned.

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_NO\_DATA** indicates that the SQL statement does not return a result set.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.

## Precautions

If SQLGetData returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.19 SQLGetDiagRec

## Description

Returns the current values of multiple fields in a diagnostic record that contains error, warning, and status information.

## Prototype

```
SQLRETURN SQLGetDiagRec(SQLSMALLINT HandleType
                        SQLHANDLE Handle,
                        SQLSMALLINT RecNumber,
                        SQLCHAR *SQLState,
                        SQLINTEGER *NativeErrorPtr,
                        SQLCHAR *MessageText,
                        SQLSMALLINT BufferLength
                        SQLSMALLINT *TextLengthPtr);
```

## Parameters

**Table 5-45** SQLGetDiagRec parameters

Keyword	Description
HandleType	A handle-type identifier that describes the type of handle for which diagnostics are desired. The value must be one of the following: <ul style="list-style-type: none"><li>• <b>SQL_HANDLE_ENV</b></li><li>• <b>SQL_HANDLE_DBC</b></li><li>• <b>SQL_HANDLE_STMT</b></li><li>• <b>SQL_HANDLE_DESC</b></li></ul>
Handle	A handle for the diagnostic data structure. Its type is indicated by <b>HandleType</b> . If <b>HandleType</b> is <b>SQL_HANDLE_ENV</b> , <b>Handle</b> may be a shared or non-shared environment handle.
RecNumber	Status record from which the application seeks information. Status records are numbered from 1.
SQLState	<b>Output parameter:</b> pointer to a buffer that saves the 5-character <b>SQLSTATE</b> code pertaining to <b>RecNumber</b> .
NativeErrorPtr	<b>Output parameter:</b> pointer to a buffer that saves the native error code.
MessageText	Pointer to a buffer that saves text strings of diagnostic information.
BufferLength	Length of <b>MessageText</b> .
TextLengthPtr	<b>Output parameter:</b> pointer to the buffer, the total number of bytes in the returned <b>MessageText</b> . If the number of bytes available to return is greater than <b>BufferLength</b> , then the diagnostics information text in <b>MessageText</b> is truncated to <b>BufferLength</b> minus the length of the null termination character.

## Return Value

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

SQLGetDiagRec does not release diagnostic records for itself. It uses the following return values to report execution results:

- **SQL\_SUCCESS** indicates that the function successfully returns diagnostic information.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that the **\*MessageText** buffer is too small to hold the requested diagnostic information. No diagnostic records are generated.
- **SQL\_INVALID\_HANDLE** indicates that the handle indicated by **HandleType** and **Handle** is an invalid handle.
- **SQL\_ERROR** indicates that the value of **RecNumber** is less than or equal to **0** or the value of **BufferLength** is less than **0**.

If an ODBC function returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, you can call SQLGetDiagRec to obtain the **SQLSTATE** value. [Table 2 SQLSTATE values](#) lists the possible **SQLSTATE** values.

**Table 5-46** SQLSTATE values

SQLSTATE	Error	Description
HY000	General error.	An error occurs when there is no specific SQLSTATE.
HY001	Memory allocation error.	The driver is unable to allocate memory required to support execution or completion of the function.
HY008	Operation canceled.	SQLCancel is called to terminate the statement execution, but the StatementHandle function is still called.
HY010	Function sequence error.	The function is called prior to sending data to data parameters or columns being executed.
HY013	Memory management error.	The function fails to be called. The error may be caused by low memory conditions.
HYT01	Connection timeout.	The timeout period expired before the application was able to connect to the data source.
IM001	Function not supported by the driver.	The called function is not supported by the StatementHandle driver.

## Examples

See [Examples](#).

## 5.4.7.20 SQLSetConnectAttr

### Description

Sets connection attributes.

### Prototype

```
SQLRETURN SQLSetConnectAttr(SQLHDBC ConnectionHandle,
                             SQLINTEGER Attribute,
                             SQLPOINTER ValuePtr,
                             SQLINTEGER StringLength);
```

### Parameters

**Table 5-47** SQLSetConnectAttr parameters

Keyword	Description
ConnectionHandle	Connection handle.
Attribute	Attribute to set.
ValuePtr	Pointer to the <b>Attribute</b> value. <b>ValuePtr</b> depends on the <b>Attribute</b> value, and is a 32-bit unsigned integer value or a pointer to a null-terminated string, a binary buffer, or a driver-specified value. If the <b>ValuePtr</b> parameter is driver-specific value, it may be a signed integer.
StringLength	If <b>ValuePtr</b> points to a string or a binary buffer, <b>StringLength</b> is the length of <b>*ValuePtr</b> . If <b>ValuePtr</b> points to an integer, <b>StringLength</b> is ignored.

### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

### Precautions

If `SQLSetConnectAttr` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.21 SQLSetEnvAttr

#### Description

Sets environment attributes.

#### Prototype

```
SQLRETURN SQLSetEnvAttr(SQLHENV EnvironmentHandle,
                        SQLINTEGER Attribute,
                        SQLPOINTER ValuePtr,
                        SQLINTEGER StringLength);
```

#### Parameters

**Table 5-48** SQLSetEnvAttr parameters

Keyword	Description
EnvironmentHandle	Environment handle.
Attribute	Environment attribute to be set. The value must be one of the following: <ul style="list-style-type: none"> <li><b>SQL_ATTR_ODBC_VERSION</b>: ODBC version.</li> <li><b>SQL_CONNECTION_POOLING</b>: connection pool attribute.</li> <li><b>SQL_OUTPUT_NTS</b>: string type returned by the driver.</li> </ul>
ValuePtr	Pointer to the <b>Attribute</b> value. <b>ValuePtr</b> depends on the <b>Attribute</b> value, and can be a 32-bit integer value or a null-terminated string.
StringLength	If <b>ValuePtr</b> points to a string or a binary buffer, <b>StringLength</b> is the length of <b>*ValuePtr</b> . If <b>ValuePtr</b> points to an integer, <b>StringLength</b> is ignored.

#### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If `SQLSetEnvAttr` returns `SQL_ERROR` or `SQL_SUCCESS_WITH_INFO`, the application can call `SQLGetDiagRec`, set `HandleType` and `Handle` to `SQL_HANDLE_ENV` and `EnvironmentHandle`, and obtain the `SQLSTATE` value. The `SQLSTATE` value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.22 SQLSetStmtAttr

## Description

Sets attributes related to a statement.

## Prototype

```
SQLRETURN SQLSetStmtAttr(SQLHSTMT StatementHandle
                          SQLINTEGER Attribute,
                          SQLPOINTER ValuePtr,
                          SQLINTEGER StringLength);
```

## Parameters

**Table 5-49** SQLSetStmtAttr parameters

Keyword	Description
StatementHandle	Statement handle.
Attribute	Attribute to set.
ValuePtr	Pointer to the <b>Attribute</b> value. <b>ValuePtr</b> depends on the <b>Attribute</b> value, and can be a 32-bit unsigned integer value or a pointer to a null-terminated string, a binary buffer, or a driver-specified value. If the <b>ValuePtr</b> parameter is driver-specific value, it may be a signed integer.
StringLength	If <b>ValuePtr</b> points to a string or a binary buffer, <b>StringLength</b> is the length of <b>*ValuePtr</b> . If <b>ValuePtr</b> points to an integer, <b>StringLength</b> is ignored.

## Return Values

- `SQL_SUCCESS` indicates that the call succeeded.
- `SQL_SUCCESS_WITH_INFO` indicates that some warning information is displayed.
- `SQL_ERROR` indicates major errors, such as memory allocation and connection failures.

- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If `SQLSetStmtAttr` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

# 5.5 Development Based on libpq

**libpq** is a C application programming interface to GaussDB. **libpq** contains a set of library functions that allow client programs to send query requests to GaussDB servers and obtain query results. It is also the underlying engine of other GaussDB application interfaces, such as ODBC. This chapter provides examples to show how to write code using **libpq**.

## 5.5.1 libpq Package, Dependent Library, and Header Files

Obtain the **libpq** package, dependent library, and header files from the release package **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Libpq.tar.gz**. Client programs that use **libpq** must include the header file **libpq-fe.h** and must connect to the **libpq** library.

## 5.5.2 Development Process

To compile and develop source programs based on **libpq**, perform the following steps:

- Decompress the **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Libpq.tar.gz** file. The required header file is stored in the **include** folder, and the **lib** folder contains the required **libpq** library file.

### NOTE

In addition to **libpq-fe.h**, the **include** folder contains the header files **postgres\_ext.h**, **gs\_thread.h**, and **gs\_threadlocal.h** by default. These three header files are the dependency files of **libpq-fe.h**.

- Develop the source program **testlibpq.c**. The source code file needs to reference the header file provided by **libpq**.

Example: `#include <libpq-fe.h>`

- To compile the **libpq** source program by running **gcc**, use the **-I directory** option to provide the installation location of the header file. (Sometimes the compiler looks for the default directory, so this option can be ignored.)

Example:

```
gcc -I (Directory where the header file is located) -L (Directory where the libpq library is located) testlibpq.c -lpq
```

```
Example: gcc -I $(GAUSSHOME)/include/libpq -L $(GAUSSHOME)/lib -lpq testlibpq.c -o testlibpq
```

- If the makefile is used, add the following option to variables *CPPFLAGS*, *LDFLAGS*, and *LIBS*:  
CPPFLAGS += -I (Directory of the header file)  
LDFLAGS += -L (Directory of the libpq library)  
LIBS += -lpq  
Example:  
CPPFLAGS += -I\$(GAUSSHOME)/include/libpq  
LDFLAGS += -L\$(GAUSSHOME)/lib

## 5.5.3 Examples

### Code for Common Functions

Example 1:

```
/*
 * testlibpq.c
 * Note: testlibpq.c source program provides basic and common application scenarios of libpq.
 * The PQconnectdb, PQexec, PQntuples, and PQfinish APIs provided by libpq are used to establish database
 * connections, execute SQL statements, obtain returned results, and clear resources.
 */
#include <stdio.h>
#include <stdlib.h>
#include <libpq-fe.h>
#include <string.h>

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

int
main(int argc, char **argv)
{
    /* The values of variables such as user and passwd must be read from environment variables or
    * configuration files. Environment variables need to be configured as required. If no environment variable is
    * used, a character string can be directly assigned. */
    const char conninfo[1024];
    PGconn *conn;
    PGresult *res;
    int nFields;
    int i,j;
    char *passwd = getenv("EXAMPLE_PASSWD_ENV");
    char *port = getenv("EXAMPLE_PORT_ENV");
    char *host = getenv("EXAMPLE_HOST_ENV");
    char *username = getenv("EXAMPLE_USERNAME_ENV");
    char *dbname = getenv("EXAMPLE_DBNAME_ENV");

    /*
    * This value is used when the user provides the value of the conninfo character string in the command
    * line.
    * Otherwise, the environment variables or all other connection parameters
    * use the default values.
    */
    if (argc > 1)
        conninfo = argv[1];
    else
        sprintf(conninfo,
            "dbname=%s port=%s host=%s application_name=test connect_timeout=5 sslmode=allow user=%s
            password=%s",
            dbname, port, host, username, passwd);

    /* Connect to the database. */
    conn = PQconnectdb(conninfo);
```

```
/* Check whether the backend connection has been successfully established. */
if (PQstatus(conn) != CONNECTION_OK)
{
    fprintf(stderr, "Connection to database failed: %s",
            PQerrorMessage(conn));
    exit_nicely(conn);
}

/*
 * Since a cursor is used in the test case, a transaction block is required.
 * Putting all data in one "select * from pg_database"
 * PQexec() is simple and is not recommended.
 */

/* Start a transaction block. */
res = PQexec(conn, "BEGIN");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "BEGIN command failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/*
 * PQclear PGresult should be executed when it is no longer needed, to avoid memory leakage.
 */
PQclear(res);

/*
 * Fetch data from the pg_database system catalog.
 */
res = PQexec(conn, "DECLARE myportal CURSOR FOR select * from pg_database");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "DECLARE CURSOR failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}
PQclear(res);

res = PQexec(conn, "FETCH ALL in myportal");
if (PQresultStatus(res) != PGRES_TUPLES_OK)
{
    fprintf(stderr, "FETCH ALL failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/* Print the attribute name. */
nFields = PQnfields(res);
for (i = 0; i < nFields; i++)
    printf("%-15s", PQfname(res, i));
printf("\n\n");

/* Print lines. */
for (i = 0; i < PQntuples(res); i++)
{
    for (j = 0; j < nFields; j++)
        printf("%-15s", PQgetvalue(res, i, j));
    printf("\n");
}

PQclear(res);

/* Close the portal. Do not check for errors. */
res = PQexec(conn, "CLOSE myportal");
PQclear(res);

/* End the transaction. */
```

```
res = PQexec(conn, "END");
PQclear(res);

/* Close the database connection and clean up the database. */
PQfinish(conn);

return 0;
}
```

### Example 2:

```
/*
 * testlibpq2.c Test PQprepare
 * PQprepare creates a prepared statement with specified parameters for PQexecPrepared to execute the
 * prepared statement.
 * Before running this example, create a table and insert data.
 * create table t01(a int, b int);
 * insert into t01 values(1, 23);

PQclear(res);

/* Close the database connection and clean up the database. */
PQfinish(conn);

return 0;
}
```

## 5.5.4 libpq Interface Reference

### NOTICE

Calls to the PQfn interface using libpq is not supported yet.

### 5.5.4.1 Database Connection Control Functions

Database connection control functions control the connections to GaussDB servers. An application can connect to multiple servers at a time. For example, a client connects to multiple databases. Each connection is represented by a PGconn object, which is obtained from the function PQconnectdb, PQconnectdbParams, or PQsetdbLogin. You can also obtain a connection object by using the PQconnectStart API together with the asynchronous PQconnectPoll polling method. Note that these functions will always return a non-null object pointer, unless memory allocation fails. The API for establishing a connection is stored in the PGconn object. The PQstatus function can be called to check the return value for a successful connection. The PGconn object stores the SSL context in a local thread. Therefore, the PGconn released thread must be the same as the allocated thread.

#### 5.5.4.1.1 PQconnectdbParams

##### Description

Establishes a new connection with the database server.

##### Prototype

```
PGconn* PQconnectdbParams(const char* const* keywords, const char* const* values, int expand_dbname);
```

## Parameters

**Table 5-50** PQconnectdbParams parameters

Keyword	Description
keywords	An array of strings, each of which is a keyword.
values	Value assigned to each keyword.
expand_dbname	When <b>expand_dbname</b> is non-zero, the <b>dbname</b> keyword value can be recognized as a connection string. Only <b>dbname</b> that first appears is treated in this way, and any subsequent <b>dbname</b> value is treated as a database name.

## Return Values

**PGconn \*** points to the object pointer that contains a connection. The memory is allocated by the function internally.

## Precautions

This function establishes a new database connection using the parameters taken from two NULL-terminated arrays. Unlike PQsetdbLogin, the parameter set can be extended without changing the function signature. Therefore, use of this function (or its non-blocking analogs PQconnectStartParams and PQconnectPoll) is preferred for new application programming.

### 5.5.4.1.2 PQconnectdb

## Description

Establishes a new connection with the database server.

## Prototype

```
PGconn* PQconnectdb(const char* conninfo);
```

## Parameters

**Table 5-51** PQconnectdb parameter

Keyword	Description
conninfo	Connection string. For details about the columns in the string, see <a href="#">5.4.5 Connection Parameters</a> .

## Return Values

**PGconn \*** points to the object pointer that contains a connection. The memory is allocated by the function internally.

## Precautions

- This function establishes a new database connection using the parameters taken from the string **conninfo**.
- The input parameter can be empty, indicating that all default parameters can be used. It can contain one or more values separated by spaces or contain a URL.

## Examples

For details, see [Examples](#).

### 5.5.4.1.3 PQbackendPID

## Supplementary Explanation

After GaussDB is multi-thread refactored based on PostgreSQL, the semantic of PQbackendPID is different from that in the native PostgreSQL libpq. In GaussDB, the return value of the PQbackendPID function indicates the slot ID of the background thread, not the backend PID of the background thread. Due to the preceding difference, you are not advised to execute this function by following the PostgreSQL semantics. To obtain the backend PID of the connection, you can use the `pg_backend_pid` system function. In addition, other driver APIs which depend on libpq and have the same names as PostgreSQL's APIs (such as the `get_backend_pid` function of the Python connection driver `psycopg2`) also comply with the preceding rule.

### 5.5.4.1.4 PQsetdbLogin

## Description

Establishes a new connection with the database server.

## Prototype

```
PGconn* PQsetdbLogin(const char* pghost, const char* pgport, const char* pgoptions, const char* pgtty,
                    const char* dbName, const char* login, const char* pwd);
```

## Parameters

**Table 5-52** PQsetdbLogin parameters

Keyword	Description
pghost	Name of the host to be connected. For details, see the <b>host</b> column described in <a href="#">Connection Parameters</a> .
pgport	Port number of the host server. For details, see the <b>port</b> column described in <a href="#">Connection Parameters</a> .
pgoptions	Command-line options to be sent to the server during running. For details, see the <b>options</b> column described in <a href="#">Connection Parameters</a> .

Keyword	Description
pgtty	Ignored. (Previously, this option declares the output direction of server logs.)
dbName	Name of the database to be connected. For details, see the <b>dbname</b> column described in <a href="#">Connection Parameters</a> .
login	Username for connection. For details, see the <b>user</b> column described in <a href="#">Connection Parameters</a> .
pwd	Password used for authentication during connection. For details, see the <b>password</b> column described in <a href="#">Connection Parameters</a> .

## Return Value

**PGconn \*** points to the object that contains the connection. The memory is allocated inside the function.

## Precautions

- This function is the predecessor of PQconnectdb with a fixed set of parameters. When an undefined parameter is called, its default value is used. The default value can be **NULL** or an empty string.
- If the **dbName** value contains an equal sign (=) or a valid prefix in the connection URL, it is taken as a conninfo string and passed to PQconnectdb, and the other parameters are consistent with those of PQconnectdbParams.

### 5.5.4.1.5 PQfinish

## Function

Closes the connection to the server and releases the memory used by the PGconn object.

## Prototype

```
void PQfinish(PGconn* conn);
```

## Parameter

**Table 5-53** PQfinish parameter

Keyword	Parameter Description
conn	The object pointer that contains the connection information.

## Precautions

If the server connection attempt fails (as indicated by PQstatus), the application should call PQfinish to release the memory used by the PGconn object. The PGconn pointer must not be used again after PQfinish has been called.

## Example

For details, see [Examples](#).

### 5.5.4.1.6 PQreset

#### Function

Resets the communication port to the server.

#### Prototype

```
void PQreset(PGconn* conn);
```

#### Parameter

Table 5-54 PQreset parameter

Keyword	Parameter Description
conn	The object pointer that contains the connection information.

## Precautions

This function will close the connection to the server and attempt to establish a new connection to the same server by using all the parameters previously used. This function is applicable to fault recovery after a connection exception occurs.

### 5.5.4.1.7 PQstatus

#### Description

Returns the connection status.

#### Prototype

```
ConnStatusType PQstatus(const PGconn* conn);
```

#### Parameters

Table 5-55 PQ status parameter

Keyword	Description
conn	The object pointer that contains the connection information.

## Return Values

**ConnStatusType** indicates the connection status. The enumerated values are as follows:

```
CONNECTION_STARTED
Waiting for the connection to be established.

CONNECTION_MADE
Connection succeeded; waiting to send.

CONNECTION_AWAITING_RESPONSE
Waiting for a response from the server.

CONNECTION_AUTH_OK
Authentication received; waiting for backend startup to complete.

CONNECTION_SSL_STARTUP
Negotiating SSL encryption.

CONNECTION_SETENV
Negotiating environment-driven parameter settings.

CONNECTION_OK
Normal connection.

CONNECTION_BAD
Failed connection.
```

## Precautions

The connection status can be one of the preceding values. After the asynchronous connection procedure is complete, only two of them, **CONNECTION\_OK** and **CONNECTION\_BAD**, can return. **CONNECTION\_OK** indicates that the connection to the database is normal. **CONNECTION\_BAD** indicates that the connection to the database fails. Generally, the **CONNECTION\_OK** state remains until PQfinish is called. However, a communication failure may cause the connection status to turn to **CONNECTION\_BAD** before the connection procedure is complete. In this case, the application can attempt to call PQreset to restore the communication.

## Examples

For details, see [Examples](#).

### 5.5.4.2 Database Statement Execution Functions

After the connection to the database server is successfully established, you can use the functions described in this section to execute SQL queries and commands.

#### 5.5.4.2.1 PQexec

### Function

Commits a command to the server and waits for the result.

## Prototype

```
PGresult* PQexec(PGconn* conn, const char* query);
```

## Parameter

**Table 5-56** PQexec parameters

Keyword	Parameter Description
conn	The object pointer that contains the connection information.
command	Query string to be executed.

## Return Value

**PGresult** indicates the object pointer that contains the query result.

## Precautions

The PQresultStatus function should be called to check the return value for any errors (including the value of a null pointer, in which **PGRES\_FATAL\_ERROR** will be returned). The PQerrorMessage function can be called to obtain more information about such errors.

### NOTICE

The command string can contain multiple SQL commands separated by semicolons (;). Multiple queries sent in a PQexec call are processed in one transaction, unless there are specific BEGIN/COMMIT commands in the query string to divide the string into multiple transactions. Note that the returned PGresult structure describes only the result of the last command executed from the string. If a command fails, the string processing stops and the returned PGresult describes the error condition.

## Example

For details, see [Examples](#).

### 5.5.4.2.2 PQprepare

## Description

Commits a request to create a prepared statement with given parameters and waits for completion.

## Prototype

```
PGresult* PQprepare(PGconn* conn, const char* stmtName, const char* query, int nParams, const Oid* paramTypes);
```

## Parameters

**Table 5-57** PQprepare parameters

Keyword	Description
conn	Object pointer that contains the connection information.
stmtName	Prepared statement to be executed.
query	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Array of the parameter type.

## Return Values

**PGresult** indicates the object pointer that contains the query result.

## Precautions

- PQprepare creates a prepared statement for later execution with PQexecPrepared. This function allows commands to be repeatedly executed, without being parsed and planned each time they are executed. PQprepare is supported only in protocol 3.0 or later. It will fail when protocol 2.0 is used.
- This function creates a prepared statement named **stmtName** from the query string, which must contain an SQL command. **stmtName** can be "" to create an unnamed statement. In this case, any pre-existing unnamed statement will be automatically replaced. Otherwise, this is an error if the statement name has been defined in the current session. If any parameters are used, they are referred to in the query as \$1, \$2, and so on. **nParams** is the number of parameters for which types are pre-specified in the array paramTypes[]. (The array pointer can be **NULL** when **nParams** is 0.) paramTypes[] specifies the data types to be assigned to the parameter symbols by OID. If **paramTypes** is **NULL**, or any element in the array is 0, the server assigns a data type to the parameter symbol in the same way as it does for an untyped literal string. In addition, the query can use parameter symbols whose numbers are greater than **nParams**. Data types of these symbols will also be inferred.

---

**NOTICE**

You can also execute the **SQLPREPARE** statement to create a prepared statement that is used with PQexecPrepared. Although there is no libpq function of deleting a prepared statement, the SQL DEALLOCATE statement can be used for this purpose.

---

## Examples

For details, see [Examples](#).

### 5.5.4.2.3 PQresultStatus

#### Description

Returns the result status of a command.

#### Prototype

```
ExecStatusType PQresultStatus(const PGresult* res);
```

#### Parameters

Table 5-58 PQresultStatus parameter

Keyword	Description
res	Object pointer that contains the query result.

#### Return Values

**PQresultStatus** indicates the command execution status. The enumerated values are as follows:

PQresultStatus can return one of the following values:

**PGRES\_EMPTY\_QUERY**

The string sent to the server was empty.

**PGRES\_COMMAND\_OK**

A command that does not return data was successfully executed.

**PGRES\_TUPLES\_OK**

A query (such as SELECT or SHOW) that returns data was successfully executed.

**PGRES\_COPY\_OUT**

The data copied from the server begins to transmit.

**PGRES\_COPY\_IN**

The data copied to the server begins to transmit.

**PGRES\_BAD\_RESPONSE**

The response from the server cannot be understood.

**PGRES\_NONFATAL\_ERROR**

A non-fatal error (notification or warning) occurred.

**PGRES\_FATAL\_ERROR**

A fatal error occurred.

**PGRES\_COPY\_BOTH**

The data copied to and from the server begins to transmit. This state occurs only in streaming replication.

**PGRES\_SINGLE\_TUPLE**

PGresult contains a result tuple from the current command. This state occurs in a single-row query.

#### Precautions

- Note that the SELECT command that happens to retrieve zero rows still returns **PGRES\_TUPLES\_OK**. **PGRES\_COMMAND\_OK** is used for commands that can never return rows (such as INSERT or UPDATE, without return

clauses). The result status **PGRES\_EMPTY\_QUERY** might indicate a bug in the client software.

- The result status **PGRES\_NONFATAL\_ERROR** will never be returned directly by PQexec or other query execution functions. Instead, such results will be passed to the notice processor.

## Examples

For details, see [Examples](#).

### 5.5.4.2.4 PQclear

#### Description

Releases the storage associated with PGresult. Any query result should be released by PQclear when it is no longer needed.

#### Prototype

```
void PQclear(PGresult* res);
```

#### Parameter

Table 5-59 PQclear parameter

Keyword	Description
res	Object pointer that contains the query result.

#### Precautions

PGresult is not automatically released. That is, it does not disappear when a new query is committed or even if you close the connection. To delete it, you must call PQclear. Otherwise, memory leakage occurs.

## Examples

For details, see [Examples](#).

### 5.5.4.2.5 PQfnumberEx

#### Description

Returns the column number associated with the given column name. Columns are numbered starting at 0.

#### Prototype

```
int PQfnumberEx(const PGresult* res, const char* field_name, bool case_sensitive);
```

## Parameters

**Table 5-60** PQfnnumberEx parameters

Keyword	Description
res	Handle to the operation result.
field_name	Column name.
case_sensitive	Specifies whether the column name is case sensitive.

## Return Value

An integer of the int type.

### 5.5.4.3 Functions for Asynchronous Command Processing

The PQexec function is adequate for committing commands in common, synchronous applications. However, it has several defects, which may be important to some users:

- PQexec waits for the end of the command, but the application may have other work to do (for example, maintaining a user interface). In this case, PQexec would not want to be blocked to wait for the response.
- As the client application is suspended while waiting for the result, it is difficult for the application to determine whether to cancel the ongoing command.
- PQexec can return only one PGresult structure. If the committed command string contains multiple SQL commands, all the PGresult structures except the last PGresult are discarded by PQexec.
- PQexec always collects the entire result of the command and caches it in a PGresult. Although this mode simplifies the error handling logic for applications, it is impractical for results that contain multiple rows.

Applications that do not want to be restricted by these limitations can use the following functions that PQexec is built from: PQsendQuery and PQgetResult. The functions PQsendQueryParams, PQsendPrepare, and PQsendQueryPrepared can also be used with PQgetResult.

#### 5.5.4.3.1 PQsendQuery

### Function

Commits a command to the server without waiting for the result. If the query is successful, **1** is returned. Otherwise, **0** is returned.

### Prototype

```
int PQsendQuery(PGconn * conn, const char * query);
```

## Parameter

**Table 5-61** PQsendQuery parameters

Keyword	Parameter Description
conn	The object pointer that contains the connection information.
command	Query string to be executed.

## Return Value

**int** indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

## Precautions

After PQsendQuery is successfully called, call PQgetResult one or more times to obtain the results. PQsendQuery cannot be called again (on the same connection) until PQgetResult returns a null pointer, indicating that the command execution is complete.

### 5.5.4.3.2 PQsendQueryParams

## Function

Commits a command with separated parameters to the server without waiting for the result.

## Prototype

```
int PQsendQueryParams(PGconn* conn, const char* command, int nParams, const Oid* paramTypes,
    const char* const* paramValues, const int* paramLengths, const int* paramFormats, int resultFormat);
```

## Parameter

**Table 5-62** PQsendQueryParams parameters

Keyword	Parameter Description
conn	The object pointer that contains the connection information.
command	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Parameter type.
paramValues	Parameter value.
paramLengths	Parameter length.
paramFormats	Parameter format.

Keyword	Parameter Description
resultFormat	Result format.

## Return Value

**int** indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

## Precautions

This function is equivalent to PQsendQuery. The only difference is that query parameters can be specified separately from the query string. The parameter processing of this function is similar to that of PQexecParams. It cannot work on connections using protocol v2.0, and it allows only one command to appear in the query string.

### 5.5.4.3.3 PQsendPrepare

## Function

Sends a request to create a prepared statement with given parameters, without waiting for completion.

## Prototype

```
int PQsendPrepare(PGconn* conn, const char* stmtName, const char* query, int nParams, const Oid* paramTypes);
```

## Parameter

**Table 5-63** PQsendPrepare parameters

Keyword	Parameter Description
conn	The object pointer that contains the connection information.
stmtName	Prepared statement to be executed.
query	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Array of the parameter type.

## Return Value

**int** indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

## Precautions

PQsendPrepare is an asynchronous version of PQprepare. If it can dispatch a request, **1** is returned. Otherwise, **0** is returned. After a successful calling of PQsendPrepare, call PQgetResult to check whether the server successfully created the prepared statement. PQsendPrepare parameters are handled in the same way as PQprepare parameters. Like PQprepare, PQsendPrepare cannot work on connections using protocol v2.0.

## Example

For details, see [Examples](#).

### 5.5.4.3.4 PQsendQueryPrepared

## Function

Sends a request to execute a prepared statement with given parameters, without waiting for the result.

## Prototype

```
int PQsendQueryPrepared(PGconn* conn, const char* stmtName, int nParams, const char* const* paramValues, const int* paramLengths, const int* paramFormats, int resultFormat);
```

## Parameter

**Table 5-64** PQsendQueryPrepared parameters

Keyword	Parameter Description
conn	The object pointer that contains the connection information.
stmtName	Prepared statement to be executed.
nParams	Parameter type.
paramValues	Parameter value.
paramLengths	Parameter length.
paramFormats	Parameter format.
resultFormat	Result format.

## Return Value

**int** indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

## Precautions

PQsendQueryPrepared is similar to PQsendQueryParams, but the command to be executed is specified by naming a previously-prepared statement, instead of

providing a query string. PQsendQueryPrepared parameters are handled in the same way as PQexecPrepared parameters. Like PQexecPrepared, PQsendQueryPrepared cannot work on connections using protocol v2.0.

### 5.5.4.3.5 PQflush

#### Description

Tries to flush any queued output data to the server.

#### Prototype

```
int PQflush(PGconn * conn);
```

#### Parameter

Table 5-65 PQflush parameter

Keyword	Description
conn	Points to the object pointer that contains the connection information.

#### Return Value

**int** indicates the operation result. If the operation is successful (or the send queue is empty), **0** is returned. If the operation fails, **-1** is returned. If all data in the send queue fails to be sent, **1** is returned. (This case occurs only when the connection is non-blocking.) The failure cause is stored in **conn->error\_message**.

#### Precautions

Call PQflush after sending any command or data over a non-blocking connection. If **1** is returned, wait for the socket to become read- or write-ready. If the socket becomes write-ready, call PQflush again. If the socket becomes read-ready, call PQconsumeInput and then call PQflush again. Repeat the operation until the value **0** is returned for PQflush. It is necessary to check read-ready and use PQconsumeInput to exhaust input because the server may prevent attempts to send data (such as NOTICE messages) to the client and does not read the client's data until the client reads its data. Once PQflush returns **0**, wait for the socket to be read-ready and then read the response as described above.

### 5.5.4.4 Functions for Canceling Queries in Progress

A client application can use the functions described in this section to cancel a command that is still being processed by the server.

### 5.5.4.4.1 PQgetCancel

#### Description

Creates a data structure that contains the information required to cancel a command issued through a specific database connection.

#### Prototype

```
PGcancel* PQgetCancel(PGconn* conn);
```

#### Parameter

**Table 5-66** PQgetCancel parameter

Keyword	Description
conn	Object pointer that contains the connection information.

#### Return Value

**PGcancel** points to the object pointer that contains the cancel information.

#### Precautions

PQgetCancel creates a PGcancel object for a given PGconn connection object. If the given connection object (**conn**) is NULL or an invalid connection, it will return NULL. The PGcancel object is an opaque structure that cannot be directly accessed by applications. It can be transferred only to PQcancel or PQfreeCancel.

### 5.5.4.4.2 PQfreeCancel

#### Function

Releases the data structure created by PQgetCancel.

#### Prototype

```
void PQfreeCancel(PGcancel * cancel);
```

#### Parameter

**Table 5-67** PQfreeCancel parameter

Keyword	Parameter Description
cancel	Points to the object pointer that contains the cancel information.

## Precautions

PQfreeCancel releases a data object previously created by PQgetCancel.

### 5.5.4.4.3 PQcancel

## Function

Requests the server to abandon processing of the current command.

## Prototype

```
int PQcancel(PGcancel* cancel, char* errbuf, int errbufsize);
```

## Parameter

**Table 5-68** PQcancel parameters

Keyword	Parameter Description
cancel	Points to the object pointer that contains the cancel information.
errbuf	Buffer for storing error information.
errbufsize	Size of the buffer for storing error information.

## Return Value

**int** indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **errbuf**.

## Precautions

- Successful sending does not guarantee that the request will have any effect. If the cancellation is valid, the current command is terminated early and an error is returned. If the cancellation fails (for example, because the server has processed the command), no result is returned.
- If **errbuf** is a local variable in a signal handler, you can safely call PQcancel from the signal handler. For PQcancel, the PGcancel object is read-only, so it can also be called from a thread that is separate from the thread that is operating the PGconn object.

## 5.5.5 Connection Parameters

**Table 5-69** Connection parameters

Parameter	Description
host	<p>Name of the host to connect to. If the host name starts with a slash (/), UDS communications instead of TCP/IP communications are used. The value is the directory where the socket file is stored. If <b>host</b> is not specified, the default behavior is to connect to the UDS in the <b>/tmp</b> directory (or the socket directory specified during GaussDB installation). On a machine without a UDS, the default behavior is to connect to <b>localhost</b>.</p> <p>You can specify multiple host names by using a character string separated by commas (.). Multiple host names can be specified.</p>
hostaddr	<p>IP address of the host to connect to. The value is in standard IPv4 address format, for example, 172.28.40.9. If a non-null character string is specified, TCP/IP communications are used.</p> <p>You can specify multiple IP addresses by using a character string separated by commas (.). Multiple IP addresses can be specified.</p> <p>Replacing <b>host</b> with <b>hostaddr</b> can prevent applications from querying host names, which may be important for applications with time constraints. However, a host name is required for GSSAPI or SSPI authentication methods. Therefore, the following rules are used:</p> <ol style="list-style-type: none"> <li>1. If <b>host</b> is specified but <b>hostaddr</b> is not, a query for the host name will be executed.</li> <li>2. If <b>hostaddr</b> is specified but <b>host</b> is not, the value of <b>hostaddr</b> is the server network address. If the host name is required for authentication, the connection attempt fails.</li> <li>3. If both <b>host</b> and <b>hostaddr</b> are specified, the value of <b>hostaddr</b> is the server network address. The value of <b>host</b> is ignored unless it is required by authentication, in which case it is used as the host name.</li> </ol> <p><b>NOTICE</b></p> <ul style="list-style-type: none"> <li>• If <b>host</b> is not the server name in the network address specified by <b>hostaddr</b>, the authentication may fail.</li> <li>• If neither <b>host</b> nor <b>hostaddr</b> is specified, libpq will use a local UDS for connection. If the machine does not have a UDS, it will attempt to connect to <b>localhost</b>.</li> </ul>
port	<p>Port number of the host server, or the socket file name extension for UDS connections.</p> <p>You can specify multiple port numbers by using a character string separated by commas (.). Multiple port numbers can be specified.</p>
vimuser	<p>Name of the user to be connected. By default, the username is the same as the OS name of the user running the application.</p>
dbname	<p>Database name. The default value is the same as the username.</p>

Parameter	Description
password	Password to be used if the server requires password authentication.
connect_timeout	Maximum timeout period of the connection, in seconds (written as a decimal integer string). The value <b>0</b> or null indicates infinity. You are advised not to set the connection timeout period to a value less than 2 seconds.
client_encoding	Client encoding for the connection. In addition to the values accepted by the corresponding server options, you can use <b>auto</b> to determine the correct encoding from the current environment in the client (the <i>LC_CTYPE</i> environment variable in the Unix system).
tty	This parameter can be ignored. (This parameter was used to specify the location to which the debugging output of the server was sent).
options	Adds command-line options to send to the server at runtime.
application_name	Current user identity.
fallback_application_name	Specifies a backup value for the <b>application_name</b> parameter. This value is used if no value is set for <b>application_name</b> through a connection parameter or the <i>PGAPPNAME</i> environment variable. In a common tool program, if you set a default name but do not want the default name to be overwritten by the user, you can specify a backup value.
keepalives	Specifies whether TCP keepalive is enabled on the client side. The default value is <b>1</b> , indicating that the function is enabled. The value <b>0</b> indicates that the function is disabled. Ignore this parameter for UDS connections.
keepalives_idle	The number of seconds of inactivity after which TCP should send a keepalive message to the server. The value <b>0</b> indicates that the default value is used. Ignore this parameter for UDS connections or if keepalive is disabled.
keepalives_interval	The number of seconds after which a TCP keepalive message that is not acknowledged by the server should be retransmitted. The value <b>0</b> indicates that the default value is used. Ignore this parameter for UDS connections or if keepalive is disabled.
keepalives_count	Controls the number of times that keepalive messages are sent through TCP. The value <b>0</b> indicates that the default value is used. Ignore this parameter for UDS connections or if keepalive is disabled.

Parameter	Description
tcp_user_timeout	Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an OS that supports the <b>TCP_USER_TIMEOUT</b> socket option. The value <b>0</b> indicates that the default value is used. Ignore this parameter for UDS connections.
tcp_syn_retries	Specifies the number of retransmissions due to SYN packet transmission failures in the three-way handshake phase when the client establishes a connection on an OS that supports the <b>TCP_SYNCNT</b> socket option. <b>0</b> indicates that the default value is used. Ignore this parameter for UDS connections.
rw_timeout	Sets the read and write timeout interval of the client connection. When the timeout is triggered on the libpq and the connection is closed, the running services delivered by the libpq to the database are forcibly terminated. This capability is controlled by the GUC parameter <b>check_disconnect_query</b> . If this parameter is set to <b>on</b> , the capability is supported. If this parameter is set to <b>off</b> , the capability is not supported.
sslmode	Specifies whether to enable SSL encryption. <ul style="list-style-type: none"> <li>• <b>disable</b>: SSL connection is disabled.</li> <li>• <b>allow</b>: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.</li> <li>• <b>prefer</b>: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.</li> <li>• <b>require</b>: SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.</li> <li>• <b>verify-ca</b>: SSL connection is required. Currently, Windows ODBC does not support certificate-based authentication.</li> <li>• <b>verify-full</b>: SSL connection is required. Currently, Windows ODBC does not support certificate-based authentication.</li> </ul>
sslcompression	If this parameter is set to <b>1</b> (default value), the data transmitted over the SSL connection is compressed (this requires that the OpenSSL version be 0.9.8 or later). If this parameter is set to <b>0</b> , compression will be disabled (this requires OpenSSL 1.0.0 or later). If a connection without SSL is established, this parameter is ignored. If the OpenSSL version in use does not support this parameter, it will also be ignored. Compression takes up CPU time, but it increases throughput when the bottleneck is the network. If CPU performance is a limiting factor, disabling compression can improve response time and throughput.
sslcert	This parameter specifies the file name of the client SSL certificate. If no SSL connection is established, this parameter is ignored.

Parameter	Description
sslkey	This parameter specifies the location of the key used for the client certificate. It can specify a key obtained from an external "engine" (the engine is a loadable module of OpenSSL). The description of an external engine should consist of a colon-separated engine name and an engine-related key identifier. If no SSL connection is established, this parameter is ignored.
sslrootcert	This parameter specifies the name of a file that contains the SSL Certificate Authority (CA) certificate. If the file exists, the system authenticates the server certificate issued by one of these authorities.
sslcr	This parameter specifies the file name of the SSL Certificate Revocation List (CRL). If a certificate listed in this file exists, the server certificate authentication will be rejected.
requirepeer	This parameter specifies the OS user of the server, for example, <b>requirepeer=postgres</b> . When a UDS connection is established, if this parameter is set, the client checks whether the server process is running under the specified username at the beginning of the connection. If not, the connection will be interrupted by an error. This parameter can be used to provide server authentication similar to that of the SSL certificate on TCP/IP connections. (Note that if the UDS is in <b>/tmp</b> or another public writable location, any user can start a server for listening to the location. Use this parameter to ensure that you are connected to a server that is run by a trusted user.) This option is supported only on platforms that implement the peer authentication method.
krbsrvname	This parameter specifies the Kerberos service name used for GSSAPI authentication. For successful Kerberos authentication, this value must match the service name specified in the server configuration.
gsslib	This parameter specifies the GSS library used for GSSAPI authentication. It is used only in the Windows OS. If this parameter is set to <b>gssapi</b> , <b>libpq</b> is forced to use the GSSAPI library to replace the default SSPI for authentication.
service	This parameter specifies the name of the service for which the additional parameter is used. It specifies a service name in <b>pg_service.conf</b> that holds the additional connection parameters. This allows the application to specify only one service name so that the connection parameters can be centrally maintained.
authtype	<b>authtype</b> is no longer used, so it is marked as a parameter not to be displayed. It is retained in an array so as not to reject the <b>conninfo</b> string from old applications that might still try to set it.
remote_node_name	Specifies the name of the remote node connected to the local node.
localhost	Specifies the local host in a connection channel.

Parameter	Description
localport	Specifies the local port in a connection channel.
fencedUdfR PCMode	Specifies whether the fenced UDF RPC protocol uses UDSs or special socket file names. The default value is <b>0</b> , indicating that the UDS mode is used and the file type is <code>.s.PGSQL.%d</code> . To use the fenced UDF mode, set this parameter to <b>1</b> . In this case, the file type is <code>.s.fencedMaster_unixdomain</code> .
replication	<p>Specifies whether the connection should use replication protocols instead of common protocols. Protocols with this parameter configured are internal protocols used for PostgreSQL replication connections and tools such as <b>pg_basebackup</b>, while they can also be used by third-party applications. The following values, which are case-insensitive, are supported:</p> <ul style="list-style-type: none"> <li>• <b>true, on, yes, and 1:</b> Specifies that the physical replication mode is connected.</li> <li>• <b>database</b> Specifies that the logical replication mode and the database specified by <b>dbname</b> are connected.</li> <li>• <b>false, off, no, and 0:</b> Specifies that the connection is a regular connection, which is the default behavior.</li> </ul> <p>In physical or logical replication mode, only simple query protocols can be used.</p>
backend_ve rsion	Specifies the backend version to be passed to the remote end.
prototype	Sets the current protocol level. The default value is <b>PROTO_TCP</b> .
enable_ce	Specifies whether a client is allowed to connect to a fully-encrypted database. The default value is <b>0</b> (disabled). To enable the encrypted equality query, set this parameter to <b>1</b> . To enable the basic capability of encrypted equality query, change the value to <b>3</b> .
key_info	This parameter is used together with <b>enable_ce</b> to set parameters for accessing an external key manager in an encrypted database.
connection_ info	<p>The value of <b>connection_info</b> is a JSON character string consisting of <b>driver_name</b>, <b>driver_version</b>, <b>driver_path</b>, and <b>os_user</b>.</p> <p>If the value is not <b>NULL</b>, use <b>connection_info</b> and ignore <b>connectionExtraInf</b>.</p> <p>If the value is null, a connection information string related to <b>libpq</b> is generated. When <b>connectionExtraInf</b> is set to <b>false</b>, the value of <b>connection_info</b> consists of only <b>driver_name</b> and <b>driver_version</b>.</p>

Parameter	Description
connectionExtraInf	Specifies whether the value of <b>connection_info</b> contains extension information. The default value is <b>0</b> . If the value contains other information, set this parameter to <b>1</b> .
target_session_attrs	<p>Specifies the type of the host to be connected. The connection is successful only when the host type is the same as the configured value. This parameter is verified only when multiple IP addresses are specified. The rules for setting <b>target_session_attrs</b> are as follows:</p> <ul style="list-style-type: none"> <li>• <b>any</b>: All types of hosts can be connected.</li> <li>• <b>read-write</b>: The connection is set up only when the connected host is readable and writable.</li> <li>• <b>read-only</b>: Only readable hosts can be connected.</li> <li>• <b>primary</b> (default value): Only the primary node in the primary/standby systems can be connected.</li> <li>• <b>standby</b>: Only the standby node in the primary/standby systems can be connected.</li> <li>• <b>prefer-standby</b>: The system first attempts to find a standby node for connection. If all hosts in the <b>hosts</b> list fail to be connected, try the <b>any</b> mode.</li> </ul>

## 5.6 Psycopg-based Development

Psycopg is a Python API used to execute SQL statements and provides a unified access API for GaussDB. Applications can perform data operations based on psycopg. Psycopg2 is the encapsulation of libpq and is implemented using the C language, which is efficient and secure. It provides cursors on both clients and servers, asynchronous communication and notification, and the COPY TO and COPY FROM functions. It supports multiple types of Python out-of-the-box and adapts to GaussDB data types. Through the flexible object adaptation system, you can extend and customize the adaptation. Psycopg2 is compatible with Unicode.

GaussDB supports the psycopg2 feature and allows psycopg2 to be connected in SSL mode.

**Table 5-70** Platforms supported by psycopg

OS	Platform	Python Version
EulerOS V2.0SP5	<ul style="list-style-type: none"> <li>• Arm64</li> <li>• x86_64</li> </ul>	3.8.5
EulerOS V2.0SP9	<ul style="list-style-type: none"> <li>• Arm64</li> <li>• x86_64</li> </ul>	3.7.4

OS	Platform	Python Version
EulerOS V2.0SP10, Kylin V10, and UnionTech20	<ul style="list-style-type: none"> <li>• Arm64</li> <li>• x86_64</li> </ul>	3.7.9
EulerOS V2.0SP11 and SUSE 12.5	<ul style="list-style-type: none"> <li>• Arm64</li> <li>• x86_64</li> </ul>	3.9.11
Huawei Cloud EulerOS 2.0	<ul style="list-style-type: none"> <li>• Arm64</li> <li>• x86_64</li> </ul>	3.9.9

#### NOTICE

During pycopg2 compilation, OpenSSL of GaussDB is linked. OpenSSL of GaussDB may be incompatible with OpenSSL of the OS. If incompatibility occurs, for example, "version 'OPENSSL\_1\_1\_1f' not found" is displayed, use the environment variable `LD_LIBRARY_PATH` to isolate the OpenSSL provided by the OS and the OpenSSL on which GaussDB depends.

For example, when the application software `client.py` that invokes pycopg2 is executed, the environment variable is explicitly assigned to the application software.

```
export LD_LIBRARY_PATH=/path/to/gaussdb/libs:$LD_LIBRARY_PATH python client.py
```

In the preceding command, `/path/to/pycopg2/lib` indicates the directory where the OpenSSL library on which the GaussDB depends is located. Change it as required.

## 5.6.1 Development Process

Figure 5-4 Application development process based on psycopg2

## 5.6.2 Psycopg Package

**Step 1** Prepare related drivers and dependent libraries. Obtain the package **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Python.tar.gz** from the release package.

After the decompression, the following folders are generated:

- **psycopg2**: **psycopg2** library file
- **lib**: **lib** library file

**Step 2** Load the driver.

- Before using the driver, perform the following operations:
  - a. Decompress the driver package of the corresponding version.  
tar zxvf xxxx-Python.tar.gz

- b. Copy **psycopg2** to the **site-packages** folder in the Python installation directory as the **root** user.

```
su root
cp psycopg2 $(python3 -c 'import site; print(site.getsitepackages()[0])') -r
```

- c. Change the **psycopg2** directory permission to **755**.

```
chmod 755 $(python3 -c 'import site; print(site.getsitepackages()[0])')/psycopg2 -R
```

- d. Add the **psycopg2** directory to the environment variable **\$PYTHONPATH** and validate it.

```
export PYTHONPATH=$(python3 -c 'import site; print(site.getsitepackages()[0])'):$PYTHONPATH
```

- e. For non-database users, configure the **lib** directory in **LD\_LIBRARY\_PATH** after decompression.

```
export LD_LIBRARY_PATH=path/to/lib:$LD_LIBRARY_PATH
```

- Load a database driver before creating a database connection.

```
import psycopg2
```

### Step 3 Connect to a database.

Connect to the database in non-SSL mode.

1. Use the `psycopg2.connect` function to obtain the connection object.
2. Use the connection object to create a cursor object.

Connect to the database in SSL mode.

When you use `psycopy2` to connect to the GaussDB server, you can enable SSL to encrypt the communication between the client and server. To enable SSL, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

1. Use the `.ini` file (the **configparser** package of Python can parse this type of configuration file) to save the configuration information about the database connection.
2. Add SSL connection parameters **sslmode**, **sslcert**, **sslkey**, and **sslrootcert** to the connection options.
  - a. **sslmode**: For details about the options, see [Table 5-71](#).
  - b. **sslcert**: client certificate path.
  - c. **sslkey**: client key path.
  - d. **sslrootcert**: root certificate path.
3. Use the `psycopg2.connect` function to obtain the connection object.
4. Use the connection object to create a cursor object.

 **CAUTION**

To use SSL to connect to the database, ensure that the Python interpreter is compiled in the mode of generating a dynamic link library (.so) file. You can perform the following steps to check the connection mode of the Python interpreter:

1. Run the **import ssl** command in the Python interpreter to import SSL.
2. Run the **ps ux** command to query the PID of the Python interpreter. Assume that the PID is **\*\*\*\*\***.
3. In the shell CLI, run the **pmap -p \*\*\*\*\* | grep ssl** command and check whether the command output contains the path related to **libssl.so**. If the command output contains the path, the Python interpreter is compiled in dynamic link mode.

**Table 5-71** sslmode options

sslmode	Enable SSL Encryption	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required, but only data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required, and the validity of the server CA must be verified.
verify-full	Yes	The SSL connection must be enabled, which is not supported by GaussDB currently.

**Step 4** Run SQL statements.

1. Construct an operation statement and use %s as a placeholder. During execution, psycopg2 will replace the placeholder with the parameter value. You can add the RETURNING clause to obtain the automatically generated column values.
2. Use the cursor.execute method to execute one row of SQL statement, and use the cursor.executemany method to execute multiple rows of SQL statements.

**Step 5** Process the result set.

1. `cursor.fetchone()`: fetches the next row in a query result set and returns a sequence. If no data is available, null is returned.
2. `cursor.fetchall()`: fetches all remaining rows in a query result and returns a list. An empty list is returned when no rows are available.

**NOTE**

For database-specific data types, such as `tinyint`, the corresponding columns in the query result are character strings.

**Step 6** Disable the connection.

After you complete required data operations in a database, close the database connection. Call the close method such as `connection.close()` to close the connection.

**CAUTION**

This method closes the database connection and does not automatically call `commit()`. If you just close the database connection without calling `commit()` first, changes will be lost.

----End

## 5.6.3 Examples: Common Operations

```
import psycopg2
import os

# Obtain the username and password from environment variables.
user = os.getenv('user')
password = os.getenv('password')

# Create a connection object.
conn=psycopg2.connect(database="database", user=user, password=password, host="localhost", port=port)
cur=conn.cursor() # Create a pointer object.

# Create a connection object (using SSL).
conn = psycopg2.connect(dbname="database", user=user, password=password, host="localhost", port=port,
    sslmode="verify-ca", sslcert="client.crt", sslkey="client.key", sslrootcert="cacert.pem")
Note: If sslcert, sslkey, and sslrootcert are not set, the following files in the .postgresql directory of the
current user are used by default: client.crt, client.key, and root.crt.

# Create a table.
cur.execute("CREATE TABLE student(id integer,name varchar,sex varchar);")

# Insert data.
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(1,'Aspirin','M'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(2,'Taxol','F'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(3,'Dixheral','M'))

# Insert data in batches.
stus = ((4,'John','M'),(5,'Alice','F'),(6,'Peter','M'))
cur.executemany("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",stus)

# Obtain the result.
cur.execute("SELECT * FROM student")
results=cur.fetchall()
print (results)
```

```
# Perform a commit.
conn.commit()

# Insert a data record.
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(7,'Lucy','F'))

# Perform a rollback.
conn.rollback()

# Close the connection.
cur.close()
conn.close()

Common connection modes of psycopg2
1. conn = psycopg2.connect(dbname="dbname", user=user, password=password, host="localhost",
port=port)
2. conn = psycopg2.connect(f"dbname=dbname user={user} password={password} host=localhost
port=port")
3. Using logs
import logging
import psycopg2
from psycopg2.extras import LoggingConnection
import os

# Obtain the username and password from environment variables.
user = os.getenv('user')
password = os.getenv('password')

logging.basicConfig(level=logging.DEBUG) # Log level
logger = logging.getLogger(__name__)

db_settings = {
    "user": user,
    "password": password,
    "host": "localhost",
    "database": "dbname",
    "port": port
}

# LoggingConnection records all SQL statements by default. You can filter unnecessary or sensitive SQL
statements. The following is an example of filtering password-related SQL statements.
class SelfLoggingConnection(LoggingConnection):

    def filter(self, msg, curs):
        if db_settings['password'] in msg.decode():
            return b'queries containing the password will not be recorded'
        return msg

conn = psycopg2.connect(connection_factory=SelfLoggingConnection, **db_settings)
conn.initialize(logger)
```

**CAUTION**

- By default, **LoggingConnection** records all SQL information and does not anonymize sensitive information. You can use the filter function to define the output SQL content.
- The log function is an additional function provided by psycopg2 for developers to explicitly debug full SQL statements. By default, the log function is not used. This function prints SQL statements before psycopg2 executes SQL statements. However, the SQL statements can be printed only when the log level is **DEBUG**. This function is not a default function. It is used only when there are special requirements. You are advised not to use this function unless there are special requirements. For details, visit <https://www.psycopg.org/docs/extras.html?highlight=loggingconnection>.

## 5.6.4 Psycopg API Reference

Psycopg APIs are a set of methods provided for users. This section describes some common APIs.

### 5.6.4.1 psycopg2.connect()

#### Description

Creates a database session and returns a new connection object.

#### Prototype

```
import os
conn=psycopg2.connect(dbname="test",user=os.getenv('user'),password=os.getenv('password'),host="127.0.0.1",port="5432")
```

#### Parameters

Table 5-72 psycopg2.connect parameters

Keyword	Description
dbname	Database name.
user	Username.
password	Password.
host	IP address of the database. You can specify multiple IP addresses and separate them with commas (,). By default, the UDS is used.
port	Connection port number. The default value is <b>5432</b> . If the host has multiple IP addresses and the port numbers are the same, specify one port number. Otherwise, the port numbers must correspond to the IP addresses one by one and are separated by commas (,).

Keyword	Description
sslmode	SSL mode, which is used for SSL connection.
sslcert	Path of the client certificate, which is used for SSL connection.
sslkey	Path of the client key, which is used for SSL connection.
sslrootcert	Path of the root certificate, which is used for SSL connection.
hostaddr	IP address of the database.
connect_timeout	Client connection timeout interval.
client_encoding	Encoding format of the client.
application_name	Value of <b>application_name</b> .
fallback_application_name	Rollback value of <b>application_name</b> .
keepalives	Determines whether to enable the TCP connection on the client. The default value is <b>1</b> , indicating that the TCP connection is enabled. The value <b>0</b> indicates that the TCP connection is disabled. If the UDS connection is used, ignore this parameter.
options	Specifies the command line options sent to the server when the connection starts.
keepalives_idle	Describes inactivity before keepalive messages are sent to the server. If <b>keepalive</b> is disabled, ignore this parameter.
keepalives_interval	Determines whether keepalive messages that are not confirmed by the server need to be resent. If <b>keepalive</b> is disabled, ignore this parameter.
keepalives_count	Specifies the number of TCP connections that may be lost before the client is disconnected from the server.
replication	Ensures that the connection uses the replication protocol instead of the common protocol.
requiressl	Supports the SSL mode.
sslcompression	Specifies the SSL compression. If this parameter is set to <b>1</b> , the data sent through the SSL connection is compressed. If this parameter is set to <b>0</b> , the compression is disabled. If no SSL connection is established, ignore this parameter.
sslcrll	Specifies the path of the certificate revocation list (CRL), which is used to check whether the SSL server certificate is available.
requirepeer	Specifies the OS username of the server.

Keyword	Description
target_session_attrs	<p>Specifies the type of the host to be connected. The connection is successful only when the host type is the same as the configured value. This parameter is verified only when multiple IP addresses are specified. The rules for setting <b>target_session_attrs</b> are as follows:</p> <ul style="list-style-type: none"> <li>• <b>any</b>: All types of hosts can be connected.</li> <li>• <b>read-write</b>: The connection is set up only when the connected host is readable and writable.</li> <li>• <b>read-only</b>: Only readable hosts can be connected.</li> <li>• <b>primary</b> (default value): Only the primary node in the primary/standby systems can be connected.</li> <li>• <b>standby</b>: Only the standby node in the primary/standby systems can be connected.</li> <li>• <b>prefer-standby</b>: The system first attempts to find a standby node for connection. If all hosts in the <b>hosts</b> list fail to be connected, try the <b>any</b> mode.</li> </ul>

## Return Value

Connection object (for connecting to a database instance)

## Examples

For details, see [Examples: Common Operations](#).

### 5.6.4.2 connection.cursor()

## Function

This method returns a new cursor object.

## Prototype

```
cursor(name=None, cursor_factory=None, scrollable=None, withhold=False)
```

## Parameter

**Table 5-73** connection.cursor parameters

Keyword	Description
name	Cursor name. The default value is <b>None</b> .
cursor_factory	Creates a non-standard cursor. The default value is <b>None</b> .
scrollable	Sets the SCROLL option. The default value is <b>None</b> .

Keyword	Description
withhold	Sets the HOLD option. The default value is <b>False</b> .

## Return Value

Cursor object (used for cursors that are programmed using Python in the entire database)

## Example

For details, see [Examples: Common Operations](#).

### 5.6.4.3 cursor.execute(query,vars\_list)

## Function

This method executes the parameterized SQL statements (that is, placeholders instead of SQL literals). The psycopg2 module supports placeholders marked with %s.

## Prototype

```
cursor.execute(query,vars_list)
```

## Parameters

Table 5-74 cursor.execute parameters

Keyword	Description
query	SQL statement to be executed.
vars_list	Variable list, which matches the %s placeholder in the query.

## Return Value

None

## Example

For details, see [Examples: Common Operations](#).

### 5.6.4.4 cursor.executemany(query,vars\_list)

## Function

This method executes an SQL command against all parameter sequences or mappings found in the sequence SQL.

## Prototype

```
curosr.executemany(query,vars_list)
```

## Parameter

**Table 5-75** curosr.executemany parameters

Keyword	Description
query	SQL statement that you want to execute.
vars_list	Variable list, which matches the %s placeholder in the query.

## Return Value

None

## Example

For details, see [Examples: Common Operations](#).

### 5.6.4.5 connection.commit()

## Description

This method commits the currently pending transaction to the database.

---

 **CAUTION**

By default, Psycopg opens a transaction before executing the first command. If **commit()** is not called, the effect of any data operation will be lost.

---

## Prototype

```
connection.commit()
```

## Parameters

None

## Return Values

None

## Examples

For details, see [Examples: Common Operations](#).

### 5.6.4.6 connection.rollback()

#### Function

This method rolls back the current pending transaction.

---

**CAUTION**

If you close the connection using **close()** but do not commit the change using **commit()**, an implicit rollback will be performed.

---

#### Prototype

```
connection.rollback()
```

#### Parameter

None

#### Return Value

None

#### Example

For details, see [Examples: Common Operations](#).

### 5.6.4.7 cursor.fetchone()

#### Function

This method extracts the next row of the query result set and returns a tuple.

#### Prototype

```
cursor.fetchone()
```

#### Parameter

None

#### Return Value

A single tuple is the first result in the result set. If no more data is available, **None** is returned.

#### Example

For details, see [Examples: Common Operations](#).

### 5.6.4.8 cursor.fetchall()

#### Function

This method gets all the (remaining) rows of the query result and returns them as a list of tuples.

#### Prototype

```
cursor.fetchall()
```

#### Parameter

None

#### Return Value

Tuple list, which contains all results of the result set. An empty list is returned when no rows are available.

#### Example

For details, see [Examples: Common Operations](#).

### 5.6.4.9 cursor.close()

#### Function

This method closes the cursor of the current connection.

#### Prototype

```
cursor.close()
```

#### Parameter

None

#### Return Value

None

#### Example

For details, see [Examples: Common Operations](#).

### 5.6.4.10 connection.close()

#### Function

This method closes the database connection.

 CAUTION

This method closes the database connection and does not automatically call **commit()**. If you just close the database connection without calling **commit()** first, changes will be lost.

## Prototype

```
connection.close()
```

## Parameter

None

## Return Value

None

## Example

For details, see [Examples: Common Operations](#).

## 5.7 ECPG-based Development

Embedded SQL C Preprocessor (ECPG) for GaussDB Kernel is an embedded SQL preprocessor for C programs. An embedded SQL program consists of code written in an ordinary programming language, in this case C, mixed with SQL commands in specially marked sections. To build the program, the source code (\*.pgc) is first passed through the embedded SQL preprocessor, which converts it to an ordinary C program (\*.c), and afterwards it can be processed by a C compiler. Converted ECPG applications call functions in the libpq library through the embedded SQL library (ecpglib), and communicate with the GaussDB Kernel server using the normal frontend-backend protocol.

Programs written for the embedded SQL interface are normal C programs with special code inserted to perform database-related actions. This special code always has the form:

```
EXEC SQL ...;
```

These statements syntactically take the place of a C statement. Depending on the particular statement, they can appear at the global level or within a function. Embedded SQL statements follow the case-sensitivity rules of normal SQL code, and allow nested C code-style comments (part of the SQL standard). However, the C part of the program follows the standards of the C program and does not support nested comments.

## 5.7.1 Development Process

Figure 5-5 ECPG-based development process

Figure 5-6 Embedded SQL-C program development process

## 5.7.2 ECPG Components

- Platforms supported by ECPG

Table 5-76 Platforms supported by ECPG

OS	Platform
EulerOS V2.0SP5	x86_64
EulerOS V2.0SP9	Arm64
Kylin V10	x86_64
Kylin V10	Arm64

- `ecpg` components
  - `ecpg`: an executable binary file used to preprocess C programs with embedded SQL statements.
  - `libecpg`: dynamic library provided by `ecpg` to implement connections, SQL statements, and transactions, including `libecpg.so`, `libecpg.so.6`, and `libecpg.so.6.4`. It is referenced by the `-lecp` parameter during C program compilation and execution.
  - `libpgtypes`: dynamic library provided by the ECPG for operating data of the numeric, date, timestamp, and interval types, including `libpgtypes.so`,

**libecpg.so.6**, and **libecpg.so.6.4**. The library is referenced by the **-lpgtypes** parameter during C program compilation and execution.

- Paths for obtaining ECPG components
  - ECPG binary file: *\$GAUSSHOME/bin*
  - Dynamic library on which the ECPG depends: *\$GAUSSHOME/lib*
  - Header file required by ECPG: *\$GAUSSHOME/include/ecpg*

### 5.7.3 ECPG Preprocessing and Compiling

Prepare C programs with embedded SQL statements with the extension `.pgc`. ECPG converts them into C programs that can be compiled by the C compiler.

The generated C program is compiled into an executable file by the GCC compiler. The executable file is run to enable the client program to access the database. For details, see [Examples](#).

- `ecpg` preprocessing and C compilation process
  - a. Preprocessing: `ecpg -I $GAUSSHOME/include -o test.c test.pgc`  
To execute ECPG preprocessing, run the following command:  
`ecpg [OPTION]...`  
The options are as follows:
    - **-o OUTFILE**: writes the result to OUTFILE, which is a C file.
    - **-I DIRECTORY**: path of the header file.
    - **-c**: automatically generates a C file.
    - **--version**: checks the current ECPG version.
  - b. Compilation: `gcc -I $GAUSSHOME/include/ecpg -I $GAUSSHOME/include -I $GAUSSHOME/include/gaussdb/server/ -L $GAUSSHOME/lib -lecpg -lrt -lpq -lpgtypes -lpthread test_ecpg.c -o test_ecpg`
  - c. Execution: `./test`

#### NOTICE

- ECPG is a compilation preprocessing tool. If an error message is displayed indicating that the related header file or function implementation cannot be found during preprocessing or compilation, you can specify the header file or link the dynamic library as required.
- ECPG requires compilation preprocessing tools such as GCC and ld. You are advised to use GCC 7.3.0.
- Other dynamic libraries and header files on which the ECPG depends are usually stored in *\$GAUSSHOME/include/libpq*, *\$GAUSSHOME/include*.
- Common dynamic library dependencies during compilation include: `-lpq`, `-lpq_ce`, and `-lpthread`. If the libpq communications library is required during development, connect to `-lpq` and `-lpq_ce`. If the multi-thread connection is required during development, connect to `-lpthread`.

## 5.7.4 Managing Database Connections

This section describes how to establish and switch a database connection.

### 5.7.4.1 Connecting to a Database

You can run the following command to connect to the database:

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name];
```

The target can be declared using the following methods. The italic part is a variable. Change it based on the actual situation.

- *dbname*[@*hostname*][:*port*]
- *tcp:gaussdb://hostname[:port]/dbname*[?*options*]
- *unix:gaussdb://hostname[:port]/dbname*[?*options*]
- An SQL string containing one of the above forms

There are also different ways to specify the username:

- *username/password*
- *username* SQLIDENTIFIED BY *password*
- *username* USING *password*

As mentioned above, the **username** and **password** parameters can be an SQL identifier, an SQL string, or a reference to a character variable.

**connection\_name** indicates the connection name. If a program uses only one connection, you can omit it. The most recently opened connection becomes the current connection.

An example is as follows:

```
#include <stdlib.h>
EXEC SQL CONNECT TO mydb@sql.mydomain.com;

EXEC SQL CONNECT TO unix:gaussdb://sql.mydomain.com/mydb AS myconnection USER username;

EXEC SQL BEGIN DECLARE SECTION;
/* The values of target, user, and passwd must be read from environment variables or configuration files.
Environment variables need to be configured as required. If no environment variable is used, a character
string can be directly assigned. */
const char *target = getenv("EXAMPLE_TARGET_ENV");
const char *user = getenv("EXAMPLE_USERNAME_ENV");
const char *passwd = getenv("EXAMPLE_PASSWD_ENV");
EXEC SQL END DECLARE SECTION;
...
EXEC SQL CONNECT TO :target USER :user USING :passwd;
/* or EXEC SQL CONNECT TO :target USER :user/:passwd; */
```

For details about the complete usage example, see the example of using the connection syntax in [CONNECT](#).

#### NOTE

- In the last form, character variables are referenced. For details about how to reference C variables in SQL statements, see [Host Variables](#).
- The format of the connection target is not described in the SQL standard. Therefore, to develop a portable application, you can use the method in the last example to encapsulate the connection target string into a variable.
- For details about the ecpg compatibility, see [ecpg Compatibility](#).

**NOTICE**

- If **ip-port** is specified in the connection statement, username and password must be specified. This rule is determined by the GaussDB Kernel kernel communication authentication. If **ip-port** is not specified, the local *\$PGPORT* (UDS) is used for communication.
- If the SSL protocol is used for connection, run the **tcp:gaussdb://hostname[:port]/[dbname][?options]** command and set **sslmode** to **disable** \require in **options**.

### 5.7.4.2 Managing Connections

SQL statements in embedded SQL programs are by default executed on the current connection, that is, the most recently opened one. If an application needs to manage multiple connections, use either of the following methods:

- **Method 1: Explicitly select a connection for each SQL statement.**  
EXEC SQL AT connection-name SELECT ...;  
This method is particularly suitable if the application needs to use several connections in mixed order.  
If the application uses multiple threads of execution, they cannot share a connection concurrently. You must either explicitly control access to the connection (using mutexes) or use a connection for each thread.
- **Method 2: Execute a statement to switch the connection.**  
EXEC SQL SET CONNECTION connection-name;  
This method is particularly suitable if many statements are executed on the same connection.

An example of managing connections is as follows:

```
#include <stdio.h>
EXEC SQL BEGIN DECLARE SECTION;
char dbname[1024];
EXEC SQL END DECLARE SECTION;

int main()
{
    EXEC SQL CONNECT TO testdb1 AS con1 USER testuser;
    EXEC SQL CONNECT TO testdb2 AS con2 USER testuser;
    EXEC SQL CONNECT TO testdb3 AS con3 USER testuser;

    /* This query will be executed in the most recently opened database testdb3. */
    EXEC SQL SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb3)\n", dbname);

    /* Use AT to run a query in testdb2. */
    EXEC SQL AT con2 SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb2)\n", dbname);

    /* Switch to connection to testdb1. */
    EXEC SQL SET CONNECTION con1;

    EXEC SQL SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb1)\n", dbname);

    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

Example output:

```
current=testdb3 (should be testdb3)
current=testdb2 (should be testdb2)
current=testdb1 (should be testdb1)
```

#### NOTICE

- In multi-thread mode, different threads cannot use the same connection name. The connection name of each thread must be unique.
- A connection must be established and closed in the same process or thread.

## 5.7.5 Running SQL Commands

The format of embedded SQL commands is EXEC SQL [Command]. In embedded SQL applications, you can run common standard SQL statements supported by GaussDB Kernel or extended SQL statements provided by ECPG. Currently, features or syntaxes such as stored procedures, anonymous blocks, and flashback are not supported.

### 5.7.5.1 Running SQL Statements

**Step 1** Create a table.

```
EXEC SQL CREATE TABLE foo (a int, b varchar);
```

**Step 2** Insert a row.

```
EXEC SQL INSERT INTO foo VALUES (5, 'abc');
```

**Step 3** Delete a row.

```
EXEC SQL DELETE FROM foo WHERE a = 5;
```

**Step 4** Update table data.

```
EXEC SQL UPDATE foo SET b = 'gdp' WHERE a = 7;
```

**Step 5** Query data in a single row.

```
EXEC SQL SELECT a INTO :var_a FROM foo WHERE b = 'def';
```

----End

A complete example is as follows:

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

int main ()
{
    ECPGdebug (1, stderr);

    EXEC SQL BEGIN DECLARE SECTION;
    int var_a;
    EXEC SQL END DECLARE SECTION;
    /* Create testdb in advance. */
    EXEC SQL CONNECT TO testdb;
    // Create a table.
    EXEC SQL CREATE TABLE foo (a int, b varchar);
    // Insert data.
    EXEC SQL INSERT INTO foo VALUES (5, 'abc');
    EXEC SQL INSERT INTO foo VALUES (6, 'def');
    EXEC SQL INSERT INTO foo VALUES (7, 'ghi');
```

```
// Delete a row.
EXEC SQL DELETE FROM foo WHERE a = 5;
// Update table data.
EXEC SQL UPDATE foo SET b = 'gdp' WHERE a = 7;
// Query table data in a single row.
EXEC SQL SELECT a INTO :var_a FROM foo WHERE b = 'def';
// Print the query results.
printf("select res is %d\n", var_a);

EXEC SQL DISCONNECT;

return 0;
}
```

### 5.7.5.2 Using Cursors

To retrieve a result set holding multiple rows, an application has to declare a cursor and fetch each row from the cursor.

**Step 1** Declare a cursor.

```
EXEC SQL DECLARE c CURSOR FOR select * from tb1;
```

**Step 2** Open a cursor.

```
EXEC SQL OPEN c;
```

**Step 3** Fetch a row of data from a cursor.

```
EXEC SQL FETCH 1 in c into :a, :str;
```

**Step 4** Close a cursor.

```
EXEC SQL CLOSE c;
```

----End

For details about how to use cursors, see [DECLARE](#). For details about the [FETCH](#) command, see [FETCH](#).

A complete example is as follows:

```
#include <string.h>
#include <stdlib.h>

int main(void)
{
exec sql begin declare section;
    int *a = NULL;
    char *str = NULL;
exec sql end declare section;

    int count = 0;
    /* Create testdb in advance. */
    exec sql connect to testdb ;
    exec sql set autocommit to off;
    exec sql begin;
    exec sql drop table if exists tb1;
    exec sql create table tb1(id int, info text);
    exec sql insert into tb1 (id, info) select generate_series(1, 100000), 'test';
    exec sql select count(*) into :a from tb1;
    printf ("a is %d\n", *a);
    exec sql commit;

    // Define a cursor.
    exec sql declare c cursor for select * from tb1;
    // Open the cursor.
    exec sql open c;
    exec sql whenever not found do break;
    while(1) {
        // Capture data.
```

```
exec sql fetch 1 in c into :a, :str;
count++;
if (count == 100000) {
    printf("Fetch res: a is %d, str is %s", *a, str);
}
}
// Close the cursor.
exec sql close c;
exec sql set autocommit to on;
exec sql drop table tb1;
exec sql disconnect;

ECPGfree_auto_mem();
return 0;
}
```

### 5.7.5.3 Transaction

In the default mode, statements are committed only when EXEC SQL COMMIT is issued. The embedded SQL interface also supports autocommit of transactions by executing the **EXEC SQL SET AUTOCOMMIT TO ON** statement. In autocommit mode, each command is automatically committed unless it is inside an explicit transaction block. This mode can be explicitly turned off by using **EXEC SQL SET AUTOCOMMIT TO OFF**.

Common transaction management commands are as follows:

- **EXEC SQL COMMIT**: commits an ongoing transaction.
- **EXEC SQL ROLLBACK**: rolls back an ongoing transaction.
- **EXEC SQL SET AUTOCOMMIT TO ON**: enables the autocommit mode.
- **SET AUTOCOMMIT TO OFF**: disables the autocommit mode. This is the default mode.

### 5.7.5.4 Prepared Statements

Prepared statements can be used when the value passed to an SQL statement is unknown at compile time or the same statement will be used multiple times.

- Statements are prepared using the **PREPARE** command. For the values that are not known yet, use the question mark (?) as the placeholder.  
EXEC SQL PREPARE stmt1 FROM "SELECT oid, datname FROM pg\_database WHERE oid = ?";
- If a statement returns a single row, the application can call EXECUTE after PREPARE to execute the statement, supplying the actual values for the placeholders with a USING clause:  
EXEC SQL EXECUTE stmt1 INTO :dboid, :dbname USING 1;
- If a statement returns multiple rows, the application can use a cursor declared based on the prepared statement. To bind input parameters, the cursor must be opened with a USING clause:  
EXEC SQL PREPARE stmt1 FROM "SELECT oid, datname FROM pg\_database WHERE oid > ?";  
EXEC SQL DECLARE foo\_bar CURSOR FOR stmt1;  
/\* When the end of the result set is reached, exit the while loop. \*/  
EXEC SQL WHENEVER NOT FOUND DO BREAK;  
EXEC SQL OPEN foo\_bar USING 100;  
...  
while (1)  
{  
 EXEC SQL FETCH NEXT FROM foo\_bar INTO :dboid, :dbname;  
 ...  
}

```
}  
EXEC SQL CLOSE foo_bar;
```

- When a prepared statement is no longer needed, it should be deallocated.  
EXEC SQL DEALLOCATE PREPARE name;

## 5.7.5.5 Embedded SQL Commands

### 5.7.5.5.1 ALLOCATE DESCRIPTOR

#### Function

Allocates a newly named SQL descriptor area.

#### Syntax

```
ALLOCATE DESCRIPTOR name
```

#### Parameter Description

**name**

SQL descriptor name. It is case sensitive and is an SQL identifier or a host variable.

#### Example

```
EXEC SQL ALLOCATE DESCRIPTOR mydesc;
```

#### Helpful Links

[DEALLOCATE DESCRIPTOR](#), [GET DESCRIPTOR](#), and [SET DESCRIPTOR](#)

### 5.7.5.5.2 CONNECT

#### Description

Establishes a connection between the client and the SQL server.

#### Syntax

```
CONNECT TO connection_target [ AS connection_name ] [ USER connection_user ]
```

#### Parameters

- **connection\_target**  
Specifies the target server to be connected in one of the following formats:
  - [ *database\_name* ] [ @ *host* ] [ : *port* ]: connection over TCP/IP.
  - unix:gaussdb://*host* [ : *port* ] / [ *database\_name* ] [ ? *connection\_option* ]: connection over UDSs.
  - tcp:gaussdb://*host* [ : *port* ] / [ *database\_name* ] [ ? *connection\_option* ]: connection over TCP/IP.
  - **SQL string constant**: one of the preceding forms.

 **CAUTION**

For details about `connection_target`, see [ecpg Compatibility](#).

- **connection\_name**

An optional identifier used for the connection, which can be referenced in other commands. It can be an SQL identifier or a host variable.

- **connection\_user**

Username for database connection.

You can use *user\_name/password*, *user\_name SQLIDENTIFIED BY password*, or *user\_name USING password* to specify the username and password.

The username and password can be SQL identifiers, string constants, or host variables.

 **NOTE**

In the preceding parameters, the information in italics refers to variables. Replace them based on the actual situation.

## Examples

Here are several variants of specifying connection parameters:

```
EXEC SQL CONNECT TO "connectdb" AS main;
EXEC SQL CONNECT TO "connectdb" AS second;
EXEC SQL CONNECT TO 'connectdb' AS main;
EXEC SQL CONNECT TO REGRESSDB1 as main;
EXEC SQL CONNECT TO connectdb AS :id;
EXEC SQL CONNECT TO connectdb AS main USER connectuser/connectdb;
EXEC SQL CONNECT TO connectdb AS main USER connectuser USING "connectdb";
EXEC SQL CONNECT TO connectdb AS main;
EXEC SQL CONNECT TO tcp:gaussdb://localhost/connectdb USER connectuser IDENTIFIED BY connectpw;
EXEC SQL CONNECT TO tcp:gaussdb://localhost:$PORT/connectdb USER connectuser SQLIDENTIFIED BY connectpw;
EXEC SQL CONNECT TO unix:gaussdb://localhost/connectdb USER connectuser SQLIDENTIFIED BY "connectpw";
EXEC SQL CONNECT TO unix:gaussdb://localhost/connectdb USER connectuser USING "connectpw";
```

The following is an example of using the connection syntax:

```
#include <stdlib.h>
#include <string.h>
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    // Define the host by defining columns such as database and password required by the connection string.
    // The actual values are read from environment variables or configuration files. Environment variables need to
    // be configured as required. If no environment variable is used, a character string can be directly assigned.
    exec sql begin declare section;
        const int max_str_len = 200;
        char db[max_str_len] = getenv("EXAMPLE_DATABASENAME_ENV");
        char pw[max_str_len] = getenv("EXAMPLE_PASSWD_ENV");
        char new_pw[max_str_len] = getenv("EXAMPLE_NEW_PASSWD_ENV");
    exec sql end declare section;

    // Print debug logs.
    ECPGdebug(1, stderr);

    // The connection statement involves the database, username, and password. The user must be created
    // in advance and have related operation permissions.
```

```
//Connection mode: EXEC SQL CONNECT TO [ database_name ][ @host ][ :port ] [ USER
connection_user ]
// Case 1: Use the default local connection mode to connect to the postgres database.
exec sql connect to postgres;
// Case 2: Use the default local connection mode to connect to the postgres database. The connection
alias is conn1.
exec sql connect to postgres as conn1;
// Case 3: Use the ip+port mode (localhost indicates the local address listened by the database, and
$PORT indicates the listening port of the database) to connect to the connectdb database, specify the
database alias, and specify the user password.
exec sql connect to connectdb@localhost:$PORT as conn2 user connectuser using :pw;
// Case 4: Use the ip+port mode (127.0.0.1 indicates the local IP address listened by the database, and
$PORT indicates the listening port of the database) to connect to the connectdb database, specify the
database alias, and specify the user password.
exec sql connect to connectdb@127.0.0.1:$PORT as conn3 user connectuser sqlidentified by :pw;
// Case 5: Close the connection to the database.
exec sql disconnect postgres;
exec sql disconnect conn1;
exec sql disconnect conn2;
exec sql disconnect conn3;

// Connection mode: EXEC SQL CONNECT TO <tcp|unix>:<gaussdb|postgresql>://host
[ :port ]/[ database_name ][ ?connection_option ]
// Case 1: Replace the URL variables with the host variables pw and db.
strcpy(pw, new_pw);
strcpy(db, "tcp:postgresql://localhost/connectdb");
exec sql connect to :db user connectuser using :pw;
// Case 2: 127.0.0.1 indicates the IP address listened by the database, and connectdb indicates the
database.
exec sql connect to tcp:postgresql://127.0.0.1/connectdb as conn4 user connectuser using :pw;
// Case 3: 127.0.0.1 indicates the IP address listened by the database, connectdb indicates the database,
and connect_timeout=14 indicates the connection string configuration parameter.
exec sql connect to tcp:gaussdb://localhost/connectdb?connect_timeout=14 as conn5 user connectuser
sqlidentified by :pw;
// Case 4: Close all connections.
exec sql close all;
// Connect to the database and execute the service.
exec sql connect to tcp:postgresql://127.0.0.1/connectdb as conn4 user connectuser using :pw;
exec sql set autocommit = on;
exec sql create table t1(a int);
exec sql insert into t1 values(1),(2);
exec sql select a from t1 where a > 1;
exec sql drop table t1;
exec sql disconnect current;
return 0;
}
```

The following is an example of using a host variable to specify connection parameters:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
/* The values of dbname, user, and pwd must be read from environment variables or configuration files.
Environment variables need to be configured as required. If no environment variable is used, a character
string can be directly assigned. */
char *dbname = getenv("EXAMPLE_DBNAME_ENV"); /* Database name */
char *user = getenv("EXAMPLE_USERNAME_ENV"); /* Username for connection */
char *pwd = getenv("EXAMPLE_PASSWD_ENV"); /* Password */
char *connection = "tcp:gaussdb://localhost:$PORT/testdb"; /* Connection string */
char ver[256]; /* Buffer for storing version strings */
EXEC SQL END DECLARE SECTION;

ECPGdebug(1, stderr);
EXEC SQL CONNECT TO :dbname;
```

```
EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
EXEC SQL SELECT version() INTO :ver;
EXEC SQL DISCONNECT;

printf("version: %s\n", ver);
EXEC SQL CONNECT TO :connection USER :user USING :pwd;
EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
EXEC SQL SELECT version() INTO :ver;
EXEC SQL DISCONNECT;

printf("version: %s\n", ver);
return 0;
}
```

## Helpful Links

[DISCONNECT](#) and [SET CONNECTION](#)

### 5.7.5.5.3 DEALLOCATE DESCRIPTOR

#### Function

Deallocates a SQL descriptor area.

#### Syntax

```
DEALLOCATE DESCRIPTOR name
```

#### Parameter Description

**name**

SQL descriptor name. It is case sensitive and is an SQL identifier or a host variable.

#### Example

```
DEALLOCATE DESCRIPTOR mydesc;
```

## Helpful Links

[ALLOCATE DESCRIPTOR](#), [GET DESCRIPTOR](#), and [SET DESCRIPTOR](#)

### 5.7.5.5.4 DECLARE

#### Description

Declares a cursor for iterating over the result set of a prepared statement. This command is slightly semantically different from the SQL command **DECLARE**: Whereas the latter executes a query and prepares the result set for retrieval, this embedded SQL command merely declares a name as a "loop variable" for iterating over the result set of a query; the actual execution happens when the cursor is opened with the **OPEN** command.

#### Syntax

```
DECLARE cursor_name [ BINARY ] [ NO SCROLL ] CURSOR [ { WITH | WITHOUT } HOLD ] FOR
prepared_name
DECLARE cursor_name [ BINARY ] [ NO SCROLL ] CURSOR [ { WITH | WITHOUT } HOLD ] FOR query
```

## Parameters

- **cursor\_name**  
Cursor name, which is case sensitive. It can be an SQL identifier or a host variable.
- **prepared\_name**  
Name of the prepared query, which can be an SQL identifier or a host variable.
- **query**  
A SELECT command for providing the rows to be returned by the cursor.

### NOTE

For details about the cursor options, see [DECLARE](#).

## Examples

Examples of declaring a cursor used for query:

```
EXEC SQL DECLARE C CURSOR FOR SELECT * FROM My_Table;  
EXEC SQL DECLARE C CURSOR FOR SELECT Item1 FROM T;  
EXEC SQL DECLARE cur1 CURSOR FOR SELECT version();
```

Example of declaring a cursor for a prepared statement:

```
EXEC SQL PREPARE stmt1 AS SELECT version();  
EXEC SQL DECLARE cur1 CURSOR FOR stmt1;
```

## Helpful Links

[OPEN](#)

### 5.7.5.5.5 DESCRIBE

## Description

Retrieves metadata information for the result columns contained in prepared statements.

## Syntax

```
DESCRIBE [ OUTPUT ] prepared_name USING SQL DESCRIPTOR descriptor_name  
DESCRIBE [ OUTPUT ] prepared_name INTO SQL DESCRIPTOR descriptor_name  
DESCRIBE [ OUTPUT ] prepared_name INTO sqlda_name
```

## Parameters

- **prepared\_name**  
Name of a prepared statement, which can be an SQL identifier or a host variable.
- **descriptor\_name**  
Descriptor name, which is case-sensitive. It can be an SQL identifier or a host variable.
- **sqlda\_name**  
SQLDA variable name. For details, see [SQLDA](#).

## Examples

```
EXEC SQL ALLOCATE DESCRIPTOR mydesc;  
EXEC SQL PREPARE stmt1 FROM :sql_stmt;  
EXEC SQL DESCRIBE stmt1 INTO SQL DESCRIPTOR mydesc;  
EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :charvar = NAME;  
EXEC SQL DEALLOCATE DESCRIPTOR mydesc;
```

## Helpful Links

[ALLOCATE DESCRIPTOR](#) and [GET DESCRIPTOR](#)

### 5.7.5.5.6 DISCONNECT

## Description

Closes one or all database connections.

## Syntax

```
DISCONNECT connection_name  
DISCONNECT [ CURRENT ]  
DISCONNECT DEFAULT  
DISCONNECT ALL
```

## Parameters

- **connection\_name**  
Specifies the name of the database connection established by the **CONNECT** command.
- **current**  
Closes the current connection, which can be a recently opened connection or a connection set by the SET CONNECTION command. This is also the default if no parameter is passed to the DISCONNECT command.
- **default**  
Closes the default connection.
- **all**  
Closes all open connections.

## Example

```
#include <stdio.h>  
#include <stdlib.h>  
#include <string.h>  
  
int main(void)  
{  
    /* Create the testdb database in advance. */  
    EXEC SQL CONNECT TO testdb AS DEFAULT;  
    EXEC SQL CONNECT TO testdb AS con1;  
    EXEC SQL CONNECT TO testdb AS con2;  
    EXEC SQL CONNECT TO testdb AS con3;  
    EXEC SQL DISCONNECT CURRENT; /* Close connection 3. */  
    EXEC SQL DISCONNECT DEFAULT; /* Close the default connection. */  
    EXEC SQL DISCONNECT ALL; /* Close connections 2 and 1. */  
    return 0;  
}
```

## Helpful Links

[CONNECT, SET CONNECTION](#)

### 5.7.5.5.7 EXECUTE IMMEDIATE

#### Function

Immediately prepares and executes a dynamically specified SQL statement without retrieving result rows.

#### Syntax

```
EXECUTE IMMEDIATE string
```

#### Parameter Description

##### string

A C string or host variable that contains the SQL statement to be executed.

#### Example

The following is an example of executing the INSERT statement using EXECUTE IMMEDIATE and a host variable named **command**:

```
sprintf(command, "INSERT INTO test (name, amount, letter) VALUES ('r1', 1, 'f');  
EXEC SQL EXECUTE IMMEDIATE :command;
```

### 5.7.5.5.8 GET DESCRIPTOR

#### Description

Retrieves information about a query result set and stores it into host variables. A descriptor area is typically populated using FETCH or SELECT before using this command to transfer the information into host language variables. This command can be in either of the following formats:

- Retrieves the descriptor "header" items, which applies to the result set in its entirety.
- Retrieves information about a particular column, requiring the column number as additional parameter.

#### Syntax

```
GET DESCRIPTOR descriptor_name VALUE column_number :cvariable = descriptor_item [, ... ]  
GET DESCRIPTOR descriptor_name:cvariable = descriptor_header_item [, ... ]
```

#### Parameters

- **descriptor\_name**  
Descriptor name.
- **descriptor\_header\_item**  
Header item to be retrieved. Currently, only COUNT that is used to obtain the number of columns in the result set is supported.

- **column\_number**  
Number of the column about which information is to be retrieved. The count starts at 1.
- **descriptor\_item**  
Information item about a column to be retrieved.
- **cvariable**  
A host variable that will receive the data retrieved from the descriptor area.

## Examples

Retrieve the number of columns in a result set.

```
EXEC SQL GET DESCRIPTOR d :d_count = COUNT;
```

Retrieve the data length in the first column.

```
EXEC SQL GET DESCRIPTOR d VALUE 1 :d_returned_octet_length = RETURNED_OCTET_LENGTH;
```

Retrieve the data body of the second column as a string.

```
EXEC SQL GET DESCRIPTOR d VALUE 2 :d_data = DATA;
```

Run **SELECT current\_database();**. The number of columns, column data length, and column data are displayed.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    int d_count = 0;
    char d_data[1024] = {0};
    int d_returned_octet_length = 0;
EXEC SQL END DECLARE SECTION;
    /* Create testdb in advance. */
EXEC SQL CONNECT TO test;
EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
EXEC SQL ALLOCATE DESCRIPTOR d;

    /* Declare and open a cursor, and allocate a descriptor to the cursor. */
EXEC SQL DECLARE cur CURSOR FOR SELECT current_database();
EXEC SQL OPEN cur;
EXEC SQL FETCH NEXT FROM cur INTO SQL DESCRIPTOR d;

    /* Obtain the total number of columns. */
EXEC SQL GET DESCRIPTOR d :d_count = COUNT;
printf("d_count = %d\n", d_count);

    /* Obtain the length of a returned column. */
EXEC SQL GET DESCRIPTOR d VALUE 1 :d_returned_octet_length = RETURNED_OCTET_LENGTH;
printf("d_returned_octet_length = %d\n", d_returned_octet_length);

    /* Fetch the returned column as a string. */
EXEC SQL GET DESCRIPTOR d VALUE 1 :d_data = DATA;
printf("d_data = %s\n", d_data);

    /* Closed */
EXEC SQL CLOSE cur;
EXEC SQL COMMIT;

EXEC SQL DEALLOCATE DESCRIPTOR d;
EXEC SQL DISCONNECT ALL;
return 0;
}
```

The following is the command output:

```
d_count          = 1  
d_returned_octet_length = 6  
d_data          = testdb
```

## Helpful Links

[ALLOCATE DESCRIPTOR](#), [DEALLOCATE DESCRIPTOR](#), [SET DESCRIPTOR](#)

### 5.7.5.5.9 OPEN

## Description

Opens a cursor and optionally binds actual values to placeholders in the cursor declaration. The cursor must have been declared using the DECLARE command. Executing the OPEN command triggers the query on the server.

## Syntax

```
OPEN cursor_name  
OPEN cursor_name USING value [, ... ]  
OPEN cursor_name USING SQL DESCRIPTOR descriptor_name
```

## Parameters

- **cursor\_name**  
Name of the cursor to be opened. It can be an SQL identifier or a host variable.
- **value**  
A value that is to be bound to a placeholder in the cursor declaration. It can be an SQL constant, a host variable, or a host variable with an indicator.
- **descriptor\_name**  
Name of the descriptor that contains the value to be bound to the placeholder in the cursor declaration. It can be an SQL identifier or a host variable.

## Example

```
EXEC SQL OPEN a;  
EXEC SQL OPEN d USING 1, 'test';  
EXEC SQL OPEN c1 USING SQL DESCRIPTOR mydesc;  
EXEC SQL OPEN :curname1;
```

## Helpful Links

[DECLARE](#)

### 5.7.5.5.10 PREPARE

## Description

Prepares the statement to be executed.

## Syntax

```
PREPARE name FROM string
```

## Parameters

- **name**  
An identifier for the prepared query.
- **string**  
A C string or host variable that contains a prepared statement, which can be SELECT, INSERT, UPDATE, or DELETE.

## Examples

```
char *stmt = "SELECT * FROM test1 WHERE a = ? AND b = ?";  
EXEC SQL ALLOCATE DESCRIPTOR outdesc;  
EXEC SQL PREPARE foo FROM :stmt;  
EXEC SQL EXECUTE foo USING SQL DESCRIPTOR indesc INTO SQL DESCRIPTOR outdesc;
```

### NOTICE

The PREPARE statement provided by ecpg is not equivalent to the PREPARE syntax provided by the kernel. Example:

GaussDB Kernel kernel syntax:

```
PREPARE name [ ( data_type [, ...] ) ] AS statement
```

Embedded SQL statement:

```
EXEC SQL PREPARE I(int, int) AS INSERT INTO T VALUES ( $1, $2 );  
EXEC SQL EXECUTE I(1, 2);
```

When the preceding statement is executed, an error message "too few arguments on" is reported. ecpg provides a dynamic SQL statement to solve the problem in the **PREPARE name [ ( data\_type [, ...] ) ] AS statement** syntax scenario.

Example of using dynamic SQL syntax rules to solve the preceding problem:

```
EXEC SQL PREPARE I AS INSERT INTO T VALUES ( $1, $2 );  
EXEC SQL EXECUTE I using 1, 2;
```

### 5.7.5.5.11 SET AUTOCOMMIT

#### Function

Sets the autocommit behavior of the current database session. By default, embedded SQL programs do not automatically commit, so you need to explicitly issue COMMIT. This command can change the session to the automatic commit mode so that each individual statement is implicitly committed.

#### Syntax

```
SET AUTOCOMMIT { = | TO } { ON | OFF }
```

### 5.7.5.5.12 SET CONNECTION

#### Function

Sets a database connection.

#### Syntax

```
SET CONNECTION [ TO | = ] connection_name
```

## Parameter Description

- **connection\_name**  
Name of a database connection established by the CONNECT command.

## Example

```
EXEC SQL SET CONNECTION TO con2;  
EXEC SQL SET CONNECTION = con1;
```

## Helpful Links

[CONNECT](#) and [DISCONNECT](#)

### 5.7.5.5.13 SET DESCRIPTOR

## Description

Populates an SQL descriptor area, which is usually used to bind parameters in a prepared query execution. This command can be in either of the following formats:

- Applies to the descriptor "header", which is independent of specific data.
- Assigns a value to specific data identified by a number.

## Syntax

```
SET DESCRIPTOR descriptor_name descriptor_header_item = value [, ... ]  
SET DESCRIPTOR descriptor_name VALUE number descriptor_item = value [, ...]
```

## Parameters

- **descriptor\_name**  
SQL descriptor name.
- **descriptor\_header\_item**  
Identifies the header information item to be set. Currently, only COUNT that can be used to set the number of descriptor items is supported.
- **number**  
Number of descriptor items to be set. The count starts at 1.
- **descriptor\_item**  
Identifies which descriptor item is to be set. Currently, only DATA, TYPE, and LENGTH are supported.
- **value**  
Value to be stored in the descriptor item. The value can be an SQL constant or a host variable.

## Examples

```
EXEC SQL SET DESCRIPTOR indesc COUNT = 1;  
EXEC SQL SET DESCRIPTOR indesc VALUE 1 DATA = 2;  
EXEC SQL SET DESCRIPTOR indesc VALUE 1 DATA = :val1;  
EXEC SQL SET DESCRIPTOR indesc VALUE 2 INDICATOR = :val1, DATA = 'some string';  
EXEC SQL SET DESCRIPTOR indesc VALUE 2 INDICATOR = :val2null, DATA = :val2;
```

## Helpful Links

[ALLOCATE DESCRIPTOR](#), [DEALLOCATE DESCRIPTOR](#), and [GET DESCRIPTOR](#)

### 5.7.5.5.14 TYPE

## Function

Defines a new data type. This command is identified only when ecpg is run with the `-c` option.

## Syntax

```
TYPE type_name IS ctype
```

## Parameter Description

### **type\_name**

Data type name

### **ctype**

C type description.

## Example

```
EXEC SQL TYPE customer IS
struct
{
    varchar name[50];
    int    phone;
};

EXEC SQL TYPE cust_ind IS
struct ind
{
    short name_ind;
    short phone_ind;
};

EXEC SQL TYPE c IS char reference;
EXEC SQL TYPE ind IS union { int integer; short smallint; };
EXEC SQL TYPE intarray IS int[AMOUNT];
EXEC SQL TYPE str IS varchar[BUFFERSIZ];
EXEC SQL TYPE string IS char[11];
```

Example of using EXEC SQL TYPE (note that the `-c` parameter needs to be added in the ecpg preprocessing phase when the following example is used):

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

EXEC SQL WHENEVER SQLERROR SQLPRINT;
EXEC SQL TYPE tt IS
struct
{
    varchar v[256];
    int    i;
};
EXEC SQL TYPE tt_ind IS
struct ind {
    short v_ind;
```

```
    short i_ind;
};

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    tt t;
    tt_ind t_ind;
EXEC SQL END DECLARE SECTION;
    EXEC SQL CONNECT TO testdb AS con1;
    EXEC SQL SELECT current_database(), 256 INTO :t:t_ind LIMIT 1;

    printf("t.v = %s\n", t.v.arr);
    printf("t.i = %d\n", t.i);

    printf("t_ind.v_ind = %d\n", t_ind.v_ind);
    printf("t_ind.i_ind = %d\n", t_ind.i_ind);

    EXEC SQL DISCONNECT con1;

    return 0;
}
```

The output of this example is as follows:

```
t.v = testdb
t.i = 256
t_ind.v_ind = 0
t_ind.i_ind = 0
```

### 5.7.5.5.15 VAR

## Function

Assigns a new C data type to a host variable. The host variable must have been declared in a DECLARE segment.

#### NOTE

- Exercise caution when using VAR. Using VAR to change the data type may cause the memory address to be invalid. As a result, the data variable is invalid and the value cannot be assigned.
- If the data type has been defined in the host variable DECLARE segment, you do not need to use the VAR statement.

## Syntax

```
VAR varname IS ctype
```

## Parameter Description

- **varname**  
Name of a C variable.
- **ctype**  
C type description.

## Example

```
EXEC SQL BEGIN DECLARE SECTION;
    short a;
EXEC SQL END DECLARE SECTION;
EXEC SQL VAR a IS int;
```

### 5.7.5.5.16 WHENEVER

## Description

Defines a behavior that is called when an SQL execution exception occurs (row not found, SQL alarm, or error).

## Syntax

```
WHENEVER { NOT FOUND | SQLERROR | SQLWARNING } action
```

## Parameters

For details about the parameter description, see [Setting Callbacks](#).

## Examples

```
EXEC SQL WHENEVER NOT FOUND CONTINUE;
EXEC SQL WHENEVER NOT FOUND DO BREAK;
EXEC SQL WHENEVER SQLWARNING SQLPRINT;
EXEC SQL WHENEVER SQLWARNING DO warn();
EXEC SQL WHENEVER SQLERROR sqlprint;
EXEC SQL WHENEVER SQLERROR SQLCALL print2();
EXEC SQL WHENEVER SQLERROR DO handle_error("select");
EXEC SQL WHENEVER SQLERROR DO sqlnotice(NULL, NONO);
EXEC SQL WHENEVER SQLERROR DO sqlprint();
EXEC SQL WHENEVER SQLERROR GOTO error_label;
EXEC SQL WHENEVER SQLERROR STOP;
```

Use WHENEVER NOT FOUND BREAK to process the loop of the result set. The following is a complete example:

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

int main(void)
{
    EXEC SQL CONNECT TO testdb AS con1;
    EXEC SQL ALLOCATE DESCRIPTOR d;
    EXEC SQL DECLARE cur CURSOR FOR SELECT current_database(), 'hoge', 256;
    EXEC SQL OPEN cur;
    EXEC SQL BEGIN DECLARE SECTION;
    char* d1;
    char* d2;
    EXEC SQL END DECLARE SECTION;
    /* When the end of the result set is reached, exit the loop. */
    EXEC SQL WHENEVER NOT FOUND DO BREAK;

    while (1)
    {
        EXEC SQL FETCH NEXT FROM cur INTO SQL DESCRIPTOR d;
        exec sql get descriptor d value 1 :d1=DATA;
        exec sql get descriptor d value 2 :d2=DATA;
        printf("d1 is %s,%s\n", d1, d2) ;
    }
    EXEC SQL CLOSE cur;
    EXEC SQL COMMIT;
    EXEC SQL DEALLOCATE DESCRIPTOR d;
    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

## 5.7.6 Querying the Result Set

- The SELECT statement that returns the result of a single row can be directly executed using EXEC SQL. For details, see [Running SQL Commands](#).

Example:

```
/* Create a table and insert data. */
EXEC SQL CREATE TABLE test_table (number1 integer, number2 integer);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (2, 1);

/* The query result is in a single row. :num is the host variable. */
EXEC SQL SELECT number1 INTO :num FROM test_table WHERE number2 = 1;
```

- To process a multi-row result set, you must use a cursor. For details, see [Using Cursors](#). (In special cases, an application can fetch multiple rows of results at a time and write them to the host variable of the array type. For details, see [Host Variables with Non-primitive Types](#).)

Example:

```
/* Create a table and insert data. */
EXEC SQL CREATE TABLE test_table (number1 integer, number2 integer);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (2, 1);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (3, 1);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (4, 1);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (5, 1);

/* Define the host variable. */
EXEC SQL BEGIN DECLARE SECTION;
int v1;
int v2;
EXEC SQL END DECLARE SECTION;

/* Declare a cursor. */
EXEC SQL DECLARE test_bar CURSOR FOR SELECT number1, number2 FROM test_table ORDER BY
number1;
/* Open the cursor. */
EXEC SQL OPEN test_bar;
/* When the cursor reaches the end of the result set, exit the loop. */
EXEC SQL WHENEVER NOT FOUND DO BREAK;
/* Obtain the query result set. */
while(1)
{
    EXEC SQL FETCH NEXT FROM test_bar INTO :v1, :v2;
    printf("number1 = %d, number2 = %d\n",v1,v2);
}
/* Close the cursor. */
EXEC SQL CLOSE test_bar;
```

## 5.7.7 Closing a Database Connection

Close the database connection after the database is used.

Close a connection.

```
EXEC SQL DISCONNECT [connection];
```

Declare the connection by using the following methods:

- connection-name
- default
- current
- all

## 5.7.8 Host Variables

This section describes how to use host variables to pass data between C programs and embedded SQL programs. In C programs with embedded SQL statements, we use the C language as the host language and regard EXEC SQL [Command] statements as embedded SQL statements of the host language. Therefore, variables used for embedded SQL statements in C programs are called host variables.

### 5.7.8.1 Overview

Passing data between a C program and SQL statements is particularly simple in embedded SQL. Instead of having the program paste data into the statements, you can simply write the name of a C variable into the SQL statement, prefixed by a colon. The following is an example:

```
EXEC SQL INSERT INTO sometable VALUES (:v1, 'foo', :v2);
```

This statement references two C variables named v1 and v2 and uses a regular SQL string, indicating that you are not restricted to use one kind of data or the other.

### 5.7.8.2 DECLARE Section

To implement data interaction between a C program with embedded SQL statements and a database, for example, to pass parameters in a query of the C program to the database, or to pass data from the database back to the program, the C variables that are intended to contain this data need to be declared in specially marked sections, so that the embedded SQL preprocessor is made aware of them.

This section starts with:

```
EXEC SQL BEGIN DECLARE SECTION;
```

And ends with:

```
EXEC SQL END DECLARE SECTION;
```

Between them, there must be regular C variable declarations. An example is as follows:

```
int x = 4;  
char foo[16], bar[16];
```

---

#### NOTICE

- The type of the host variables declared between the start and end of the marked section must be one of the supported data types. For details, see [Table 5-77](#).
  - You can also declare variables with the following syntax which implicitly creates a DECLARE section: EXEC SQL int i = 4.
  - Variables that are not intended to be used in SQL commands can be declared normally outside these special sections.
  - The definition of a structure or union also must be listed inside a DECLARE section. Otherwise, the preprocessor cannot process these types.
-

### 5.7.8.3 Retrieving Query Results

To retrieve the results of a query, embedded SQL provides special variants of the usual commands SELECT and FETCH. These commands have a special INTO clause that specifies which host variables the retrieved values are to be stored in. SELECT is used for a query that returns only a single row, and FETCH is used for a query that returns multiple rows, using a cursor.

- Use SELECT.

```
/*
 * Assume a table:
 * CREATE TABLE test1 (a int, b varchar(50));
 */
EXEC SQL BEGIN DECLARE SECTION;
    int v1;
    VARCHAR v2;
EXEC SQL END DECLARE SECTION;

...

EXEC SQL SELECT a, b INTO :v1, :v2 FROM test;
```

The INTO clause appears between the SELECT list and the FROM clause. The number of elements in the SELECT list and the list after INTO (also called the target list) must be equal.

- Use FETCH.

```
EXEC SQL BEGIN DECLARE SECTION;
    int v1;
    VARCHAR v2;
EXEC SQL END DECLARE SECTION;

...

EXEC SQL DECLARE foo CURSOR FOR SELECT a, b FROM test;
...
do
{
    ...
    EXEC SQL FETCH NEXT FROM foo INTO :v1, :v2;
    ...
} while (...);
```

The INTO clause appears after all SQL clauses.

### 5.7.8.4 Type Mapping

When ecpg applications exchange values between the GaussDB Kernel server and the C program, such as when retrieving query results from the server or executing SQL statements with input parameters, the values need to be converted between GaussDB Kernel data types and host language variable types (C language data types, concretely). There are two data types available: Simple GaussDB Kernel data types, such as integer and text, can be directly read and written by applications. Other GaussDB Kernel data types, such as timestamp and numeric, can be accessed only by using special library functions. For details, see [ECPG API Reference](#).

**Table 5-77** Mapping between GaussDB Kernel data types and C variable types

GaussDB Kernel Data Type	Host Variable Type
smallint	short

GaussDB Kernel Data Type	Host Variable Type
integer	int
bigint	long long int
boolean	boolean
character(n), varchar(n), text	char[n+1], VARCHAR[n+1]
double precision	double
real	float
smallserial	short
serial	int
bigserial	long long int
oid	unsigned int
name	char[NAMEDATALEN]
date	date [a]
timestamp	timestamp [a]
interval	interval [a]
decimal	decimal [a]
numeric	numeric [a]

 **NOTE**

[a] This type can be accessed through [Accessing Special Data Types](#).

**NOTICE**

- Currently, only basic data types of the C language can be used or combined. The string data type in the C++ language cannot be used as the host variable type.
- Currently, ecpg maps only common data types of GaussDB Kernel SQL. For details about the supported data types, see [Table 5-77](#).

### 5.7.8.5 Handling Character Strings

To handle SQL character string data types, such as varchar and text, there are two possible methods to declare the host variables.

1. Method 1: Use char[] (a char string), which is the most common method for processing character data in C programs.

```
EXEC SQL BEGIN DECLARE SECTION;
char str[50];
EXEC SQL END DECLARE SECTION;
```

Note that you have to take care of the length yourself. If you use this host variable as the target variable of a query which returns a string with more than 49 characters, a buffer overflow occurs.

- Method 2: Use the VARCHAR type, which is a special type provided by ECPG. The definition on an array of type VARCHAR is converted into a named struct for every variable. The statement is as follows:

```
VARCHAR var[180];
```

It will be converted into:

```
struct varchar_var
{
    int len;
    char arr[180];
} var;
```

To store a string in a VARCHAR host variable, the host variable has to be declared as a string including the zero-byte terminator. **arr** stores the string including a terminating zero byte. **len** stores the length of the string stored in **arr** without the terminating zero byte. The terminator is not included when the length is calculated. When a host variable is used as input for a query, if the values of **strlen(arr)** and **len** are different, the shorter one is used.

---

**CAUTION**

- VARCHAR can be written in upper or lower case, but not in mixed case.
  - char and VARCHAR host variables can also hold values of other SQL types, which will be stored in their string forms.
- 

### 5.7.8.6 Host Variables with Non-primitive Types

Non-primitive host variables can be arrays, typedefs, structures, and pointers.

- Arrays

There are two use cases for arrays as host variables. The first case is to store some text strings in `char[]` or `VARCHAR[]`. The second case is to retrieve multiple rows from a query result without using a cursor. Without an array, to process a query result consisting of multiple rows, it is required to use a cursor and the `FETCH` command. But with array host variables, multiple rows can be retrieved at once. The length of the array has to be defined to be able to accommodate all rows; otherwise, a buffer overflow will occur.

For example, scan the `pg_database` system catalog and display the OIDs and names of all available databases.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    int dbid[8];
    char dbname[8][16];
    int i;
EXEC SQL END DECLARE SECTION;
```

```
memset(dbname, 0, sizeof(char)* 16 * 8);
memset(dbid, 0, sizeof(int) * 8);
/* Connect to the testdb database. The testdb database must be created in advance. */
EXEC SQL CONNECT TO testdb;
/* Retrieve multiple rows to arrays at a time. */
EXEC SQL SELECT oid,datname INTO :dbid, :dbname FROM pg_database;
for (i = 0; i < 8; i++)
    printf("oid=%d, dbname=%s\n", dbid[i], dbname[i]);
EXEC SQL COMMIT;
EXEC SQL DISCONNECT ALL;
return 0;
}
```

The following is the example output (the exact value depends on the local environment).

```
oid=1, dbname=template1
oid=11510, dbname=template0
oid=11511, dbname=postgres
oid=313780, dbname=testdb
oid=0, dbname=
oid=0, dbname=
oid=0, dbname=
```

- Structures

A structure whose member names match the column names of a query result, can be used to retrieve multiple columns at once. The structure enables handling multiple column values in a single host variable.

The following example retrieves OIDs, names, and sizes of the available databases from the `pg_database` system catalog and using the `pg_database_size()` function. In this example, a structure variable with members whose names match each column in the `SELECT` result is used to retrieve one result row without putting multiple host variables in the `FETCH` statement.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct
{
    int oid;
    char datname[65];
    long long int size;
} dbinfo_t;

dbinfo_t dbval;
EXEC SQL END DECLARE SECTION;
memset(&dbval, 0, sizeof(dbinfo_t));

EXEC SQL DECLARE cur1 CURSOR FOR SELECT oid, datname, pg_database_size(oid) AS size FROM
pg_database;
EXEC SQL OPEN cur1;

/* Exit the while loop when the end of the result set is reached. */
EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    /* Fetch multiple columns into one structure. */
    EXEC SQL FETCH FROM cur1 INTO :dbval;
    /* Print the members of the structure. */
    printf("oid=%d, datname=%s, size=%lld\n", dbval.oid, dbval.datname, dbval.size);
}
EXEC SQL CLOSE cur1;
```

The following is the example output (the exact value depends on the local environment).

```
oid=1, datname=template1, size=4324580
oid=11510, datname=template0, size=4243460
```

```
oid=11511, datname=postgres, size=4324580
oid=313780, datname=testdb, size=8183012
```

Structure host variables "absorb" as many columns in the query result as the structure columns. Additional columns can be allocated to other host variables. The above program could also be restructured like this, with the **size** variable outside the structure:

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct
{
    int oid;
    char datname[65];
} dbinfo_t;

dbinfo_t dbval;
long long int size;
EXEC SQL END DECLARE SECTION;

memset(&dbval, 0, sizeof(dbinfo_t));

EXEC SQL DECLARE cur1 CURSOR FOR SELECT oid, datname, pg_database_size(oid) AS size FROM
pg_database;
EXEC SQL OPEN cur1;

/* Exit the while loop when the end of the result set is reached. */
EXEC SQL WHENEVER NOT FOUND DO BREAK;
while (1)
{
    /* Fetch multiple columns into one structure. */
    EXEC SQL FETCH FROM cur1 INTO :dbval, :size;
    /* Print the members of the structure. */
    printf("oid=%d, datname=%s, size=%lld\n", dbval.oid, dbval.datname, size);
}

EXEC SQL CLOSE cur1;
```

- **typedef**

Use the **typedef** keyword to map new types to existing types.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef char mychartype[40];
typedef long serial_t;
EXEC SQL END DECLARE SECTION;
```

You can also run the following command:

```
EXEC SQL TYPE serial_t IS long;
```

This declaration does not need to be part of a **DECLARE** section.

- **Pointers**

You can declare pointers to the most common types.

```
EXEC SQL BEGIN DECLARE SECTION;
int *intp;
char **charp;
EXEC SQL END DECLARE SECTION;
```

### 5.7.8.7 Accessing Special Data Types

ECPG supports the numeric, decimal, date, timestamp, and interval data types. These data types cannot be mapped to primitive host variable types because they have a complex internal structure. Applications deal with these types by declaring host variables in special types and accessing them using functions in the `pgtypes` library. For details about the functions in the `pgtypes` library, see [ECPG API Reference](#).

- **timestamp and date**

First, the program must include the header file for the timestamp type.

```
#include <pgtypes_timestamp.h>
```

Then, declare a host variable of the timestamp type in the DECLARE section.

```
EXEC SQL BEGIN DECLARE SECTION;
    timestamp ts;
EXEC SQL END DECLARE SECTION;
```

After the value is read to the host variable, the `pgtypes` library function is used for processing. In the following example, the `PGTYPEStimestamp_to_asc()` function is used to convert the **timestamp** value to the text format:

```
EXEC SQL SELECT now()::timestamp INTO :ts;
printf("ts = %s\n", PGTYPEStimestamp_to_asc(ts));
```

A command output example is as follows:

```
ts = 2022-06-27 18:03:56.949343
```

In addition, the date type can be processed in the same way. The program must contain the **pgtypes\_date.h** header file, declare a host variable as the date type, and use the `PGTYPEdata_to_asc()` function to convert the variable to the text format.

- interval

The handling of the interval type is also similar to the timestamp and date types. However, to allocate memory for an interval type value explicitly, the memory space for the variable must be allocated from the heap memory.

The following is an example:

```
#include <stdio.h>
#include <stdlib.h>
#include <pgtypes_interval.h>
int main(void)
{
    EXEC SQL BEGIN DECLARE SECTION;
        interval *in;
    EXEC SQL END DECLARE SECTION;
    /* Connect to the testdb database. The testdb database must be created in advance.*/
    EXEC SQL CONNECT TO testdb;
    in = PGTYPEStimestamp_new();
    EXEC SQL SELECT '1 min'::interval INTO :in;
    printf("interval = %s\n", PGTYPEStimestamp_to_asc(in));
    PGTYPEStimestamp_free(in);
    EXEC SQL COMMIT;
    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

- numeric and decimal

The handling of the numeric and decimal types is similar to the interval type: It requires defining a pointer, allocating some memory space from the heap, and accessing the variable using the `pgtypes` library functions.

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <pgtypes_numeric.h>
EXEC SQL WHENEVER SQLERROR STOP;
int main(void)
{
    EXEC SQL BEGIN DECLARE SECTION;
        numeric *num;
        numeric *num2;
        decimal *dec;
    EXEC SQL END DECLARE SECTION;

    /* Connect to the testdb database. The testdb database must be created in advance.*/
    EXEC SQL CONNECT TO testdb;
```

```
num = PGTYPENumeric_new();
dec = PGTYPEDecimal_new();

EXEC SQL SELECT 12.345::numeric(4,2), 23.456::decimal(4,2) INTO :num, :dec;
printf("numeric = %s\n", PGTYPENumeric_to_asc(num, 0));
printf("numeric = %s\n", PGTYPENumeric_to_asc(num, 1));
printf("numeric = %s\n", PGTYPENumeric_to_asc(num, 2));
/* Convert decimal to numeric to show a decimal value. */
num2 = PGTYPENumeric_new();
PGTYPENumeric_from_decimal(dec, num2);
printf("decimal = %s\n", PGTYPENumeric_to_asc(num2, 0));
printf("decimal = %s\n", PGTYPENumeric_to_asc(num2, 1));
printf("decimal = %s\n", PGTYPENumeric_to_asc(num2, 2));
PGTYPENumeric_free(num2);
PGTYPEDecimal_free(dec);
PGTYPENumeric_free(num);

EXEC SQL COMMIT;
EXEC SQL DISCONNECT ALL;
return 0;
}
```

### 5.7.8.8 Handling Non-primitive SQL Data Types

This section describes how to handle non-scalar and user-defined SQL-level data types in ECPG applications. Note that this is distinct from the handling of host variables of non-primitive types described in [Host Variables with Non-primitive Types](#).

- Arrays

Multi-dimensional SQL-level arrays are not directly supported in ECPG. One-dimensional SQL-level arrays can be mapped into C array host variables and vice-versa. However, when creating a statement, ECPG does not know the types of the columns, so that it cannot check if a C array is input into a corresponding SQL-level array. When processing the output of an SQL statement, ECPG has to check if both are arrays.

If a query accesses elements of an array separately, a host variable with a type that can be mapped to the element type should be used. For example, if a column type is array of integer, a host variable of type `int` can be used. Also if the element type is `varchar` or `text`, a host variable of type `char[]` or `VARCHAR[]` can be used.

Example:

```
CREATE TABLE t3 (
  ii integer[]
);
testdb=> SELECT * FROM t3;
  ii
-----
{1,2,3,4,5}
(1 row)
```

The following example retrieves the fourth element of an array and stores it in a host variable of the `int` type:

```
EXEC SQL BEGIN DECLARE SECTION;
  int ii;
EXEC SQL END DECLARE SECTION;

EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii[4] FROM t3;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
```

```
{
  EXEC SQL FETCH FROM cur1 INTO :ii ;
  printf("ii=%d\n", ii);
}
EXEC SQL CLOSE cur1;
```

Example output:

```
ii=4
```

To map multiple array elements to the multiple elements in an array type host variable, each element of the array column and each element of the host variable array must be managed separately. For example:

```
EXEC SQL BEGIN DECLARE SECTION;
  int ii_a[8];
EXEC SQL END DECLARE SECTION;

EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii[1], ii[2], ii[3], ii[4] FROM t3;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;
while (1)
{
  EXEC SQL FETCH FROM cur1 INTO :ii_a[0], :ii_a[1], :ii_a[2], :ii_a[3];
  ...
}
```

Note:

```
EXEC SQL BEGIN DECLARE SECTION;
  int ii_a[8];
EXEC SQL END DECLARE SECTION;

EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii FROM t3;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
  /* Error */
  EXEC SQL FETCH FROM cur1 INTO :ii_a;
  ...
}
```

It does not work out because you cannot map an array type column to an array host variable directly.

- Composite types

Composite types are not directly supported in ECPG. For example, you cannot declare member variables as date type in a structure. However, you can access each attribute separately or use the external string representation.

In the following example, each attribute can be accessed separately:

```
CREATE TYPE comp_t AS (intval integer, textval varchar(32));
CREATE TABLE t4 (compval comp_t);
INSERT INTO t4 VALUES ( (256, 'GaussDB') );
```

The following program retrieves data from the example table by selecting each attribute of the `comp_t` type separately:

```
EXEC SQL BEGIN DECLARE SECTION;
  int intval;
  varchar textval[33];
EXEC SQL END DECLARE SECTION;

/* Put each element of the composite type column in the SELECT list. */
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).intval, (compval).textval FROM t4;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;
while (1)
```

```
{
  /* Fetch each element of the composite type column into host variables. */
  EXEC SQL FETCH FROM cur1 INTO :intval, :textval;
  printf("intval=%d, textval=%s\n", intval, textval.arr);
}
EXEC SQL CLOSE cur1;
```

The host variables storing values in the **FETCH** command can be gathered into one structure. For more details about the host variables in the structure form, see [Handling Character Strings](#). In the following example, the two host variables, *intval* and *textval*, become members of the *comp\_t* structure, and the structure is specified in the **FETCH** command:

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct
{
  int intval;
  varchar textval[33];
} comp_t;
comp_t compval;
EXEC SQL END DECLARE SECTION;

/* Put each element of the composite type column in the SELECT list. */
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).intval, (compval).textval FROM t4;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;
while (1)
{
  /* Put all values in the SELECT list into one structure. */
  EXEC SQL FETCH FROM cur1 INTO :compval;
  printf("intval=%d, textval=%s\n", compval.intval, compval.textval.arr);
}
EXEC SQL CLOSE cur1;
```

Although a structure is used in the **FETCH** command, the attribute names in the **SELECT** clause are specified one by one. This can be enhanced by using a **\*** to ask for all attributes of the composite type value. For example:

```
...
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).* FROM t4;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
  /* Put all values in the SELECT list into one structure. */
  EXEC SQL FETCH FROM cur1 INTO :compval;
  printf("intval=%d, textval=%s\n", compval.intval, compval.textval.arr);
}
...
```

In this way, composite types can be mapped into structures, even though ECPG does not understand the composite type itself.

- User-defined base types

When ECPG uses host variables to store query results, only the data types provided by ECPG are supported. User-defined data types are not supported. Data types created using **CREATE TYPE** cannot be mapped using host variables.

However, you can use external string representations and host variables of the `char[]` or `VARCHAR[]` type to handle user-defined types.

The external string representation of that type is `(%lf,%lf)`, which is defined in function `complex_in()`. The following example inserts complex type values **(1,1)** and **(3,3)** into columns **a** and **b** and then queries them from the table.

```
EXEC SQL BEGIN DECLARE SECTION;
  varchar a[64];
  varchar b[64];
EXEC SQL END DECLARE SECTION;
EXEC SQL INSERT INTO test_complex VALUES ('(1,1)', '(3,3)');
EXEC SQL DECLARE cur1 CURSOR FOR SELECT a, b FROM test_complex;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
  EXEC SQL FETCH FROM cur1 INTO :a, :b;
  printf("a=%s, b=%s\n", a.arr, b.arr);
}
EXEC SQL CLOSE cur1;
```

Example output:  
a=(1,1), b=(3,3)

## 5.7.9 Executing Dynamic SQL Statements

In most cases, the SQL statements executed by an application are known when the application is written. However, in some cases, SQL statements are constructed at runtime or provided by external sources. In these cases, the SQL statements cannot be directly embedded into the C source code, but dynamic SQL statements allow you to call the provided SQL statements in a string variable.

### 5.7.9.1 Executing Statements Without a Result Set

An example of running the **EXECUTE IMMEDIATE** command is as follows:

```
EXEC SQL BEGIN DECLARE SECTION;
  const char *stmt = "CREATE TABLE test1 (...);";
EXEC SQL END DECLARE SECTION;
EXEC SQL EXECUTE IMMEDIATE :stmt;
```

**EXECUTE IMMEDIATE** can be used for SQL statements that do not return a result set, such as DDL, INSERT, UPDATE, and DELETE statements. However, statements for retrieving data, such as SELECT statements, cannot be executed in this way.

### 5.7.9.2 Executing a Statement with Input Parameters

Prepare a normal statement and execute a specific version of it by replacing its parameters (with question marks). Use the EXECUTE statement to execute the prepared statement by specifying parameters in the USING clause. Example:

```
EXEC SQL BEGIN DECLARE SECTION;
  const char *stmt = "INSERT INTO test1 VALUES(?, ?);";
EXEC SQL END DECLARE SECTION;
/* PREPARE Prepare a statement for execution. */
EXEC SQL PREPARE mystmt FROM :stmt;
...
/* Single quotation marks are valid characters. If a character string is used, use double quotation marks. */
EXEC SQL EXECUTE mystmt USING 42, 'foobar';

/* When you no longer need a prepared statement, you should deallocate it. */
EXEC SQL DEALLOCATE PREPARE name;
```

### 5.7.9.3 Executing a Statement with a Result Set

EXECUTE can be used to execute SQL statements with a result set. To save the result, add an INTO clause. Example:

```
EXEC SQL BEGIN DECLARE SECTION;
  const char *stmt = "SELECT a, b, c FROM test1 WHERE a > ?";
```

```
int v1, v2;
VARCHAR v3[50];
EXEC SQL END DECLARE SECTION;

EXEC SQL PREPARE mystmt FROM :stmt;
...
EXEC SQL EXECUTE mystmt INTO :v1, :v2, :v3 USING 37;
```

#### NOTE

The EXECUTE statement supports the INTO and USING clauses.

If a query may return multiple result rows, use cursors. For details about cursors, see [Using Cursors](#). Example:

```
EXEC SQL BEGIN DECLARE SECTION;
char dbaname[128];
char datname[128];
char *stmt = "SELECT u.username as dbaname, d.datname "
            " FROM pg_database d, pg_user u "
            " WHERE d.datdba = u.usesysid";
EXEC SQL END DECLARE SECTION;

EXEC SQL CONNECT TO testdb AS con1 USER testuser;

EXEC SQL PREPARE stmt1 FROM :stmt;

EXEC SQL DECLARE cursor1 CURSOR FOR stmt1;
EXEC SQL OPEN cursor1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    EXEC SQL FETCH cursor1 INTO :dbaname, :datname;
    printf("dbaname=%s, datname=%s\n", dbaname, datname);
}
EXEC SQL CLOSE cursor1;

EXEC SQL COMMIT;
EXEC SQL DISCONNECT ALL;
```

## 5.7.10 Error Handling

There are two non-exclusive methods to handle errors and warnings in an embedded SQL program:

- Callbacks can be configured to handle errors or warnings using the WHENEVER command.
- Detailed information about the errors or warnings can be obtained from the *sqlca* variable.

### 5.7.10.1 Setting Callbacks

One simple method to catch errors and warnings is to set a specific action to be executed whenever a particular condition occurs. To set the callback, run the following command:

```
EXEC SQL WHENEVER condition action;
```

**condition** can be one of the following:

- **SQLERROR**: The specified action is called whenever an error occurs during the execution of an SQL statement.
- **SQLWARNING**: The specified action is called whenever a warning occurs during the execution of an SQL statement.

- **NOT FOUND:** The specified action is called whenever an SQL statement retrieves or affects zero rows.

**action** can be one of the following:

- **CONTINUE:** ignores the callback error condition and continues the execution. It is usually used to stop a break condition. This is the default value.
- **GOTO *label*/GO TO *label*:** jumps to a specified label (using the C goto statement).
- **SQLPRINT:** prints a message to the standard error.
- **STOP:** calls `exit(1)` to terminate the program.
- **DO BREAK:** executes the C statement `BREAK`. This statement is used only in loops or switch statements.

The following is an example.

```
/* It prints a simple message when a warning occurs and aborts the program when an error happens. */  
EXEC SQL WHENEVER SQLWARNING SQLPRINT;  
EXEC SQL WHENEVER SQLERROR STOP;
```

## NOTICE

- The statement `EXEC SQL WHENEVER` is a directive of the SQL preprocessor, not a C statement. The error or warning actions that it sets apply to all embedded SQL statements that appear below the point where the handler is set, unless a different action was set for the same condition between the first `EXEC SQL WHENEVER` and the SQL statement causing the condition, regardless of the flow of control in the C program. Therefore, neither of the following C programs can achieve the expected effect:

```
/*  
 * ERROR  
 */  
void func()  
{  
    ...  
    if (verbose) {  
        EXEC SQL WHENEVER SQLWARNING SQLPRINT;  
    }  
    ...  
    EXEC SQL SELECT ...;  
    ...  
}  
/*  
 * ERROR  
 */  
void func()  
{  
    ...  
    set_error_handler();  
    ...  
    EXEC SQL SELECT ...;  
    ...  
}  
static void set_error_handler(void)  
{  
    EXEC SQL WHENEVER SQLERROR STOP;  
}
```

- `DO BREAK` can be used only in the `while`, `for`, and `switch` scenarios. After `DO BREAK` is used, use the `CONTINUE` statement to ignore it.

### 5.7.10.2 sqlca

The embedded SQL API provides a global variable *sqlca* (short for SQL communication area). *sqlca* covers warnings and errors. If multiple warnings or errors occur during the execution of a statement, then *sqlca* will only contain information about the last one. In a multithreaded program, every thread automatically gets its own copy of *sqlca*.

The data structure is as follows:

```
struct
{
    char sqlcaid[8];
    long sqlabc;
    long sqlcode;
    struct
    {
        int sqlerrml;
        char sqlerrmc[SQLERRMC_LEN];
    } sqlerrm;
    char sqlerrp[8];
    long sqlerrd[6];
    char sqlwarn[8];
    char sqlstate[5];
} sqlca;
```

If no error occurred in the last SQL statement, **sqlca.sqlcode** will be **0** and **sqlca.sqlstate** will be **00000**. If a warning or error occurred, then **sqlca.sqlcode** will be negative and **sqlca.sqlstate** will be different from **00000**. For details about the values of **SQLSTATE** and **SQLCODE**, see [SQLSTATE and SQLCODE](#).

If the last SQL statement was successful, then **sqlca.sqlerrd[1]** contains the OID of the processed row, if applicable, and **sqlca.sqlerrd[2]** contains the number of processed or returned rows, if applicable to the command.

In case of an error or warning, **sqlca.sqlerrm.sqlerrmc** will contain a string that describes the error. **sqlca.sqlerrm.sqlerrml** contains the length of the error message that is stored in **sqlca.sqlerrm.sqlerrmc**, that is, the result of **strlen()**. Note that some messages are too long to fit in the fixed-size **sqlerrmc** array; they will be truncated.

When a warning is generated, **sqlca.sqlwarn[2]** is set to **W**.

The columns **sqlcaid**, **sqlabc**, **sqlerrp**, and the remaining elements of **sqlerrd** and **sqlwarn** currently contain no useful information.

Example:

```
/* Integrate WHENEVER and sqlca to implement error handling. */
EXEC SQL WHENEVER SQLERROR SQLCALL print_sqlca();

void print_sqlca()
{
    fprintf(stderr, "==== sqlca ====\n");
    fprintf(stderr, "sqlcode: %ld\n", sqlca.sqlcode);
    fprintf(stderr, "sqlerrm.sqlerrml: %d\n", sqlca.sqlerrm.sqlerrml);
    fprintf(stderr, "sqlerrm.sqlerrmc: %s\n", sqlca.sqlerrm.sqlerrmc);
    fprintf(stderr, "sqlerrd: %ld %ld %ld %ld %ld %ld\n", sqlca.sqlerrd[0], sqlca.sqlerrd[1], sqlca.sqlerrd[2],
        sqlca.sqlerrd[3], sqlca.sqlerrd[4], sqlca.sqlerrd[5]);
    fprintf(stderr, "sqlwarn: %d %d %d %d %d %d %d %d\n", sqlca.sqlwarn[0], sqlca.sqlwarn[1],
sqlca.sqlwarn[2],
        sqlca.sqlwarn[3], sqlca.sqlwarn[4], sqlca.sqlwarn[5],
        sqlca.sqlwarn[6], sqlca.sqlwarn[7]);
    fprintf(stderr, "sqlstate: %5s\n", sqlca.sqlstate);
    fprintf(stderr, "=====\n");
}
```

The output is similar to the following (here is a misspelled table name):

```
==== sqlca ====
sqlcode: -400
sqlerrm.sqlerrml: 49
sqlerrm.sqlerrmc: relation "pg_databasep" does not exist on line 38
sqlerrd: 0 0 0 0 0 0
sqlwarn: 0 0 0 0 0 0 0
sqlstate: 42P01
=====
```

### 5.7.10.3 SQLSTATE and SQLCODE

SQLSTATE is a five-character array. The five characters contain digits or upper-case letters that represent codes of various error and warning conditions. SQLSTATE has a hierarchical scheme: the first two characters indicate the general class of the condition, the last three characters indicate a subclass of the general condition. For example, the code 00000 indicates the success state.

SQLCODE is a simple integer. The value 0 indicates success, a positive value indicates success with additional information, and a negative value indicates an error. The SQL standard only defines the positive value + 100, which indicates that the last command returned or affected zero rows, and no specific negative values.

**Table 5-78** Mapping between SQLSTATE and SQLCODE

SQLCODE Value	SQLSTATE Value	Description
0 (ECPG_NO_ERROR)	SQLSTATE 00000	Indicates no error.
100 (ECPG_NOT_FOUND)	SQLSTATE 02000	<p>This is a harmless condition indicating that the last command retrieved or processed zero rows, or that you are at the end of the cursor.</p> <p>When processing a cursor in a loop, you could use this code as a way to detect when to abort the loop. The following is an example:</p> <pre>while (1) {     EXEC SQL FETCH ... ;     if (sqlca.sqlcode == ECPG_NOT_FOUND)         break; }</pre> <p>Actually, WHENEVER NOT FOUND DO BREAK effectively does this internally, so there is usually no advantage in writing this out explicitly.</p>
-12 (ECPG_OUT_OF_MEMORY)	SQLSTATE YE001	Indicates that your virtual memory is exhausted. The numeric value is defined as <b>-ENOMEM</b> .
-200 (ECPG_UNSUPPORTED)	SQLSTATE YE000	Indicates that the preprocessor has generated something that the library does not know about.

SQLCODE Value	SQLSTATE Value	Description
-201 (ECPG_TOO_MANY_ARGUMENTS)	SQLSTATE 07001 or 07002	Indicates that the command specified more host variables than the command expected.
-202 (ECPG_TOO_FEW_ARGUMENTS)	SQLSTATE 07001 or 07002	Indicates that the command specified fewer host variables than the command expected.
-203 (ECPG_TOO_MANY_MATCHES)	SQLSTATE 21000	Indicates that a query has returned multiple rows, but the statement is ready to store only one result row.
-204 (ECPG_INT_FORMAT)	SQLSTATE 42804	The host variable is of the int type and the data in the database is of a different type and contains a value that cannot be interpreted as an int. The library uses strtol() for this conversion.
-205 (ECPG_UINT_FORMAT)	SQLSTATE 42804	The host variable is of the unsigned int type and the data in the database is of a different type and contains a value that cannot be interpreted as an unsigned int. The library uses strtoul() for this conversion.
-206 (ECPG_FLOAT_FORMAT)	SQLSTATE 42804	The host variable is of the float type and the data in the database is of another type and contains a value that cannot be interpreted as a float value. The library uses strtod() for this conversion.
-207 (ECPG_NUMERIC_FORMAT)	SQLSTATE 42804	The host variable is of the numeric type and the data in the database is of another type and contains a value that cannot be interpreted as a numeric value.
-208 (ECPG_INTERVAL_FORMAT)	SQLSTATE 42804	The host variable is of the interval type and the data in the database is of another type and contains a value that cannot be interpreted as an interval value.
-209 (ECPG_DATE_FORMAT)	SQLSTATE 42804	The host variable is of the date type and the data in the database is of another type and contains a value that cannot be interpreted as a date value.
-210 (ECPG_TIMESTAMP_FORMAT)	SQLSTATE 42804	The host variable is of the timestamp type and the data in the database is of another type and contains a value that cannot be interpreted as a timestamp value.

SQLCODE Value	SQLSTATE Value	Description
-211 (ECPG_CONVERT_B OOL)	SQLSTATE 42804	The host variable is of the Boolean type, but the data in the database is neither 't' nor 'f'.
-212 (ECPG_EMPTY)	SQLSTATE YE000	The statement sent to the SQL server was empty. (This usually does not occur in an embedded SQL program, so it may point to an internal error.)
-213 (ECPG_MISSING_IND ICATOR)	SQLSTATE 22002	A null value was returned and no null indicator variable was provided.
-214 (ECPG_NO_ARRAY)	SQLSTATE 42804	An ordinary variable was used in a place that requires an array.
-215 (ECPG_DATA_NOT_A RRAY)	SQLSTATE 42804	The database returned an ordinary variable in a place that requires array value.
-216 (ECPG_ARRAY_INSERT)	SQLSTATE 42804	The value cannot be inserted into the array.
-220 (ECPG_NO_CONN)	SQLSTATE 08003	The program tried to access a connection that does not exist.
-221 (ECPG_NOT_CONN)	SQLSTATE YE000	The program tried to access a connection that does exist but is not open. (This is an internal error.)
-230 (ECPG_INVALID_ST MT)	SQLSTATE 26000	The statement you are trying to use has not been prepared.
-239 (ECPG_INFORMIX_D UPLICATE_KEY)	SQLSTATE 23505	Duplicate key error, violation of unique constraint.
-240 (ECPG_UNKNOWN_ DESCRIPTOR)	SQLSTATE 33000	The specified descriptor was not found. The statement you are trying to use has not been prepared.
-241 (ECPG_INVALID_DES CRIPTOR_INDEX)	SQLSTATE 07009	The specified descriptor was out of range.
-242 (ECPG_UNKNOWN_ DESCRIPTOR_ITEM)	SQLSTATE YE000	An invalid descriptor item was requested. (This is an internal error.)

SQLCODE Value	SQLSTATE Value	Description
-243 (ECPG_VAR_NOT_NUMERIC)	SQLSTATE 07006	During the execution of a dynamic statement, the database returned a numeric value and the host variable was not numeric.
-244 (ECPG_VAR_NOT_CHARACTER)	SQLSTATE 07006	During the execution of a dynamic statement, the database returned a non-numeric value and the host variable was numeric.
-284 (ECPG_INFORMIX_SUBSELECT_NOT_ONE)	SQLSTATE 21000	The result of the subquery was not a single row.
-400 (ECPG_PGSQL)	-	Some error caused by the SQL server. This message contains an error message from the SQL server.
-401 (ECPG_TRANS)	SQLSTATE 08007	The SQL server notified that the transaction cannot be started, committed, or rolled back.
-402 (ECPG_CONNECT)	SQLSTATE 08001	The connection attempt to the database did not succeed.
-403 (ECPG_DUPLICATE_KEY)	SQLSTATE 23505	Duplicate key error, violation of unique constraint.
-404 (ECPG_SUBSELECT_NOT_ONE)	SQLSTATE 21000	The result of the subquery was not a single row.
-602 (ECPG_WARNING_UNKNOWN_CURSOR)	SQLSTATE 34000	An invalid cursor name was specified.
-603 (ECPG_WARNING_IN_TRANSACTION)	SQLSTATE 25001	A transaction is in progress.
-604 (ECPG_WARNING_NO_TRANSACTION)	SQLSTATE 25P01	There is no active (in-progress) transaction.
-605 (ECPG_WARNING_CURSOR_EXISTS)	SQLSTATE 42P03	An existing cursor name was specified.

 **CAUTION**

- The SQLSTATE codes 22002, 07001, 07002, 07006, 07009, 33000, 42601, 42804, 42P03, YE000, and YE001 are newly added to ecpg for embedded SQL statements. Other SQLSTATE codes are inherited from the kernel SQLSTATE codes.
- If the value of **SQLSCODE** is **-400**, ECPG detects that the kernel server returns an error. The error code of the kernel SQLSTATE is used.

## 5.7.11 Preprocessor Directives

This section describes the preprocessing instructions provided by ECPG. The preprocessing instructions are used to process program instructions for macro definition, file inclusion, and conditional compilation.

### 5.7.11.1 Including Files

To include an external file in an embedded SQL program, use the following statements:

```
EXEC SQL INCLUDE filename;  
EXEC SQL INCLUDE <filename>;  
EXEC SQL INCLUDE "filename";
```

 **NOTE**

- ECPG searches for files in the following sequence:
  1. Current directory
  2. /usr/local/include
  3. GaussDB Kernel directory, which is defined at build time
  4. /usr/include
- When **EXEC SQL INCLUDE "filename"** is used, only the current directory is searched.
- In each directory, ECPG will first look for the file name as given, and if not found will append .h to the file name and try again (unless the specified file name already has that suffix).
- The file name is case sensitive.

### 5.7.11.2 Directives: ifdef, ifndef, else, elif, and endif

ecpg provides ifdef, ifndef, else, elif, and endif conditional compilation instructions. During preprocessing, different parts of the program are compiled based on different conditions. When using the program, you need to add the EXEC SQL prefix keyword.

Example:

```
EXEC SQL ifndef TZVAR;  
EXEC SQL SET TIMEZONE TO 'GMT';  
EXEC SQL elif TZNAME;  
EXEC SQL SET TIMEZONE TO TZNAME;  
EXEC SQL else;  
EXEC SQL SET TIMEZONE TO TZVAR;  
EXEC SQL endif;
```

### 5.7.11.3 Directives define and undef

Similar to the directive **#define** that is known from C, embedded SQL has a similar concept.

```
EXEC SQL DEFINE name;  
EXEC SQL DEFINE name value;  
EXEC SQL UNDEF name;
```

Example:

```
/* Define a name. */  
EXEC SQL DEFINE HAVE_FEATURE;  
  
/* Define constants. */  
EXEC SQL DEFINE MYNUMBER 12;  
EXEC SQL DEFINE MYSTRING 'abc';  
  
/* Use undef to remove a previous definition. */  
EXEC SQL UNDEF MYNUMBER;
```

You can also use the C versions **#define** and **#undef** in your embedded SQL program. The difference is where your defined values get evaluated. If you use **EXEC SQL DEFINE**, then ECPG evaluates the definitions and substitutes the values. In the following example, ECPG does the substitution and the compiler will never see any name or identifier **MYNUMBER**:

```
EXEC SQL DEFINE MYNUMBER 12;  
...  
EXEC SQL UPDATE Tbl SET col = MYNUMBER;
```

#### NOTICE

Note that you cannot use **#define** for a constant that you are going to use in an embedded SQL query because in this case the embedded SQL precompiler is not able to see this declaration.

## 5.7.12 Using Library Functions

- **ECPGdebug(int on, FILE \*stream)**: If the first parameter of the function is not 0, the debug log function is enabled. The second parameter indicates the standard output stream of the log to be printed. Debug logs are executed on the standard output stream. The logs contain all input SQL statements and results from the GaussDB Kernel server.

Example:

```
#include <stdio.h>  
#include <stdlib.h>  
#include <string.h>  
#include "sqlca.h"  
  
int main()  
{  
    ECPGdebug(1, stderr);  
    /* Create testdb in advance. */  
    EXEC SQL CONNECT TO testdb;  
    EXEC SQL SET AUTOCOMMIT TO ON;  
    EXEC SQL CREATE TABLE T1(a int);  
    return (0);  
}
```

- **ECPGget\_PGconn(const char \*connection\_name)**: returns the database connection handle identified by the given name. If *connection\_name* is set to

**NULL**, the current connection handle is returned. If no connection handle can be identified, the function returns **NULL**.

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "sqlca.h"

int main()
{
    ECPGdebug(1, stderr);
    /* Create testdb in advance. */
    EXEC SQL CONNECT TO testdb as con1;
    EXEC SQL SET AUTOCOMMIT TO ON;
    EXEC SQL DROP TABLE IF EXISTS T1;
    PGconn *conn;
    conn = ECPGget_PGconn("con1");
    printf("conn = %p\n", conn);
    conn = ECPGget_PGconn(NULL);
    printf("conn = %p\n", conn);
    EXEC SQL CREATE TABLE T1(a int);
    return (0);
}
```

- **ECPGtransactionStatus(const char \* *connection\_name*)**: returns the current transaction status of the *connection\_name* connection. The possible return values are as follows:

```
PQTRANS_IDLE, /* connection idle */
PQTRANS_ACTIVE, /* command in progress */
PQTRANS_INTRANS, /* idle, within transaction block */
PQTRANS_INERROR, /* idle, within failed transaction */
PQTRANS_UNKNOWN /* cannot determine status */
```

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "sqlca.h"

int main()
{
    ECPGdebug(1, stderr);
    /* Create testdb in advance. */
    EXEC SQL CONNECT TO testdb as con1;
    EXEC SQL DROP TABLE IF EXISTS T1;
    int a = ECPGtransactionStatus("con1");
    printf("%d\n", a);
    EXEC SQL CREATE TABLE T1(a int);
    EXEC SQL COMMIT;
    return (0);
}
```

- **ECPGfree\_auto\_mem()**: releases all memory allocated for output host variables. This function is called (return\exit) when the program ends.

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "sqlca.h"

int main()
{
    EXEC SQL BEGIN DECLARE SECTION;
    int *ip1=0;
    char **cp2=0;
    int *ipointer1=0;
    int *ipointer2=0;
    int column;
```

```
EXEC SQL END DECLARE SECTION;
int i;

ECPGdebug(1, stderr);

EXEC SQL WHENEVER SQLERROR DO sqlprint();
EXEC SQL CONNECT TO REGRESSDB1;
/* Create testdb in advance. */

EXEC SQL CREATE TABLE test (a int, b text);
EXEC SQL INSERT INTO test VALUES (1, 'one');
EXEC SQL INSERT INTO test VALUES (2, 'two');
EXEC SQL INSERT INTO test VALUES (NULL, 'three');
EXEC SQL INSERT INTO test VALUES (NULL, NULL);

EXEC SQL ALLOCATE DESCRIPTOR mydesc;
EXEC SQL SELECT * INTO SQL DESCRIPTOR mydesc FROM test;
EXEC SQL GET DESCRIPTOR mydesc :column=COUNT;
EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :ip1=DATA, :ipointer1=INDICATOR;
EXEC SQL GET DESCRIPTOR mydesc VALUE 2 :cp2=DATA, :ipointer2=INDICATOR;

printf("Result (%d columns):\n", column);
for (i=0; i < sqlca.sqlerrd[2]; ++i)
{
    if (ipointer1[i]) printf("NULL, ");
    else printf("%d, ", ip1[i]);

    if (ipointer2[i]) printf("NULL, ");
    else printf("%s, ", cp2[i]);
    printf("\n");
}
ECPGfree_auto_mem();
printf("\n");

EXEC SQL DEALLOCATE DESCRIPTOR mydesc;
EXEC SQL ROLLBACK;
EXEC SQL DISCONNECT;
return 0;
}
```

## 5.7.13 SQL Descriptor Area

An SQL descriptor area (SQLDA) is a more sophisticated method for processing the result of a SELECT, FETCH, or DESCRIBE statement. An SQLDA groups the data of one row of data together with metadata items into one data structure. `ecpg` provides two ways to use descriptor areas: named SQLDA and C-structure SQLDA.

### 5.7.13.1 Named SQLDA

A named SQLDA consists of a header and one or more item descriptor areas, which basically each describe one column in the result row. The header contains information concerning the entire descriptor area, and each item descriptor area describes a column in the result row.

- Before using an SQLDA, you need to allocate it.  
EXEC SQL ALLOCATE DESCRIPTOR identifier;
- When you no longer need the SQLDA, deallocate it in time.  
EXEC SQL DEALLOCATE DESCRIPTOR identifier;
- To use a descriptor area, declare it using the INTO clause.  
EXEC SQL FETCH NEXT FROM mycursor INTO SQL DESCRIPTOR mydesc;

If the result set is empty, the descriptor area still contains the metadata from the query.

- For a prepared query that has not been executed, you can use DESCRIBE to obtain the metadata of its result set.

```
EXEC SQL BEGIN DECLARE SECTION;
char *sql_stmt = "SELECT * FROM table1";
EXEC SQL END DECLARE SECTION;

EXEC SQL PREPARE stmt1 FROM :sql_stmt;
EXEC SQL DESCRIBE stmt1 INTO SQL DESCRIPTOR mydesc;
```

In DESCRIBE and FETCH statements, the INTO and USING keywords are used similarly: they produce a result set and metadata in a descriptor area.

- To retrieve the value in a descriptor area from the header and store it into a host variable, use the following command:  
EXEC SQL GET DESCRIPTOR name :hostvar = field;
- Currently, only one header descriptor area **COUNT** is defined, which tells how many item descriptor areas exist (that is, how many columns are contained in the result). The host variable must be of the integer type. To retrieve a specific value from the item descriptor area, run the following command:  
EXEC SQL GET DESCRIPTOR name VALUE num :hostvar = field;

**num** can be a character integer or a host variable that contains an integer.

Possible data types are as follows:

- CARDINALITY (integer): number of rows in the result set
  - DATA: actual data item (therefore, the data type of this field depends on the query)
  - DATETIME\_INTERVAL\_CODE (integer): When **TYPE** is **9**, **DATETIME\_INTERVAL\_CODE** will have a value of **1** for DATE, **2** for TIME, **3** for TIMESTAMP, **4** for TIME WITH TIME ZONE, or **5** for TIMESTAMP WITH TIME ZONE.
  - INDICATOR (integer): indicator (indicating a null value or a value truncation)
  - LENGTH (integer): data length in characters
  - NAME(string): column name
  - OCTET\_LENGTH (integer): length of the character representation of the data in bytes
  - PRECISION (integer): precision (for the numeric type)
  - RETURNED\_LENGTH (integer): data length in characters
  - RETURNED\_OCTET\_LENGTH (integer): length of the character representation of the data in bytes
  - SCALE (integer): ratio (for the numeric type)
  - TYPE (integer): numeric code of the data type of the column
- Retrieve the column value and store it in a host variable.  
EXEC SQL GET DESCRIPTOR mydesc VALUE num :hostvar = field
- num** can be a character integer or a host variable that contains an integer.
- Possible columns are as follows:
- DATA
  - Actual data item (the data type of this column depends on the query)
  - NAME(string)
  - Column name
- To manually create a descriptor area to provide input parameters for a query or cursor, run the following command:

```
EXEC SQL SET DESCRIPTOR name VALUE numfield = :hostvar;
```

- To retrieve multiple rows of records in a FETCH statement and use a host variable of the array type to store data, run the following commands:

```
EXEC SQL BEGIN DECLARE SECTION;  
int id[5];  
EXEC SQL END DECLARE SECTION;  
EXEC SQL FETCH 5 FROM mycursor INTO SQL DESCRIPTOR mydesc;  
EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :id = DATA;
```

### 5.7.13.2 SQLDA

SQLDA is a C language structure used to store a query result set. A structure stores a record of a result set.

```
EXEC SQL include sqllda.h;  
sqllda_t *mysqlda;  
EXEC SQL FETCH 3 FROM mycursor INTO DESCRIPTOR mysqlda;
```

Note that the SQL keyword is omitted. The paragraphs about the use cases of the INTO and USING keywords in section [Named SQLDA](#) also apply here. In a DESCRIBE statement, if the INTO keyword is used, the DESCRIPTOR keyword can be omitted.

```
EXEC SQL DESCRIBE prepared_statement INTO mysqlda;
```

- Procedure
  - a. Prepare a query and declare a cursor for it.
  - b. Declare an SQLDA for the result row.
  - c. Declare SQLDA for input parameters, initialize parameters, and allocate memory.
  - d. Open a cursor with the input SQLDA.
  - e. Fetch rows from the cursor and store them in the output SQLDA.
  - f. Read the value from the output SQLDA to the host variable.
  - g. Close the cursor.
  - h. Deallocate the memory allocated to the SQLDA.
- There are three types of SQLDA data structures: sqllda\_t, sqlvar\_t, and struct sqlname.

a. sqllda\_t

The definition of sqllda\_t is as follows:

```
struct sqllda_struct  
{  
char sqldaid[8];  
long sqldabc;  
short sqln;  
short sqld;  
struct sqllda_struct *desc_next;  
struct sqlvar_struct sqlvar[1];  
};  
typedef struct sqllda_struct sqllda_t;
```

The structure members are described as follows:

- **sqldaid**: contains a string "SQLDA".
- **sqldabc**: contains the size (in bytes) of the allocated space.
- **sqln**: contains the number of input parameters for a parameterized query in case it is passed into OPEN, DECLARE or EXECUTE

statements using the USING keyword. When **sqln** is used as the output of a SELECT, EXECUTE, or FETCH statement, its value is the same as that of **sqld**.

- **sqld**: contains the number of fields in a result set.
- **desc\_next**: If the query returns more than one record, multiple linked SQLDA structures are returned, and **desc\_next** holds a pointer to the next SQLDA structure in the list.
- **sqlvar**: indicates the array of the columns in the result set.

b. `sqlvar_t`

The structure type `sqlvar_t` holds a column value and metadata (such as type and length). The definition of this type is as follows:

```
struct sqlvar_struct
{
    short    sqltype;
    short    sqllen;
    char     *sqldata;
    short    *sqlind;
    struct sqlname sqlname;
};
typedef struct sqlvar_struct sqlvar_t;
```

The structure members are described as follows:

- **sqltype**: contains the type identifier of the field.
- **sqllen**: contains the binary length of the field, for example, 4 bytes for `ECPGt_int`.
- **sqldata**: points to the data. For details about the data format, see [Type Mapping](#).
- **sqlind**: points to a null indicator. The value **0** indicates not null, and the value **-1** indicates null.
- **sqlname**: indicates the name of the field.

c. `struct sqlname`

A `struct sqlname` structure holds a column name. It is treated as a member of the `sqlvar_t` structure. The definition of this type is as follows:

```
#define NAMEDATALEN 64
struct sqlname
{
    short    length;
    char     data[NAMEDATALEN];
};
```

The structure members are described as follows:

- **length**: contains the length of the field name.
  - **data**: contains the actual field name.
- Use an SQLDA to retrieve a result set.  
The general procedure for retrieving a query result set through an SQLDA is as follows:
    - a. Declare an `sqlda_t` structure to receive the result set.

- b. Execute the **FETCH**, **EXECUTE**, or **DESCRIBE** command to process a query for which an SQLDA has been declared.
- c. Check the number of records in the result set by looking at `sqln`, a member of the `sqlda_t` structure.
- d. Fetch the values of each column from `sqlvar[0]`, `sqlvar[1]`, ..., members of the `sqlda_t` structure.
- e. Go to next row (`sqlda_t`) by following the `desc_next` pointer, a member of the `sqlda_t` structure.
- f. Repeat the preceding steps as required.

**Example:**

```
/* Declare an sqlda_t structure to receive the result set. */
sqlda_t *sqlda1;
/* Next, specify an SQLDA in a command. This is an example of the FETCH command. */
EXEC SQL FETCH NEXT FROM cur1 INTO DESCRIPTOR sqlda1;
/* Run a loop to retrieve rows along the linked list. */
sqlda_t *cur_sqlda;
for (cur_sqlda = sqlda1;
     cur_sqlda != NULL;
     cur_sqlda = cur_sqlda->desc_next)
{
    ...
}
/* Inside the loop, run another loop to retrieve the data of each column in the row (sqlvar_t). */
for (i = 0; i < cur_sqlda->sqln; i++)
{
    sqlvar_t v = cur_sqlda->sqlvar[i];
    char *sqldata = v.sqldata;
    short sqllen = v.sqlllen;
    ...
}
/* To fetch the values of a column, check the value of the sqltype member of the sqlvar_t structure.
Then, switch to an appropriate method based on the column type to copy data from the sqlvar field
to a host variable. */
char var_buf[1024];
switch (v.sqltype)
{
    case ECPGt_char:
        memset(&var_buf, 0, sizeof(var_buf));
        memcpy(&var_buf, sqldata, (sizeof(var_buf) <= sqllen ? sizeof(var_buf) - 1 : sqllen));
        break;

    case ECPGt_int:
        memcpy(&intval, sqldata, sqllen);
        snprintf(var_buf, sizeof(var_buf), "%d", intval);
        break;
    ...
}
```

- Use an SQLDA to pass query parameters.

The general procedure for passing input parameters to a prepared query using an SQLDA is as follows:

- a. Create a prepared query (prepared statement).
- b. Declare an `sqlda_t` structure as an SQLDA.
- c. Allocate a memory area for the SQLDA.
- d. Set (copy) the input values in the allocated memory.
- e. Open a cursor declaring the SQLDA.

**Example:**

```
/* First, create a prepared statement. */
EXEC SQL BEGIN DECLARE SECTION;
```

```
char query[1024] = "SELECT d.oid, * FROM pg_database d, pg_stat_database s WHERE d.oid =
s.datid AND (d.datname = ? OR d.oid = ?)";
EXEC SQL END DECLARE SECTION;
EXEC SQL PREPARE stmt1 FROM :query;

/* Allocate memory for an SQLDA and set the number of input parameters in the sqln member
variable of the sqlda_t structure.
* When the prepared query requires two or more input parameters, the application must allocate
extra memory space. The space size is calculated as follows: (Number of parameters - 1) x
sizeof(sqlvar_t).
* The example here shows how to allocate memory space for two input parameters.
*/
sqlda_t *sqlda2;
sqlda2 = (sqlda_t *) malloc(sizeof(sqlda_t) + sizeof(sqlvar_t));
memset(sqlda2, 0, sizeof(sqlda_t) + sizeof(sqlvar_t));
sqlda2->sqln = 2; /* Number of input variables */
/* After memory allocation, store the parameter values into the sqlvar[] array. (This is same array
used for retrieving column values when the SQLDA is receiving a result set.)
* In this example, the input parameters are testdb (string type) and 1 (integer type). */
sqlda2->sqlvar[0].sqltype = ECPGt_char;
sqlda2->sqlvar[0].sqldata = "testdb";
sqlda2->sqlvar[0].sqlllen = 8;
int intval = 1;
sqlda2->sqlvar[1].sqltype = ECPGt_int;
sqlda2->sqlvar[1].sqldata = (char *) &intval;
sqlda2->sqlvar[1].sqlllen = sizeof(intval);
/* Input parameters are passed to the prepared statement by opening a cursor and declaring the
SQLDA that has been created. */
EXEC SQL OPEN cur1 USING DESCRIPTOR sqlda2;
/* Finally, the allocated memory must be explicitly released after you use the input SQLDA, which is
different from the SQLDA used to receive query results. */
free(sqlda2);
```

## 5.7.14 Examples

### ECPG Example Code

```
#include <locale.h>
#include <string.h>
#include <stdlib.h>

exec sql whenever sqlerror sqlprint;
exec sql include sqlca;

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
char *temp_str = (char *)malloc(11);
EXEC SQL END DECLARE SECTION;

ECPGdebug(1, stderr);
/* Create the testdb database in advance. */
exec sql connect to testdb;

/* Enable the automatic commit function. You do not need to manually commit the exec sql command. */
exec sql set autocommit = on;
exec sql drop table if exists test_t;
/* Create a table and insert data. */
exec sql create table test_t(f float, i int, a int[10], mstr char(10));
exec sql insert into test_t(f, i, a, mstr) values(1.01,1,'{0,1,2,3,4,5,6,7,8,9}', 'China');

/* Disable the automatic commit function. The following SQL statements for inserting data must be
manually committed: */
exec sql set autocommit = off;
exec sql insert into test_t(f, i, a, mstr) values(2.01,2,'{0,1,2,3,4,5,6,7,8,9}', 'USA');
exec sql commit;

exec sql insert into test_t(f, i, a, mstr) values(3.01,3,'{0,1,2,3,4,5,6,7,8,9}', 'AUS');
```

```
exec sql insert into test_t(f, i, a, mstr) values(4.01,4,'{0,1,2,3,4,5,6,7,8,9}', 'JAP');
exec sql commit;

EXEC SQL BEGIN DECLARE SECTION;

## Example Code of the pgtypes Library Function

Example 1: Use library functions to perform different operations on time and date types. For details, see [Using Library Functions](#).

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <limits.h>
#include <pgtypes_date.h>
#include <pgtypes_timestamp.h>

char *dates[] = { "19990108foobar",
                  "19990108 foobar",
                  "1999-01-08 foobar",
                  "January 8, 1999",
                  "1999-01-08",
                  "1/8/1999",
                  "1/18/1999",
                  "01/02/03",
                  "1999-Jan-08",
                  "Jan-08-1999",
                  "08-Jan-1999",
                  "99-Jan-08",
                  "08-Jan-99",
                  "08-Jan-06",
                  "Jan-08-99",
                  "19990108",
                  "990108",
                  "1999.008",
                  "J2451187",
                  "January 8, 99 BC",
                  NULL
                };

/* The value cannot conflict with the value of times of libc. */
static char *times[] = { "0:04",
                        "1:59 PDT",

## 5.7.15 ecpg and Pro\*C Compatibility Comparison

ecpg, provided by GaussDB, is an embedded SQL preprocessor for C programs. It differs from the Pro\*C preprocessor of the ORA-compatible database in the behavior and semantics of compiling and executing commands, syntax, and embedded statements.

Comparison between ecpg and Pro\*C:

- Currently, ecpg does not support EXEC SQL CONTEXT ALLOCATE, EXEC SQL CONTEXT USE, and EXEC SQL Context FREE.

### NOTE

Currently, ecpg does not support context allocation, use, and release. ecpg has an independent memory management mechanism. In multi-thread mode, ecpg independently establishes connections, executes SQL statements, and releases related resources in each thread. This usage mode is the same as the processing logic for each thread to allocate and release contexts in Pro\*C multi-thread mode.

- Currently, ecpg does not support EXEC SQL COMMIT WORK RELEASE.

### NOTE

In ecpg, after the COMMIT statement is executed, the **RELEASE** option is not available. You need to execute the EXEC SQL DISCONNECT and EXEC SQL CLOSE statements to release related resources. In Pro\*C, EXEC SQL COMMIT has the **RELEASE** option, which is used to release all resource information such as connections and cursors held by the program.

- Currently, ecpg does not support EXEC SQL ENABLE THREAD.

### NOTE

To enable macro definition in the ecpg compilation options, you need to define ENABLE\_THREAD\_SAFETY in the .pgc file of the main function.

- Currently, ecpg does not support features or syntaxes such as stored procedures, anonymous blocks, and flashback.

## 5.7.16 ECPG API Reference

The ECPG API reference describes the data type-related interfaces provided by the pgtypes library for users to use in embedded SQL-C programs. The pgtypes library maps SQL data types to C data types and provides some interfaces to implement basic functions and calculations.

### 5.7.16.1 Interval Type

[Table 5-79](#) lists the common APIs for interval data provided by the ECPG.

**Table 5-79** Common interval type APIs

API	Description	Remarks
interval* PGTYPEInterval_new(void)	Returns a pointer to an allocated interval variable.	This function creates an interval variable on the heap. The return value is of the interval* type.
void PGTYPEInterval_free(interval* inval)	Releases the memory that has been allocated to an interval variable.	This function releases the memory allocated to the interval* variable created by the PGTYPEInterval_new function.
interval* PGTYPEInterval_from_asc(char* str, char** endptr)	Parses an interval from its textual representation.	This function parses the input string <b>str</b> and returns a pointer to an allocated interval variable. Currently, ECPG parses the entire character string and does not support storing the address of the first invalid character in <b>*endptr</b> . You can set <b>endptr</b> to <b>NULL</b> .
char* PGTYPEInterval_to_asc(interval* span)	Converts a variable of the interval type into its textual representation.	This function converts the interval variable to which the span points into a char*.
int PGTYPEInterval_copy(interval* intvlsrc, interval* intvldest)	Copies a variable of the interval type.	This function copies the interval variable that intvlsrc points to into the variable that intvldest points to.

## Examples

For details, see [Examples](#).

### 5.7.16.2 Numeric Types

[Table 5-80](#) lists the common APIs for numeric (numeric or decimal) data provided by the ECPG.

**Table 5-80** Common numeric type APIs

API	Description	Remarks
numeric* PGTYPESnumeric_new(vo id)	Requests a pointer to a newly allocated numeric variable.	This function creates a numeric variable on the heap. The return value is of the numeric* type.
decimal* PGTYPESdecimal_new(vo id)	Requests a pointer to a newly allocated decimal variable.	This function creates a decimal variable on the heap. The return value is of the decimal* type.
void PGTYPESnumeric_free(nu meric* var)	Frees the memory of a variable of the numeric type.	This function frees a numeric* variable created by using the PGTYPESnumeric_new function.
void PGTYPESdecimal_free(de cimal*)	Frees the memory of a variable of the decimal type.	This function frees a decimal* variable created by using the PGTYPESdecimal_new function.
numeric* PGTYPESnumeric_from_a sc(char* str, char** endptr)	Converts a string to the numeric type.	For example, the valid formats are -2, .794, +3.44, 592.49E07, or -32.84e-4. If the value could be parsed successfully, a valid pointer is returned; otherwise, a null pointer is returned. ECPG only parses complete character strings. Currently, ECPG does not support storing the address of the first invalid character in *endptr. However, endptr can be set to null.
char* PGTYPESnumeric_to_asc( numeric* num, int dscale)	Returns a pointer to a string allocated by malloc that contains the string representation of the numeric type num.	The numeric value will be printed using dscale decimal places and will be rounded if necessary.

API	Description	Remarks
int PGTYPESnumeric_add(numeric* var1, numeric* var2, numeric* result)	Adds two numeric variables to the third numeric variable.	This function adds the variables <i>var1</i> and <i>var2</i> to the result variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_sub(numeric* var1, numeric* var2, numeric* result)	Subtracts two numeric variables and returns the result to the third numeric variable.	This function subtracts <i>var2</i> from <i>var1</i> . The result of this operation is stored in the variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_mul(numeric* var1, numeric* var2, numeric* result)	Multiplies two numeric variables and returns the result to the third numeric variable.	This function multiplies variables <i>var1</i> and <i>var2</i> . The result of this operation is stored in the variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_div(numeric* var1, numeric* var2, numeric* result)	Divides two numeric variables and returns the result to the third numeric variable.	This function divides variable <i>var1</i> by variable <i>var2</i> . The result of this operation is stored in the variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_cmp(numeric* var1, numeric* var2)	Compares two numeric variables.	This function compares two numeric variables. If an error occurs, <i>INT_MAX</i> is returned. On success, this function returns one of the following three possible results: <ul style="list-style-type: none"> <li>• If <i>var1</i> is greater than <i>var2</i>, <b>1</b> is returned.</li> <li>• If <i>var1</i> is smaller than <i>var2</i>, <b>-1</b> is returned.</li> <li>• If <i>var1</i> and <i>var2</i> are equal, <b>0</b> is returned.</li> </ul>

API	Description	Remarks
int PGTYPESnumeric_from_int(signed int int_val, numeric* var)	Converts an int variable into a numeric variable.	This function accepts a signed int variable and stores it in the numeric variable <i>var</i> . The function returns <b>0</b> on success and <b>-1</b> in case of failure.
int PGTYPESnumeric_from_long(signed long int long_val, numeric* var)	Converts a long int variable into a numeric variable.	This function accepts a long int variable and stores it in the numeric variable <i>var</i> . The function returns <b>0</b> on success and <b>-1</b> in case of failure.
int PGTYPESnumeric_copy(numeric* src, numeric* dst)	Copies a numeric variable to another one.	This function copies the value of the variable that <b>src</b> points to into the variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_from_double(double d, numeric* dst)	Converts a double-precision variable into a numeric variable.	This function accepts a double-precision variable and stores the result in the variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_to_double(numeric* nv, double* dp)	Converts a numeric variable into a double-precision variable.	This function converts the numeric value in the variable that <b>nv</b> points to into a double-precision variable that <b>dp</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> .

API	Description	Remarks
int PGTYPE numeric_to_int( numeric* nv, int* ip)	Converts a numeric variable into an int variable.	This function converts the numeric value in the variable that <b>nv</b> points to into an int variable that the IP address points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> .
int PGTYPE numeric_to_long( numeric* nv, long* ip)	Converts a numeric variable into a long int variable.	This function converts the numeric value in the variable that <b>nv</b> points to into a long int variable that the IP points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> .
int PGTYPE numeric_to_decimal( numeric* src, decimal* dst)	Converts a numeric variable into a decimal variable.	This function converts the numeric value in the variable that <b>src</b> points to into a decimal variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> .

API	Description	Remarks
int PGTYPESnumeric_from_decimal(decimal* src, numeric* dst)	Converts a decimal variable into a numeric variable.	This function converts the decimal value in the variable that <b>src</b> points to into a numeric variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow).

## Examples

For details, see [Examples](#).

### 5.7.16.3 Date Type

[Table 5-81](#) lists the common date type APIs provided by ECPG.

**Table 5-81** Common date type APIs

API	Description	Remarks
date* PGTYPESdate_new(void)	Returns a pointer to an allocated date variable.	This function creates a date variable on the heap. The return value is of the date* type.
void PGTYPESdate_free(date*)	Releases the memory that has been allocated to a date variable.	Frees a date* variable created using the PGTYPESdate_free function.

API	Description	Remarks
<p>date PGTYPESdate_from_asc(char* str, char** endptr)</p>	<p>Parses a date from its textual representation.</p>	<p>This function accepts a C string <b>str</b> and a pointer to a C string <b>endptr</b>. ECPG converts the date expressed in text into a character string. Currently, ECPG does not support storing the address of the first invalid character in <b>*endptr</b>. However, <b>endptr</b> can be set to null.</p> <p>Note that the function always assumes MDY-formatted dates and there is currently no variable to change that within ECPG.</p>
<p>char* PGTYPESdate_to_asc(date dDate)</p>	<p>Returns the textual representation of a date variable.</p>	<p>This function accepts the date <b>dDate</b> as its unique parameter. It will output the date in the YYYY-MM-DD format.</p>
<p>date PGTYPESdate_from_timestamp(timestamp dt)</p>	<p>Extracts the date part from a timestamp.</p>	<p>This function accepts a timestamp as its unique parameter and returns the extracted date part from the timestamp.</p>
<p>void PGTYPESdate_julmdy(date jd, int* mdy)</p>	<p>Extracts the values of day, month, and year from a variable of the date type.</p>	<p>This function accepts the date <b>jd</b> and a pointer to an array of three integer values <b>mdy</b>. The variable name indicates the sequence. <b>mdy[0]</b> indicates the month, <b>mdy[1]</b> indicates the day, and <b>mdy[2]</b> indicates the year.</p>

API	Description	Remarks
void PGTYPEdate_mdyjul(int * mdy, date* jdate)	Creates a date using the specified integer value.	This function accepts an array consisting of three integers ( <b>mdy</b> ) as its first parameter. The three integers are used to indicate the day, month, and year, respectively. The second parameter is a pointer to a variable of the date type, which is used to store the result of the operation.
int PGTYPEdate_dayofweek(date d)	Returns a number indicating the day of a week for a date value.	This function accepts the date variable <b>d</b> as its unique parameter and returns an integer indicating the day of the week.
void PGTYPEdate_today(date * d)	Returns the current date.	This function accepts a pointer to a date variable <i>d</i> and sets the parameter to the current date. <ul style="list-style-type: none"> <li>● <b>0</b>: Sunday</li> <li>● <b>1</b>: Monday</li> <li>● <b>2</b>: Tuesday</li> <li>● <b>3</b>: Wednesday</li> <li>● <b>4</b>: Thursday</li> <li>● <b>5</b>: Friday</li> <li>● <b>6</b>: Saturday</li> </ul>

API	Description	Remarks
int PGTYPEStime_defmt_asc( date* d, const char* fmt, char* str)	Converts a C char* string to a value of the date type using a format mask.	This function accepts a pointer <b>d</b> pointing to a date value for storing the operation result, a format mask <b>fmt</b> for parsing the date, and a C char* string <b>str</b> containing the textual representation of the date. The textual representation is expected to match the format mask. However, you do not need to have a 1:1 mapping of the string to the format mask. The function only analyzes the sequential order and looks for the literals "yy" or "yyyy" that indicate the position of the year, "mm" indicating the position of the month and "dd" indicating the position of the day.  Example of valid input (fmt, str): yy/mm/dd 1994, February 3rd

API	Description	Remarks
int PGTYPEdate_fmt_asc( t dDate, const char* fmtstring, char* outbuf)	Converts a variable of the date type into its textual representation using a format mask.	This function accepts the date <b>dDate</b> to be converted, the format mask <b>fmtstring</b> , and the string <b>outbuf</b> of the textual representation of the date to be saved.  The function returns <b>0</b> on success and a negative value in case of error.  The following is an example of valid input: <pre> 112359 //mmddy 59/11/23 //yy/mm/dd Nov.23,1959 //mmm.dd,yyyy Mon,Nov.23,1959 // ddd,mmm.dd,yyyy                     </pre> Format: <ul style="list-style-type: none"> <li>• <b>dd</b>: indicates the day of a month.</li> <li>• <b>mm</b>: indicates the month of a year.</li> <li>• <b>yy</b>: indicates a two-digit year.</li> <li>• <b>yyyy</b>: indicates a four-digit year.</li> <li>• <b>ddd</b>: indicates the day of a week.</li> <li>• <b>mmm</b>: indicates the month.</li> </ul>

## Examples

For details, see [Examples](#).

### 5.7.16.4 Timestamp Type

[Table 5-82](#) lists the common APIs for timestamp data provided by ECPG.

**Table 5-82** Common timestamp type APIs

API	Description	Remarks
timestamp PGTYPEStimestamp_from_asc(char *str, char **endptr)	Parses a timestamp from its textual representation into a timestamp variable.	This function accepts a string <b>str</b> to parse and a pointer to a C char* <b>endptr</b> . It returns the parsed timestamp on success and <b>PGTYPEStimestamp</b> in case of error. In addition, <b>errno</b> is set to <b>PGTYPEStimestamp</b> when an error occurs.  The valid input of <b>PGTYPEStimestamp_from_asc</b> is as follows: 1999-01-08 04:05:06 January 8 04:05:06 1999 PST 1999-Jan-08 04:05:06.789-8 1999-01-08 04:05:06.789 (time zone specifier ignored) J2451187 04:05-08:00 1999-01-08 04:05:00 (time zone specifier ignored)
char *PGTYPEStimestamp_to_asc(timestamp tstamp)	Converts a date to a C char* string.	This function accepts the timestamp <b>tstamp</b> as its unique parameter and returns an allocated string containing the textual representation of the timestamp. The result must be released using <b>PGTYPEStimestamp_free()</b> .
void PGTYPEStimestamp_current(timestamp *ts)	Returns the current timestamp.	This function obtains the current timestamp and saves it to the timestamp variable that <b>ts</b> points to.

API	Description	Remarks
<p>int PGTYPEtimestamp_fmt_asc(timestamp *ts, char *output, int str_len, char *fmtstr)</p>	<p>Converts a timestamp variable into a char* using a format mask.</p>	<p>This function accepts a pointer pointing to the timestamp <b>ts</b> to be converted, a pointer pointing to the output buffer <b>output</b>, the maximum length allocated to the output buffer <b>str_len</b>, and the format mask <b>fmtstr</b> for conversion as its parameters.</p> <p>The function returns <b>0</b> on success and a negative value in case of error.</p>
<p>int PGTYPEtimestamp_sub(timestamp *ts1, timestamp *ts2, interval *iv)</p>	<p>Subtracts a timestamp from another timestamp and saves the result in an interval variable.</p>	<p>This function subtracts the timestamp variable that <b>ts2</b> points to from the timestamp variable that <b>ts1</b> points to, and stores the result in the interval variable that <b>iv</b> points to.</p> <p>The function returns <b>0</b> on success and a negative value in case of error.</p>
<p>int PGTYPEtimestamp_defmt_asc(char *str, char *fmt, timestamp *d)</p>	<p>Parses the timestamp value from its textual representation using a format mask.</p>	<p>This function accepts a timestamp textual representation placed in the variable <b>str</b> and a format mask placed in the variable <b>fmt</b> that will be used for conversion. The result will be stored in the variable that <b>d</b> points to.</p> <p>If the format mask <b>fmt</b> is null, the function rolls back to use the default format <b>mask %Y- %m- %d %H: %M: %S</b>.</p>

API	Description	Remarks
int PGTYPEtimestamp_add_ interval(timestamp *tin, interval *span, timestamp *tout)	Adds an interval variable to a timestamp variable.	This function accepts a pointer <b>tin</b> pointing to the timestamp variable and a pointer <b>span</b> pointing to the interval variable. It adds the interval to the timestamp and then saves the result timestamp in the variable that <b>tout</b> points to.  The function returns <b>0</b> on success and a negative value in case of error.
int PGTYPEtimestamp_sub_ interval(timestamp* tin, interval* span, timestamp* tout)	Subtracts an interval variable from a timestamp variable.	This function subtracts the interval variable that <b>span</b> points to from the timestamp variable that <b>tin</b> points to, and then saves the result in the variable that <b>tout</b> points to.  The function returns <b>0</b> on success and a negative value in case of error.

## Examples

For details, see [Examples](#).

# 5.8 Development Based on the Go Driver

## 5.8.1 Setting Up the Go Driver Environment

### Environment Class

- **Configure the Go environment.**  
You need to configure the following parameters in the environment variables:
  - **GO111MODULE**: Set **GO111MODULE** to **on** when installing the Go driver by importing a file online. If you do not want to reconstruct the **go mod** project, set **GO111MODULE** to **off** and manually download the dependency package. The dependency package must be at the same level as the driver root directory and service code.

- **GOPROXY**: When importing data online, you need to configure the path that contains the Go driver package.
- You can configure other Go environment variables based on your scenario parameters.

Run the **go env** command to view the Go environment variable configuration result and check whether the Go version is 1.13 or later.

- **Install the Go driver.**

- Obtain the Go driver package **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Go.tar.gz** from the release package. Decompress the package to obtain the Go driver source code package.
- Go to the root path of the Go driver code and run the **go mod tidy** command to download related dependencies. You need to configure **GOPATH=\${Path for storing the Go driver dependency package}** in the environment variables.
- If the dependencies have been downloaded to the local host, you can add a line "Replace the Go driver package with the local Go driver package address through replace" to **go.mod**, indicating that all import Go driver packages in the code are stored in the local path and the dependencies are not downloaded from the proxy.

---

 **CAUTION**

- When you run the **go mod tidy** command to download dependencies, some of them may be downloaded as an earlier version. If the earlier version has vulnerabilities, you can change the dependency version in the **go.mod** file and update the dependency to the version after the vulnerability is fixed to avoid risks.
  - Users are not involved in the driver development and can call Go driver 1.13 or later. The runtime library needs to be updated to 1.18 or later.
- 

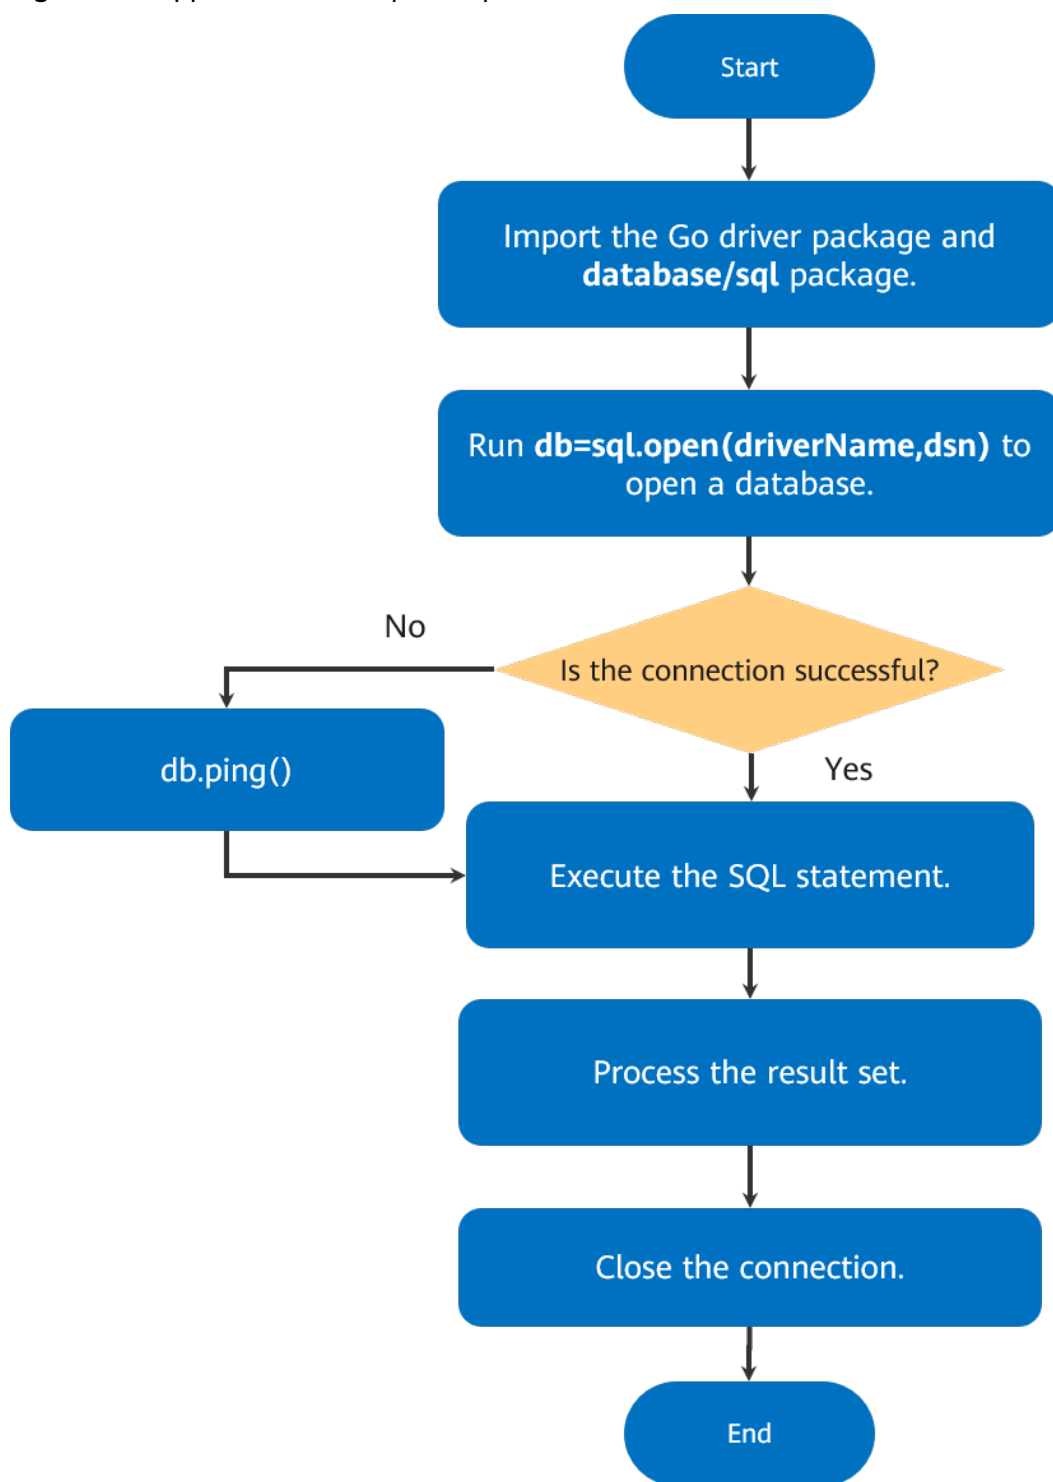

## Driver Class

When creating a database connection, you need to enter the database driver name **gaussdb**. For details about the Go driver, see [Go Driver Compatibility](#).

## 5.8.2 Development Process

The Go driver of the database complies with the rule of the Go language third-party library. You only need to import the driver to the application program and save the driver code in the directory specified by **GOPATH**.

Figure 5-7 Application development process based on Go

According to [Figure 5-7](#), the Go driver application development process depends on the native SQL package of Go driver and the driver developed by GaussDB. The SQL package provides standard interfaces that are used for the implementation of GaussDB for users.

## 5.8.3 Connecting to the Database

When you call the standard SQL API **open** of the Go language to create a database connection, a connection object is returned to transfer the driver name and description string.

### Function Prototype

The Go driver provides the following method to generate a database connected object:

```
func Open(driverName, dataSourceName string) (*DB, error)
```

Parameter description:

- **driverName** indicates the driver name. The database driver name is **gaussdb**.
  - **dataSourceName** indicates the data source to be connected. The value can be in DSN or URL format.
    - DSN format: key1 = value1 key2 = value2.... Different groups of keywords are separated by space. The space on the left and right of the equal sign (=) is optional.
    - URL format: driverName://[userspec@][hostspec][/dbname][?paramspec]
- driverName** indicates the driver name. The database driver name is **gaussdb**.
- userspec** indicates user[:password]. When a URL is used for connection, the password cannot contain separators in the URL string. If the password contains separators, the DSN format is recommended.
- hostspec** indicates [host][:port][, ...].
- dbname** indicates the database name. Note: The initial user cannot be used for remote login. **paramspec** indicates name=value[&...].

**NOTICE**

- In the DSN format, if there are multiple IP addresses:
  - When the value of **num(ip)** is the same as that of **num(port)**, the IP address matches the port number.
  - When the value of **num(ip)** is greater than that of **num(port)**, the IP address that cannot match the port number matches the first port number. For example, the mapping condition result of **host = ip1, ip2, ip3 port = port1, port2** is **ip1:port1, ip2:port2, ip3:port1**.
  - If the value of **num(ip)** is smaller than that of **num(port)**, the extra port numbers are discarded. For example, the mapping result of **host = ip1, ip2, ip3 port = port1, port2, port3, port4** is **ip1:port1, ip2:port2, ip3:port3**.
- In the URL format, if there are multiple IP addresses:
  - In the URL, *ip.port* must appear in pairs, that is, the value of **num(ip)** is the same as that of **num(port)**. Use commas (,) to separate multiple pairs. Example: **gaussdb://user:password@ip1:port1, ip2:port2, ip3:port3/gaussdb**.
  - The URL contains only multiple IP addresses. The port number is specified by the environment variable or uses the default value 5432. For example, in the case of **gaussdb://user:password@ip1, ip2, ip3/gaussdb**, if the environment variable is set as **PGPORT = "port1, port2"**, the mapping is **ip1:port1, ip2:port2, ip3:port1**; if the environment variable is not set, the mapping is **ip1:5432, ip2:5432, ip3:5432**.

## Parameters

**Table 5-83** Database connection parameters

Parameter	Description
host	IP address of the host server, which can also be specified by the environment variable <code>\${PGHOST}</code>
port	Port number of the host server, which can also be specified by the environment variable <code>\${PGPORT}</code>
dbname	Database name, which can also be specified by the environment variable <code>\${PGDATABASE}</code>
user	Username to be connected, which can also be specified by the environment variable <code>\${PGUSER}</code>
password	Password of the user to be connected
connect_timeout	Timeout interval for connecting to the server, which can also be specified by the environment variable <code>\${PGCONNECT_TIMEOUT}</code>

Parameter	Description
sslmode	<p>SSL encryption mode, which can also be specified by the environment variable <i>PGSSLMODE</i></p> <p>Value range:</p> <ul style="list-style-type: none"> <li>• <b>disable</b>: SSL connection is disabled.</li> <li>• <b>allow</b>: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.</li> <li>• <b>prefer</b>: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.</li> <li>• <b>require</b>: SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.</li> <li>• <b>verify-ca</b>: SSL connection is required, and whether the server certificate is issued by a trusted CA is verified.</li> <li>• <b>verify-full</b>: SSL connection is required, and whether the server certificate is issued by a trusted CA and whether the host name of the server is the same as that in the certificate are verified.</li> </ul>
sslkey	<p>Key location of the client certificate. If SSL connection is required and this parameter is not specified, you can set the environment variable <i>PGSSLKEY</i> to specify the location.</p>
sslcert	<p>File name of the client SSL certificate, which can also be specified by the environment variable <i>PGSSLCERT</i></p>
sslrootcert	<p>Name of the file that contains the SSL CA certificate, which can also be specified by the environment variable <i>PGSSLROOTCERT</i></p>
sslcrl	<p>File name of the SSL CRL. If a certificate listed in this file exists, the server certificate authentication will be rejected and the connection will fail. The value can also be specified by the environment variable <i>PGSSLCRL</i>.</p>
sslpassword	<p>Passphrase used to decrypt a key into plaintext. If this parameter is specified, the SSL key is an encrypted file. Currently, the SSL key supports DES encryption and AES encryption.</p> <p><b>NOTE</b> The DES encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.</p>
disable_prepared_binary_result	<p>The value of this parameter is a string. If it is set to <b>yes</b>, the connection should not use the binary format when the query results are received from prepared statements. This parameter is used only for debugging.</p> <p>Value range: <b>yes</b> and <b>no</b>.</p>

Parameter	Description
binary_parameters	Specifies whether <code>[]byte</code> is always sent in binary format. The value is a string. Value range: <b>yes</b> and <b>no</b> . If this parameter is set to <b>yes</b> , you are advised to bind parameters based on <code>[]byte</code> to reduce internal type conversion.
target_session_attrs	<p>Connection type of the database, which can also be specified by the environment variable <code>PGTARGETSESSIONATTRS</code>. This parameter is used to identify the primary and standby nodes. There are six value options, namely, <b>any</b>, <b>master</b>, <b>slave</b>, <b>preferSlave</b>, <b>read-write</b>, and <b>read-only</b>. The default value is <b>any</b>.</p> <ul style="list-style-type: none"> <li>• <b>any</b>: attempts to connect to any DN in the URL connection string.</li> <li>• <b>master</b>: attempts to connect to a primary DN in the URL connection string. If the primary DN cannot be found, an exception is thrown.</li> <li>• <b>slave</b>: attempts to connect to a standby DN in the URL connection string. If the standby DN cannot be found, an exception is thrown.</li> <li>• <b>preferSlave</b>: attempts to connect to a standby DN (if available) in the URL connection string. Otherwise, it connects to the primary DN.</li> <li>• <b>read-write</b>: specifies that only the primary DN can be connected.</li> <li>• <b>read-only</b>: specifies that only the standby DN can be connected.</li> </ul>
loggerLevel	<p>Log level, which is used to print debugging information. The value can also be specified by the environment variable <code>PGLOGGERLEVEL</code>.</p> <p>The value can be <b>trace</b>, <b>debug</b>, <b>info</b>, <b>warn</b>, <b>error</b>, or <b>none</b>, in descending order of priority.</p>
application_name	Name of the Go driver that is being connected. The default value is <b>go-driver</b> . You are advised not to configure this parameter.
RuntimeParams	Value of the GUC parameter of the set type that is run by default when a session is connected, for example, <b>search_path</b> , <b>application_name</b> , and <b>timezone</b> . For details about the parameters, see the default settings of the client connection. You can run the <b>SHOW</b> command to check whether the parameters are set successfully.

Parameter	Description
autoBalance	<p>Character string type. Use this parameter to enable load balancing connections in the distributed environment. The value can be <b>true</b>, <b>balance</b>, <b>roundrobin</b>, <b>shuffle</b>, <b>priorityn</b> and <b>false</b>. The default value is <b>false</b>.</p> <ol style="list-style-type: none"> <li> <p>If this parameter is set to <b>true</b>, <b>balance</b>, or <b>roundrobin</b>, the Go SQL load balancing function is enabled to balance multiple connections of an application to each CN available in the cluster.</p> <p>For example:  <pre>gaussdb://user:password@host1:port1,host2:port2/database?autoBalance=true</pre> </p> <p>The driver periodically obtains the list of available CNs in the entire cluster. For example, the obtained list is <b>host1:port1,host2:port2,host3:port3,host4:port4</b>. The <b>refreshCNlpsTime</b> parameter specifies the interval for obtaining the list, and the default value is <b>10s</b>.</p> <p>When <b>autoBalance</b> is enabled on <b>host1</b> and <b>host2</b>, HA is implemented only for the first connection. The driver will select available CNs from <b>host1</b>, <b>host2</b>, <b>host3</b>, and <b>host4</b> in sequence to update the available CN list and <b>Connector.Connect</b> will be called on <b>host1</b>, <b>host2</b>, <b>host3</b>, and <b>host4</b> using the RoundRobin algorithm.</p> </li> <li> <p><b>priorityn</b> indicates that the driver priority-based load balancing function is enabled. Multiple connections of an application are balanced to the first <i>n</i> available CNs configured in the URL. When the first <i>n</i> CNs are unavailable, connections are randomly allocated to other available CNs in the database cluster. <i>n</i> is a number not less than 0 and less than the number of CNs configured in the URL.</p> <p>Example:  <pre>gaussdb://user:password@host1:port1,host2:port2,host3:port3/database?autoBalance=priority2</pre> </p> <p>The driver periodically obtains the list of available CNs in the entire cluster (defined by <b>refreshCNlpsTime</b>). For example, the obtained list is <b>host1:port1,host2:port2,host3:port3,host4:port4,host5:port5,host6:port6</b>, where <b>host1</b> and <b>host2</b> are in <b>AZ1</b>, and <b>host3</b> and <b>host4</b> are in <b>AZ2</b>.</p> <p>The driver preferentially selects <b>host1</b> and <b>host2</b> for load balancing. If both <b>host1</b> and <b>host2</b> are unavailable, the driver randomly selects a CN from <b>host3</b>, <b>host4</b>, <b>host5</b>, and <b>host6</b> for connection.</p> </li> <li> <p>If this parameter is set to <b>shuffle</b>, the driver random load balancing is enabled to randomly and evenly distribute multiple connections of the application to available CNs in the database cluster.</p> <p>Example:  <pre>gaussdb://user:password@host1:port1,host2:port2,host3:port3/database?autoBalance=shuffle</pre> </p> </li> </ol>

Parameter	Description
	<p>The driver periodically obtains the list of available CNs in the entire cluster. For example, the obtained list is <b>host1:port1,host2:port2,host3:port3,host4:port4</b>. The <b>refreshCNlpsTime</b> parameter specifies the interval for obtaining the list, and the default value is <b>10s</b>.</p> <p>For the first connection, <b>host1:port1,host2:port2,host3:port3</b> is used for HA. For subsequent connections, the shuffle algorithm is used to randomly select a CN from the refreshed CN list.</p> <p>4. If this parameter is set to <b>false</b> in the centralized scenarios, the driver load balancing and priority-based load balancing functions are disabled. The default value is <b>false</b>.</p> <p><b>NOTE</b></p> <p>Load balancing is based on the connection level rather than the transaction level. If the connection is persistent and the load on the connection is unbalanced, the load on the CN may be unbalanced.</p> <p>Load balancing can be used only in distributed scenarios and cannot be used in centralized scenarios.</p>
recheckTime	<p>Integer type. Use this parameter to specify the interval at which the driver periodically checks the status of CNs in the database cluster and obtains the IP address list of available CNs. The value ranges from 5s to 60s and the default value is <b>10s</b>.</p>
usingEip	<p>Boolean type. The value specifies whether to use the elastic IP address for load balancing. The default value is <b>true</b>, indicating that an elastic IP address is used for load balancing. The value <b>false</b> indicates that a data IP address is used for load balancing.</p>

## 5.8.4 Connecting to the Database (Using SSL)

The Go driver supports SSL connections to the database. After the SSL mode is enabled, if the Go driver connects to the database server in SSL mode, the Go driver uses the standard TLS 1.3 protocol by default, and the TLS version must be 1.2 or later. This section describes how applications configure the client in SSL mode through the Go driver. For details about how to configure the server, contact the administrator. To use the method described in this section, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

### NOTE

In SSL-based certificate authentication mode, you do not need to specify the user password in the connection string.

## Configuring the Client

Upload the **client.key**, **client.crt**, and **cacert.pem** files generated during server configuration to the client. For details about server configuration, contact the administrator.

### Example 1:

```
package main

// Set the dependency package based on the dependency package path in the environment.
import (
    "database/sql"
    "fmt"
    _ "gitee.com/opengauss/openGauss-connector-go-pq"
    "log"
)

// Mutual authentication is used as an example. In this example, the username and password are stored in
// environment variables. Before running this example, set environment variables in the local environment (set
// the environment variable name based on the actual situation).
func main() {
    hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment
    // variable.
    port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment
    // variable.
    username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username for writing environment
    // variables.
    passwd := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the
    // environment variable.
    sslpasswd := os.Getenv("GOSSLPASSWD") // GOSSLPASSWD indicates the passphrase written into the
    // environment variable.
    dsnStr := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "
    dbname=gaussdb sslcert=certs/client.crt sslkey=certs/client.key sslpassword=" + sslpasswd
    parameters := []string{
        " sslmode=require",
        " sslmode=verify-ca sslrootcert=certs/cacert.pem",
    }

    for _, param := range parameters {
        db, err := sql.Open("gaussdb", dsnStr+param)
        if err != nil {
            log.Fatal(err)
        }

        var f1 int
        err = db.QueryRow("select 1").Scan(&f1)
        if err != nil {
            log.Fatal(err)
        } else {
            fmt.Printf("RESULT: select 1: %d\n", f1)
        }
    }

    db.Close()
}
```

### Example 2:

```
package main

// Set the dependency package based on the dependency package path in the environment.
import (
    "database/sql"
    _ "gitee.com/opengauss/openGauss-connector-go-pq"
    "log"
    "strings"
)

// For example, verify sslpassword. In this example, the username and password are stored in environment
// variables. Before running this example, set environment variables in the local environment (set the
```

```

environment variable name based on the actual situation).
func main() {
    hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment
    variable.
    port := os.Getenv("GOPORT")    // GOPORT indicates the port number written into the environment
    variable.
    username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username for writing environment
    variables.
    passwd := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the
    environment variable.
    dsnStr := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "
    dbname=gaussdb"
    sslpasswd := os.Getenv("GOSSLPASSWD") // GOSSLPASSWD indicates the passphrase written into the
    environment variable.
    connStrs := []string{
        " sslmode=verify-ca sslcert=certs/client_rsa.crt sslkey=certs/client_rsa.key sslpassword=" + sslpasswd + "
    sslrootcert=certs/cacert_rsa.pem",
        " sslmode=verify-ca sslcert=certs/client_ecdsa.crt sslkey=certs/client_ecdsa.key sslpassword=" + sslpasswd +
    " sslrootcert=certs/cacert_ecdsa.pem",
    }
    for _, connStr := range connStrs {
        db, err := sql.Open("gaussdb", dsnStr+connStr)
        if err != nil {
            log.Fatal(err)
        }
        var f1 int
        err = db.QueryRow("select 1").Scan(&f1)
        if err != nil {
            if !strings.HasPrefix(err.Error(), "connect failed.") {
                log.Fatal(err)
            }
        }
        db.Close()
    }
}

```

## 5.8.5 Go APIs

### 5.8.5.1 sql.Open

The following table describes sql.Open.

Method	Description	Return Value
Open(driverName, dataSourceName string)	Opens a database based on a specified database driver and the dedicated data source of the driver.	*DB and error

For details about driverName and dataSourceName, see [Connecting to the Database](#).

### 5.8.5.2 type DB

The following table describes type DB.

Method	Description	Return Value
(db *DB)Begin()	Starts a transaction. The isolation level of the transaction is determined by the driver.	*Tx and error
(db *DB)BeginTx(ctx context.Context, opts *TxOptions)	Starts a transaction with a specified transaction isolation level. A specified context is used until the transaction is committed or rolled back. If the context is canceled, the SQL package rolls back the transaction.	*Tx and error
(db *DB)Close()	Closes the database and releases all the opened resources.	error
(db *DB)Exec(query string, args ...interface{})	Performs an operation that does not return rows of data.	Result and error
(db *DB)ExecContext(ctx context.Context, query string, args ...interface{})	Performs an operation that does not return rows of data in a specified context.	Result and error
(db *DB)Ping()	Checks whether the database connection is still valid and establishes a connection if necessary.	error
(db *DB)PingContext(ctx context.Context)	Checks whether the database connection is still valid in a specified context and establishes a connection if necessary.	error
(db *DB)Prepare(query string)	Creates a prepared statement for subsequent queries or executions.	*Stmt and error
(db *DB)PrepareContext(ctx context.Context, query string)	Creates a prepared statement for subsequent queries or executions in a specified context.	*Stmt and error
(db *DB)Query(query string, args ...interface{})	Executes a query and returns multiple rows of data.	*Rows and error
(db *DB)QueryContext(ctx context.Context, query string, args ...interface{})	Executes a query and returns multiple rows of data in a specified context.	*Rows and error

Method	Description	Return Value
(db *DB)QueryRow(query string, args ...interface{})	Executes a query that returns only one row of data.	*Row
(db *DB)QueryRowContext(ctx context.Context, query string, args ...interface{})	Executes a query that returns only one row of data in a specified context.	*Row

## Parameters

Parameter	Description
ctx	Specified context.
query	Executed SQL statement.
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see <a href="#">Examples</a> .
opts	Transaction isolation level and transaction access mode. The transaction isolation level (opts.Isolation) supports sql.LevelReadUncommitted,sql.LevelReadCommitted,sql.LevelRepeatableRead,sql.LevelSerializable. The transaction access mode ( <b>opts.ReadOnly</b> ) can be <b>true</b> (read only) or <b>false</b> (read write).

### NOTICE

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in [type Rows](#). If the result is not obtained through the Next() API, unexpected errors may occur.

## Examples

```
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables in the local environment (set the environment variable names based on
// the actual situation).
package main
/* The location of the Go driver dependency package is set based on the configured go.mod. */
```

```

import (
    "database/sql"
    _ "gitee.com/opengauss/openGauss-connector-go-pq"
    "log"
)

func main() {
    hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment
    port := os.Getenv("GOPORT")    // GOPORT indicates the port number written into the environment
    username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username for writing environment
    password := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the
    str := "host=" + hostip + " port=" + port + " user=" + username + " password=" + password + "
    dbname=gaussdb sslmode=disable"
    db, err := sql.Open("gaussdb", str)
    if err != nil {
        log.Fatal(err)
    }
    defer db.Close()

    err = db.Ping()
    if err != nil {
        log.Fatal(err)
    }

    _, err = db.Exec("create table test_bound(id int, name text)")

    // Binding by location
    _, err = db.Exec("insert into test_bound(id, name) values(:1, :2)", 1, "Zhang San")
    if err != nil {
        log.Fatal(err)
    }

    // Binding by name
    _, err = db.Exec("insert into test_bound(id, name) values(:id, :name)", sql.Named("id", 1),
    sql.Named("name", "Zhang San"))
    if err != nil {
        log.Fatal(err)
    }
}

```

### 5.8.5.3 type Stmt

The following table describes type Stmt.

Method	Description	Return Value
(s *Stmt)Close()	Closes a specified prepared statement.	error

<code>(s *Stmt)Exec(args ...interface{})</code>	Executes a prepared statement with specified parameters and returns a <b>Result</b> value. The Prepare-Bind-Execute (PBE) feature is supported. PBE is a method of sending and executing queries. The CN can receive PBE packets through complex query protocols to execute statements.	Result and error
---	---	------------------

	<p><b>NOTE</b></p> <ol style="list-style-type: none"><li>1. The placeholder of a prepared statement can be a dollar sign (\$) or a question mark (?).</li><li>2. The number of placeholders in a prepared statement is determined by the database. When the number of table columns exceeds the database limit or does not match the number of current table columns, the server returns an error.</li><li>3. Batch PBE processing supports addition, deletion, and modification. During the batch operation, the maximum length of a U packet is limited to 1 GB minus 1 byte, that is, 0x3fffffff bytes. If the length exceeds the limit, "bind message length XXX too long. This can be caused by very large or incorrect length specifications on InputStream parameters" will be reported.</li><li>4. When a record is inserted, the performance of PBE deteriorates greatly compared with that of a single-query statement (conn.simpleExec). Therefore, you are advised to use single-query statements, rather than the PBE statement.</li><li>5. After the underlying error processing of the driver is reconstructed, the PBE performance decreases by less than 5%.</li></ol>	
--	---	--

(s *Stmt)ExecContext(ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns a <b>Result</b> value.	Result and error
(s *Stmt)Query(args ...interface{})	Executes a prepared statement with specified parameters and returns <b>*Rows</b> as the query result.	*Rows and error
(s *Stmt)QueryContext(ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns <b>*Rows</b> as the query result.	*Rows and error
(s *Stmt)QueryRow(args ...interface{})	Executes a prepared statement with specified parameters and returns <b>*Row</b> as the result.	*Row
(s *Stmt)QueryRowContext (ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns <b>*Row</b> as the result.	*Row

## Parameters

Parameter	Description
ctx	Specified context.
query	Executed SQL statement.
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see <a href="#">Examples</a> in section "type DB."

**NOTICE**

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in **type Rows**. If the result is not obtained through the Next() API, unexpected errors may occur.

### 5.8.5.4 type Tx

The following table describes type Tx.

Method	Description	Return Value
(tx *Tx)Commit()	Commits a transaction.	error
(tx *Tx)Exec(query string, args ...interface{})	Performs an operation that does not return rows of data.	Result and error
(tx *Tx)ExecContext(ctx context.Context, query string, args ...interface{})	Performs an operation that does not return rows of data in a specified context.	Result and error
(tx *Tx)Prepare(query string)	Creates a prepared statement for subsequent queries or executions. The returned statement is executed within a transaction and cannot be used when the transaction is committed or rolled back.	*Stmt and error

<p>(tx *Tx)PrepareContext(ctx context.Context, query string)</p>	<p>Creates a prepared statement for subsequent queries or executions. The returned statement is executed within a transaction and cannot be used when the transaction is committed or rolled back.</p> <p>The specified context will be used in the preparation phase, not in the transaction execution phase. The statement returned by this method will be executed in the transaction context.</p>	<p>*Stmt and error</p>
<p>(tx *Tx)Query(query string, args ...interface{})</p>	<p>Executes a query that returns rows of data.</p>	<p>*Rows and error</p>
<p>(tx *Tx)QueryContext(ctx context.Context, query string, args ...interface{})</p>	<p>Executes a query that returns rows of data in a specified context.</p>	<p>*Rows and error</p>
<p>(tx *Tx)QueryRow(query string, args ...interface{})</p>	<p>Executes a query that returns only one row of data.</p>	<p>*Row</p>
<p>(tx *Tx)QueryRowContext(ctx context.Context, query string, args ...interface{})</p>	<p>Executes a query that returns only one row of data in a specified context.</p>	<p>*Row</p>
<p>(tx *Tx) Rollback()</p>	<p>Rolls back a transaction.</p>	<p>error</p>
<p>(tx *Tx)Stmt(stmt *Stmt)</p>	<p>Returns a transaction-specific prepared statement for an existing statement.</p> <p>Example:  <pre>str, err := db.Prepare("insert into t1 values(:1, :2)") tx, err := db.Begin() res, err := tx.Stmt(str).Exec(1, "aaa")</pre> </p>	<p>*Stmt</p>
<p>(tx *Tx)StmtContext(ctx context.Context, stmt *Stmt)</p>	<p>Returns a transaction-specific prepared statement for an existing statement in a specified context.</p>	<p>*Stmt</p>

## Parameters

Parameter	Description
ctx	Specified context.
query	Executed SQL statement.
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see <a href="#">Examples</a> in section "type DB."
stmt	Existing prepared statement, which is generally the prepared statement returned by the PREPARE statement

### NOTICE

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in [type Rows](#). If the result is not obtained through the Next() API, unexpected errors may occur.

### 5.8.5.5 type Rows

The following table describes type Rows.

Method	Description	Return Value
(rs *Rows)Close()	Closes <b>Rows</b> to stop the iteration of the data set.	error
(rs *Rows)ColumnTypes()	Returns column information.	[]*ColumnType and error
(rs *Rows)Columns()	Returns the name of each column.	[]string and error
(rs *Rows)Err()	Returns any errors that occur during iteration.	error

(rs *Rows)Next()	Prepares the next data row to be read with the Scan method. If there is an additional result set, <b>true</b> is returned. Otherwise, <b>false</b> is returned.	boolean
(rs *Rows)Scan(dest ...interface{})	Copies the columns of the current iterated row of data to the value specified by <b>dest</b> .	error
(rs *Rows)NextResultSet()	Specifies whether there is an additional result set.	boolean

## Parameters

Parameter	Description
dest	The column to be queried needs to be copied to the value specified by this parameter.

### 5.8.5.6 type Row

The following table describes type Row.

Method	Description	Return Value
(r *Row)Scan(dest ...interface{})	Copies the columns in the current row of data to the value specified by <b>dest</b> .	error
(r *Row)Err()	Returns errors that occur during execution.	error

## Parameter Description

Parameter	Description
dest	The column to be queried needs to be copied to the value specified by this parameter.

### 5.8.5.7 type ColumnType

The following table describes type ColumnType.

Method	Description	Return Value
--------	-------------	--------------

(ci *ColumnType)DatabaseTypeName()	Returns the name of the column-type database system. If an empty string is returned, driver-type names are not supported.	error
(ci *ColumnType)DecimalSize()	Returns the scale and precision of the decimal type. If the value of <b>ok</b> is <b>false</b> , the specified type is unavailable or not supported.	precision, scale int64, ok boolean
(ci *ColumnType)Length()	Returns the length of the data column type. If the value of <b>ok</b> is <b>false</b> , the specified type does not have a length.	length int64, ok boolean
(ci *ColumnType)ScanType()	Returns a Go type that can be used for scanning by using Rows.Scan.	reflect.Type
(ci *ColumnType)Name()	Returns the name of a data column.	string

### 5.8.5.8 type Result

The following table describes type Result.

Method	Description	Return Value
(res Result)RowsAffected()	Returns the number of rows affected by the INSERT, DELETE, UPDATE, SELECT, MOVE, FETCH, and COPY operations.	int64 and error

## 5.9 Compatibility Reference

### JDBC Compatibility Package

Obtain the package **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Jdbc.tar.gz** from the release package.

After the decompression, you will obtain the following JDBC packages in .jar format:

- **gsjdbc4.jar**: The main class name is **org.postgresql.Driver**, and the URL prefix of the database connection is **jdbc:postgresql**. This driver package applies to the scenario where services are migrated from PostgreSQL. The driver class and loading path are the same as those before the migration, but the

supported APIs are different. The APIs that are not supported need to be adjusted on the service side.

- **gsjdbc200.jar**: This driver package applies to the scenario where services are migrated from Gauss200. The driver class and loading path are the same as those before the migration, but the supported APIs are different. The APIs that are not supported need to be adjusted on the service side.
- **opengaussjdbc.jar**: The main class name is **com.huawei.opengauss.jdbc.Driver**, and the URL prefix of the database connection is **jdbc:opengauss**. This driver package is used when both PostgreSQL and GaussDB are accessed in a JVM process.

---

**NOTICE**

- The loading paths and URL prefixes of driver classes vary in different driver packages, but the functions are the same.
  - The **gsjdbc4** driver package cannot be used to operate the PostgreSQL database. Although the connection can be successfully established in some versions, some API behaviors are different from those of PostgreSQL JDBC, which may cause unknown errors.
  - The PostgreSQL driver package cannot be used to operate GaussDB. Although the connection can be successfully established in some versions, some API behaviors are different from those of GaussDB JDBC, which may cause unknown errors.
- 

## Go Driver Compatibility

- The Go driver provided by the database does not adapt to mature ORM frameworks (such as XORM) in the industry. As such, the driver name input during database connection creation must be compatible with Postgres and PostgreSQL.
- The Go driver of the database cannot coexist with that of PostgreSQL.

## ecpg Compatibility

ecpg provides the URL connection syntax which supports GaussDB and is compatible with PostgreSQL.

Connection syntax:

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name];
```

To support PostgreSQL, **target** is set as follows:

- `tcp:postgresql://hostname[:port][/dbname][?options]`
- `unix:postgresql://hostname[:port][/dbname][?options]`

## 5.10 Commissioning

To control the output of log files and better understand the operating status of the database, modify specific configuration parameters in the **gaussdb.conf** file in the instance data directory.

**Table 5-84** describes the adjustable configuration parameters.

**Table 5-84** Configuration parameters

Parameter	Description	Value Range	Remarks
client_min_messages	Level of messages to be sent to clients.	<ul style="list-style-type: none"> <li>• DEBUG5</li> <li>• DEBUG4</li> <li>• DEBUG3</li> <li>• DEBUG2</li> <li>• DEBUG1</li> <li>• LOG</li> <li>• NOTICE</li> <li>• WARNING</li> <li>• ERROR</li> <li>• FATAL</li> <li>• PANIC</li> </ul> Default value: <b>NOTICE</b>	Messages of the set level or lower will be sent to clients. The lower the level is, the fewer the messages will be sent.
log_min_messages	Level of messages to be recorded in server logs.	<ul style="list-style-type: none"> <li>• DEBUG5</li> <li>• DEBUG4</li> <li>• DEBUG3</li> <li>• DEBUG2</li> <li>• DEBUG1</li> <li>• INFO</li> <li>• NOTICE</li> <li>• WARNING</li> <li>• ERROR</li> <li>• LOG</li> <li>• FATAL</li> <li>• PANIC</li> </ul> Default value: <b>WARNING</b>	Messages higher than the set level will be recorded in logs. The higher level indicates that the fewer server logs will be recorded.

Parameter	Description	Value Range	Remarks
log_min_error_statement	Level of SQL error statements to be recorded in server logs.	<ul style="list-style-type: none"> <li>DEBUG5</li> <li>DEBUG4</li> <li>DEBUG3</li> <li>DEBUG2</li> <li>DEBUG1</li> <li>INFO</li> <li>NOTICE</li> <li>WARNING</li> <li>ERROR</li> <li>FATAL</li> <li>PANIC</li> </ul> Default value: <b>ERROR</b>	SQL error statements of the set level or higher will be recorded in server logs. Only a system administrator is allowed to modify this parameter.
log_min_duration_statement	Minimum execution duration of a statement. If the execution duration of a statement is equal to or longer than the set milliseconds, the statement and its duration will be recorded in logs. Enabling this function can help you track the query attempts to be optimized.	INT type. Default value: <b>-1</b> . Unit: millisecond	The value <b>-1</b> indicates that the function is disabled. Only a system administrator is allowed to modify this parameter.
log_connections/ log_disconnections	Specifies whether to record a server log message when each session is connected or disconnected.	<ul style="list-style-type: none"> <li><b>on</b>: The system records a log server when each session is connected or disconnected.</li> <li><b>off</b>: The system does not record a log server when each session is connected or disconnected.</li> </ul> Default value: <b>off</b>	-

Parameter	Description	Value Range	Remarks
log_duration	Specifies whether to record the duration of each executed statement.	<ul style="list-style-type: none"> <li>• <b>on</b>: The system records the duration of each executed statement.</li> <li>• <b>off</b>: The system does not record the duration of each executed statement.</li> </ul> Default value: <b>off</b>	Only a system administrator is allowed to modify this parameter.
log_statement	SQL statements to be recorded in logs.	<ul style="list-style-type: none"> <li>• <b>none</b>: The system does not record any SQL statements.</li> <li>• <b>ddl</b>: The system records data definition statements.</li> <li>• <b>mod</b>: The system records data definition statements and data operation statements.</li> <li>• <b>all</b>: The system records all statements.</li> </ul> Default value: <b>none</b>	Only a system administrator is allowed to modify this parameter.
log_hostname	Specifies whether to record host names.	<ul style="list-style-type: none"> <li>• <b>on</b>: The system records host names.</li> <li>• <b>off</b>: The system does not record host names.</li> </ul> Default value: <b>off</b>	By default, connection logs only record the IP addresses of connected hosts. With this function, the host names will also be recorded.  This parameter has an impact on viewing audit results, <a href="#">PG_STAT_ACTIVITY</a> , and the GUC parameter <a href="#">log_line_prefix</a> .

**Table 5-85** describes the parameter levels of **Table 5-84**.

**Table 5-85** Description of log level parameters

Level	Description
DEBUG[1-5]	Provides information that can be used by developers. Level 1 is the lowest level whereas level 5 is the highest level.
INFO	Provides information about users' hidden requests, for example, information about the VACUUM VERBOSE process.
NOTICE	Provides information that may be important to users, for example, truncations of long identifiers or indexes created as a part of a primary key.
WARNING	Provides warning information for users, for example, COMMIT out of transaction blocks.
ERROR	Reports an error that causes a command to terminate.
LOG	Reports information that administrators may be interested in, for example, the activity levels of check points.
FATAL	Reports the reason that causes a session to terminate.
PANIC	Reports the reason that causes all sessions to terminate.

# 6 SQL Optimization

---

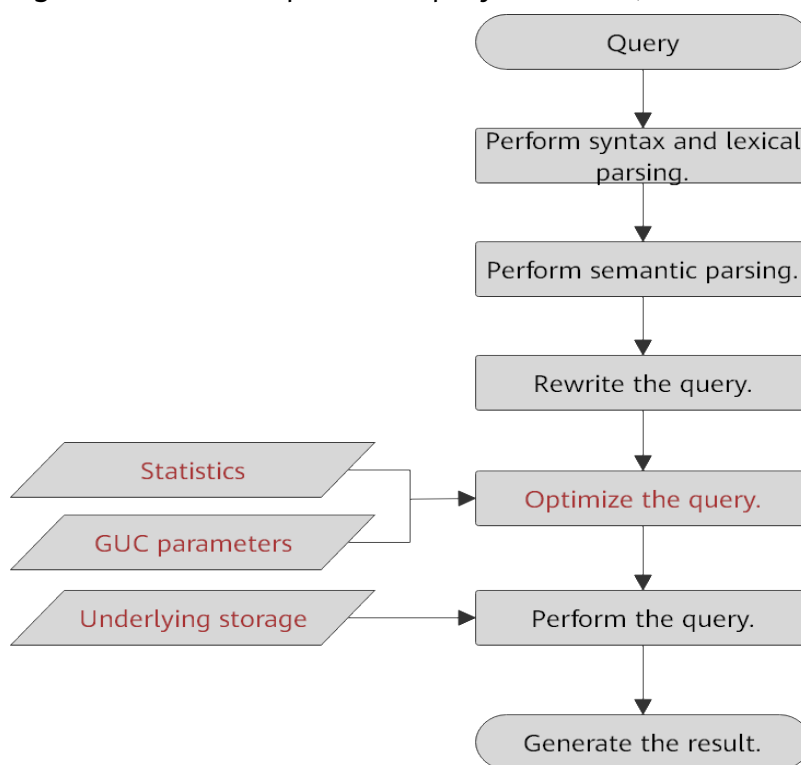

The aim of SQL optimization is to maximize the utilization of resources, including CPU, memory, disk I/O, and network I/O. All optimization methods are intended for resource utilization. To maximize resource utilization is to run SQL statements as efficiently as possible to achieve the highest performance at a lower cost. For example, when performing a typical point query, you can use a combination of Seq Scan and filter (that is, read each tuple and match the point query condition). You can also use Index Scan, which can implement the query at a lower cost but achieve the same effect.

You can determine a proper cluster deployment solution and table definition based on hardware resources and service characteristics. This is the basis of meeting performance requirements. The following performance tuning sections assume that you have finished installation based on a proper cluster solution in the software installation guide and performed database design based on the guide for database design and development.

## 6.1 Query Execution Process

The process from receiving SQL statements to the statement execution by the SQL engine is shown in [Figure 6-1](#) and described in [Table 6-1](#). The texts in red are steps where database administrators can optimize queries.

**Figure 6-1** Execution process of query-related SQL statements by the SQL engine

**Table 6-1** Execution process of query-related SQL statements by the SQL engine

Step	Description
1. Perform syntax and lexical parsing.	Converts the input SQL statements from the string data type to the formatted structure stmt based on the specified SQL statement rules.
2. Perform semantic parsing.	Converts the formatted structure obtained from the previous step into objects that can be recognized by the database.
3. Rewrite the query statements.	Converts the output of the previous step into the structure that optimizes the query execution.
4. Optimize the query.	Determines the execution mode of SQL statements (the execution plan) based on the result obtained from the previous step and the internal database statistics. For details about how the internal database statistics and GUC parameters affect the query optimization (execution plan), see <a href="#">Optimizing Queries Using Statistics</a> and <a href="#">Optimizing Queries Using GUC parameters</a> .
5. Perform the query.	Executes the SQL statements based on the execution path specified in the previous step. Selecting a proper underlying storage mode improves the query execution efficiency.

## Optimizing Queries Using Statistics

The GaussDB optimizer is a typical cost-based optimization (CBO). By using CBO, the database calculates the number of tuples and the execution cost for each step under each execution plan based on the number of table tuples, column width, null record ratio, and characteristic values, such as distinct, MCV, and HB values, and certain cost calculation methods. The database then selects the execution plan that takes the lowest cost for the overall execution or for the return of the first tuple. These characteristic values are the statistics, which is the core for optimizing a query. Accurate statistics helps the analyzer select the most appropriate query plan. Generally, you can collect statistics of a table or that of some columns in a table using ANALYZE. You are advised to periodically execute ANALYZE or execute it immediately after you modified most contents in a table.

## Optimizing Queries Using GUC parameters

Optimizing queries aims to select an efficient execution mode.

Take the following SQL statement as an example:

```
select count(1)
from customer inner join store_sales on (ss_customer_sk = c_customer_sk);
```

During execution of **customer inner join store\_sales**, GaussDB supports nested loop, merge join, and hash join. The optimizer estimates the result set size and the execution cost of each join mode based on the statistics on the **customer** and **store\_sales** tables. It then compares the costs and selects the one costing the least.

As mentioned above, the execution cost is calculated based on certain methods and statistics. If the actual execution cost cannot be accurately estimated, you need to optimize the execution plan by setting GUC parameters. For example, the **random\_page\_cost** parameter indicates the optimizer's calculation of the cost of a non-sequentially-fetched disk page. The default value is **4**. When the random read speed of a machine disk (for example, an SSD) is high, you can decrease the value of this parameter. After the change, the cost of index scanning is reduced, and the index scanning mode is preferred when a plan is generated.

## Optimizing Queries by Rewriting SQL Statements

Besides the preceding methods that improve the performance of the execution plan generated by the SQL engine, database administrators can also enhance SQL statement performance by rewriting SQL statements while retaining the original service logic based on the execution mechanism of the database and abundant practices.

This requires that database administrators know the customer services well and have professional knowledge of SQL statements. Below chapters will describe some common SQL rewriting scenarios.

## 6.2 Introduction to the SQL Execution Plan

## 6.2.1 Overview

The SQL execution plan is a node tree, which displays detailed procedure when GaussDB runs an SQL statement. A database operator indicates one step.

You can run the **EXPLAIN** command to view the execution plan generated for each query by an optimizer. The output of **EXPLAIN** has one row for each execution node, showing the basic node type and the cost estimation that the optimizer made for the execution of this node. The following is an example:

```
gaussdb=# explain select * from t1,t2 where t1.c1=t2.c2;
          QUERY PLAN
-----
Streaming (type: GATHER) (cost=14.17..29.07 rows=20 width=180)
Node/s: All datanodes
-> Hash Join (cost=13.29..27.75 rows=20 width=180)
   Hash Cond: (t2.c2 = t1.c1)
   -> Streaming(type: REDISTRIBUTE) (cost=0.00..14.31 rows=20 width=104)
       Spawn on: All datanodes
       -> Seq Scan on t2 (cost=0.00..13.13 rows=20 width=104)
   -> Hash (cost=13.13..13.13 rows=21 width=76)
       -> Seq Scan on t1 (cost=0.00..13.13 rows=20 width=76)
(9 rows)
```

- Nodes at the bottom level are scan nodes. They scan tables and return raw rows. The types of scan nodes (sequential scans and index scans) vary depending on the table access methods. Objects scanned by the bottom layer nodes may not be row-store data (not directly read from a table), such as VALUES clauses and functions that return rows, which have their own types of scan nodes.
- If the query requires join, aggregation, sorting, or other operations on the raw rows, there will be other nodes above the scan nodes to perform these operations. In addition, there is more than one way to perform these operations, so different types of execution nodes may be displayed here.
- The first row (the upper-layer node) estimates the total execution cost of the execution plan. Such an estimate indicates the value that the optimizer tries to minimize.

## Execution Plan Display Format

GaussDB provides four display formats: normal, pretty, summary, and run.

- normal: indicates that the default printing format is used.
- pretty: indicates that the new plan display format improved by GaussDB is used. The new format contains a plan node ID, directly and effectively analyzing performance.
- summary: indicates that the printing information analysis is added based on the pretty format.
- run: indicates that the information based on the summary format is exported as a CSV file for further analysis.

An example of an execution plan using the pretty format is as follows:

```
gaussdb=# explain select * from t1,t2 where t1.c1=t2.c2;
 id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
 1 | -> Streaming (type: GATHER) | 20 | 180 | 29.07
 2 | -> Hash Join (3,5) | 20 | 180 | 27.75
```

```

3 | -> Streaming(type: REDISTRIBUTE) | 20 | 104 | 14.31
4 | -> Seq Scan on t2 | 20 | 104 | 13.13
5 | -> Hash | 21 | 76 | 13.13
6 | -> Seq Scan on t1 | 20 | 76 | 13.13
(6 rows)

-----
Predicate Information (identified by plan id)
-----
2 --Hash Join (3,5)
Hash Cond: (t2.c2 = t1.c1)
(2 rows)

```

You can change the display format of execution plans by setting the GUC parameter **explain\_perf\_mode**. Later examples use the pretty format by default.

## Execution Plan Information

In addition to setting different display formats for an execution plan, you can use different EXPLAIN syntax to display execution plan information in detail. The following lists the common EXPLAIN syntax. For details about more EXPLAIN syntax, see [EXPLAIN](#).

- EXPLAIN *statement*: only generates an execution plan and does not execute. The *statement* indicates SQL statements.
- EXPLAIN ANALYZE *statement*: generates and executes an execution plan, and displays the execution summary. Then actual execution time statistics are added to the display, including the total elapsed time expended within each plan node (in milliseconds) and the total number of rows it actually returned.
- EXPLAIN PERFORMANCE *statement*: generates and executes the execution plan, and displays all execution information.

To measure the run time cost of each node in the execution plan, the current execution of EXPLAIN ANALYZE or EXPLAIN PERFORMANCE adds profiling overhead to query execution. Executing EXPLAIN ANALYZE or EXPLAIN PERFORMANCE on a query sometimes takes longer time than executing the query normally. The amount of time that exceeds depends on the complexity of the query itself and the platform used.

Therefore, if an SQL statement is not finished after being running for a long time, run the **EXPLAIN** command to view the execution plan and then locate the fault. If the SQL statement has been properly executed, execute EXPLAIN ANALYZE or EXPLAIN PERFORMANCE to check the execution plan and information to locate the fault.

### 6.2.2 Description

As described in [Overview](#), EXPLAIN displays the execution plan, but will not actually run SQL statements. EXPLAIN ANALYZE and EXPLAIN PERFORMANCE both will actually run SQL statements and return the execution information. This section describes the execution plan and execution information in detail.

## Execution Plans

The following SQL statement is used as an example:

```
SELECT * FROM t1, t2 WHERE t1.c1 = t2.c2;
```

Run the **EXPLAIN** command and the output is as follows:

```
gaussdb=# EXPLAIN SELECT * FROM t1,t2 WHERE t1.c1 = t2.c2;
          QUERY PLAN
-----
Hash Join (cost=23.73..341.30 rows=16217 width=180)
  Hash Cond: (t1.c1 = t2.c2)
    -> Seq Scan on t1 (cost=0.00..122.17 rows=5317 width=76)
    -> Hash (cost=16.10..16.10 rows=610 width=104)
        -> Seq Scan on t2 (cost=0.00..16.10 rows=610 width=104)
(5 rows)
```

### Interpretation of the execution plan column (horizontal):

- **id**: ID of a node corresponding to each execution operator
- **operation**: name of an execution operator  
Streaming is a special operator. It implements the core data shuffle function of the distributed architecture. Streaming has three types, which correspond to different data shuffle functions in the distributed architecture:
  - Streaming (type: GATHER): The CN collects data from DNs.
  - Streaming (type: REDISTRIBUTE): Data is redistributed to all the DNs based on selected columns.
  - Streaming (type: BROADCAST): Data on the current DN is broadcast to other DNs.
- **E-rows**: number of output rows estimated by each operator
- **E-memory**: estimated memory used by each operator on a DN. Only operators executed on DNs are displayed. In certain scenarios, the memory upper limit enclosed in parentheses will be displayed following the estimated memory usage. This column is displayed only when the memory usage estimation function is enabled after the **enable\_dynamic\_workload** parameter is set to **on** and the estimated value of an operator is greater than 0.
- **E-width**: estimated width of an output tuple of each operator
- **E-costs**: execution cost estimated by each operator
  - **E-costs** is measured by the optimizer based on an overhead unit. Usually, fetching a disk page is defined as a unit. Other overhead parameters are set based on the unit.
  - The overhead of each node (specified by **E-costs**) includes the overheads of all its child nodes.
  - Such an overhead reflects only what the optimizer is concerned about, but does not consider the time for transferring result rows to the client. Although the time may play a very important role in the actual total time, it is ignored by the optimizer, because it cannot be changed by modifying the plan.

### Interpretation of the execution plan level (vertical):

1. Layer 1: **Seq Scan on t2**  
The table scan operator scans the table **t2** using Seq Scan. At this layer, data in the table **t2** is read from a buffer or disk, and then transferred to the upper-layer node for calculation.
2. Layer 2: **Hash**

Hash operator. It is used to calculate the hash value of the operator transferred from the lower layer for subsequent hash join operations.

### 3. Layer 3: Seq Scan on t1

The table scan operator scans the table **t1** using Seq Scan. At this layer, data in the table **t1** is read from a buffer or disk, and then transferred to the upper-layer node for hash join calculation.

### 4. Layer 4: Hash Join

Join operator. It is used to join data in the **t1** and **t2** tables using the hash join method and output the result data.

## ⚠ CAUTION

If the operator in the top layer is **Data Node Scan**, set **enable\_fast\_query\_shipping** to **off** to view the detailed execution plan. The following is an example plan:

```
gaussdb=# explain select c1,count(1) from t1 group by c1;
          QUERY PLAN
-----
Data Node Scan (cost=0.00..0.00 rows=0 width=0)
Node/s: All datanodes
(2 rows)
```

After **enable\_fast\_query\_shipping** is set, the execution plan will be displayed as follows:

```
gaussdb=# set enable_fast_query_shipping=off;
SET
gaussdb=# explain select c1,count(1) from t1 group by c1;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
1 | -> Streaming (type: GATHER) | 20 | 12 | 14.23
2 | -> HashAggregate | 20 | 12 | 13.30
3 | -> Seq Scan on t1 | 20 | 4 | 13.13
(3 rows)
```

## Keywords in the execution plan:

### 1. Table access modes

- Seq Scan

Scans all rows of the table in sequence.

- Index Scan

The optimizer uses a two-step plan: the child plan node visits an index to find the locations of rows matching the index condition, and then the upper plan node actually fetches those rows from the table itself. Fetching rows separately is much more expensive than reading them sequentially, but because not all pages of the table have to be visited, this is still cheaper than a sequential scan. The upper-layer planning node sorts index-identified rows based on their physical locations before reading them. This minimizes the independent capturing overhead.

If there are separate indexes on multiple columns referenced in the WHERE statement, the optimizer might choose to use an AND or OR combination of the indexes.

The following index scans featured with different sorting mechanisms are involved:

- Bitmap index scan  
Fetches data pages using a bitmap.
  - Index scan using index\_name  
Uses simple index search, which fetches data from an index table in the sequence of index keys. This mode is commonly used when only a small amount of data needs to be fetched from a large data table or when the ORDER BY condition is used to match the index sequence to reduce the sorting time.
  - Index-Only Scan  
Scans the index that contains all required data, instead of referencing a table.
  - Bitmap Heap Scan  
Reads pages from bitmaps created by other operations and filters out the rows that do not meet the conditions. Bitmap heap scan can avoid random I/Os and accelerate read speed.
  - TID Scan  
Scans a table by a tuple ID.
  - Index Ctid Scan  
Scans a table based on the CTID index.
  - CTE Scan  
Specifies that CTE evaluates subquery operations and stores query results as a temporary table. The temporary table is scanned by the CTE Scan operator.
  - Foreign Scan  
Reads data from a remote data source.
  - Function Scan  
Obtains result sets returned by functions and returns them as the rows read from tables.
  - Sample Scan  
Queries and returns sampled data.
  - Subquery Scan  
Reads subquery results.
  - Values Scan  
Reads constants as part of the **VALUES** command.
  - WorkTable Scan  
Scans a work table. Data is read in the middle of an operation which is usually a recursive operation declared using WITH RECURSIVE.
2. Table connection modes
- Nested Loop  
A nested loop is used for queries that have a smaller dataset connected. In a nested loop join, the outer table drives the inner table and each row returned from the outer table should have a matching row in the inner table. The returned result set of all queries should be less than 10,000.

The table that returns a smaller subset will work as an outer table, and indexes are recommended for connection columns of the inner table.

- (Sonic) Hash Join

A hash join is used for large tables. The optimizer uses a hash join, in which rows of one table are entered into an in-memory hash table, after which the other table is scanned and the hash table is probed for matches to each row. Sonic and non-Sonic hash joins differ in their hash table structures, which do not affect the execution result set.

- Merge Join

In most cases, the execution performance of a merge join is lower than that of a hash join. However, if the source data has been pre-sorted and no more sorting is needed during the merge join, its performance excels.

### 3. Operators

- sort

Sorts the result set.

- filter

The EXPLAIN output shows the WHERE clause being applied as a filter condition attached to the Seq Scan plan node. This means that the plan node checks the condition for each row it scans, and returns only the ones that meet the condition. The estimated number of output rows is reduced because of the WHERE clause. However, the scan will still have to visit all 10,000 rows, as a result, the cost is not decreased. It increases a bit (by 10,000 x **cpu\_operator\_cost**) to reflect the extra CPU time spent on checking the WHERE condition.

- LIMIT

Limits the number of output execution results. If a LIMIT condition is added, not all rows are retrieved.

- Append

Appends sub-operation results.

- Aggregate

Aggregates the results generated from querying rows. It can be an aggregation of statements such as GROUP BY, UNION, and SELECT DISTINCT.

- BitmapAnd

Specifies the AND operation of a bitmap, which is used to form a bitmap that matches more complex conditions.

- BitmapOr

Specifies the OR operation of a bitmap, which is used to form a bitmap that matches more complex conditions.

- Gather

Gathers data of parallel threads.

- Group

Groups rows to perform the GROUP BY operation.

- GroupAggregate

Aggregates the pre-sorted rows of the GROUP BY operation.

- Hash  
Hashes rows for the parent query. It is usually used to perform the JOIN operation.
- HashAggregate  
Aggregates the result rows of GROUP BY by using a hash table.
- Merge Append  
Merges subquery results in a way that preserves the sort order. It can be used to merge sorted rows in a table partition.
- ProjectSet  
Executes a function on the returned result set.
- Recursive Union  
Performs a union operation on all steps of a recursive function.
- SetOp  
Specifies a set operation, such as INTERSECT or EXCEPT.
- Unique  
Removes duplicates from an ordered result set.
- HashSetOp  
Specifies a strategy for set operations such as INTERSECT or EXCEPT. It uses Append to avoid pre-sorted input.
- LockRows  
Locks problematic rows to prevent other queries from writing, but allows reading.
- Materialize  
Stores subquery results in the memory so that the parent query can quickly access and obtain the subquery results.
- Result  
Returns a value without scanning.
- WindowAgg  
Specifies a window aggregate function, which is generally triggered by the OVER statement.
- Merge  
Performs a merge operation.
- StartWith Operator  
Specifies the hierarchical query operator, which is used to perform recursive query operations.
- Rownum  
Filters the row number in the query result. It usually appears in the ROWNUM clause.
- Index Cond  
Specifies the index scan conditions.
- Unpivot  
A transpose operator.

4. Partition pruning

- Iterations

Specifies the number of iterations performed by the partition iteration operator on level-1 partitions. If **PART** is displayed, dynamic pruning is used.

For example, **Iterations: 4** indicates that the iteration operator needs to traverse four level-1 partitions. **Iterations: PART** indicates that the number of level-1 partitions to be traversed is determined by parameter conditions of the partition key.

- Selected Partitions

Specifies the selected level-1 partitions for pruning. **m..n** indicates that partitions **m** to **n** are selected. Multiple inconsecutive partitions are separated by commas (,).

For example, **Selected Partitions: 2..4,7** indicates that partitions 2, 3, 4, and 7 are selected.

5. Other keywords

- Partitioned

Indicates operations on a specific partition.

- Partition Iterator

Partition iterator, which usually indicates that a subquery is an operation on a partition.

- InitPlan

Indicates a non-related subplan.

- Remote Query

Indicates a query statement pushed down to a DN.

- Exec Nodes

Indicates nodes where plans are executed.

- Data Node Scan on

Indicates that a statement has been pushed down to a DN for execution.

## Execution Information

In SQL optimization process, you can use EXPLAIN ANALYZE or EXPLAIN PERFORMANCE to check the SQL statement execution information. By comparing estimation differences between actual implementation and the optimizer, basis for service optimization is provided. EXPLAIN PERFORMANCE provides the execution information on each DN, whereas EXPLAIN ANALYZE does not.

The following SQL statement is used as an example:

```
select count(1) from t1;
```

The output of running EXPLAIN PERFORMANCE is as follows:

```
gaussdb=# explain performance select count(1) from t1;
id | operation | A-time | A-rows | E-rows | E-distinct | Peak Memory | E-memory | A-
width | E-width | E-costs
-----+-----+-----+-----+-----+-----+-----+-----+-----
1 | -> Aggregate | 9.326 | 1 | 1 | | 14KB | | | 8 |
```

```

209.10
2 | -> Streaming (type: GATHER) | 9.281 | 2 | 2 | | 80KB | | | 8
| 209.10
3 | -> Aggregate | [5.981,6.491] | 2 | 2 | | [13KB, 13KB] | 1MB | |
8 | 209.01
4 | -> Seq Scan on public.t1 | [2.553,2.909] | 20000 | 20000 | | [15KB, 15KB] | 1MB
| | 0 | 184.00

```

The preceding example shows that the execution information can be classified into the following seven aspects:

1. The plan is displayed as a table, which contains 11 columns: **id**, **operation**, **A-time**, **A-rows**, **E-rows**, **E-distinct**, **Peak Memory**, **E-memory**, **A-width**, **E-width**, and **E-costs**. The meanings of the plan-type columns (**id**, **operation**, or columns started with **E**) are the same as those when EXPLAIN is executed. For details, see [Execution Plans](#). The meanings of **A-time**, **A-rows**, **E-distinct**, **Peak Memory**, and **A-width** are described as follows:
  - **A-time**: execution completion time of the operator. Generally, **A-time** of the operator is two values enclosed with square brackets ([ ]), indicating the shortest time and longest time for completing the operator on all DNs, respectively.
  - **A-rows**: number of actual output tuples of the operator
  - **E-distinct**: estimated distinct value of the hash join operator
  - **Peak Memory**: peak memory of the operator on each DN
  - **A-width**: actual tuple width in each row of the current operator. This parameter is valid only for heavy memory operators, including (Vec)HashJoin, (Vec)HashAgg, (Vec)HashSetOp, (Vec)Sort, and (Vec)Materialize. The (Vec)HashJoin calculation width is the width of its right subtree operator and will be displayed on the right subtree.
2. **Predicate Information (identified by plan id)**:

This part displays the static information that does not change in the plan execution process, such as some join conditions and filter information.

3. **Memory Information (identified by plan id):**  
This part displays the memory usage information printed by certain operators (mainly Hash and Sort), including **peak memory**, **control memory**, **operator memory**, **width**, **auto spread num**, and **early spilled**; and spill details, including **spill Time(s)**, **inner/outer partition spill num**, **temp file num**, spilled data volume, and **written disk IO** [*min*, *max*].
4. **Targetlist Information (identified by plan id):**  
This part displays the target columns provided by each operator.
5. **DataNode Information (identified by plan id):**  
The execution time, CPU, and buffer usage of each operator are printed in this part.
6. **User Define Profiling:**  
This part displays CNs and DN, DN and DN connection time, and some execution information at the storage layer.
7. **=====  
Query Summary  
=====:**  
The total execution time and network traffic, including the maximum and minimum execution time in the initialization and end phases on each DN, the time in the initialization, execution, and end phases on each CN, the system available memory and statement estimation memory information during the current statement execution, are printed in this part.

---

#### NOTICE

- The difference between **A-rows** and **E-rows** shows the deviation between the optimizer estimation and actual execution. Generally, if the deviation is larger, the plan generated by the optimizer is more improper, and more manual intervention and optimization are required.
  - If the difference of the **A-time** values is larger, the operator computing skew (difference between execution time on different DNs) is larger, and more manual intervention and optimization are required.
  - **Max Query Peak Memory** is often used to estimate the consumed memory of SQL statements, and is also used as an important basis for setting a running memory parameter during SQL statement optimization. Generally, the output from EXPLAIN ANALYZE or EXPLAIN PERFORMANCE is provided for the input for further optimization.
- 

## 6.3 Optimization Process

You can analyze slow SQL statements to optimize them.

### Procedure

- Step 1** Collect all table statistics associated with the SQL statements. In a database, statistics indicate the source data of a plan generated by an optimizer. If no collection statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance. According to past experience, about 10%

performance problems occurred because no statistics are collected. For details, see [Updating Statistics](#).

- Step 2** View the execution plan to find out the cause. If the SQL statements have been running for a long period of time and not ended, run the **EXPLAIN** command to view the execution plan and then locate the fault. If the SQL statement has been properly executed, execute **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** to check the execution plan and information to locate the fault. For details about the execution plan, see [Introduction to the SQL Execution Plan](#).
- Step 3** Review and modify a table definition. For details, see [Reviewing and Modifying a Table Definition](#).
- Step 4** For details about **EXPLAIN** or **EXPLAIN PERFORMANCE**, the reason why SQL statements are slowly located, and how to solve this problem, see [Typical SQL Optimization Methods](#).
- Step 5** Generally, some SQL statements can be converted to its equivalent statements in all or certain scenarios by rewriting queries. SQL statements are simpler after they are rewritten. Some execution steps can be simplified to improve the performance. Query rewriting methods are universal in all databases. [Experience in Rewriting SQL Statements](#) describes several tuning methods by rewriting SQL statements.

----End

## 6.4 Updating Statistics

In a database, statistics indicate the source data of a plan generated by an optimizer. If no collection statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance.

### Context

The **ANALYZE** statement collects statistic about table contents in databases, which will be stored in the **PG\_STATISTIC** system catalog. Then, the query optimizer uses the statistics to work out the most efficient execution plan.

After executing batch insertions and deletions, you are advised to run the **ANALYZE** statement on the table or the entire library to update statistics. By default, 30,000 rows of statistics are sampled. That is, the default value of the GUC parameter **default\_statistics\_target** is **100**. If the total number of rows in the table exceeds 1,600,000, you are advised to set **default\_statistics\_target** to **-2**, indicating that 2% of the statistics are collected.

For an intermediate table generated during the execution of a batch script or stored procedure, you also need to run the **ANALYZE** statement.

If there are multiple inter-related columns in a table and the conditions or grouping operations based on these columns are involved in the query, collect statistics about these columns so that the query optimizer can accurately estimate the number of rows and generate an effective execution plan.

If the table has a GSI, perform **ANALYZE** on the base table first and then on the GSI.

## Procedure

Update the statistics about a table or the entire database.

```
ANALYZE tablename;           -- Update statistics about a table.  
ANALYZE;                       -- Update statistics about the entire database.
```

Update statistics about the GSI on the table.

```
ANALYZE GLOBAL INDEX indexname FOR TABLE tablename;
```

### NOTE

To update the statistics about the GSI, perform ANALYZE on the base table first.

Perform statistics-related operations on multiple columns.

```
ANALYZE tablename ((column_1, column_2));           -- Collect statistics about column_1 and  
column_2 of tablename.  
  
ALTER TABLE tablename ADD STATISTICS ((column_1, column_2)); -- Declare statistics about column_1  
and column_2 of tablename.  
ANALYZE tablename;                                     -- Collect statistics about one or more columns.  
  
ALTER TABLE tablename DELETE STATISTICS ((column_1, column_2)); -- Delete statistics about column_1  
and column_2 of tablename or their statistics declaration.
```

### NOTICE

After the statistics are declared for multiple columns by executing the ALTER TABLE *tablename* ADD STATISTICS statement, the system collects the statistics about these columns next time ANALYZE is performed on the table or the entire database.

To collect the statistics, run the **ANALYZE** command.

### NOTE

Use EXPLAIN to show the execution plan of each SQL statement. If **rows** is set to **10** (the default value, probably indicating that the table has not been analyzed) is displayed in the SEQ SCAN output of a table, execute the ANALYZE statement for this table.

## 6.5 Reviewing and Modifying a Table Definition

### 6.5.1 Overview

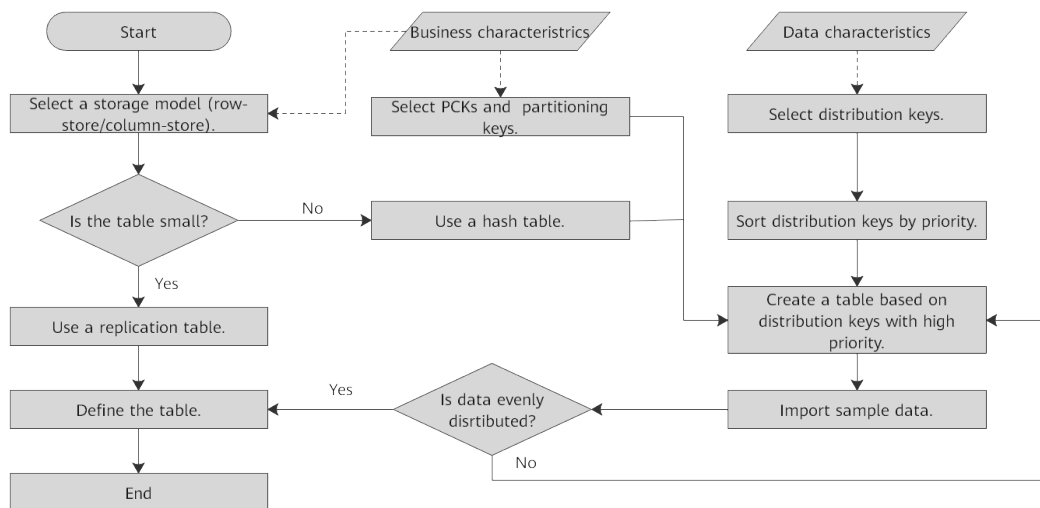

In a distributed framework, data is distributed on DNs. Data on one or more DNs is stored on a physical storage device. To properly define a table, you must:

1. Evenly distribute data on each DN to avoid the available capacity decrease of a cluster caused by insufficient storage space of the storage device associated with a DN. Specifically, select a proper distribution key to avoid data skew.
2. Evenly assign table scanning tasks on each DN to avoid that a single DN is overloaded by the table scanning tasks. Specifically, do not select columns in the equivalent filter of a base table as the distribution key.
3. Reduce the data volume scanned by using the partition pruning mechanism.

4. Minimize random I/Os by using clustering.
5. Avoid data shuffle and reduce the network pressure by selecting the **join-condition** or **group by** column as the distribution key.

The distribution key is the core for defining a table. **Figure 6-2** shows the procedure of defining a table. The table definition is created during the database design and is reviewed and modified during the SQL statement optimization.

**Figure 6-2** Procedure of defining a table

## 6.5.2 Selecting a Distribution Mode

In replication mode, full data in a table is copied to each DN in the cluster. This mode is used for tables containing a small volume of data. The advantage of this storage mode is that each DN has full data of the table. During the join operation, data does not need to be redistributed, reducing network overheads and reducing plan segments (each plan segment starts a corresponding thread). The disadvantage is that each DN retains the complete data of the table, resulting in data redundancy. Generally, this mode is only used for small dimension tables.

In hash mode, hash values are generated for one or more columns. You can obtain the storage location of a tuple based on the mapping between DNs and the hash values. In a hash table, I/O resources on each node can be used during data read/write, which improves the read/write speed of a table. Generally, a table containing a large amount of data is defined as a hash table.

Range distribution and list distribution are user-defined distribution policies. Values in a distribution key are within a certain range or fall into a specific value range of the corresponding target DN. The two distribution modes facilitate flexible data management, which, however, requires users equipped with certain data abstraction capability. For details, see **Table 6-2**.

**Table 6-2** Policies and application scenarios

Policy	Description	Application Scenario
Hash	Table data is distributed on all DNs in the cluster.	Fact tables containing a large amount of data
Replication	Full data in a table is stored on every DN in the cluster.	Small tables and dimension tables
Range	Table data is mapped to specified columns based on the range and distributed to the corresponding DNs.	Users need to customize distribution rules.
List	Table data is mapped to specified columns based on specific values and distributed to corresponding DNs.	Users need to customize distribution rules.

As shown in [Figure 6-3](#), **T1** is a replication table and **T2** is a hash table.

**Figure 6-3** Replication tables and hash tables

**NOTE**

- When you insert, modify, or delete data in a replication table, if you use the shippable or immutable function to encapsulate components that cannot be pushed down, data on different DNs in the replication table may be inconsistent.
- If statements with unstable results, such as window functions, user-defined functions, and ROWNUM and limit clauses are used to insert or modify data in a replication table, data on different nodes may be different.

### 6.5.3 Selecting Distribution Keys

Selecting a distribution key for a hash table is essential. Details are as follows:

1. Ensure that the column values are discrete so that data can be evenly distributed to each DN. You can select the primary key of the table as the

distribution key. For example, for a person information table, choose the ID card number column as the distribution key.

2. Do not select the column that has a constant filter. If a constant constraint (for example, `zqdh='000001'`) exists on the `zqdh` column in some queries on the `dwjck` table, you are advised not to use `zqdh` as the distribution key.
3. Select the join condition as the distribution key, so that join tasks can be pushed down to DNs to execute, reducing the amount of data transferred between the DNs.

For a hash table, an improper distribution key may cause data skew or poor I/O performance on certain DNs. Therefore, you need to check the table to ensure that data is evenly distributed on each DN. You can run the following SQL statements to check for data skew:

```
select
xc_node_id, count(1)
from tablename
group by xc_node_id
order by xc_node_id desc;
```

`xc_node_id` corresponds to a DN. Generally, over 5% difference between the amount of data on different DNs is regarded as data skew. If the difference is over 10%, choose another distribution key.

Multiple distribution keys can be selected in GaussDB to evenly distribute data.

You can select the distribution key of the range or list distribution table as required. In addition to selecting a proper distribution key, pay attention to the impact of distribution rules on data distribution.

## 6.5.4 Using Partitioned Tables

Partitioning refers to splitting what is logically one large table into smaller physical pieces based on specific schemes. The table based on the logic is called a partitioned table, and a physical piece is called a partition. Data is stored on these physical partitions, instead of the logical partitioned table. A partitioned table has the following advantages over an ordinary table:

1. High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
2. High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
3. Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.

GaussDB supports range partitioned tables, list partitioned tables, and hash partitioned tables.

- Range partitioned table: Data in different ranges is mapped to different partitions. The range is determined by the partition key specified during the partitioned table creation. The partition key is usually a date. For example, sales data is partitioned by month.
- List partitioned table: Key values contained in the data are stored in different partitions, and the data is mapped to each partition in sequence. The key values contained in the partitions are specified when the partitioned table is created.

- Hash partitioned table: Data is mapped to each partition based on the internal hash algorithm. The number of partitions is specified when the partitioned table is created.

## 6.5.5 Selecting a Data Type

Use the following principles to select efficient data types:

1. **Select data types that facilitate data calculation.**

Generally, the calculation of integers (including common comparison calculations, such as =, >, <, ≥, ≤, and ≠ and GROUP BY) is more efficient than that of strings and floating point numbers.

2. **Select data types with a short length.**

Data types with short length reduce both the data file size and the memory used for computing, improving the I/O and computing performance. For example, use SMALLINT instead of INT, and INT instead of BIGINT.

3. **Use the same data type for a join.**

You are advised to use the same data type for a join. To join columns with different data types, the database needs to convert them to the same type, which leads to additional performance overheads.

## 6.6 Typical SQL Optimization Methods

SQL optimization involves continuous analysis and trying. Queries are run before they are used for services to determine whether the performance meets requirements. If it does not, queries will be optimized by [checking the execution plan](#) and identifying the causes. Then, the queries will be run and optimized again until they meet the requirements.

### 6.6.1 Optimizing SQL Self-diagnosis

Performance issues may occur when you query data or run the INSERT, DELETE, UPDATE, or CREATE TABLE AS statement.

Alarms that can trigger SQL self-diagnosis depend on the settings of the GUC parameter **resource\_track\_level**. If **resource\_track\_level** is set to **query**, alarms about the failures in collecting column statistics and pushing down SQL statements will trigger the diagnosis. If **resource\_track\_level** is set to **operator**, all alarms will trigger the diagnosis.

Whether an SQL plan will be diagnosed depends on the settings of the GUC parameter **resource\_track\_cost**. An SQL plan will be diagnosed only if its execution cost is greater than **resource\_track\_cost**. You can use the EXPLAIN keyword to check the plan execution cost.

The SQL self-diagnosis function is affected by the **enable\_analyze\_check** parameter. Ensure that the function is enabled before using it.

If a large number of statements are executed, certain data may fail to be collected due to memory control. In this case, you can increase the value of **instr\_unique\_sql\_count**.

## Alarms

Currently, the following performance alarms will be reported:

- Some column statistics are not collected.

An alarm will be reported if some column statistics are not collected.

Example alarms:

No statistics about a table are not collected.

```
Statistic Not Collect:  
schema_test.t1
```

The statistics about a single column are not collected.

```
Statistic Not Collect:  
schema_test.t2(c1,c2)
```

The statistics about multiple columns are not collected.

```
Statistic Not Collect:  
schema_test.t3((c1,c2))
```

The statistics about a single column and multiple columns are not collected.

```
Statistic Not Collect:  
schema_test.t4(c1,c2) schema_test.t4((c1,c2))
```

- SQL statements are not pushed down.  
The cause details are displayed in the alarms. For details about the optimization method, see [Optimizing Statement Pushdown](#).
  - If the pushdown failure is caused by functions, the function names are displayed in the alarm.
  - If the pushdown failure is because of the syntax, the alarm indicates that the syntax does not support pushdown. For example, syntaxes containing the **With Recursive**, **Distinct On**, or **Row** expression do not support pushdown.

Example alarms:

```
SQL is not plan-shipping, reason : "With Recursive" can not be shipped"  
SQL is not plan-shipping, reason : "Function now() can not be shipped"  
SQL is not plan-shipping, reason : "Function string_agg() can not be shipped"
```

- In a hash join, the larger table is used as the inner table.

An alarm will be reported if the number of rows in the inner table reaches or exceeds 10 times of that in the outer table, more than 100,000 inner-table rows are processed on each DN in average, and the join statement has spilled to disks. You can check whether a hash join is used. For details about the optimization, see [Hint-based Optimization](#).

- **nestloop** is used in a large-table equivalent join.

An alarm will be reported if **nestloop** is used in an equivalent join where more than 100,000 larger-table rows are processed on each DN in average. You can check whether **nestloop** is used. For details about the optimization, see [Hint-based Optimization](#).

Example alarms:

```
PlanNode[5] Large Table with Equal-Condition use Nestloop"Nested Loop"
```

- A large table is broadcasted.

An alarm will be reported if more than 100 thousand of rows are broadcast on each DN in average. For details about the optimization, see [Hint-based Optimization](#).

Example alarms:

```
PlanNode[5] Large Table in Broadcast "Streaming(type: BROADCAST dop: 1/2)"
```

- Data skew occurs.

An alarm will be reported if the number of rows processed on any DN exceeds 100,000, and the number of rows processed on a DN reaches or exceeds 10 times of that processed on another DN.

Example alarms:

```
PlanNode[6] DataSkew:"Seq Scan", min_dn_tuples:0, max_dn_tuples:524288
```

- Estimation is inaccurate.

An alarm will be reported if the maximum number or the estimated maximum number of rows processed on a DN is over 100,000, and the larger number reaches or exceeds 10 times of the smaller one. For details about the optimization, see [Hint-based Optimization](#).

Example alarms:

```
PlanNode[5] Inaccurate Estimation-Rows: "Hash Join" A-Rows:0, E-Rows:52488
```

## Restrictions

1. An alarm contains a maximum of 2048. If the length of an alarm exceeds this value (for example, a large number of long table names and column names are displayed in the alarm when their statistics are not collected), a warning instead of an alarm will be reported.  

```
WARNING, "Planner issue report is truncated, the rest of planner issues will be skipped"
```
2. If a query statement contains the **Limit** operator, alarms of operators lower than **Limit** will not be reported.
3. For alarms about data skew and inaccurate estimation, only alarms on the lower-layer nodes in a plan tree will be reported. This is because the same alarms on the upper-level nodes may be triggered by problems on the lower-layer nodes. For example, if data skew occurs on the **Scan** node, data skew may also occur in operators (for example, **Hashagg**) at the upper layer.

## 6.6.2 Optimizing Statement Pushdown

### Statement Pushdown

Currently, the GaussDB optimizer can use three methods to develop statement execution policies in the distributed framework: generating a statement pushdown plan, a distributed execution plan, or a distributed execution plan for sending statements.

- A statement pushdown plan pushes complete query statements from a CN down to DNs for execution and returns the execution results to the CN.
- In a distributed execution plan, a CN compiles and optimizes query statements, generates a plan tree, and then sends the plan tree to DNs for

execution. After the statements have been executed, execution results will be returned to the CN.

- A distributed execution plan for sending statements pushes queries that can be pushed down (mostly base table scanning statements) to DNs for execution. Then, the plan obtains the intermediate results and sends them to the CN, on which the remaining queries are to be executed.

The third policy sends many intermediate results from DNs to the CN for further execution. In this case, the CN performance bottleneck (in bandwidth, storage, and computing) is caused by statements that cannot be pushed down to DNs. Therefore, you are advised not to use the query statements where only the third policy applies.

Statements cannot be pushed down if they have **functions that do not support pushdown** or **syntax that does not support pushdown**. Generally, you can rewrite the execution statements to solve the problem.

## Typical Scenarios of Statement Pushdown

In the GaussDB optimizer, if you want to support statement pushdown, set the GUC parameter **enable\_fast\_query\_shipping** to **on**. Generally, no execution plan operator is displayed after the EXPLAIN statement. If the keyword "Data Node Scan on" in the execution plan is displayed in the first line (excluding the plan format), the statement has been pushed down to DNs for execution. The following describes statement pushdown and its supported scope from multiple scenarios:

### 1. Pushdown of single-table query statements

In a distributed database, to query a single table, whether the current statement can be pushed down depends on whether the CN needs to participate in calculation instead of simply collecting data. If the CN needs to further calculate the DN result, the statement cannot be pushed down. Generally, statements with keywords such as `agg`, `windows function`, `limit/offset`, `sort`, `distinct` cannot be pushed down.

- Pushdown: Simple queries can be pushed down without further calculation on the CN.

```
gaussdb=# explain select * from t where c1 > 1;
          QUERY PLAN
-----
Data Node Scan on "_REMOTE_FQS_QUERY_" (cost=0.00..0.00 rows=0 width=0)
Node/s: All datanodes
(2 rows)
```

- Non-pushdown: A CN with the `limit` clause cannot simply send statements to DNs and collect data, which is inconsistent with the semantics of the `limit` clause.

```
gaussdb=# explain select * from t limit 1;
          QUERY PLAN
-----
Limit (cost=0.00..0.00 rows=1 width=12)
-> Data Node Scan on "_REMOTE_LIMIT_QUERY_" (cost=0.00..0.00 rows=1 width=12)
Node/s: All datanodes
(3 rows)
```

- Non-pushdown: A CN with the aggregate function cannot simply push down statements. Instead, it needs to further aggregate the results collected from DNs.

```
gaussdb=# explain select sum(c1), count(*) from t;
          QUERY PLAN
```

```
-----
Aggregate (cost=0.10..0.11 rows=1 width=20)
-> Data Node Scan on "__REMOTE_GROUP_QUERY__" (cost=0.00..0.00 rows=20 width=4)
   Node/s: All datanodes
(3 rows)
```

## 2. Pushdown of multi-table query statements

In the multi-table query scenario, whether a statement can be pushed down depends on the join condition and distribution keys. That is, if the join condition matches the distribution keys of the table, the statement can be pushed down. Otherwise, the statement cannot be pushed down. Generally, a replication table can be pushed down.

- Create two hash distribution tables.

```
gaussdb=# create table t(c1 int, c2 int, c3 int) distribute by hash(c1);
CREATE TABLE
gaussdb=# create table t1(c1 int, c2 int, c3 int) distribute by hash(c1);
CREATE TABLE
```

- Pushdown: The join condition meets the hash distribution key attributes of two tables.

```
gaussdb=# explain select * from t1 join t on t.c1 = t1.c1;
QUERY PLAN
```

```
-----
Data Node Scan on "__REMOTE_FQS_QUERY__" (cost=0.00..0.00 rows=0 width=0)
  Node/s: All datanodes
(2 rows)
```

- Non-pushdown: The join condition does not meet the hash distribution key attribute. That is, **t1.c2** is not the distribution key of **t1**.

```
gaussdb=# explain select * from t1 join t on t.c1 = t1.c2;
QUERY PLAN
```

```
-----
Hash Join (cost=0.25..0.53 rows=20 width=24)
  Hash Cond: (t1.c2 = t.c1)
  -> Data Node Scan on t1 "__REMOTE_TABLE_QUERY__" (cost=0.00..0.00 rows=20 width=12)
       Node/s: All datanodes
  -> Hash (cost=0.00..0.00 rows=20 width=12)
       -> Data Node Scan on t "__REMOTE_TABLE_QUERY__" (cost=0.00..0.00 rows=20 width=12)
           Node/s: All datanodes
(7 rows)
```

- Delete two hash distribution tables.

```
gaussdb=# DROP TABLE t;
DROP TABLE
gaussdb=# DROP TABLE t1;
DROP TABLE
```

## 3. Collection operation and CTE pushdown

Whether statements in the collection operation scenario can be pushed down depends on whether the left and right subqueries can be pushed down. The rules are as follows:

- UNION ALL can be pushed down only when both the left and right branches can be pushed down and the DNs of the left and right branches are the same.
- The collection operation can be pushed down only when the left and right branches of UNION/INTERSECT/INTERSECT ALL/EXCEPT/EXCEPT ALL can be pushed down to the same single node.

```
-- The test environment contains one CN and six DNs.
-- Create a node group. You can run the SELECT node_name FROM PGXC_NODE WHERE node_type = 'D' command to query the DN name in the node group. In the query result, replace the DN name following WITH in the CREATE NODE GROUP statement as required.
gaussdb=# CREATE NODE GROUP ng WITH(datanode1, datanode2, datanode3, datanode4, datanode5, datanode6);
CREATE NODE GROUP
```

```

-- Create a table.
gaussdb=# CREATE TABLE t1(a int, b int, c int) DISTRIBUTE BY HASH(a) TO GROUP ng;
CREATE TABLE
gaussdb=# CREATE TABLE t2(a int, b int, c int) DISTRIBUTE BY HASH(a) TO GROUP ng;
CREATE TABLE
-- Both sides of UNION ALL can be pushed down. Therefore, UNION ALL can be pushed down.
gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t1 UNION ALL SELECT * FROM t2;
QUERY PLAN
-----
Data Node Scan
  Node/s: All datanodes
(2 rows)

-- Both sides of UNION can be pushed down, but not to a single DN. Therefore, UNION cannot
be pushed down.
gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t1 UNION SELECT * FROM t2;
QUERY PLAN
-----
Streaming (type: GATHER)
  Node/s: All datanodes
  -> HashAggregate
    Group By Key: t1.a, t1.b, t1.c
    -> Append
      -> Seq Scan on t1
      -> Seq Scan on t2
(7 rows)

-- Both sides of UNION can be pushed down to the same DN. Therefore, UNION can be pushed
down.
gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t1 WHERE a = 1 UNION SELECT * FROM t2
WHERE a = 1;
QUERY PLAN
-----
Data Node Scan
  Node/s: (ng) datanode5
(2 rows)

gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t1 WHERE a = 1;
QUERY PLAN
-----
Data Node Scan
  Node/s: (ng) datanode5
(2 rows)

gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t2 WHERE a = 3;
QUERY PLAN
-----
Data Node Scan
  Node/s: (ng) datanode4
(2 rows)

-- Both sides of UNION can be pushed down, but not to the same DN. Therefore, UNION
cannot be pushed down.
gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t1 WHERE a = 1 UNION SELECT * FROM t2
WHERE a = 3;
QUERY PLAN
-----
Streaming (type: GATHER)
  Node/s: (GenGroup) datanode4, datanode5
  -> Unique
    -> Sort
      Sort Key: t1.a, t1.b, t1.c
    -> Append
      -> Seq Scan on t1
        Filter: (a = 1)
      -> Seq Scan on t2
        Filter: (a = 3)
(10 rows)

```

Whether statements in the CTE scenario can be pushed down depends on whether statements in the CTE scenario can be pushed down. The rules are as follows:

- The entire CTE can be pushed down only when statements in a CTE can be pushed down.
- For a recursive CTE, the recursive part references its CTE. When determining whether the recursive part can be pushed down, the pushdown information of the self-referenced CTE depends on the pushdown information of the non-recursive part. That is, the non-recursive statement can be regarded as a subquery of the self-referenced CTE.
- An entire recursive CTE can be pushed down only when statements in the recursive CTE can be pushed down, and the recursive and non-recursive statements can be pushed down to the same DN.

```
-- Statements in the CTE can be pushed down. Therefore, the CTE can be pushed down.
gaussdb=# EXPLAIN (COSTS OFF) WITH cte AS (SELECT * FROM t1) SELECT * FROM cte;
QUERY PLAN
```

```
-----
Data Node Scan
Node/s: All datanodes
(2 rows)
```

```
-- Statements in the CTE can be pushed down to a single DN. Therefore, the CTE can be pushed down to a single DN.
```

```
gaussdb=# EXPLAIN (COSTS OFF) WITH cte AS (SELECT * FROM t1 WHERE a = 1) SELECT * FROM cte;
QUERY PLAN
```

```
-----
Data Node Scan
Node/s: (ng) datanode5
(2 rows)
```

```
-- Statements in the CTE cannot be pushed down. Therefore, the CTE cannot be pushed down.
gaussdb=# EXPLAIN (COSTS OFF) WITH cte AS (SELECT * FROM t1 ORDER BY a ) SELECT * FROM cte;
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Sort
Sort Key: t1.a
-> Seq Scan on t1
(5 rows)
```

```
-- Statements in the recursive CTE can be pushed down, and the recursive and non-recursive parts can be pushed down to multiple same DNs. Therefore, the recursive CTE can be pushed down to multiple DNs.
```

```
gaussdb=# EXPLAIN (COSTS OFF)
WITH RECURSIVE cte AS (
SELECT * FROM t1
UNION ALL
SELECT t2.* FROM t2, cte WHERE cte.a = t2.a) SELECT *FROM cte;
QUERY PLAN
```

```
-----
Data Node Scan
Node/s: All datanodes
(2 rows)
```

```
-- Statements in the recursive CTE can be pushed down, and the recursive and non-recursive parts can be pushed down to a single DN. Therefore, the recursive CTE can be pushed down to the single DN.
```

```
gaussdb=# EXPLAIN (COSTS OFF)
WITH RECURSIVE cte AS (
SELECT * FROM t1 WHERE a = 1
```

```

UNION ALL
SELECT t2.* FROM t2, cte WHERE cte.a = t2.a AND t2.a = 1) SELECT * FROM cte;
QUERY PLAN
-----
Data Node Scan
  Node/s: (ng) datanode5
(2 rows)

-- Statements in the recursive CTE cannot be pushed down. Therefore, the recursive CTE cannot
be pushed down.
gaussdb=# EXPLAIN (COSTS OFF)
WITH RECURSIVE cte AS (
SELECT * FROM t1
UNION
SELECT t2.* FROM t2, cte WHERE cte.a = t2.a
) SELECT *FROM cte;
QUERY PLAN
-----
CTE Scan on cte
  CTE cte
  -> Recursive Union
    -> Data Node Scan on t1 "_REMOTE_TABLE_QUERY_"
      Node/s: All datanodes
    -> Hash Join
      Hash Cond: (cte.a = t2.a)
      -> WorkTable Scan on cte
      -> Hash
        -> Data Node Scan on t2 "_REMOTE_TABLE_QUERY_"
          Node/s: All datanodes
(11 rows)
gaussdb=# DROP TABLE t1;
DROP TABLE
gaussdb=# DROP TABLE t2;
DROP TABLE
gaussdb=# DROP NODE GROUP ng;
DROP NODE GROUP

```

#### 4. Special scenarios

The pushdown rules and restrictions in some special scenarios are as follows:

- A statement cannot be pushed down if it is not a SELECT statement but contains WITH RECURSIVE CTE, common CTE, or collection operation.
- A statement cannot be pushed down if it contains elements that cannot be pushed down (such as volatile functions, not shippable functions, agg functions, returning clauses, and triggers that cannot be pushed down).
- If a CTE, recursive CTE, collection operation, subquery, or sublink cannot tailor a DN based on constant conditions, you can rewrite the statement to write conditions to the CTE, recursive CTE, collection operation, subquery, or sublink.
- When a CTE, recursive CTE, or collection operation is joined with the main query, the entire statement can be pushed down only when the distribution information of the CTE, recursive CTE, or collection operation is the same as that of objects in the main query and the pushdown conditions are met.
- In multi-table query scenarios, if a distributed table contains multiple distribution keys and the distribution keys in query conditions contain parameters, the gplan cannot be pushed down.

### Checking Whether the Execution Plan Has Been Pushed Down

Perform the following procedure to quickly determine whether the execution plan can be pushed down:

**Step 1** Set the GUC parameter **enable\_fast\_query\_shipping** to **off** to use the distributed framework policy for the query optimizer.

```
SET enable_fast_query_shipping = off;
```

**Step 2** View the execution plan.

If the execution plan contains Data Node Scan nodes, the execution plan is a distributed execution plan for sending statements and cannot be pushed down. If the execution plan contains Streaming nodes, the SQL statements can be pushed down to DNs.

For example:

```
gaussdb=# explain select
count(ss.ss_sold_date_sk order by ss.ss_sold_date_sk)c1
from store_sales ss, store_returns sr
where
sr.sr_customer_sk = ss.ss_customer_sk;
```

The execution plan is as follows, which indicates that the SQL statement cannot be pushed down.

```

-----
QUERY PLAN
-----
Aggregate
-> Hash Join
Hash Cond: (ss.ss_customer_sk = sr.sr_customer_sk)
-> Data Node Scan on store_sales "_REMOTE_TABLE_QUERY_"
Node/s: All datanodes
-> Hash
-> Data Node Scan on store_returns "_REMOTE_TABLE_QUERY_"
Node/s: All datanodes
(8 rows)

```

----End

## Syntax That Does Not Support Pushdown

SQL syntax that does not support pushdown is described using the following table definition examples:

```
gaussdb=# CREATE TABLE CUSTOMER1
(
  C_CUSTKEY    BIGINT NOT NULL
, C_NAME      VARCHAR(25) NOT NULL
, C_ADDRESS   VARCHAR(40) NOT NULL
, C_NATIONKEY INT NOT NULL
, C_PHONE     CHAR(15) NOT NULL
, C_ACCTBAL   DECIMAL(15,2) NOT NULL
, C_MKTSEGMENT CHAR(10) NOT NULL
, C_COMMENT   VARCHAR(117) NOT NULL
)
DISTRIBUTE BY hash(C_CUSTKEY);
gaussdb=# CREATE TABLE test_stream(a int, b float); --float does not support redistribution.
gaussdb=# CREATE TABLE sal_emp ( c1 integer[] ) DISTRIBUTE BY replication;
```

- The RETURNING statement cannot be pushed down.

```
gaussdb=# explain update customer1 set C_NAME = 'a' returning c_name;
QUERY PLAN
-----
Update on customer1 (cost=0.00..0.00 rows=30 width=187)
Node/s: All datanodes
Node expr: c_custkey
-> Data Node Scan on customer1 "_REMOTE_TABLE_QUERY_" (cost=0.00..0.00 rows=30 width=187)
Node/s: All datanodes
(5 rows)
```

- The ORDER BY statement cannot be pushed down in aggregate functions.  
gaussdb=# explain verbose select count ( c\_custkey order by c\_custkey) from customer1;

```

QUERY PLAN
-----
Aggregate (cost=2.50..2.51 rows=1 width=8)
Output: count(customer1.c_custkey ORDER BY customer1.c_custkey)
-> Data Node Scan on customer1 "_REMOTE_TABLE_QUERY_" (cost=0.00..0.00 rows=30 width=8)
   Output: customer1.c_custkey
   Node/s: All datanodes
   Remote query: SELECT c_custkey FROM ONLY public.customer1 WHERE true
(6 rows)

```

- If an SQL statement contains COUNT(DISTINCT expr) and columns in COUNT(DISTINCT expr) do not support redistribution, this statement cannot be pushed down.

```

gaussdb=# explain verbose select count(distinct b) from test_stream;
QUERY PLAN
-----
Aggregate (cost=2.50..2.51 rows=1 width=8)
Output: count(DISTINCT test_stream.b)
-> Data Node Scan on test_stream "_REMOTE_TABLE_QUERY_" (cost=0.00..0.00 rows=30 width=8)
   Output: test_stream.b
   Node/s: All datanodes
   Remote query: SELECT b FROM ONLY public.test_stream WHERE true
(6 rows)

```

- A statement containing DISTINCT ON cannot be pushed down.

```

gaussdb=# explain verbose select distinct on (c_custkey) c_custkey from customer1 order by c_custkey;
QUERY PLAN
-----
Unique (cost=49.83..54.83 rows=30 width=8)
Output: customer1.c_custkey
-> Sort (cost=49.83..52.33 rows=30 width=8)
   Output: customer1.c_custkey
   Sort Key: customer1.c_custkey
   -> Data Node Scan on customer1 "_REMOTE_TABLE_QUERY_" (cost=0.00..0.00 rows=30 width=8)
      Output: customer1.c_custkey
      Node/s: All datanodes
      Remote query: SELECT c_custkey FROM ONLY public.customer1 WHERE true
(9 rows)

```

- A statement containing array expressions cannot be pushed down.

```

gaussdb=# explain verbose select array[c_custkey,1] from customer1 order by c_custkey;
QUERY PLAN
-----
Sort (cost=49.83..52.33 rows=30 width=8)
Output: (ARRAY[customer1.c_custkey, 1::bigint]), customer1.c_custkey
Sort Key: customer1.c_custkey
-> Data Node Scan on "_REMOTE_SORT_QUERY_" (cost=0.00..0.00 rows=30 width=8)
   Output: (ARRAY[customer1.c_custkey, 1::bigint]), customer1.c_custkey
   Node/s: All datanodes
   Remote query: SELECT ARRAY[c_custkey, 1::bigint], c_custkey FROM ONLY public.customer1
WHERE true ORDER BY 2
(7 rows)

```

- **Table 1 Scenarios where a statement containing WITH RECURSIVE cannot be pushed down** describes scenarios where a statement containing WITH RECURSIVE cannot be pushed down in the current version, as well as the causes.

**Table 6-3** Scenarios where a statement containing WITH RECURSIVE cannot be pushed down

No.	Scenario	Cause of Not Supporting Pushdown
1	The query contains foreign tables.	<p>LOG: SQL can't be shipped, reason: RecursiveUnion contains ForeignScan is not shippable (In this table, <b>LOG</b> describes the cause of not supporting pushdown.)</p> <p>In the current version, queries containing foreign tables do not support pushdown.</p>
2	Multiple node groups exist.	<p>LOG: SQL can't be shipped, reason: With-Recursive under multi-nodegroup scenario is not shippable</p> <p>In the current version, pushdown is supported only when all base tables are stored and computed in the same node group.</p>
3	UNION does not contain ALL, and deduplication is required.	<p>LOG: SQL can't be shipped, reason: With-Recursive does not contain "ALL" to bind recursive &amp; none-recursive branches</p> <p>For example:</p> <pre data-bbox="1002 1223 1431 1503"> WITH recursive t_result AS ( SELECT dm,sj_dm,name,1 as level FROM test_rec_part WHERE sj_dm &gt; 10 UNION SELECT t2.dm,t2.sj_dm,t2.name  ' &gt; '   t1.name,t1.level+1 FROM t_result t1 JOIN test_rec_part t2 ON t2.sj_dm = t1.dm ) SELECT * FROM t_result t;                     </pre>

No.	Scenario	Cause of Not Supporting Pushdown
4	A base table contains a system catalog.	<p>LOG: SQL can't be shipped, reason: With-Recursive contains system table is not shippable</p> <p>For example:</p> <pre>WITH RECURSIVE x(id) AS ( select count(1) from pg_class where oid=1247 UNION ALL SELECT id+1 FROM x WHERE id &lt; 5 ), y(id) AS ( select count(1) from pg_class where oid=1247 UNION ALL SELECT id+1 FROM x WHERE id &lt; 10 ) SELECT y.*, x.* FROM y LEFT JOIN x USING (id) ORDER BY 1;</pre>
5	Only the VALUES clause is used for scanning base tables. In this case, the statement need to be executed only on the CN.	<p>LOG: SQL can't be shipped, reason: With-Recursive contains only values rte is not shippable</p> <p>For example:</p> <pre>WITH RECURSIVE t(n) AS ( VALUES (1) UNION ALL SELECT n+1 FROM t WHERE n &lt; 100 ) SELECT sum(n) FROM t;</pre>
6	Only the recursion part has correlation conditions of correlated subqueries, and the non-recursion part has no correlation condition.	<p>LOG: SQL can't be shipped, reason: With-Recursive recursive term correlated only is not shippable</p> <p>For example:</p> <pre>select a.ID,a.Name, ( with recursive cte as ( select ID, PID, NAME from b where b.ID = 1 union all select parent.ID,parent.PID,parent.NAME from cte as child join b as parent on child.pid=parent.id where child.ID = a.ID ) select NAME from cte limit 1 ) cName from ( select id, name, count(*) as cnt from a group by id,name ) a order by 1,2;</pre>

No.	Scenario	Cause of Not Supporting Pushdown
7	The <b>replicate</b> plan is used for limit in the non-recursion part but the <b>hash</b> plan is used in the recursion part, resulting in conflicts.	<p>LOG: SQL can't be shipped, reason: With-Recursive contains conflict distribution in none-recursive(Replicate) recursive(Hash)</p> <p>For example:</p> <pre>WITH recursive t_result AS ( select * from( SELECT dm,sj_dm,name,1 as level FROM test_rec_part WHERE sj_dm &lt; 10 order by dm limit 6 offset 2) UNION all SELECT t2.dm,t2.sj_dm,t2.name  ' &gt; '   t1.name,t1.level+1 FROM t_result t1 JOIN test_rec_part t2 ON t2.sj_dm = t1.dm ) SELECT * FROM t_result t;</pre>
8	<b>recursive</b> of multiple-layers are nested. That is, a <b>recursive</b> is nested in the recursion part of another <b>recursive</b> .	<p>LOG: SQL can't be shipped, reason: Recursive CTE references recursive CTE "cte"</p> <p>For example:</p> <pre>with recursive cte as ( select * from rec_tb4 where id&lt;4 union all select h.id,h.parentID,h.name from ( with recursive cte as ( select * from rec_tb4 where id&lt;4 union all select h.id,h.parentID,h.name from rec_tb4 h inner join cte c on h.id=c.parentID ) ) SELECT id ,parentID,name from cte order by parentID ) h inner join cte c on h.id=c.parentID ) SELECT id ,parentID,name from cte order by parentID,1,2,3;</pre>

Delete the tables.

```
gaussdb=# DROP TABLE CUSTOMER1;
DROP TABLE
gaussdb=# DROP TABLE test_stream;
DROP TABLE
gaussdb=# DROP TABLE sa_emp;
DROP TABLE
```

## Functions That Do Not Support Pushdown

The following describes the volatility of functions. In GaussDB, every function has a volatility classification, with the possibilities being:

- **IMMUTABLE**  
Indicates that the function always returns the same result if the parameter values are the same.
- **STABLE**  
Indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same parameter value, but its result varies by SQL statements.
- **VOLATILE**  
Indicates that the function value can change in a single table scan and no optimization is performed.

The volatility of a function can be obtained by querying for its **provolatile** column in `pg_proc`. The value **i** indicates immutable, **s** indicates stable, and **v** indicates volatile. The valid values of the **proshippable** column in `pg_proc` are **t**, **f**, and **NULL**. This column and the **provolatile** column together describe whether a function is pushed down.

- If the **provolatile** of a function is **i**, the function can be pushed down regardless of the value of **proshippable**.
- If the **provolatile** of a function is **s** or **v**, the function can be pushed only if the value of **proshippable** is **t**.
- CTEs containing **random**, **exec\_hadoop\_sql**, or **exec\_on\_extension** are not pushed down, because pushdown may lead to incorrect results.

When creating a user-defined function, you can specify the values of **provolatile** and **proshippable**. For details, see [CREATE FUNCTION](#).

In scenarios where a function does not support pushdown, perform one of the following as required:

- If it is a system function, replace it with a functionally equivalent one.
- If it is a user-defined function, check whether its **provolatile** and **proshippable** are correctly defined.

## Example: User-Defined Function

Define a user-defined function that generates fixed output for a certain input as the immutable type.

Take the sales information of TPC Benchmark DS (TPC-DS) as an example. If you want to write a function to calculate the discount data of a product, you can define the function as follows:

```
CREATE FUNCTION func_percent_2 (NUMERIC, NUMERIC) RETURNS NUMERIC
AS 'SELECT $1 / $2 WHERE $2 > 0.01'
LANGUAGE SQL
VOLATILE;
```

Run the following statements:

```
SELECT func_percent_2(ss_sales_price, ss_list_price)
FROM store_sales;
```

The execution plan is as follows.

```
Data Node Scan on store_sales "REMOTE_TABLE_QUERY"  
Output: func_percent_2(store_sales.ss_sales_price, store_sales.ss_list_price)  
Remote query: SELECT ss_sales_price, ss_list_price FROM ONLY store_sales WHERE true  
(3 rows)
```

**func\_percent\_2** is not pushed down, and **ss\_sales\_price** and **ss\_list\_price** are executed on a CN. In this case, a large amount of resources on the CN is consumed, and the performance deteriorates as a result.

In this example, the function generates the same output when the same input is provided. Therefore, we can modify the function to the following one:

```
CREATE FUNCTION func_percent_1 (NUMERIC, NUMERIC) RETURNS NUMERIC  
AS 'SELECT $1 / $2 WHERE $2 > 0.01'  
LANGUAGE SQL  
IMMUTABLE;
```

Run the following statements:

```
SELECT func_percent_1(ss_sales_price, ss_list_price)  
FROM store_sales;
```

The execution plan is as follows.

```
Data Node Scan  
Output: (func_percent_1(store_sales.ss_sales_price, store_sales.ss_list_price))  
Remote query: SELECT func_percent_1(ss_sales_price, ss_list_price) AS func_percent_1 FROM store_sales  
(3 rows)
```

The **func\_percent\_1** function is pushed down to DNs for execution.

## 6.6.3 Optimizing Subqueries

### Context

When an application runs an SQL statement to operate the database, a large number of subqueries are used because they are more clear than table join. Especially in complicated query statements, subqueries have more complete and independent semantics, which makes SQL statements clearer and easier to understand. Therefore, subqueries are widely used.

In GaussDB, subqueries can also be called sublinks based on the location of subqueries in SQL statements.

- Subquery: corresponds to a range table (RangeTblEntry) in the query parse tree. That is, a subquery is a SELECT statement following immediately after the FROM keyword.
- Sublink: corresponds to an expression in the query parsing tree. That is, a sublink is a statement in the **WHERE** or **ON** clause or in the target list.

In conclusion, a subquery is a range table and a sublink is an expression in the query parsing tree. A sublink can be found in constraint conditions and expressions. In GaussDB, sublinks can be classified into the following types:

- exist\_sublink: corresponds to the EXIST and NOT EXIST statements.
- any\_sublink: corresponds to the *op* ANY(SELECT...) statement. *op* can be the <, >, or = operator. IN/NOT IN (SELECT...) also belongs to this type.
- all\_sublink: corresponds to the *op* ALL(SELECT...) statement. *op* can be the <, >, or = operator.
- rowcompare\_sublink: corresponds to the RECORD *op* (SELECT...) statement.

- `expr_sublink`: corresponds to the (SELECT with a single target list item...) statement.
- `array_sublink`: corresponds to the ARRAY(SELECT...) statement.
- `cte_sublink`: corresponds to the WITH(...) query statement.

The `exist_sublink` and `any_sublink` are pulled up by the optimization engine of GaussDB. In addition, `expr_sublink` can also be pulled up. However, because of the flexible use of subqueries in SQL statements, complex subqueries may affect query performance. If you do not want to pull up `expr_sublink`, set the GUC parameter **rewrite\_rule**. Subqueries are classified into non-correlated subqueries and correlated subqueries.

- **Non-correlated subqueries**

The execution of a subquery is independent from attributes of the outer query. In this way, a subquery can be executed before outer queries.

For example:

```
gaussdb=# explain select t1.c1,t1.c2
from t1
where t1.c1 in (
  select c2
  from t2
  where t2.c2 IN (2,3,4)
);
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Right Semi Join
   Hash Cond: (t2.c2 = t1.c1)
   -> Streaming(type: REDISTRIBUTE)
       Spawn on: All datanodes
       -> Seq Scan on t2
           Filter: (c2 = ANY ('{2,3,4}'::integer[]))
   -> Hash
       -> Seq Scan on t1
(10 rows)
```

- **Correlated subqueries**

The execution of a subquery depends on some attributes (used as **AND** conditions of the subquery) of outer queries. In the following example, **t1.c1** in the **t2.c1 = t1.c1** condition is a correlated attribute. Such a subquery depends on outer queries and needs to be executed once for each outer query.

For example:

```
gaussdb=# explain select t1.c1,t1.c2
from t1
where t1.c1 in (
  select c2
  from t2
  where t2.c1 = t1.c1 AND t2.c2 in (2,3,4)
);
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on t1
   Filter: (SubPlan 1)
   SubPlan 1
   -> Result
       Filter: (t2.c1 = t1.c1)
       -> Materialize
           -> Streaming(type: BROADCAST)
```

```
Spawn on: All datanodes
-> Seq Scan on t2
   Filter: (c2 = ANY ('{2,3,4}'::integer[]))
(12 rows)
```

## Sublink Optimization on GaussDB

To optimize a sublink, a subquery is pulled up to join with tables in outer queries, preventing the subquery from being converted into a plan involving subplans and broadcast. You can run the EXPLAIN statement to check whether a sublink is converted into the combination of a subplan and broadcast.

Example

- **Sublink-release scenarios supported by GaussDB**

- Pulling up the **IN** sublink

- The subquery cannot contain columns in the outer query (columns in more outer queries are allowed).
- The subquery cannot contain volatile functions.

Example

- Pulling up the **EXISTS** sublink

The WHERE clause must contain a column in the outer query. Other parts of the subquery cannot contain the column. Other restrictions are as follows:

- The subquery must contain the FROM clause.
- The subquery cannot contain the **WITH** clause.
- The subquery cannot contain aggregate functions.
- The subquery cannot contain a **SET, SORT, LIMIT, WindowAgg, or HAVING** operation.
- The subquery cannot contain volatile functions.

Example:

- Pulling up an equivalent correlated query containing aggregate functions  
The WHERE condition of the subquery must contain a column from the outer query. Equivalence comparison must be performed between this column and related columns in tables of the subquery. These conditions must be connected using AND. Other parts of the subquery cannot contain the column. Other restrictions are as follows:

- The columns in the expression in the WHERE condition of the subquery must exist in tables.
- After the SELECT keyword of the subquery, there must be only one output column. The output column must be an aggregate function (for example, **MAX**), and the parameter (for example, **t2.c2**) of the aggregate function cannot be columns of a table (for example, **t1**) in outer queries. The aggregate function cannot be COUNT.

For example, the following subquery can be pulled up:

```

select * from t1 where c1 >(
  select max(t2.c1) from t2 where t2.c1=t1.c1
);

```

The following subquery cannot be pulled up because the subquery has no aggregate function:

```

select * from t1 where c1 >(
  select t2.c1 from t2 where t2.c1=t1.c1
);

```

The following subquery cannot be pulled up because the subquery has two output columns:

```

select * from t1 where (c1,c2) >(
  select max(t2.c1),min(t2.c2) from t2 where t2.c1=t1.c1
);

```

- The subquery must be a FROM clause.
- The subquery cannot contain a GROUP BY, HAVING, or SET operation.
- The subquery can only be an inner join.

For example, the following subquery cannot be pulled up:

```

select * from t1 where c1 >(
  select max(t2.c1) from t2 full join t3 on (t2.c2=t3.c2) where t2.c1=t1.c1
);

```

- The target list of the subquery cannot contain the function that returns a set.
- The **WHERE** condition of the subquery must contain a column from the outer query. Equivalence comparison must be performed between this column and related columns in tables of the subquery.

These conditions must be connected using **AND**. Other parts of the subquery cannot contain the column. For example, the following subquery can be pulled up:

```
select * from t3 where t3.c1=(
  select t1.c1
  from t1 where c1 >(
    select max(t2.c1) from t2 where t2.c1=t1.c1
  ));
```

If another condition is added to the subquery in the previous example, the subquery cannot be pulled up because the subquery references to the column in the outer query. Example:

```
select * from t3 where t3.c1=(
  select t1.c1
  from t1 where c1 >(
    select max(t2.c1) from t2 where t2.c1=t1.c1 and t3.c1>t2.c2
  ));
```

– Pulling up a sublink in the **OR** clause

If the WHERE condition contains an EXIST correlated sublink connected by OR, the following is an example:

```
select a, c from t1
where t1.a = (select avg(a) from t3 where t1.b = t3.b) or
exists (select * from t4 where t1.c = t4.c);
```

The process of pulling up such a sublink is as follows:

- i. Extract **opExpr** from the OR clause in the WHERE condition. The value is **t1.a = (select avg(a) from t3 where t1.b = t3.b)**.
- ii. The **opExpr** operation contains a subquery. If the subquery can be pulled up, the subquery is rewritten as **select avg(a), t3.b from t3 group by t3.b**, generating the NOT NULL condition **t3.b is not null**. **opExpr** is replaced by this NOT NULL condition. In this case, the SQL statement changes to:

```
select a, c
from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b) as t3 on (t1.a = avg
and t1.b = t3.b)
where t3.b is not null or exists (select * from t4 where t1.c = t4.c);
```

- iii. Extract the **EXISTS** sublink **exists (select \* from t4 where t1.c = t4.c)** from the OR clause to check whether the sublink can be pulled up. If it can be pulled up, the subquery is converted into **select t4.c from t4 group by t4.c**, generating the NOT NULL condition **t4.c is not null**. In this case, the SQL statement changes to:

```
select t1.a, t1.c from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b) as t3 on
(t1.a = avg and t1.b = t3.b) left join (select t5.c from t5 group by t5.c) as t5 on (t1.c =
t5.c) where t3.b is not null or t5.c is not null;
```

• **Sublink-release scenarios not supported by GaussDB**

Except the sublinks described above, all the other sublinks cannot be pulled up. In this case, a join subquery is planned as the combination of subplans and broadcast. As a result, if inner tables have a large amount of data, query performance may be poor.

If a correlated subquery joins with two tables in outer queries, the subquery cannot be pulled up. You need to change the outer query into a WITH clause and then perform the join.

For example:

```
select distinct t1.a, t2.a
from t1 left join t2 on t1.a=t2.a and not exists (select a,b from test1 where test1.a=t1.a and
test1.b=t2.a);
```

The rewriting is as follows:

```
with temp as
(
  select * from (select t1.a as a, t2.a as b from t1 left join t2 on t1.a=t2.a)
)
select distinct a,b
from temp
where not exists (select a,b from test1 where temp.a=test1.a and temp.b=test1.b);
```

- The subquery (without COUNT) in the target list cannot be pulled up.

For example:

```
gaussdb=# explain (costs off)
select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
from t1
where t1.c2 > 10;
```

The execution plan is as follows:

```
gaussdb=# explain (costs off)
select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
from t1
where t1.c2 > 10;
QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on t1
Filter: (c2 > 10)
SubPlan 1
-> Result
Filter: (t1.c1 = t2.c1)
-> Materialize
-> Streaming(type: BROADCAST)
Spawn on: All datanodes
-> Seq Scan on t2
(11 rows)
```

The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met. Therefore, use a right outer join to join **t2** and **t1** so that the SSQ can return padding values when the condition **t1.c1=t2.c1** is not met.

#### NOTE

ScalarSubQuery (SSQ) and Correlated-ScalarSubQuery (CSSQ) are described as follows:

- SSQ: a sublink that returns a scalar value of a single row with a single column
- CSSQ: an SSQ containing correlation conditions

The preceding SQL statement can be changed into:

```
with ssq as
(
  select * from t1 where t1.c2 > 10
)
select t2.c2,ssq.c2 from t2 right join ssq on ssq.c1 = t2.c1;
```

The execution plan after the change is as follows:

```
QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Right Join
Hash Cond: (t2.c1 = t1.c1)
-> Seq Scan on t2
-> Hash
-> Seq Scan on t1
```

Filter: (c2 > 10)  
(8 rows)

In the preceding example, the SSQ in the target list is pulled up to right join, preventing poor performance caused by the plan involving subplans and broadcast when the table (**t2**) in the subquery is too large.

- The subquery (with COUNT) in the target list cannot be pulled up.

For example:

```
select (select count(*) from t2 where t2.c1=t1.c1) cnt, t1.c1, t3.c1
from t1,t3
where t1.c1=t3.c1 order by cnt, t1.c1;
```

The execution plan is as follows:

```
QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Sort
    Sort Key: ((SubPlan 1)), t1.c1
-> Hash Join
    Hash Cond: (t1.c1 = t3.c1)
-> Seq Scan on t1
-> Hash
    -> Seq Scan on t3
SubPlan 1
-> Aggregate
    -> Result
        Filter: (t2.c1 = t1.c1)
    -> Materialize
        -> Streaming(type: BROADCAST)
            Spawn on: All datanodes
        -> Seq Scan on t2
```

(17 rows)

The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met. Therefore, use left outer join to join **T1** and **T2** so that SSQ can return padding values when the condition **t1.c1=t2.c1** is not met. However, COUNT is used, which requires that **0** is returned when the condition is not met. Therefore, case-when NULL then 0 else count(\*) can be used.

The preceding SQL statement can be changed into:

```
with ssq as
(
    select count(*) cnt, c1 from t2 group by c1
)
select case when
    ssq.cnt is null then 0
    else ssq.cnt
end cnt, t1.c1, t3.c1
from t1 left join ssq on ssq.c1 = t1.c1,t3
where t1.c1 = t3.c1
order by ssq.cnt, t1.c1;
```

The execution plan after the change is as follows:

```
QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Sort
    Sort Key: (count(*)), t1.c1
-> Hash Join
    Hash Cond: (t1.c1 = t3.c1)
-> Hash Left Join
    Hash Cond: (t1.c1 = t2.c1)
    -> Seq Scan on t1
```

```

-> Hash
   -> HashAggregate
       Group By Key: t2.c1
       -> Seq Scan on t2
-> Hash
   -> Seq Scan on t3
(15 rows)

```

- Non-equivalent correlated subqueries cannot be pulled up.

For example:

```

select t1.c1, t1.c2
from t1
where t1.c1 = (select agg() from t2.c2 > t1.c2);

```

Non-equivalent correlated sublinks cannot be pulled up. You can perform join twice (one CorrelationKey and one rownum self-join) to rewrite the statement.

You can rewrite the statement in either of the following ways:

- Subquery rewriting:

```

select t1.c1, t1.c2
from t1, (
  select t1.rowid, agg() aggref
  from t1,t2
  where t1.c2 > t2.c2 group by t1.rowid
) dt /* derived table */
where t1.rowid = dt.rowid AND t1.c1 = dt.aggref;

```

- CTE rewriting:

```

WITH dt as
(
  select t1.rowid, agg() aggref
  from t1,t2
  where t1.c2 > t2.c2 group by t1.rowid
)
select t1.c1, t1.c2
from t1, dt
where t1.rowid = dt.rowid AND
t1.c1 = dt.aggref;

```

## NOTICE

- Currently, GaussDB does not have an effective way to provide globally unique row IDs for tables and intermediate result sets. Therefore, the rewriting is difficult. It is recommended that this issue is avoided at the service layer or by using **t1.xc\_nodeid + t1.ctid** to associate row IDs. However, the high repetition rate of **xc\_nodeid** leads to low association efficiency, and **xc\_node\_id+ctid** cannot be used as the join condition of a hash join.
- If the AGG type is COUNT(\*), **0** is used for data padding when **CASE-WHEN** is not matched. If the type is not COUNT(\*), **NULL** is used.
- CTE rewriting works better by using sharescan.

## More Optimization Examples

Example 1: Change the base table to a replication table and create an index on the filter column.

```
create table master_table (a int);
create table sub_table(a int, b int);
select a from master_table group by a having a in (select a from sub_table);
```

In this example, a correlated subquery is contained. To improve the query performance, you can change **sub\_table** to a replication table when creating a table and create an index on the **a** column.

Example 2: Modify the SELECT statement to change the subquery to a join relationship between the main table and the parent query, or modify the subquery to improve the query performance. Ensure that the subquery to be used is semantically correct.

```
gaussdb=# explain (costs off)select * from master_table as t1 where t1.a in (select t2.a from sub_table as t2
where t1.a = t2.b);
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on master_table t1
   Filter: (SubPlan 1)
   SubPlan 1
   -> Result
       Filter: (t1.a = t2.b)
       -> Materialize
           -> Streaming(type: BROADCAST)
               Spawn on: All datanodes
               -> Seq Scan on sub_table t2
(11 rows)
```

In the preceding example, a subplan is used. To remove the subplan, you can modify the statement as follows:

```
gaussdb=# explain(costs off) select * from master_table as t1 where exists (select t2.a from sub_table as t2
where t1.a = t2.b and t1.a = t2.a);
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Semi Join
   Hash Cond: (t1.a = t2.b)
   -> Seq Scan on master_table t1
   -> Hash
       -> Streaming(type: REDISTRIBUTE)
           Spawn on: All datanodes
           -> Seq Scan on sub_table t2
(9 rows)
```

In this way, the subplan is replaced by the semi-join between the two tables, greatly improving the execution efficiency.

## 6.6.4 Optimizing Statistics

### Context

GaussDB generates optimal execution plans based on the cost estimation. Optimizers need to estimate the number of data rows and the cost based on statistics collected using ANALYZE. Therefore, the statistics is vital for the estimation of the number of rows and cost. Global statistics are collected using ANALYZE: **relpages** and **reltuples** in the pg\_class table; **stadiinct**, **stanullfrac**, **stanumbersN**, **stavaluesN**, and **histogram\_bounds** in the pg\_statistic table.

## Example 1: Poor Query Performance Due to the Lack of Statistics

In most cases, the lack of statistics about tables or columns involved in the query greatly affects the query performance.

The table structure is as follows:

```
CREATE TABLE LINEITEM
(
  L_ORDERKEY      BIGINT      NOT NULL
, L_PARTKEY      BIGINT      NOT NULL
, L_SUPPKEY      BIGINT      NOT NULL
, L_LINENUMBER   BIGINT      NOT NULL
, L_QUANTITY     DECIMAL(15,2) NOT NULL
, L_EXTENDEDPRICE DECIMAL(15,2) NOT NULL
, L_DISCOUNT   DECIMAL(15,2) NOT NULL
, L_TAX         DECIMAL(15,2) NOT NULL
, L_RETURNFLAG   CHAR(1)     NOT NULL
, L_LINESTATUS   CHAR(1)     NOT NULL
, L_SHIPDATE     DATE        NOT NULL
, L_COMMITDATE   DATE        NOT NULL
, L_RECEIPTDATE  DATE        NOT NULL
, L_SHIPINSTRUCT CHAR(25)    NOT NULL
, L_SHIPMODE     CHAR(10)    NOT NULL
, L_COMMENT      VARCHAR(44) NOT NULL
) distribute by hash(L_ORDERKEY);

CREATE TABLE ORDERS
(
  O_ORDERKEY      BIGINT      NOT NULL
, O_CUSTKEY      BIGINT      NOT NULL
, O_ORDERSTATUS   CHAR(1)     NOT NULL
, O_TOTALPRICE   DECIMAL(15,2) NOT NULL
, O_ORDERDATE    DATE        NOT NULL
, O_ORDERPRIORITY CHAR(15)    NOT NULL
, O_CLERK        CHAR(15)    NOT NULL
, O_SHIPPRIORITY  BIGINT      NOT NULL
, O_COMMENT      VARCHAR(79) NOT NULL
) distribute by hash(O_ORDERKEY);
```

The query statements are as follows:

```
explain verbose select
count(*) as numwait
from
lineitem l1,
orders
where
o_orderkey = l1.l_orderkey
and o_orderstatus = 'F'
and l1.l_receiptdate > l1.l_commitdate
and not exists (
select
*
from
lineitem l3
where
l3.l_orderkey = l1.l_orderkey
and l3.l_suppkey <> l1.l_suppkey
and l3.l_receiptdate > l3.l_commitdate
)
order by
numwait desc;
```

If such an issue occurs, you can use the following methods to check whether statistics in tables or columns has been collected using ANALYZE:

1. Execute EXPLAIN VERBOSE to analyze the execution plan and check the warning information:

```
WARNING:Statistics in some tables or columns(public.lineitem.l_receiptdate,  
public.lineitem.l_commitdate, public.lineitem.l_orderkey, public.lineitem.l_suppkey,  
public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.  
HINT:Do analyze for them in order to generate optimized plan.
```

2. Check whether the following information exists in the log file in the **gs\_log** directory; if it does, the poor query performance was caused by the lack of statistics in some tables or columns:

```
2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] LOG:Statistics in some tables  
or columns(public.lineitem.l_receiptdate, public.lineitem.l_commitdate, public.lineitem.l_orderkey,  
public.linei  
tem.l_suppkey, public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.  
2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] HINT:Do analyze for them in  
order to generate optimized plan.
```

By using any of the preceding methods, you can identify tables or columns whose statistics have not been collected using ANALYZE. You can execute ANALYZE to warnings or tables and columns recorded in logs to resolve the problem.

## Example 2: Optimization is Not Accurate When Intermediate Results Exist in the Query Where JOIN Is Used for Multiple Tables

**Symptom:** Query the personnel who have registered in an Internet cafe within 15 minutes before and after the registration of a specified person.

```
SELECT  
C.WBM,  
C.DZQH,  
C.DZ,  
B.ZJHM,  
B.SWKSSJ,  
B.XWSJ  
FROM  
b_zyk_wbswxx A,  
b_zyk_wbswxx B,  
b_zyk_wbcs C  
WHERE  
A.ZJHM = '522522*****3824'  
AND A.WBDM = B.WBDM  
AND A.WBDM = C.WBDM  
AND abs(to_date(A.SWKSSJ,'yyyymmddHH24MISS') - to_date(B.SWKSSJ,'yyyymmddHH24MISS')) <  
INTERVAL '15 MINUTES'  
ORDER BY  
B.SWKSSJ,  
B.ZJHM  
limit 10 offset 0  
;
```

**Figure 6-4** shows the execution plan. This query takes about 12s.

Figure 6-4 Using an unlogged table (1)

```

QUERY PLAN
-----
Limit (cost=221021.41..221021.43 rows=10 width=120)
-> Sort (cost=221021.41..221022.01 rows=240 width=120)
    Sort Key: b.swkssj, b.zjhm
    -> Streaming (type: GATHER) (cost=221015.62..221016.22 rows=240 width=120)
        Node/s: All datanodes
        -> Limit (cost=9205.98..9209.01 rows=10 width=120)
            Sort Key: b.swkssj, b.zjhm
            -> Nested Loop (cost=23.27..9186.34 rows=1048 width=120)
                Join Filter: (((a.zjhm)::text <> (b.zjhm)::text) AND ((a.wbdm)::text = (b.wbdm)::text)
                AND (abs(((to_date((a.swkssj)::text, 'yyyymmddHH24MISS')::text
                - to_date((b.swkssj)::text, 'yyyymmddHH24MISS')::text))::numeric) < .0104166666666667))
                -> Streaming (type: BROADCAST) (cost=0.00..6.33 rows=24 width=135)
                    Spawn on: All datanodes
                    -> Nested Loop (cost=0.00..106.80 rows=1 width=135)
                        -> Streaming (type: BROADCAST) (cost=0.00..24.75 rows=264 width=48)
                            Spawn on: All datanodes
                            -> Partition Iterator (cost=0.00..48.44 rows=11 width=48)
                                Iterations: 25
                                -> Partitioned Index Scan using idx_b_zyk_wbswxx_zjhm on b_zyk_wbswxx a (cost=0.00..48.44 rows=11 width=48)
                                    Index Cond: ((zjhm)::text = '522522*****3824')::text
                                    Selected Partitions: 1..25
                                -> Index Scan using idx_b_zyk_wbcs_wbdm on b_zyk_wbcs c (cost=0.00..2.82 rows=1 width=87)
                                    Index Cond: ((wbdm)::text = (a.wbdm)::text)
                            -> Partition Iterator (cost=23.27..7306.33 rows=2454 width=63)
                                Iterations: 25
                                -> Partitioned Bitmap Heap Scan on b_zyk_wbswxx b (cost=23.27..7306.33 rows=2454 width=63)
                                    Recheck Cond: ((wbdm)::text = (c.wbdm)::text)
                                    Filter: ('522522198405243824')::text <> (zjhm)::text
                                    Selected Partitions: 1..25
                                -> Partitioned Bitmap Index Scan on idx_b_zyk_wbswxx_wbdm (cost=0.00..22.65 rows=2454 width=0)
                                    Index Cond: ((wbdm)::text = (c.wbdm)::text)

```

**Optimization analysis:**

1. In the execution plan, index scan is used for node scanning, the Join Filter calculation in the external NEST LOOP JOIN statement consumes most of the query time, and the calculation uses the string addition and subtraction, and unequal-value comparison.
2. Use an unlogged table to record the Internet access time of the specified person. The start time and end time are processed during data insertion, and this reduces subsequent addition and subtraction operations.

```

// Create a temporary unlogged table.
CREATE UNLOGGED TABLE temp_tsw
(
    ZJHM      NVARCHAR2(18),
    WBDM      NVARCHAR2(14),
    SWKSSJ_START NVARCHAR2(14),
    SWKSSJ_END   NVARCHAR2(14),
    WBM        NVARCHAR2(70),
    DZQH       NVARCHAR2(6),
    DZ         NVARCHAR2(70),
    IPDZ       NVARCHAR2(39)
)
;
// Insert the Internet access record of the specified person, and process the start time and end time.
INSERT INTO
temp_tsw
SELECT
A.ZJHM,
A.WBDM,
to_char((to_date(A.SWKSSJ,'yyyymmddHH24MISS') - INTERVAL '15
MINUTES'),'yyyymmddHH24MISS'),
to_char((to_date(A.SWKSSJ,'yyyymmddHH24MISS') + INTERVAL '15
MINUTES'),'yyyymmddHH24MISS'),
B.WBM,B.DZQH,B.DZ,B.IPDZ
FROM
b_zyk_wbswxx A,
b_zyk_wbcs B
WHERE
A.ZJHM='522522*****3824' AND A.WBDM = B.WBDM
;

// Query the personnel who have registered in an Internet cafe before and after 15 minutes of the
registration of the specified person. Convert their ID card number format to int8 in comparison.

```

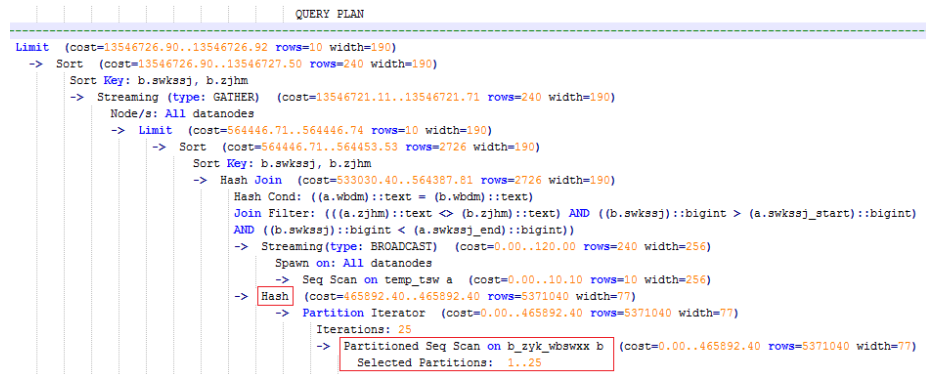

```

SELECT
A.WBM,
A.DZQH,
A.DZ,
A.IPDZ,
B.ZJHM,
B.XM,
to_date(B.SWKSSJ,'yyyymmddHH24MISS') as SWKSSJ,
to_date(B.XWSJ,'yyyymmddHH24MISS') as XWSJ,
B.SWZDH
FROM temp_tsw A,
b_zyk_wbswxx B
WHERE
A.ZJHM <> B.ZJHM
AND A.WBDM = B.WBDM
AND (B.SWKSSJ)::int8 > (A.swkssj_start)::int8
AND (B.SWKSSJ)::int8 < (A.swkssj_end)::int8
order by
B.SWKSSJ,
B.ZJHM
limit 10 offset 0
;

```

The query takes about 7s. [Figure 6-5](#) shows the execution plan.

**Figure 6-5** Using an unlogged table (2)

3. In the previous plan, a hash join has been executed, and a Hash table has been created for the large table `b_zyk_wbswxx` (Internet access information in the Internet cafe). The table contains large amounts of data, so the creation takes long time.

`temp_tsw` (Internet access user information) contains only hundreds of records, and an equal-value connection is created between `temp_tsw` and `b_zyk_wbswxx` (Internet access information in the Internet cafe) using `wbdm` (an Internet cafe code). Therefore, if JOIN is changed to NEST LOOP JOIN, index scan can be used for node scanning, and the performance will be boosted.

4. Change JOIN to NEST LOOP JOIN.  
SET enable\_hashjoin = off;

[Figure 6-6](#) shows the execution plan. The query takes about 3s.

Figure 6-6 Using an unlogged table (3)

```

QUERY PLAN
-----
Limit (cost=240002336196.14..240002336196.17 rows=10 width=190)
-> Sort (cost=240002336196.14..240002336196.74 rows=240 width=190)
    Sort Key: b.swkssj, b.zjhm
    -> Streaming (type: GATHER) (cost=240002336190.35..240002336190.95 rows=240 width=190)
        Node/s: All datanodes
        -> Limit (cost=10000097341.26..10000097341.29 rows=10 width=190)
            -> Sort (cost=10000097341.26..10000097348.08 rows=2726 width=190)
                Sort Key: b.swkssj, b.zjhm
                -> Nested Loop (cost=10000000000.00..10000097282.36 rows=2726 width=190)
                    -> Streaming (type: BROADCAST) (cost=0.00..120.00 rows=240 width=256)
                        Spawn on: All datanodes
                        -> Seq Scan on temp_tsw a (cost=0.00..10.10 rows=10 width=256)
                    -> Partition Iterator (cost=0.00..9648.34 rows=273 width=77)
                        Iterations: 25
                        -> Partitioned Index Scan using idx_b_zyk_wbswxx_wbdm on b_zyk_wbswxx b (cost=0.00..9648.34 rows=273 width=77)
                            Index Cond: ((wbdm)::text = (a.wbdm)::text)
                            Filter: (((a.zjhm)::text <> (zjhm)::text) AND ((swkssj)::bigint > (a.swkssj_start)::bigint)
                                AND ((swkssj)::bigint < (a.swkssj_end)::bigint))
                            Selected Partitions: 1..25
(10 rows)

```

5. Save the query result set in the unlogged table for paging display.

If paging display needs to be achieved on the upper-layer application page, change the **offset** value to determine the result set on the target page. In this way, the previous query statement will be executed every time after a page turning operation, which causes long response latency.

To resolve this problem, the unlogged table is recommended to save the result set.

```

// Create an unlogged table to save the result set.
CREATE UNLOGGED TABLE temp_result
(
WBM NVARCHAR2(70),
DZQH NVARCHAR2(6),
DZ NVARCHAR2(70),
IPDZ NVARCHAR2(39),
ZJHM NVARCHAR2(18),
XM NVARCHAR2(30),
SWKSSJ date,
XWSJ date,
SWZDH NVARCHAR2(32)
);

// Insert the result set to the unlogged table. The insertion takes about 3s.
INSERT INTO
temp_result
SELECT
A.WBM,
A.DZQH,
A.DZ,
A.IPDZ,
B.ZJHM,
B.XM,
to_date(B.SWKSSJ,'yyyymmddHH24MISS') as SWKSSJ,
to_date(B.XWSJ,'yyyymmddHH24MISS') as XWSJ,
B.SWZDH
FROM temp_tsw A,
b_zyk_wbswxx B
WHERE
A.ZJHM <> B.ZJHM
AND A.WBDM = B.WBDM
AND (B.SWKSSJ)::int8 > (A.swkssj_start)::int8
AND (B.SWKSSJ)::int8 < (A.swkssj_end)::int8
;

// Perform paging query on the result set. The paging query takes about 10 ms.
SELECT
*
FROM
temp_result
ORDER BY
SWKSSJ,

```

```
ZJHM
LIMIT 10 OFFSET 0;
```

**CAUTION**

Collecting more accurate statistics usually improves the query performance, but may also deteriorate the performance. If the performance deteriorates, you can:

- Restore to the default statistics.
- Use hints to force the optimizer to use the optimal query plan. (For details, see [Hint-based Optimization](#).)

## 6.6.5 Optimizing Operators

### Context

A query statement needs to go through multiple operator procedures to generate the final result. Sometimes, the overall query performance deteriorates due to long execution time of certain operators, which are regarded as bottleneck operators. In this case, you need to run the **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** command to view the bottleneck operators, and then perform optimization.

For example, in the following execution process, the execution time of the Hashagg operator accounts for about 66% [(51016-13535)/56476 ≈ 66%] of the total execution time. Therefore, the Hashagg operator is the bottleneck operator for this query. Optimize this operator first.

id	operation	A-time	A-rows	E-rows	Peak Memory	E-memory	A-width	E-width	E-costs
1	-> Row Adapter	56476.397	10000000	237060	19KB			20	2093222.75
2	-> Vector Streaming (type: GATHER)	85664.220	10000000	237060	249KB			20	2093222.75

### Example

Example 1: Scan the base table. For queries requiring large volume of data filtering, such as point queries or queries that need range scanning, a full table scan using SeqScan will take a long time. To facilitate scanning, you can create indexes on the condition column and select IndexScan for index scanning.

```
gaussdb=# explain (analyze on,costs off) select * from t1 where c2=10004;
id | operation | A-time | A-rows | Peak Memory | A-width
-----+-----+-----+-----+-----+-----
1 | -> Streaming (type: GATHER) | 20.040 | 5 | 85KB |
2 | -> Seq Scan on t1 | [17.239,17.376] | 5 | [18KB,18KB] |
(2 rows)

Predicate Information (identified by plan id)
-----
2 --Seq Scan on t1
Filter: (c2 = 10004)
Rows Removed by Filter: 90002
(3 rows)
gaussdb=# create index idx on t1(c2);
CREATE INDEX
gaussdb=# explain (analyze on,costs off) select * from t1 where c2=10004;
```

```

id | operation | A-time | A-rows | Peak Memory | A-width
-----+-----+-----+-----+-----+-----
1 | -> Streaming (type: GATHER) | 3.206 | 5 | 85KB |
2 | -> Index Scan using idx on t1 | [0.122,0.146] | 5 | [73KB,73KB] |
(2 rows)

Predicate Information (identified by plan id)
-----+-----
2 --Index Scan using idx on t1
Index Cond: (c2 = 10004)
(2 rows)

```

In this example, the full table scan filters large amounts of data and returns 5 records. After an index has been created on the **c2** column, the scanning efficiency is significantly boosted and the duration of IndexScan is reduced from 20 ms to 3 ms.

Example 2: If NestLoop is used for joining tables with a large number of rows, the join may take a long time. In the following example, NestLoop takes 5s. If **enable\_mergejoin** is set to **off** to disable merge join and **enable\_nestloop** is set to **off** to disable NestLoop so that the optimizer selects hash join, the join duration is reduced to 86 ms.

```

gaussdb=# explain analyze select count(*) from t2,t1 where t1.c1=t2.c2;
id | operation | A-time | A-rows | E-rows | Peak Memory | A-width | E-
width | E-costs
-----+-----+-----+-----+-----+-----+-----+-----
1 | -> Aggregate | 5070.296 | 1 | 1 | 14KB | | 8 |
2148.49
2 | -> Streaming (type: GATHER) | 5070.219 | 2 | 2 | 81KB | | 8 |
2148.49
3 | -> Aggregate | [4828.705,5062.289] | 2 | 2 | [11KB,11KB] | | 8 |
2148.40
4 | -> Nested Loop (5,6) | [4828.565,5062.142] | 996 | 40 | [4KB,4KB] | |
0 | 2148.34
5 | -> Seq Scan on t1 | [13.574,14.508] | 90007 | 20000 | [15KB,15KB] | |
4 | 184.00
6 | -> Materialize | [1508.956,1579.488] | 22413670 | 20 | [35KB,36KB] | |
4 | 14.37
7 | -> Streaming(type: REDISTRIBUTE) | [55.825,56.842] | 498 | 20 | [44KB,44KB] | |
4 | 14.31
8 | -> Seq Scan on t2 | [0.105,0.132] | 498 | 20 | [13KB,13KB] | | 4 |
13.13
(8 rows)

Predicate Information (identified by plan id)
-----+-----
4 --Nested Loop (5,6)
Join Filter: (t2.c2 = t1.c1)
Rows Removed by Join Filter: 22412672
(3 rows)

```

After the parameters are set:

```

gaussdb=# set enable_mergejoin=off;
SET
gaussdb=# set enable_nestloop=off;
SET
gaussdb=# explain analyze select count(*) from t2,t1 where t1.c1=t2.c2;
id | operation | A-time | A-rows | E-rows | Peak Memory | A-width | E-
width | E-costs
-----+-----+-----+-----+-----+-----+-----+-----
1 | -> Aggregate | 92.911 | 1 | 1 | 14KB | | 8 | 224.45
2 | -> Streaming (type: GATHER) | 92.855 | 2 | 2 | 81KB | | 8 |
224.45
3 | -> Aggregate | [84.295,87.102] | 2 | 2 | [11KB,11KB] | | 8 |

```

```

224.36
4 |      -> Hash Join (5,6)          | [84.171,86.966] | 996 | 40 | [6KB,6KB] | | 0 |
224.30
5 |      -> Seq Scan on t1          | [11.885,13.103] | 90007 | 20000 | [15KB,15KB] | | 4 |

(8 rows)

Predicate Information (identified by plan id)
-----
4 --Hash Join (5,6)
   Hash Cond: (t1.c1 = t2.c2)
(2 rows)

```

Example 3: Generally, query performance can be improved by selecting HashAgg. If Sort and GroupAgg are used for a large result set, you need to set **enable\_sort** to **off**. HashAgg consumes less time than Sort and GroupAgg.

```

gaussdb=# explain analyze select count(*) from t1 group by c2;
id | operation | A-time | A-rows | E-rows | Peak Memory | E-memory | A-width | E-costs
-----+-----+-----+-----+-----+-----+-----+-----+-----
1 | -> GroupAggregate | 244.817 | 40000 | 5000 | 15KB | | | 12 |
2131.52
2 | -> Sort | 156.344 | 40000 | 10000 | 5603KB | | | 12 |
2131.52
3 | -> Streaming (type: GATHER) | 91.595 | 40000 | 10000 | 82KB | | | 12 |
1442.14
4 | -> GroupAggregate | [90.317,96.852] | 40000 | 10000 | [12KB,12KB] | 16MB | | 12 |
973.39
5 | -> Sort | [59.775,64.724] | 90007 | 20000 | [5MB,5MB] | 16MB | | [896220,903920] | 4 | 873.39
184.00
6 | -> Seq Scan on t1 | [18.092,21.033] | 90007 | 20000 | [12KB,12KB] | 1MB | | 4 |
184.00
(6 rows)

```

After the parameters are set:

```

gaussdb=# set enable_sort=off;
SET
gaussdb=# explain analyze select count(*) from t1 group by c2;
id | operation | A-time | A-rows | E-rows | Peak Memory | E-memory | A-width | E-costs
-----+-----+-----+-----+-----+-----+-----+-----+-----
1 | -> HashAggregate | 228.260 | 40000 | 5000 | 6663KB | | | 12 | 752.75
2 | -> Streaming (type: GATHER) | 95.506 | 40000 | 10000 | 82KB | | | 12 |
752.75

(4 rows)

```

## 6.6.6 Optimizing Data Skew

Data skew breaks the balance among nodes in the distributed MPP architecture. If the amount of data stored or processed by a node is much greater than that by other nodes, the following problems may occur:

- Storage skew severely limits the system capacity. The skew on a single node hinders system storage utilization.

- Computing skew severely affects performance. The data to be processed on the skew node is much more than that on other nodes, deteriorating overall system performance.
- Data skew severely affects the scalability of the MPP architecture. During storage or computing, data with the same values is often placed on the same node. Therefore, even if we add nodes after a data skew occurs, the skew data (data with the same values) is still placed on the node and affects the system capacity or performance bottleneck.

GaussDB provides a complete solution to data skew, including storage and computing skew.

## Data Skew in the Storage Layer

In GaussDB, data is distributed and stored on each DN. You can improve the query efficiency by using distributed execution. However, if data skew occurs, bottlenecks exist on some DNs during distribution execution, affecting the query performance. This is because the distribution key is not properly selected. This can be solved by adjusting the distribution key.

Example:

```
gaussdb=# explain performance select count(*) from inventory;
5 --Seq Scan on lmz.inventory
   dn_6001_6002 (actual time=0.444..83.127 rows=42000000 loops=1)
   dn_6003_6004 (actual time=0.512..63.554 rows=27000000 loops=1)
   dn_6005_6006 (actual time=0.722..99.033 rows=45000000 loops=1)
   dn_6007_6008 (actual time=0.529..100.379 rows=51000000 loops=1)
   dn_6009_6010 (actual time=0.382..71.341 rows=36000000 loops=1)
   dn_6011_6012 (actual time=0.547..100.274 rows=51000000 loops=1)
   dn_6013_6014 (actual time=0.596..118.289 rows=60000000 loops=1)
   dn_6015_6016 (actual time=1.057..132.346 rows=63000000 loops=1)
   dn_6017_6018 (actual time=0.940..110.310 rows=54000000 loops=1)
   dn_6019_6020 (actual time=0.231..41.198 rows=21000000 loops=1)
   dn_6021_6022 (actual time=0.927..114.538 rows=54000000 loops=1)
   dn_6023_6024 (actual time=0.637..118.385 rows=60000000 loops=1)
   dn_6025_6026 (actual time=0.288..32.240 rows=15000000 loops=1)
   dn_6027_6028 (actual time=0.566..118.096 rows=60000000 loops=1)
   dn_6029_6030 (actual time=0.423..82.913 rows=42000000 loops=1)
   dn_6031_6032 (actual time=0.395..78.103 rows=39000000 loops=1)
   dn_6033_6034 (actual time=0.376..51.052 rows=24000000 loops=1)
   dn_6035_6036 (actual time=0.569..79.463 rows=39000000 loops=1)
```

In the performance information, the number of scan lines on each DN in the inventory table is displayed. The maximum number of scan lines is 63,000,000, and the minimum number is 15,000,000, which is four times of the actual number. This value difference on the performance of data scan is acceptable, but if the join operator exists in the upper-layer, the impact on the performance cannot be ignored.

Generally, the data table is hash distributed on each DN; therefore, it is important to choose a proper distribution key. Run **table\_skewness()** to view data skew of each DN in the inventory table. The query result is as follows:

```
gaussdb=# select table_skewness('inventory');
      table_skewness
-----
("dn_6015_6016",63000000,8.046%)
("dn_6013_6014",60000000,7.663%)
("dn_6023_6024",60000000,7.663%)
("dn_6027_6028",60000000,7.663%)
("dn_6017_6018",54000000,6.897%)
```

```

("dn_6021_6022",54000000,6.897%)
("dn_6007_6008",51000000,6.513%)
("dn_6011_6012",51000000,6.513%)
("dn_6005_6006",45000000,5.747%)
("dn_6001_6002",42000000,5.364%)
("dn_6029_6030",42000000,5.364%)
("dn_6031_6032",39000000,4.981%)
("dn_6035_6036",39000000,4.981%)
("dn_6009_6010",36000000,4.598%)
("dn_6003_6004",27000000,3.448%)
("dn_6033_6034",24000000,3.065%)
("dn_6019_6020",21000000,2.682%)
("dn_6025_6026",15000000,1.916%)
(18 rows)

```

The table definition indicates that the table uses the **inv\_date\_sk** column as the distribution key, which causes a data skew. Based on the data distribution of each column, change the distribution key to **inv\_item\_sk** when creating a table. The skew status is as follows:

```

gaussdb=# select table_skewness('inventory');
 table_skewness
-----
("dn_6001_6002",43934200,5.611%)
("dn_6007_6008",43829420,5.598%)
("dn_6003_6004",43781960,5.592%)
("dn_6031_6032",43773880,5.591%)
("dn_6033_6034",43763280,5.589%)
("dn_6011_6012",43683600,5.579%)
("dn_6013_6014",43551660,5.562%)
("dn_6027_6028",43546340,5.561%)
("dn_6009_6010",43508700,5.557%)
("dn_6023_6024",43484540,5.554%)
("dn_6019_6020",43466800,5.551%)
("dn_6021_6022",43458500,5.550%)
("dn_6017_6018",43448040,5.549%)
("dn_6015_6016",43247700,5.523%)
("dn_6005_6006",43200240,5.517%)
("dn_6029_6030",43181360,5.515%)
("dn_6025_6026",43179700,5.515%)
("dn_6035_6036",42960080,5.487%)
(18 rows)

```

Data skew is solved.

In addition to the `table_skewness()` view, you can use the [table\\_distribution](#) function and the [PGXC\\_GET\\_TABLE\\_SKEWNESS](#) view to efficiently query the data skew status of each table.

## Data Skew in the Computing Layer

Even if data is balanced across nodes after you change the distribution key of a table, data skew may still occur during a query. If data skew occurs in the result set of an operator on a DN, skew will also occur during the computing that involves the operator. Generally, this is caused by data redistribution during the execution.

During a query, JOIN keys and GROUP BY keys are not used as distribution keys. Data is redistributed among DNs based on the hash values of data on the keys. The redistribution is implemented using the Redistribute operator in an execution plan. Data skew in redistribution columns can lead to data skew during system operation. After the redistribution, some nodes will have much more data, process more data, and will have much lower performance than other nodes.

In the following example, the **s** and **t** tables are joined, and **s.x** and **t.x** columns in the join condition are not their distribution keys. Table data is redistributed using the REDISTRIBUTE operator. Data skew occurs in the **s.x** column and not in the **t.x** column. The result set of the Streaming operator (**id** being **6**) on datanode2 has data three times that of other DNs and causes a skew.

```
gaussdb=# explain select * from skew s,test t where s.x = t.x order by s.a limit 1;
id |          operation          |  A-time
-----+-----+-----
 1 | -> Limit                    | 52622.382
 2 | -> Streaming (type: GATHER) | 52622.374
 3 | -> Limit                    | [30138.494,52598.994]
 4 | -> Sort                     | [30138.486,52598.986]
 5 | -> Hash Join (6,8)          | [30127.013,41483.275]
 6 | -> Streaming(type: REDISTRIBUTE) | [11365.110,22024.845]
 7 | -> Seq Scan on public.skew s | [2019.168,2175.369]
 8 | -> Hash                     | [2460.108,2499.850]
 9 | -> Streaming(type: REDISTRIBUTE) | [1056.214,1121.887]
10 | -> Seq Scan on public.test t | [310.848,325.569]
(10 rows)
6 --Streaming(type: REDISTRIBUTE)
   datanode1 (rows=5050368)
   datanode2 (rows=15276032)
   datanode3 (rows=5174272)
   datanode4 (rows=5219328)
```

Computing skew is more difficult to detect than storage skew. To solve computing skew, GaussDB provides the Runtime Load Balance Technology (RLBT) solution, controlled by the GUC parameter **skew\_option**. The RLBT solution addresses how to detect and solve data skew.

#### 1. Detect data skew.

The solution first checks whether skew data exists in redistribution columns used for computing. RLBT provides three solutions: statistics, specified hints, and rules.

- Detection based on statistics

Execute the ANALYZE statement to collect statistics on tables. The optimizer will automatically identify skew data on redistribution keys based on the statistics and generate optimization plans for queries having potential skew. When the redistribution key has multiple columns, statistics information can be used for identification only when all columns belong to the same base table.

The statistics information can only provide the skew of the base table. When a column in the base table is skewed, other columns have filtering conditions, or after the join of other tables, the skewed data may still exist on the skewed column. If the GUC parameter **skew\_option** is set to **normal**, the system considers that skew data still exists and optimizes the skew identified in the base table. If the GUC parameter **skew\_option** is set to **lazy**, the system considers that skew data does not exist and does not perform optimization.

- Detection based on specified hints

The intermediate results of complex queries are difficult to estimate based on statistics. In this case, you can specify hints to provide the skew information based on which the optimizer optimizes queries. For details about the syntax of hints, see [Skew Hints](#).

- Detection based on rules

In a business intelligence (BI) system, a large number of SQL statements having outer joins (including left joins, right joins, and full joins) are generated, and many NULL values will be generated in empty columns that have no match for outer joins. If JOIN or GROUP BY operations are performed on the columns, data skew will occur. RLBT can automatically identify this scenario and generate an optimization plan for NULL value skew.

2. Solve computing skew.

Join and Aggregate operators are optimized to solve skew.

- Join optimization

Skew and non-skew data is separately processed. Details are as follows:

- a. When redistribution is required on both sides of a join:
  - Use PART\_REDISTRIBUTE\_PART\_ROUNDROBIN on the side with skew. Specifically, perform round-robin on skew data and redistribution on non-skew data.
  - Use PART\_REDISTRIBUTE\_PART\_BROADCAST on the side with no skew. Specifically, perform broadcast on skew data and redistribution on non-skew data.
- b. When redistribution is required on only one side of a join:
  - Use PART\_REDISTRIBUTE\_PART\_ROUNDROBIN on the side where redistribution is required.
  - Use PART\_LOCAL\_PART\_BROADCAST on the side where redistribution is not required. Specifically, perform broadcast on skew data and retain other data locally.
- c. When a table has NULL values padded:
  - Use PART\_REDISTERIBUTE\_PART\_LOCAL on the table. Specifically, retain the NULL values locally and perform redistribution on other data.

In the example query, the **s.x** column contains skewed data and its value is **0**. The optimizer identifies the skew data in statistics and generates the following optimization plan:

id	operation	A-time
1	-> Limit	23642.049
2	-> Streaming (type: GATHER)	23642.041
3	-> Limit	[23310.768,23618.021]
4	-> Sort	[23310.761,23618.012]
5	-> Hash Join (6,8)	[20898.341,21115.272]
6	-> Streaming(type: PART REDISTRIBUTE PART ROUNDROBIN)	[7125.834,7472.111]
7	-> Seq Scan on public.skew s	[1837.079,1911.025]
8	-> Hash	[2612.484,2640.572]
9	-> Streaming(type: PART REDISTRIBUTE PART BROADCAST)	[1193.548,1297.894]
10	-> Seq Scan on public.test t	[314.343,328.707]
(10 rows)		
5	-- Hash Join (6,8)	
	Hash Cond: s.x = t.x	
	Skew Join Optimized by Statistic	
6	--Streaming(type: PART REDISTRIBUTE PART ROUNDROBIN)	
	datanode1 (rows=7635968)	
	datanode2 (rows=7517184)	
	datanode3 (rows=7748608)	
	datanode4 (rows=7818240)	

In the preceding execution plan, **Skew Join Optimized by Statistic** indicates that this is an optimized plan used for handling data skew. The

Statistic keyword indicates that the plan optimization is based on statistics. The hint keyword indicates that the optimization is based on hints. The Rule keyword indicates that the optimization is based on rules. In this plan, skew and non-skew data are separately processed. Non-skew data in the **s** table is redistributed based on its hash values, and skew data (whose value is **0**) is evenly distributed on all nodes in round-robin mode. In this way, data skew is solved.

To ensure result correctness, the **t** table also needs to be processed. In the **t** table, the data whose value is **0** (skew value in the **s.x** table) is broadcast and other data is redistributed based on its hash values.

In this way, data skew in JOIN operations is solved. The above result shows that the output of the **Streaming** operator (**id** being **6**) is balanced and the end-to-end performance of the query is doubled.

- Aggregate optimization

For aggregation, distribution keys on each DN are deduplicated based on the GROUP BY KEY and then redistributed. After the deduplication on DNs, each DN has only one value for each redistribution key. The global occurrences of each value will not be greater than the number of DNs. Therefore, no serious data skew will occur. Take the following query as an example:

```
select c1, c2, c3, c4, c5, c6, c7, c8, c9, count(*) from t group by c1, c2, c3, c4, c5, c6, c7, c8, c9 limit 10;
```

The command output is as follows:

id	operation	A-time	A-rows
1	-> Streaming (type: GATHER)	130621.783	12
2	-> GroupAggregate	[85499.711,130432.341]	12
3	-> Sort	[85499.509,103145.632]	36679237
4	-> Streaming(type: REDISTRIBUTE)	[25668.897,85499.050]	36679237
5	-> Seq Scan on public.t	[9835.069,10416.388]	36679237
(5 rows)			
4 --Streaming(type: REDISTRIBUTE)			
datanode1 (rows=36678837)			
datanode2 (rows=100)			
datanode3 (rows=100)			
datanode4 (rows=200)			

A large amount of skew data exists. As a result, after data is redistributed based on its GROUP BY key, the data volume of datanode1 is hundreds of thousands of times that of others. After optimization, a GROUP BY operation is performed on the DN to deduplicate data. After redistribution, no data skew occurs.

id	operation	A-time
1	-> Streaming (type: GATHER)	10961.337
2	-> HashAggregate	[10953.014,10953.705]
3	-> HashAggregate	[10952.957,10953.632]
4	-> Streaming(type: REDISTRIBUTE)	[10952.859,10953.502]
5	-> HashAggregate	[10084.280,10947.139]
6	-> Seq Scan on public.t	[4757.031,5201.168]
(6 rows)		
Predicate Information (identified by plan id)		
-----		
3 --HashAggregate		
Skew Agg Optimized by Statistic		
(2 rows)		
4 --Streaming(type: REDISTRIBUTE)		
datanode1 (rows=17)		

```
datanode2 (rows=8)  
datanode3 (rows=8)  
datanode4 (rows=14)
```

#### Applicability

- Join operator
  - The nest loop, merge join, and hash join are supported.
  - If skew data is on the left to the join, the inner join, left join, semi join, and anti join are supported. If skew data is on the right to the join, the inner join, right join, right semi join, and right anti join are supported.
  - For an optimization plan generated based on statistics, the optimizer checks whether it is optimal by estimating its cost. Optimization plans based on hints or rules are forcibly generated.
- Aggregate operator
  - Optimization is not supported in the `array_agg`, `string_agg`, and subplan in `agg qual` scenarios.
  - A plan generated based on statistics is affected by its cost, the `plan_mode_seed` parameter, and the `best_agg_plan` parameter. A plan generated based on hints or rules is not affected by them.

## 6.7 Experience in Rewriting SQL Statements

Based on the SQL execution mechanism and a large number of practices, SQL statements can be optimized by following certain rules to enable the database to execute SQL statements more quickly and obtain correct results. You can comply with these rules to improve service query efficiency.

- Replace UNION with UNION ALL.  
UNION eliminates duplicate rows while merging two result sets but UNION ALL merges the two result sets without deduplication. Therefore, replace UNION with UNION ALL if you are sure that the two result sets do not contain duplicate rows based on the service logic.
- Add not null to the join columns.  
If there are many NULL values in the join columns, you can add the filter criterion IS NOT NULL to filter data in advance to improve the join efficiency.
- Convert NOT IN to NOT EXISTS.  
Nested loop anti join must be used to implement NOT IN, and hash anti join is required for NOT EXISTS. If no NULL value exists in the join columns, NOT IN is equivalent to NOT EXISTS. Therefore, if you are sure that no NULL value exists, you can convert NOT IN to NOT EXISTS to generate hash join and to improve the query performance.

As shown in the following statement, if the `t2.d2` column does not contain NULL values (it is set to **NOT NULL**), the query can be modified as follows:

```
SELECT * FROM t1 WHERE NOT EXISTS (SELECT * FROM t2 WHERE t1.c1=t2.d2);
```

The generated execution plan is as follows:

**Figure 6-7** NOT EXISTS execution plan

```

id | operation
-----+-----
1 | -> Streaming (type: GATHER)
2 |   -> Hash Anti Join (3, 4)
3 |     -> Seq Scan on t1
4 |     -> Hash
5 |       -> Streaming (type: REDISTRIBUTE)
6 |       -> Seq Scan on t2
(6 rows)

Predicate Information (identified by plan id)
-----+-----
2 --Hash Anti Join (3, 4)
    Hash Cond: (t1.c1 = t2.d2)
(2 rows)

```

- Use **hashagg**.

If a plan involving groupAgg and SORT operations generated by the GROUP BY statement is poor in performance, you can set **work\_mem** to a larger value to generate a HashAgg plan, which does not require sorting and improves the performance.

- Replace functions with CASE statements.

The GaussDB performance greatly deteriorates if a large number of functions are called. In this case, you can change the pushdown functions to CASE statements.

- Do not use functions or expressions for indexes.

Using functions or expressions for indexes stops indexing. Instead, it enables scanning on the full table.

- Do not use the !=, <, or > operator, NULL, OR, or implicit parameter conversion in WHERE clauses.

- If the values of >= and <= are the same in WHERE condition, change the condition to = because range equivalence class derivation is not supported currently.

```
SELECT * FROM t1 WHERE c1 >= 1 AND c1 <= 1
```

Change the preceding content to the following:

```
SELECT * FROM t1 WHERE c1 = 1
```

For range queries, the optimizer has a larger error when calculating selectivity than equivalent queries. Therefore, change range queries to equivalent queries as much as possible.

- Split complex SQL statements.

You can split an SQL statement into several ones and save the execution result to a temporary table if the SQL statement is too complex to be tuned using the solutions above, including but not limited to the following scenarios:

- The same subquery is involved in multiple SQL statements of a job and the subquery contains large amounts of data.
- Incorrect plan cost causes a small hash bucket of subquery. For example, the actual number of rows is 10 million, but only 1000 rows are in hash bucket.

- Functions such as substr and to\_number cause incorrect measures for subqueries containing large amounts of data.
- BROADCAST subqueries are performed on large tables in multi-DN environment.

## 6.8 Configuring Key Parameters for SQL Tuning

This section describes key CN configuration parameters that affect GaussDB SQL performance optimization. Contact the administrator to configure parameters.

**Table 6-4** CN parameters

Parameter/ Reference Value	Description
enable_nestloop=on	<p>Specifies how the optimizer uses Nest Loop Join. If this parameter is set to <b>on</b>, the optimizer preferentially uses Nest Loop Join. If it is set to <b>off</b>, the optimizer preferentially uses other methods, if any.</p> <p><b>NOTE</b> If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement: SET enable_nestloop to off;</p> <p>You can determine whether to disable this function based on the actual requirements. Three types of joins are supported: nested loops, merge joins, and hash joins. Specifically, nested loops are best suited for scenarios with small data volumes or indexes, while hash joins are ideal for big data analysis.</p>
enable_bitmapscan=on	<p>Specifies whether the optimizer uses bitmap scan. If the value is <b>on</b>, bitmap scan is used. If the value is <b>off</b>, it is not used.</p> <p><b>NOTE</b> If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement: SET enable_bitmapscan to off;</p> <p>The bitmap scan applies only in the query condition <b>where a &gt; 1 and b &gt; 1</b> and indexes are created on columns <b>a</b> and <b>b</b>. However, the performance of bitmapscan is sometimes inferior to that of indexscan. During tuning, if the query performance is poor and bitmapscan operators are in the execution plan, set this parameter to <b>off</b> and check whether the performance is improved.</p>

Parameter/ Reference Value	Description
enable_fast_query_shipping=on	<p>Specifies whether the optimizer uses a distribution framework to execute quick execution plans. If the value is <b>on</b>, the execution plan is generated on both CNs and DN. If the value is <b>off</b>, the distribution framework is used, that is, the execution plan is generated on the CN and then sent to the DN for execution.</p> <p><b>NOTE</b> If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement: SET enable_fast_query_shipping to off;</p>
enable_hashagg=on	Specifies whether the optimizer uses hash aggregate plans.
enable_hashjoin=on	Specifies whether the optimizer uses hash join plans.
enable_mergejoin=on	Specifies whether the optimizer uses merge join plans.
enable_indexscan=on	Specifies whether the optimizer uses index scan plans.
enable_gsitablesca n=on	Specifies whether the optimizer uses GSI scan plans.
enable_indexonlysc an=on	Specifies whether the optimizer uses index-only scan plans.
enable_gsiscan=on	Specifies whether the optimizer uses GSI-only scan plans.
enable_seqscan=on	Specifies whether the optimizer uses sequential scan plans. It is impossible to suppress sequential scans entirely, but setting this variable to <b>off</b> encourages the optimizer to choose other methods if available.
enable_sort=on	Specifies the optimizer sorting order. It is impossible to fully suppress explicit sorting, but setting this variable to <b>off</b> encourages the optimizer to choose other methods if available.
enable_broadcast=on	Specifies whether the optimizer uses data broadcast. In data broadcast, a large amount of data is transferred on the network. When the number of transmission nodes (stream) is large and the estimation is inaccurate, set this parameter to <b>off</b> and check whether the performance is improved.

Parameter/ Reference Value	Description
rewrite_rule	Specifies whether the optimizer enables the LAZYAGG, MAGICSET, PARTIALPUSH, DISABLEREP, UNIQUECHECK, INTARGETLIST, PREDPUSH, PREDPUSHFORCE, PREDPUSHNORMAL, DISABLE_PULLUP_EXPR_SUBLINK, ENABLE_SUBLINK_PULLUP_ENHANCED, DISABLE_PULLUP_NOT_IN_SUBLINK, DISABLE_ROWNUM_PUSHDOWN, or DISABLE_WINDOWAGG_PUSHDOWN rewriting rule.
sql_beta_feature	Specifies whether the optimizer enables the SEL_SEMI_POISSON, NO_UNIQUE_INDEX_FIRST, JOIN_SEL_WITH_CAST_FUNC, SEL_EXPR_INSTR, PARAM_PATH_GEN, RAND_COST_OPT, PARAM_PATH_OPT, PAGE_EST_OPT, CANONICAL_PATHKEY, INDEX_COST_WITH_INDEX_COST_WITH_LEAF_PAGES_ONLY, PARTITION_OPFUSION, PREDPUSH_SAME_LEVEL, DISABLE_BITMAP_COST_WITH_LOSSY_PAGES, or ENABLE_UPSERT_EXECUTE_GPLAN beta feature.
enable_inner_unique_opt	Specifies whether the optimizer uses Inner Unique.

## 6.9 Hint-based Optimization

### 6.9.1 Plan Hint Optimization

In plan hints, you can specify a join order; join, stream, and scan operations, the number of rows in a result, and redistribution skew information to tune an execution plan, improving query performance.

GaussDB also provides the SQL patch function. You can create an SQL patch to make hints take effect without modifying service statements.

#### Description

Plan hints are specified in the following format after keywords such as SELECT, INSERT, UPDATE, DELETE, and MERGE:

```
/*+ <plan hint>*/
```

You can specify multiple hints for a query plan and separate them with spaces. A hint specified for a query plan does not apply to its subquery plans. To specify a hint for a subquery, add the hint following the SELECT of this subquery.

For example:

```
select /*+ <plan_hint1> <plan_hint2> */ * from t1, (select /*+ <plan_hint3> */ * from t2) where 1=1;
```

In the preceding command, *<plan\_hint1>* and *<plan\_hint2>* are the hints of a query, and *<plan\_hint3>* is the hint of its subquery.

You can use the EXPLAIN syntax to analyze the plan hint optimization effect. You can use EXPLAIN to view the plan of the target SQL statement after the plan hint is used and check whether the plan meets the requirements to verify the plan hint effect. EXPLAIN has multiple plan display modes, which are controlled by **explain\_perf\_mode**. In some examples in this section, **explain\_perf\_mode** is set to **pretty** to display complete plan information. In some examples, **explain\_perf\_mode** is set to **normal** to simplify the output information.

---

#### NOTICE

If a hint is specified in the CREATE VIEW statement, the hint will be applied each time this view is used.

If the random plan function is enabled (**plan\_mode\_seed** is set to a value other than 0), the specified hint will not be used.

---

## Scope

Currently, the following hints are supported:

- Join order hints (**leading**).
- Join operation hints, excluding the **semi join**, **anti join**, and **unique plan** hints.
- Rows hints.
- Stream operation hints.
- Scan operation hints, supporting only the **tablescan**, **indexscan**, **indexonlyscan**, and **gsi** hints.
- Sublink name hints.
- Skew hints, supporting only the skew in the redistribution involving Join or HashAgg.
- Hints of GUC parameters, which take effect in a query and do not take effect in views.
- Hints that use the custom plan or generic plan and are valid only for query statements executed by PBE.
- Hints specifying not to expand subqueries.
- Hints specifying that the current query statement does not enter the global plan cache. The hints are valid only when **enable\_global\_plancache** is enabled and the current statement is executed by PBE.
- Hints for internal table materialization.
- Bitmap scan hints.
- Hints of the Agg method

## Precautions

- Hints do not support Sort, Setop, or Subplan.
- Hints do not support SMP or node groups.

## Examples

Create tables and indexes.

```
create table t1(c1 int, c2 int, c3 int);
create table t2(c1 int, c2 int, c3 int);
create table t3(c1 int, c2 int, c3 int);
create index it1 on t1(c1,c2);
create index it2 on t2(c1,c2);
create index it3 on t1(c3,c2);
-- The following TPC-H data table needs to be inserted with 10 times of the data to match the provided
plan example:
create table store
(
  s_store_sk          integer          not null,
  s_store_id         char(16)         not null,

```

## 6.9.2 Hint Specifying the Query Block Where the Hint Is Located

### Description

This function allows users to use `@queryblock` in hints to implement block-level hint control. Users can specify the query block to which the hint takes effect. For example, you can specify the hint of an inner query block in the outer query block.

### Syntax

Add `@queryblock` at the beginning of the hint parameter. `Hint_SEPC` is a specific hint.

```
Hint_SEPC([@queryblock])
```

### Parameters

`Hint_SEPC` is the hint name, and `@queryblock` can be left empty. If `@queryblock` is left empty, the hint takes effect in the current query block declared by the hint. If `@queryblock` is left empty and `Hint_SPEC` has no parameter, use `Hint_SPEC` instead of `Hint_SPEC()`. Parentheses are unnecessary. The following describes how to name a query block and how to make a hint take effect. Some hints do not take effect only at the outermost layer and cannot be specified using `@queryblock`. For details, see the syntax description of each hint.

- Query the name of a query block.  
Each query block must have a name for accurately specifying a hint. There are two naming methods: user-specified and system-specified.
  - You can use the `blockname` hint to specify the block to be queried. For details, see [Sublink Name Hints](#).
  - If no alias is specified for a query block, the default block name is automatically generated based on the processing sequence. Generally, the default alias of each query block consists of the first three letters of the query block name, `$`, and the number of the query block. For example, the alias of the first `SELECT` query block is `sel$1`. In pretty mode, you can use the `explain` method with a specified block name to view the name of the query block where the processing operator of each table is located. In distributed scenarios, only stream plans can be displayed in pretty mode.

```
gaussdb=# set explain_perf_mode = pretty;
SET
gaussdb=# set enable_fast_query_shipping = off;
SET
gaussdb=# explain (blockname on, costs off) select * from t1, (select c1 from t2 group by c1)
sub1 where t1.c1 = sub1.c1;
 id | operation | Query Block
-----+-----+-----
 1 | -> Streaming (type: GATHER) | sel$1
 2 | -> Hash Join (3,4) | sel$1
 3 | -> Seq Scan on t1@"sel$1" | sel$1
 4 | -> Hash |
 5 | -> HashAggregate | sel$2
 6 | -> Seq Scan on t2@"sel$2" | sel$2
(6 rows)
```

You can see that `Seq Scan` of `t2` is located in the `sel$2` query block.

- **@queryblock** specifies the query block.

For the preceding example, if you want to modify the indexscan mode in **t2**, run the following command:

```
select /*+indexscan(@sel$2 t2) tablescan(t1)*/ * from t1, (select c1 from t2 group by c1) sub1 where t1.c1 = sub1.c1;
```

Both indexscan and tablescan are scan hints. For details about scan hints, see [Scan Hints](#). You can specify the hint of indexscan(**@sel\$2 t2**) in the **sel\$1** query block to move the hint to the **sel\$2** query block. The hint takes effect for **t2**. If the **sel\$2** query block is promoted to **sel\$1** during subsequent rewriting, the hint is also promoted together to **sel\$1** and continues to take effect for **t2**.

```
gaussdb=# explain (blockname on, costs off) select /*+indexscan(@sel$2 t2) tablescan(t1)*/ * from t1,
(select c1 from t2 group by c1) sub1 where t1.c1 = sub1.c1;
id | operation | Query Block
-----+-----+-----
1 | -> Streaming (type: GATHER) | sel$1
2 | -> Hash Join (3,4) | sel$1
3 | -> Seq Scan on t1@"sel$1" | sel$1
4 | -> Hash |
5 | -> HashAggregate | sel$2
6 | -> Index Only Scan using it2 on t2@"sel$2" | sel$2
(6 rows)
```

**CAUTION**

Sometimes, query rewriting in the optimizer phase expands some query blocks. As a result, the plan does not display related query blocks in the explain method. The hint specifies a query block based on the name of the query block before the optimizer phase. If a query block to be queried may be expanded in the planning phase, you can add the `no_expand` hint (see [Hints Specifying Not to Expand Subqueries](#)) to prevent it from being expanded.

1. The `sel$2` query block is a simple query. The optimizer performs query rewriting during subsequent processing, and `t1` is promoted to `sel$1` for processing. Therefore, the operation in the `sel$2` query block is not displayed in the plan.

```
gaussdb=# explain (blockname on, costs off) select * from t2, (select c1 from t1 where t1.c3 = 2) sub1
where t2.c1 = sub1.c1;
id | operation | Query Block
-----+-----+-----
1 | -> Streaming (type: GATHER) | sel$1
2 | -> Nested Loop (3,4) | sel$1
3 | -> Index Scan using it3 on t1@"sel$2" | sel$1
4 | -> Index Scan using it2 on t2@"sel$1" | sel$1
(4 rows)
```

2. The `sel$2` query block is a simple query. During subsequent processing, the optimizer skips query rewriting because of the `no_expand` hint, and `t1` is still processed in the original query block.

```
gaussdb=# explain (blockname on, costs off) select * from t2, (select /*+ no_expand*/ c1 from t1 where
t1.c3 = 2) sub1 where t2.c1 = sub1.c1;
id | operation | Query Block
-----+-----+-----
1 | -> Streaming (type: GATHER) | sel$1
2 | -> Nested Loop (3,4) | sel$1
3 | -> Index Scan using it3 on t1@"sel$2" | sel$2
4 | -> Index Scan using it2 on t2@"sel$1" | sel$1
(4 rows)
```

3. Because `t1` is processed in the `sel$2` query block after the `no_expand` hint is added, you can use `@sel$2` to specify the query block for the hint.

```
explain (blockname on, costs off) select /*+ tablescan(@sel$2 t1)*/ * from t2, (select c1 from t1 where
t1.c3 = 2) sub1 where t2.c1 = sub1.c1;
id | operation | Query Block
-----+-----+-----
1 | -> Streaming (type: GATHER) | sel$1
2 | -> Nested Loop (3,4) | sel$1
3 | -> Seq Scan on t1@"sel$2" | sel$1
4 | -> Index Scan using it2 on t2@"sel$1" | sel$1
(4 rows)
```

4. The query block number in the view depends on the sequence of the statement using the view. Therefore, do not use hints to specify query blocks when creating a view. The behavior is uncontrollable.

```
gaussdb=# create view v1 as select /*+ no_expand */ c1 from t1 where c1 in (select /*+ no_expand */ c1
from t2 where t2.c3=4 );
CREATE VIEW
gaussdb=# explain (blockname on, costs off) select * from v1;
id | operation | Query Block
-----+-----+-----
1 | -> Streaming (type: GATHER) | sel$1
2 | -> Seq Scan on t1@"sel$2" | sel$2
3 | -> Materialize [2, SubPlan 1] |
4 | -> Streaming(type: BROADCAST) |
5 | -> Seq Scan on t2@"sel$3" | sel$3
(5 rows)

Predicate Information (identified by plan id)
```

```
-----
2 --Seq Scan on t1@"sel$2"
  Filter: (hashed SubPlan 1)
5 --Seq Scan on t2@"sel$3"
  Filter: (c3 = 4)
(4 rows)
```

In this case, the statements in **v1** belong to **sel\$2** and **sel\$3**.

5. Some hints take effect only at the outermost layer and cannot be specified using **@queryblock**. For details, see the syntax description of each hint.

## 6.9.3 Hint Specifying the Query Block and Schema of a Table

### Description

In a query, the table name can be duplicate in different query blocks and different schemas. Therefore, when specifying a table in a query, you can use a hint to specify the query block and schema where the table is located to avoid ambiguity. This function is applicable to all hints whose table names need to be specified.

### Syntax

When specifying a table using a hint, specify a schema using a period (**schema.**) and a query block using the at sign (**@queryblock**). Both the schema and query block can be left empty.

```
[schema.]relname[@queryblock]
```

### Parameters

- **relname** indicates the name of the table in the query. If the table has an alias, use the alias first. In this case, **relname** is set to the alias. If the table name contains special characters, such as at sign (@) and period (.), **relname** must be enclosed in double quotation marks (") to avoid conflict with the declaration of the query block and schema names. For example, if the table name is **relnametest@1**, enter "**relnametest@1**".
- **schema** indicates the schema where the table is located. It can be left empty. If no schema is specified, the hint searches all schemas for **relname**.
- **queryblock** indicates the query block where the table is located. It can be left empty. If no query block is specified, the hint searches all query blocks for **relname**.

### Example

1. **t1** of **sel\$2** is promoted to **sel\$1** for processing, and **t1** is unclear.  

```
gaussdb=# explain(blockname on,costs off) select /*+ tablescan(t1)*/ * from t1, (select c2 from t1
where c1=1) tt1 where t1.c1 = tt1.c2;
WARNING: Error hint: TableScan(t1), relation name "t1" is ambiguous.
...
```
2. **t1@sel\$2** is specified to perform tablescan on **t1** of **sel\$2** (Filter: (c1 = 1)).  

```
gaussdb=# explain(blockname on,costs off) select /*+ tablescan(t1@sel$2)*/ * from t1, (select c2 from
t1 where c1=1) tt1 where t1.c1 = tt1.c2;
id | operation | Query Block
-----+-----+-----
1 | -> Streaming (type: GATHER) | sel$1
2 | -> Nested Loop (3,5) | sel$1
```

```
3 | -> Streaming(type: REDISTRIBUTE) | sel$1
4 | -> Seq Scan on t1@"sel$2" | sel$1
5 | -> Index Scan using it1 on t1@"sel$1" | sel$1
(5 rows)

Predicate Information (identified by plan id)
-----
4 --Seq Scan on t1@"sel$2"
   Filter: (c1 = 1)
5 --Index Scan using it1 on t1@"sel$1"
   Index Cond: (c1 = public.t1.c2)
(4 rows)
```

## 6.9.4 Join Order Hints

### Description

Specifies the join order and outer/inner tables.

### Syntax

- Specify only the join order.

```
leading([@queryblock] join_table_list)
```

- Specify the join order and outer/inner tables. The outer/inner tables are specified by the outermost parentheses.

```
leading([@queryblock] (join_table_list))
```

### Parameters

**join\_table\_list** specifies the tables to be joined. The values can be table names or table aliases. If a subquery is pulled up, the value can also be the subquery alias. Separate the values with spaces. You can add parentheses to specify the join priorities of tables.

For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.

---

#### NOTICE

A table name or alias can only be a string without a schema name.

An alias (if any) is used to represent a table.

---

To prevent semantic errors, tables specified by **join\_table\_list** must meet the following requirements:

- The tables must exist in the query or its subquery to be pulled up.
- The table names must be unique in the query or subquery to be pulled up. If they are not, their aliases must be unique.
- A table appears only once in the list.
- An alias (if any) is used to represent a table.

For example:

**leading(t1 t2 t3 t4 t5):** t1, t2, t3, t4, and t5 are joined. The join sequence and outer/inner tables are not specified.

**leading((t1 t2 t3 t4 t5)):** t1, t2, t3, t4, and t5 are joined in sequence. The table on the right is used as the inner table in each join.

**leading(t1 (t2 t3 t4) t5):** First, t2, t3, and t4 are joined and the outer/inner tables are not specified. Then, the result is joined with t1 and t5, and the outer/inner tables are not specified.

**leading((t1 (t2 t3 t4) t5)):** First, t2, t3, and t4 are joined and the outer/inner tables are not specified. Then, the result is joined with t1, and (t2 t3 t4) is used as the inner table. Finally, the result is joined with t5, and t5 is used as the inner table.

**leading((t1 (t2 t3) t4 t5) leading((t3 t2)):** First, t2 and t3 are joined and t2 is used as the inner table. Then, the result is joined with t1, and (t2 t3) is used as the inner table. Finally, the result is joined with t4 and then t5, and the table on the right in each join is used as the inner table.

## Examples

Hint the query plan in [Examples](#) as follows:

```
explain
select /*+ leading((((store_sales store) promotion) item) customer) ad2) store_returns) leading((store
store_sales)*/ i_product_name product_name ...
```

First, **store\_sales** and **store** are joined and **store\_sales** is the inner table. Then, the result is joined with **promotion**, **item**, **customer**, **ad2**, and **store\_returns** in sequence. The optimized plan is as follows.

```
WARNING: Duplicated or conflict hint: Leading(store_sales store), will be discarded.
```

id	operation	E-rows	E-width	E-costs
1	-> Streaming (type: GATHER)	2	880	78.79
2	-> HashAggregate	2	880	78.15
3	-> Nested Loop (4,24)	2	776	78.11
4	-> Streaming(type: REDISTRIBUTE)	2	784	71.39
5	-> Nested Loop (6,23)	2	784	70.75
6	-> Streaming(type: REDISTRIBUTE)	2	424	64.04
7	-> Nested Loop (8,22)	2	424	63.67
8	-> Streaming(type: REDISTRIBUTE)	2	424	56.96
9	-> Nested Loop (10,12)	2	424	56.59
10	-> Streaming(type: BROADCAST)	2	208	13.67
11	-> Seq Scan on item	1	208	13.36
12	-> Materialize	20	216	42.81
13	-> Hash Join (14,20)	20	216	42.79
14	-> Streaming(type: REDISTRIBUTE)	20	220	29.35
15	-> Hash Join (16,17)	20	220	27.73
16	-> Seq Scan on store	20	166	13.13
17	-> Hash	21	62	14.31
18	-> Streaming(type: REDISTRIBUTE)	20	62	14.31
19	-> Seq Scan on store_sales	20	62	13.13
20	-> Hash	21	4	13.13
21	-> Seq Scan on promotion	20	4	13.13
22	-> Index Scan using customer_pkey on customer	1	8	3.35
23	-> Index Scan using customer_address_pkey on customer_address ad2	1	368	3.35
24	-> Index Only Scan using store_returns_pkey on store_returns	1	8	3.35

(24 rows)

For details about the warning at the top of the plan, see [Hint Errors, Conflicts, and Other Warnings](#).

## 6.9.5 Join Operation Hints

### Description

Specifies the join method, which can be nested loop join, hash join, or merge join.

## Syntax

```
[no] nestloop|hashjoin|mergejoin([@queryblock] table_list)
```

## Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **no** indicates that the specified hint will not be used for a join.
- **table\_list** specifies the tables to be joined. The values are the same as those of [join\\_table\\_list](#) but contain no parentheses.

For example:

**no nestloop(t1 t2 t3):** **nestloop** is not used for joining **t1**, **t2**, and **t3**. The three tables may be joined in either of the two ways: Join **t2** and **t3**, and then **t1**; join **t1** and **t2**, and then **t3**. This hint takes effect only for the last join. If necessary, you can hint other joins. For example, you can add **no nestloop(t2 t3)** to join **t2** and **t3** first and to forbid the use of **nestloop**.

## Example

Hint the query plan in [Examples](#) as follows:

```
explain
select /*+ nestloop(store_sales store_returns item) */ i_product_name product_name ...
```

**nestloop** is used for the last join between **store\_sales**, **store\_returns**, and **item**. The optimized plan is as follows.

id	operation	E-rows	E-width	E-costs
1	-> HashAggregate	1	880	53.76
2	-> Streaming (type: GATHER)	2	880	53.76
3	-> HashAggregate	2	880	53.11
4	-> Nested Loop (5,20)	2	776	53.07
5	-> Streaming(type: REDISTRIBUTE)	2	416	46.36
6	-> Nested Loop (7,19)	2	416	45.99
7	-> Streaming(type: REDISTRIBUTE)	2	258	39.27
8	-> Nested Loop (9,18)	2	258	38.99
9	-> Streaming(type: REDISTRIBUTE)	2	262	32.28
10	-> Nested Loop (11,17)	2	262	32.00
11	-> Streaming(type: REDISTRIBUTE)	2	262	25.28
12	-> Nested Loop (13,16)	2	262	25.00
13	-> Nested Loop (14,15)	2	270	21.64
14	-> Seq Scan on item	1	208	13.36
15	-> Index Scan using store_sales_pkey on store_sales	1	62	8.27
16	-> Index Only Scan using store_returns_pkey on store_returns	1	8	3.35
17	-> Index Scan using customer_pkey on customer	1	8	3.35
18	-> Index Only Scan using promotion_pkey on promotion	1	4	3.35
19	-> Index Scan using store_pkey on store	1	166	3.35
20	-> Index Scan using customer_address_pkey on customer_address ad2	1	368	3.35

(20 rows)

## 6.9.6 Rows Hints

### Description

Specifies the number of rows in an intermediate result set. Both absolute values and relative values are supported.

### Syntax

```
rows( [@queryblock] table_list #|+|-* const)
```

## Parameters

- For details about `@queryblock`, see [Hint Specifying the Query Block Where the Hint Is Located](#). `@queryblock` can be omitted, indicating that the hint takes effect in the current query block.
- `#`, `+`, `-`, and `*` are operators used for hinting the estimation. `#` indicates that the original estimation is used without any calculation. `+`, `-`, and `*` indicate that the original estimation is calculated using these operators. The minimum calculation result is 1. `table_list` specifies the tables to be joined. The values are the same as those of `table_list` in [Join Operation Hints](#).
- `const` can be any non-negative number and supports scientific notation.

For example:

`rows(t1 #5)`: The result set of `t1` is five rows.

`rows(t1 t2 t3 *1000)`: The result set of joined `t1`, `t2`, and `t3` is multiplied by 1000.

## Suggestion

- The hint using `*` for two tables is recommended. This hint will be triggered if the two tables appear on two sides of a join. For example, if the hint is `rows(t1 t2 * 3)`, the join result of `(t1 t3 t4)` and `(t2 t5 t6)` will be multiplied by 3 because `t1` and `t2` appear on both sides of the join.
- `rows` hints can be specified for the result sets of a single table, multiple tables, function tables, and subquery scan tables.

## Example

Hint the query plan in [Examples](#) as follows:

```
explain
select /*+ rows(store_sales store_returns *50) */ i_product_name product_name ...
```

Multiply the result set of joined `store_sales` and `store_returns` by 50. The optimized plan is as follows.

id	operation	E-rows	E-width	E-costs
1	-> Streaming (type: GATHER)	4	880	58.44
2	-> HashAggregate	4	880	57.15
3	-> Nested Loop (4,20)	5	776	57.07
4	-> Streaming(type: REDISTRIBUTE)	2	784	50.34
5	-> Nested Loop (6,19)	2	784	49.71
6	-> Streaming(type: REDISTRIBUTE)	2	424	43.00
7	-> Nested Loop (8,18)	2	424	42.63
8	-> Streaming(type: REDISTRIBUTE)	2	266	35.91
9	-> Nested Loop (10,17)	2	266	35.63
10	-> Streaming(type: REDISTRIBUTE)	2	270	28.92
11	-> Nested Loop (12,16)	2	270	28.63
12	-> Streaming(type: REDISTRIBUTE)	2	270	21.92
13	-> Nested Loop (14,15)	2	270	21.64
14	-> Seq Scan on item	1	208	13.36
15	-> Index Scan using store_sales_pkey on store_sales	1	62	8.27
16	-> Index Scan using customer_pkey on customer	1	8	3.35
17	-> Index Only Scan using promotion_pkey on promotion	1	4	3.35
18	-> Index Scan using store_pkey on store	1	166	3.35
19	-> Index Scan using customer_address_pkey on customer_address ad2	1	368	3.35
20	-> Index Only Scan using store_returns_pkey on store_returns	1	8	3.35

(20 rows)

The estimation value after the hint in row 11 is **360**, and the original value is rounded off to 7.

## 6.9.7 Stream Operation Hints

### Description

Specifies a stream operation, which can be broadcast or redistribute. You can also directly generate a gather plan.

### Syntax

```
[no] broadcast|redistribute|local_roundrobin( [@queryblock] table_list)  
gather( [@queryblock] REL|JOIN|ALL)
```

### Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **broadcast**, **redistribute**, and **local\_roundrobin** indicate data distribution methods.
  - **no** specifies that the specified hint will not be used for a stream operation.
  - **table\_list** specifies the table on which a stream operation is to be performed or the tables to be joined. For details, see [Parameters](#).
- **gather**  
The gather hint can specify the following plan generation modes:
  - **REL**: Only the gather path based on the base table is generated, and then the remaining plan is executed on the CN.
  - **JOIN**: A join-based gather path is generated as much as possible and is added to the join subplan that can be pushed down (the join subplan does not contain the redistribution node), and the remaining plan is executed on the CN. For a join plan that requires node redistribution, such a join-based gather path cannot be generated. Instead, a base table-based gather path is generated.

---

 **CAUTION**

After **Hint(JOIN)** is specified, the plan expected by **Hint(JOIN)** cannot be generated if the distributed table and replication table are joined, because the optimizer has found a better plan for replacement.

---

- **ALL**: The **Gather Rel** or **Gather Join** path is selected based on the optimal mode.

### Examples

Hint the query plan in [Examples](#) as follows:

```
explain  
select /*+ no redistribute(store_sales store_returns item store) leading(((store_sales store_returns item  
store) customer)) */ i_product_name product_name ...
```

In the original plan, the join result of **store\_sales**, **store\_returns**, **item**, and **store** is redistributed before it is joined with **customer**. After the hinting, the redistribution is disabled and the join order is retained. The optimized plan is as follows.

id	operation	E-rows	E-width	E-costs
1	-> HashAggregate	1	880	62.28
2	-> Streaming (type: GATHER)	2	880	62.28
3	-> HashAggregate	2	880	61.63
4	-> Nested Loop (5,21)	2	776	61.59
5	-> Streaming (type: REDISTRIBUTE)	2	416	54.88
6	-> Nested Loop (7,20)	2	416	54.51
7	-> Streaming (type: REDISTRIBUTE)	2	420	47.79
8	-> Nested Loop (9,17)	2	420	47.42
9	-> Nested Loop (10,16)	2	420	32.00
10	-> Streaming (type: REDISTRIBUTE)	2	262	25.28
11	-> Nested Loop (12,15)	2	262	25.00
12	-> Nested Loop (13,14)	2	270	21.64
13	-> Seq Scan on item	1	208	13.36
14	-> Index Scan using store_sales_pkey on store_sales	1	62	8.27
15	-> Index Only Scan using store_returns_pkey on store_returns	1	8	3.35
16	-> Index Scan using store_pkey on store	1	166	3.35
17	-> Materialize	40	8	15.23
18	-> Streaming (type: BROADCAST)	40	8	15.18
19	-> Seq Scan on customer	20	8	13.13
20	-> Index Only Scan using promotion_pkey on promotion	1	4	3.35
21	-> Index Scan using customer_address_pkey on customer_address ad2	1	368	3.35

(21 rows)

Specify the gather hint for a statement.

1. Generate the gather plan **/\*+ GATHER(REL)\*/** based on the base table.

```
gaussdb=# explain select /*+ GATHER(REL)*/ from t1, t2, t3 where t1.c2 = t2.c2 and t2.c2 = t3.c2;
```

id	operation	E-rows	E-width	E-costs
1	-> Hash Join (2,8)	20	36	44.10
2	-> Hash Join (3,5)	20	24	29.22
3	-> Streaming (type: GATHER)	20	12	14.35
4	-> Seq Scan on t1	20	12	13.13
5	-> Hash	20	12	14.35
6	-> Streaming (type: GATHER)	20	12	14.35
7	-> Seq Scan on t2	20	12	13.13
8	-> Hash	20	12	14.35
9	-> Streaming (type: GATHER)	20	12	14.35
10	-> Seq Scan on t3	20	12	13.13

(10 rows)

Predicate Information (identified by plan id)

```
1 --Hash Join (2,8)
  Hash Cond: (t1.c2 = t3.c2)
2 --Hash Join (3,5)
  Hash Cond: (t1.c2 = t2.c2)
```

(4 rows)

2. Generate the join gather plan **/\*+ GATHER(JOIN)\*/** that can be pushed down.

```
gaussdb=# explain select /*+ GATHER(JOIN)*/ from t1, t2, t3 where t1.c1 = t2.c1 and t2.c2 = t3.c2;
```

id	operation	E-rows	E-width	E-costs
1	-> Hash Join (2,7)	20	36	42.37
2	-> Streaming (type: GATHER)	20	24	27.49
3	-> Hash Join (4,5)	20	24	26.56
4	-> Seq Scan on t1	20	12	13.13
5	-> Hash	21	12	13.13
6	-> Seq Scan on t2	20	12	13.13
7	-> Hash	20	12	14.35
8	-> Streaming (type: GATHER)	20	12	14.35
9	-> Seq Scan on t3	20	12	13.13

(9 rows)

Predicate Information (identified by plan id)

```
1 --Hash Join (2,7)
  Hash Cond: (t2.c2 = t3.c2)
3 --Hash Join (4,5)
```

```
Hash Cond: (t1.c1 = t2.c1)
(4 rows)
```

3. Generate the gather plan **/\*+ GATHER(ALL)\*/** based on the optimal mode. The **GATHER(REL)** or **GATHER(JOIN)** path is selected based on the optimal mode and rules.

```
gaussdb=# explain select /*+ GATHER(ALL)*/ from t1, t2, t3 where t1.c1 = t2.c1 and t2.c2 = t3.c2;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
1 | -> Hash Join (2,7) | 20 | 36 | 42.37
2 | -> Streaming (type: GATHER) | 20 | 24 | 27.49
3 | -> Hash Join (4,5) | 20 | 24 | 26.56
4 | -> Seq Scan on t1 | 20 | 12 | 13.13
5 | -> Hash | 21 | 12 | 13.13
6 | -> Seq Scan on t2 | 20 | 12 | 13.13
7 | -> Hash | 20 | 12 | 14.35
8 | -> Streaming (type: GATHER) | 20 | 12 | 14.35
9 | -> Seq Scan on t3 | 20 | 12 | 13.13
(9 rows)
```

Predicate Information (identified by plan id)

```
-----+-----
1 --Hash Join (2,7)
Hash Cond: (t2.c2 = t3.c2)
3 --Hash Join (4,5)
Hash Cond: (t1.c1 = t2.c1)
(4 rows)
```

local\_roundrobin hint usage:

SET enable\_fast\_query\_shipping=off; -- Disable FQS optimization.

SET query\_dop=4; -- Set the degree of parallelism.

```
gaussdb=# EXPLAIN(costs off) SELECT /*+ local_roundrobin(t2) scandop(t2 1) scandop(t1 4)*/ FROM
t1, t2 WHERE t1.c1 = t2.c1;
```

```
id | operation
-----+-----
1 | -> Streaming (type: GATHER)
2 | -> Streaming(type: LOCAL GATHER dop: 1/4)
3 | -> Nested Loop (4,6)
4 | -> Streaming(type: LOCAL BROADCAST dop: 4/4)
5 | -> Seq Scan on t1
6 | -> Materialize
7 | -> Streaming(type: LOCAL ROUNDROBIN dop: 4/1)
8 | -> Seq Scan on t2
(8 rows)
```

Predicate Information (identified by plan id)

```
-----+-----
3 --Nested Loop (4,6)
Join Filter: (t1.c1 = t2.c1)
(2 rows)
```

The local\_roundrobin data distribution mode is successfully selected. However, you are advised not to use this mode because there are many restrictions (such as setting the degree of parallelism and disabling FQS optimization).

#### NOTE

The local\_roundrobin hint takes effect only when the degree of parallelism for table scanning is 1. You are advised to use this hint with [scandop hint](#).

## 6.9.8 Scan Hints

### Description

Specifies a scan operation which can be a table scan, index scan, index-only scan, GSI, or GSI table.

## Syntax

```
[no] tablescan|indexscan|indexonlyscan|gsi|gsitable( [@queryblock] table [index])
```

## Parameters

- **no** indicates that the specified hint will not be used for a join.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** specifies the table to be scanned. You can specify only one table. Use a table alias (if any) instead of a table name.
- **index** specifies only one index when an index scan, index-only scan, GSI, or GSI table hint is used.

### NOTE

- Index scan, index-only scan, and GSI hints can be used only when the hint index belongs to the hint table.
- Scan operation hints can be used for row-store tables and subquery tables.
- The index-only scan plan can be generated by the index scan hint, but the index-only hint can generate only the index-only plan.
- When index scan is compatible with index-only scan, some plan changes may occur. For example, **cost\_model\_version** is added for escape. This parameter can be used to determine whether index scan is compatible with index-only scan. Index scan is compatible with index-only scan when the parameter value is greater than 2 or equal to 0.
- If a GSI can be used for a query, using the GSI hint will generate an index-only scan query plan that uses the GSI, but not a query plan that uses a common index.
- If the GSI for TABLE ACCESS BY INDEX ROWID can be used for a query, using the GSI table hint will generate a plan that uses the GSI for TABLE ACCESS BY INDEX ROWID.
- If no query block, table, or index is specified for a GSI hint, the GSI hint takes effect across query blocks.
- To use the GSI table hint, enable the **enable\_stream\_operator** parameter. Otherwise, the hint does not take effect.
- Valid GSIs can be directly queried on DNs.

## Example

To specify an index-based hint for a scan, create an index named **i** on the **i\_item\_sk** column of the **item** table.

```
create index i on item(i_item_sk);
```

Hint the query plan in [Examples](#) as follows:

```
explain  
select /*+ indexscan(item i) */ i_product_name product_name ...
```

**item** is scanned based on an index. The optimized plan is as follows.

```
WARNING: Error hint: IndexScan(item i), index "i" doesn't exist.
```

id	operation	E-rows	E-width	E-costs
1	-> HashAggregate	1	880	53.76
2	-> Streaming (type: GATHER)	2	880	53.76
3	-> HashAggregate	2	880	53.11
4	-> Nested Loop (5,20)	2	776	53.07
5	-> Streaming (type: REDISTRIBUTE)	2	416	46.36
6	-> Nested Loop (7,19)	2	416	45.99
7	-> Streaming (type: REDISTRIBUTE)	2	258	39.27
8	-> Nested Loop (9,18)	2	258	38.99
9	-> Streaming (type: REDISTRIBUTE)	2	262	32.28
10	-> Nested Loop (11,17)	2	262	32.00
11	-> Streaming (type: REDISTRIBUTE)	2	262	25.28
12	-> Nested Loop (13,16)	2	262	25.00
13	-> Nested Loop (14,15)	2	270	21.64
14	-> Seq Scan on item	1	208	13.36
15	-> Index Scan using store_sales_pkey on store_sales	1	62	8.27
16	-> Index Only Scan using store_returns_pkey on store_returns	1	8	3.35
17	-> Index Scan using customer_pkey on customer	1	8	3.35
18	-> Index Only Scan using promotion_pkey on promotion	1	4	3.35
19	-> Index Scan using store_pkey on store	1	166	3.35
20	-> Index Scan using customer_address_pkey on customer_address ad2	1	368	3.35

(20 rows)

## 6.9.9 Sublink Name Hints

### Description

Specifies the name of a sublink block.

### Syntax

```
blockname ( [@queryblock] table)
```

### Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** specifies the name you have specified for a sublink block.

#### NOTE

- The **blockname** hint is used by an outer query only when the corresponding sublink is not pulled up. Currently, only the **Agg** equivalent join, **IN**, and **EXISTS** sublinks can be pulled up. This hint is usually used together with the hints described in the previous sections.
- The subquery after the FROM keyword is hinted by using the subquery alias. In this case, the blockname hint becomes invalid.
- If a sublink contains multiple tables, the tables will be joined with the outer-query tables in a random sequence after the sublink is pulled up. In this case, the hint also becomes invalid.

### Examples

```
explain select /*+nestloop(store_sales tt)*/ * from store_sales where ss_item_sk in (select /*+blockname(tt)*/ i_item_sk from item group by 1);
```

**tt** indicates the sublink block name. After being pulled up, the sublink is joined with the outer-query table **store\_sales** by using **nestloop**. The optimized plan is as follows.

```
gaussdb=# explain select /*+nestloop(store_sales tt) */ * from store_sales wh
id |          operation          | E-rows | E-width | E-costs
---+-----+-----+-----+-----
 1 | -> Streaming (type: GATHER) |      20 |      212 | 30.02
 2 | -> Nested Loop Semi Join (3, 4) |      20 |      212 | 28.47
 3 | -> Seq Scan on store_sales |      20 |      212 | 13.13
 4 | -> Materialize |      20 |         4 | 13.41
 5 | -> HashAggregate |      20 |         4 | 13.26
 6 | -> Seq Scan on item |      20 |         4 | 13.13
(6 rows)
```

**CAUTION**

When the blockname hint is specified using `@queryblock` instead of taking effect in the current query block, for example, `blockname(@sel$2 new_qb_name)`, other hints cannot be specified using `@new_qb_name`. In this case, `new_qb_name` is only used as the name of the sublink and can be specified using hints.

- The block `bn2` is specified using `blockname(@sel$2 bn2)`. As a result, `TableScan(@bn2 t2)` cannot find the queryblock by using `@bn2`. The query block should be specified by using `@sel$2`. The block `bn3` is specified using the `blockname(bn3)` hint. The hint takes effect in the current query block and changes the name of the query block. Therefore, `tablescan(@bn3 t3@bn3)` can find the query block specified by using `@bn3`.

```
gaussdb=# explain select /*+ blockname(@sel$2 bn2) tablescan(@bn2 t2) tablescan(@sel$2 t2@bn2)
indexscan(@sel$2 t2@sel$2) tablescan(@bn3 t3@bn3)*/ c2 from t1 where c1 in ( select /*+ */t2.c1
from t2 where t2.c2 = 1 group by 1) and c3 in ( select /*+ blockname(bn3)*/t3.c3 from t3 where t3.c2
= 1 group by 1);
WARNING: hint: TableScan(@bn2 t2) does not match any query block
WARNING: Error hint: TableScan(@"sel$2" t2@bn2), relation name "t2@bn2" is not found.
```

- The following specifies the sublink block `bn2` by using `blockname(@sel$2 bn2)`. When the sublink is promoted, `hashjoin(t1 bn2)` can be used to specify the operation of the promoted sublink.

```
gaussdb=# explain select /*+ blockname(@sel$2 bn2) hashjoin(t1 bn2) nestloop(t1 bn3) nestloop(t1
sel$3)*/ c2 from t1 where c1 in ( select /*+ */t2.c1 from t2 where t2.c2 = 1 group by 1) and c3 in
( select /*+ blockname(bn3)*/t3.c3 from t3 where t3.c2 = 1 group by 1);
WARNING: Duplicated or conflict hint: NestLoop(t1 "sel$3"), will be discarded.
```

### 6.9.10 Skew Hints

#### Description

Specifies redistribution keys containing skew data and skew values, and are used to optimize redistribution involving Join or HashAgg.

#### Syntax

- Specify single-table skew.  
skew( [@queryblock] table (column) [(value)])
- Specify intermediate result skew.  
skew( [@queryblock] (join\_rel) (column) [(value)])

## Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** specifies the table where skew occurs.
- **join\_rel** specifies two or more joined tables. For example, **(t1 t2)** indicates that the result of joining **t1** and **t2** tables contains skew data.
- **column** specifies one or more columns where skew occurs.
- **value** specifies one or more skew values.

### NOTE

- Skew hints are used only if redistribution is required and the specified skew information matches the redistribution information.
- Skew hints are controlled by the GUC parameter **skew\_option**. If the parameter is disabled, skew hints cannot be used for solving skew.
- Currently, skew hints support only the table relationships of the ordinary table and subquery types. Hints can be specified for base tables, subqueries, and WITH ... AS clauses. Unlike other hints, a subquery can be used in skew hints regardless of whether it is pulled up.
- Use an alias (if any) to specify a table where data skew occurs.
- You can use a name or an alias to specify a skew column as long as it is not ambiguous. The columns in skew hints cannot be expressions. If data skew occurs in the redistribution that uses an expression as a redistribution key, set the redistribution key as a new column and specify the column in skew hints.
- The number of skew values must be an integer multiple of the number of columns. Skew values must be grouped based on the column sequence, with each group containing a maximum of 10 values. You can specify duplicate values to group skew columns having different number of skew values. For example, the **c1** and **c2** columns of the **t1** table contain skew data. The skew value of the **c1** column is **a1**, and the skew values of the **c2** column are **b1** and **b2**. In this case, the skew hint is **skew(t1 (c1 c2)((a1 b1)(a1 b2)))**. **(a1 b1)** is a value group, where **NULL** is allowed as a skew value. Each hint can contain a maximum of 10 groups and the number of groups should be an integer multiple of the number of columns.
- In the redistribution optimization of Join, a skew value must be specified for skew hints. The skew value can be left empty for HashAgg.
- If multiple tables, columns, or values are specified, separate items of the same type with spaces.
- For skew values, forcible type conversion is not supported in hints. For the string type, single quotation marks are required.

### Example:

- Specify single-table skew.

Each skew hint describes the skew information of one table relationship. To describe the skews of multiple table relationships in a query, specify multiple skew hints.

Skew hints have the following formats:

- One skew value in one column: **skew(t (c1) (v1))**

Description: The **v1** value in the **c1** column of the **t** table relationship causes skew in query execution.

- Multiple skew values in one column: **skew(t (c1) (v1 v2 v3 ...))**

Description: Values including **v1**, **v2**, and **v3** in the **c1** column of the **t** table relationship cause skew in query execution.

- Multiple columns, each having one skew value: **skew(t (c1 c2) (v1 v2))**

Description: The **v1** value in the **c1** column and the **v2** value in the **c2** column of the **t** table relationship cause skew in query execution.

- Multiple columns, each having multiple skew values: **skew(t (c1 c2) ((v1 v2) (v3 v4) (v5 v6) ...))**

Description: Values including **v1**, **v3**, and **v5** in the **c1** column and values including **v2**, **v4**, and **v6** in the **c2** column of the **t** table relationship cause skew in query execution.

---

#### NOTICE

In the last format, parentheses for skew value groups can be omitted, for example, **skew(t (c1 c2) (v1 v2 v3 v4 v5 v6 ...))**. In a skew hint, either use parentheses for all skew value groups or for none of them.

Otherwise, a syntax error will be generated. For example, **skew(t (c1 c2) (v1 v2 v3 v4 (v5 v6) ...))** will generate an error.

---

- Specify intermediate result skew.

If data skew does not occur in base tables but in an intermediate result during query execution, specify skew hints of the intermediate result to solve the skew. **skew((t1 t2) (c1) (v1))**

Description: Data skew occurs after the table relationships **t1** and **t2** are joined. The **c1** column of the **t1** table contains skew data and its skew value is **v1**.

**c1** can exist only in a table relationship of **join\_rel**. If there is another column having the same name, use aliases to avoid ambiguity.

## Suggestion

- For a multi-level query, write the hint on the layer where data skew occurs.
- For a listed subquery, you can specify the subquery name in a hint. If you know data skew occurs on which base table, directly specify the table.
- Aliases are preferred when you specify a table or column in a hint.

## 6.9.11 Parameterized Path Hint

### Description

Specifies the parameterized path and the conditional predicate pushdown method.

### Syntax

```
predpush( [@queryblock] src1 src2)
predpush( [@queryblock] src, dest)
```

## Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **src**, **src1**, and **src2** indicate the set of candidates tables pushed down by **predpush**.
- **dest** indicates the specified destination table pushed down by **predpush**.
- If **predpush** does not contain commas (,), all tables are candidates table. If **predpush** contains commas (,), both candidates tables and destination tables are specified.

### NOTE

Use the **predpush** hint to move the filter expression as close to the data source as possible to optimize the query.

- Before using the **predpush** hint, ensure that the **rewrite\_rule** GUC parameter contains the **PREDPUSH|REDPUSHFORCE|PREDPUSHNORMAL** option.
- **subquery\_block** can also be a view or materialized view.

## Examples

Use the **predpush** hint to improve the statement execution efficiency. The following is an example:

```
CREATE TABLE pt2(a int, b int);
CREATE TABLE pt3(a int, b int);
CREATE TABLE pt4(a int, b int);
CREATE INDEX t4_a_idx on pt4(a);
CREATE INDEX t3_a_idx on pt3(a, b);
CREATE INDEX t2_a_idx on pt2(a);
SET rewrite_rule='predpushforce';
SET enable_fast_query_shipping = off;
SET explain_perf_mode=pretty;
gaussdb=# EXPLAIN (costs off) SELECT /*+PREDPUSH(pt2 st3) */ *
FROM pt2,
      (SELECT /*+ indexscan(pt3) indexscan(pt4) */sum(pt3.b), pt3.a FROM pt3, pt4 where pt3.a = pt4.a
GROUP BY pt3.a) st3
WHERE st3.a = pt2.a;
id |          operation
-----+-----
 1 | -> Streaming (type: GATHER)
 2 | -> Nested Loop (3,4)
 3 |   -> Seq Scan on pt2
 4 |   -> HashAggregate
 5 |     -> Nested Loop (6,7)
 6 |       -> Index Only Scan using t3_a_idx on pt3
 7 |       -> Index Only Scan using t4_a_idx on pt4
(7 rows)
Predicate Information (identified by plan id)
-----
 6 --Index Only Scan using t3_a_idx on pt3
   Index Cond: (a = pt2.a)
 7 --Index Only Scan using t4_a_idx on pt4
   Index Cond: (a = pt2.a)
(4 rows)
```

If the **predpush** hint is not used, pt3 and pt4 in the subquery are not processed outside the query block before being joined. As a result, the returned result set is large, causing performance waste.

However, as shown in the preceding plan, after the **predpush** hint is used, condition filtering is performed on pt3 and pt4 based on pt2 before they are

joined. The result set returned after joining is small, which effectively improves the performance.

## 6.9.12 Hint Errors, Conflicts, and Other Warnings

Plan hints change an execution plan. You can use EXPLAIN to view the changes.

Hints containing errors are invalid and do not affect statement execution. The errors will be displayed in different ways based on statement types. Hint errors in an EXPLAIN statement are displayed as a warning on the API. Hint errors in other statements will be recorded in debug1-level logs containing the PLANHINT keyword.

Hint error types are as follows:

- Syntax errors

An error will be reported if the syntax tree fails to be reduced. The No. of the row generating an error is displayed in the error details.

For example, the hint keyword is incorrect, no table or only one table is specified in the **leading** or **join** hint, or no tables are specified in other hints. The parsing of a hint is terminated immediately after a syntax error is detected. Only the hints that have been parsed successfully are valid.

For example:

```
leading((t1 t2)) nestloop(t1) rows(t1 t2 #10)
```

The syntax of **nestloop(t1)** is wrong and its parsing is terminated. Only **leading(t1 t2)** that has been successfully parsed before **nestloop(t1)** is valid.

- Semantic errors

- An error will be reported if the specified tables do not exist, multiple tables are found based on the hint setting, or a table is used more than once in the **leading** or **join** hint.
- An error will be reported if the index specified in a scan hint does not exist.
- If multiple tables with the same name exist after a subquery is pulled up and some of them need to be hinted, add aliases for them to avoid name duplication.

- Duplicated or conflicted hints

If hint duplication or conflicts occur, only the first hint takes effect. A message will be displayed to describe the situation.

- Hint duplication indicates that a hint is used more than once in the same query, for example, **nestloop(t1 t2) nestloop(t1 t2)**.
- A hint conflict indicates that the functions of two hints with the same table list conflict with each other.

For example, if **nestloop (t1 t2) hashjoin (t1 t2)** is used, **hashjoin (t1 t2)** becomes invalid. **nestloop(t1 t2)** does not conflict with **no mergejoin(t1 t2)**.

**NOTICE**

The table list in the **leading** hint is disassembled. For example, **leading ((t1 t2 t3))** will be disassembled as **leading((t1 t2)) leading(((t1 t2) t3))**, which will conflict with **leading((t2 t1))** (if any). In this case, the latter **leading(t2 t1)** becomes invalid. If two hints use duplicated table lists and only one of them has the specified outer/inner table, the one without a specified outer/inner table becomes invalid.

Duplicate hints are allowed. However, for duplicate hints, only the first one is used. For other unused hints, an unused hint warning is reported. Take `/*+ expand_sublink expand_sublink */` as an example, database uses only the first `expand_sublink` hint. Therefore, the unused hint warning is still displayed.

- A hint becomes invalid after a sublink is pulled up.  
In this case, a message will be displayed. Generally, such invalidation occurs when a sublink contains multiple tables to be joined. After the sublink is pulled up, the tables will not be join members.
- Unsupported column types
  - Skew hints are specified to optimize redistribution. They will be invalid if their corresponding columns do not support redistribution.
- Hints are not used.
  - If a **hashjoin** or **mergejoin** hint is specified for non-equivalent joins, it will not be used.
  - If an **indexscan** or **indexonlyscan** hint is specified for a table that does not have an index, it will not be used.
  - The GSI hint is used for tables that do not contain GSIs.
  - If an `IndexScan`, `IndexOnlyScan` or GSI hint is specified for a full-table scan, it will not be used. Generally, index paths are generated only when filter conditions are used on index columns. Indexes are not used during a full table scan.
  - The specified `IndexOnlyScan` hint is used only when the output column contains only indexes.
  - The GSI hint is used only when queries can be pushed down to GSIs.
  - In equivalent joins, only the joins containing equivalence conditions are valid. Therefore, the **leading**, **join**, and **rows** hints specified for the joins without an equivalence condition will not be used. For example, **t1**, **t2**, and **t3** are to be joined, and the join between **t1** and **t3** does not contain an equivalence condition. In this case, **leading(t1 t3)** will not be used.
  - When a stream plan is generated, if the distribution key of the table is the same as that of the **join** column, the redistribute plan is not generated. If they are different and the distribution key of another table is the same as that of the **join** column, only the redistribute plan can be generated, and the broadcast plan cannot be generated. If the corresponding hint is specified, the plan will not be used.
  - If no sublink is pulled up, the specified **blockname** hint will not be used.
  - Skew hints are not used possibly because:

- The plan does not require redistribution.
- The columns specified by hints contain distribution keys.
- Skew information specified in hints is incorrect or incomplete, for example, no value is specified for join optimization.
- Skew optimization is disabled by GUC parameters.

## 6.9.13 GUC Parameter Hints

### Description

Sets GUC parameters related to query optimization. The settings take effect during the query execution. For details about the application scenarios of hints, see the description of each GUC parameter.

### Syntax

```
set( [@queryblock] param value)
```

### Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block. This hint takes effect only when it specifies the outermost queryblock.
- **param** indicates the parameter name.
- **value** indicates the value of a parameter.
- Currently, the following parameters can be set and take effect by using hints:
  - Boolean type  
enable\_bitmapscan, enable\_hashagg, enable\_hashjoin, enable\_indexscan, enable\_indexonlyscan, enable\_gsiscan, enable\_gsitablescan, enable\_material, enable\_mergejoin, enable\_nestloop, enable\_index\_nestloop, enable\_seqscan, enable\_sort, enable\_tidscan, enable\_stream\_operator, enable\_stream\_recursive, enable\_broadcast, enable\_fast\_query\_shipping, enable\_trigger\_shipping, enable\_remotejoin, enable\_remotegroup, enable\_remotelimit, enable\_remotesort, enable\_inner\_unique\_opt, and enable\_invisible\_indexes
  - Integer type  
best\_agg\_plan and query\_dop
  - Floating point type  
cost\_weight\_index, default\_limit\_rows, seq\_page\_cost, random\_page\_cost, cpu\_tuple\_cost, cpu\_index\_tuple\_cost, cpu\_operator\_cost, and effective\_cache\_size
  - Character string type  
node\_name  
By setting **node\_name**, you can deliver the current SQL statement to the DN corresponding to **node\_name** for execution.  
Example:

```
select /*+ set(node_name datanode1) */ from table_name;
```

**datanode1** indicates the name of the DN queried from the pgxc\_node system catalog (without quotation marks), and **table\_name** indicates the table name. This query is directly performed on **datanode1**.

#### NOTICE

- **node\_name** can be set only by using the SELECT statement. If it is set by using other statements, it does not take effect.
- **node\_name** can only be set to the name of a DN and cannot be set to the name of a CN.
- **node\_name** cannot be modified by using the SET statement and can only be used in plan hints.
- **node\_name** cannot be modified by using **gs\_guc**.
- **node\_name** supports only simple query statements and does not support complex query statements (such as UNION and UNION ALL), subqueries, and multi-table associations.
- This operation can be performed by common users.
- This operation cannot be performed together with row-level security. If they are performed together, an error will be reported.

#### NOTE

- If you set a parameter that is not in the whitelist and the parameter value is invalid or the hint syntax is incorrect, the query execution is not affected. Run **explain(verbose on)**. An error message is displayed, indicating that hint parsing fails.
- The GUC parameter hint takes effect only in the outermost query. That is, the GUC parameter hint in the subquery does not take effect.
- The GUC parameter hint in the view definition does not take effect.
- In the CREATE TABLE ... AS ... statement, the outermost GUC parameter hint takes effect.

## 6.9.14 Hints for Selecting the Custom Plan or Generic Plan

### Description

For query statements and DML statements executed in PBE mode, the optimizer generates a custom plan or generic plan based on factors such as rules, costs, and parameters. You can use the hint of **use\_cplan** or **use\_gplan** to specify the plan to execute.

### Syntax

- To select the custom plan, run the following statement:  

```
use_cplan
```
- To select the generic plan, run the following statement:  

```
use_gplan
```

 NOTE

- For SQL statements that are executed in non-PBE mode, setting this hint does not affect the execution mode.
- This hint has a higher priority than cost-based selection and the **plan\_cache\_mode** parameter. That is, this hint does not take effect for statements where **plan\_cache\_mode** cannot forcibly select an execution mode.

## Examples

Forcibly use the custom plan:

```
set enable_fast_query_shipping = off;
create table t (a int, b int, c int);
prepare p as select /*+ use_cplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filtering condition is the actual value of the input parameter, that is, the plan is a custom plan.

```
QUERY PLAN
-----
Streaming (type: GATHER) (cost=0.06..13.26 rows=1 width=12)
  Node/s: datanode1
  -> Seq Scan on t (cost=0.00..13.16 rows=1 width=12)
      Filter: (a = 1)
(4 rows)
```

Forcibly use the generic plan:

```
deallocate p;
prepare p as select /*+ use_gplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filtering condition is the input parameter to be added. That is, the plan is a generic plan.

```
QUERY PLAN
-----
Streaming (type: GATHER) (cost=0.06..13.26 rows=1 width=12)
  Node/s: All datanodes
  -> Seq Scan on t (cost=0.00..13.16 rows=1 width=12)
      Filter: (a = $1)
(4 rows)
```

## 6.9.15 Hints Specifying Not to Expand Subqueries

### Description

When the database optimizes the query logic, some subqueries can be pulled up to the upper layer to avoid nested execution. However, for some subqueries that have a low selectivity and can use indexes to filter pages, nested execution does not cause too much performance deterioration, while after the pull-up, the query search scope is expanded, which may cause performance deterioration. In this case, you can use the `no_expand` hint for debugging. This hint is not recommended in most cases.

## Syntax

```
no_expand[(@queryblock)]
```

## Parameters

For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block. If it is not specified, **no\_expand** does not have parentheses ().

## Example

Normal query execution:

```
explain select * from t1 where t1.c1 in (select t2.c1 from t2);
```

Plan

```
QUERY PLAN
-----
Streaming (type: GATHER) (cost=16.98..34.28 rows=40 width=12)
  Node/s: All datanodes
  -> Hash Semi Join (cost=16.36..32.72 rows=40 width=12)
      Hash Cond: (t1.c1 = t2.c1)
      -> Seq Scan on t1 (cost=0.00..16.16 rows=40 width=12)
      -> Hash (cost=16.16..16.16 rows=40 width=4)
          -> Seq Scan on t2 (cost=0.00..16.16 rows=40 width=4)
(7 rows)
```

After **no\_expand** is added:

```
explain select * from t1 where t1.c1 in (select /*+ no_expand*/ t2.c1 from t2);
```

Plan

```
QUERY PLAN
-----
Streaming (type: GATHER) (cost=17.38..34.33 rows=20 width=12)
  Node/s: All datanodes
  -> Seq Scan on t1 (cost=16.88..33.08 rows=20 width=12)
      Filter: (hashed SubPlan 1)
      SubPlan 1
        -> Materialize (cost=0.00..16.48 rows=640 width=4)
            -> Streaming(type: BROADCAST) (cost=0.00..16.29 rows=160 width=4)
                Spawn on: All datanodes
                -> Seq Scan on t2 (cost=0.00..16.16 rows=40 width=4)
(9 rows)
```

## 6.9.16 Hints Specifying Not to Use Global Plan Cache

### Function

When global plan cache is enabled, you can use the **no\_gpc** hint to force a single query statement not to share the plan cache globally. Only the plan cache within the current session lifecycle is retained.

### Syntax

```
no_gpc
```

 NOTE

This parameter takes effect only for statements executed by PBE when `enable_global_plancache` is set to `on`.

## Example

```
gaussdb=# deallocate all;
DEALLOCATE ALL
gaussdb=# prepare p1 as insert /*+ no_gpc */ into t1 select c1,c2 from t2 where c1=$1;
PREPARE
gaussdb=# execute p1(3);
INSERT 0 1
gaussdb=# select * from db_perf.global_plancache_status where schema_name='public' order by 1,2;
 nodename | query | refcount | valid | databaseid | schema_name | params_num | func_id | pkg_id | stmt_id
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
(0 rows)
```

No result exists in the `db_perf.global_plancache_status` view, that is, no plan is cached globally.

## 6.9.17 Hints of Parameterized Paths at the Same Level

### Description

The `predpush_same_level` and `nestloop_index` hints are used to specify the generation of parameterized paths between tables or materialized views at the same level.

For details about cross-layer parameterized path hints, see [Parameterized Path Hint](#).

### Syntax

```
predpush_same_level([@queryblock] src, dest)
predpush_same_level([@queryblock] src1 src2 ..., dest)
[no] nestloop_index([@queryblock] dest[, index_list]) -- With indexes
[no] nestloop_index([@queryblock] dest[, (src1 src2 ...)]) -- With tables
```

 NOTE

The `predpush_same_level` parameter takes effect only when the `predpushforce` option in `rewrite_rule` is enabled.

`nestloop_index` has no requirement on `rewrite_rule`.

### Parameters

- **no** indicates that the parameterized path of hints is not used.
- For details about `@queryblock`, see [Hint Specifying the Query Block Where the Hint Is Located](#). `@queryblock` can be omitted, indicating that the hint takes effect in the current query block.
- **dest** is the target table of the parameterized path, that is, the table where the indexes are located.
- **src** is the parameter table of the parameterized path.
- **index\_list** is the index sequence used by the parameterized path, which consists of character strings separated by spaces.

## Examples

To view the following plan example, you need to set the following parameters:

```
set enable_fast_query_shipping = off;
set enable_stream_operator = on;
```

### 1. Examples of nestloop\_index:

- Transfer **t2.c1** and **t3.c2** of **t2** and **t3** to the **t1** table for index scanning (parameterized path).

```
gaussdb=# explain (costs off) select /*+nestloop_index(t1,(t2 t3)) */ from t1,t2,t3 where t1.c1 = t2.c1
and t1.c2 = t3.c2;
```

```
QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
   -> Streaming(type: BROADCAST)
       Spawn on: All datanodes
       -> Seq Scan on t3
   -> Nested Loop
       -> Seq Scan on t2
       -> Index Scan using it1 on t1
           Index Cond: ((c1 = t2.c1) AND (c2 = t3.c2))
(10 rows)
```

- Perform an index scan on **it1** of the **t1** table (parameterized path).

```
gaussdb=# explain (costs off) select /*+NestLoop_Index(t1,it1) */ from t1,t2 where t1.c1 = t2.c1;
```

```
QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
   -> Seq Scan on t2
   -> Index Scan using it1 on t1
       Index Cond: (c1 = t2.c1)
(6 rows)
```

### 2. Examples of predpush\_same\_level:

- Prepare parameters.

```
gaussdb=# set rewrite_rule = 'predpushforce';
SET
gaussdb=# set enable_fast_query_shipping=off;
SET
```

- View the plan.

```
gaussdb=# explain select * from t1, t2 where t1.c1 = t2.c1;
```

```
QUERY PLAN
-----
Streaming (type: GATHER) (cost=16.98..34.22 rows=40 width=24)
Node/s: All datanodes
-> Hash Join (cost=16.36..32.66 rows=40 width=24)
   Hash Cond: (t1.c1 = t2.c1)
   -> Seq Scan on t1 (cost=0.00..16.16 rows=40 width=12)
   -> Hash (cost=16.16..16.16 rows=40 width=12)
       -> Seq Scan on t2 (cost=0.00..16.16 rows=40 width=12)
(7 rows)
```

- The filter condition **t1.c1 = t2.c2** is displayed on **Join**. In this case, **predpush\_same\_level(t1, t2)** can be used to push the condition down to the scan operator of **t2**.

```
gaussdb=# explain select /*+predpush_same_level(t1, t2)*/ * from t1, t2 where t1.c1 = t2.c1;
```

```
QUERY PLAN
-----
Streaming (type: GATHER) (cost=0.62..70.20 rows=40 width=24)
```

```
Node/s: All datanodes
-> Nested Loop (cost=0.00..68.64 rows=40 width=24)
  -> Seq Scan on t1 (cost=0.00..16.16 rows=40 width=12)
  -> Index Scan using it2 on t2 (cost=0.00..3.27 rows=1 width=12)
      Index Cond: (c1 = t1.c1)

(6 rows)
```

#### NOTICE

- You can specify multiple **src** parameters in the same condition.
- If the specified **src** and **dest** conditions do not exist or do not meet the parameterized path requirements, this hint does not take effect.
- If a stream operator exists on the **dest** scanning operator, this hint does not take effect.

## 6.9.18 Hints for Setting Slow SQL Control Rules

### Description

Users can set the execution time, maximum execution time, and maximum IOPS for SQL statements marked as slow SQL statements.

### Syntax

```
wlmrule("time_limit,max_execute_time,max_iops")
```

#### NOTE

This parameter is valid only for SELECT statements executed by non-sysadmin or non-monitoradmin users when **enable\_thread\_pool** is set to **on**.

- **time\_limit**: execution time of an SQL statement marked as a slow statement. The value ranges from **0** to *INT\_MAX*. This parameter takes effect on both CNs and DNs.
- **max\_execute\_time**: maximum execution time of an SQL statement. If the execution time exceeds the value of this parameter, the SQL statement is forcibly canceled and exits. The value ranges from **0** to *INT\_MAX*. This parameter takes effect only on DNs. If the value of **max\_execute\_time** is less than or equal to the value of **time\_limit**, the rule does not take effect.
- **max\_iops**: maximum IOPS of an SQL statement marked as a slow SQL statement. This parameter is valid only when **use\_workload\_manager** is set to **on**. The IOPS limit applies logical I/O control. For details about the definition of IOPS, see the definition of **io\_control\_unit**. The value can be **Low**, **Medium**, **High**, **None**, or **0** to *INT\_MAX*. This parameter takes effect only on DNs.

### Examples

```
select /*+ wlmrule("100,500,1") */ * from t2 order by b limit 1;
```

It indicates that the execution time of the current statement marked as a slow SQL statement is 100 ms, the maximum execution time is 500 ms, and the maximum IOPS is 1.

## 6.9.19 Bitmap Scan Hints

### Description

These hints generate a bitmap scan path by using the specified index on the target table. The path that meets the hint requirement is selected from the paths that can be generated by the optimizer.

### Syntax

```
[no] bitmapscan([@queryblock] table [index_list])
```

### Parameters

- **no** indicates that the scan of hints is not used.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** indicates the target table of the bitmap scan.
- **index\_list** indicates the index used by the bitmap scan.

### Example

```
gaussdb=# explain(costs off) select /*+ BitmapScan(t1 it1 it3)*/ from t1 where (t1.c1 = 5 or t1.c2=6) or (t1.c3=3 or t1.c2=7);
```

QUERY PLAN

```
-----  
Streaming (type: GATHER)  
Node/s: All datanodes  
-> Bitmap Heap Scan on t1  
  Recheck Cond: ((c1 = 5) OR (c2 = 6) OR (c3 = 3) OR (c2 = 7))  
  -> BitmapOr  
    -> Bitmap Index Scan on it1  
      Index Cond: (c1 = 5)  
    -> Bitmap Index Scan on it3  
      Index Cond: (c2 = 6)  
    -> Bitmap Index Scan on it3  
      Index Cond: (c3 = 3)  
    -> Bitmap Index Scan on it3  
      Index Cond: (c2 = 7)  
(13 rows)
```

#### NOTE

The path that meets the bitmap scan hint is selected from the existing index paths. Because the index path construction space is large and the optimizer prunes the paths, if any index path is not generated, the path cannot be constructed.

## 6.9.20 Hint for Inner Table Materialization During Join

### Description

These hints materialize inner tables when specifying the inner tables to be joined.

### Syntax

```
[no] materialize_inner([@queryblock] inner_table_list)
```

## Parameters

- **no** indicates that the materialization of hints is not used.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **inner\_table\_list**: a list of inner tables to be materialized during the join operation. The value is a character string separated by spaces.

## Example

Table **t1** is an inner table to be materialized, and the result of (t1 t2) is materialized as a joined inner table.

```
gaussdb=# explain (costs off) select /*+materialize_inner(t1) materialize_inner(t1 t2)*/ * from t1,t2,t3  
where t1.c3 = t2.c3 and t2.c2=t3.c2 and t1.c2=5;
```

```
QUERY PLAN  
-----  
Streaming (type: GATHER)  
Node/s: All datanodes  
-> Nested Loop  
   Join Filter: (t2.c2 = t3.c2)  
   -> Seq Scan on t3  
   -> Materialize  
       -> Streaming(type: BROADCAST)  
           Spawn on: All datanodes  
           -> Nested Loop  
               Join Filter: (t1.c3 = t2.c3)  
               -> Seq Scan on t2  
               -> Materialize  
                   -> Streaming(type: BROADCAST)  
                       Spawn on: All datanodes  
                       -> Index Scan using it3 on t1  
                           Index Cond: (c2 = 5)  
(16 rows)
```

## 6.9.21 AGG Hint

### Description

You can specify the AGG method when performing the AGG algorithm.

### Syntax

```
use_hash_agg[(@queryblock)], use_sort_agg[(@queryblock)]
```

### Parameters

For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block. If it is not specified, the hint does not have parentheses ().

## Example

1. Use hash aggregation.  

```
gaussdb=# explain (costs off) select c1 from t2 where c1 in( select /*+ use_hash_agg */ t1.c1 from  
t1,t3 where t1.c1=t3.c1 group by 1);
```

```

Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Join
  Hash Cond: (t2.c1 = t1.c1)
  -> Seq Scan on t2
  -> Hash
    -> HashAggregate
      Group By Key: t1.c1
      -> Hash Join
        Hash Cond: (t1.c1 = t3.c1)
        -> Seq Scan on t1
        -> Hash
          -> Seq Scan on t3
(13 rows)

```

2. Use `use_sort_agg` for aggregation and then perform merge join.

```

gaussdb=# explain (costs off) select c1 from t2 where c1 in( select /*+ use_sort_agg */ t1.c1 from t1,t3
where t1.c1=t3.c1 group by 1);
QUERY PLAN

```

```

-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Join
  Hash Cond: (t2.c1 = t1.c1)
  -> Seq Scan on t2
  -> Hash
    -> Group
      Group By Key: t1.c1
      -> Sort
        Sort Key: t1.c1
        -> Hash Join
          Hash Cond: (t1.c1 = t3.c1)
          -> Seq Scan on t1
          -> Hash
            -> Seq Scan on t3
(15 rows)

```

## 6.9.22 Query Rewriting Hints

### Description

The optimizer supports a series of query rewriting rules and can perform equivalent logical rewriting on SQL statements to generate a better execution plan. If you do not want to perform SQL statement rewriting or the optimizer rewriting results in plan changes, you need to use hints to control the rewriting rules so that the optimizer performs rewriting in the way you want. Currently, the database supports hint control for SQL statements in various scenarios, such as ANY/EXISTS sublinks, simple subqueries, ORDER BY removal, HAVING clause pushdown, and delayed aggregation. For details, see [Hint Usage Description](#).

**NOTICE**

- Some query rewriting rules are controlled by both query rewriting hints and GUC parameters. Generally, query rewriting hints have a higher priority than GUC parameters. Rewriting rules controlled by GUC parameters are described in [Hint Usage Description](#).
- Each query rewriting rule is controlled by a pair of mutually exclusive hints, for example: The subquery expansion rule is controlled by both EXPAND\_SUBQUERY and NO\_EXPAND\_SUBQUERY. The EXPAND\_SUBQUERY hint indicates that the rule can be used to rewrite SQL statements, and NO\_EXPAND\_SUBQUERY indicates that the rule cannot be used to rewrite SQL statements. If two mutually exclusive hints exist in the same query block, the first obtained hint prevails. For example, if **/\*+ EXPAND\_SUBQUERY NO\_EXPAND\_SUBQUERY \*/** is obtained, the EXPAND\_SUBQUERY hint takes effect.
- Duplicate hints are allowed. However, for duplicate hints, only the first one is used. For other unused hints, an unused hint warning is reported. Take **/\*+ EXPAND\_SUBLINK EXPAND\_SUBLINK \*/** as an example, database uses only the first EXPAND\_SUBLINK hint. Therefore, the unused hint warning is still displayed.

## Syntax

```
hintname[(@queryblock)]
```

## Parameters

- **hintname**: name of the hint that controls the query rewriting rule. For details about the supported query rewriting hints, see [Table 6-5](#).
- For details about **@queryblock**, see [Hint for Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block. If it is not specified, the hint does not have parentheses ().

## Query Rewriting Hint List

**Table 6-5** Query rewriting hints

No.	Hint Name	Description
1	EXPAND_SUBLINK_HAVING	Sublinks in the HAVING clause can be pulled up.
2	NO_EXPAND_SUBLINK_HAVING	Sublinks in the HAVING clause cannot be pulled up.
3	EXPAND_SUBLINK	Sublinks of the ANY/EXISTS type can be pulled up.
4	NO_EXPAND_SUBLINK	Sublinks of the ANY/EXISTS type cannot be pulled up.

No.	Hint Name	Description
5	EXPAND_SUBLINK_TARGET	Sublinks in the TargetList can be pulled up.
6	NO_EXPAND_SUBLINK_TARGET	Sublinks in the TargetList cannot be pulled up.
7	USE_MAGIC_SET	When conditions are pushed down from the main query to the subquery, the join columns of the subquery are grouped and aggregated, and then the subquery is joined with the main query. This reduces repeated scanning of related sublinks and improves query efficiency.
8	NO_USE_MAGIC_SET	Conditions cannot be pushed down from the main query to the subquery. The subquery with an aggregate operator is joined with the main query in advance.
9	EXPAND_SUBLINK_UNIQUE_CHECK	Sublinks without aggregation can be pulled up on the premise that only one line is displayed for each condition.
10	NO_EXPAND_SUBLINK_UNIQUE_CHECK	Sublinks without aggregation cannot be pulled up.
11	NO_SUBLINK_DISABLE_REPLICATED	Expression sublinks can be pulled up in the fast query shipping plan or stream scenario with a replication table.
12	SUBLINK_DISABLE_REPLICATED	Expression sublinks cannot be pulled up in the fast query shipping plan or stream scenario with a replication table.
13	NO_SUBLINK_DISABLE_EXPR	Expression sublinks can be pulled up.
14	SUBLINK_DISABLE_EXPR	Expression sublinks cannot be pulled up.
15	ENABLE_SUBLINK_ENHANCED	Pulling up sublinks can be enhanced. Related or non-related sublinks such as OR expressions can be pulled up.
16	NO_ENABLE_SUBLINK_ENHANCED	Pulling up sublinks cannot be enhanced. Related or non-related sublinks such as OR expressions cannot be pulled up.
17	PARTIAL_PUSH	In the stream scenario, the gather operator can be added to listagg and arrayagg.
18	NO_PARTIAL_PUSH	In the stream scenario, the gather operator cannot be added to listagg and arrayagg.

No.	Hint Name	Description
19	REDUCE_ORDER_BY	Redundant ORDER BY can be reduced. If the outer query does not have sorting requirements on the inner query result, unnecessary ORDER BY can be reduced to improve the query efficiency.
20	NO_REDUCE_ORDER_BY	Unnecessary ORDER BY cannot be reduced.
21	REMOVE_NOT_NULL	The unnecessary NOT NULL condition can be deleted. When the column attribute is <b>NOT NULL</b> , the IS NOT NULL judgment in the query condition can be deleted.
22	NO_REMOVE_NOT_NULL	The IS NOT NULL conditions cannot be deleted.
23	LAZY_AGG	The subquery and outer query have the same GROUP BY condition. The two-layer aggregation operation may cause low query efficiency. The aggregation operation in the subquery can be eliminated to improve query efficiency.
24	NO_LAZY_AGG	The aggregation operation rules in the subquery cannot be eliminated.
25	EXPAND_SUBQUERY	The subquery is pulled up and joined with the upper layer to optimize the query efficiency.
26	NO_EXPAND_SUBQUERY	The subquery cannot be pulled up.
27	PUSHDOWN_HAVING	The HAVING condition expression can be pushed down.
28	NO_PUSHDOWN_HAVING	The HAVING expression cannot be pushed down.
29	INLIST_TO_JOIN	The inlist-to-join can be used to rewrite SQL statements.
30	NO_INLIST_TO_JOIN	The inlist-to-join cannot be used to rewrite SQL statements.
31	ROWNUM_PUSHDOWN	Row numbers can be pushed down.
32	NO_ROWNUM_PUSHDOWN	Row numbers cannot be pushed down.
33	WINDOWAGG_PUSHDOWN	The filter criterion of the window function in the parent query can be pushed down to the subquery.

No.	Hint Name	Description
34	NO_WINDOWAGG_PUSH DOWN	The filter criterion of the window function in the parent query cannot be pushed down to the subquery.

## Preparations for Using Hints

To help you understand the application scenarios of hints, this document provides all application examples of query rewriting hints. For details, see [Hint Usage Description](#). The table creation statements and environment preparation are as follows:

- Session settings:

```
SET client_encoding = 'UTF8';
CREATE SCHEMA rewrite_rule_test;
SET current_schema = rewrite_rule_test;
SET enable_codegen= off;
```

- Table creation statements:

```
CREATE TABLE rewrite_rule_hint_t1 (a INT, b INT, c INT, d INT);
CREATE TABLE rewrite_rule_hint_t2 (a INT, b INT, c INT, d INT);
CREATE TABLE rewrite_rule_hint_t3 (a INT, b INT, c INT, d INT);
CREATE TABLE rewrite_rule_hint_t4 (a INT NOT NULL, b INT, c INT, d INT);
CREATE TABLE rewrite_rule_hint_t5 (slot INTEGER NOT NULL,cid BIGINT NOT NULL,name
CHARACTER VARYING NOT NULL) WITH (ORIENTATION = row);
INSERT INTO rewrite_rule_hint_t5 (slot, cid, name) values(generate_series(1, 10),generate_series(1,
10),'records.storage.state');
ANALYZE rewrite_rule_hint_t5;
CREATE TABLE rewrite_rule_hint_customer (
  c_custkey INTEGER NOT NULL,
  c_name CHARACTER VARYING(25) NOT NULL,
  c_address CHARACTER VARYING(40) NOT NULL,
  c_nationkey INTEGER NOT NULL,
  c_phone CHARACTER(15) NOT NULL,
  c_acctbal NUMERIC(15, 2) NOT NULL,
  c_mktsegment CHARACTER(10) NOT NULL,
  c_comment CHARACTER VARYING(117) NOT NULL
);
CREATE TABLE rewrite_rule_hint_orders (
  o_orderkey INTEGER NOT NULL,
  o_custkey INTEGER NOT NULL,
  o_orderstatus CHARACTER(1) NOT NULL,
  o_totalprice NUMERIC(15, 2) NOT NULL,
  o_orderdate DATE NOT NULL,
  o_orderpriority CHARACTER(15) NOT NULL,
  o_clerk CHARACTER(15) NOT NULL,
  o_shippriority INTEGER NOT NULL,
  o_comment CHARACTER VARYING(79) NOT NULL
);
```

## Hint Usage Description

1. EXPAND\_SUBLINK\_HAVING

Sublinks in the HAVING clause can be pulled up. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is **enable\_sublink\_pullup\_enhanced**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and **NO\_EXPAND\_SUBLINK\_HAVING** are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT /*+EXPAND_SUBLINK_HAVING*/ a,sum(b) AS value FROM
rewrite_rule_hint_t1 GROUP BY a HAVING sum(a) >= (SELECT avg(b) FROM rewrite_rule_hint_t1)
ORDER BY value DESC;
```

QUERY PLAN

```
-----
Streaming (type: GATHER)
Merge Sort Key: inner_subquery.value DESC
Node/s: All datanodes
InitPlan 1 (returns $0)
-> Aggregate
-> Streaming(type: BROADCAST)
Spawn on: All datanodes
-> Aggregate
-> Seq Scan on rewrite_rule_hint_t1
-> Sort
Sort Key: inner_subquery.value DESC
-> Subquery Scan on inner_subquery
-> HashAggregate
Group By Key: rewrite_rule_test.rewrite_rule_hint_t1.a
Filter: ((sum(rewrite_rule_test.rewrite_rule_hint_t1.a))::numeric >= $0)
-> Seq Scan on rewrite_rule_hint_t1
```

(16 rows)

## 2. NO\_EXPAND\_SUBLINK\_HAVING

Sublinks in the HAVING clause cannot be pulled up. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is not **enable\_sublink\_pullup\_enhanced**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and EXPAND\_SUBLINK\_HAVING are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT /*+NO_EXPAND_SUBLINK_HAVING*/ a,sum(b) AS value FROM
rewrite_rule_hint_t1 GROUP BY a HAVING sum(a) >= (SELECT avg(b) FROM rewrite_rule_hint_t1)
ORDER BY value DESC;
```

QUERY PLAN

```
-----
Streaming (type: GATHER)
Merge Sort Key: (sum(rewrite_rule_test.rewrite_rule_hint_t1.b)) DESC
Node/s: All datanodes
InitPlan 1 (returns $0)
-> Aggregate
-> Streaming(type: BROADCAST)
Spawn on: All datanodes
-> Aggregate
-> Seq Scan on rewrite_rule_hint_t1
-> Sort
Sort Key: (sum(rewrite_rule_test.rewrite_rule_hint_t1.b)) DESC
-> HashAggregate
Group By Key: rewrite_rule_test.rewrite_rule_hint_t1.a
Filter: ((sum(rewrite_rule_test.rewrite_rule_hint_t1.a))::numeric >= $0)
-> Seq Scan on rewrite_rule_hint_t1
```

(15 rows)

## 3. EXPAND\_SUBLINK

Sublinks can be pulled up. It can control scenarios such as non-correlated sublinks of the [Not]Any type or related sublinks of the [Not]Exists type. The hint of this rule and the NO\_EXPAND hint are mutually exclusive, and this hint has a higher priority than NO\_EXPAND. This hint and NO\_EXPAND\_SUBLINK are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT * FROM rewrite_rule_hint_t1 WHERE a > ANY(SELECT /*
+EXPAND_SUBLINK*/ a FROM rewrite_rule_hint_t2) AND b > ANY (SELECT /*+EXPAND_SUBLINK*/a
FROM rewrite_rule_hint_t3);
```

QUERY PLAN

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
```

```

-> Nested Loop Semi Join
  Join Filter: (rewrite_rule_hint_t1.b > rewrite_rule_hint_t3.a)
-> Nested Loop Semi Join
  Join Filter: (rewrite_rule_hint_t1.a > rewrite_rule_hint_t2.a)
  -> Seq Scan on rewrite_rule_hint_t1
  -> Materialize
    -> Streaming(type: BROADCAST)
        Spawn on: All datanodes
    -> Seq Scan on rewrite_rule_hint_t2
-> Materialize
  -> Streaming(type: BROADCAST)
        Spawn on: All datanodes
    -> Seq Scan on rewrite_rule_hint_t3
(15 rows)

```

#### 4. NO\_EXPAND\_SUBLINK

Sublinks cannot be pulled up. It can control scenarios such as non-correlated sublinks of the [Not]Any type or related sublinks of the [Not]Exists type. The hint of this rule is equivalent to the NO\_EXPAND hint. This hint and EXPAND\_SUBLINK are mutually exclusive.

```

gaussdb=# EXPLAIN(costs off)SELECT * FROM rewrite_rule_hint_t1 WHERE a > ANY(SELECT /*
+NO_EXPAND_SUBLINK*/ a FROM rewrite_rule_hint_t2) AND b > ANY (SELECT /*
+EXPAND_SUBLINK*/a FROM rewrite_rule_hint_t3);

```

```

QUERY PLAN
-----
Streaming (type: GATHER)
  Node/s: All datanodes
  -> Seq Scan on rewrite_rule_hint_t1
    Filter: ((NOT (hashed SubPlan 2)) AND (SubPlan 1))
    SubPlan 2
      -> Materialize
        -> Streaming(type: BROADCAST)
            Spawn on: All datanodes
        -> Seq Scan on rewrite_rule_hint_t3
    SubPlan 1
      -> Materialize
        -> Streaming(type: BROADCAST)
            Spawn on: All datanodes
        -> Seq Scan on rewrite_rule_hint_t2
(14 rows)

```

#### 5. EXPAND\_SUBLINK\_TARGET

Sublinks in the TargetList can be pulled up. The hint of this rule and the NO\_EXPAND hint are mutually exclusive, and this hint has a higher priority than NO\_EXPAND. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is **intargetlist**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO\_EXPAND\_SUBLINK\_TARGET are mutually exclusive.

```

gaussdb=# EXPLAIN(costs off)SELECT a,(SELECT /*+EXPAND_SUBLINK_TARGET*/ avg(b) FROM
rewrite_rule_hint_t1 WHERE rewrite_rule_hint_t1.b = rewrite_rule_hint_t2.b) FROM
rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t2.a < 100 ORDER BY rewrite_rule_hint_t2.b;

```

```

QUERY PLAN
-----
Streaming (type: GATHER)
  Merge Sort Key: rewrite_rule_test.rewrite_rule_hint_t2.b
  Node/s: All datanodes
  -> Merge Left Join
    Merge Cond: (rewrite_rule_test.rewrite_rule_hint_t2.b = rewrite_rule_hint_t1.b)
  -> Sort
    Sort Key: rewrite_rule_test.rewrite_rule_hint_t2.b
  -> Streaming(type: REDISTRIBUTE)
        Spawn on: All datanodes
    -> Seq Scan on rewrite_rule_hint_t2
        Filter: (a < 100)

```

```

-> Sort
  Sort Key: rewrite_rule_hint_t1.b
  -> HashAggregate
    Group By Key: rewrite_rule_hint_t1.b
    -> Streaming(type: REDISTRIBUTE)
      Spawn on: All datanodes
      -> Hash Right Semi Join
        Hash Cond: (rewrite_rule_test.rewrite_rule_hint_t2.b = rewrite_rule_hint_t1.b)
        -> Streaming(type: BROADCAST)
          Spawn on: All datanodes
          -> Seq Scan on rewrite_rule_hint_t2
            Filter: (a < 100)
        -> Hash
          -> Seq Scan on rewrite_rule_hint_t1

```

(25 rows)

## 6. NO\_EXPAND\_SUBLINK\_TARGET

Sublinks in the TargetList cannot be pulled up. The hint of this rule is equivalent to the NO\_EXPAND hint. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is not **intargetlist**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and EXPAND\_SUBLINK\_TARGET are mutually exclusive.

```

gaussdb=# EXPLAIN(costs off)SELECT a,(SELECT /*+NO_EXPAND_SUBLINK_TARGET*/ avg(b) FROM
rewrite_rule_hint_t1 WHERE rewrite_rule_hint_t1.b = rewrite_rule_hint_t2.b) FROM
rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t2.a < 100 ORDER BY rewrite_rule_hint_t2.b;
QUERY PLAN

```

```

-----
Streaming (type: GATHER)
  Merge Sort Key: rewrite_rule_hint_t2.b
  Node/s: All datanodes
  -> Sort
    Sort Key: rewrite_rule_hint_t2.b
    -> Seq Scan on rewrite_rule_hint_t2
      Filter: (a < 100)
    SubPlan 1
      -> Aggregate
        -> Result
          Filter: (rewrite_rule_hint_t1.b = rewrite_rule_hint_t2.b)
        -> Materialize
          -> Streaming(type: BROADCAST)
            Spawn on: All datanodes
          -> Seq Scan on rewrite_rule_hint_t1

```

(15 rows)

## 7. USE\_MAGIC\_SET

When conditions are pushed down from the main query to the subquery, the join columns of the subquery are grouped and aggregated, and then the subquery is joined with the main query. This reduces repeated scanning of related sublinks and improves query efficiency. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is **magicset**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO\_USE\_MAGIC\_SET are mutually exclusive.

```

gaussdb=# EXPLAIN(costs off) SELECT rewrite_rule_hint_t1 FROM rewrite_rule_hint_t1 WHERE
rewrite_rule_hint_t1.b = 10 AND rewrite_rule_hint_t1.c < (SELECT /*+USE_MAGIC_SET*/ sum(c) FROM
rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a);
QUERY PLAN

```

```

-----
Nested Loop
  Join Filter: ((rewrite_rule_test.rewrite_rule_hint_t1.c < (sum(rewrite_rule_hint_t2.c))) AND

```

```
(rewrite_rule_test.rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a)
-> Data Node Scan on rewrite_rule_hint_t1 "_REMOTE_TABLE_QUERY_"
   Node/s: All datanodes
-> HashAggregate
   Group By Key: rewrite_rule_hint_t2.a
-> Hash Semi Join
   Hash Cond: (rewrite_rule_hint_t2.a = rewrite_rule_test.rewrite_rule_hint_t1.a)
-> Data Node Scan on rewrite_rule_hint_t2 "_REMOTE_TABLE_QUERY_"
   Node/s: All datanodes
-> Hash
   -> Data Node Scan on rewrite_rule_hint_t1 "_REMOTE_TABLE_QUERY_"
       Node/s: All datanodes
(13 rows)
```

## 8. NO\_USE\_MAGIC\_SET

Conditions cannot be pushed down from the main query to the subquery. The subquery with an aggregate operator is joined with the main query in advance. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is not **magicset**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and **USE\_MAGIC\_SET** are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off) SELECT rewrite_rule_hint_t1 FROM rewrite_rule_hint_t1 WHERE
rewrite_rule_hint_t1.b = 10 AND rewrite_rule_hint_t1.c < (SELECT /*+NO_USE_MAGIC_SET*/ sum(c)
FROM rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a);
QUERY PLAN
```

```
-----
Hash Join
Hash Cond: (rewrite_rule_hint_t2.a = rewrite_rule_hint_t1.a)
Join Filter: (rewrite_rule_hint_t1.c < (sum(rewrite_rule_hint_t2.c)))
-> Data Node Scan on "_REMOTE_GROUP_QUERY_"
   Node/s: All datanodes
-> Hash
   -> Data Node Scan on rewrite_rule_hint_t1 "_REMOTE_TABLE_QUERY_"
       Node/s: All datanodes
(8 rows)
```

## 9. EXPAND\_SUBLINK\_UNIQUE\_CHECK

Sublinks without aggregation can be pulled up if only one line is output for each condition. Sublinks with aggregation can be automatically pulled up. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is **uniquecheck**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and **NO\_EXPAND\_SUBLINK\_UNIQUE\_CHECK** are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT rewrite_rule_hint_t1.a FROM rewrite_rule_hint_t1 WHERE
rewrite_rule_hint_t1.a = (SELECT /*+EXPAND_SUBLINK_UNIQUE_CHECK*/ rewrite_rule_hint_t2.a FROM
rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.b);
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Join
   Hash Cond: (rewrite_rule_hint_t1.a = subquery."?column?")
   -> Seq Scan on rewrite_rule_hint_t1
   -> Hash
       -> Subquery Scan on subquery
           -> HashAggregate
               Group By Key: rewrite_rule_hint_t2.b
               Filter: (rewrite_rule_hint_t2.b = rewrite_rule_hint_t2.a)
               Unique Check Required
           -> Seq Scan on rewrite_rule_hint_t2
(12 rows)
```

## 10. NO\_EXPAND\_SUBLINK\_UNIQUE\_CHECK

Sublinks without aggregation cannot be pulled up. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is not **uniquecheck**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and **EXPAND\_SUBLINK\_UNIQUE\_CHECK** are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT rewrite_rule_hint_t1.a FROM rewrite_rule_hint_t1 WHERE
rewrite_rule_hint_t1.a = (SELECT /*+NO_EXPAND_SUBLINK_UNIQUE_CHECK*/ rewrite_rule_hint_t2.a
FROM rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.b);
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on rewrite_rule_hint_t1
Filter: (a = (SubPlan 1))
SubPlan 1
-> Result
Filter: (rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.b)
-> Materialize
-> Streaming(type: BROADCAST)
Spawn on: All datanodes
-> Seq Scan on rewrite_rule_hint_t2
(11 rows)
```

## 11. NO\_SUBLINK\_DISABLE\_REPLICATED

Sublinks can be pulled up in the fast query shipping plan or stream scenario with a replication table. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is not **disablerep**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and **SUBLINK\_DISABLE\_REPLICATED** are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT * FROM rewrite_rule_hint_t1 WHERE (0 =(SELECT /*
+NO_SUBLINK_DISABLE_REPLICATED*/ count(*) FROM rewrite_rule_hint_t2 WHERE
rewrite_rule_hint_t2.a = rewrite_rule_hint_t1.a) OR NOT EXISTS(SELECT /*
+NO_SUBLINK_DISABLE_REPLICATED*/1 FROM rewrite_rule_hint_t3 WHERE rewrite_rule_hint_t3.b =
rewrite_rule_hint_t1.b));
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Left Join
Hash Cond: (rewrite_rule_hint_t1.b = rewrite_rule_hint_t3.b)
Filter: (((subquery."?column?" IS NOT NULL) AND (0 = COALESCE(subquery.count, 0))) OR
(rewrite_rule_hint_t3.b IS NULL))
-> Streaming(type: REDISTRIBUTE)
Spawn on: All datanodes
-> Hash Left Join
Hash Cond: (rewrite_rule_hint_t1.a = subquery."?column?")
-> Seq Scan on rewrite_rule_hint_t1
-> Hash
-> Subquery Scan on subquery
-> HashAggregate
Group By Key: rewrite_rule_hint_t2.a
-> Seq Scan on rewrite_rule_hint_t2
-> Hash
-> HashAggregate
Group By Key: rewrite_rule_hint_t3.b
-> Streaming(type: REDISTRIBUTE)
Spawn on: All datanodes
-> Seq Scan on rewrite_rule_hint_t3
(21 rows)
```

## 12. SUBLINK\_DISABLE\_REPLICATED

Sublinks cannot be pulled up in the fast query shipping plan or stream scenario with a replication table. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is **disablerep**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO\_SUBLINK\_DISABLE\_REPLICATED are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT * FROM rewrite_rule_hint_t1 WHERE (0 =(SELECT /*
+SUBLINK_DISABLE_REPLICATED*/ count(*) FROM rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t2.a
= rewrite_rule_hint_t1.a) OR NOT EXISTS(SELECT /*+NO_SUBLINK_DISABLE_REPLICATED*/1 FROM
rewrite_rule_hint_t3 WHERE rewrite_rule_hint_t3.b = rewrite_rule_hint_t1.b));
QUERY PLAN
```

```
-----
Seq Scan on rewrite_rule_hint_t1
  Filter: ((0 = (SubPlan 1)) OR (NOT (alternatives: SubPlan 2 or hashed SubPlan 3)))
  SubPlan 1
    -> Aggregate
        -> Seq Scan on rewrite_rule_hint_t2
            Filter: (a = rewrite_rule_hint_t1.a)
  SubPlan 2
    -> Seq Scan on rewrite_rule_hint_t3
        Filter: (b = rewrite_rule_hint_t1.b)
  SubPlan 3
    -> Seq Scan on rewrite_rule_hint_t3
(11 rows)
```

## 13. NO\_SUBLINK\_DISABLE\_EXPR

Expressions in sublinks can be pulled up. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is not **disable\_pullup\_expr\_sublink**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and SUBLINK\_DISABLE\_EXPR are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT a FROM rewrite_rule_hint_t1 WHERE rewrite_rule_hint_t1.b =
(SELECT /*+NO_SUBLINK_DISABLE_EXPR*/ max(b) FROM rewrite_rule_hint_t2 WHERE
rewrite_rule_hint_t2.a = rewrite_rule_hint_t1.a);
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
  Node/s: All datanodes
  -> Hash Join
      Hash Cond: ((rewrite_rule_hint_t1.a = subquery."?column?") AND (rewrite_rule_hint_t1.b =
subquery.max))
      -> Seq Scan on rewrite_rule_hint_t1
      -> Hash
          -> Subquery Scan on subquery
              -> HashAggregate
                  Group By Key: rewrite_rule_hint_t2.a
                  -> Seq Scan on rewrite_rule_hint_t2
(10 rows)
```

## 14. SUBLINK\_DISABLE\_EXPR

Expressions in sublinks cannot be pulled up. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is **disable\_pullup\_expr\_sublink**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO\_SUBLINK\_DISABLE\_EXPR are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT a FROM rewrite_rule_hint_t1 WHERE rewrite_rule_hint_t1.b =
(SELECT /*+SUBLINK_DISABLE_EXPR*/ max(b) FROM rewrite_rule_hint_t2 WHERE
rewrite_rule_hint_t2.a = rewrite_rule_hint_t1.a);
```

```

        -> WindowAgg
            -> Sort
                Sort Key: rewrite_rule_hint_t2.b, rewrite_rule_hint_t2.c
            -> Data Node Scan on rewrite_rule_hint_t2 "_REMOTE_TABLE_QUERY_"
                Node/s: All datanodes
(15 rows)

```

## 19. REDUCE\_ORDER\_BY

Unnecessary ORDER BY can be reduced. If the outer query does not have sorting requirements on the inner query result, unnecessary ORDER BY can be reduced to improve the query efficiency. This hint and NO\_REDUCE\_ORDER\_BY are mutually exclusive.

```

gaussdb=# EXPLAIN(costs off)SELECT * FROM rewrite_rule_hint_t1,(SELECT /*+REDUCE_ORDER_BY*/ *
FROM rewrite_rule_hint_t2 ORDER BY a DESC);

```

```

QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
    -> Streaming(type: BROADCAST)
        Spawn on: All datanodes
    -> Seq Scan on rewrite_rule_hint_t1
-> Materialize
    -> Seq Scan on rewrite_rule_hint_t2
(8 rows)

```

## 20. NO\_REDUCE\_ORDER\_BY

Unnecessary ORDER BY cannot be reduced. This hint and REDUCE\_ORDER\_BY are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT * FROM rewrite_rule_hint_t1,(SELECT /*
+NO_REDUCE_ORDER_BY*/ * FROM rewrite_rule_hint_t2 ORDER BY a DESC);
QUERY PLAN
-----
Streaming (type: GATHER)
 Node/s: All datanodes
  -> Nested Loop
     -> Streaming(type: BROADCAST)
        Spawn on: All datanodes
        -> Seq Scan on rewrite_rule_hint_t1
     -> Materialize
        -> Sort
           Sort Key: rewrite_rule_hint_t2.a DESC
           -> Seq Scan on rewrite_rule_hint_t2
(10 rows)
```

## 21. REMOVE\_NOT\_NULL

Unnecessary IS NOT NULL conditions can be deleted. When the column attribute is **NOT NULL**, the IS NOT NULL judgment in the query condition can be deleted. This scenario is also controlled by the GUC parameter **enable\_constraint\_optimization**. If the hint of this rule is not used and the value of **enable\_constraint\_optimization** is **on**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO\_REMOVE\_NOT\_NULL are mutually exclusive.

```
gaussdb=# SET enable_fast_query_shipping=off;
EXPLAIN(costs off)SELECT /*+REMOVE_NOT_NULL*/ * FROM rewrite_rule_hint_t4 WHERE b > 10 OR a
IS NOT NULL;
QUERY PLAN
-----
Streaming (type: GATHER)
 Node/s: All datanodes
  -> Seq Scan on rewrite_rule_hint_t4
(3 rows)
```

## 22. NO\_REMOVE\_NOT\_NULL

Unnecessary IS NOT NULL conditions cannot be deleted. This scenario is also controlled by the GUC parameter **enable\_constraint\_optimization**. If the hint of this rule is not used and the value of **enable\_constraint\_optimization** is **off**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and REMOVE\_NOT\_NULL are mutually exclusive.

```
gaussdb=# SET enable_fast_query_shipping=off;
EXPLAIN(costs off)SELECT /*+NO_REMOVE_NOT_NULL*/ * FROM rewrite_rule_hint_t4 WHERE b > 10
OR a IS NOT NULL;
QUERY PLAN
-----
Streaming (type: GATHER)
 Node/s: All datanodes
  -> Seq Scan on rewrite_rule_hint_t4
     Filter: ((b > 10) OR (a IS NOT NULL))
(4 rows)
```

## 23. LAZY\_AGG

The subquery and outer query have the same GROUP BY condition. The two-layer aggregation operation may cause low query efficiency. The aggregation operation in the subquery can be eliminated to improve query efficiency. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is **lazyagg**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO\_LAZY\_AGG are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT rewrite_rule_hint_t1.b,sum(cc) FROM (SELECT /*+LAZY_AGG*/
b,sum(c) AS cc FROM rewrite_rule_hint_t2 GROUP BY b) s1,rewrite_rule_hint_t1 WHERE s1.b =
rewrite_rule_hint_t1.b GROUP BY rewrite_rule_hint_t1.b ORDER BY 1,2;
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Merge Sort Key: rewrite_rule_hint_t1.b, (sum((rewrite_rule_hint_t2.c)::bigint))
Node/s: All datanodes
-> Sort
Sort Key: rewrite_rule_hint_t1.b, (sum((rewrite_rule_hint_t2.c)::bigint))
-> HashAggregate
Group By Key: rewrite_rule_hint_t1.b
-> Hash Join
Hash Cond: (rewrite_rule_hint_t2.b = rewrite_rule_hint_t1.b)
-> Streaming(type: REDISTRIBUTE)
Spawn on: All datanodes
-> Seq Scan on rewrite_rule_hint_t2
-> Hash
-> Streaming(type: REDISTRIBUTE)
Spawn on: All datanodes
-> Seq Scan on rewrite_rule_hint_t1
```

(16 rows)

#### 24. NO\_LAZY\_AGG

The aggregation operation rules in the subquery cannot be eliminated. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is not **lazyagg**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and **LAZY\_AGG** are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT rewrite_rule_hint_t1.b,sum(cc) FROM (SELECT /*
+NO_LAZY_AGG*/b,sum(c) AS cc FROM rewrite_rule_hint_t2 GROUP BY b) s1,rewrite_rule_hint_t1
WHERE s1.b = rewrite_rule_hint_t1.b GROUP BY rewrite_rule_hint_t1.b ORDER BY 1,2;
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Merge Sort Key: rewrite_rule_hint_t1.b, (sum(s1.cc))
Node/s: All datanodes
-> Sort
Sort Key: rewrite_rule_hint_t1.b, (sum(s1.cc))

-> Seq Scan on rewrite_rule_hint_t1
-> Hash
-> Subquery Scan on s1
-> HashAggregate
Group By Key: rewrite_rule_hint_t2.b
-> Streaming(type: REDISTRIBUTE)
Spawn on: All datanodes
-> Seq Scan on rewrite_rule_hint_t2
```

(19 rows)

#### 25. EXPAND\_SUBQUERY

The subquery is pulled up and joined with the upper layer to optimize the query efficiency. The hint of this rule and the **NO\_EXPAND** hint are mutually exclusive. When both this hint and **NO\_EXPAND** are used, this hint has a higher priority. This hint and **NO\_EXPAND\_SUBQUERY** are mutually exclusive.

```
gaussdb=# SET enable_fast_query_shipping=off;
EXPLAIN(costs off) SELECT * FROM rewrite_rule_hint_t1,(SELECT /*+EXPAND_SUBQUERY*/ * FROM
rewrite_rule_hint_t2 WHERE a > 1) tt WHERE rewrite_rule_hint_t1.a = tt.a;
QUERY PLAN
```

```
Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Join
  Hash Cond: (rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a)
-> Seq Scan on rewrite_rule_hint_t1
  Filter: (a > 1)
-> Hash
  -> Seq Scan on rewrite_rule_hint_t2
    Filter: (a > 1)
(9 rows)
```

## 26. NO\_EXPAND\_SUBQUERY

The subquery cannot be pulled up. This hint is equivalent to the NO\_EXPAND hint, but this hint has a higher priority. This hint and EXPAND\_SUBQUERY are mutually exclusive.

```
gaussdb=# SET enable_fast_query_shipping=off;
EXPLAIN(costs off) SELECT * FROM rewrite_rule_hint_t1,(SELECT /*+NO_EXPAND_SUBQUERY*/ *
FROM rewrite_rule_hint_t2 WHERE a > 1) tt WHERE rewrite_rule_hint_t1.a = tt.a;
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Join
  Hash Cond: (rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a)
-> Seq Scan on rewrite_rule_hint_t1
-> Hash
  -> Seq Scan on rewrite_rule_hint_t2
    Filter: (a > 1)
(8 rows)
```

## 27. PUSHDOWN\_HAVING

The HAVING condition expression can be pushed down. This hint and NO\_PUSHDOWN\_HAVING are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT /*+PUSHDOWN_HAVING*/ sum(a),b,c FROM
rewrite_rule_hint_t1 WHERE b > 0 GROUP BY b,c HAVING sum(a) > 100 AND c > 0;
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> HashAggregate
  Group By Key: b, c
  Filter: (sum(a) > 100)
-> Streaming(type: REDISTRIBUTE)
  Spawn on: All datanodes
  -> Seq Scan on rewrite_rule_hint_t1
    Filter: ((b > 0) AND (c > 0))
(9 rows)
```

## 28. NO\_PUSHDOWN\_HAVING

The HAVING expression cannot be pushed down. This hint and PUSHDOWN\_HAVING are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT /*+NO_PUSHDOWN_HAVING*/ sum(a),b,c FROM
rewrite_rule_hint_t1 WHERE b > 0 GROUP BY b,c HAVING sum(a) > 100 AND c > 0;
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> HashAggregate
  Group By Key: b, c
  Filter: ((sum(a) > 100) AND (c > 0))
-> Streaming(type: REDISTRIBUTE)
  Spawn on: All datanodes
  -> Seq Scan on rewrite_rule_hint_t1
    Filter: (b > 0)
(9 rows)
```

## 29. INLIST\_TO\_JOIN

The inlist-to-join can be used to rewrite SQL statements. This scenario is also controlled by the GUC parameter **qrw\_inlist2join\_optmode**. If the hint of this rule is not used and the value of **qrw\_inlist2join\_optmode** is **rule\_base**, this rule takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and **NO\_INLIST\_TO\_JOIN** are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off)SELECT * FROM rewrite_rule_hint_t5 WHERE slot = '5' AND (name) IN
(SELECT /*+INLIST_TO_JOIN*/ name FROM rewrite_rule_hint_t5 WHERE slot = '5'AND cid IN
(5,1000,1001,1002,1003,1004,1005,1006,1007,2000,4000,10781986,10880002)LIMIT 50);
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop Semi Join
  Join Filter: ((rewrite_rule_test.rewrite_rule_hint_t5.name)::text =
(rewrite_rule_test.rewrite_rule_hint_t5.name)::text)
  Skew Join Optimized by Statistic
  -> Streaming(type: PART REDISTRIBUTE PART ROUNDROBIN)
    Spawn on: datanode2

          -> Limit
            -> Hash Right Semi Join
              Hash Cond: (**VALUES**).column1 =
rewrite_rule_test.rewrite_rule_hint_t5.cid)
            -> Values Scan on **VALUES**
            -> Hash
              -> Seq Scan on rewrite_rule_hint_t5
                Filter: (slot = 5)

(22 rows)
```

### NOTE

**INLIST\_TO\_JOIN**[@queryblock threshold]: supports no parameter or any integer greater than or equal to 0. It is compatible with the value of the GUC parameter **qrw\_inlist2join\_optmode**. The default value is recommended.

Parameter description:

- **threshold**: specifies the query rewriting threshold. This parameter is optional. For details, see the value range part.

Default value: **1** (Optional. If it is not set, the default value is used.)

Value range:

- **0**: cost\_base
- **1**: rule\_base
- Any other positive integer: specifies the query rewriting threshold. If the number of elements in the list is greater than the threshold, the inlist2join query rewriting is performed.

## 30. NO\_INLIST\_TO\_JOIN

The inlist-to-join cannot be used to rewrite SQL statements. This scenario is also controlled by the GUC parameter **qrw\_inlist2join\_optmode**. If the hint of this rule is not used and the value of **qrw\_inlist2join\_optmode** is **disable**, this rule does not take effect. However, when both the hint and GUC

parameter of this rule are used, the hint precedes the GUC parameter. This hint and INLIST\_TO\_JOIN are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off)SELECT * FROM rewrite_rule_hint_t5 WHERE slot = '5' AND (name) IN
(SELECT /*+NO_INLIST_TO_JOIN*/ name FROM rewrite_rule_hint_t5 WHERE slot = '5'AND cid IN
(5,1000,1001,1002,1003,1004,1005,1006,1007,2000,4000,10781986,10880002)LIMIT 50);

(18 rows)
```

### 31. ROWNUM\_PUSHDOWN

Row numbers can be pushed down. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is **disable\_rownum\_pushdown**, pushdown is allowed. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO\_ROWNUM\_PUSHDOWN are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off) SELECT * FROM (SELECT /*+ROWNUM_PUSHDOWN*/rownum rn, a
FROM rewrite_rule_hint_t1) WHERE rn BETWEEN 5 AND 10;
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Subquery Scan on __unnamed_subquery__
Filter: ((__unnamed_subquery__.rn >= 5::numeric) AND (__unnamed_subquery__.rn <=
10::numeric))
-> Rownum
StopKey: (ROWNUM <= 10::numeric)
-> Streaming(type: BROADCAST)
Spawn on: All datanodes
-> Rownum
StopKey: (ROWNUM <= 10::numeric)
-> Seq Scan on rewrite_rule_hint_t1
(11 rows)
```

### 32. NO\_ROWNUM\_PUSHDOWN

Row numbers cannot be pushed down. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is **disable\_rownum\_pushdown**, pushdown is not allowed. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and ROWNUM\_PUSHDOWN are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off) SELECT * FROM (SELECT /*+NO_ROWNUM_PUSHDOWN*/rownum rn,
a FROM rewrite_rule_hint_t1) WHERE rn BETWEEN 5 AND 10;
QUERY PLAN
```

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Subquery Scan on __unnamed_subquery__
   Filter: ((__unnamed_subquery__.rn >= 5::numeric) AND (__unnamed_subquery__.rn <=
10::numeric))
   -> Rownum
       -> Streaming(type: BROADCAST)
           Spawn on: All datanodes
           -> Seq Scan on rewrite_rule_hint_t1
(8 rows)
```

### 33. WINDOWAGG\_PUSHDOWN

The filter criterion of the window function in the parent query can be pushed down to the subquery. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is not used and the value of **rewrite\_rule** is **disable\_windowagg\_pushdown**, the filter criterion of the window function in the parent query cannot be pushed down to the subquery. If the hint of this rule is used and the value of **rewrite\_rule** is **disable\_windowagg\_pushdown**, the hint precedes the GUC parameter, and the filter criterion of the window function in the parent query can be pushed down to the subquery. This hint and **NO\_WINDOWAGG\_PUSHDOWN** are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off) SELECT * FROM (SELECT /*+WINDOWAGG_PUSHDOWN*/
row_number() over() rid, rewrite_rule_hint_t1.a FROM rewrite_rule_hint_t1) WHERE rid BETWEEN 5
AND 10;
```

#### QUERY PLAN

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Subquery Scan on __unnamed_subquery__
   Filter: (__unnamed_subquery__.rid >= 5)
   -> WindowAgg
       row_number_filter: (row_number() OVER () <= 10)
       -> Streaming(type: BROADCAST)
           Spawn on: All datanodes
           -> WindowAgg
               row_number_filter: (row_number() OVER () <= 10)
               -> Seq Scan on rewrite_rule_hint_t1
(11 rows)
```

### 34. NO\_WINDOWAGG\_PUSHDOWN

The filter criterion of the window function in the parent query cannot be pushed down to the subquery. This scenario is also controlled by the GUC parameter **rewrite\_rule**. If the hint of this rule is used or the value of **rewrite\_rule** is **disable\_windowagg\_pushdown**, the filter criterion of the window function in the parent query cannot be pushed down to the subquery. This hint and **WINDOWAGG\_PUSHDOWN** are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off) SELECT * FROM (SELECT /*+NO_WINDOWAGG_PUSHDOWN*/
row_number() over() rid, rewrite_rule_hint_t1.a FROM rewrite_rule_hint_t1) WHERE rid BETWEEN 5
AND 10;
```

#### QUERY PLAN

```
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Subquery Scan on __unnamed_subquery__
   Filter: ((__unnamed_subquery__.rid >= 5) AND (__unnamed_subquery__.rid <= 10))
   -> WindowAgg
       -> Streaming(type: BROADCAST)
           Spawn on: All datanodes
           -> Seq Scan on rewrite_rule_hint_t1
(8 rows)
```

## 6.9.23 Hints for Specifying ANY Sublink Pullup

### Description

A method of optimizing operators is specified when an ANY sublink is pulled up.

### Syntax

```
[no] hashed_sublink[(@queryblock)]
```

### Parameters

- **no** indicates that the optimization is not used.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block. If it is not specified, the hint does not have parentheses ().
- **hashed\_sublink** uses hash table optimization for specified sublinks.

### Examples

Table creation and preparation:

```
set work_mem='64kB'; -- Reduce the work memory to reproduce the scenario.
set explain_perf_mode = pretty; -- Open the explain pretty option to view a detailed plan.
CREATE TABLE nt1 (a int);
CREATE TABLE nt2 (a int);
INSERT INTO nt1 VALUES(generate_series(1, 50000));
INSERT INTO nt2 VALUES(generate_series(1, 50000));
ANALYZE nt1;
ANALYZE nt2;
```

#### Example:

-- Do not use hashed\_sublink hints.

```
gaussdb=# EXPLAIN SELECT * FROM nt1 WHERE nt1.a NOT IN (SELECT /*+ no_expand*/ a FROM nt2);
```

id	operation	E-rows	E-memory	E-width	E-costs
1	-> Streaming (type: GATHER)	25000		4	5079922.80
2	-> Seq Scan on nt1	25000	1MB	4	5079011.27
3	-> Materialize [2, SubPlan 1]	1800000	32MB	4	468.98
4	-> Streaming(type: BROADCAST)	300000	2MB	4	218.98
5	-> Seq Scan on nt2	50000	1MB	4	121.33

(5 rows)

Predicate Information (identified by plan id)

```
2 --Seq Scan on nt1
  Filter: (NOT (SubPlan 1))
(2 rows)
```

-- Use hashed\_sublink hints.

```
gaussdb=# EXPLAIN SELECT * FROM nt1 WHERE nt1.a NOT IN (SELECT /*+ hashed_sublink no_expand*/ a FROM nt2);
```

id	operation	E-rows	E-memory	E-width	E-costs
1	-> Streaming (type: GATHER)	25000		4	2272.68
2	-> Seq Scan on nt1	25000	1MB	4	1361.14
3	-> Materialize [2, SubPlan 1]	1800000	32MB	4	468.98
4	-> Streaming(type: BROADCAST)	300000	2MB	4	218.98
5	-> Seq Scan on nt2	50000	1MB	4	121.33

(5 rows)

Predicate Information (identified by plan id)

```
-----
2 --Seq Scan on nt1
  Filter: (NOT (hashed SubPlan 1))
(2 rows)
-- work_mem affects plan generation and execution. If you perform other operations, you need to reset it.
reset work_mem; -- Roll back the memory settings.
```

The hashed operation is performed on the sublink. If the hint is not used, a common plan is used.

## 6.9.24 Hints for Specifying the Degree of Parallelism for Scans

### Description

The degree of parallelism (DOP) is specified for table scans in a parallel execution plan.

### Syntax

```
scandop([@queryblock] table dop_num)
```

### Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** specifies the table to be scanned. You can specify only one table. Use a table alias (if any) instead of a table name.
- **dop\_num** specifies the DOP for table scans.
- **scandop** specifies a hint for specifying the DOP for scans.

### Examples

```
-- Preparation
CREATE TABLE cst1(a int, b int, c int, d bigint);
set explain_perf_mode = pretty; -- Open the explain pretty option to view a detailed plan.
set enable_fast_query_shipping = off; -- Disable FQS optimization.
-- Usage
gaussdb=# EXPLAIN (costs off) SELECT /*+ Set(query_dop 2) scandop(cst1 2)*/ * FROM cst1;
id |          operation
-----+-----
1 | -> Streaming (type: GATHER)
2 | -> Streaming(type: LOCAL GATHER dop: 1/2)
3 | -> Seq Scan on cst1
(3 rows)
```

In a parallel plan, you can use scandop hints to specify the degree of parallelism.

#### NOTE

The hint takes effect only when **dop\_num** is the same as the current degree of parallelism (**query\_dop**) or is set to **1**.

```
gaussdb=# EXPLAIN (costs off) SELECT /*+ Set(query_dop 2) scandop(cst1 4)*/ * FROM cst1;
id |          operation
-----+-----
1 | -> Seq Scan on cst1
(1 row)
```

## 6.9.25 Hints for Specifying Whether to Use Semi-Join

### Description

Specifies whether to select semi-join.

### Syntax

```
[no] semijoin([@queryblock] table_list)
```

### Parameters

- **no** indicates that semi-join is not used.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table\_list** specifies the tables to be joined. The values are the same as those of [join\\_table\\_list](#) but contain no parentheses.
- **semijoin** specifies whether semi-join is used for table join.

### Examples

```
-- Preparation
CREATE TABLE se_t1 (a int, b int);
CREATE TABLE se_t2 (a int, b int);
CREATE TABLE se_t3 (a int, b int);
set explain_perf_mode = pretty; -- Open the explain pretty option to view a detailed plan.
-- Scenarios where hints are not used
gaussdb=# EXPLAIN(costs off) SELECT a FROM se_t2 WHERE a IN( SELECT se_t1.a FROM se_t1,se_t3
WHERE se_t1.a=se_t3.a GROUP BY 1);
id |          operation
-----+-----
 1 | -> Streaming (type: GATHER)
 2 | -> Hash Join (3,4)
 3 | -> Seq Scan on se_t2
 4 | -> Hash
 5 | -> HashAggregate
 6 | -> Hash Join (7,8)
 7 | -> Seq Scan on se_t1
 8 | -> Hash
 9 | -> Seq Scan on se_t3
(9 rows)

Predicate Information (identified by plan id)
-----+-----
 2 --Hash Join (3,4)
   Hash Cond: (se_t2.a = se_t1.a)
 6 --Hash Join (7,8)
   Hash Cond: (se_t1.a = se_t3.a)
(4 rows)

-- Scenarios where hints are used
gaussdb=# EXPLAIN(costs off) SELECT /*+ SemiJoin(se_t2@"sel$1" "sel$2") */ a FROM se_t2 WHERE a
IN( SELECT se_t1.a FROM se_t1,se_t3 WHERE se_t1.a=se_t3.a GROUP BY 1);
id |          operation
-----+-----
 1 | -> Streaming (type: GATHER)
 2 | -> Hash Semi Join (3, 4)
 3 | -> Seq Scan on se_t2
 4 | -> Hash
 5 | -> HashAggregate
 6 | -> Hash Join (7,8)
```

```
7 |          -> Seq Scan on se_t1
8 |          -> Hash
9 |          -> Seq Scan on se_t3
(9 rows)

Predicate Information (identified by plan id)
-----
2 --Hash Semi Join (3, 4)
   Hash Cond: (se_t2.a = se_t1.a)
6 --Hash Join (7,8)
   Hash Cond: (se_t1.a = se_t3.a)
(4 rows)
```

You can see that the semijoin hint can determine whether to use semi-join.

## 6.9.26 Hints for Specifying Whether to Use Minmax Optimization

### Description

Specifies whether a statement is rewritten using minmax.

### Syntax

```
[no] use_minmax[(@queryblock)]
```

### Parameters

- **no** indicates that minmax is not used for query rewriting.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **use\_minmax** uses minmax optimization for statement query rewriting.

### Examples

```
-- Preparation
create table minmaxtest(f1 int);
create index minmaxtesti on minmaxtest(f1);
insert into minmaxtest values(11), (12);
set explain_perf_mode=pretty; -- Open the explain pretty option to view a detailed plan.

-- Common scenario
gaussdb=# explain (costs off) select min(f1), max(f1) from minmaxtest;
id |          operation
-----+-----
1 | -> Result
2 | -> Aggregate [1, InitPlan 1 (returns $0)]
3 | -> Streaming (type: GATHER)
4 | -> Limit
5 | -> Index Only Scan using minmaxtesti on minmaxtest
6 | -> Aggregate [1, InitPlan 2 (returns $1)]
7 | -> Streaming (type: GATHER)
8 | -> Limit
9 | -> Index Only Scan Backward using minmaxtesti on minmaxtest
(9 rows)

Predicate Information (identified by plan id)
-----
5 --Index Only Scan using minmaxtesti on minmaxtest
  Index Cond: (f1 IS NOT NULL)
9 --Index Only Scan Backward using minmaxtesti on minmaxtest
```

```

Index Cond: (f1 IS NOT NULL)
(4 rows)

-- Use hints to disable minmax rewriting.
gaussdb=# explain (costs off)select /*+ no use_minmax*/ min(f1), max(f1) from minmaxtest;
id |          operation
-----+-----
 1 | -> Aggregate
 2 | -> Streaming (type: GATHER)
 3 | -> Aggregate
 4 | -> Seq Scan on minmaxtest
(4 rows)

```

After the `no use_minmax` hint is used, the SQL statement does not use minmax optimization.

```

-- Use minmax hints.
analyze; -- Collect statistics.
gaussdb=# explain (costs off) select min(f1), max(f1) from minmaxtest;
id |          operation
-----+-----
 1 | -> Aggregate
 2 | -> Streaming (type: GATHER)
 3 | -> Aggregate
 4 | -> Seq Scan on minmaxtest
(4 rows)

-- Use the use_minmax hint to select minmax rewriting.
gaussdb=# explain (costs off) select /*+ indexonlyscan(minmaxtest) use_minmax*/ min(f1), max(f1) from
minmaxtest;
id |          operation
-----+-----
 1 | -> Result
 2 | -> Aggregate [1, InitPlan 1 (returns $0)]
 3 | -> Streaming (type: GATHER)
 4 | -> Limit
 5 | -> Index Only Scan using minmaxtesti on minmaxtest
 6 | -> Aggregate [1, InitPlan 2 (returns $1)]
 7 | -> Streaming (type: GATHER)
 8 | -> Limit
 9 | -> Index Only Scan Backward using minmaxtesti on minmaxtest
(9 rows)

```

The `use_minmax` hint takes effect.

#### NOTE

The `use_minmax` optimization takes effect only when index scan is used for table scanning.

## 6.10 Checking the Implicit Conversion Performance

In some scenarios, implicit data type conversion may cause performance problems. See the following scenario:

```

SET enable_fast_query_shipping = off;
CREATE TABLE t1(c1 VARCHAR, c2 VARCHAR);
CREATE INDEX on t1(c1);
EXPLAIN verbose SELECT * FROM t1 WHERE c1 = 10;

```

The execution plan of the preceding query is as follows.

```
-----  
QUERY PLAN  
-----  
Streaming (type: GATHER) (cost=0.06..13.29 rows=1 width=64)  
  Output: c1, c2  
  Node/s: All datanodes  
  -> Seq Scan on public.t1 (cost=0.00..13.20 rows=1 width=64)  
    Output: c1, c2  
    Distribute Key: c1  
    Filter: ((t1.c1)::bigint = 10)  
(7 rows)
```

The data type of **c1** is **varchar**. When the filter criterion is **c1 = 10**, the optimizer implicitly converts the data type of **c1** to **bigint** by default. As a result, the following two consequences occur:

- DN tailoring is not allowed. The plan is delivered to all DNs for execution.
- The Index Scan mode cannot be used to scan data in the plan.

These may cause performance problems.

After knowing the causes, you can rewrite the SQL statements. In the preceding scenario, you only need to convert the constant display in the filter criteria to the **varchar** type. The result is as follows:

```
EXPLAIN verbose SELECT * FROM t1 WHERE c1 = 10::varchar;
```

```
-----  
QUERY PLAN  
-----  
Streaming (type: GATHER) (cost=0.06..8.36 rows=1 width=64)  
  Output: c1, c2  
  Node/s: datanode2  
  -> Index Scan using t1_c1_idx on public.t1 (cost=0.00..8.27 rows=1 width=64)  
    Output: c1, c2  
    Distribute Key: c1  
    Index Cond: ((t1.c1)::text = '10'::text)  
(7 rows)
```

To identify the performance impact of implicit type conversion in advance, GaussDB provides a GUC option: **check\_implicit\_conversions**. After this parameter is enabled, the system checks the index columns that are implicitly converted in the query in the path generation phase. If no candidate index scan path is generated for the index columns, an error message is displayed. For example:

```
SET check_implicit_conversions = on;  
SELECT * FROM t1 WHERE c1 = 10;  
ERROR: There is no optional index path for index column: "t1"."c1".
```

#### NOTE

- The **check\_implicit\_conversions** parameter is used only to check for potential performance problems caused by implicit type conversion. In the formal production environment, set this parameter to **off** (default value) to disable it.
- When enabling **check\_implicit\_conversions**, you must disable **enable\_fast\_query\_shipping**. Otherwise, you cannot view the result of restoring the implicit type conversion.
- A candidate path of a table may include multiple possible data scan modes such as sequential scan and index scan. A table scan mode used in the final execution plan is determined by the cost of the execution plan. Therefore, even if a candidate path for index scan is generated, other scan modes may also be used in the final execution plan.

## 6.11 Performing Optimization with SQL Patches

SQL patches are designed for database administrators (DBAs), O&M personnel, and other roles who need to optimize SQL statements. If performance problems caused by poor plans of service statements are identified through other O&M views or fault locating methods, you can create SQL patches to optimize service statements based on hints. Currently, the following hints are supported: number of rows, scanning mode, join mode, join sequence, PBE custom/generic plan selection, statement-level parameter setting, and parameterized path. In addition, in case that services are unavailable due to internal system errors that are triggered by specific statements, you can create SQL patches to rectify single-point failures without changing service statements. In this way, errors can be reported in advance to avoid greater loss.

### Restrictions

1. Patches can be created only by unique SQL ID. If unique SQL IDs conflict, SQL patches that are used for hint-based optimization may affect performance but do not affect semantic correctness.
2. Only hints that do not change SQL semantics can be used as patches. SQL rewriting is not supported.
3. This tool is not applicable to logical backup and restoration.
4. SQL patches cannot be created on DNs.
5. Only the initial user, O&M administrators, monitor administrators, and system administrators have the permission to perform this operation.
6. Patches are not shared between databases. When creating SQL patches, you need to connect to the target database. If the CN where the SQL PATCH is created is removed and a full build is triggered, the SQL PATCH in the target CN of the full build is inherited. Therefore, you are advised to create the corresponding SQL PATCH on each CN.
7. CNs do not share SQL patches because their unique SQL IDs are different. You need to manually create SQL patches on different CNs.
8. SQL patches in a stored procedure and global SQL patches cannot coexist.
9. SQL patches cannot be used for prepared statement that are executed using the PREPARE + EXECUTE syntax. There are special cases. For details, see [Special Cases](#).
10. It is not recommended that the SQL patches be used in the database for a long time. It should be used only as a workaround. If the database service is unavailable due to a kernel fault triggered by a specific statement or SQL hints are used for performance optimization, you must rectify the service fault or upgrade the kernel as soon as possible. After the upgrade, the method of generating unique SQL IDs may change. Therefore, the workaround may become invalid.
11. Currently, except DML statements, unique SQL IDs of SQL statements (such as CREATE TABLE) are generated by hashing the statement text. Therefore, SQL patches are sensitive to uppercase and lowercase letters, spaces, and linefeeds. That is, even statements of different texts have the same semantics, you still need to create different SQL patches for them. For DML operations,

an SQL patch can take effect for the same statement with different input parameters, regardless of uppercase letters, lowercase letters, and spaces.

## Example

The SQL patch is implemented based on the unique SQL ID. Therefore, you need to enable related O&M parameters (**enable\_resource\_track = on**, **instr\_unique\_sql\_count > 0**) for the SQL patch to take effect. The unique SQL ID can be obtained from both the WDR and slow SQL view. You need to specify the unique SQL ID when creating the SQL patch. For SQL statements in a stored procedure, you need to set **instr\_unique\_sql\_track\_type** to 'all' and query unique SQL ID in the `dbe_perf.statement_history` view.

The following provides simple examples:

Scenario 1: Use an SQL patch to optimize specific statements based on hints.

```
gaussdb=# create table hint_t1(a int, b int, c int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# create index on hint_t1(a);
CREATE INDEX
gaussdb=# insert into hint_t1 values(1,1,1);
INSERT 0 1
gaussdb=# analyze hint_t1;
ANALYZE
gaussdb=# set track_stmt_stat_level = 'L1,L1'; -- Enable full SQL statistics.
SET
gaussdb=# set enable_fast_query_shipping = off; -- Disable statement pushdown so that plans are
generated on the CN.
SET
gaussdb=# set explain_perf_mode = normal; -- Adjust the plan display format.
SET
gaussdb=# select * from hint_t1 where hint_t1.a = 1; -- Execute SQL statements.
 a | b | c
---+---+---
 1 | 1 | 1
(1 row)
gaussdb=# \x -- Switch to the extended display mode to facilitate plan observation.
Expanded display is on.
gaussdb=# select unique_query_id, query, query_plan from dbe_perf.statement_history where query like
'%hint_t1%';-- Obtain the query plan and unique SQL ID. This statement needs to query the slow SQL view
dbe_perf.statement_history in the postgres database.
-[ RECORD 1 ]-----+-----
unique_query_id | 3929365485
query           | select * from hint_t1 where hint_t1.a = ?;
query_plan      | Coordinator Name: coordinator1
                | Streaming (type: GATHER) (cost=0.06..1.11 rows=1 width=12)
                | Node/s: datanode1
                | -> Seq Scan on hint_t1 (cost=0.00..1.01 rows=1 width=12)
                |     Filter: (a = '***')
                |
gaussdb=# \x -- Disable the extended display mode.

gaussdb=# select * from dbe_sql_util.create_hint_sql_patch('patch1', 3929365485, 'indexscan(hint_t1)');
create_hint_sql_patch
-----

gaussdb=# select * from dbe_sql_util.create_abort_sql_patch('patch2', 3929365485); -- Create an abort
patch for the unique SQL ID of the statement.
 create_abort_sql_patch
-----
 t
(1 row)

gaussdb=# select * from hint_t1 t1 where t1.a = 1; -- An error is reported in advance when the statement is
executed again.
ERROR: Statement 2578396627 canceled by abort patch patch2

```

Scenario 3: Create an SQL patch for SQL statements in a stored procedure.

```

gaussdb=# create table test_proc_patch(a int,b int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# insert into test_proc_patch values(1,2);
INSERT 0 1
gaussdb=# create procedure mypro() as num int;
gaussdb$# begin

```

```
-- Observe and analyze the returned slow SQL statement and plan, and perform local optimization and verification to obtain a proper hint_str.

-- Run the following statement on any CN to create an SQL patch, where node_name and unique_query_id are obtained from step 1:
select * from db_sql_util.create_remote_hint_sql_patch(<node_name>, <patch_name>, <unique_query_id>, <hint_str>);
```

## Special Cases

According to the example, SQL patches can be used only when the correct unique SQL IDs are used. Therefore, SQL patches do not support prepared statement executed by the PREPARE + EXECUTE syntax.

```
-- Generally, an SQL ID with PREPARE is obtained. Therefore, the SQL patch cannot be used.
unique_query_id |          query
-----+-----
658407023 | prepare p1 as
| SELECT /*+ tablescan(rewrite_rule_hint_t1)*/+
| FROM rewrite_rule_hint_t1,
| (SELECT * FROM rewrite_rule_hint_t2 WHERE a > 1) tt+
| WHERE rewrite_rule_hint_t1.a = tt.a;
```

However, if the plan cache becomes invalid, the plan cache uses the statement in PREPARE to generate a unique SQL ID again. If the unique SQL ID is used to apply the SQL patch, the SQL patch can be used normally.

```
-- Example
-- Create a table.
gaussdb=# DROP TABLE rewrite_rule_hint_t1;
gaussdb=# DROP TABLE rewrite_rule_hint_t2;
gaussdb=# CREATE TABLE rewrite_rule_hint_t1 (a int, b int, c int, d int);
gaussdb=# CREATE TABLE rewrite_rule_hint_t2 (a int, b int, c int, d int);

-- Enable FullSQL statistics.
gaussdb=# SET track_stmt_stat_level = 'L1,L1';

-- Clear the sql_patch and environment.
gaussdb=# SELECT db_sql_util.drop_sql_patch('patch1');
gaussdb=# DEALLOCATE all;

-- Disable FQS.
gaussdb=# SET enable_fast_query_shipping=off;

-- PRARARE
gaussdb=# PREPARE p1 AS SELECT * FROM rewrite_rule_hint_t1,(SELECT * FROM rewrite_rule_hint_t2
WHERE a > 1) tt WHERE rewrite_rule_hint_t1.a = tt.a;

-- View the unique SQL ID.
gaussdb=# SELECT unique_query_id,QUERY FROM db_perf.statement_history WHERE QUERY LIKE
'%rewrite_rule_hint%' ORDER BY finish_time DESC LIMIT 1;
unique_query_id |
query
-----+-----
25719777 | prepare p1 as SELECT * FROM rewrite_rule_hint_t1,(SELECT * FROM rewrite_rule_hint_t2
WHERE a > 1) tt WHERE rewrite_rule_hint_t1.a = tt.a;

-- In this case, the unique SQL ID cannot make the SQL patch take effect.

-- Insert and analyze data to invalidate the cache.
gaussdb=# INSERT INTO rewrite_rule_hint_t1 VALUES(generate_series(1, 10000), generate_series(1, 10000),
generate_series(1, 10000),generate_series(1, 10000));
gaussdb=# ANALYZE rewrite_rule_hint_t1;

-- Generate a unique SQL ID again.
gaussdb=# EXPLAIN EXECUTE p1(1);
```

```

QUERY PLAN
-----
Streaming (type: GATHER) (cost=13.47..116.77 rows=7 width=32)
Node/s: All datanodes
-> Hash Join (cost=13.22..116.40 rows=7 width=32)
    Hash Cond: (rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a)
    -> Seq Scan on rewrite_rule_hint_t1 (cost=0.01..90.50 rows=9999 width=16)
        Filter: (a > 1)
    -> Hash (cost=13.16..13.16 rows=6 width=16)
        -> Seq Scan on rewrite_rule_hint_t2 (cost=0.00..13.16 rows=7 width=16)
            Filter: (a > 1)
(9 rows)

-- Check the new unique SQL ID.
gaussdb=# SELECT unique_query_id,QUERY FROM dbe_perf.statement_history WHERE QUERY LIKE
'%rewrite_rule_hint%' ORDER BY finish_time DESC LIMIT 1;
 unique_query_id |
query
-----
+-----
2936377667 | prepare p1 as SELECT * FROM rewrite_rule_hint_t1,(SELECT * FROM rewrite_rule_hint_t2
WHERE a > ?) tt WHERE rewrite_rule_hint_t1.a = tt.a;

The unique SQL ID changes and is generated using the SQL statement in PREPARE. In this case, the unique
SQL ID is available.

-- Use SQL_PATCH.
gaussdb=# SELECT * FROM dbe_sql_util.create_hint_sql_patch('patch1', 2936377667 , 'set(enable_hashjoin
off) NO_EXPAND_SUBQUERY(@sel$2)');

-- Check whether it takes effect.
gaussdb=# EXPLAIN EXECUTE p1(1);
          QUERY PLAN
-----
Streaming (type: GATHER) (cost=0.25..391.59 rows=7 width=32)
Node/s: All datanodes
-> Nested Loop (cost=0.00..391.21 rows=7 width=32)
    Join Filter: (rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a)
    -> Seq Scan on rewrite_rule_hint_t1 (cost=0.00..78.00 rows=10000 width=16)
    -> Materialize (cost=0.00..13.22 rows=7 width=16)
        -> Seq Scan on rewrite_rule_hint_t2 (cost=0.00..13.16 rows=7 width=16)
            Filter: (a > 1)
(8 rows)

-- The SQL patch takes effect and the corresponding plan is generated.

```

For details about the system functions, system catalogs, system views, and functions related to the SQL patch, see [Table 1 System functions, system catalogs, system views, and functions related to SQL PATCH](#).

**Table 6-6** System functions, system catalogs, system views, and functions related to SQL PATCH

Category	Name	Description
System function	<a href="#">global_sql_patch_func()</a>	SQL patch information on each global node, which is used to return the result of the global_sql_patch view.

Category	Name	Description
System catalog	<a href="#">GS_SQL_PATCH</a>	GS_SQL_PATCH records the status information about all SQL patches.
System view	<a href="#">GLOBAL_SQL_PATCH</a>	GLOBAL_SQL_PATCH stores information about all SQL patches. This view is available only in the PG_CATALOG schema.
Function <a href="#">DBE_SQL_UTIL</a> Schema	<a href="#">DBE_SQL_UTIL.create_hint_sql_patch</a>	create_hint_sql_patch creates hint SQL patches on the connected CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.create_abort_sql_patch</a>	create_abort_sql_patch creates abort SQL patches on the connected CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.drop_sql_patch</a>	drop_sql_patch deletes SQL patches from the connected CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.enable_sql_patch</a>	enable_sql_patch enables SQL patches on the connected CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.disable_sql_patch</a>	disable_sql_patch disables SQL patches on the connected CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.show_sql_patch</a>	show_sql_patch displays the SQL patch corresponding to a specified patch name and return the running result.
	<a href="#">DBE_SQL_UTIL.create_hint_sql_patch</a>	create_hint_sql_patch creates hint SQL patches and returns whether the execution is successful. This function is an overloaded function of the original function. The value of <b>parent_unique_sql_id</b> can be used to limit the effective range of the hint patch.
	<a href="#">DBE_SQL_UTIL.create_abort_sql_patch</a>	create_abort_sql_patch creates abort SQL patches and returns whether the execution is successful. This function is an overloaded function of the original function. The value of <b>parent_unique_sql_id</b> can be used to limit the effective range of the abort patch.

Category	Name	Description
	<a href="#">DBE_SQL_UTIL.create_remote_hint_sql_patch</a>	create_remote_hint_sql_patch creates hint SQL patches on a specified CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.create_remote_abort_sql_patch</a>	create_remote_abort_sql_patch creates abort SQL patches on a specified CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.drop_remote_sql_patch</a>	drop_remote_sql_patch deletes SQL patches from a specified CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.enable_remote_sql_patch</a>	enable_remote_sql_patch enables SQL patches on a specified CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.disable_remote_sql_patch</a>	disable_remote_sql_patch disables SQL patches on a specified CN and returns whether the execution is successful.

## 6.12 Optimization Cases

### 6.12.1 Case: Selecting an Appropriate Distribution Key

#### Symptom

Tables are defined as follows:

```
CREATE TABLE t1 (a int, b int);
CREATE TABLE t2 (a int, b int);
```

The following query is executed:

```
SELECT * FROM t1, t2 WHERE t1.a = t2.b;
```

#### Optimization Analysis

If **a** is the distribution key of **t1** and **t2**:

```
CREATE TABLE t1 (a int, b int) DISTRIBUTE BY HASH (a);
CREATE TABLE t2 (a int, b int) DISTRIBUTE BY HASH (a);
```

Then **Streaming** exists in the execution plan and the data volume is heavy among DNs, as shown in [Figure 6-8](#).

**Figure 6-8** Selecting an appropriate distribution key (1)

```
openGauss=> explain select * from t1, t2 where t1.a = t2.b;
QUERY PLAN
-----
Streaming (type: GATHER) (cost=245.40..582.15 rows=240 width=16)
Node/s: All datanodes
-> Hash Join (cost=10.22..24.26 rows=10 width=16)
    Hash Cond: (t1.a = t2.b)
    -> Seq Scan on t1 (cost=0.00..10.10 rows=10 width=8)
    -> Hash (cost=3.79..3.79 rows=10 width=8)
        -> Streaming(type: REDISTRIBUTE) (cost=0.00..3.79 rows=10 width=8)
            Spawn on: All datanodes
            -> Seq Scan on t2 (cost=0.00..10.10 rows=10 width=8)
(9 rows)
```

If **a** is the distribution key of **t1** and **b** is the distribution key of **t2**:

```
CREATE TABLE t1 (a int, b int) DISTRIBUTE BY HASH (a);
CREATE TABLE t2 (a int, b int) DISTRIBUTE BY HASH (b);
```

Then **Streaming** does not exist in the execution plan, and the data volume among DN is decreasing and the query performance is increasing, as shown in [Figure 6-9](#).

**Figure 6-9** Selecting an appropriate distribution key (2)

```
openGauss=> explain select * from t1, t2 where t1.a = t2.b;
QUERY PLAN
-----
Streaming (type: GATHER) (cost=245.40..491.10 rows=240 width=16)
Node/s: All datanodes
-> Hash Join (cost=10.22..20.46 rows=10 width=16)
    Hash Cond: (t1.a = t2.b)
    -> Seq Scan on t1 (cost=0.00..10.10 rows=10 width=8)
    -> Hash (cost=10.10..10.10 rows=10 width=8)
        -> Seq Scan on t2 (cost=0.00..10.10 rows=10 width=8)
(7 rows)
```

## 6.12.2 Case: Creating an Appropriate Index

### Symptom

Query the information about all personnel in the sales department.

```
-- Create a table.
CREATE TABLE staffs (staff_id NUMBER(6) NOT NULL, first_name VARCHAR2(20), last_name
VARCHAR2(25), employment_id VARCHAR2(10), section_id NUMBER(4), state_name VARCHAR2(10), city
VARCHAR2(10));
CREATE TABLE sections (section_id NUMBER(4), place_id NUMBER(4), section_name VARCHAR2(20));
CREATE TABLE states (state_id NUMBER(4));
CREATE TABLE places (place_id NUMBER(4), state_id NUMBER(4));
-- Query before optimization.
EXPLAIN SELECT staff_id,first_name,last_name,employment_id,state_name,city
FROM staffs,sections,states,places
WHERE sections.section_name='Sales'
AND staffs.section_id = sections.section_id
AND sections.place_id = places.place_id
AND places.state_id = states.state_id
ORDER BY staff_id;
-- Query after optimization.
CREATE INDEX loc_id_pk ON places(place_id);
CREATE INDEX state_c_id_pk ON states(state_id);
```

```
EXPLAIN SELECT staff_id,first_name,last_name,employment_id,state_name,city
FROM staffs,sections,states,places
WHERE sections.section_name='Sales'
AND staffs.section_id = sections.section_id
AND sections.place_id = places.place_id
AND places.state_id = states.state_id
ORDER BY staff_id;
```

## Optimization Analysis

The original execution plan is as follows before creating the **places.place\_id** and **states.state\_id** indexes:

id	operation	E-rows	E-width	E-costs
1	-> Streaming (type: GATHER)	2	254	54.08
2	-> Sort	2	254	53.90
3	-> Nested Loop (4,5)	2	254	53.88
4	-> Seq Scan on staffs	20	266	13.13
5	-> Materialize	4	12	40.37
6	-> Streaming(type: BROADCAST)	4	12	40.36
7	-> Nested Loop (8,9)	2	12	40.20
8	-> Seq Scan on states	20	12	13.13
9	-> Materialize	2	24	26.69
10	-> Streaming(type: REDISTRIBUTE)	2	24	26.68
11	-> Nested Loop (12,14)	2	24	26.57
12	-> Streaming(type: REDISTRIBUTE)	1	24	13.28
13	-> Seq Scan on sections	1	24	13.16
14	-> Seq Scan on places	20	24	13.13

(14 rows)

Predicate Information (identified by plan id)

```
3 --Nested Loop (4,5)
  Join Filter: (sections.section_id = staffs.section_id)
7 --Nested Loop (8,9)
  Join Filter: (places.state_id = states.state_id)
11 --Nested Loop (12,14)
  Join Filter: (sections.place_id = places.place_id)
13 --Seq Scan on sections
  Filter: ((section_name)::text = 'Sales'::text)
```

(8 rows)

The optimized execution plan is as follows (two indexes have been created on the **places.place\_id** and **states.state\_id** columns):

id	operation	E-rows	E-width	E-costs
1	-> Streaming (type: GATHER)	2	254	42.26
2	-> Sort	2	254	42.08
3	-> Nested Loop (4,5)	2	254	42.06
4	-> Seq Scan on staffs	20	266	13.13
5	-> Materialize	4	12	28.55
6	-> Streaming(type: BROADCAST)	4	12	28.54
7	-> Nested Loop (8,13)	2	12	28.38
8	-> Streaming(type: REDISTRIBUTE)	2	24	21.66
9	-> Nested Loop (10,12)	2	24	21.56
10	-> Streaming(type: REDISTRIBUTE)	1	24	13.28
11	-> Seq Scan on sections	1	24	13.16
12	-> Index Scan using loc_id_pk on places	1	24	8.27
13	-> Index Only Scan using state_c_id_pk on states	1	12	3.35

(13 rows)

Predicate Information (identified by plan id)

```
3 --Nested Loop (4,5)
  Join Filter: (sections.section_id = staffs.section_id)
11 --Seq Scan on sections
```

```

Filter: ((section_name)::text = 'Sales'::text)
12 --Index Scan using loc_id_pk on places
    Index Cond: (place_id = sections.place_id)
13 --Index Only Scan using state_c_id_pk on states
    Index Cond: (state_id = places.state_id)
(8 rows)
    
```

### 6.12.3 Case: Adjusting Distribution Keys

#### Symptom

During a site test, the information is displayed after **EXPLAIN ANALYZE** is run:

id	operation	A-time	A-rows	E-rows	Peak Memory	E-memory	A-width	E-width	E-costs
1	Streaming (type: GATHER)	[94158, 404]	0	670912	292KB				
2	Insert on temp_calc_emprate0101_t3	[93259, 538, 93430, 438]	310	670912	[1108KB, 1108KB]	1MB		73	102576573.63
3	Streaming (type: REDISTRIBUTE)	[93259, 507, 93410, 400]	310	670912	[2091KB, 2093KB]	1MB		73	102534641.63
4	Subquery Scan on **SELECT**	[93212, 430, 93419, 995]	310	670912	[7KB, 7KB]	1MB		73	102533776.79
5	HashAggregate	[93212, 425, 93419, 980]	310	670912	[145KB, 197KB]	16MB	[65, 65]	45	102533645.74
6	Streaming (type: REDISTRIBUTE)	[93212, 374, 93419, 924]	5886	670994	[2091KB, 2093KB]	1MB		45	102533305.05
7	Hash Join (S,12)	[2657, 406, 93339, 924]	5886	670994	[20KB, 20KB]	1MB		45	102532655.39
8	Seq Scan on s_riskrate_setting a	[38, 885, 7340, 983]	17753027	7859418	[612KB, 903KB]	1MB		56	215264.71
9	Hash	[1241, 538, 2713, 381]	8536241	8536241	[1031KB, 97803KB]	16MB	[48, 48]	46	50870.88
10	Streaming (type: REDISTRIBUTE)	[210, 226, 2617, 195]	8536241	8536241	[2091KB, 2093KB]	1MB		46	50870.88
11	Seq Scan on temp_calc_emprate0101 b	[86, 790, 141, 293]	8536241	8536241	[16KB, 16KB]	1MB		46	11564.79

According to the execution information, Hash Join becomes the performance bottleneck of the whole plan. Based on the execution time of Hash Join [2657.406,93339.924] (for details about the values, see [Description](#)), it can be seen that severe skew occurs on different DN's during the Hash Join operation.

In the memory information (as shown in the following figure), it can be seen that the data skew occurs in the memory usage of each node.

```

..... Memory Information (identified by plan id) .....
-----
Coordinator:
--Query Peak Memory: 4MB
Datanode:
--Max Query Peak Memory: 118MB
--Min Query Peak Memory: 24MB
-- 12 --Hash
..... Max Buckets: 131072 Max Batches: 1 Max Memory Usage: 91857kB
..... Min Buckets: 131072 Min Batches: 1 Min Memory Usage: 0kB
(8 rows)
    
```

#### Optimization Analysis

The preceding two features indicate that this SQL statement has extremely serious computing unbalance. The further lower-layer analysis on the Hash Join operator shows that serious computing skew [38.885,2940.983] occurs in **Seq Scan on s\_riskrate\_setting**. Based on the description of the Scan, we can infer that the performance problems of this plan lie in data skew occurred in the **s\_riskrate\_setting** table. Later, it is proved that serious data skew occurred in the **s\_riskrate\_setting** table. After performance optimization, the execution time is reduced from 94s to 50s.

### 6.12.4 Case: Adjusting the GUC Parameter best\_agg\_plan

#### Symptom

The **agg\_t1** table is defined as follows:

```
create table agg_t1(a int, b int, c int) distribute by hash(a);
```

Assume that the distribution key of the result set provided by the agg lower-layer operator is **setA**, and the **group by** column of the agg operation is **setB**, the agg operations can be performed in two scenarios in the Stream framework.

1. **setA** is a subset of **setB**.

In this scenario, the aggregation result of the lower-layer is correct and can be directly used by upper-level operators. Example:

```
gaussdb=# explain select a, count(1) from agg_t1 group by a;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
1 | -> Streaming (type: GATHER) | 20 | 12 | 14.23
2 | -> HashAggregate | 20 | 12 | 13.30
3 | -> Seq Scan on agg_t1 | 20 | 4 | 13.13
(3 rows)
```

2. **setA** is not a subset of **setB**.

In this scenario, the Stream execution framework is classified into the following three plans:

- hashagg + gather(redistribute) + hashagg;
- redistribute + hashagg(+ gather);
- hashagg + redistribute + hashagg(+ gather).

GaussDB provides the GUC parameter **best\_agg\_plan** to intervene the execution plan, and forces the plan to generate the corresponding execution plan. This parameter can be set to **0, 1, 2, or 3**.

- When the parameter is set to **1**, the first plan is forcibly generated.
- When the parameter is set to **2** and if the **group by** column can be redistributed, the second plan is forcibly generated. Otherwise, the first plan is generated.
- When the parameter is set to **3** and if the **group by** column can be redistributed, the third plan is generated. Otherwise, the first plan is generated.
- When the parameter is set to **0**, the query optimizer chooses the most optimal plan by the three preceding plans' evaluation cost.

The impact is as follows:

```
gaussdb=# set best_agg_plan to 1;
SET
gaussdb=# explain select b,count(1) from agg_t1 group by b;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
1 | -> HashAggregate | 10 | 12 | 14.23
2 | -> Streaming (type: GATHER) | 20 | 12 | 14.23
3 | -> HashAggregate | 20 | 12 | 13.30
4 | -> Seq Scan on agg_t1 | 20 | 4 | 13.13
(4 rows)
gaussdb=# set best_agg_plan to 2;
SET
gaussdb=# explain select b,count(1) from agg_t1 group by b;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
1 | -> Streaming (type: GATHER) | 20 | 12 | 14.52
2 | -> HashAggregate | 20 | 12 | 13.58
3 | -> Streaming(type: REDISTRIBUTE) | 20 | 4 | 13.42
4 | -> Seq Scan on agg_t1 | 20 | 4 | 13.13
(4 rows)
gaussdb=# set best_agg_plan to 3;
SET
gaussdb=# explain select b,count(1) from agg_t1 group by b;
id | operation | E-rows | E-width | E-costs
```

```

-----+-----+-----+-----+
 1 | -> Streaming (type: GATHER)          | 20 | 12 | 14.97
 2 | -> HashAggregate                    | 20 | 12 | 13.76
 3 | -> Streaming(type: REDISTRIBUTE) | 20 | 12 | 13.56
 4 | -> HashAggregate                    | 20 | 12 | 13.30
 5 | -> Seq Scan on agg_t1              | 20 | 4 | 13.13
(5 rows)

```

## Optimization

Generally, the optimizer chooses an optimal execution plan, but the cost estimation, especially that of the intermediate result set, has large deviations, which may result in large deviations in agg calculation. In this case, you need to use **best\_agg\_plan** to adjust the agg calculation model.

When the aggregation convergence ratio is very small, that is, the number of result sets does not become small obviously after the agg operation (5 times is a critical point), you can select the redistribute+hashagg or hashagg+redistribute+hashagg execution mode.

## 6.12.5 Case: Rewriting SQL Statements to Eliminate Subqueries

### Symptom

```

select
  1,
  (select count(*) from customer_address_001 a4 where a4.ca_address_sk = a.ca_address_sk) as GZCS
from customer_address_001 a;

```

This SQL performance is poor. SubPlan exists in the execution plan as follows.

```

openGauss=# explain select 1,(select count(*)
openGauss(#          from customer_address_001 a4
openGauss(#          where a4.ca_address_sk = a.ca_address_sk
openGauss(#          ) as GZCS from customer_address_001 a;
 id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+
 1 | -> Streaming (type: GATHER)          | 320 | 4 | 4529.27
 2 | -> Seq Scan on customer_address_001 a | 320 | 4 | 4496.27
 3 | -> Aggregate [2, SubPlan 1]         | 32 | 4 | 139.50
 4 | -> Result                           | 10240 | 4 | 138.69
 5 | -> Materialize                      | 10240 | 4 | 138.69
 6 | -> Streaming(type: BROADCAST)       | 10240 | 4 | 137.09
 7 | -> Seq Scan on customer_address_001 a4 | 320 | 4 | 32.32
(7 rows)

```

## Optimization

The core of this optimization is to eliminate subqueries. Based on the service scenario analysis, **a.ca\_address\_sk** is not **NULL**. In terms of SQL syntax, you can rewrite the SQL statement as follows:

```

select
count(*)
from customer_address_001 a4, customer_address_001 a
where a4.ca_address_sk = a.ca_address_sk
group by a.ca_address_sk;

```

 NOTE

To ensure that the modified statements have the same functions, NOT NULL is added to `customer_address_001.ca_address_sk`.

## 6.12.6 Case: Rewriting SQL Statements to Eliminate Pruning Interference

### Symptom

In a test at a site, `ddw_f10_op_cust_asset_mon` is a partitioned table and the partitioning key is `year_mth` whose value is a combined string of month and year values.

The tested SQL statements are displayed as follows:

```
select
  count(1)
from t_ddw_f10_op_cust_asset_mon b1
where b1.year_mth between to_char(add_months(to_date('20170222','yyyymmdd'), -11),'yyyymm') and
substr('20170222',1,6);
```

The test result shows the Scan operation on the tables in the SQL statement takes 135s. This may be the performance bottleneck.

 NOTE

`add_months` is a local adaptation function.

```
CREATE OR REPLACE FUNCTION ADD_MONTHS(date, integer) RETURNS date
AS $$
SELECT
CASE
WHEN (EXTRACT(day FROM $1) = EXTRACT(day FROM (date_trunc('month', $1) + INTERVAL '1
month - 1 day')) THEN
  date_trunc('month', $1) + CAST($2 + 1 || ' month - 1 day' as interval)
ELSE
  $1 + CAST($2 || ' month' as interval)
END
$$
LANGUAGE SQL
IMMUTABLE;
```

### Optimization

According to the statement execution plan, the base table filter is displayed as follows:

```
Filter: (((year_mth)::text <= '201702'::text) AND ((year_mth)::text >=
to_char(add_months(to_date('20170222'::text, 'YYYYMMDD'::text), (-11)), 'YYYYMM'::text)))
```

The filter condition contains a non-constant expression `to_char(add_months(to_date('20170222','yyyymmdd'), -11),'yyyymm')`, which cannot be used for pruning. Therefore, the query statement scans all data in the partitioned table.

`to_date` and `to_char` are stable functions as queried in `pg_proc`. According to the function behavior described in the database, this type of functions cannot be converted to Const values in the preprocessing phase, which is the root cause why partition pruning cannot be performed.

Based on the preceding analysis, the optimization expression can be used for partition pruning, which is the key to performance optimization. The original SQL statements can be written to as follows:

```
select
  count(1)
from t_ddw_f10_op_cust_asset_mon b1
where b1.year_mth between(substr(ADD_MONTHS('20170222'::date, -11), 1, 4)||
  substr(ADD_MONTHS('20170222'::date, -11), 6, 2)) and substr('20170222',1,6 );
```

The execution time of modified SQL statements is reduced from 135s to 18s.

## 6.12.7 Case: Rewriting SQL Statements and Deleting in-clause

### Symptom

in-clause/any-clause is a common SQL statement constraint. Sometimes, the clause following **in** or **any** is a constant. For example:

```
select
  count(1)
from calc_empfyc_c1_result_tmp_t1
where ls_pid_cusr1 in ('20120405', '20130405');
```

Or:

```
select
  count(1)
from calc_empfyc_c1_result_tmp_t1
where ls_pid_cusr1 in any('20120405', '20130405');
```

Sometimes, the **in** or **any** clause is used as follows:

```
SELECT
  ls_pid_cusr1,COALESCE(max(round((current_date-bthdate)/365)),0)
FROM calc_empfyc_c1_result_tmp_t1 t1,p10_md_tmp_t2 t2
WHERE t1.ls_pid_cusr1 = any(values(id),(id15))
GROUP BY ls_pid_cusr1;
```

**id** and **id15** are columns in **p10\_md\_tmp\_t2**, and **t1.ls\_pid\_cusr1 = any(values(id),(id15))** is equivalent to **t1.ls\_pid\_cusr1 = id or t1.ls\_pid\_cusr1 = id15**.

Therefore, join-condition is essentially an inequality, and nestloop must be used for this unequal join operation. The corresponding execution plan is as follows.

```
Streaming (type: GATHER) (cost=1641429284.14..1641429283.98 rows=3840 width=49)
  Nodes/s: All datanodes
  -> Insert on channel_calc_empfyc_c1_result_age_tmp (cost=1641429280.14..1641429283.98 rows=3840 width=49)
  -> HashAggregate (cost=1641429280.14..1641429283.98 rows=3840 width=25)
  Output: t1.ls_pid_cusr1, COALESCE(max(max(round((((('2017-03-29 00:00:00'::timestamp without time zone - t2.bthdate) / 365)::double precision))::numeric, 0))), 0)::numeric)
  Group By Key: t1.ls_pid_cusr1
  -> Streaming (type: RESORT) (cost=820714640.07..820714642.69 rows=3968 width=25)
  Output: t1.ls_pid_cusr1, (max(round((((('2017-03-29 00:00:00'::timestamp without time zone - t2.bthdate) / 365)::double precision))::numeric, 0)))
  Distribute Key: t1.ls_pid_cusr1
  Spawn on: All datanodes
  -> HashAggregate (cost=820714640.07..820714642.69 rows=3968 width=25)
  Output: t1.ls_pid_cusr1, max(round((((('2017-03-29 00:00:00'::timestamp without time zone - t2.bthdate) / 365)::double precision))::numeric, 0))
  Group By Key: t1.ls_pid_cusr1
  -> Nested Loop (cost=0.00..615567760.93 rows=875293350960 width=25)
  Output: t1.ls_pid_cusr1, t2.bthdate
  Join Filter: (SubPlan 1)
  -> Seq Scan on channel_calc_empfyc_c1_result_tmp_t1 t1 (cost=0.00..127030.52 rows=443523960 width=64)
  Output: t2.id, t2.id15, t2.bthdate, t2.mandeg
  -> Materialize (cost=0.00..147.29 rows=252608 width=17)
  Output: t1.ls_pid_cusr1
  -> Streaming (type: BROADCAST) (cost=0.00..127.56 rows=252608 width=17)
  Output: t1.ls_pid_cusr1
  Spawn on: All datanodes
  -> Seq Scan on channel_calc_empfyc_c1_result_tmp_t1 t1 (cost=0.00..1.62 rows=3947 width=17)
  Output: t1.ls_pid_cusr1
  SubPlan 1
  -> Values Scan on "VALUES*" (cost=0.00..0.01 rows=4 width=39)
  Output: "VALUES".column1
```

### Optimization

The test result shows that both result sets are too large. As a result, nestloop is time-consuming with more than one hour to return results. Therefore, the key to

performance optimization is to eliminate nestloop, using more efficient hash join. From the perspective of semantic equivalence, the SQL statements can be written as follows:

```
select
ls_pid_cusr1,COALESCE(max(round(ym/365)),0)
from
(
    (
        SELECT
            ls_pid_cusr1,(current_date-bthdate) as ym
        FROM calc_empfyc_c1_result_tmp_t1 t1,p10_md_tmp_t2 t2
        WHERE t1.ls_pid_cusr1 = t2.id and t1.ls_pid_cusr1 != t2.id15
    )
    union all
    (
        SELECT
            ls_pid_cusr1,(current_date-bthdate) as ym
        FROM calc_empfyc_c1_result_tmp_t1 t1,p10_md_tmp_t2 t2
        WHERE t1.ls_pid_cusr1 = id15
    )
)
GROUP BY ls_pid_cusr1;
```

The optimized SQL query consists of two equivalent join subqueries, and each subquery can be used for hash join in this scenario. The optimized execution plan is as follows.

id	operation	A-time	A-rows	B-rows	Peak Memory	Ememory	A-width
1	-> Streaming (type: GATHER)	6737.281	0	192	292KB		
2	-> Insert on channel.calc_empfyc_c1_result_age_tmp	[4665.024,4990.666]	0	192	[1109KB, 1109KB]	1MB	
3	-> HashAggregate	[4664.996,4990.644]	0	192	[12KB, 12KB]	10KB	
4	-> Streaming (type: BROADCAST)	[4664.991,4990.637]	0	3992	[2090KB, 2090KB]	1MB	
5	-> HashAggregate	[3416.939,4958.348]	0	3992	[14KB, 14KB]	16KB	
6	-> Append	[3416.936,4958.340]	0	4011	[1KB, 1KB]	1MB	
7	-> Hash Join (8,9)	[2011.226,3090.697]	0	3947	[6KB, 6KB]	1MB	
8	-> Seq Scan on channel.p10_md_tmp_t2 t2	[803.782,1238.984]	443523717	443523360	[12KB, 12KB]	1MB	
9	-> Hash	[4.337,328.979]	252608	252608	[482KB, 482KB]	10KB	[36, 39]
10	-> Streaming (type: BROADCAST)	[2.345,326.320]	252608	252608	[2090KB, 2090KB]	1MB	
11	-> Seq Scan on channel.calc_empfyc_c1_result_tmp_t1 t1	[0.011,0.030]	3947	3947	[11KB, 11KB]	1MB	
12	-> Hash Join (13,14)	[1376.258,2066.110]	0	64	[5KB, 5KB]	1MB	
13	-> Seq Scan on channel.p10_md_tmp_t2 t2	[777.552,1388.499]	443523717	443523360	[12KB, 12KB]	1MB	
14	-> Hash	[2.812,4.217]	252608	252608	[482KB, 482KB]	10KB	[36, 37]
15	-> Streaming (type: BROADCAST)	[1.276,1.868]	252608	252608	[2090KB, 2090KB]	1MB	
16	-> Seq Scan on channel.calc_empfyc_c1_result_tmp_t1 t1	[0.010,0.033]	3947	3947	[11KB, 11KB]	1MB	

(16 rows)

Before the optimization, no result is returned for more than 1 hour. After the optimization, the result is returned within 7s.

## 6.12.8 Case: Modifying the GUC Parameter rewrite\_rule

**rewrite\_rule** contains multiple query rewriting rules: magicset, partialpush, uniquecheck, disablerep, intargetlist, and predpush. The following describes the application scenarios of some important rules.

### Preparing the Case Environment

To demonstrate rule application scenarios, you need to prepare the following table creation statements:

```
-- Clean the environment.
DROP SCHEMA IF EXISTS rewrite_rule_guc_test CASCADE;
CREATE SCHEMA rewrite_rule_guc_test;
SET current_schema=rewrite_rule_guc_test;
-- Create a test table.
CREATE TABLE t(c1 INT, c2 INT, c3 INT, c4 INT);
CREATE TABLE t1(c1 INT, c2 INT, c3 INT, c4 INT);
CREATE TABLE t2(c1 INT, c2 INT, c3 INT, c4 INT);
```

## partialpush: Partial Pushdown

Queries are pushed down to DNs for distributed execution, greatly accelerating queries. If a query statement contains a factor that cannot be pushed down, the entire statement cannot be pushed down. As a result, a stream plan cannot be generated and executed on DNs for the distributed execution, and the performance is poor.

The following is an example:

```
gaussdb=# set rewrite_rule='none';
SET
gaussdb=# explain (verbose on, costs off) select group_concat(tt.c1, tt.c2) from (select t1.c1,t2.c2 from t1,t2 where t1.c1=t2.c2) tt(c1,c2);
          QUERY PLAN
-----
Aggregate
  Output: group_concat(t1.c1, t2.c2 SEPARATOR ',')
  -> Hash Join
      Output: t1.c1, t2.c2
      Hash Cond: (t1.c1 = t2.c2)
      -> Data Node Scan on t1 "_REMOTE_TABLE_QUERY_"
          Output: t1.c1
          Node/s: All datanodes
          Remote query: SELECT c1 FROM ONLY public.t1 WHERE true
      -> Hash
          Output: t2.c2
          -> Data Node Scan on t2 "_REMOTE_TABLE_QUERY_"
              Output: t2.c2
              Node/s: All datanodes
              Remote query: SELECT c2 FROM ONLY public.t2 WHERE true
```

The `group_concat()` function cannot be pushed down. As a result, the remote query plan is executed:

1. Deliver the **select c1 from t1 where true** statement to DNs to read all data in the **t1** table.
2. Deliver the **select c2 from t2 where true** statement to DNs to read all data in the **t2** table.
3. Perform HASH JOIN on the CN.
4. Perform the `group_concat` calculation and return the final result.

This plan is slow because a large amount of data is transmitted over the network and then HASH JOIN is executed on the CN. As a result, cluster resources cannot be fully used.

**partialpush** is added to push the preceding 1, 2, and 3 operations down to DNs for distributed execution, greatly improving statement performance.

```
gaussdb=# set rewrite_rule='partialpush';
SET
gaussdb=# explain (verbose on, costs off) select group_concat(tt.c1, tt.c2) from (select t1.c1,t2.c2 from t1,t2 where t1.c1=t2.c2) tt(c1,c2);
          QUERY PLAN
-----
Aggregate
  Output: group_concat(t1.c1, t2.c2 SEPARATOR ',')
  -> Streaming (type: GATHER) -- The Gather plan is executed on DNs in a distributed manner.
      Output: t1.c1, t2.c2
      Node/s: All datanodes
      -> Hash Join
          Output: t1.c1, t2.c2
          Hash Cond: (t2.c2 = t1.c1)
          -> Streaming(type: REDISTRIBUTE)
```

```

Output: t2.c2
Distribute Key: t2.c2
Spawn on: All datanodes
Consumer Nodes: All datanodes
-> Seq Scan on public.t2
    Output: t2.c2
    Distribute Key: t2.c1
-> Hash
    Output: t1.c1
    -> Seq Scan on public.t1
        Output: t1.c1
        Distribute Key: t1.c1
(21 rows)

```

## intargetlist: Target Column Subquery Performance Improvement

The query performance can be greatly improved by converting the subquery in the target column to JOIN. The following is an example:

```

gaussdb=# set rewrite_rule='none';
SET
gaussdb=# explain (verbose on, costs off) select c1,(select avg(c2) from t2 where t2.c2=t1.c2) from t1
where t1.c1<100 order by t1.c2;
QUERY PLAN
-----
Streaming (type: GATHER)
  Output: t1.c1, ((SubPlan 1)), t1.c2
  Merge Sort Key: t1.c2
  Node/s: All datanodes
  -> Sort
    Output: t1.c1, ((SubPlan 1)), t1.c2
    Sort Key: t1.c2
    -> Seq Scan on public.t1
      Output: t1.c1, (SubPlan 1), t1.c2
      Distribute Key: t1.c1
      Filter: (t1.c1 < 100)
      SubPlan 1
        -> Aggregate
          Output: avg(t2.c2)
          -> Result
            Output: t2.c2
            Filter: (t2.c2 = t1.c2)
            -> Materialize
              Output: t2.c2
              -> Streaming(type: BROADCAST)
                Output: t2.c2
                Spawn on: All datanodes
                Consumer Nodes: All datanodes
                -> Seq Scan on public.t2
                  Output: t2.c2
                  Distribute Key: t2.c1
(26 rows)

```

Because the subquery (select avg(c2) from t2 where t2.c2=t1.c2) in the target column cannot be pulled up, the subquery is executed once each time a data row of **t1** is scanned, and the query efficiency is low. If the **intargetlist** parameter is enabled, the subquery is converted to JOIN to improve the query performance.

```

gaussdb=# set rewrite_rule='intargetlist';
SET
gaussdb=# explain (verbose on, costs off) select c1,(select avg(c2) from t2 where t2.c2=t1.c2) from t1
where t1.c1<100 order by t1.c2;
QUERY PLAN
-----
Streaming (type: GATHER)
  Output: t1.c1, (avg(t2.c2)), t1.c2
  Merge Sort Key: t1.c2
  Node/s: All datanodes

```

```

-> Sort
  Output: t1.c1, (avg(t2.c2)), t1.c2
  Sort Key: t1.c2
  -> Hash Right Join
    Output: t1.c1, (avg(t2.c2)), t1.c2
    Hash Cond: (t2.c2 = t1.c2)
    -> Streaming(type: BROADCAST)
      Output: (avg(t2.c2)), t2.c2
      Spawn on: All datanodes
      Consumer Nodes: All datanodes
      -> HashAggregate
        Output: avg(t2.c2), t2.c2
        Group By Key: t2.c2
        -> Streaming(type: REDISTRIBUTE)
          Output: t2.c2
          Distribute Key: t2.c2
          Spawn on: All datanodes
          Consumer Nodes: All datanodes
          -> Seq Scan on public.t2
            Output: t2.c2
            Distribute Key: t2.c1
      -> Hash
        Output: t1.c1, t1.c2
        -> Seq Scan on public.t1
          Output: t1.c1, t1.c2
          Distribute Key: t1.c1
          Filter: (t1.c1 < 100)
(31 rows)

```

## uniquecheck: Performance Improvement of Subqueries Without Aggregate Functions

To ensure subquery pullup, each condition must have only one line of output. The subqueries with aggregate functions can be automatically pulled up. For subqueries without aggregate functions, as shown in the following example:

```
select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c2);
```

Rewrite as follows:

```
select t1.c1 from t1 join (select t2.c1 from t2 where t2.c1 is not null group by t2.c1(unique check)) tt(c1) on tt.c1=t1.c1;
```

Note that unique check in the preceding SQL statement indicates that **t2.c1** needs to be checked. If the SQL statement is abnormal, the SQL statement cannot be directly executed. To ensure semantic equivalence, the subquery **tt** must ensure that each **group by t2.c1** has only one line of output. Enable the **uniquecheck** query rewriting parameter to ensure that the query can be pulled up and equivalent. If more than one row of data is output at run time, an error is reported.

```

gaussdb=# set rewrite_rule='uniquecheck';
SET
gaussdb=# explain verbose select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c1) ;
          QUERY PLAN
-----
Streaming (type: GATHER)
  Output: t1.c1
  Node/s: All datanodes
  -> Nested Loop
    Output: t1.c1
    Join Filter: (t1.c1 = subquery."?column?")
    -> Seq Scan on public.t1
      Output: t1.c1, t1.c2, t1.c3
      Distribute Key: t1.c1
    -> Materialize

```

```

Output: subquery."?column?", subquery.c1
-> Subquery Scan on subquery
  Output: subquery."?column?", subquery.c1
    -> HashAggregate
      Output: t2.c1, t2.c1
      Group By Key: t2.c1
      Filter: (t2.c1 IS NOT NULL)
      Unique Check Required -- If more than one row of data is output during running, an
error is reported.
    -> Index Only Scan using t2idx on public.t2
      Output: t2.c1
      Distribute Key: t2.c1
(21 rows)

```

Note: Because **group by t2.c1 unique check** occurs before the filter condition **t2.c1=t1.c1**, an error may be reported after the query that does not report an error is rewritten. An example is as follows:

There are tables **t1** and **t2**. The data in the tables is as follows:

```

gaussdb=# select * from t1 order by c2;
 c1 | c2 | c3
-----+-----+-----
  1 |  1 |  1
  2 |  2 |  2
  3 |  3 |  3
  4 |  4 |  4
  5 |  5 |  5
  6 |  6 |  6
  7 |  7 |  7
  8 |  8 |  8
  9 |  9 |  9
 10 | 10 | 10
(10 rows)

```

```

gaussdb=# select * from t2 order by c1;
 c1 | c2 | c3
-----+-----+-----
  1 |  1 |  1
  2 |  2 |  2
  3 |  3 |  3
  4 |  4 |  4
  5 |  5 |  5
  6 |  6 |  6
  7 |  7 |  7
  8 |  8 |  8
  9 |  9 |  9
 10 | 10 | 10
 11 | 11 | 11
 11 | 11 | 11
 12 | 12 | 12
 12 | 12 | 12

ERROR: more than one row returned by a subquery used as an expression
```

## predpush, predpushnormal, and predpushforce: Condition Pushdown to Subqueries

Generally, the optimizer performs optimization by query block, and different query blocks are independently optimized. If a predicate condition involving cross-query blocks exists, it is difficult to consider the location of a predicate application from a global perspective. The predpush may push down the predicate to the subquery block, so that performance can be improved in a scenario in which the data volume in the parent query block is relatively small and an index can be used in the subquery. There are three rewriting rules related to predpush:

- **predpushnormal**: attempts to push down predicates to subqueries. The STREAM operators, such as BROADCAST, are used to implement distributed plans.
- **predpushforce**: attempts to push down predicates to subqueries and uses the index of the parameterized path for scanning as much as possible.
- **predpush**: selects an optimal distributed plan from predpushnormal and predpushforce at a cost, but increases optimization time.

The following is an example of a plan for disabling and enabling the query rewriting rule:

```
gaussdb=# set enable_fast_query_shipping = off; -- Disable FQS optimization.
SET
gaussdb=# show rewrite_rule;
rewrite_rule
-----
magicset
(1 row)

gaussdb=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1 = t1.c1;
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
   Join Filter: (t1.c1 = t2.c1)
   -> HashAggregate
       Group By Key: t2.c1
```

```
-> Seq Scan on t2
-> Seq Scan on t1
(8 rows)

gaussdb=# set rewrite_rule='predpushnormal';
SET
gaussdb=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1 =
t1.c1;
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
    -> Seq Scan on t1
    -> HashAggregate
        Group By Key: t2.c1
    -> Result
        Filter: (t1.c1 = t2.c1)
    -> Seq Scan on t2
(9 rows)

-- You can see that the filter criteria are pushed to the subquery for execution.

gaussdb=# set rewrite_rule='predpushforce';
SET

gaussdb=# explain (costs off) select /*+predpush(t1 st2)*/ * from t1, (select sum(c2), c1 from t2 group by
c1) st2 where st2.c1 = t1.c1;
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
    -> Seq Scan on t1
    -> HashAggregate
        Group By Key: t2.c1
    -> Index Scan using t2_c1_idx on t2
        Index Cond: (t1.c1 = c1)
(8 rows)

-- When used together with predpush hints, you can see that parameterized paths are used.

gaussdb=# set rewrite_rule = 'predpush';
SET
gaussdb=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1 =
t1.c1;
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Nested Loop
    -> Seq Scan on t1
    -> HashAggregate
        Group By Key: t2.c1
    -> Index Scan using t2_c1_idx on t2
        Index Cond: (t1.c1 = c1)
(8 rows)
```

## Forbidding Pullup of Subquery Parameter `disablerep` for Replication Tables

When querying a replication table, the query actually takes effect on a DN only. Pulling up the subquery parameter `disablerep` may deteriorate the performance. The following is an example:

```
gaussdb=# create table t_rep(a int) distribute by replication;
CREATE TABLE
gaussdb=# create table t_dis(a int);
```

```
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# set rewrite_rule = '';
SET
gaussdb=# explain (costs off) select * from t_dis where a = any(select a from t_rep) or a > 100;
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Hash Left Join
    Hash Cond: (t_dis.a = subquery.a)
    Filter: ((subquery.a IS NOT NULL) OR (t_dis.a > 100))
-> Seq Scan on t_dis
-> Hash
    -> Subquery Scan on subquery
        Filter: (Hash By subquery.a)
-> HashAggregate
    Group By Key: t_rep.a
-> Seq Scan on t_rep

(12 rows)
```

For a replication table, the data stored on all DNs is the same. Therefore, you do not need to scan the replication table on all nodes.

```
gaussdb=# set rewrite_rule = disablerep;
SET
gaussdb=# explain (costs off) select * from t_dis where a = any(select a from t_rep) or a > 100;
          QUERY PLAN
-----
Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on t_dis
    Filter: ((hashed SubPlan 1) OR (a > 100))
    SubPlan 1
-> Seq Scan on t_rep

(6 rows)
```

## 6.12.9 Using DN Gather to Reduce Stream Nodes in the Plan

The DN Gather is used to remove the stream nodes from the distribution plan and send data to a node for calculation. This reduces the cost of data redistribution during the execution of the distribution plan and improves the single query efficiency and the overall throughput capability of the system. However, DN Gather is oriented to small-data-volume scenarios of TP. For small-data-volume queries, performance can be improved because the cost of data redistribution is reduced and the computing power of a single node is sufficient. Multi-node parallel computing is more advantageous for large-data-volume computing. You need to enable and disable DN Gather to determine which one is faster. (The default value of **dngather\_min\_rows** is **500**. The following uses the default value.)

### Preparing the Case Environment

To facilitate case demonstration, you need to prepare the following table creation statements:

```
-- Clean the environment.
DROP SCHEMA IF EXISTS dn_gather_test CASCADE;
CREATE SCHEMA dn_gather_test;
SET current_schema=dn_gather_test;
-- Create a test table.
CREATE TABLE t1(a INT, b INT, c INT, d INT);
CREATE TABLE t2(a INT, b INT, c INT, d INT);
CREATE TABLE t3(a INT, b INT, c INT, d INT);
CREATE TABLE t4(a INT, b INT, c INT, d INT);
```

## Gather Join

To converge the join results to a single DN, the following conditions must be met:

- The number of data rows estimated by the optimizer before and after join is less than the threshold.
- The subnodes of join are all stream nodes.

For example, the subnodes of join are all stream nodes, and broadcast is disabled.

```
gaussdb=# set enable_broadcast=false;
SET
gaussdb=# set explain_perf_mode=pretty;
SET
gaussdb=# set enable_dngather=false;
SET
gaussdb=# explain select count(*) from t1, t2 where t1.b = t2.b;

```

## Union/Union all

To converge union/union all results to a single DN, the following condition must be met:

- At least one subnode must meet the requirements in the preceding three cases (Gather Join, Gather Groupby/Agg, and Gather window function).

For example, the subnodes of join are all stream nodes, and broadcast is disabled.

```

gaussdb=# set explain_perf_mode=pretty;
SET
gaussdb=# set enable_broadcast=false;
SET
gaussdb=# set enable_dngather=false;
SET
gaussdb=# explain select t1.a, t2.b from t1, t2 where t1.b = t2.b union all select t3.a, t3.b from t3, t4 where t3.b = t4.b;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
1 | -> Streaming (type: GATHER) | 60 | 8 | 65.31

## 7.1 GaussDB SQL

### What Is SQL?

SQL is a standard computer language used to control the access to databases and manage data in databases.

SQL provides different statements to enable you to:

- Query data.
- Insert, update, and delete rows.
- Create, replace, modify, and delete objects.
- Control the access to a database and its objects.
- Maintain the consistency and integrity of a database.

SQL consists of commands and functions that are used to manage databases and database objects. SQL can also forcibly implement the rules for data types, expressions, and texts. Therefore, [SQL Reference](#) describes data types, expressions, functions, and operators in addition to SQL syntax.

### Development of SQL Standards

Released SQL standards are as follows:

- 1986: ANSI X3.135-1986, ISO/IEC 9075:1986, SQL-86
- 1989: ANSI X3.135-1989, ISO/IEC 9075:1989, SQL-89
- 1992: ANSI X3.135-1992, ISO/IEC 9075:1992, SQL-92 (SQL2)
- 1999: ISO/IEC 9075:1999, SQL:1999 (SQL3)
- 2003: ISO/IEC 9075:2003, SQL:2003 (SQL4)
- 2011: ISO/IEC 9075:200N, SQL:2011 (SQL5)

### SQL Standards Supported by GaussDB

By default, GaussDB supports most features of SQL5.

## 7.2 Keywords

SQL statements are classified into reserved keywords and non-reserved keywords. For details about common SQL keywords, see [Table 7-1](#). Standards require that reserved keywords not be used as other identifiers. Non-reserved keywords have special meanings only in a specific environment and can be used as identifiers in other environments.

---

### NOTICE

1. Currently, the non-reserved keywords have the following restrictions when being used as the identifier of a database object:
    1. It cannot be directly used as a column alias. That is, usage similar to `SELECT 1 ABORT` may cause errors.
    2. Keywords `ENTITYESCAPING`, `NOENTITYESCAPING`, and `WELLFORMED` cannot be used as identifiers of table names, column names, table aliases, column aliases, and function names if they are not enclosed in double quotation marks.
    3. The `RAW` keyword without double quotation marks cannot be used as the identifier of a table name or function name.
    4. The `SET` keyword without double quotation marks cannot be used as an identifier of a table alias. That is, usage similar to `SELECT * FROM T1 SET` may cause errors.
    5. Keywords such as `BEGIN`, `BY`, `CLOSE`, `CURSOR`, `DECLARE`, `DELETE`, `EXECUTE`, `FUNCTION`, `IF`, `IMMEDIATE`, `INSERT`, `LOOP`, `MOVE`, `OF`, `REF`, `RELEASE`, `RETURN`, `SAVEPOINT`, `STRICT`, `TYPE`, and `UPDATE` without double quotation marks cannot be used as variable names.
    6. When the `SYS_REFCURSOR` keyword is used as the identifier of a database object, if double quotation marks are not attached, a database object named **REFCURSOR** is created. If double quotation marks are attached, a database object named **SYS\_REFCURSOR** is created.
  2. Similar to the non-reserved keywords, the non-reserved (cannot be a function or type) keywords cannot be directly used as column aliases, either.
  3. The reserved keyword `CURRENT_TIMESTAMP` with double quotation marks cannot be used as a function name.
- 

### Identifier Naming Conventions

Identifier naming must comply with the following rules:

- An identifier name can only contain letters, digits, underscores (`_`), and dollar signs (`$`).
- An identifier name must start with a letter or an underscore (`_`).

 NOTE

- The naming rules are recommended but not required.
- In special cases, double quotation marks (") can be used to avoid special character errors.

## SQL Keywords

**Table 7-1** SQL keywords

Keyword	GaussDB	SQL:1999	SQL-92

## 7.3 Data Types

A data type is a basic data attribute. Occupied storage space and allowed operations vary according to data types. Data is stored in tables in a database. Each column of a data table specifies a data type and data must be stored according to data types.

GaussDB supports implicit conversions between certain data types. For details, see [PG\\_CAST](#).

### 7.3.1 Numeric Types

[Table 7-2](#) lists all available types. For arithmetic operators and related built-in functions, see [Arithmetic Functions and Operators](#).

**Table 7-2** Integer types

Name	Description	Storage Space	Range
TINYINT [UNSIGNED]	Tiny integer. The signed alias is INT1, and the unsigned alias is UINT1.	1 byte	<ul style="list-style-type: none"> <li>The signed value ranges from 0 to +255.</li> <li>The unsigned value ranges from 0 to +255.</li> <li>When <code>sql_compatibility</code> is set to 'MYSQL', <code>b_format_version</code> is set to '5.7', and <code>b_format_dev_version</code> is set to 's1', the signed value ranges from -128 to +127.</li> </ul>
SMALLINT [UNSIGNED]	Small integer. The signed alias is INT2, and the unsigned alias is UINT2.	2 bytes	<ul style="list-style-type: none"> <li>The signed value ranges from -32,768 to +32,767.</li> <li>The unsigned value ranges from 0 to +65,535.</li> </ul>
MEDIUMINT [UNSIGNED]	Medium-sized integer. The signed alias is INT4, and the unsigned alias is UINT4.	4 bytes	<ul style="list-style-type: none"> <li>The signed value ranges from -2147483648 to +2147483647.</li> <li>The unsigned value ranges from 0 to +4294967295.</li> </ul>

Name	Description	Storage Space	Range
INTEGER [UNSIGNED]	Common integer. The signed alias is INT4, and the unsigned alias is UINT4.	4 bytes	<ul style="list-style-type: none"> <li>The signed value ranges from -2147483648 to +2147483647.</li> <li>The unsigned value ranges from 0 to +4294967295.</li> </ul>
BINARY_INTEGER	Common integer. The signed alias is INTEGER.	4 bytes	-2,147,483,648 to +2,147,483,647.
BIGINT [UNSIGNED]	Large integer. The signed alias is INT8, and the unsigned alias is UINT8.	8 bytes	<ul style="list-style-type: none"> <li>The signed value ranges from -9,223,372,036,854,775,808 to +9,223,372,036,854,775,807.</li> <li>The unsigned value ranges from 0 to +18,446,744,073,709,551,615.</li> </ul>
INT16 [SIGNED]	A 16-byte integer cannot be used to create tables.	16 bytes	-170,141,183,460,469,231,731,687,303,715,884,105,728 to +170,141,183,460,469,231,731,687,303,715,884,105,727

 NOTE

- When **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', integers support the display width and **ZEROFILL** attributes.
- The display width does not limit the range of values that can be stored in a column, nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as SMALLINT(3) has the usual SMALLINT range of -32768 to 32767, and values outside the range permitted by three digits are displayed in full using more than three digits.
- When the display width is used in conjunction with the **ZEROFILL** attribute, zeros are padded in front of the numeric value to achieve the display width. For example, for a column declared as **INT(4) ZEROFILL**, a value of 5 is retrieved as 0005.
- If you specify **ZEROFILL** for a numeric column, the **UNSIGNED** attribute is automatically added.
- If **ZEROFILL** is not specified for a numeric column and only the width information is specified, the width information is not displayed in the table structure description.

Example:

```
-- Create a database.
gaussdb=# CREATE DATABASE b_database dbcompatibility = 'MYSQL';
gaussdb=# \c b_database
-- Create a table containing TINYINT data.
b_database=# CREATE TABLE int_type_t1
(
  IT_COL1 TINYINT,
```

```
        IT_COL2 TINYINT UNSIGNED
    );

-- Insert data.
b_database=# INSERT INTO int_type_t1 VALUES(10,20);

-- View data.
b_database=# SELECT * FROM int_type_t1;
it_col1 | it_col2
-----+-----
    10 |     20
(1 row)

-- Drop the table.
b_database=# DROP TABLE int_type_t1;
-- Create a table containing TINYINT, INTEGER, and BIGINT data.
b_database=# CREATE TABLE int_type_t2
(
  a TINYINT,
  b TINYINT,
  c INTEGER,
  d INTEGER UNSIGNED,
  e BIGINT,
  f BIGINT UNSIGNED
);

-- Insert data.
b_database=# INSERT INTO int_type_t2 VALUES(100, 10, 1000, 10000, 200, 2000);

-- View data.
b_database=# SELECT * FROM int_type_t2;
 a | b | c | d | e | f
-----+-----+-----+-----+-----+-----
100 | 10 | 1000 | 10000 | 200 | 2000

-- Drop the table.
b_database=# DROP TABLE int_type_t2;

-- Delete the database.
b_database=# \c postgres
gaussdb=# DROP DATABASE b_database;
```

 NOTE

- Numbers of the TINYINT, SMALLINT, INTEGER, BIGINT, or INT16 type, that is, integers can be stored. Saving a number with a decimal in any of the data types will result in errors.
- If **UNSIGNED** is specified, negative values are not allowed.
- The INTEGER type is the common choice, as it offers the best balance between range, storage size, and performance. Generally, use the SMALLINT type only if you are sure that the value range is within the SMALLINT value range. The storage speed of INTEGER is much faster. BIGINT is used only when the range of INTEGER is not large enough.
- The unsigned numeric type can be used only in the row storage engine when **sql\_compatibility** is set to 'MYSQL'.
- When a minus sign, plus sign, or multiplication sign is used between integer values (one of which is of the UNSIGNED type), the result is unsigned.
- The return value of the addition (+), subtraction (-), and multiplication (x) operations of the INT1, UINT1, UINT2, UINT4, or UINT8 type can exceed the range of the corresponding type. The return value of the addition (+), subtraction (-), and multiplication (x) operations of the INT2, INT4, or INT8 type cannot exceed the range of the corresponding type.
- The UNSIGNED type cannot be converted to the SET type. Do not calculate or compare the UNSIGNED type with the SET type.
- When **sql\_compatibility** is set to 'MYSQL', non-numeric characters are automatically truncated or the value **0** is returned.

**Table 7-3** Arbitrary precision types

Name	Description	Storage Space	Range
NUMERIC[(p[,s])], DECIMAL[(p[,s])]	<ul style="list-style-type: none"> <li>The value range of <b>p</b> is [1,1000], and the value range of <b>s</b> is [0,p].</li> <li>When <b>sql_compatibility</b> is set to 'MYSQL', <b>b_format_version</b> is set to '5.7', and <b>b_format_dev_version</b> is set to 's1', if the precision and scale are not specified, the default precision <b>p</b> is <b>10</b> and the scale <b>s</b> is <b>0</b>. If a numeric type is not attached with parentheses, it is set to numeric (10,0) only when being applied to table columns. In other scenarios, the numeric type is used based on the original range by default.</li> </ul> <p><b>NOTE</b>  <b>p</b> indicates the total digits, and <b>s</b> indicates the decimal digit.</p>	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified.

Name	Description	Storage Space	Range
NUMBER[(p[,s])]	Alias of the NUMERIC type.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified.

**Example:**

```
-- Create a table.
gaussdb=# CREATE TABLE decimal_type_t1
(
  DT_COL1 DECIMAL(10,4)
);

-- Insert data.
gaussdb=# INSERT INTO decimal_type_t1 VALUES(123456.122331);

-- Query data in the table.
gaussdb=# SELECT * FROM decimal_type_t1;
 dt_col1
-----
123456.1223
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE decimal_type_t1;
-- Create a table.
gaussdb=# CREATE TABLE numeric_type_t1
(
  NT_COL1 NUMERIC(10,4)
);

-- Insert data.
gaussdb=# INSERT INTO numeric_type_t1 VALUES(123456.12354);

-- Query data in the table.
gaussdb=# SELECT * FROM numeric_type_t1;
 nt_col1
-----
123456.1235
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE numeric_type_t1;
```

 NOTE

- Compared to the integer types, the arbitrary precision numbers require larger storage space and have lower storage efficiency, operation efficiency, and poorer compression ratio results. The INTEGER type is the common choice when number types are defined. Arbitrary precision numbers are used when numbers exceed the maximum range indicated by the integers.
- When NUMERIC/DECIMAL is used for defining a column, you are advised to specify the precision (p) and scale (s) for the column.
- When **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', the input and output range specifications of the NUMERIC[(p[,s])] and DECIMAL[(p[,s])] types are different.
  - Input format: The value can be a number or a numeric string.
    - If the value of **sql\_mode** contains **strict\_trans\_tables**, an error is reported if the input value is invalid or exceeds the range.
    - If the value of **sql\_mode** does not contain **strict\_trans\_tables** and the input value is invalid or exceeds the range, a warning message is reported and **0** or the truncated value is returned.
  - Output format: The output format of the DECIMAL[(p[,s])] type is different from that of the NUMERIC[(p[,s])] type when the precision and scale are not specified. If NUMERIC has no precision or scale, the decimal part is retained during type conversion. For details, see the output format in the scenario where no parameter is set. If DECIMAL has no precision or scale, the precision is **10** and the scale is **0** during type conversion.

**Table 7-4** Sequence integer

Name	Description	Storage Space	Range
SMALLSERIAL	Two-byte serial integer	2 bytes.	-32,768 to +32,767.
SERIAL	Four-byte serial integer	4 bytes.	-2,147,483,648 to +2,147,483,647.
BIGSERIAL	Eight-byte serial integer	8 bytes.	-9,223,372,036,854,775,808 to +9,223,372,036,854,775,807.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE smallserial_type_tab(a SMALLSERIAL);

-- Insert data.
gaussdb=# INSERT INTO smallserial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO smallserial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM smallserial_type_tab;
 a
---
 1
 2
```

```
(2 rows)

-- Create a table.
gaussdb=# CREATE TABLE serial_type_tab(b SERIAL);

-- Insert data.
gaussdb=# INSERT INTO serial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO serial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM serial_type_tab;
 b
---
 1
 2
(2 rows)

-- Create a table.
gaussdb=# CREATE TABLE bigserial_type_tab(c BIGSERIAL);

-- Insert data.
gaussdb=# INSERT INTO bigserial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO bigserial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM bigserial_type_tab;
 c
---
 1
 2
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE smallserial_type_tab;

gaussdb=# DROP TABLE serial_type_tab;

gaussdb=# DROP TABLE bigserial_type_tab;
```

#### NOTE

SMALLSERIAL, SERIAL, and BIGSERIAL are not real types. They are concepts used for setting a unique identifier for a table. Therefore, an integer column is created and its default value is set to be read from a sequencer. A NOT NULL constraint is used to ensure NULL is not inserted. In most cases, you may also want to attach a UNIQUE or PRIMARY KEY constraint to prevent duplicate values from being inserted unexpectedly. Finally, the sequencer belongs to the column. When the column or table is deleted, the sequencer is deleted at the same time. Currently, the **SERIAL** column can be specified only when you create a table. You cannot add the **SERIAL** column in an existing table. In addition, **SERIAL** columns cannot be created in temporary tables because **SERIAL** is not a real type. Therefore, column types in temporary tables cannot be converted to **SERIAL**.

**Table 7-5** shows the floating point type.

#### NOTE

- The REAL(p,s), DOUBLE, DOUBLE(p,s), and FLOAT(p,s) floating-point types can be used only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'. For the behavior of the REAL, FLOAT, and DEC[[p[,s]]] data types when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', see **Table 7-5**.
- In **Table 7-5**, **p** is the precision, indicating the minimum acceptable total number of integral places, and **s** indicates the decimal digit.

**Table 7-5** Floating point types

Name	Description	Storage Space	Range
REAL, FLOAT4	Single precision floating points, inexact  The REAL data type is mapped to the double-precision floating-point number FLOAT8 when the scenario described in <b>Description</b> is met. For details about the application scenario, see FLOAT8.	4 bytes.	-3.402E+38 to +3.402E+38, 6-bit decimal digits.
REAL(p,s)	The value range of <b>p</b> is [1,1000], and the value range of <b>s</b> is [0, <i>p</i> ].  If the precision and scale are not specified, the precision <b>p</b> is <b>10</b> and the scale <b>s</b> is <b>0</b> by default.  This type maps to NUMERIC. For details about the application scenario, see NUMERIC.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.
DOUBLE PRECISION , FLOAT8	Double precision floating points, inexact	8 bytes.	-1.79E+308 to +1.79E+308, 15-bit decimal digits.

Name	Description	Storage Space	Range
DOUBLE	<p>Double precision floating points, inexact</p> <p>This type maps to double-precision floating-point number FLOAT8. For details about the application scenario, see FLOAT8.</p>	8 bytes.	-1.79E+308 to +1.79E+308, 15-bit decimal digits.
DOUBLE(p, s)	<p>The value range of <b>p</b> is [1,1000], and the value range of <b>s</b> is [0,<i>p</i>].</p> <p>If the precision and scale are not specified, the precision <b>p</b> is <b>10</b> and the scale <b>s</b> is <b>0</b> by default.</p> <p>This type maps to NUMERIC. For details about the application scenario, see NUMERIC.</p>	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.

Name	Description	Storage Space	Range
FLOAT[(p)]	<p>Floating points, inexact. The value range of precision (p) is [1,53].</p> <p>The type is selected based on the precision <b>p</b>. When <b>p</b> is less than or equal to 24, the mapping type is REAL. When <b>p</b> is greater than 24 or not specified, the mapping type is DOUBLE PRECISION.</p> <p>In the scenario described in <b>NOTE</b>, if the precision <b>p</b> is less than or equal to 24, or it is not specified, the mapping type is FLOAT4. If <b>p</b> is greater than 24, the mapping type is DOUBLE PRECISION.</p>	4 bytes or 8 bytes.	N/A
FLOAT(p,s)	<p>The value range of <b>p</b> is [1,1000], and the value range of <b>s</b> is [0,p].</p> <p>If the precision and scale are not specified, the precision <b>p</b> is <b>10</b> and the scale <b>s</b> is <b>0</b> by default.</p> <p>This type maps to NUMERIC. For details about the application scenario, see NUMERIC.</p>	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.

Name	Description	Storage Space	Range
BINARY_DOUBLE	DOUBLE PRECISION alias, compatible with Oracle.	8 bytes.	-1.79E+308 to +1.79E+308, 15-bit decimal digits.
DEC[(p[,s])]	<p>The value range of <b>p</b> is [1,1000], and the value range of <b>s</b> is [0,<i>p</i>].</p> <p>If the scenario in <b>Note</b> is met and the precision and scale are not specified, the precision <b>p</b> is <b>10</b> and the scale <b>s</b> is <b>0</b> by default.</p> <p>This type maps to NUMERIC. For details about the application scenario, see NUMERIC.</p>	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.
INTEGER[(p[,s])]	<p>The value range of <b>p</b> is [1,1000], and the value range of <b>s</b> is [0,<i>p</i>].</p> <p>If the precision and scale are not specified, the precision <b>p</b> is <b>10</b> and the scale <b>s</b> is <b>0</b> by default.</p> <p>If the precision and scale are not specified, this type is mapped to INTEGER. If the precision and scale are specified, this type is mapped to NUMERIC.</p>	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	<p>Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.</p> <p>If the precision and scale are not specified, the value ranges from -2,147,483,648 to +2,147,483,647.</p>

 NOTE

For the precision of the floating-point type, only the number of precision bits can be ensured when the data is directly read. When distributed computing is involved, the computation is executed on each DN and is finally aggregated to a CN. Therefore, the error may be amplified as the number of compute nodes increases.

When **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', the input and output ranges of the FLOAT[(p[,s])], DOUBLE[(p[,s])], DEC[(p[,s])] and REAL[(p[,s])] types are different.

- Input format: The value can be a number or a numeric string.
  - If the value of **sql\_mode** contains **strict\_trans\_tables**, an error is reported if the input value is invalid or exceeds the range.
  - If the value of **sql\_mode** does not contain **strict\_trans\_tables** and the input value is invalid or exceeds the range, a warning message is reported and **0** or the truncated value is returned.
- Output format: The output format of the DEC[(p[,s])] type is different from that of the mapping NUMERIC[(p[,s])] type when the precision and scale are not specified. If NUMERIC has no precision or scale, the decimal part is retained during type conversion. For details, see the output format in the scenario where no parameter is set. If DEC has no precision or scale, the precision is **10** and the scale is **0** during type conversion.

## Example:

```
-- Create a table.
gaussdb=# CREATE TABLE float_type_t2
(
  FT_COL1 INTEGER,
  FT_COL2 FLOAT4,
  FT_COL3 FLOAT8,
  FT_COL4 FLOAT(3),
  FT_COL5 BINARY_DOUBLE,
  FT_COL6 DECIMAL(10,4),
  FT_COL7 INTEGER(6,3)
)DISTRIBUTE BY HASH ( ft_col1);

-- Insert data.
gaussdb=# INSERT INTO float_type_t2 VALUES(10,10.365456,123456.1234,10.3214, 321.321, 123.123654,
123.123654);

-- View data.
gaussdb=# SELECT * FROM float_type_t2 ;
 ft_col1 | ft_col2 | ft_col3 | ft_col4 | ft_col5 | ft_col6 | ft_col7
-----+-----+-----+-----+-----+-----+-----
      10 | 10.3655 | 123456.1234 | 10.3214 | 321.321 | 123.1237 | 123.124
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE float_type_t2;

-- Example: REAL(p,s), FLOAT(p,s), DOUBLE, and DOUBLE(p,s).
gaussdb=# CREATE DATABASE gaussdb_m WITH dbcompatibility 'MYSQL';
gaussdb=# \c gaussdb_m
-- Set compatible version control parameters.
gaussdb_m=# SET b_format_version='5.7';
gaussdb_m=# SET b_format_dev_version='s1';
-- Create a table.
gaussdb_m=# CREATE TABLE t1(a real(10,2), b float(10,2), c double, d double(10,2));
-- Insert data.
gaussdb_m=# INSERT INTO t1 VALUES (1000.12, 2000.23, 3000.34, 4000.45);
-- Query data in the table.
gaussdb_m=# SELECT * FROM t1;
  a | b | c | d
-----+-----+-----+-----
1000.12 | 2000.23 | 3000.34 | 4000.45
```

```
(1 row)
-- Delete the table and database.
gaussdb=# DROP TABLE t1;
gaussdb=# \c postgres;
gaussdb=# DROP DATABASE gaussdb_m;

-- Reset parameters.
gaussdb=# RESET ALL;
```

## 7.3.2 Monetary Types

The monetary type stores a currency amount with fixed fractional precision.

The range shown in [Table 7-6](#) assumes there are two fractional digits. Input is accepted in a variety of formats, including integer and floating-point literals, as well as typical currency formatting, such as "\$1,000.00". Output is generally in the last format but depends on the locale.

**Table 7-6** Monetary type

Name	Description	Storage Space	Range
money	Currency amount	8 bytes	-92233720368547758.08 ~ +92233720368547758.07

Values of the numeric, int, and bigint data types can be cast to money. Conversion from the real or double precision data type to a money value can be done by casting to numeric type first, for example:

```
gaussdb=# SELECT '12.34'::float8::numeric::money;
money
-----
$12.34
(1 row)
```

However, this is not recommended. Floating point numbers should not be used to handle money due to the potential for rounding errors.

A money value can be cast to numeric without loss of precision. Conversion to other types could potentially lose precision, and must also be done in two stages:

```
gaussdb=# SELECT '52093.89'::money::numeric::float8;
float8
-----
52093.89
(1 row)
```

When a money value is divided by another money value, the result is of the double precision type (that is, the digit type instead of the money type); the currency units cancel each other out in the division.

## 7.3.3 Boolean Types

[Table 7-7](#) lists the Boolean types supported by GaussDB.

**Table 7-7** Boolean Types

Name	Description	Storage Space	Value
BOOLEAN	Boolean Types	1 byte	<ul style="list-style-type: none"> <li>• <b>true</b></li> <li>• <b>false</b></li> <li>• <b>null</b>: unknown</li> </ul>

- Valid literal values for the "true" state are:  
**TRUE**, **t**, **true**, **y**, **yes**, **1**, **TRUE**, **true**, **on**, and all non-zero values.
- Valid literal values for the "false" state include:  
**FALSE**, **f**, **false**, **n**, **no**, **0**, **0**, **FALSE**, **false**, and **off**.

**TRUE** and **FALSE** are standard expressions, compatible with SQL statements.

## Examples

Boolean values are displayed using the letters t and f.

```
-- Create a table.
gaussdb=# CREATE TABLE bool_type_t1
(
  BT_COL1 BOOLEAN,
  BT_COL2 TEXT
)DISTRIBUTE BY HASH(BT_COL2);

-- Insert data.
gaussdb=# INSERT INTO bool_type_t1 VALUES (TRUE, 'sic est');

gaussdb=# INSERT INTO bool_type_t1 VALUES (FALSE, 'non est');

-- View data.
gaussdb=# SELECT * FROM bool_type_t1;
bt_col1 | bt_col2
-----+-----
t       | sic est
f       | non est
(2 rows)

gaussdb=# SELECT * FROM bool_type_t1 WHERE bt_col1 = 't';
bt_col1 | bt_col2
-----+-----
t       | sic est
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE bool_type_t1;
```

## 7.3.4 Character Types

**Table 7-8** lists the character types supported by GaussDB. For string operators and related built-in functions, see [Character Processing Functions and Operators](#).

**Table 7-8** Character types

Name	Description	Storage Space
CHAR(n) CHARACTER(n) NCHAR(n)	Fixed-length character string, blank padded. <b>n</b> indicates the string length. If it is not specified, the default precision <b>1</b> is used.	The maximum value of <b>n</b> is <b>10485760</b> (10 MB).
	<p>When <b>sql_compatibility</b> is set to 'MYSQL', if <b>b_format_version</b> is set to '5.7' and <b>b_format_dev_version</b> is set to 's1':</p> <ul style="list-style-type: none"> <li>• Type: <b>n</b> indicates the character length. The value range is [0,10485760]. If the precision <b>n</b> is not specified, the default precision <b>1</b> is used. Fixed-length character string, blank padded.</li> <li>• Input <ul style="list-style-type: none"> <li>- Data type of table columns and temporary variables: If the number of characters in an input string is within the range, the string can be entered normally. If the value of <b>sql_mode</b> contains <b>strict_trans_tables</b>, an error is reported. Otherwise, the string is truncated based on the maximum string length specified by <b>n</b> and an alarm is generated.</li> </ul> </li> <li>• Output <ul style="list-style-type: none"> <li>- Data type of table columns and temporary variables: If the value of <b>sql_mode</b> contains <b>pad_char_to_full_length</b>, the character string containing spaces at the end is output. Otherwise, the character string without spaces at the end is output.</li> <li>- Function parameter and return value or stored procedure parameter: The length cannot be verified. For example, if the input parameter of a user-defined function is of the CHAR(5) type and a string '123456' is input, the parameter can be directly transferred without length verification.</li> </ul> </li> </ul>	The value contains a maximum of 10M characters.

Name	Description	Storage Space
VARCHAR(n) CHARACTER VARYING(n)	Variable-length string. In PG-compatible mode, <b>n</b> indicates the string length. In other compatibility modes, <b>n</b> indicates the byte length.	The maximum value of <b>n</b> is <b>10485760</b> (10 MB).  If <b>n</b> is not specified, the maximum storage length is 1 GB – 85 – Length of the first <i>n</i> columns. For example, the maximum length of (a int, b varchar) is 1,073,741,735 (= 1 GB – 85 – 4).
	When <b>sql_compatibility</b> is set to 'MYSQL', if <b>b_format_version</b> is set to '5.7' and <b>b_format_dev_version</b> is set to 's1': <ul style="list-style-type: none"> <li>• <b>n</b> indicates the string length. The value range is [0,10485760]. If the precision <b>n</b> is not specified, there is no length limit by default. The length is the same as that of the TEXT type.</li> <li>• Input               <ul style="list-style-type: none"> <li>– Data type of table columns and temporary variables: If the number of characters in an input string is within the range, the string can be entered normally. If the value of <b>sql_mode</b> contains <b>strict_trans_tables</b>, an error is reported. Otherwise, the string is truncated based on the maximum string length specified by <b>n</b> and an alarm is generated.</li> </ul> </li> <li>• Output: The original character string is output.</li> </ul>	If <b>n</b> is specified, the maximum storage length is 10 MB. If <b>n</b> is not specified, the maximum storage length is 1 GB – 85 – Length of the first <i>n</i> columns. For example, the maximum storage length of (a int, b varchar) is 1,073,741,735 (= 1 GB – 85 – 4).

Name	Description	Storage Space
VARCHAR2(n)	Variable-length string. It is the alias of the VARCHAR(n) type.	<p>The maximum value of <b>n</b> is <b>10485760</b> (10 MB).</p> <p>If <b>n</b> is not specified, the maximum storage length is 1 GB – 85 – Length of the first <i>n</i> columns. For example, the maximum length of (a int, b varchar) is 1,073,741,735 (= 1 GB – 85 – 4).</p>
NVARCHAR2(n)	Variable-length string. In the SQL_ASCII character set, <b>n</b> indicates bytes. In the non-SQL_ASCII character set, <b>n</b> indicates characters.	<p>The maximum value of <b>n</b> is <b>10485760</b> (10 MB).</p> <p>If <b>n</b> is not specified, the maximum storage length is 1 GB – 85 – Length of the first <i>n</i> columns. For example, the maximum length of (a int, b varchar) is 1,073,741,735 (= 1 GB – 85 – 4).</p>

Name	Description	Storage Space
TEXT	Variable-length string.	<p>The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the TEXT type may be less than 1 GB minus 1 byte.</p>
CLOB	Big text object.	<p>For Ustore, the maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the CLOB type may be less than 1 GB minus 1 byte.</p>

Name	Description	Storage Space
TINYTEXT MEDIUMTEXT LONGTEXT	When <b>sql_compatibility</b> is set to 'MYSQL', if <b>b_format_version</b> is set to '5.7' and <b>b_format_dev_version</b> is set to 's1', these types can be used.  Converts a data type to the TEXT type. The application scenario is the same as that of the TEXT type.	The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the TEXT type may be less than 1 GB minus 1 byte.

 NOTE

1. In addition to the restriction on the size of each column, the total size of each tuple cannot exceed 1 GB minus 1 byte and is affected by the control header information of the column, the control header information of the tuple, and whether null fields exist in the tuple.
2. NCHAR is the alias of the bpchar type, and VARCHAR2(n) is the alias of the VARCHAR(n) type.
3. Only advanced package db\_lob supports CLOBs whose size is greater than 1 GB. System functions do not support CLOBs whose size is greater than 1 GB.
4. In A-compatible mode, the received empty string is converted to null by default.

**Table 7-9** lists the two other fixed-length character types supported by GaussDB. The name type exists only for the storage of identifiers in the internal system catalogs and is not intended for use by general users. Its length is currently defined as 64 bytes (63 usable characters plus terminator). The char type uses only one byte of storage. It is internally used in the system catalogs as a simplistic enumeration type.

**Table 7-9** Special character types

Name	Description	Storage Space
name	Internal type for object names	64 bytes
"char"	Single-byte internal type	1 byte

## 7.3.5 Binary Types

**Table 7-10** lists the binary types supported by GaussDB.

**Table 7-10** Binary types

Name	Description	Storage Space
BLOB	<p>Binary large object (BLOB). Currently, BLOB only supports the following external access APIs:</p> <ul style="list-style-type: none"> <li>• DBE_LOB.GET_LENGTH</li> <li>• DBE_LOB.READ</li> <li>• DBE_LOB.WRITE</li> <li>• DBE_LOB.WRITE_APPEND</li> <li>• DBE_LOB.COPY</li> <li>• DBE_LOB.ERASE</li> </ul> <p>For details about the APIs, see <a href="#">DBE_LOB</a>.</p>	<p>For Ustore, the maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the BLOB type may be less than 1 GB minus 1 byte.</p>
	<p>When <b>sql_compatibility</b> is set to 'MYSQL', if <b>b_format_version</b> is set to '5.7' and <b>b_format_dev_version</b> is set to 's1', the BLOB type is mapped to the BYTEA type, and the alias is BYTEA.</p>	<p>For details about the storage specifications, see the BYTEA type.</p>
TINYBLOB MEDIUMBLOB LONGBLOB	<p>Binary large object (BLOB). This type can be used only when <b>sql_compatibility</b> is set to 'MYSQL', <b>b_format_version</b> is set to '5.7', and <b>b_format_dev_version</b> is set to 's1'. The type is mapped to the BYTEA type, and the alias is BYTEA.</p>	<p>For details about the storage specifications, see the BYTEA type.</p>

Name	Description	Storage Space
RAW	Variable-length hexadecimal string.	4 bytes plus the actual binary string. The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of this type may be less than 1 GB minus 1 byte.
BYTEA	Variable-length binary string.	4 bytes plus the actual binary string. The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of this type may be less than 1 GB minus 1 byte.
BYTEAWITHOUTORDERWITH EQUALCOL	Variable-length binary character string (new type for the encryption feature. If the encryption type of an encrypted column is specified as deterministic encryption, the column type is BYTEAWITHOUTORDERWITH EQUALCOL). The original data type is displayed when an encrypted table is printed by running the meta command.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).
BYTEAWITHOUTORDERCOL	Variable-length binary character string (new type for the encryption feature. If the encryption type of an encrypted column is specified as random encryption, the column type is BYTEAWITHOUTORDERCOL). The original data type is displayed when an encrypted table is printed by running the meta command.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).

Name	Description	Storage Space
_BYTEAWITHOUTORDERWITH EQUALCOL	Variable-length binary string, which is a new type for the encryption feature.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).
_BYTEAWITHOUTORDERCOL	Variable-length binary string, which is a new type for the encryption feature.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).

 NOTE

- In addition to the size limit of each column, the total size of each tuple cannot exceed 1 GB minus 1 byte.
- BYTEAWITHOUTORDERWITHEQUALCOL, BYTEAWITHOUTORDERCOL, \_BYTEAWITHOUTORDERWITHEQUALCOL, and \_BYTEAWITHOUTORDERCOL cannot be directly used to create a table.
- RAW(*n*), where *n* indicates the recommended byte length and is not used to verify the byte length of the input raw type.
- When **sql\_compatibility** is set to 'MYSQL', if **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1', the TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB types are displayed as BYTEA. For example, when the table structure is queried, the TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB types are displayed as BYTEA.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE blob_type_t1
(
  BT_COL1 INTEGER,
  BT_COL2 BLOB,
  BT_COL3 RAW,
  BT_COL4 BYTEA
) DISTRIBUTE BY REPLICATION;

-- Insert data.
gaussdb=# INSERT INTO blob_type_t1 VALUES(10,empty_blob(),
HEXTORAW('DEADBEEF'),E'\xDEADBEEF');

-- Query data in the table.
gaussdb=# SELECT * FROM blob_type_t1;
 bt_col1 | bt_col2 | bt_col3 | bt_col4
-----+-----+-----+-----
      10 |      | DEADBEEF | \xdeadbeef
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE blob_type_t1;

-- Example: TINYBLOB, MEDIUMBLOB, and LONGBLOB types
gaussdb=# CREATE DATABASE gaussdb_m WITH dbcompatibility 'MYSQL';
gaussdb=# \c gaussdb_m
-- Set compatible version control parameters.
gaussdb_m=# SET b_format_version='5.7';
gaussdb_m=# SET b_format_dev_version='s1';
-- Create a table.
gaussdb_m=# CREATE TABLE t1(num int, a tinyblob, b blob, m mediumblob, l longblob);
```

```
-- Insert data.
gaussdb_m=# INSERT INTO t1 VALUES (1, 'tinyblobtest', 'blobtest', 'mediumblobtest', 'longblobtest');
-- Query data in the table.
gaussdb_m=# SELECT * FROM t1;
 num | a      | b      | m      | l
-----+-----+-----+-----+-----
  1 | tinyblobtest | blobtest | mediumblobtest | longblobtest
(1 row)

-- Delete the table and database.
gaussdb_m=# DROP TABLE t1;
gaussdb_m=# \c postgres;
gaussdb=# DROP DATABASE gaussdb_m;
-- Reset parameters.
gaussdb=# RESET ALL;
```

## 7.3.6 Date/Time Types

**Table 7-11** lists the date/time types that can be used in GaussDB. For the operators and built-in functions of the types, see [Date and Time Processing Functions and Operators](#).

### NOTE

If the time format of another database is different from that of GaussDB, modify the value of the **DateStyle** parameter to keep them consistent.

**Table 7-11** Date/Time types

Name	Description	Storage Space
DATE	<p>Date and time.</p> <p>Minimum value: <b>4713-01-01BC</b> (4713 B.C.). Maximum value: <b>5874897-12-31AD</b> (5874897 A.C.)</p> <p>After <b>sql_compatibility</b> is set to <b>'MYSQL'</b>, <b>b_format_version</b> is set to <b>'5.7'</b>, and <b>b_format_dev_version</b> is set to <b>'s1'</b>, the input and output formats and ranges are different.</p> <ul style="list-style-type: none"> <li>● Input format: YYYY-MM-DD with separators and YYYYMMDD without separators are supported. <ul style="list-style-type: none"> <li>– In the scenario where separators are used, the plus sign (+) and colon (:) cannot be used as separators between the year, month, and day of a date. (Some separators are not supported when they are used together. The specifications inherit the existing implementation. Example: <b>date'2020-12?12'</b>.) The input format is not affected by the <b>DateStyle</b> parameter.</li> <li>– In the scenario where separators are not used, the output result may be incorrect though no error is reported.</li> </ul> </li> <li>● Output format: Only YYYY-MM-DD is supported and the format is not affected by the <b>DateStyle</b> parameter.</li> <li>● Value range: 4713-01-01 BC to 5874897-12-31 AD. <ul style="list-style-type: none"> <li>– If the value of <b>sql_mode</b> contains <b>strict_trans_tables</b>, an error is reported if the value is invalid or exceeds the range.</li> <li>– If the value of <b>sql_mode</b> does not contain</li> </ul> </li> </ul>	4 bytes (8 bytes in ORA-compatible mode)

Name	Description	Storage Space
	<p><b>strict_trans_tables</b>, the values of year, month, and day can be 0. However, the values will be converted to valid values in the sequence of year, month, and day. For example, '0000-00-10' will be converted to 0002-12-10 BC. If the input is invalid or exceeds the range, a warning message is reported and the value <b>0000-00-00 00:00:00</b> is returned.</p> <p><b>NOTE</b>            For ORA compatibility, the database treats empty strings as <b>NULL</b> and replaces <b>DATE</b> with <b>TIMESTAMP(0) WITHOUT TIME ZONE</b>.</p>	

Name	Description	Storage Space
<p>TIME [(p)] [WITHOUT TIME ZONE]</p>	<p>Time within one day (without a time zone).</p> <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <p>Minimum value: <b>00:00:00</b>. Maximum value: <b>24:00:00</b>.</p> <p>After <b>sql_compatibility</b> is set to <b>'MYSQL'</b>, <b>b_format_version</b> is set to <b>'5.7'</b>, and <b>b_format_dev_version</b> is set to <b>'s1'</b>, they are not limited to the time in a day. For example, they can indicate concepts such as duration and relative time, and the format, range, and precision are different.</p> <ul style="list-style-type: none"> <li>• Input format: [D] hh:mm:ss.ffffff with separators and hhmms.ffffff without separators are supported. <b>D</b> indicates the number of days. The value is an integer (negative numbers are supported). This parameter is optional. The value is converted into the number of hours on the basis of 24 hours in a day. The value is displayed after hh is added. Only colons (:) can be used as separators.</li> <li>• Output format: hh:mm:ss.ffffff. All zeros at the end of the decimal part are automatically ignored during display.</li> <li>• Value range: -838:59:59.000000 to 838:59:59.000000. <ul style="list-style-type: none"> <li>- If the value of <b>sql_mode</b> contains <b>strict_trans_tables</b>, <b>00:00:00</b> is returned for invalid input. If the value exceeds the range, an error is reported.</li> <li>- If the value of <b>sql_mode</b> does not contain <b>strict_trans_tables</b>, <b>00:00:00</b> is returned for invalid input. If the input is valid but</li> </ul> </li> </ul>	<p>8 bytes</p>

Name	Description	Storage Space
	<p>exceeds the range, the nearest boundary value is returned. For example, inputting 838:59:59.000001 returns 838:59:59, and inputting -838:59:59.000001 returns -838:59:59.</p> <ul style="list-style-type: none"> <li>• Precision: <b>p</b> indicates the precision after the decimal point. The value ranges from 0 to 6. If <b>p</b> is set to a value greater than 6, the value <b>6</b> is used. <ul style="list-style-type: none"> <li>- When it is used as the data type of a table column, the default precision is <b>0</b>.</li> <li>- When it is used as an expression (for example, time '10:10:10.123456'), the default precision is <b>6</b>.</li> </ul> </li> </ul>	
TIME [(p)] [WITH TIME ZONE]	<p>Time within one day (with a time zone).</p> <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <p>Minimum value: <b>00:00:00+15:59</b>. Maximum value: <b>24:00:00-15:59</b>.</p>	12 bytes

Name	Description	Storage Space
<p>TIMESTAMP[(p)] [WITHOUT TIME ZONE]</p>	<p>Date and time (without a time zone).</p> <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <p>Minimum value: <b>4713-11-24 BC 00:00:00.000000</b> (4713 B.C.). Maximum value: <b>294277-01-09 AD 00:00:00.000000</b> (294277 A.D.).</p> <p>After <b>sql_compatibility</b> is set to <b>'MYSQL'</b>, <b>b_format_version</b> is set to <b>'5.7'</b>, and <b>b_format_dev_version</b> is set to <b>'s1'</b>, they will be replaced with the <b>TIMESTAMP[(p)] [WITH TIME ZONE]</b> type. However, the format, range, and precision specifications are different.</p> <ul style="list-style-type: none"> <li>• Input format: YYYY-MM-DD hh:mm:ss.ffffff+timezone with separators and YYYYMMDDhhmmss.ffffff without separators are supported. <ul style="list-style-type: none"> <li>- If separators are used, the plus sign (+) and colon (:) cannot be used as separators between the year, month, and day. (Some separators are not supported when they are used together. The specifications inherit the existing implementation. For example, timestamp '2020-12?12 00:00:00'.) Only colons (:) can be used as separators in the time part. The input format is not affected by the <b>DateStyle</b> parameter.</li> <li>- In the scenario where separators are not used and the input is incomplete, the output result may be incorrect though no error is reported.</li> <li>- If the year has only two digits, 00–69 corresponds to</li> </ul> </li> </ul>	<p>8 bytes</p>

Name	Description	Storage Space
	<p>2000–2069, and 70–99 corresponds to 1970–1999.</p> <ul style="list-style-type: none"> <li>– If the year contains only one digit, for example, timestamp '1-1-1 00:00:00', the result is '0001-01-01 00:00:00'.</li> <li>• Output format: Only YYYY-MM-DD hh:mm:ss.ffffff is supported and the format is not affected by the <b>DateStyle</b> parameter. All zeros at the end of the decimal part of the time are automatically ignored.</li> <li>• Range <ul style="list-style-type: none"> <li>– If the value of <b>sql_mode</b> contains <b>strict_trans_tables</b>, the value range is the same as that of <b>TIMESTAMP[(p)] WITH TIME ZONE</b>. If the value is invalid or exceeds the range, an error is reported.</li> <li>– If the value of <b>sql_mode</b> does not contain <b>strict_trans_tables</b>, the values of year, month, and day can be 0. However, the values will be converted to valid values in the sequence of year, month, and day. For example, '0000-00-10 00:00:00' will be converted to 0002-12-10 00:00:00 BC. If the input is invalid or exceeds the range, a warning message is reported and the value <b>0000-00-00 00:00:00</b> is returned.</li> </ul> </li> <li>• Precision: <b>p</b> indicates the precision after the decimal point. The value ranges from 0 to 6. If <b>p</b> is set to a value greater than 6, the value <b>6</b> is used. <ul style="list-style-type: none"> <li>– When it is used as the data type of a table column, the default precision is <b>0</b>.</li> <li>– When it is used as an expression (for example,</li> </ul> </li> </ul>	

Name	Description	Storage Space
	<p>timestamp '2000-01-01 00:00:00.123456'), the default precision is <b>6</b>.</p> <ul style="list-style-type: none"><li>• Time zone: The value ranges from -15:59 to +15:59. You can also use the time zone name (see the system view <a href="#">PG_TIMEZONE_NAMES</a>). The time zone specifications are the same as those of the <code>TIMESTAMP[(p)] WITH TIME ZONE</code> type. Converts the time value of a specified time zone to the time of the UTC-0 time zone. When it is displayed, the time in the UTC-0 time zone is converted to the time in the current time zone of the server. You can run <b>SHOW TIME ZONE</b> to view the time zone of the server. Therefore, when you use the <code>SET TIME ZONE</code> statement to change the time zone of the server, the displayed result also changes.</li></ul>	

Name	Description	Storage Space
<p>TIMESTAMP[(p)] [WITH TIME ZONE]</p>	<p>Date and time (with time zone). TIMESTAMP is also called TIMESTAMPTZ.</p> <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <p>Minimum value: <b>4713-11-24 BC 00:00:00.000000</b> (4713 B.C.). Maximum value: <b>294277-01-09 AD 00:00:00.000000</b> (294277 A.D.).</p> <p>Time zone update: In some countries or regions, the time zone information is frequently updated due to political, economic, and war factors. Therefore, the database system needs to modify the time zone file to ensure that the time is correct.</p> <p>Currently, the GaussDB time zone type involves only timestamp with timezone. When a new time zone file takes effect, the existing data is not changed, and the new data is adjusted based on the time zone file information.</p>	<p>8 bytes</p>
<p>SMALLDATETIME</p>	<p>Date and time (without a time zone).</p> <p>The precision level is minute. 30s to 59s are rounded into one minute.</p> <p>Minimum value: <b>4713-11-24BC 00:00:00.000000</b> (4713 B.C.). Maximum value: <b>294277-01-09AD 00:00:00.000000</b> (294277 A.D.).</p>	<p>8 bytes</p>
<p>INTERVAL DAY (l) TO SECOND (p)</p>	<p>Specifies the time interval (<i>X</i> days <i>X</i> hours <i>X</i> minutes <i>X</i> seconds).</p> <ul style="list-style-type: none"> <li>• <b>l</b>: indicates the precision of days. The value ranges from 0 to 6. For compatibility, the precision functions are not supported.</li> <li>• <b>p</b>: indicates the precision of seconds. The value ranges from 0 to 6. The digit 0 at the end of a decimal number is not displayed.</li> </ul>	<p>16 bytes</p>

Name	Description	Storage Space
INTERVAL [FIELDS] [ (p) ]	Time interval. <ul style="list-style-type: none"> <li>• <b>FIELDS:</b> YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, DAY TO HOUR, DAY TO MINUTE, DAY TO SECOND, HOUR TO MINUTE, HOUR TO SECOND, or MINUTE TO SECOND.</li> <li>• <b>p:</b> indicates the precision of seconds. The value ranges from 0 to 6. <b>p</b> takes effect only when <b>FIELDS</b> is set to <b>SECOND</b>, <b>DAY TO SECOND</b>, <b>HOUR TO SECOND</b>, or <b>MINUTE TO SECOND</b>. The digit 0 at the end of a decimal number is not displayed.</li> </ul>	12 bytes
reltime	Relative time interval. <ul style="list-style-type: none"> <li>• The format is as follows: X years X mons X days XX:XX:XX.</li> <li>• The Julian calendar is used. It specifies that a year has 365.25 days and a month has 30 days. The relative time interval needs to be calculated based on the input value.</li> </ul>	4 bytes
abstime	Date and time. <ul style="list-style-type: none"> <li>• Format: YYYY-MM-DD hh:mm:ss +timezone.</li> <li>• The value range is from 1901-12-13 20:45:53 GMT to 2038-01-18 23:59:59 GMT. The precision is second.</li> </ul>	4 bytes

Name	Description	Storage Space
datetime[(p)]	<p>Date and time.</p> <p>This parameter takes effect only when <b>sql_compatibility</b> is set to <b>'MYSQL'</b>, <b>b_format_version</b> is set to <b>'5.7'</b>, and <b>b_format_dev_version</b> is set to <b>'s1'</b>. The datetime[(p)] type is replaced by the <b>TIMESTAMP[(p)] WITHOUT TIME ZONE</b> type, but the format, range, precision, and time zone processing specifications are different.</p> <ul style="list-style-type: none"> <li>• Input format: YYYY-MM-DD hh:mm:ss.ffffff+timezone with separators and YYYYMMDDhhmmss.ffffff without separators are supported. <ul style="list-style-type: none"> <li>- If separators are used, the plus sign (+) and colon (:) cannot be used as separators between the year, month, and day. (Some separators are not supported when they are used together. The specifications inherit the existing implementation. For example, <b>datetime '2020-12?12 00:00:00'</b>.) Only colons (:) can be used as separators in the time part. The input format is not affected by the <b>DateStyle</b> parameter.</li> <li>- In the scenario where separators are not used and the input is incomplete, the output result may be incorrect though no error is reported.</li> <li>- If the year has only two digits, 00–69 corresponds to 2000–2069, and 70–99 corresponds to 1970–1999.</li> <li>- If the year contains only one digit, for example, datetime '1-1-1 00:00:00', the result is '0001-01-01 00:00:00'.</li> </ul> </li> </ul>	8 bytes

Name	Description	Storage Space
	<ul style="list-style-type: none"> <li>● Output format: Only YYYY-MM-DD hh:mm:ss.ffffff is supported and the format is not affected by the <b>DateStyle</b> parameter. All zeros at the end of the decimal part of the time are automatically ignored.</li> <li>● Range                             <ul style="list-style-type: none"> <li>– If the value of <b>sql_mode</b> contains <b>strict_trans_tables</b>, the value range is the same as that of <code>TIMESTAMP[(p)] WITHOUT TIME ZONE</code>. If the value is invalid or exceeds the range, an error is reported.</li> <li>– If the value of <b>sql_mode</b> does not contain <b>strict_trans_tables</b>, the values of year, month, and day can be 0. However, the values will be converted to valid values in the sequence of year, month, and day. For example, '0000-00-10 00:00:00' will be converted to 0002-12-10 00:00:00 BC. If the input is invalid or exceeds the range, a warning message is reported and the value <b>0000-00-00 00:00:00</b> is returned.</li> </ul> </li> <li>● Precision: <b>p</b> indicates the precision after the decimal point. The value ranges from 0 to 6. If the specified precision exceeds 6, the value <b>6</b> is used.                             <ul style="list-style-type: none"> <li>– When it is used as the data type of a table column, the default precision is <b>0</b>.</li> <li>– When it is used as an expression (for example, <code>datetime '2000-01-01 00:00:00.123456'</code>), the default precision is <b>6</b>.</li> </ul> </li> <li>● Time zone: The value ranges from -15:59 to +15:59. You can also use the time zone name (see the system view</li> </ul>	

Name	Description	Storage Space
	<p><b>PG_TIMEZONE_NAMES</b>). The time zone specifications are the same as those of the <code>TIMESTAMP[(p)] WITH TIME ZONE</code> type. It converts the time value of a specified time zone to the time of the current time zone of the server. You can run <b>SHOW TIME ZONE</b> to view the time zone of the server. If the converted date and time are saved to the table, the time zone is not converted when the time zone of the server changes.</p>	

Name	Description	Storage Space
year[(w)]	<p>Year.</p> <p>It takes effect only after <b>sql_compatibility</b> is set to <b>'MYSQL'</b>.</p> <ul style="list-style-type: none"> <li>• Input formats: <ul style="list-style-type: none"> <li>– A string of four digits, ranging from '1901' to '2155' (that is, the years from 1901 to 2155).</li> <li>– Four digits, ranging from 1901 to 2155 (that is, the years from 1901 to 2155).</li> <li>– A string of one or two digits, ranging from '0' to '99'. The values '0' to '69' indicate the years from 2000 to 2069, and the values '70' to '99' indicate the years from 1970 to 1999. <b>'0'</b> and <b>'00'</b> indicate the year 2000.</li> <li>– One or two digits, ranging from <b>0</b> to <b>99</b>. The values <b>1</b> to <b>69</b> indicate the years from 2001 to 2069, and <b>70</b> to <b>99</b> indicate the years from 1970 to 1999. The value <b>0</b> indicates 0000.</li> <li>– Return values of other time functions, for example, now().</li> </ul> </li> <li>• Output format: Only the YYYY format is supported. <b>w</b> indicates the number of digits in the output format. Only four digits are supported. If not specified, the default value is 4.</li> <li>• Value range: <b>1901</b> to <b>2155</b>. <ul style="list-style-type: none"> <li>– If the value of <b>sql_mode</b> contains <b>strict_trans_tables</b>, an error is reported if the value is invalid or exceeds the range.</li> <li>– If the value of <b>sql_mode</b> does not contain <b>strict_trans_tables</b>, the invalid value is converted to</li> </ul> </li> </ul>	1 byte

Name	Description	Storage Space
	<b>0000</b> and inserted, and an alarm is generated.	

 **NOTE**

1. The data of the time type automatically ignores all zeros at the end of the data when it is displayed.
2. The default value of **p** is **6**.
3. For the INTERVAL type, the date and time are stored in the int32 and double types in the system. Therefore, the value ranges of the two types are the same as those of the corresponding data type.
4. If the insertion time is out of the range, the system may not report an error, but may not ensure that the operation is normal.

 **NOTE**

If the values of **a\_format\_version** and **a\_format\_dev\_version** are **10c** and **s1**, the default DATE value is determined by the following:

- Year: returned through SYSDATE
- Month: returned through SYSDATE
- Day: 01 (first day of the month)
- Hour, minute, and second: all 0

**Example:**

```
-- Create a table.
gaussdb=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
   coll
-----
2010-12-10
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE date_type_tab;

-- Create a table.
gaussdb=# CREATE TABLE time_type_tab (da time without time zone ,dai time with time zone,dfgh
timestamp without time zone,dfga timestamp with time zone, vbg smalldatetime);

-- Insert data.
gaussdb=# INSERT INTO time_type_tab VALUES ('21:21:21','21:21:21 pst','2010-12-12','2013-12-11
pst','2003-04-12 04:05:06');

-- View data.
gaussdb=# SELECT * FROM time_type_tab;
   da |   dai   | dfgh | dfga | vbg
-----+-----+-----+-----+-----

```

## Date Inputs

Date and time input is accepted in almost any reasonable formats, including ISO 8601 and SQL-compatible. The system allows you to customize the sequence of day, month, and year in the date input. Set the **DateStyle** parameter to **MDY** to select month-day-year interpretation, **DMY** to select day-month-year interpretation, or **YMD** to select year-month-day interpretation.

Remember that any date or time literal input needs to be enclosed with single quotation marks ('), and the syntax is as follows:

```
type [ ( p ) ] 'value'
```

The **p** that can be selected in the precision statement is an integer, indicating the number of fractional digits in the **seconds** column. [Table 7-12](#) shows the input formats of the date type.

**Table 7-12** Date input formats

Example	Description
1999-01-08	ISO 8601 (recommended format). January 8, 1999 in any format.
January 8, 1999	Unambiguous in any <b>datestyle</b> input mode
1/8/1999	January 8 in MDY format. August 1 in DMY format.
1/18/1999	January 18 in MDY format, rejected in other formats.
01/02/03	<ul style="list-style-type: none"> <li>January 2, 2003 in MDY format.</li> <li>February 1, 2003 in DMY format.</li> <li>February 3, 2001 in YMD format.</li> </ul>
1999-Jan-08	January 8 in any mode
Jan-08-1999	January 8 in any mode
08-Jan-1999	January 8 in any mode
99-Jan-08	January 8 in <b>YMD</b> mode, else error

Example	Description
08-Jan-99	January 8, except error in YMD format.
Jan-08-99	January 8, except error in YMD format.
19990108	ISO 8601. January 8, 1999 in any format.
990108	ISO 8601. January 8, 1999 in any format.
1999.008	Year and day of year.
J2451187	Julian date.
January 8, 99 BC	Year 99 B.C.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
      coll
-----
2010-12-10
(1 row)

-- View the date format.
gaussdb=# SHOW datestyle;
DateStyle
-----
ISO, MDY
(1 row)

-- Set the date format.
gaussdb=# SET datestyle='YMD';
SET

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES(date '2010-12-11');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
      coll
-----
2010-12-10
2010-12-11
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE date_type_tab;
```

## Time

The time-of-day types are **TIME [(p)] [WITHOUT TIME ZONE]** and **TIME [(p)] [WITH TIME ZONE]**. **TIME** alone is equivalent to **TIME WITHOUT TIME ZONE**.

If a time zone is specified in the input for **TIME WITHOUT TIME ZONE**, it is silently ignored.

For details about the time input types, see [Table 7-13](#). For details about time zone input types, see [Table 7-14](#).

**Table 7-13** Time input types

Example	Description
05:06.8	ISO 8601
4:05:06	ISO 8601
4:05	ISO 8601
040506	ISO 8601
4:05 AM	Same as 04:05. Input hours must be less than or equal to 12.
4:05 PM	Same as 16:05. Input hours must be less than or equal to 12.
04:05:06.789-8	ISO 8601
04:05:06-08:00	ISO 8601
04:05-08:00	ISO 8601
040506-08	ISO 8601
04:05:06 PST	Time zone specified by abbreviation
2003-04-12 04:05:06 America/ New_York	Time zone specified by full name

**Table 7-14** Time zone input types

Example	Description
PST	Abbreviation (for Pacific Standard Time)
America/New_York	Full time zone name
-8:00	ISO-8601 offset for PST
-800	ISO-8601 offset for PST
-8	ISO-8601 offset for PST

Example:

```
gaussdb=# SELECT time '04:05:06';
time
-----
04:05:06
(1 row)

gaussdb=# SELECT time '04:05:06 PST';
```

```

time
-----
04:05:06
(1 row)

gaussdb=# SELECT time with time zone '04:05:06 PST';
timetz
-----
04:05:06-08
(1 row)

```

## Special Values

The special values supported by GaussDB are converted to common date/time values when being read. For details, see [Table 7-15](#).

**Table 7-15** Special values

Input String	Applicable Type	Description
epoch	date and timestamp	1970-01-01 00:00:00+00 (Unix system time zero)
infinity	timestamp	Later than any other timestamps
-infinity	timestamp	Earlier than any other timestamps
now	date, time, and timestamp	Start time of the current transaction
today	date and timestamp	Midnight today
tomorrow	date and timestamp	Midnight tomorrow
yesterday	date and timestamp	Midnight yesterday
allballs	time	00:00:00.00 UTC

### Example:

```

-- Create a table.
gaussdb=# CREATE TABLE realtime_type_special(col1 varchar(20), col2 date, col3 timestamp, col4 time);

-- Insert data.
gaussdb=# INSERT INTO realtime_type_special VALUES('epoch', 'epoch', 'epoch', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('now', 'now', 'now', 'now');
gaussdb=# INSERT INTO realtime_type_special VALUES('today', 'today', 'today', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('tomorrow', 'tomorrow', 'tomorrow', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('yesterday', 'yesterday', 'yesterday', NULL);

-- View data.
gaussdb=# SELECT * FROM realtime_type_special;
 col1 | col2 | col3 | col4
-----+-----+-----+-----
epoch | 1970-01-01 00:00:00 | 1970-01-01 00:00:00 |
now | 2023-02-27 11:38:13 | 2023-02-27 11:38:13.032815 | 11:38:13.032815

(3 rows)

-- Drop the table.
gaussdb=# DROP TABLE realtime_type_special;

```

## Interval Input

The input of **reltime** can be any valid interval in text format. It can be a number (negative numbers and decimals are also allowed) or a specific time, which must be in SQL standard format or ISO-8601 format. In addition, the text input needs to be enclosed with single quotation marks (').

For details about interval input, see [Table 7-16](#).

**Table 7-16** Interval input types

Input	Output	Description
60	2 mons	Numbers are used to indicate intervals. The default unit is day. Decimals and negative numbers are allowed. Particularly, a negative interval syntactically means how long before.
31.25	1 mons 1 days 06:00:00	
-365	-12 mons -5 days	
1 years 1 mons 8 days 12:00:00	1 years 1 mons 8 days 12:00:00	Intervals are in POSTGRES format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input.
-13 months -10 hours	-1 years -25 days -04:00:00	
-2 YEARS +5 MONTHS 10 DAYS	-1 years -6 mons -25 days -06:00:00	
P-1.1Y10M	-3 mons -5 days -06:00:00	Intervals are in ISO-8601 format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input.
-12H	-12:00:00	

**Example:**

```
-- Create a table.
gaussdb=# CREATE TABLE reltime_type_tab(col1 character(30), col2 reltime);

-- Insert data.
gaussdb=# INSERT INTO reltime_type_tab VALUES ('90', '90');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('-366', '-366');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('1975.25', '1975.25');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('-2 YEARS +5 MONTHS 10 DAYS', '-2 YEARS +5 MONTHS 10 DAYS');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('30 DAYS 12:00:00', '30 DAYS 12:00:00');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('P-1.1Y10M', 'P-1.1Y10M');

-- View data.
gaussdb=# SELECT * FROM reltime_type_tab;
      col1      |      col2
-----+-----
90              | 3 mons
-366            | -1 years -18:00:00
1975.25         | 5 years 4 mons 29 days
-2 YEARS +5 MONTHS 10 DAYS | -1 years -6 mons -25 days -06:00:00
30 DAYS 12:00:00 | 1 mon 12:00:00
P-1.1Y10M      | -3 mons -5 days -06:00:00
(6 rows)

-- Drop the table.
gaussdb=# DROP TABLE reltime_type_tab;
```

## 7.3.7 Geometric Types

**Table 7-17** lists the geometric types that can be used in GaussDB. The most fundamental type, the point, forms the basis for all of the other types.

**Table 7-17** Geometric types

Name	Storage Space	Description	Representation
point	16 bytes	Point on a plane	(x,y)
lseg	32 bytes	Finite line segment	((x1,y1),(x2,y2))
box	32 bytes	Rectangle	((x1,y1),(x2,y2))
path	16 + 16 <i>n</i> bytes	Closed path (similar to polygon)	((x1,y1),...)
path	16 + 16 <i>n</i> bytes	Open path	[(x1,y1),...]
polygon	40 + 16 <i>n</i> bytes	Polygon (similar to closed paths)	((x1,y1),...)
circle	24 bytes	Circle	<(x,y),r> (center point and radius)

A rich set of functions and operators is available in GaussDB to perform various geometric operations, such as scaling, translation, rotation, and determining intersections. For details, see [Geometric Functions and Operators](#).

### Points

Points are the fundamental two-dimensional building block for geometric types. Values of the **point** type are specified using either of the following syntax:

```
( x , y )
x , y
```

**x** and **y** are the respective coordinates, as floating-point numbers. The value type of the points is float8.

Points are output using the first syntax.

Example:

```
gaussdb=# SELECT point(1.1, 2.2);
 point
-----
(1.1,2.2)
(1 row)
```

### Line Segments

Line segments (**lseg**) are represented by pairs of points. Values of the **lseg** type are specified using any of the following syntaxes:

```
[ ( x1 , y1 ) , ( x2 , y2 ) ]  
( ( x1 , y1 ) , ( x2 , y2 ) )  
( x1 , y1 ) , ( x2 , y2 )  
x1 , y1 , x2 , y2
```

**(x1,y1)** and **(x2,y2)** are the end points of the line segment. The value type of the points is float8.

Line segments are output using the first syntax.

Example:

```
gaussdb=# SELECT lseg(point(1.1, 2.2), point(3.3, 4.4));  
      lseg  
-----  
[(1.1,2.2),(3.3,4.4)]  
(1 row)
```

## Rectangles

Rectangles are represented by pairs of points that are opposite corners of a rectangle. Values of the **box** type are specified using any of the following syntaxes:

```
(( x1 , y1 ) , ( x2 , y2 ) )  
( x1 , y1 ) , ( x2 , y2 )  
x1 , y1 , x2 , y2
```

**(x1,y1)** and **(x2,y2)** are any two opposite corners of the rectangle. The value type of the points is float8.

Rectangles are output using the second syntax.

Any two opposite corners can be supplied on input, but in this order, the values will be reordered as needed to store the upper right and lower left corners.

Example:

```
gaussdb=# SELECT box(point(1.1, 2.2), point(3.3, 4.4));  
      box  
-----  
(3.3,4.4),(1.1,2.2)  
(1 row)
```

## Paths

Paths are represented by lists of connected points. The path may be open, that is, the first and last points in the list are not connected. The path may also be closed, that is, the first point in the list is connected to the last point in sequence.

Values of the **path** type are specified using any of the following syntaxes:

```
[ ( x1 , y1 ) , ... , ( xn , yn ) ]  
( ( x1 , y1 ) , ... , ( xn , yn ) )  
( x1 , y1 ) , ... , ( xn , yn )  
( x1 , y1 , ... , xn , yn )  
x1 , y1 , ... , xn , yn
```

The points are the end points of the line segments comprising the path. The value type of the points is float8. Square brackets ([]) indicate an open path, while parentheses (()) indicate a closed path. When the outermost parentheses are omitted, as in the third through fifth syntax, a closed path is assumed.

Paths are output using the first or second syntax.

Example:

```
gaussdb=# SELECT path(polygon '((0,0),(1,1),(2,0)'));
 path
-----
((0,0),(1,1),(2,0))
(1 row)
```

## Polygons

Polygons are represented by lists of points (the vertexes of the polygon). Polygons are very similar to closed paths, but are stored differently and have their own set of support functions.

Values of the **polygon** type are specified using any of the following syntaxes:

```
(( x1 , y1 ) , ... , ( xn , yn ) )
( x1 , y1 ) , ... , ( xn , yn )
( x1 , y1 , ... , xn , yn )
x1 , y1 , ... , xn , yn
```

A point indicates the vertex of a polygon. The value type of a point is float8.

Polygons are output using the first syntax.

Example:

```
gaussdb=# SELECT polygon(box '((0,0),(1,1)'));
 polygon
-----
((0,0),(0,1),(1,1),(1,0))
(1 row)
```

## Circles

Circles are represented by a center point and radius. Values of the **circle** type are specified using the following syntax:

```
< ( x , y ) , r >
(( x , y ) , r )
( x , y ) , r
x , y , r
```

**(x,y)** is the center point and **r** is the radius of the circle. The value type of the points is float8.

Circles are output using the first syntax.

Example:

```
gaussdb=# SELECT circle(point(0,0),1);
 circle
-----
<(0,0),1>
(1 row)
```

## 7.3.8 Network Address Types

GaussDB offers data types to store IPv4, IPv6, and MAC addresses.

It is better to use these types instead of plain-text types to store network addresses, because these types offer input error checking and specialized operators and functions (see [Network Address Functions and Operators](#)).

**Table 7-18** Network address types

Name	Storage Space	Description
cidr	7 or 19 bytes	IPv4 or IPv6 networks
inet	7 or 19 bytes	IPv4 or IPv6 hosts and networks
macaddr	6 bytes	MAC address

When sorting **inet** or **cidr** data types, IPv4 addresses will always sort before IPv6 addresses, including IPv4 addresses encapsulated or mapped to IPv6 addresses, such as `::10.2.3.4` or `::ffff:10.4.3.2`.

## cidr

The **cidr** type (Classless Inter-Domain Routing) holds an IPv4 or IPv6 network address, as described in [Table 7-19](#). The format for specifying networks is **address/y** where **address** is the network represented as an IPv4 or IPv6 address, and **y** is the number of bits in the netmask. If **y** is omitted, it is calculated using assumptions from the older classful network numbering system, except it will be at least large enough to include all of the octets written in the input.

**Table 7-19** cidr type input examples

cidr Input	cidr Output	abbrev(cidr)
192.168.100.128/25	192.168.100.128/25	192.168.100.128/25
192.168/24	192.168.0.0/24	192.168.0/24
192.168/25	192.168.0.0/25	192.168.0.0/25
192.168.1	192.168.1.0/24	192.168.1/24
192.168	192.168.0.0/24	192.168.0/24
10.1.2	10.1.2.0/24	10.1.2/24
10.1	10.1.0.0/16	10.1/16
10	10.0.0.0/8	10/8
10.1.2.3/32	10.1.2.3/32	10.1.2.3/32
2001:4f8:3:ba::/64	2001:4f8:3:ba::/64	2001:4f8:3:ba::/64
2001:4f8:3:ba:2e0:81ff:fe22:d1f1/128	2001:4f8:3:ba:2e0:81ff:fe22:d1f1/128	2001:4f8:3:ba:2e0:81ff:fe22:d1f1
::ffff:127.0.0.0/120	::ffff:127.0.0.0/120	::ffff:127.0.0.0/120
::ffff:127.0.0.0/128	::ffff:127.0.0.0/128	::ffff:127.0.0.0/128

## inet

The **inet** type holds an IPv4 or IPv6 host address, and optionally its subnet, all in one field. The subnet is represented by the number of network address bits present in the host address (the "netmask"). If the netmask is 32 and the address is an IPv4 address, then the value does not indicate a subnet, only a single host. In IPv6, because the address length is 128 bits, 128 bits specify a unique host address.

The input format for this type is **address/y** where **address** is an IPv4 or IPv6 address and **y** is the number of bits in the netmask. If the **/y** portion is omitted, the netmask is 32 for an IPv4 address and 128 for an IPv6 address, and the value represents just a single host. On display, the **/y** portion is suppressed if the netmask specifies a single host.

The essential difference between the **inet** and **cidr** data types is that **inet** accepts values with nonzero bits to the right of the netmask, whereas **cidr** does not.

## macaddr

The **macaddr** type stores MAC addresses, known for example from Ethernet card hardware addresses (although MAC addresses are used for other purposes as well). Input is accepted in the following formats:

```
'08:00:2b:01:02:03'  
'08-00-2b-01-02-03'  
'08002b:010203'  
'08002b-010203'  
'0800.2b01.0203'  
'08002b010203'
```

These examples specify the same address. Data bits **a** to **f** are case-insensitive and are displayed in the first format.

## 7.3.9 Bit String Types

Bit strings are strings of 1's and 0's. They can be used to store bit masks.

GaussDB supports two bit string types: **bit(*n*)** and **bit varying(*n*)**. Here, *n* is a positive integer. The maximum value of *n* is **83886080**, which is equivalent to 10 MB.

The bit type data must match the length *n* exactly. An error will be reported if the data length of the storage is not matched. Data of the bit varying type is of variable length up to the maximum length *n*. Longer strings will be rejected. Writing **bit** without a length is equivalent to **bit(1)**, while bit varying without a length specification means unlimited length.

### NOTE

- If you convert a bit string value to **bit(*n*)**, the content that exceeds *n* digits on the right of the bit string value will be truncated, or the bit string value will be padded with zeros to *n* digits on the right if the bit string value is less than *n* digits. In this case, no error message is displayed.
- Similarly, if one explicitly casts a bit-string value to **bit varying(*n*)**, the bit-string value will be truncated on the right if it is more than *n* bits.
- When the ADMS platform driver version 8.1.3-200 or earlier is used, use **::bit varying** to convert the bit type. Otherwise, an error may occur.

```
-- Create a table.
gaussdb=# CREATE TABLE bit_type_t1
(
  BT_COL1 INTEGER,
  BT_COL2 BIT(3),
  BT_COL3 BIT VARYING(5)
) DISTRIBUTE BY REPLICATION;

-- Insert data.
gaussdb=# INSERT INTO bit_type_t1 VALUES(1, B'101', B'00');

-- Specify the type length. An error is reported if an inserted string exceeds this length.
gaussdb=# INSERT INTO bit_type_t1 VALUES(2, B'10', B'101');
ERROR: bit string length 2 does not match type bit(3)
CONTEXT: referenced column: bt_col2

-- Specify the type length. Data is converted if it exceeds this length.
gaussdb=# INSERT INTO bit_type_t1 VALUES(2, B'10'::bit(3), B'101');

-- View data.
gaussdb=# SELECT * FROM bit_type_t1;
 bt_col1 | bt_col2 | bt_col3
-----+-----+-----
      1 | 101    | 00
      2 | 100    | 101
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE bit_type_t1;
```

## 7.3.10 UUID Type

The data type UUID stores Universally Unique Identifiers (UUID) as defined by RFC 4122, ISO/IEF 9834-8:2005, and related standards. This identifier is a 128-bit quantity that is generated by an algorithm chosen to make it very unlikely that the same identifier will be generated by anyone else in the known universe using the same algorithm.

Therefore, for distributed systems, these identifiers provide a better uniqueness guarantee than sequence generators, which are only unique within a single database.

A UUID is written as a sequence of lower-case hexadecimal digits, in several groups separated by hyphens, specifically a group of 8 digits followed by three groups of 4 digits followed by a group of 12 digits, for a total of 32 digits representing the 128 bits. An example of a UUID in this standard form is:

```
a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
```

GaussDB also accepts the following alternative forms for input: use of upper-case letters and digits, the standard format surrounded by braces, omitting some or all hyphens, adding a hyphen after any group of four digits. An example is provided as follows:

```
A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11
{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}
a0eebc999c0b4ef8bb6d6bb9bd380a11
a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11
```

Output is always in the standard form.

## 7.3.11 JSON/JSONB Types

JavaScript Object Notation (JSON) data can be a single scalar, an array, or a key-value pair object. The array and object can be called a container:

- Scalar: a number, Boolean, string, or null
- Array: defined in a pair of square brackets (`[]`), in which elements can be any type of JSON data, and are not necessarily of the same type.
- Object: defined in a pair of braces (`{}`), in which objects are stored in the format of `key:value`. Each key must be a string enclosed by a pair of double quotation marks (`""`), and its value can be any type of JSON data. In case of duplicate keys, the last key value will be used.

GaussDB offers two types for storing JSON data: JSON and JSONB. The JSON data type stores a complete copy of the input, retaining the entered spaces, duplicate keys, and sequence. The JSONB data type stores data in a decomposed binary form, removing semantic-irrelevant details and duplicate keys, and sorting key-values. Therefore, the JSONB data does not need to be parsed.

It can be found that both are of JSON type, and the same strings can be entered as input. The main difference between them is the efficiency. Because JSON data type stores an exact copy of the input text, the data must be parsed on every execution. In contrast, JSONB data is stored in its parsed binary form and can be processed faster, though this makes it slightly slower to input due to the conversion mechanism. In addition, because the JSONB data type is normalized, it supports more operations, for example, comparing sizes according to a specific rule. JSONB also supports indexing, which is a significant advantage.

### Input Format

An input must be a JSON-compliant string, which is enclosed in single quotation marks (`'`).

`null` (`null-json`): The value can only be **null** in lowercase.

```
gaussdb=# SELECT 'null':json; -- suc
json
-----
null
(1 row)

gaussdb=# SELECT 'NULL':jsonb; -- err
ERROR:  invalid input syntax for type json
```

`Number` (`num-json`): The value can be a positive or negative integer, decimal fraction, or 0. The scientific notation is supported.

```
gaussdb=# SELECT '1':json;
json
-----
1
(1 row)

gaussdb=# SELECT '-1.5':json;
json
-----
-1.5
(1 row)

gaussdb=# SELECT '-1.5e-5':jsonb, '-1.5e+2':jsonb;
```

```

jsonb | jsonb
-----+-----
-0.000015 | -150
(1 row)

```

gaussdb=# SELECT '001':json, '+15':json, 'NaN':json; -- Redundant leading zeros, plus signs (+), NaN, and infinity are not supported.  
ERROR: invalid input syntax for type json

**Boolean (bool-json):** The value can only be **true** or **false** in lowercase.

```

gaussdb=# SELECT 'true':json;
json
-----
true
(1 row)

```

```

gaussdb=# select 'false':jsonb;
jsonb
-----
false
(1 row)

```

**String (str-json):** The value must be a string enclosed in double quotation marks ("").

```

gaussdb=# SELECT "'a':json;
json
-----
"a"
(1 row)

```

```

gaussdb=# select "'abc':jsonb;
jsonb
-----
"abc"
(1 row)

```

**Array (array-json):** Arrays are enclosed in square brackets ([]). Elements in the array can be any valid JSON data, and are unnecessarily of the same type.

```

gaussdb=# SELECT '[1, 2, "foo", null]:json;
json
-----
[1, 2, "foo", null]
(1 row)

```

```

gaussdb=# SELECT '[]':json;
json
-----
[]
(1 row)

```

```

gaussdb=# SELECT '[1, 2, "foo", null, [], {}]:jsonb;
jsonb
-----
[1, 2, "foo", null, [], {}]
(1 row)

```

**Object (object-json):** The value is enclosed in braces ({}). The key must be a JSON-compliant string, and the value can be any valid JSON string.

```

gaussdb=# SELECT '{}':json; json
-----
{}
(1 row)

```

```

gaussdb=# SELECT '{"a": 1, "b": {"a": 2, "b": null}}':json;
json

```

```
-----
{"a": 1, "b": {"a": 2, "b": null}}
(1 row)

gaussdb=# SELECT '{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}::jsonb;
          jsonb
-----
{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}
(1 row)
```

#### NOTICE

- Note that **'null::json** and **null::json** are different, which are similar to the strings **str="null"** and **str=null**.
- For numbers, when scientific notation is used, JSONB expands them, while JSON stores an exact copy of the input text.

## JSONB Advanced Features

- Precautions
  - It cannot be used as a partition key.
  - Foreign tables are not supported.

The main difference between JSON and JSONB lies in the storage mode. JSONB stores parsed binary data, which reflects the JSON hierarchy and facilitates direct access. Therefore, JSONB has many advanced features that JSON does not have.

- Format normalization
  - After the input object-json string is parsed into JSONB binary, semantically irrelevant details are naturally discarded, for example, spaces:
 

```
gaussdb=# SELECT ' [1, " a ", {"a" :1  } ] '::jsonb;
          jsonb
-----
[1, " a ", {"a": 1}]
(1 row)
```
  - For object-json, duplicate key-values are deleted and only the last key-value is retained. For example:
 

```
gaussdb=# SELECT '{"a" : 1, "a" : 2}::jsonb;
          jsonb
-----
{"a": 2}
(1 row)
```
  - For object-json, key-values will be re-sorted. The sorting rule is as follows: 1. Longer key-values are sorted last. 2. If the key-values are of the same length, the key-values with a larger ASCII code are sorted after the key-values with a smaller ASCII code:
 

```
gaussdb=# SELECT '{"aa" : 1, "b" : 2, "a" : 3}::jsonb;
          jsonb
-----
{"a": 3, "b": 2, "aa": 1}
(1 row)
```
- Size comparison
 

Format normalization ensures that only one form of JSONB data exists in the same semantics. Therefore, sizes may be compared according to a specific rule.

- First, type comparison: object-jsonb > array-jsonb > bool-jsonb > num-jsonb > str-jsonb > null-jsonb
- Content comparison if the data type is the same:
  - str-jsonb: The default text sorting rule of the database is used for comparison. A positive value indicates greater than, a negative value indicates less than, and 0 indicates equal.
  - num-jsonb: numeric comparison
  - bool-jsonb: **true > false**
  - array-jsonb: long elements > short elements. If the lengths are the same, compare each element in sequence.
  - object-jsonb: If the length of a key-value pair is longer than that of a short key-value pair, the keys are compared first, and then the values are compared.

---

 **CAUTION**

For comparison within the object-jsonb type, the final result after format sorting is used for comparison. Therefore, the comparison result may not be intuitive compared with the direct input.

---

- Creating indexes and primary keys
  - B-tree index

B-tree indexes and primary keys can be created for the JSONB type.

- Inclusion and existence

Querying whether a JSON contains some elements or whether some elements exist in a JSON is an important capability of JSONB.

```
-- Simple scalar/primitive values contain only the identical value.
gaussdb=# SELECT "'foo'::jsonb @> 'foo'::jsonb;
?column?
-----
t
(1 row)

-- The array on the left contains the character string on the right.
gaussdb=# SELECT '[1, "aa", 3]::jsonb ? 'aa';
?column?
-----
t
(1 row)

-- The array on the left contains all elements of the array on the right, regardless of the sequence and repetition.
gaussdb=# SELECT '[1, 2, 3]::jsonb @> '[1, 3, 1]::jsonb;
?column?
-----
t
(1 row)

-- The object-json on the left contains all key-value pairs of object-json on the right.
gaussdb=# SELECT '{"product": "PostgreSQL", "version": 9.4, "jsonb":true}'::jsonb @>
 '{"version":9.4}'::jsonb;
?column?
-----
```

```
t
(1 row)

-- The array on the left does not contain all elements of the array on the right. The three elements on
the left are 1, 2, and [1,3], but the elements on the right are 1 and 3.
gaussdb=# SELECT '[1, 2, [1, 3]]::jsonb @> '[1, 3]]::jsonb;
?column?
-----
f
(1 row)

gaussdb=# SELECT '{"foo": {"bar": "baz"}}::jsonb @> '{"bar": "baz"}}::jsonb;
?column?
-----
f
(1 row)
```

For details about the operators, see [JSON/JSONB Functions and Operators](#).

- Functions and operators

For details about the functions and operators supported by the JSON/JSONB type, see [JSON/JSONB Functions and Operators](#).

### 7.3.12 HLL Type

HyperLoglog (HLL) is an approximation algorithm for efficiently counting the number of distinct values in a dataset. It features faster computing and lower space usage. You only need to store HLL data structures, instead of data sets. When new data is added to a dataset, make hash calculation on the data and insert the result to an HLL. Then, you can obtain the final result based on the HLL.

[Table 7-20](#) compares HLL with other algorithms.

**Table 7-20** Comparison between HLL and other algorithms

Item	Sorting Algorithm	Hash Algorithm	HLL
Time complexity	$O(n \log n)$	$O(n)$	$O(n)$
Space complexity	$O(n)$	$O(n)$	$\log(\log n)$
Error rate	0	0	$\approx 0.8\%$
Storage space requirement	Size of original data	Size of original data	The maximum size is 16 KB by default.

HLL has advantages over others in the computing speed and storage space requirement. In terms of time complexity, the sorting algorithm needs  $O(n \log n)$  time for sorting, and the hash algorithm and HLL need  $O(n)$  time for full table scanning. In terms of storage space requirements, the sorting algorithm and hash algorithm need to store raw data before collecting statistics, whereas the HLL algorithm needs to store only the HLL data structures rather than the raw data, and thereby occupying a fixed space of about 16 KB.

**NOTICE**

- In the current default specifications, the maximum number of distinct values that can be calculated is about  $1.1e + 15$ , and the error rate is 0.8%. If the calculation result exceeds the maximum, the error rate of the calculation result will increase, or the calculation will fail and an error will be reported.
- When using this feature for the first time, you need to evaluate the distinct values of the service, properly select configuration parameters, and perform verification to ensure that the accuracy meets requirements.
  - By default, the distinct value is  $1.1e + 15$ . If the distinct value is NaN, you need to adjust `log2m` or use another algorithm to calculate the distinct value.
  - The hash algorithm has an extremely low probability of collision. However, you are still advised to select 2 or 3 hash seeds for verification when using the hash algorithm for the first time. If there is only a small difference between the distinct values, you can select any one of the seeds as the hash seed.

**Table 7-21** describes main HLL data structures.

**Table 7-21** Main HLL data structures

Data Type	Description
hll	The HLL header is a 27-byte field. By default, the data length ranges from 0 KB to 16 KB. The distinct value can be obtained.

When you create an HLL data type, 0 to 4 input parameters are supported. The parameter meanings and specifications are the same as those of the `hll_empty` function. The first parameter is **log2m**, indicating the logarithm of the number of buckets, and its value ranges from 10 to 16. The second parameter is **log2explicit**, indicating the threshold in explicit mode, and its value ranges from 0 to 12. The third parameter is **log2sparse**, indicating the threshold of the Sparse mode, and its value ranges from 0 to 14. The fourth parameter is **duplicatecheck**, indicating whether to enable duplicatecheck, and its value ranges from 0 to 1. When the input parameter is set to **-1**, the default value of the HLL parameter is used. You can run the `\d` or `\d+` command to view the parameters of the HLL type.

 **NOTE**

When the HLL data type is created, the result varies depending on the input parameter behavior:

- When creating an HLL type, do not set the input parameter or set it to **-1**. Use the default value of the corresponding HLL parameter.
- If a valid value is set for the input parameter, the corresponding HLL parameter uses the input value.
- If the input value is invalid, an error is reported when the HLL type is created.

```
-- Create an HLL table without specifying input parameters.
gaussdb=# CREATE TABLE t1 (id integer, set hll);
```

```
gaussdb=# \d t1
      Table "public.t1"
  Column | Type   | Modifiers
-----+-----+-----
 id     | integer |
 set    | hll    |

-- Create an HLL table, specify the first two input parameters, and use the default values for the last two
input parameters.
gaussdb=# CREATE TABLE t2 (id integer, set hll(12,4));
gaussdb=# \d t2
      Table "public.t2"
  Column | Type           | Modifiers
-----+-----+-----
 id     | integer        |
 set    | hll(12,4,12,0) |

-- Create an HLL table, specify the third input parameter, and use default values for other parameters.
gaussdb=# CREATE TABLE t3(id int, set hll(-1,-1,8,-1));
gaussdb=# \d t3
      Table "public.t3"
  Column | Type           | Modifiers
-----+-----+-----
 id     | integer        |
 set    | hll(14,10,8,0) |

-- When a user creates an HLL table and specifies an invalid input parameter, an error is reported.
gaussdb=# CREATE TABLE t4(id int, set hll(5,-1));
ERROR: log2m = 5 is out of range, it should be in range 10 to 16, or set -1 as default

-- Drop the created HLL table.
gaussdb=# DROP TABLE t1,t2,t3;
DROP TABLE
```

#### NOTE

When inserting an HLL object to an HLL table, ensure that the parameters of the HLL type are the same as those of the inserted object. Otherwise, an error is reported.

```
-- Create an HLL table.
gaussdb=# CREATE TABLE t1(id integer, set hll(14));

-- Insert an HLL object to a table. The insertion succeeds because parameter types are consistent.
gaussdb=# INSERT INTO t1 VALUES (1, hll_empty(14,-1));

-- Insert an HLL object to a table. The insertion fails because parameter types are inconsistent.
gaussdb=# INSERT INTO t1(id, set) VALUES (1, hll_empty(14,5));
ERROR: log2explicit does not match: source is 5 and dest is 10

-- Drop the table.
gaussdb=# DROP TABLE t1;
```

The following describes HLL application scenarios:

- Scenario 1: "Hello World"

The following example shows how to use the HLL data type:

```
-- Create an HLL table.
gaussdb=# CREATE TABLE helloworld (id integer, set hll);

-- Insert an empty HLL to the table.
gaussdb=# INSERT INTO helloworld(id, set) VALUES (1, hll_empty());

-- Add a hashed integer to the HLL.
gaussdb=# UPDATE helloworld SET set = hll_add(set, hll_hash_integer(12345)) WHERE id = 1;

-- Add a hashed string to the HLL.
gaussdb=# UPDATE helloworld SET set = hll_add(set, hll_hash_text('hello world')) WHERE id = 1;

-- Obtain the number of distinct values of the HLL.
```

```
gaussdb=# SELECT hll_cardinality(set) FROM helloworld WHERE id = 1;
hll_cardinality
-----
                2
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE helloworld;
```

- Scenario 2: Collect statistics about website visitors.

The following example shows how an HLL collects statistics on the number of users visiting a website within a period of time:

```
-- Create a raw data table to show that a user has visited the website at a certain time.
gaussdb=# CREATE TABLE facts (
    date      date,
    user_id   integer
);

-- Create a raw data table to show that a user has visited the website at a certain time.
gaussdb=# INSERT INTO facts VALUES ('2019-02-20', generate_series(1,100));
gaussdb=# INSERT INTO facts VALUES ('2019-02-21', generate_series(1,200));
gaussdb=# INSERT INTO facts VALUES ('2019-02-22', generate_series(1,300));
gaussdb=# INSERT INTO facts VALUES ('2019-02-23', generate_series(1,400));
gaussdb=# INSERT INTO facts VALUES ('2019-02-24', generate_series(1,500));
gaussdb=# INSERT INTO facts VALUES ('2019-02-25', generate_series(1,600));
gaussdb=# INSERT INTO facts VALUES ('2019-02-26', generate_series(1,700));
gaussdb=# INSERT INTO facts VALUES ('2019-02-27', generate_series(1,800));

-- Create another table and specify an HLL column:
gaussdb=# CREATE TABLE daily_uniques (
    date      date UNIQUE,
    users     hll
);

-- Group data by date and insert the data into the HLL.
gaussdb=# INSERT INTO daily_uniques(date, users)
SELECT date, hll_add_agg(hll_hash_integer(user_id))
FROM facts
GROUP BY 1;

-- Calculate the numbers of users visiting the website every day.
gaussdb=# SELECT date, hll_cardinality(users) FROM daily_uniques ORDER BY date;
date | hll_cardinality
-----+-----
2019-02-20 | 100
2019-02-21 | 200.217913059312
2019-02-22 | 301.76494508014
2019-02-23 | 400.862858326446
2019-02-24 | 502.626933349694
2019-02-25 | 601.922606454213
2019-02-26 | 696.602316769498
2019-02-27 | 798.111731634412
(8 rows)

-- Calculate the number of users who had visited the website in the week from February 20, 2019 to
February 26, 2019.
gaussdb=# SELECT hll_cardinality(hll_union_agg(users)) FROM daily_uniques WHERE date >=
'2019-02-20'::date AND date <= '2019-02-26'::date;
hll_cardinality
-----
696.602316769498
(1 row)

-- Calculate the number of users who had visited the website yesterday but have not visited the
website today:
gaussdb=# SELECT date, (#hll_union_agg(users) OVER two_days) - #users AS lost_uniques FROM
daily_uniques WINDOW two_days AS (ORDER BY date ASC ROWS 1 PRECEDING); -- The default
compatibility details (M-compatibility) are listed as
follows:
```

```
date | lost_uniques
-----+-----
2019-02-20 | 0
2019-02-21 | 0
2019-02-22 | 0
2019-02-23 | 0
2019-02-24 | 0
2019-02-25 | 0
2019-02-26 | 0
2019-02-27 | 0
(8 rows)
```

```
-- Drop the table.
gaussdb=# DROP TABLE facts;
gaussdb=# DROP TABLE daily_uniques;
```

- Scenario 3: The data to be inserted does not meet the requirements of the HLL data structure.

When inserting data into a column of the HLL type, ensure that the data meets the requirements of the HLL data structure. If the data does not meet the requirements after being parsed, an error will be reported. In the following example, 'E\1234' to be inserted does not meet the requirements of the HLL data structure after being parsed. As a result, an error is reported.

```
gaussdb=# CREATE TABLE test(id integer, set hll);
gaussdb=# INSERT INTO test VALUES(1, 'E\1234');
ERROR: not a hll type, size=6 is not enough
gaussdb=# DROP TABLE test;
```

### 7.3.13 Range Types

A range type is a data type that represents the range of a value of an element type (called the *subtype* of a range). For example, the range of timestamp may be used to express a time range in which a conference room is reserved. In this case, the data type is `tsrange` (short for timestamp range), and timestamp is the subtype. The subtype must have an overall order so that the element value can be clearly specified within a range, before, or after.

Range types are useful because they can express multiple element values in a single range value and can clearly express concepts such as range overlapping (time and date range of time arrangement). It can also be expressed in scenarios such as price range and instrument measurement range.

#### Built-in Range

The following built-in ranges are available:

- `int4range`: integer range.
- `int8range`: bigint range.
- `numrange`: numeric range.
- `tsrange`: range of timestamp without the time zone.
- `tstzrange`: range of timestamp with the time zone
- `daterange`: date range.

In addition, you can customize range types. For details, see [CREATE TYPE](#).

#### Example

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE reservation (room int, during tsrange);
```

```
gaussdb=# INSERT INTO reservation VALUES (1108, '[2010-01-01 14:30, 2010-01-01 15:30)');
-- Inclusion
gaussdb=# SELECT int4range(10, 20) @> 3;
?column?
-----
f
(1 row)

-- Determine whether the two ranges overlap.
gaussdb=# SELECT numrange(11.1, 22.2) && numrange(20.0, 30.0);
?column?
-----
t
(1 row)

-- Extract the upper bound.
gaussdb=# SELECT upper(int8range(15, 25));
upper
-----
25
(1 row)

-- Calculate the intersection.
gaussdb=# SELECT int4range(10, 20) * int4range(15, 25);
?column?
-----
[15,20)
(1 row)

-- Determine whether the range is empty.
gaussdb=# SELECT isempty(numrange(1, 5));
isempty
-----
f
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE reservation;
```

See the complete list of operators and functions on a range type in [Range Functions and Operators](#).

## Including and Excluding Bounds

Each non-empty range has two bounds, a lower bound and an upper bound. All values between the upper and lower bounds are included in the range. An inclusion bound means that the bound value itself is included in the range, while an exclusion bound means that the bound value is not included in the range.

In the textual form of a range, the inclusion lower bound is expressed as "[", and the exclusion lower bound is expressed as "("; the inclusion upper bound is expressed as "]", and the exclusion upper bound is expressed as ")".

The `lower_inc` and `upper_inc` functions test the upper and lower bounds of a range value, respectively.

## Infinite (Unbounded) Range

When the lower bound of a range is unbounded, it means that all values less than the upper bound are included in the range. Similarly, when the upper bound of a range is unbounded, all values greater than the lower bound are included in the range. When both the upper and lower bounds are unbounded, all values of the element type are considered within the range. When the upper bound and the lower bound of the range are not set, that is, the upper bound is positive infinity

and the lower bound is negative infinity, the range is an infinite (unbounded) range.

Element types with the **infinity** values can be used as explicit bound values. For example, in the timestamp range **[today, infinity)** and **[today, infinity]**, **[today, infinity)** indicates that the special timestamp values **infinity** is not included, and **[today, infinity]** indicates that the special timestamp value **infinity** is included.

The `lower_inf` and `upper_inf` functions test the infinite upper and lower bounds of a range, respectively.

## Range Input/Output

Range input mode:

```
(lower-bound, upper-bound)
(lower-bound, upper-bound]
[lower-bound, upper-bound)
[lower-bound, upper-bound]
Empty
```

Range output mode:

```
[lower-bound, upper-bound)
Empty
```

() or [] indicates whether the upper and lower bounds are excluded or included, respectively. **empty** indicates an empty range (a range that does not contain vertices).

The value of *lower-bound* can be a valid input string of the subtype or null, indicating that there is no lower bound. Similarly, *upper-bound* can be a valid input string of the subtype or null, indicating that there is no upper bound.

Each bound value can be referenced using the quotation marks (") character. This is necessary if a bound value contains parentheses (), square brackets [], commas (,), quotation marks (""), or backslashes (\), because otherwise those characters will be considered part of the range syntax. To put the quotation mark or backslash in a referenced bound value, put a backslash in front of it (and a pair of double quotation marks in its quoted bound value represents one quotation mark character, which is similar to the single quotation mark rule in SQL character strings). In addition, you can avoid referencing or use backslash escapes to protect all data characters. Otherwise, the data characters will be used as part of the range syntax. If you want to write a bound value that is an empty string, write "", indicating infinite bounds.

Spaces are allowed before and after a range value, but any space between parentheses or square brackets is used as part of the upper or lower bound value (depending on the element type, the space may or may not represent a value).

Examples:

```
-- All values between 3 (included) and 7 (excluded) are included.
gaussdb=# SELECT '[3,7)':int4range;
int4range
-----
[3,7)
(1 row)
-- All values between 3 (excluded) and 7 (excluded) are included.
gaussdb=# SELECT '(3,7)':int4range;
int4range
```

```
-----  
[4,7)  
(1 row)  
-- Only value 4 is included.  
gaussdb=# SELECT '[4,4]':int4range;  
int4range  
-----  
[4,5)  
(1 row)  
-- No value is included (and will be normalized to null).  
gaussdb=# SELECT '[4,4)':int4range;  
int4range  
-----  
Empty  
(1 row)
```

## Constructing Range

Each range type has a constructor function with the same name. Using constructor functions is often more convenient than writing a range literal constant because it avoids extra references to bound values. Constructor functions receive two or three parameters. Two parameters form a range in the standard form, where the lower bound is included and the upper bound is excluded, and three parameters form a range according to the bound specified by the third parameter. The third parameter must be one of the following character strings: (), (], [, or [].

```
-- The complete format is: lower bound, upper bound, and textual parameters indicating the inclusion/  
exclusion of bounds.  
gaussdb=# SELECT numrange(1.0, 14.0, '[');  
numrange  
-----  
(1.0,14.0]  
(1 row)  
-- If the third parameter is ignored, it is assumed to be '['.  
gaussdb=# SELECT numrange(1.0, 14.0);  
numrange  
-----  
[1.0,14.0)  
(1 row)  
-- Although '[' is specified here, the value will be converted to the standard format when displayed,  
because int8range is a discrete range type.  
gaussdb=# SELECT int8range(1, 14, '[');  
int8range  
-----  
[2,15)  
(1 row)  
-- Using NULL for a bound causes the range to be unbounded on that side.  
gaussdb=# SELECT numrange(NULL, 2.2);  
numrange  
-----  
(,2.2)  
(1 row)
```

## Discrete Range

A range element type has a well-defined "step" such as integer or date. In these types, if there is no valid value between two elements, they can be said to be adjacent. This is in contrast to a continuous range in which other element values can always be identified between two given values. For example, a range above the numeric type is continuous, and the range of timestamp is also continuous. (Although timestamp has limited precision and can be considered as discrete in theory, it can be considered as continuous because the step is not normally considered.)

Another way to consider discrete range types is to have a clear "next" or "previous" value for each element value. You can switch between inclusion and exclusion expressions of a range bound by replacing it with the original given next or previous element value. For example, in an integer range type, [4,8] and (3,9) represent the same set of values, but not for numeric ranges.

A discrete range type should have a regularization function that knows the specified step size of the element type. The regularization function can convert the equivalents of the range type to the same expression, in particular consistent with the inclusion or exclusion bounds. If you do not specify a regularization function, ranges with different formats will always be considered as unequal, even if they actually express the same set of values.

The built-in range types `int4range`, `int8range`, and `daterange` use a regularized form that includes the lower bound and excludes the upper bound, that is, []. However, user-defined range types can use other conventions.

## Index

In addition, B-tree indexes can be created on table columns of the range type. For these index types, basically the only useful range operation is equivalence. Using the corresponding < and > operators, there is a B-tree sort order for range value definitions, but that order is fairly arbitrary and is often less useful in the reality. The B-tree support for range types is primarily designed to allow sorting within a query, rather than creating an index.

### 7.3.14 Object Identifier Types

Object identifiers (OIDs) are used internally by GaussDB as primary keys for various system catalogs. OIDs are not added to user-created tables by the system. The `OID` type represents an object identifier.

The `OID` type is currently implemented as an unsigned four-byte integer. So, using a user-created table's `OID` column as a primary key is discouraged.

**Table 7-22** Object identifier types

Name	Reference	Description	Example
OID	N/A	Numeric object identifier	564182
CID	N/A	Command identifier. This is the data type of the system columns <code>cmin</code> and <code>cmax</code> . Command identifiers are 32-bit quantities.	N/A
XID	N/A	A transaction identifier. This is the data type of the system columns <code>xmin</code> and <code>xmax</code> . Transaction identifiers are 64-bit quantities.	N/A

Name	Reference	Description	Example
TID	N/A	Row identifier. This is the data type of the system column <b>ctid</b> . A row ID is a pair (block number, tuple index within block) that identifies the physical location of the row within its table.	N/A
REGCONFIG	pg_ts_config	Text search configuration	english
REGDICTIONARY	pg_ts_dict	Text search dictionary	simple
REGOPER	pg_operator	Operator name	N/A
REGOPERATOR	pg_operator	Operator with argument types	*(integer,integer) or -(NONE,integer)
REGPROC	pg_proc	Function name	sum
REGPROCEDURE	pg_proc	Function with argument types	sum(int4)
REGCLASS	pg_class	Relation name	pg_type
REGTYPE	pg_type	Data type name	integer

The OID type is used for a column in the database system catalog.

Example:

```
gaussdb=# SELECT oid FROM pg_class WHERE relname = 'pg_type';
oid
-----
1247
(1 row)
```

The alias type for **OID** is **REGCLASS** which allows simplified search for **OID** values.

Example:

```
gaussdb=# SELECT attrelid,attname,attypid,attstattarget FROM pg_attribute WHERE attrelid =
'pg_type'::REGCLASS;
attrelid | attname | attypid | attstattarget
-----+-----+-----+-----
1247 | xc_node_id | 23 | 0
1247 | tableoid | 26 | 0
1247 | cmax | 29 | 0
1247 | xmax | 28 | 0
1247 | cmin | 29 | 0
1247 | xmin | 28 | 0
1247 | oid | 26 | 0
1247 | ctid | 27 | 0
1247 | typname | 19 | -1
```

1247	typnamespace	26	-1
1247	typowner	26	-1
1247	typplen	21	-1
1247	typbyval	16	-1
1247	typstype	18	-1
1247	typcategory	18	-1
1247	typispreferred	16	-1
1247	typisdefined	16	-1
1247	typdelim	18	-1
1247	typrelid	26	-1
1247	typelem	26	-1
1247	typarray	26	-1
1247	typinput	24	-1
1247	typoutput	24	-1
1247	typreceive	24	-1
1247	typsend	24	-1

1247	typelemmod	23	-1

(39 rows)

### 7.3.15 Pseudo-Types

GaussDB type system contains a number of special-purpose entries that are collectively called pseudo-types. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type.

Each of the available pseudo-types is useful in situations where a function's behavior does not correspond to simply taking or returning a value of a specific SQL data type. [Table 7-23](#) lists all pseudo-types.

**Table 7-23** Pseudo-types

Name	Description
any	Indicates that a function accepts any input data type.
anyelement	Indicates that a function accepts any data type.
anyarray	Indicates that a function accepts any array data type.
anynonarray	Indicates that a function accepts any non-array data type.
anyenum	Indicates that a function accepts any enum data type.
anyrange	Indicates that a function accepts any range data type.
cstring	Indicates that a function accepts or returns a null-terminated C string.
internal	Indicates that a function accepts or returns a server-internal data type.

Name	Description
language_handler	Indicates that a procedural language call handler is declared to return <b>language_handler</b> .
fdw_handler	Indicates that a foreign-data wrapper handler is declared to return <b>fdw_handler</b> .
record	Identifies a function returning an unspecified row type.
trigger	Indicates that a trigger function is declared to return <b>trigger</b> .
void	Indicates that a function returns no value.
opaque	Indicates an obsolete type name that formerly served all the above purposes.

Functions coded in C language (whether built in or dynamically loaded) can be declared to accept or return any of these pseudo data types. It is up to the function author to ensure that the function will behave safely when a pseudo-type is used as an argument type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. At present the procedural languages all forbid use of a pseudo-type as argument type, and allow only **void** and **record** as a result type. Some also support polymorphic functions using the anyelement, anyarray, anynonarray, anyenum, and anyrange types.

Each location (parameter or return value) declared as the anyelement type is allowed to have any specific actual data type, but they must all be of the same actual type in any given query.

The internal pseudo-type is used to declare functions that are meant only to be called internally by the database system, and not by direct calling in an SQL query. If a function has at least one internal-type argument then it cannot be called from SQL. You are advised not to create any function that is declared to return internal unless it has at least one internal argument.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t1 (a int);

-- Insert two data records.
gaussdb=# INSERT INTO t1 values(1),(2);

-- Create the showall() function.
gaussdb=# CREATE OR REPLACE FUNCTION showall() RETURNS SETOF record
AS $$ SELECT count(*) from t1; $$
LANGUAGE SQL;

-- Call the showall() function.
gaussdb=# SELECT showall();
showall
-----
(2)
(1 row)
```

```
-- Delete the function.
gaussdb=# DROP FUNCTION showall();

-- Delete the table.
gaussdb=# DROP TABLE t1;
```

### 7.3.16 Data Types Used by the Ledger Database

The ledger database uses the hash16 data type to store row-level hash digests or table-level hash digests, and uses the hash32 data type to store global hash digests or history table verification hashes.

**Table 7-24** Hash types of the ledger database

Name	Description	Storage Space	Range
HASH16	Stored as an unsigned 64-bit integer.	8 bytes	0 to +18446744073709551615
HASH32	Stored as an unsigned integer array of 16 elements.	16 bytes	Value range of an unsigned integer array of 16 elements

The hash16 data type is used to store row-level or table-level hash digests in the ledger database. After obtaining the hash sequence of a 16-character hexadecimal string, the system calls the hash16in function to convert the sequence into an unsigned 64-bit integer and stores the integer in a hash16 variable. For example:

```
Hexadecimal string: e697da2eaa3a775b; 64-bit unsigned integer: 16615989244166043483
Hexadecimal string: ffffffff; 64-bit unsigned integer: 18446744073709551615
```

The hash32 data type is used to store the global hash digest or history table verification hash in the ledger database. After obtaining the hash sequence of a 32-character hexadecimal string, the system calls the hash32in function to convert the sequence to an unsigned integer array of 16 elements. For example:

```
Hexadecimal string: 685847ed1fe38e18f6b0e2b18c00edee
Hash32 array: [104,88,71,237,31,227,142,24,246,176,226,177,140,0,237,238]
```

### 7.3.17 XML Type

The XML data type can be used to store Extensible Markup Language (XML) data. The internal format of XML is the same as that of the TEXT data type. Its advantage over storing XML data in a TEXT field is that, XML data supports standard XML operation functions based on LIBXML2 and XML standardization check.

The XML data type can store well-formed documents as defined by the XML standard, as well as content fragments, which are defined by referencing broader "DOCUMENT NODE" XQuery and XPath data models. Roughly speaking, this means that there can be more than one top-level element or character node in a content fragment. The expression **XMLVALUE IS DOCUMENT** can be used to

evaluate whether a particular XML value is a complete document or just a document fragment.

The XML parser converts an XML document into an XML DOM object. The document object model (DOM) defines standard methods for accessing and manipulating documents. XML DOM defines standard methods for accessing and manipulating XML documents. XML DOM views XML documents as a tree structure. All elements can be accessed through the DOM tree. You can modify or delete their contents and create new elements. Elements, their text, and their attributes are considered as nodes.

The XML bottom layer uses the same data structure as the TEXT type for storage. The maximum size is 1 GB.

Example:

```
gaussdb=# CREATE TABLE xmltest ( id int, data xml );
gaussdb=# INSERT INTO xmltest VALUES (1, 'one');
gaussdb=# INSERT INTO xmltest VALUES (2, 'two');
gaussdb=# SELECT * FROM xmltest ORDER BY 1;
 id | data
-----+-----
 1 | one
 2 | two
(2 rows)
gaussdb=# SELECT xmlconcat(xmlcomment('hello'),
                           xmlelement(NAME qux, 'xml'),
                           xmlcomment('world'));
          xmlconcat
-----+-----
<!--hello--><qux>xml</qux><!--world-->
(1 row)
gaussdb=# DROP TABLE xmltest;
```

 NOTE

- The XML type does not support the following operations:
  - Logical expressions AND, OR, and NOT
  - Input parameter of a system function that is used as a non-XML operation function
  - Used as a distribution key, partition key, level-2 partition key, primary key, or unique constraint.
  - Implicit conversion related to XML, including the conversion between strings and the XML data type
  - Array expression, row expression, and subquery expression
  - Use columns of the XML data format as common indexes, unique indexes, global indexes, local indexes, and partial indexes.
  - Comparison expressions >, <, >=, <=, =, <>, !=, ^=, <=>, BETWEEN AND, IS DISTINCT FROM, and IS NOT DISTINCT FROM
  - Condition expressions DECODE, NULLIF, GREATEST, and LEAST
  - Used as DISTINCT, GROUP BY, or ORDER BY parameters
  - Aggregate functions include sum, max, min, avg, list\_agg, corr, covar\_pop, covar\_samp, stddev, stddev\_pop, stddev\_samp, var\_pop, var\_samp, variance, bit\_and, bit\_or, bool\_and, bool\_or, every, regr\_avgx, regr\_avgy, regr\_count, regr\_intercept, regr\_r2, regr\_slope, regr\_sxx, regr\_sxy, regr\_syy, rank, and spread.
  - ODBC-related APIs with binding parameters
- The XML type supports the following operations:
  - Physical backup and restoration
  - Comparison expressions IS NULL and IS NOT NULL
  - Condition expressions CASE and COALESCE
  - Global temporary tables and local temporary tables
  - Forcible type conversion
  - Expression indexes
  - Input XML values that comply with the XML standard
  - gs\_dump and gs\_restore
  - Parallel query, supporting Astore and Ustore.
  - Input parameters, output parameters, customized variables, and return values of a user-defined function
  - Input parameters, output parameters, customized variables, and return values of a stored procedure, as well as stored procedures that support autonomous transactions.
  - Character processing function quote\_literal(string text) (explicitly converted to the character type) and quote\_nullable(string text) (explicitly converted to the character type)
  - Aggregate functions count, array\_agg, and checksum (explicitly converted to the character type), and string\_agg (explicitly converted to the character type)
  - JDBC and ODBC operations on XML data types are supported. The SELECT, UPDATE, INSERT, and DELETE operations can be performed on an XML column. You can enter an XML value using the SQL syntax and use the getSQLXML method of the ResultSet class to obtain the XML value. JDBC-related APIs with binding parameters are supported. For example, you can use the setSQLXML method in the PreparedStatement API and the getSQLXML(int columnIndex) method in the ResultSet execution result set API.

In the calling process, use the java.sql.SQLXML API class to construct an XML object, set the specified object type to Oid.XML, and send the type ID and XML value to the server. After obtaining the result returned from the server, call ResultSet.getString. Then, use the java.sql.SQLXML API class to construct an XML

object based on the obtained character string. In this case, the system checks whether the content complies with the XML standard again. Therefore, you can also use `ResultSet.getString` to directly obtain the XML string object.

## 7.3.18 XMLType

The XMLType data type is used to store XMLType data. Currently, data is stored in character strings in the internal format. Its advantage over storing XML data in a TEXT field is that, XMLTYPE data supports standard XML operation functions based on LIBXML2 and XML standardization check.

The XMLType type can store well-formed "documents" that comply with the XML standard.

The XML parser converts an XML document into an XML DOM object. The document object model (DOM) defines standard methods for accessing and manipulating documents. XML DOM defines standard methods for accessing and manipulating XML documents. XML DOM views XML documents as a tree structure. All elements can be accessed through the DOM tree. You can modify or delete their contents and create new elements. Elements, their text, and their attributes are considered as nodes. The maximum size is 1 GB.

Example:

```
gaussdb=# CREATE TABLE xmltypetest(id int, data xmltype);
gaussdb=# INSERT INTO xmltypetest VALUES (1, '<ss/>');
gaussdb=# INSERT INTO xmltypetest VALUES (2, '<xx/>');
gaussdb=# SELECT * FROM xmltypetest ORDER BY 1;
 id | data
----+-----
  1 | <ss/>
  2 | <xx/>
(2 rows)
gaussdb=# DROP TABLE xmltypetest;
```

 NOTE

- The XMLType type does not support the following operations:
  - Logical expressions AND, OR, and NOT
  - Input parameter of a system function that is used as a non-XMLType operation function
  - Used as a distribution key, partition key, level-2 partition key, primary key, or unique constraint.
  - Implicit conversion related to XMLType, including the conversion between strings and the XMLType data type
  - Array expression, row expression, and subquery expression
  - Use columns of the XMLType data format as common indexes, unique indexes, global indexes, local indexes, and partial indexes.
  - Comparison expressions >, <, >=, <=, =, <>, !=, ^=, <=>, BETWEEN AND, IS DISTINCT FROM, and IS NOT DISTINCT FROM
  - Condition expressions DECODE, NULLIF, GREATEST, and LEAST
  - Used as DISTINCT, GROUP BY, or ORDER BY parameters
  - Aggregate functions include sum, max, min, avg, list\_agg, corr, covar\_pop, covar\_samp, stddev, stddev\_pop, stddev\_samp, var\_pop, var\_samp, variance, bit\_and, bit\_or, bool\_and, bool\_or, every, regr\_avgx, regr\_avgy, regr\_count, regr\_intercept, regr\_r2, regr\_slope, regr\_sxx, regr\_sxy, regr\_syy, rank, and spread.
  - ODBC-related APIs with binding parameters
- The XMLType type supports the following operations:
  - Physical backup and restoration
  - Comparison expressions IS NULL and IS NOT NULL
  - Condition expressions CASE and COALESCE
  - Global temporary tables and local temporary tables
  - Forcible type conversion
  - Expression indexes
  - Input XMLType values that comply with the XML standard
  - gs\_dump and gs\_restore
  - Parallel query, supporting Astore and Ustore.
  - Input parameters, output parameters, customized variables, and return values of a user-defined function
  - Input parameters, output parameters, customized variables, and return values of a stored procedure, as well as stored procedures that support autonomous transactions.
  - Character processing function quote\_literal(string text) (explicitly converted to the character type) and quote\_nullable(string text) (explicitly converted to the character type)
  - Aggregate functions count, array\_agg, and checksum (explicitly converted to the character type), and string\_agg (explicitly converted to the character type)
  - You can perform the SELECT, UPDATE, INSERT, or DELETE operation on the column and use the SQL syntax to enter the XMLTYPE value.
- You can create a schema named **xmltype**. In the schema, you can create functions, but cannot use schema.func() to call functions defined in the schema.

## 7.3.19 ACLItem Type

The aclitem data type is used to store object permission information. The internal implementation is of the int type, and the supported format is '*user1=privs/user2*'.

The `aclitem[]` data type is an array consisting of ACL items. The supported format is `{user1 = privs1/user3, user2 = privs2/user3}`.

`user1`, `user2`, and `user3` indicate the existing users or roles in the database, and `privs` indicates the permissions supported by the database. For details, see [Table 12-71](#).

Example:

```
-- Create a user.
gaussdb=# CREATE USER user1 WITH PASSWORD '*****';
gaussdb=# CREATE USER user2 WITH PASSWORD '*****';
gaussdb=# CREATE USER omm WITH PASSWORD '*****';

-- Create a data table table_acl that contains three columns of the int, aclitem, and aclitem[] types.
gaussdb=# CREATE TABLE table_acl (id int,priv aclitem,privs aclitem[]);

-- Insert a data record whose content is (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}') into the
table_acl table.
gaussdb=# INSERT INTO table_acl VALUES (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}');

-- Insert a data record whose content is (2,'user1=aw/omm','{omm=d/user2}') into the table_acl table.
gaussdb=# INSERT INTO table_acl VALUES (2,'user1=aw/omm','{omm=d/user2}');
gaussdb=# SELECT * FROM table_acl;
 id |  priv  |      privs
-----+-----+-----
  1 | user1=arw/omm | {omm=d/user2,omm=w/omm}
  2 | user1=aw/omm  | {omm=d/user2}
(2 rows)

-- Delete the table and user.
gaussdb=# DROP USER user1;
gaussdb=# DROP USER user2;
gaussdb=# DROP USER omm;
gaussdb=# DROP TABLE table_acl;
```

## 7.3.20 Array Types

Array types can be used to store several elements of the same type.

### Array Type Definition

Generally, an array data type is named by adding square brackets ([]) to the end of the data type name of an array element.

Example 1:

```
-- Create a table named sal_emp. The table contains the following columns: name of the text type,
indicating employee names; pay_by_quarter of the integer element type, indicating an array of quarterly
salaries; phone_numbers of the varchar(11) element type, indicating an array of mobile numbers.
gaussdb=# CREATE TABLE sal_emp (
 name          text,
 pay_by_quarter integer[],
 phone_numbers varchar(11)[]
);
gaussdb=# DROP TABLE sal_emp;
```

Example 2: Define an array type in other ways. For details about the definition method and behavior, see the comments in the example.

```
gaussdb=# CREATE TABLE sal_emp (
 name          text,
 pay_by_quarter1 integer[[]], -- Two-dimensional array of the int type.
 pay_by_quarter2 integer[3],  -- One-dimensional array of the int type. The size is 3.
 pay_by_quarter3 integer[3][3], -- Two-dimensional array of the int type. The size of each dimension is 3.
 pay_by_quarter4 integer ARRAY, -- One-dimensional array of the int type.
```

```
pay_by_quarter5 integer ARRAY[3] -- One-dimensional array of the int type. The size is 3.
);
gaussdb=# DROP TABLE saL_emp;
```

**CAUTION**

- The definition of the number of dimensions of an array does not take effect (which does not affect the runtime behavior). You are advised to use the method described in example 1 to define the array type and do not use multidimensional array data.
- The definition of the array size does not take effect (which does not affect the runtime behavior). You are advised to use the method described in example 1 to define the array type.
- The maximum number of dimensions of an array is 6.
- The restrictions on the number of array elements are as follows:
  - The maximum number of elements is 134217727.
  - The maximum storage space of all elements cannot exceed 1 GB minus 1 byte, that is, 1073741823 bytes.

## Array Constructor

An array constructor is an expression that can build array values. A simple array constructor consists of the keyword ARRAY and an expression list of array element values which are separated by commas and enclosed (,) by square brackets ([]). For example:

```
gaussdb=# SELECT ARRAY[1, 2, 3 + 4];
array
-----
{1,2,7}
(1 row)
```

By default, the element type of an array is the common type of member expressions and is determined by the same rules as the UNION or CASE structure ([UNION, CASE, and Related Constructs](#)). You can construct an array to the desired data type through explicit type conversion. The following is an example:

```
gaussdb=# SELECT ARRAY[1, 2, 3]::varchar[];
array
-----
{1,2,3}
(1 row)

gaussdb=# SELECT ARRAY['a', 'b', 'c']::varchar[];
array
-----
{a,b,c}
(1 row)
```

In addition to the preset basic types, the record type and table type can also be defined as array types. The following is an example:

```
gaussdb=# CREATE TYPE rec IS (c1 int, c2 int);
gaussdb=# SELECT ARRAY[(1, 1), (2, 2)]::rec[];
array
-----
{"(1,1)","(2,2)"}
(1 row)
```

```
gaussdb=# CREATE TABLE tab (c1 int, c2 int);
gaussdb=# SELECT ARRAY[(1, 1), (2, 2)]::tab[];
      array
-----
{"(1,1)","(2,2)"}
(1 row)

gaussdb=# DROP TYPE rec;
gaussdb=# DROP TABLE tab;
```

An array must have a type. Therefore, when constructing an empty array, you must construct it as the required type. For example:

```
gaussdb=# SELECT ARRAY[]::int[];
      array
-----
{}
(1 row)
```

You can also construct an array from the result of a subquery. In this case, the array constructor consists of the keyword `ARRAY` and a subquery enclosed in parentheses. The subquery must return only one separate column. The generated one-dimensional array generates an element for each row of the result in the subquery. The element type matches the output column of the subquery. For example:

```
gaussdb=# SELECT ARRAY(SELECT generate_series(1, 6));
      array
-----
{1,2,3,4,5,6}
(1 row)
```

Multidimensional array values can be made by nesting array constructors. The `ARRAY` keyword in the inner constructor can be omitted. For example, the following two examples show the same result:

```
gaussdb=# SELECT ARRAY[ARRAY[1,2], ARRAY[3,4]];
      array
-----
{{1,2},{3,4}}
(1 row)

gaussdb=# SELECT ARRAY[[1,2], [3,4]];
      array
-----
{{1,2},{3,4}}
(1 row)
```

#### NOTE

- Inner constructors at the same layer must generate subarrays of the same dimension.
- Any type conversion applied to the outer `ARRAY` constructor is automatically applied to all inner constructors.

## String Inputs of the Array Type

To write an array value as a literal constant (constant input), enclose the element values with braces and separate them with commas. The general format of an array constant is as follows:

```
'{ val1 delim val2 delim ... }'
```

In the preceding format, **delim** indicates the delimiter of the element type and is recorded in the **typdelim** column in the `pg_type` catalog of the type. Each **val** can be a constant of the array element type or a subarray. For example:

```
gaussdb=# SELECT '{1, 2, 3}::int[] AS RESULT;
result
-----
{1,2,3}
(1 row)

gaussdb=# SELECT '{{1, 2, 3}, {4, 5, 6}, {7, 8, 9}}::int[] AS RESULT;
result
-----
{{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

Double quotation marks can be used around any element value, and double quotation marks must be used when the element value contains special characters such as commas or braces.

For example:

-- This example indicates that there is an array of the `varchar` type and there are seven `varchar` elements in total. The elements are as follows:

- Character string containing a space
- Character string whose value is **NULL**
- **NULL**
- Character string with a backslash (\)
- Character string with a left brace ({)
- Character string with a right brace (}) and a comma (,).

```
gaussdb=# SELECT '{" ", "NULL", null, "\\ ", "{", "}", ", "}'::varchar[] AS RESULT;
result
-----
{" ", "NULL", NULL, "\\ ", "{", "}", ", "}
(1 row)
```

#### NOTE

- For array string constant inputs, if the array element value is an empty string, contains braces, delimiters, double quotation marks, backslashes, or spaces, or matches the keyword `NULL`, then element inputs are enclosed in double quotation marks. An additional backslash is input if the element value contains double quotation marks or backslashes.
- The keyword `NULL` is case-insensitive.
- The input spaces not enclosed in double quotation marks are automatically skipped.
- You are advised to use the array constructor instead of character constants to construct array data.

## String Outputs of the Array Type

The output of an array value consists of the output of the array element type plus some modifiers indicating the array structure. These modifiers consist of braces ({}), around array values plus delimiters between adjacent items. In a multidimensional array, each dimension has its own level of braces and contains delimiters between adjacent braces at the same level.

The data of the array type contains special characters (in the following description). The following is an example of character string output:

```
gaussdb=# SELECT ARRAY[{' ', 'hello, world', '', '\', ' ', NULL}] AS RESULT;
          array
-----
{"{' ','hello, world',' ','\\',' ',' ',NULL}
(1 row)
```

#### NOTE

For array string constant outputs, if the array element value is an empty string or contains braces, delimiters, double quotation marks, backslashes, or spaces, or the element is NULL, then element outputs are enclosed in double quotation marks. An additional backslash is output if the element value contains double quotation marks or backslashes. This parameter corresponds to the string constant inputs.

## Use of Array Types

The following is an example of using the array type:

```
-- Create a table with array columns and insert some data.
gaussdb=# CREATE TABLE orders (
  name varchar,
  items varchar[]
);
gaussdb=# INSERT INTO orders VALUES('a', ARRAY['Apple', 'Orange', 'Pear']);
gaussdb=# INSERT INTO orders VALUES('b', ARRAY['Mineral water', 'Coke', 'Sprite']);
gaussdb=# INSERT INTO orders VALUES('c', ARRAY['Mouse', 'Keyboard', 'Earphone']);
gaussdb=# INSERT INTO orders VALUES('d', '{Cabbage, Potato, Eggplant}');

-- Query data.
gaussdb=# SELECT * FROM orders ORDER BY name;
 name | items
-----+-----
 a    | {Apple,Orange,Pear}
 b    | {Mineral water,Coke,Sprite}
 c    | {Mouse,Keyboard,Earphone}
 d    | {Cabbage,Potato,Eggplant}
(4 rows)

-- Access array elements.
gaussdb=# SELECT items[1] FROM orders ORDER BY name;
 items
-----
 Apple
Mineral water
 Mouse
Cabbage
(4 rows)

-- If the accessed element exceeds the range or the accessed index is NULL, NULL is returned.
gaussdb=# SELECT items[4] FROM orders ORDER BY name;
 items
-----

(4 rows)

gaussdb=# SELECT items[null] FROM orders ORDER BY name;
 items
-----

(4 rows)
```

```
-- Access a subarray.
gaussdb=# SELECT items[1:2] FROM orders ORDER BY name;
items
-----
{Apple,Orange}
{Mineral water,Coke}
{Mouse,Keyboard}
{Cabbage,Potato}
(4 rows)

-- Updates the entire array.
gaussdb=# UPDATE orders SET items = ARRAY['Banana', 'Watermelon', 'Strawberry'] WHERE name = 'a';
gaussdb=# SELECT items FROM orders WHERE name = 'a';
items
-----
{Banana,Watermelon,Strawberry}
(1 row)

-- Updates the elements of an array.
gaussdb=# UPDATE orders SET items[1] = 'Mango' WHERE name = 'a';
gaussdb=# SELECT items FROM orders WHERE name = 'a';
items
-----
{Mango,Watermelon,Strawberry}
(1 row)

-- Updates the element fragment of an array.
gaussdb=# UPDATE ORDERS SET items[1:2] = ARRAY['Computer', 'Mobile phone'] WHERE name = 'c';
gaussdb=# SELECT items FROM ORDERS WHERE name = 'c';
items
-----
{Computer,Mobile phone,Earphone}
(1 row)

-- Add an array element. All unassigned elements between the last element of the original array and the
new element are set to NULL.
gaussdb=# UPDATE orders SET items[4] = 'Display' WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
items
-----
{Computer,Mobile phone,Earphone,Display}
(1 row)

gaussdb=# UPDATE orders SET items[6] = 'Display 2' WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
items
-----
{Computer,Mobile phone,Earphone,Display,NULL,Display 2}
(1 row)
```

## 7.4 Character Sets and Collations

A character set provides character encoding rules, and a collation provides character sorting rules. This section describes the character sets and collations in MySQL-compatible GaussDB (**sql\_compatibility = 'MYSQL'**). The following character sets, collation rules, and syntax are supported only in MySQL-compatible mode:

For details about the character sets supported by GaussDB, see "ENCODING" in [CREATE DATABASE](#). For details about the supported collations, see the PG\_COLLATION system catalog.

Some character sets have default collations in MySQL-compatible mode. For details, see [Table 7-240](#).

The character set and collations are described as follows:

- Each character set has one or more collations and has only one default collation.
- Each collation has only one associated character set.
- The sorting results of the same data using different collations may be different.
- In GaussDB, utf8mb4 and utf8 are the same character set.
- When **sql\_compatibility** is set to 'MYSQL', the BINARY and SQL\_ASCII character sets are the same.
- You are advised to select the same character set for table columns and server\_encoding to avoid performance loss caused by transcoding.

GaussDB supports the following functions:

- Multiple character sets can be used to store character strings.
- Collations can be used to compare character strings.
- Database-level, schema-level, table-level, and column-level character sets and collations are supported.

 **NOTE**

Character strings with different character sets and collations cannot be used in the same server, database, table, or SQL statement.

## 7.4.1 Character Sets and Collations of the Client Connection

When data containing character set attributes is transmitted between the server and client, encoding conversion is automatically performed. After receiving an SQL statement from a client, the server converts the character set of the SQL statement from the client character set `client_encoding` to the database character set `server_encoding`. Before the query result data is sent to the client, the data is encoded and converted to the `client_encoding` character set of the client.

### System parameters:

- `server_encoding`  
Character set specified during database creation. For details, see [CREATE DATABASE](#).
- `client_encoding`  
Character set of the client, which can be modified using the SET NAMES statement. For details, see [SET](#). For details about the parameter, see **client\_encoding** in "Configuring GUC Parameters > GUC Parameters > Locale and Formatting" in *Administrator Guide*.
- `character_set_connection`  
Default character set of string constants for which no character sets are specified in SQL statements. For details about the parameter, see **character\_set\_connection** in "Configuring GUC Parameters > GUC Parameters > Locale and Formatting" in *Administrator Guide*.
- `collation_connection`  
Default collation of string constants for which no collations are specified in SQL statements. For details about the parameter, see **collation\_connection** in

"Configuring GUC Parameters > GUC Parameters > Locale and Formatting" in *Administrator Guide*.

- `character_set_results`

Character set of the returned result. For details about the parameter, see **`character_set_results`** in "Configuring GUC Parameters > GUC Parameters > Locale and Formatting" in *Administrator Guide*.

#### NOTE

- For an expression that converts a non-character type object to a character type, the result character set and collation are **`character_set_connection`** and **`collation_connection`**, respectively.
- By default, the character set and collation number of a binding parameter of the character type are the values of **`character_set_connection`** and **`collation_connection`**, respectively.
- During character data conversion, the character encoding is verified. If the character encoding does not meet the requirements, an error message is displayed.

## 7.4.2 Database-level Character Sets and Collations

When creating a database, you can specify the character set and collation of the database.

```
CREATE DATABASE [IF NOT EXISTS] database_name
  [ ENCODING [=] encoding ] |
  [ LC_COLLATE [=] lc_collate ] |
  [ LC_CTYPE [=] lc_ctype ] ;
```

#### Parameters:

- **`database_name`**

Specifies the database name.

Value range: a string. It must comply with the naming convention.

- **`ENCODING [=] encoding`**

Specifies the character encoding used by the database. The value can be a string (for example, 'SQL\_ASCII') or an integer.

- **`LC_COLLATE [=] lc_collate`**

Specifies the character set used by the new database. For example, set this parameter by using `lc_collate = 'zh_CN.gb18030'`.

The use of this parameter affects the sort order of strings (for example, the order of using ORDER BY for execution and the order of using indexes on text columns). By default, the sorting order of the template database is used.

Value range: character sets supported by the OS.

- **`LC_CTYPE [=] lc_ctype`**

Specifies the character class used by the new database. For example, set this parameter by using `lc_ctype = 'zh_CN.gb18030'`. The use of this parameter affects the character class, such as uppercase letters, lowercase letters, and digits. By default, the character class of the template database is used.

Value range: character classes supported by the OS.

 NOTE

- The database-level character set and collation syntax can be used in all modes. For details about the syntax, see [CREATE DATABASE](#).
- The LC\_COLLATE/LC\_CTYPE syntax does not support the collations specific to MySQL-compatible mode. The parameter value range depends on the character sets supported by the local environment. You can run the `locale -a` command to view the parameter value range.

## 7.4.3 Schema-level Character Sets and Collations

Create a schema and specify the default character set and collation.

```
CREATE SCHEMA schema_name  
  [ [DEFAULT] CHARACTER SET | CHARSET [=] default_charset ]  
  [ [DEFAULT] COLLATE [=] default_collation ];
```

Modify the default character set and collation attributes of the schema.

```
ALTER SCHEMA schema_name  
  [ [DEFAULT] CHARACTER SET | CHARSET [=] default_charset ] [ [DEFAULT] COLLATE [=]  
  default_collation ];
```

### Parameter description:

- **schema\_name**  
Specifies the schema name.  
Value range: a string. It must comply with the [naming convention](#).
- **default\_charset**  
Specifies the default character set of a schema. If you specify a character set separately, the default collation of the schema is set to the default collation of the specified character set.
- **default\_collation**  
Specifies the default collation of a schema. If you specify a collation separately, the default character set of the schema is set to the character set corresponding to the specified collation.

GaussDB selects a character set and collation of a schema in the following ways:

- If both **default\_charset** and **default\_collation** are set, the character set **default\_charset** and collation **default\_collation** are used. In addition, **default\_charset** and **default\_collation** must correspond to each other. Otherwise, an error is reported.
- If only **default\_charset** is set, the character set **default\_charset** and its default collation are used.
- If only **default\_collation** is set, the collation **default\_collation** and its corresponding character set are used.
- If neither **default\_charset** nor **default\_collation** is specified, the schema has no default character set or default collation.

 NOTE

- Only character sets with a default collation support **default\_charset**. If the specified character set does not have a default collation, an error is reported.
- Only the collations in MySQL-compatible mode (**sql\_compatibility = 'MYSQL'**) support **default\_collation**. If another collation is specified, an error is reported.
- The character set and collation of the new schema must be **server\_encoding** of the database.

**Example:**

```
-- Set only the character set. The collation is the default collation of the character set.
gaussdb=# CREATE SCHEMA test CHARSET utf8;

-- Set only the collation. The character set is the character set associated with the collation.
gaussdb=# CREATE SCHEMA test COLLATE utf8_bin;

-- Set both the character set and collation. The character set and collation must correspond to each other.
gaussdb=# CREATE SCHEMA test CHARSET utf8 COLLATE utf8_bin;

-- Change the default character set of test to utf8mb4 and the default collation to utf8mb4_bin.
gaussdb=# ALTER SCHEMA test CHARSET utf8mb4 COLLATE utf8mb4_bin;
```

## 7.4.4 Table-level Character Sets and Collations

Set the default character set and default collation for a table.

```
CREATE TABLE table_name (column_list)
  [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ]
  [ [DEFAULT] COLLATE [ = ] default_collation ]
```

Modify the default character set and collation of a table. The modification does not affect the existing columns in the table.

```
ALTER TABLE table_name
  [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ]
  [ [DEFAULT] COLLATE [ = ] default_collation ]
```

 NOTE

Currently, you cannot modify the default character set and collation of a table to the specified values, set the character set and collation of all columns with character type to the specified value, or convert the data in the column to new character set encoding. The syntax is as follows:

```
ALTER TABLE table_name
  CONVERT TO CHARACTER SET | CHARSET charset [ COLLATE collation ]
```

**Parameters**

- **table\_name**  
Specifies the name of the table.
- **default\_charset**  
Specifies the default character set of a table. If you specify a character set separately, the default collation of the table is set to the default collation of the specified character set.
- **default\_collation**  
Specifies the default collation of a table. If you specify a collation separately, the default character set of the table is set to the character set corresponding to the specified collation.

GaussDB selects a character set and collation of a table in the following ways:

- If both **default\_charset** and **default\_collation** are set, the character set **default\_charset** and collation **default\_collation** are used. In addition, **default\_charset** and **default\_collation** must correspond to each other. Otherwise, an error is reported.
- If only **default\_charset** is set, the character set **default\_charset** and its default collation are used.
- If only **default\_collation** is set, the collation **default\_collation** and its corresponding character set are used.
- If neither **default\_charset** nor **default\_collation** is set, the default character set and collation of the schema where the table is located are used as the default character set and collation of the table.

**NOTE**

- Only character sets with a default collation support **default\_charset**. If the specified character set does not have a default collation, an error is reported.
- Only the collations in MySQL-compatible mode (**sql\_compatibility = 'MYSQL'**) support **default\_collation**. If another collation is specified, an error is reported.
- If the default collation of a table is binary, the text types whose collation is not specified in the table are converted to the corresponding binary type, and the collation is set to binary.
- Currently, the default character set and collation of a table must be server\_encoding of the database.
- Currently, the data of columns of the character type in the table cannot be converted into encoding.

**Example:**

```
-- Set only the character set. The collation is the default collation of the character set.
gaussdb=# CREATE TABLE test(c1 text) CHARSET utf8;

-- Set only the collation. The character set is the character set associated with the collation.
gaussdb=# CREATE TABLE test(c1 text) COLLATE utf8_bin;

-- Set both the character set and collation. The character set and collation must correspond to each other.
gaussdb=# CREATE TABLE test(c1 text) CHARSET utf8 COLLATE utf8_bin;

-- Change the default character set of the table to utf8mb4 and the default collation to utf8mb4_bin.
gaussdb=# ALTER TABLE test CHARSET utf8mb4 COLLATE utf8mb4_bin;
```

## 7.4.5 Column-level Character Sets and Collations

You can set the character set and collation for each column of the string type (CHAR, VARCHAR, or TEXT).

```
CREATE TABLE table_name (
  column_name data_type
  [ CHARACTER SET | CHARSET charset ]
  [ COLLATE collation ]
);
```

**Syntax description:**

- **table\_name**  
Specifies the name of the table.
- **data\_type**  
Specifies the data type of a column. The value can be character set or collation syntax.

- **CHARACTER SET | CHARSET charset**  
Specifies the character set of a table column. If this parameter is specified separately, the collation of the table column is set to the default collation of the specified character set.
- **COLLATE collation**  
The COLLATE clause specifies the collation of a column (the data type of the column must support collation). If no collation is specified, the default collation is used.

GaussDB selects a character set and collation of a table column in the following ways:

- If both **charset** and **collation** are specified, **charset** and **collation** are used. **charset** and **collation** must correspond to each other. Otherwise, an error is reported.
- If only **charset** is specified, the character set **charset** and its default collation are used.
- If only **collation** is specified, the character set associated with collation and the specified collation are used.
- If neither **charset** nor **collation** is specified, the default character set and collation of the table are used.

#### NOTE

- Only character sets with a default collation support **default\_charset**. If the specified character set does not have a default collation, an error is reported.
- Only the collations in MySQL-compatible mode support **default\_collation**. If another collation is specified, an error is reported.
- If a table column is of the text type and the specified collation is binary, the text type is converted to the corresponding binary type and the collation is the specified binary collation.
- The character set of the partition key of the partitioned table must be the same as that of the database.
- Currently, the default character set and collation of a table column must be `server_encoding` of the database.

#### Example:

```
-- Set only the character set. The collation is the default collation of the character set.
gaussdb=# CREATE TABLE test(c1 text CHARSET utf8);

-- Set only the collation. The character set is the character set associated with the collation.
gaussdb=# CREATE TABLE test(c1 text COLLATE utf8_bin);

-- Set both the character set and collation. The character set and collation must correspond to each other.
gaussdb=# CREATE TABLE test(c1 text CHARSET utf8 COLLATE utf8_bin);
```

## 7.4.6 Character Sets and Collations of Expressions of the String Type

Each expression of the string type contains character sets and collation attributes.

In MySQL-compatible mode (`sql_compatibility` is set to 'MYSQL'), if `b_format_version` is set to '5.7' and `b_format_dev_version` is set to 's2', the default character sets and collations of string constants are determined by the system parameters `character_set_connection` and `collation_connection`.

Otherwise, the default character set is the same as `server_encoding` of the database, and the default collation is **default**.

#### Character set syntax:

GaussDB does not support the character set of string constants specified by the following syntax:

```
[_charset_name]'string'
```

#### Collation syntax:

You can also specify the collation for expressions of other character string types.

```
EXPRESSION [COLLATE collation_name]
```

#### Parameters:

##### COLLATE collation\_name

Collation name, which is the collation attribute of the string.

- The data type of the expression must be a data type that supports collations.
- The specified collation must be supported by the character set of the expression.

#### Example:

```
-- Use the COLLATE statement to specify the collation.  
gaussdb=# SELECT 'a' COLLATE utf8mb4_general_ci = 'A';
```

## 7.4.7 Rules for Combining Character Sets and Collations

In MySQL-compatible database (`sql_compatibility = 'MYSQL'`), if `b_format_version` is set to '5.7' and `b_format_dev_version` is set to 's2', expressions with different character sets and collations are processed based on certain priorities to determine the collations used for character string comparison and the character sets of the expressions.

#### Collation priority

The priorities of different expressions in descending order are as follows:

- The COLLATE syntax has the highest priority.
- Expressions with collation conflicts (for example, two character strings with different collations).
- Columns of data types that support collation, user-defined variables, stored procedure parameters, and CASE expressions.
- Specific system functions (such as `version()` and `opengauss_version()` function expressions).
- String constants and bound parameters.
- NULL expression.
- If a data type of an expression does not support collation, the expression has the lowest priority.

When the collations of two expressions are different, the collation of the expression with the highest priority is used.

#### Example:

```
gaussdb=# CREATE TABLE t_utf8(c1 varchar(16) character set utf8mb4 collate utf8mb4_bin);
gaussdb=# INSERT INTO t_utf8 VALUES('STRING');

-- If the utf8mb4_bin collation is used for comparison, the result is false.
gaussdb=# SELECT c1 = 'string' AS result FROM t_utf8;
result
-----
f
(1 row)

-- If the utf8mb4_general_ci collation is used for comparison, the result is true.
gaussdb=# SELECT c1 = 'string' COLLATE utf8mb4_general_ci AS result FROM t_utf8;
result
-----
t
(1 row)

-- Define the collation of the bound parameter $1 as collation_connection.
gaussdb=# PREPARE test_collation(text) AS SELECT c1 = $1 AS result FROM t_utf8;

-- The collation of the bound parameter is at the same level as that of the string constant. Even if the input
expression contains an explicit collation, the collation of c1 is still used for comparison.
gaussdb=# EXECUTE test_collation('string' COLLATE utf8mb4_general_ci);
result
-----
f
(1 row)

-- The CASE expression is at the same level as the c1 column. Even if the expression contains an explicit
collation, the collation of the c1 column is still used for comparison. The two collations are different. "same
level" is displayed.
gaussdb=# SELECT CASE 'string' COLLATE utf8mb4_general_ci WHEN c1 THEN 'different level' ELSE 'same
level' END AS result FROM t_utf8;
result
-----
same level
(1 row)

-- The IN subquery has the same level as the c1 column. Even if the expression contains an explicit
collation, the collation of c1 is still used for comparison. The two collations are different.
gaussdb=# SELECT c1 FROM t_utf8 WHERE c1 in (SELECT 'string' COLLATE utf8mb4_general_ci);
c1
----
(0 rows)
```

If the collations of two expressions with the same priority are different, the following processing method is used:

- If the two character sets are the same, the collation suffixed with **\_bin** is preferred.
- If the two character sets are the same, the default collation is not preferred.
- If the preceding conditions are not met, the two expressions are marked as a collation conflict, and the collations are marked as invalid.
  - If a conflict occurs because the COLLATE syntax specifies different collations for the same character set, an exception is displayed.
  - If the two conflicting collations are supported in MySQL-compatible mode (**sql\_compatibility = 'MYSQL'**), an exception occurs.
  - If the conflicting character set is different from server\_encoding of the database, an exception occurs.
  - If an invalid collation is used for sorting operations (such as > and <), an exception occurs.
  - During equivalent comparison of character strings, if the collation is invalid, the character strings are compared as binary values.

**Example:**

```
gaussdb=# CREATE TABLE t_utf8mb4_charset(
  c_utf8_bin varchar(16) character set utf8mb4 collate utf8mb4_bin,
  c_utf8_uni varchar(16) character set utf8mb4 collate utf8mb4_unicode_ci,
  c_utf8_gen varchar(16) character set utf8mb4 collate utf8mb4_general_ci);
gaussdb=# INSERT INTO t_utf8mb4_charset VALUES('STRING', 'String', 'string');

-- The utf8mb4_bin collation is preferentially used for comparison. The result is false.
gaussdb=# SELECT c_utf8_bin = c_utf8_uni FROM t_utf8mb4_charset;

-- Collation conflict. Binary comparison is performed, and the result is false.
gaussdb=# SELECT c_utf8_uni = c_utf8_gen FROM t_utf8mb4_charset;

-- Conflict of the explicitly specified collation. An exception is reported.
gaussdb=# SELECT c_utf8_uni COLLATE utf8mb4_unicode_ci = c_utf8_gen COLLATE utf8mb4_general_ci
FROM t_utf8mb4_charset;
```

 **NOTE**

- Only the character sets of objects and expressions of the string type (excluding "char", name, and clob) can be different from those of the database.
- Data types such as ARRAY, XML, JSON, and TSVECTOR contain text data. The character sets in the text data of the objects and expressions of these data types must be the character sets of the database.
- According to the rules for combining character sets and collations, the character sets corresponding to C, POSIX, and DEFAULT collations are server\_encoding.

## 7.5 Constant and Macro

[Table 7-25](#) lists the constants and macros that can be used in GaussDB.

**Table 7-25** Constant and macro

Parameter	Description	Example
CURRENT_CATALOG	Specifies the current database.	testdb=# SELECT CURRENT_CATALOG; current_database ----- testdb (1 row)
CURRENT_ROLE	Specifies the current user.	gaussdb=# SELECT CURRENT_ROLE; current_user ----- omm (1 row)
CURRENT_SCHEMA	Specifies the current database mode.	gaussdb=# SELECT CURRENT_SCHEMA; current_schema ----- public (1 row)
CURRENT_USER	Specifies the current user.	gaussdb=# SELECT CURRENT_USER; current_user ----- omm (1 row)

Parameter	Description	Example
LOCALTIMESTAMP	Specifies the current session time (without time zone).	<pre>gaussdb=# SELECT LOCALTIMESTAMP; timestamp ----- 2015-10-10 15:37:30.968538 (1 row)</pre>
NULL	This parameter is left blank.	N/A
SESSION_USER	Specifies the current system user.	<pre>gaussdb=# SELECT SESSION_USER; session_user ----- omm (1 row)</pre>
SYSDATE	Specifies the current system date.	<pre>gaussdb=# SELECT SYSDATE; sysdate ----- 2015-10-10 15:48:53 (1 row)</pre>
USER	Specifies the current user, also called <b>CURRENT_USER</b> .	<pre>gaussdb=# SELECT USER; current_user ----- omm (1 row)</pre>

## 7.6 Functions and Operators

Operators can be used to process one or more operands and can be placed before, after, or between operands. Results are returned after the processing.

Functions encapsulate service logic to implement specific functions. A function may or may not have parameters. After a function is executed, the result is returned.

Users can modify system functions. However, after the modification, the meaning of the functions may change, which results in disorder in system control. Therefore, users are not allowed to manually modify system functions.

### NOTE

When the GUC parameter **behavior\_compat\_options** contains the 'enable\_funcname\_with\_argname' option, the projection alias displays the complete function.

### 7.6.1 Logical Operators

Common logical operators include AND, OR, and NOT. The operation result has three values: **TRUE**, **FALSE**, and **NULL**. NULL indicates unknown. Their priorities are NOT > AND > OR.

**Table 7-26** lists the calculation rules, where a and b represent logical expressions.

**Table 7-26** Operation rules

a	b	a AND b Result	a OR b Result	NOT a Result
TRUE	TRUE	TRUE	TRUE	FALSE
TRUE	FALSE	FALSE	TRUE	FALSE
TRUE	NULL	NULL	TRUE	FALSE
FALSE	FALSE	FALSE	FALSE	TRUE
FALSE	NULL	FALSE	NULL	TRUE
NULL	NULL	NULL	NULL	NULL

 **NOTE**

- The operators AND and OR are commutative, that is, you can switch the left and right operand without affecting the result.
- Operations on XML data are not supported.

## 7.6.2 Comparison Operators

Comparison operators are available for the most data types and return Boolean values.

All comparison operators are binary operators. Only data types that are the same or can be implicitly converted can be compared using comparison operators.

[Table 7-27](#) describes comparison operators provided by GaussDB.

**Table 7-27** Comparison operations

Operator	Description
<	Less than
>	Greater than
<=	Less than or equal to
>=	Greater than or equal to
=	Equal to
<>, !=, or ^=	Not equal to

- For comparison operators <=, <>, >=, and ^=, if there is a space between two symbols, it does not affect normal operations. For !=, if there is a space between the exclamation mark (!) and an equal sign (=), the exclamation mark will be identified as factorial, which may cause the result to be inconsistent with the expected result.

- Comparison operators are available for all relevant data types. All comparison operators are binary operators that returned values of Boolean type. The calculation priority of the inequality sign is higher than that of the equality sign. If the entered data type is different and cannot be implicitly converted, the comparison fails. For example, an expression such as **1 < 2 < 3** is invalid because the less-than sign (<) cannot be used to compare Boolean values and 3.
- Besides, each comparison operator has a corresponding function in the pg\_proc system catalog. If the value of the **proleakproof** attribute of the corresponding function is **f**, the function is not used to prevent data leakage. If a user only has the permission for a system view, but does not have the permission for the corresponding table, the query plan may not be optimal when the user searches the system view.
- This operator does not support data of the XML type.

### 7.6.3 Character Processing Functions and Operators

String functions and operators provided by GaussDB are for concatenating strings with each other, concatenating strings with non-strings, and matching the patterns of strings. Note: Except length-related functions, other functions and operators of string processing functions do not support parameters of CLOB whose size is greater than 1 GB.

- **bin(number)**  
Description: Returns a binary string of a given number.

Parameter	Type	Description
number	<ul style="list-style-type: none"> <li>Integer types: tinyint, smallint, mediumint, int, and bigint.</li> <li>Unsigned integer types: tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned.</li> <li>Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range.</li> <li>Floating-point types: float, real, and double.</li> <li>Fixed-point types: numeric, decimal, and dec.</li> <li>Boolean type: bool.</li> </ul>	Given number.

Return type: text.

Example:

```
gaussdb=# SELECT bin(5);
 bin
-----
 101
(1 row)
```

 **NOTE**

- The bin function takes effect only when **sql\_compatibility** is set to 'MYSQL'.
  - If the value of the input parameter **number** is a decimal, round it down.
  - If the absolute value of the input parameter **number** exceeds the maximum value of the bigint unsigned type, convert the input parameter **number** to the maximum value of the bigint unsigned type.
- **bit\_length(string)**  
Description: Specifies the number of bits occupied by a string.  
Return type: int.  
Example:

```
gaussdb=# SELECT bit_length('world');
 bit_length
-----
         40
(1 row)
```

- `btrim(string text [, characters text])`

Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start and end of **string**.

Return type: text.

Example:

```
gaussdb=# SELECT btrim('sring', 'ing');
 btrim
-----
sr
(1 row)
```

- `char_length(string) or character_length(string)`

Description: Specifies the number of characters in a string.

Return type: int.

Example:

```
gaussdb=# SELECT char_length('hello');
 char_length
-----
          5
(1 row)
```

- `dump(expr[, return_fmt [, start_position [, length ] ] ])`

Description: Returns the data type code, byte length, and internal representation of the input expression. **return\_fmt** specifies the number system of the internal representation, **start\_position** specifies the byte from which the internal representation starts, and **length** indicates the length of the data to be read.

Return type: text.

#### NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `elt(pos,str1,str2,...)`

Description: Returns the *pos*th string.

Parameter	Type	Description
pos	<ul style="list-style-type: none"> <li>• Integer types: tinyint, smallint, mediumint, int, and bigint.</li> <li>• Unsigned integer types: tinyint unsigned, smallint unsigned, and int unsigned.</li> <li>• Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range.</li> <li>• Floating-point types: float, real, and double.</li> <li>• Fixed-point types: numeric, decimal, and dec.</li> <li>• Boolean type: bool.</li> </ul>	Specified position of the parameter.

Parameter	Type	Description
str1,str2,...	<ul style="list-style-type: none"> <li>Integer types: tinyint, smallint, mediumint, int, and bigint.</li> <li>Unsigned integer types: tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned.</li> <li>Character and text types: char, varchar, tinytext, text, mediumtext, and longtext.</li> <li>Floating-point types: float, real, and double.</li> <li>Fixed-point types: numeric, decimal, and dec.</li> <li>Boolean type: bool.</li> <li>Large object types: tinyblob, blob, mediumblob, and longblob.</li> <li>Date types: datetime, timestamp, date, and time.</li> </ul>	List of character strings.

Return type: text.

Example:

```
gaussdb=# SELECT elt(3, 'a', 'b', 'c');
elt
-----
c
(1 row)
```

 **NOTE**

- The elt function takes effect only when **sql\_compatibility** is set to 'MYSQL'.
- If the input parameter **pos** is less than 1 or exceeds the number of parameters, **NULL** is returned.
- field(str,str1,str2,str3,...)

Description: The field function returns the position of **str** in the {str1,str2,str3,...} list. The position increases from 1. If **0** is returned, **str** is not found. If **str** is **NULL**, **0** is returned. If the input parameters of a function are

all digits, the comparison is performed based on digits. If the input parameters are all non-digits, the comparison is performed based on character strings. If the input parameters contain both digits and non-digits, the comparison is performed based on the double type.

Parameter	Type	Description
str,str1, str2,str3, ..	<ul style="list-style-type: none"> <li>Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned.</li> <li>Boolean types: true and false.</li> <li>Floating-point types: float(p), float, real, double, float(m, d), double(m, d), and real(m, d).</li> <li>Fixed-point types: numeric, decimal, and dec.</li> <li>Text types: tinytext, text, mediumtext, and longtext.</li> <li>Character string types: char and varchar.</li> <li>Large object types: tinyblob, blob, mediumblob, and longblob.</li> <li>Date types: datetime, timestamp, date, and time.</li> </ul>	List of character strings.

Return type: int.

Example:

```
gaussdb=# SELECT field( 'abc','1',1,'abc','abcd' );
field
-----
3
(1 row)
```

 NOTE

- The field function takes effect only when **sql\_compatibility** is set to 'MYSQL'.
  - Since the version whose **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1', the sql\_mode parameter **pad\_char\_to\_full\_length** specifies whether to add spaces at the end of the char type, which affects the field comparison result. For details, see [Table 7-8](#).
  - Since the version whose **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1', the behavior of the character, binary, numeric, and date and time types is M-compatible, which affects the field comparison result. For details, see [Data Types](#). For the floating-point type in the numeric type, the precision may be different from that in MySQL due to different connection parameter settings. Therefore, this scenario is not recommended, or the numeric type is used instead. For details, see [Connection Parameters](#).
  - Since the version whose **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's2', characters can be escaped and constant character strings can obtain collations. The collations affect the field comparison result. For details, see the SET NAMES syntax in [SET](#). For details about the rules for combining different collations of the character types, see [Rules for Combining Character Sets and Collations](#).
- insert(str1, pos, len, str2)

Description: Returns the processing result of *str1*. The substring starts from *pos* and the number of *len* characters in the character string is replaced with *str2*. If any input parameter is **NULL**, the return value is **NULL**.

Parameter	Type	Description
pos, len	<ul style="list-style-type: none"> <li>• Integer types: tinyint, smallint, mediumint, int, and bigint.</li> <li>• Unsigned integer types: tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned.</li> <li>• Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported.</li> <li>• Floating-point types: float, real, and double.</li> <li>• Fixed-point types: numeric, decimal, and dec.</li> </ul>	<p><b>pos</b> indicates the parameter in the specified position, and <b>len</b> indicates the replacement length.</p>

Parameter	Type	Description
str1, str2	<ul style="list-style-type: none"> <li>• NULL.</li> <li>• Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. However, the integer value exceeds the range from 81 negative nines to 81 positive nines, and the return value is different from that of MySQL. This difference is an inherent difference between GaussDB and MySQL and is not caused by this function.</li> <li>• Floating-point and fixed-point types: float, real, and double for floating-point types; numeric, decimal, and dec for fixed-point types. However, when the value is expressed in scientific notation, the trailing zeros in GaussDB are displayed, and those in M* are not displayed. The value is printed in scientific notation. This is an inherent display difference and is not caused by this function.</li> <li>• Character string types: char and varchar.</li> <li>• Text types: tinytext, text, mediumtext, and longtext.</li> </ul>	String.

Parameter	Type	Description
	<ul style="list-style-type: none"> <li>Large object types: tinyblob, blob, mediumblob, and longblob.</li> <li>Date types: datetime, timestamp, date, and time.</li> </ul>	

Return value type: The return value of the function is of the text type (both **s1** and **s2** are of the text type) or bytea type (any of **s1** or **s2** is of the bytea type).

Example:

```
gaussdb=# SELECT INSERT('abcdef',2,3,'gg');
insert
-----
aggef
(1 row)
```

 NOTE

- The insert function takes effect only when **sql\_compatibility** is set to 'MYSQL'.
- The value range of the input parameter of the Int64 type is limited. If the value exceeds the value range of -9223372036854775808 to 9223372036854775807, an error is reported. MySQL has no restriction on the range of input parameters of the numeric type. If an exception occurs, an alarm is generated and the upper or lower limit is used. Input parameters of the character string are restricted. The maximum length of the input parameter of the text type is  $2^{30} - 5$  bytes, and the maximum length of the input parameter of the bytea type is  $2^{30} - 512$  bytes.

- **instr(text,text,int,int)**

Description: **instr(string1,string2,int1,int2)** returns the position matching *string2* in *string1* for the *int2*th time from the position specified by *int1*. *int1* indicates the start position for matching, and *int2* indicates the number of matching times.

Return type: int.

Example:

```
gaussdb=# SELECT instr( 'abcdabcdabcd', 'bcd', 2, 2 );
instr
-----
6
(1 row)
```

- **instrb(text,text,int,int)**

Description: **instrb(string1,string2,int1,int2)** returns the position matching *string2* in *string1* for the *int2*th time from the position specified by *int1*. *int1* indicates the start position for matching, and *int2* indicates the number of matching times. Different from the instr function, instrb is calculated in bytes and is not affected by the character set in use.

Return type: int.

Example:

```
gaussdb=# SELECT instrb( 'abcdabcdabcd', 'bcd', 2, 2 );
instrb
-----
      6
(1 row)
```

 **NOTE**

- This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s1** in an ORA-compatible database.
- If the values of *int1* and *int2* are decimals, the values are truncated instead of being rounded off.

- **lengthb(text/bpchar)**

Description: Obtains the number of bytes of a specified string.

Return type: int.

Example:

```
gaussdb=# SELECT lengthb('hello');
lengthb
-----
      5
(1 row)
```

- **left(str text, n int)**

Description: Returns the first *n* characters in a string. When *n* is negative, all but the last */n/* characters are returned.

Return type: text.

Example:

```
gaussdb=# SELECT left('abcde', 2);
left
-----
ab
(1 row)
```

- **length(string bytea, encoding name)**

Description: Specifies the number of characters in **string** in the given **encoding**. The **string** must be valid in this encoding.

Return type: int.

Example:

```
gaussdb=# SELECT length('jose', 'UTF8');
length
-----
      4
(1 row)
```

 **NOTE**

If the length of the bytea type is queried and UTF8 encoding is specified, the maximum length can only be **536870888**.

- **locate(substr, str[, pos])**

Description: Returns the position where *substr* appears for the first time in *str*, starting from *pos* (1 by default). If *substr* cannot be found in *str*, this function returns **0**.

Parameter	Type	Description
substr, str	<ul style="list-style-type: none"> <li>Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned.</li> <li>Floating-point types: float and double.</li> <li>Arbitrary precision type: numeric.</li> <li>Character types: char, varchar, and text.</li> <li>Binary types: bytea and blob.</li> <li>Date/Time types: date, time, datetime, and timestamp.</li> </ul>	<ol style="list-style-type: none"> <li><b>substr</b> (required): substring to be searched for.</li> <li><b>str</b> (required): character string to be searched for.</li> </ol>
pos	<ul style="list-style-type: none"> <li>Integer types: tinyint, smallint, mediumint, int, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned.</li> <li>Floating-point types: float and double.</li> <li>Arbitrary precision type: numeric.</li> <li>Character types: char, varchar, and text.</li> <li>Boolean types: true and false.</li> </ul>	(Optional) Start position of the search.

Return type: int.

Example:

```
gaussdb=# SELECT locate( 'b','abcabc');
locate
-----
      2
(1 row)
```

```
gaussdb=# SELECT locate( 'b','abcabc',3);
locate
-----
      5
(1 row)
```

 **NOTE**

The locate function takes effect only when **sql\_compatibility** is set to 'MYSQL'.

- `lpad_s(string text, length int [, fill text])`

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If the length of **string** is longer than **length**, an error is reported.

Return type: text.

 NOTE

In the scenario where this function is in an ORA-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on ORA-compatible requirements.
- During the function execution, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the left of the string.
- If the value of **length** is a decimal, the value is rounded down instead of being rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.

In other cases:

- The **length** parameter indicates the total length of characters in a character string. The length of a single character is fixed to 1.
  - If the value of **length** is a decimal, the value is rounded off.
  - The **string** and **fill** parameters do not comply with the encoding specifications.
- `lpad(string text, length int [, fill text])`

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

Return type: text.

 NOTE

In the scenario where this function is in an ORA-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on ORA-compatible requirements.
- During the function execution, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the left of the string.
- If the value of **length** is a decimal, the value is rounded down instead of being rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.

In other cases:

- The **length** parameter indicates the total length of characters in a character string. The length of a single character is fixed to 1.
  - If the value of **length** is a decimal, the value is rounded off.
  - The **string** and **fill** parameters do not comply with the encoding specifications.
- `make_set(bits,str1,str2...)`

Description: **str1** corresponds to bit 0 of the bits input parameter in the bit format, **str2** corresponds to bit 1, and so on. If the lower bit of the corresponding bit form is **1**, the corresponding **str** parameter is appended to the result and returned with a comma as the separator.

Parameter	Type	Description
make_set	<ul style="list-style-type: none"> <li>• The input parameter <b>bits</b> supports the following types:               <ul style="list-style-type: none"> <li>– NULL.</li> <li>– Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned.</li> <li>– Floating-point and fixed-point types: float, real, and double; numeric, decimal, and dec.</li> <li>– Bit type: bit. GaussDB does not fully support the bit type. In the code design, when input parameter <b>1</b> is a hexadecimal number, for example, "x'FFF'", and the length is an odd number, MySQL reports an error.</li> <li>– Character string types: char and varchar. Only integer strings are supported. For strings containing decimals, the returned results are different because the rounding rule is different from that of M*. The character string consisting of digits and letters is not supported. The value range of an integer string is in the value range of a value of the bigint type.</li> <li>– Text types: tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range. If the integer range is exceeded, the returned result is different from that in MySQL. The returned results of character strings with decimal places are different from those of MySQL due to different rounding rules. The text type combined by digits and letters is not supported. The value range of an integer string is in the value</li> </ul> </li> </ul>	<p>The returned result consists of some character strings selected from <i>str1, str2, ..., strN</i> and separated by commas (,).</p>

Parameter	Type	Description
	<p>range of a value of the bigint type.</p> <ul style="list-style-type: none"> <li>- Large object types: tinyblob, blob, mediumblob, and longblob.</li> <li>• The input parameter <b>str</b> supports the following types: <ul style="list-style-type: none"> <li>- <b>NULL</b></li> <li>- Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. However, the integer value exceeds the range from 81 negative nines to 81 positive nines, and the return value is different from that of MySQL. This difference is an inherent difference between GaussDB and M* and is not caused by this function.</li> <li>- Floating-point and fixed-point types: float, real, and double for floating-point types; numeric, decimal, and dec for fixed-point types. However, when the value is expressed in scientific notation, the trailing zeros in GaussDB are displayed, and those in MySQL are not displayed. The value is printed in scientific notation. This is an inherent display difference and is not caused by this function.</li> <li>- Character string types: char and varchar.</li> <li>- Text types: tinytext, text, mediumtext, and longtext.</li> <li>- Large object types: tinyblob, blob, mediumblob, and longblob.</li> <li>- Date types: datetime, timestamp, date, and time.</li> </ul> </li> </ul>	

Return type: text.

```
gaussdb=# SELECT overlay('hello' placing 'world' from 2 for 3 );
overlay
-----
hworldo
(1 row)
```

- `position(substring in string)`

Description: Specifies the position of a substring. Parameters are case-sensitive.

Return type: int. If the character string does not exist, **0** is returned.

Example:

```
gaussdb=# SELECT position('ing' in 'string');
position
-----
         4
(1 row)
```

- `pg_client_encoding()`

Description: Specifies the current client encoding name.

Return type: name

Example:

```
gaussdb=# SELECT pg_client_encoding();
pg_client_encoding
-----
UTF8
(1 row)
```

- `quote(str)`

Description: Returns a string enclosed in single quotation marks and adds a backslash (\) before the instances of backslashes (\), single quotation marks ('), ASCII NUL (\0), and Control+Z (\Z). If the parameter is **NULL**, the return value is **NULL** without single quotation marks.

Parameter	Type	Description
quote	<ul style="list-style-type: none"> <li>• NULL.</li> <li>• Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. However, the integer value exceeds the range from 81 negative nines to 81 positive nines, and the return value is different from that of M*. This difference is an inherent difference between GaussDB and M* and is not caused by this function.</li> <li>• Floating-point and fixed-point types: float, real, and double for floating-point types; numeric, decimal, and dec for fixed-point types. However, when the value is expressed in scientific notation, the trailing zeros in GaussDB are displayed, and those in M* are not displayed. The value is printed in scientific notation. This is an inherent display difference and is not caused by this function.</li> <li>• Character string types: char and varchar.</li> <li>• Text types: tinytext, text, mediumtext, and longtext.</li> </ul>	<p>Adds quotation marks to the input string and adds a backslash (\) before the backslash (\) and single quotation mark (').</p>

Parameter	Type	Description
	<ul style="list-style-type: none"> <li>Large object types: tinyblob, blob, mediumblob, and longblob.</li> <li>Date types: datetime, timestamp, date, and time.</li> </ul>	

Return type: text.

Example:

```
gaussdb=# SELECT quote('hello\ world');
quote
-----
'hello\ world'
(1 row)
```

 **NOTE**

- The function takes effect only when **sql\_compatibility** is set to **'MYSQL'**.
  - To enable the GUC parameters, run the following commands:  

```
SET standard_conforming_strings=off;
SET escape_string_warning=off;
SET backslash_quote=on;
```
  - If the **str** character string contains **\Z**, **\r**, **\%**, or **\\_**, GaussDB does not escape it, which is different from MySQL. The slash followed by digits may also cause differences, for example, **\563**. This function difference is the escape character difference between GaussDB and MySQL, which is not caused by this function.
  - The output format of **\b** in the **str** character string is different from that in MySQL. This is an inherent difference between GaussDB and MySQL and is not caused by this function.
  - If the **str** character string contains **\0**, GaussDB cannot identify the character because the UTF-8 character set cannot identify the character. As a result, the input fails. This is an inherent difference between GaussDB and MySQL and is not caused by this function.
  - If **str** is of the bit or Boolean type, this type is not supported because it is different in GaussDB and MySQL.
  - GaussDB supports a maximum of 1 GB data transfer. The maximum length of the **str** input parameter is 536870908, and the maximum size of the result string returned by the function is 1 GB.
- quote\_ident(string text)**

Description: Returns the given string suitably quoted to be used as an identifier in an SQL statement string (quotation marks are used as required). Quotation marks are added only if necessary (that is, if the string contains non-identifier characters or would be case-folded). Embedded quotation marks are properly doubled.

Return type: text.

Example:

```
gaussdb=# SELECT quote_ident('hello world');
quote_ident
```

```
-----
"hello world"
(1 row)
```

- `quote_literal(string text)`

Description: Returns the given string suitably quoted to be used as text in an SQL statement string (quotation marks are used as required).

It supports XML data that is explicitly converted to the character type.

Return type: text.

Example:

```
gaussdb=# SELECT quote_literal('hello');
quote_literal
-----
'hello'
(1 row)
```

If a command similar to the following exists, the text will be escaped.

```
gaussdb=# SELECT quote_literal(E'O'hello);
quote_literal
-----
'O'hello'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
gaussdb=# SELECT quote_literal('O\hello');
quote_literal
-----
E'O\\hello'
(1 row)
```

If the parameter is **NULL**, **NULL** is returned. If the parameter may be null, you are advised to use **quote\_nullable**.

```
gaussdb=# SELECT quote_literal(NULL);
quote_literal
-----
(1 row)
```

- `quote_literal(value anyelement)`

Description: Converts the given value to text and then quotes it as a literal.

Return type: text.

Example:

```
gaussdb=# SELECT quote_literal(42.5);
quote_literal
-----
'42.5'
(1 row)
```

If a command similar to the following exists, the given value will be escaped.

```
gaussdb=# SELECT quote_literal(E'O'42.5);
quote_literal
-----
'O'42.5'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
gaussdb=# SELECT quote_literal('O\42.5');
quote_literal
-----
E'O\\42.5'
(1 row)
```

- `quote_nullable(string text)`

Description: Returns the given string suitably quoted to be used as a string in an SQL statement string (quotation marks are used as required).

It supports XML data that is explicitly converted to the character type.

Return type: text.

Example:

```
gaussdb=# SELECT quote_nullable('hello');
quote_nullable
-----
'hello'
(1 row)
```

If a command similar to the following exists, the text will be escaped.

```
gaussdb=# SELECT quote_nullable(E'O'hello');
quote_nullable
-----
'O'hello'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
gaussdb=# SELECT quote_nullable('O\hello');
quote_nullable
-----
E'O\\hello'
(1 row)
```

If the parameter is **NULL**, **NULL** is returned.

```
gaussdb=# SELECT quote_nullable(NULL);
quote_nullable
-----
NULL
(1 row)
```

- `quote_nullable(value anyelement)`

Description: Converts the given value to text and then quotes it as a literal.

Return type: text.

Example:

```
gaussdb=# SELECT quote_nullable(42.5);
quote_nullable
-----
'42.5'
(1 row)
```

If a command similar to the following exists, the given value will be escaped.

```
gaussdb=# SELECT quote_nullable(E'O'42.5');
quote_nullable
-----
'O'42.5'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
gaussdb=# SELECT quote_nullable('O\42.5');
quote_nullable
-----
E'O\\42.5'
(1 row)
```

If the parameter is **NULL**, **NULL** is returned.

```
gaussdb=# SELECT quote_nullable(NULL);
quote_nullable
```

```
-----
NULL
(1 row)
```

- `space(count)`

Description: Returns a string consisting of a specified number of spaces.

Parameter	Type	Description
<code>count</code>	<ul style="list-style-type: none"> <li>• Integer types: <code>tinyint</code>, <code>smallint</code>, <code>mediumint</code>, <code>int</code>, and <code>bigint</code>.</li> <li>• Unsigned integer types: <code>tinyint unsigned</code>, <code>smallint unsigned</code>, and <code>int unsigned</code>.</li> <li>• Character and text types: <code>char</code>, <code>varchar</code>, <code>tinytext</code>, <code>text</code>, <code>mediumtext</code>, and <code>longtext</code>. Only numeric integer strings are supported, and the integer range is within the <code>bigint</code> range.</li> <li>• Floating-point types: <code>float</code>, <code>real</code>, and <code>double</code>.</li> <li>• Fixed-point types: <code>numeric</code>, <code>decimal</code>, and <code>dec</code>.</li> <li>• Boolean type: <code>bool</code>.</li> </ul>	Number of spaces.

Return type: text.

Example:

```
gaussdb=# SELECT space(5);
space
```

```
-----
(1 row)
```

 **NOTE**

- The `space` function takes effect only when `sql_compatibility` is set to `'MYSQL'`.
- If the input parameter `count` is less than **1073741819** and greater than **0**, a string of `count` spaces is returned. Otherwise, an empty string is returned.
- `substring_inner(string [from int] [for int])`

Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of characters truncated.

Return type: text.

Example:

```
gaussdb=# SELECT substring_inner('adcde', 2,3);
substring_inner
-----
dcd
(1 row)
```

- `substring(string [from int] [for int])`

Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of characters truncated.

Return type: text.

Example:

```
gaussdb=# SELECT substring('Thomas' from 2 for 3);
substring
-----
hom
(1 row)
```

 **NOTE**

This function is in the MySQL database. When the GUC parameter **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1', **[from int]** can be a negative number, indicating the sequence number of the character counted from back to front. If this parameter is not set, **[from int]** is a negative number and the result is empty.

- `substring(string, pos, len)`

Description: Extracts a substring. **pos** indicates the start position of the truncation. **len** indicates the number of characters truncated.

The parameters are described as follows.

**Table 7-28** Parameter

Parameter	Type	Description	Value Range
string	text	Character string to be truncated.	-
pos	int	Start position of the character string to be truncated.	The absolute value is less than the string length.
len	int	Length of the character string to be truncated.	The value is greater than 0.

Return type: text.

Example:

```
gaussdb=# SELECT substring('substrteststring', -5, 5);
substring
-----
tring
(1 row)
```

 NOTE

This function is in the MySQL database. When the GUC parameter **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1', **pos** can be a negative number, indicating the sequence number of the character counted from back to front. If this parameter is not set, **pos** is a negative number and the result is empty.

- `substring_index(str,split,index)`

Description: **str** is a string, **split** is a separator string, and **index** is the position from which the string is split. This function returns all contents on the left or right (left if the value of **index** is positive and right if the value of **index** is negative) of the **str** string that is split by **split** from the position specified by **index**.

Parameters: See [Table 7-29](#).

**Table 7-29** Parameters of `substring_index`

Parameter	Type	Description
<code>str</code>	text	Character string to be truncated.
<code>split</code>	text	Target character string to be split.
<code>index</code>	int	Position from which the string is split. If the value of <b>index</b> is a positive number, all contents on the left of the position are obtained. If the value of <b>index</b> is a negative number, all contents on the right are obtained.

Return type: text.

Example:

```
gaussdb=# SELECT substring_index('Test1splitTest2splitTest3splitTest4', 'split', 2);
substring_index
-----
Test1splitTest2
(1 row)
```

```
gaussdb=# SELECT substring_index('Test1splitTest2splitTest3splitTest4', 'split', -2);
substring_index
-----
Test3splitTest4
(1 row)
```

- `substring(string from pattern)`

Description: Extracts substrings matching the POSIX-style regular expression. It returns the text that matches the pattern. If no match record is found, a null value is returned.

Return type: text.

Example:

```
gaussdb=# SELECT substring('Thomas' from '...$');
substring
-----
mas
(1 row)
```

```
gaussdb=# SELECT substring('foobar' from 'o(.)b');
result
-----
o
(1 row)
gaussdb=# SELECT substring('foobar' from '(o(.)b)');
result
-----
oob
(1 row)
```

### NOTE

If the POSIX regular expression contains any parentheses, the portion of the text that matched the first parenthesized sub-expression (the one whose left parenthesis comes first) is returned. You can put parentheses around the whole expression if you want to use parentheses within it without triggering this exception.

- `substring(string from pattern for escape)`

Description: Extracts substrings matching the SQL regular expression. The declared schema must match the entire data string; otherwise, the function fails and returns a null value. To indicate the part of the schema that should be returned on success, the schema must contain two occurrences of the escape character followed by a double quotation mark ("). The text matching the portion of the pattern between these marks is returned.

Return type: text.

Example:

```
gaussdb=# SELECT substring('Thomas' from '%"o_a#"_' for '#');
substring
-----
oma
(1 row)
```

- `rawcat(raw,raw)`

Description: Indicates the string concatenation function.

Return type: raw.

Example:

```
gaussdb=# SELECT rawcat('ab','cd');
rawcat
-----
ABCD
(1 row)
```

- `regexp_like(text,text,text)`

Description: Indicates the mode matching function of a regular expression.

Return type: Boolean

Example:

```
gaussdb=# SELECT regexp_like('str','[ac]');
regexp_like
-----
f
(1 row)
```

- `regexp_substr(string text, pattern text [, position int [, occurrence int [, flags text]])`

Description: Extracts substrings from a regular expression. Its function is similar to **substr**. When a regular expression contains multiple parallel brackets, it also needs to be processed.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **occurrence**: sequence number of the matched substring to be extracted. This parameter is optional. The default value is **1**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in [Table 7-30](#).

**Table 7-30** Options supported by flags

Option	Description
'b'	Indicates the BRE matching without extension.
'c'	Indicates the case-sensitive matching.
'e'	Indicates the ERE matching with extension.
'i'	Indicates the case-insensitive matching.
'm'	Indicates the multi-line matching. If <b>flags</b> contains <b>'m'</b> , use the multi-line matching. Otherwise, use the single-line matching.
'n'	<p>The meaning of <b>'n'</b> is related to the GUC parameter <b>behavior_compat_options</b> and the compatibility mode of the current database.</p> <ul style="list-style-type: none"> <li>• If the SQL compatibility mode of the database is <b>ORA</b> or <b>MYSQL</b> and the value of the GUC parameter <b>behavior_compat_options</b> contains <b>aformat_regexp_match</b>, the <b>n</b> option indicates that "." matches the linefeed '\n'. If <b>'n'</b> is not specified, "." does not match the linefeed.</li> <li>• In other cases, the <b>'n'</b> option has the same meaning as the <b>'m'</b> option.</li> </ul>
'p'	Indicates partial linefeed-sensitive matching, which is similar to the linefeed-sensitive matching ( <b>'m'</b> or <b>'n'</b> ) and affects "." and square bracket expression, but does not affect ^ and \$.
'q'	Indicates common character matching.
's'	Indicates the single-line matching. The meaning is opposite to those of <b>'m'</b> and <b>'n'</b> .
't'	Indicates the compact matching. The whitespace characters match themselves.
'w'	Indicates the reverse partial linefeed-sensitive matching. The meaning is opposite to that of <b>'p'</b> .

Option	Description
'x'	Indicates the loose matching. The whitespace characters are ignored.

Return type: text.

Example:

```
gaussdb=# SELECT regexp_substr('str','[ac]');
regexp_substr
```

-----  
(1 row)

```
gaussdb=# SELECT regexp_substr('foobarbaz', 'b(..)', 3, 2) AS RESULT;
result
```

-----  
baz  
(1 row)

- `regexp_count(string text, pattern text [, position int [, flags text]])`

Description: obtains the number of substrings used for matching.

Parameters:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in [Table 7-30](#).

#### NOTE

When the function is in an ORA-compatible database, the value of **a\_format\_version** is **10c**, and the value of **a\_format\_dev\_version** is **s1**, the **pattern** parameter ending with a backslash (\) is valid.

Return type: int.

Example:

```
gaussdb=# SELECT regexp_count('foobarbaz','b(..)', 5) AS RESULT;
result
```

-----  
1  
(1 row)

- `regexp_instr(string text, pattern text [, position int [, occurrence int [, return_opt int [, flags text]]]])`

Description: obtains the position (starting from 1) of the substring that meets the matching condition. If no substring is matched, **0** is returned.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.

- **occurrence**: sequence number of the matched substring to be obtained. This parameter is optional. The default value is **1**.
- **return\_opt**: specifies whether to return the position of the first or last character of the matched substring. This parameter is optional. If the value is **0**, the position of the first character (starting from 1) of the matched substring is returned. If the value is greater than 0, the position of the next character of the end character of the matched substring is returned. The default value is **0**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in [Table 7-30](#).

Return type: int.

Example:

```
gaussdb=# SELECT regexp_instr('foobarbaz','b(..)', 1, 1, 0) AS RESULT;
result
-----
4
(1 row)

gaussdb=# SELECT regexp_instr('foobarbaz','b(..)', 1, 2, 0) AS RESULT;
result
-----
7
(1 row)
```

- `regexp_matches(string text, pattern text [, flags text])`

Description: Returns all captured substrings resulting from matching a POSIX-style regular expression against **string**. If the pattern does not match, the function returns no rows. If the pattern contains no parenthesized sub-expressions, then each row returned is a single-element text array containing the substring matching the whole pattern. If the pattern contains parenthesized sub-expressions, the function returns a text array whose *n*th element is the substring matching the *n*th parenthesized sub-expression of the pattern.

The optional **flags** parameter contains zero or multiple single-letter flags that change the behavior of a function. **i** indicates that the matching is not related to uppercase and lowercase. **g** indicates that each matched substring is replaced, instead of replacing only the first one.

#### NOTICE

If the last parameter is provided but the parameter value is an empty string ("") and the SQL compatibility mode of the database is set to ORA, the returned result is an empty set. This is because the ORA compatible mode treats the empty string ("") as **NULL**. To resolve this problem, you can:

- Change the database SQL compatibility mode to TD.
- Do not provide the last parameter or do not set the last parameter to an empty string.

Return type: SETOF text[[]].

Example:

```
gaussdb=# SELECT regexp_matches('foobarbequebaz', '(bar)(beque)');
regexp_matches
```

```

-----
{bar,beque}
(1 row)
gaussdb=# SELECT regexp_matches('foobarbequebaz', 'barbeque');
regexp_matches
-----
{barbeque}
(1 row)
gaussdb=# SELECT regexp_matches('foobarbequebazilbarfbonk', '(b[^b]+)(b[^b]+)', 'g');
regexp_matches
-----
{bar,beque}
{bazil,barf}
(2 rows)

```

- `regexp_match(string text, pattern text [, flags text])`

Description: Returns a string array, which is the first substring obtained by matching the POSIX regular expression with the specified string. If the pattern does not match, the function returns a blank line. If the pattern contains no parenthesized sub-expressions, then each row returned is a single-element text array containing the substring matching the whole pattern. If the pattern contains parenthesized sub-expressions, the function returns a text array whose *n*th element is the substring matching the *n*th parenthesized sub-expression of the pattern.

The **flags** parameter is optional. If **flags** is not specified, tight syntax matching is used by default. The **flags** parameter contains zero or multiple single-letter flags that change the behavior of a function. The following table lists the supported flags.

**Table 7-31** Parameters of flags

Option	Description
'b'	Converts the POSIX regular expression to a BRE.
'c'	Indicates the case-sensitive matching.
'e'	Converts the POSIX regular expression to an ERE.
'i'	Indicates the case-insensitive matching.
'n'	Indicates newline-sensitive matching. A character string is regarded as multiple lines. Caret (^) and dollar sign (\$) match the beginning and end of each line. Periods (.) do not match linefeed.
'm'	Indicates newline-sensitive matching. A character string is regarded as multiple lines. Caret (^) and dollar sign (\$) match the beginning and end of each line. Periods (.) do not match linefeed. The matching mode of <i>n</i> is the same.
'p'	Indicates partial newline-sensitive matching. Periods (.) do not match linefeed. Caret (^) can only match the beginning of the first line and dollar sign (\$) can only match the end of the last line.
'q'	Represents the regular expression is a text string, all of which are common characters.

Option	Description
's'	Indicates non-newline-sensitive matching. That is, a character string is regarded as a single line, and caret (^) and dollar sign (\$) match the beginning and end of the line, respectively. In this mode, periods (.) in the regular expression can match any character, including the linefeed character.
't'	Indicates the tight syntax matching.
'w'	Indicates inverse partial newline-sensitive matching. In the regular expression, caret (^) matches the beginning of each line, and dollar sign (\$) matches only the end of the last line. Period (.) can match any character, including the linefeed character.
'x'	Indicates the extended syntax matching, ignoring whitespace characters and comments in regular expressions. The following three scenarios are excluded: <ul style="list-style-type: none"> <li>• The whitespace characters or comments starting with the number sign (#) that are prefixed with slashes (\) will be retained.</li> <li>• The whitespace characters or comments starting with the number sign (#) in square brackets will be retained.</li> <li>• The whitespace characters and comments are not allowed in multi-character symbols, such as, left parenthesis (), question mark (?), and colon (:).</li> </ul>

#### NOTICE

If the parameter contains an empty string ("") and the compatibility mode of the database is set to **ORA**, the returned result is **NULL**. This is because the empty string is processed as **NULL** in ORA-compatible mode.

Return type: SETOF text[[]].

Example:

```
gaussdb=# SELECT regexp_match('foobarbequebaz', '(bar)(beque)');
regexp_match
-----
{bar,beque}
(1 row)
gaussdb=# SELECT (regexp_match('foobarbequebaz', 'bar.*que'))[1];
regexp_match
-----
barbeque
(1 row)
gaussdb=# SELECT regexp_match('Learning #PostgreSQL', 'R', 'c');
regexp_match
-----
(1 row)
gaussdb=# SELECT regexp_match('hello world', 'h e l l o', 'x');
regexp_match
-----
{hello}
(1 row)
```

- `regexp_split_to_array(string text, pattern text [, flags text ])`

Description: Splits **string** using a POSIX-style regular expression as the delimiter. The `regexp_split_to_array` function behaves the same as `regexp_split_to_table`, except that `regexp_split_to_array` returns its result as an array of text.

Return type: `text[]`.

Example:

```
gaussdb=# SELECT regexp_split_to_array('hello world', E'\\s+');
 regexp_split_to_array
-----
{hello,world}
(1 row)
```

- `regexp_split_to_table(string text, pattern text [, flags text])`

Description: Splits **string** using a POSIX-style regular expression as the delimiter. If there is no match to the pattern, the function returns the string. If there is at least one match, for each match it returns the text from the end of the last match (or the beginning of the string) to the beginning of the match. When there are no more matches, it returns the text from the end of the last match to the end of the string.

The **flags** parameter contains zero or multiple single-letter flags that change the behavior of a function. **i** indicates that the matching is not related to uppercase and lowercase. By default, each matching substring is replaced, instead of replacing only the first one.

Return type: SETOF text.

Example:

```
gaussdb=# SELECT regexp_split_to_table('hello world', E'\\s+');
 regexp_split_to_table
-----
hello
world
(2 rows)
```

- `repeat(string text, number int)`

Description: Repeats **string** the specified number of times.

Return type: text.

Example:

```
gaussdb=# SELECT repeat('Pg', 4);
 repeat
-----
PgPgPgPg
(1 row)
```

#### NOTE

The maximum size of memory allocated at a time cannot exceed 1 GB due to the memory allocation mechanism of the database. Therefore, the maximum value of **number** cannot exceed  $(1 \text{ GB} - x) / \text{lengthb}(\text{string}) - 1$ . **x** indicates the length of the header information, which is usually greater than 4 bytes. The value varies among different scenarios.

- `replace(string text, from text, to text)`

Description: Replaces all occurrences in **string** of substring **from** with substring **to**.

Return type: text.

Example:

```
gaussdb=# SELECT replace('abcdefabcdef', 'cd', 'XXX');
replace
-----
abXXXefabXXXef
(1 row)
```

- `replace(string, substring)`

Description: Deletes all substrings in a string.

String type: text.

Substring type: text.

Return type: text.

Example:

```
gaussdb=# SELECT replace('abcdefabcdef', 'cd');
replace
-----
abefabef
(1 row)
```

- `reverse(str)`

Description: Returns a reversed string (by character).

Return type: text.

Example:

```
gaussdb=# SELECT reverse('abcde');
reverse
-----
edcba
(1 row)
```

- `right(str text, n int)`

Description: Returns the last *n* characters in a string. When *n* is negative, all but the first */n/* characters are returned.

Return type: text.

Example:

```
gaussdb=# SELECT right('abcde', 2);
right
-----
de
(1 row)

gaussdb=# SELECT right('abcde', -2);
right
-----
cde
(1 row)
```

- `rpad(string text, length int [, fill text])`

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

Return type: text.

 NOTE

In the scenario where this function is in an ORA-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on O-compatible requirements.
- During the function execution, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the right of the string.
- If the value of *length* is a decimal, the value is truncated instead of being rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.

In other cases:

- The **length** parameter indicates the total length of characters in a character string. The length of a single character is fixed to 1.
- If the value of **length** is a decimal, the value is rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.

- **substrb(text,int,int)**

Description: Extracts a substring. The first **int** indicates the start position of the subtraction. The second **int** indicates the number of characters extracted.

Return type: text.

Example:

```
gaussdb=# SELECT substrb('string',2,3);
substrb
-----
tri
(1 row)
```

- **substrb(text,int)**

Description: Extracts a substring. **int** indicates the start position of the extraction.

Return type: text.

Example:

```
gaussdb=# SELECT substrb('string',2);
substrb
-----
tring
(1 row)
```

- **substr(text,int)/substr(str FROM pos)**

Description: **str** is the target string, and **pos** is the position in the string. The string of **str** from the **pos** position is output to the end of the character.

Return type: text.

Example:

```
gaussdb=# SELECT substr('stringtest' from 4);
substr
-----
ingtest
(1 row)

gaussdb=# SELECT substr('stringtest', 4);
substr
-----
ingtest
(1 row)
```

- `substr(str FROM pos FOR len)`  
Description: Extracts a substring. The first **int** indicates the start position of the subtraction. The second **int** indicates the number of characters extracted. The value of **pos** can be a negative number. If the value is a negative number, the value is extracted from back to front.  
Return type: text.  
Example:

```
gaussdb=# SELECT substr('teststring' from 5 for 2);
substr
-----
st
(1 row)
```
- `substr(bytea,from,count)`  
Description: Extracts a substring from **bytea**. **from** specifies the position where the extraction starts. **count** specifies the length of the extracted substring.  
Return type: text.  
Example:

```
gaussdb=# SELECT substr('string',2,3);
substr
-----
tri
(1 row)
```
- `string || string`  
Description: Concatenates strings.  
Return type: text.  
Example:

```
gaussdb=# SELECT 'MPP' || 'DB' AS RESULT;
result
-----
MPPDB
(1 row)
```
- `string || non-string or non-string || string`  
Description: Concatenates strings and non-strings.  
Return type: text.  
Example:

```
gaussdb=# SELECT 'Value: ' || 42 AS RESULT;
result
-----
Value: 42
(1 row)
```
- `split_part(string text, delimiter text, field int)`  
Description: Splits **string** on **delimiter** and returns the *field*th column (counting from text of the first appeared delimiter).  
Return type: text.  
Example:

```
gaussdb=# SELECT split_part('abc~@~def~@~ghi', '~@~', 2);
split_part
-----
def
(1 row)
```

- `strpos(string, substring)`  
Description: Specifies the position of a substring. It is the same as **position(substring in string)**. However, the parameter sequences of them are reversed.  
Return type: int.  
Example:

```
gaussdb=# SELECT strpos('source', 'rc');
strpos
-----
      4
(1 row)
```
- `to_hex(number int or bigint)`  
Description: Converts a number to a hexadecimal expression.  
Return type: text.  
Example:

```
gaussdb=# SELECT to_hex(2147483647);
to_hex
-----
7fffffff
(1 row)
```
- `translate(string text, from text, to text)`  
Description: Any character in **string** that matches a character in **from** is replaced by the corresponding character in **to**. If **from** is longer than **to**, extra characters occurred in **from** are removed.  
Return type: text.  
Example:

```
gaussdb=# SELECT translate('12345', '143', 'ax');
translate
-----
a2x5
(1 row)
```
- `length(string)`  
Description: Obtains the number of characters in a string. When **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', if the string is of the string or text type, the number of bytes of the string is returned.  
Return type: integer.
- `lengthb(string)`  
Description: Obtains the number of bytes in a string. The value depends on character sets (GBK and UTF8).  
Return type: integer.  
Example:

```
gaussdb=# SELECT lengthb('Chinese');
lengthb
-----
      7
(1 row)
```
- `substr(string,from)`  
Description:  
Extracts substrings from a string.

**from** indicates the start position of the extraction.

- If **from** starts at 0, the value **1** is used.
- If the value of **from** is positive, all characters from **from** to the end are extracted.
- If the value of **from** is negative, the last  $n$  characters in the string are extracted, and  $n$  indicates the absolute value of **from**.

Return type: varchar.

Example:

If the value of **from** is positive:

```
gaussdb=# SELECT substr('ABCDEF',2);
substr
-----
BCDEF
(1 row)
```

If the value of **from** is negative:

```
gaussdb=# SELECT substr('ABCDEF',-2);
substr
-----
EF
(1 row)
```

- **substr(string,from,count)**

Description:

Extracts substrings from a string.

**from** indicates the start position of the extraction.

**count** indicates the length of the extracted substring.

- If **from** starts at 0, the value **1** is used.
- If the value of **from** is positive, extract **count** characters starting from **from**.
- If the value of **from** is negative, extract the last  $n$  **count** characters in the string, in which  $n$  indicates the absolute value of **from**.
- If the value of **count** is smaller than **1**, **null** is returned.

Return type: varchar.

Example:

If the value of **from** is positive:

```
gaussdb=# SELECT substr('ABCDEF',2,2);
substr
-----
BC
(1 row)
```

If the value of **from** is negative:

```
gaussdb=# SELECT substr('ABCDEF',-3,2);
substr
-----
DE
(1 row)
```

- **substrb(string,from)**

Description: The functionality of this function is the same as that of **SUBSTR(string,from)**. However, the calculation unit is byte.

Return type: bytea.

Example:

```
gaussdb=# SELECT substrb('ABCDEF',-2);
substrb
-----
EF
(1 row)
```

- `substrb(string,from,count)`

Description: The functionality of this function is the same as that of `SUBSTR(string,from,count)`. However, the calculation unit is byte.

Return type: `bytea`.

Example:

```
gaussdb=# SELECT substrb('ABCDEF',2,2);
substrb
-----
BC
(1 row)
```

- `to_single_byte(char)`

Description: Converts all multi-byte characters in a string to single-byte characters.

Return type: `text`.

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `to_multi_byte(char)`

Description: Converts all single-byte characters in a string to multi-byte characters.

Return type: `text`.

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `trim([leading |trailing |both] [characters] from string)`

Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start, end, or both sides of **string**.

Return type: `text`.

Example:

```
gaussdb=# SELECT trim(BOTH 'x' FROM 'xTomxx');
btrim
-----
Tom
(1 row)
gaussdb=# SELECT trim(LEADING 'x' FROM 'xTomxx');
ltrim
-----
Tomxx
(1 row)
gaussdb=# SELECT trim(TRAILING 'x' FROM 'xTomxx');
rtrim
-----
xTom
(1 row)
```

- `rtrim(string [, characters])`

Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the end of **string**.

Return type: text.

Example:

```
gaussdb=# SELECT rtrim('TRIMxxxx','x');
rtrim
-----
TRIM
(1 row)
```

- **ltrim(string [, characters])**

Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start of **string**.

Return type: text.

Example:

```
gaussdb=# SELECT ltrim('xxxxTRIM','x');
ltrim
-----
TRIM
(1 row)
```

- **upper(string)**

Description: Converts the string into the uppercase.

Return type: text.

Example:

```
gaussdb=# SELECT upper('tom');
upper
-----
TOM
(1 row)
```

- **lower(string)**

Description: Converts the string into the lowercase.

Return type: text.

Example:

```
gaussdb=# SELECT lower('TOM');
lower
-----
tom
(1 row)
```

- **nls\_upper(string [, nlsparam])**

Description: Converts a character string to uppercase letters. You can specify a sorting rule to process special uppercase conversion rules in some languages. The format of **nlsparam** is '**nls\_sort=sort\_name**', where **sort\_name** is replaced by the specific sorting rule name. When the **nlsparam** parameter is not set, this function is equivalent to **upper**.

Return type: text.

Example:

```
gaussdb=# SELECT nls_upper('groÙe');
nls_upper
-----
GROÙE
(1 row)
gaussdb=# SELECT nls_upper('groÙe', 'nls_sort = XGerman');
nls_upper
-----
```

```
GROSSE
(1 row)
```

 **NOTE**

This function can be used only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `nls_lower(string [, nlsparam])`

Description: Converts a character string to lowercase letters. You can specify a sorting rule to process special lowercase conversion rules in some languages. The format of **nlsparam** is '**nls\_sort=sort\_name**', where **sort\_name** is replaced by the specific sorting rule name. When the **nlsparam** parameter is not set, this function is equivalent to **lower**.

Return type: text.

Example:

```
gaussdb=# SELECT nls_lower('INDIVISIBILITY');
 nls_lower
-----
indivisibility
(1 row)
gaussdb=# SELECT nls_lower('INDIVISIBILITY', 'nls_sort = XTurkish');
 nls_lower
-----
indivisibility
(1 row)
```

 **NOTE**

This function can be used only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `instr(string,substring[,position,occurrence])`

Description: Queries and returns the value of the substring position that occurs the *occurrence* (**1** by default) times from the *position* (**1** by default) in the string.

- If the value of *position* is **0**, **0** is returned.
- If the value of *position* is a negative number, searches backwards from the last *n*th character in the string, in which *n* indicates the absolute value of *position*.

In this function, the calculation unit is character. One Chinese character is one character.

Return type: integer.

Example:

```
gaussdb=# SELECT instr('corporate floor','or', 3);
 instr
-----
      5
(1 row)
gaussdb=# SELECT instr('corporate floor','or',-3,2);
 instr
-----
      2
(1 row)
```

- `initcap(string)`

Description: Capitalizes the first letter of each word in a string.

Return type: text.

Example:

```
gaussdb=# SELECT initcap('hi THOMAS');
initcap
-----
Hi Thomas
(1 row)
```

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2**, if a case-insensitive character, such as Chinese, is followed by a case-sensitive character, only the first letter of the case-sensitive character is capitalized. Therefore, you are advised to set **a\_format\_version** to **10c** and **a\_format\_dev\_version** to **s2**.

- **ascii(string)**

Description: Indicates the ASCII code of the first character in the string.

Return type: integer.

Example:

```
gaussdb=# SELECT ascii('xyz');
ascii
-----
120
(1 row)
```

- **ascii2(string)**

Description: Returns the decimal code of the first character of the input string in the database character set.

Return type: integer.

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- **asciistr(string)**

Description: Converts non-ASCII characters in the input string to `\XXXX`, where `XXXX` indicates the UTF-16 code unit.

Return type: varchar.

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- **unistr(string)**

Description: Converts the coding sequence in a string into the corresponding character. Other characters remain unchanged.

Return type: text.

 **NOTE**

- This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.
- The backslash (`\`) must be followed by four hexadecimal characters to indicate the coding sequence, or another backslash (`\`) indicates that a single backslash (`\`) is entered.
- If the input parameter is of the time type, the time type is implicitly converted to the character string type.

- `vsize(expr)`

Description: Returns the number of bytes of the input expression.

Return type: int.

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `replace(string varchar, search_string varchar, replacement_string varchar)`

Description: Replaces all **search\_string** in the string with **replacement\_string**.

Return type: varchar.

Example:

```
gaussdb=# SELECT replace('jack and jue','j','bl');
replace
-----
black and blue
(1 row)
```

- `concat(str1,str2)`

Description: Connects `str1` and `str2` and returns the string. Note: **concat** calls the output function of the data type and the return value is uncertain. As a result, the optimizer cannot calculate the result in advance when generating a plan. If there are performance requirements, you are advised to use the operator `||`.

 **NOTE**

- If **sql\_compatibility** is set to **'MYSQL'** and **str1** or **str2** is set to **NULL**, the returned result is **NULL**.
- The return value of the `concat` function is of the variable-length type. When the `concat` function is compared with table data, the character string length is lost in the combination result. As a result, the comparison results are different.

Return type: varchar.

Example:

```
gaussdb=# SELECT concat('Hello', ' World!');
concat
-----
Hello World!
(1 row)
gaussdb=# SELECT concat('Hello', NULL);
concat
-----
(1 row)
gaussdb=# CREATE TABLE test_space(c char(10));
CREATE TABLE
gaussdb=# INSERT INTO test_space values('a');
INSERT 0 1
-- After spaces are padded, the character string is still a fixed-length character string. It is expected
that the result can be found.
gaussdb=# SELECT * FROM test_space WHERE c = 'a ';
c
-----
a
(1 row)
-- The combination result is a variable-length character string. The comparison fails and the result
cannot be found.
gaussdb=# SELECT * FROM test_space WHERE c = 'a' || ' ';
c
```

```
---  
(0 rows)
```

- **chr(integer)**

Description: For the UTF-8 character set, the input is encoded as Unicode and a UTF-8 character is returned. For other character sets, an ASCII character is returned.

Return type: text.

 **NOTE**

- When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an ORA-compatible database, the value is truncated instead of being rounded off if the value of *integer* is a decimal.
- For details about how to set and modify the character set and collation, see [Character Sets and Collations](#).

Example:

```
gaussdb=# SELECT chr(65);  
chr  
-----  
A  
(1 row)  
  
-- In the case of UTF-8 character set  
gaussdb=# select chr(19968);  
chr  
-----  
—  
(1 row)
```

- **chr(cvalue int|bigint)**

Description: Converts *cvalue* to the character of the corresponding byte order and returns the character.

*cvalue* can be converted into a value of the int or bigint type. The value range is  $[0, 2^{32} - 1]$ , corresponding to the range of unsigned int. A character array consisting of one to four bytes is returned based on the value of *n*. The byte arrays returned in different character sets are the same. However, due to different encoding rules, the result of the returned character string varies depending on the character set encoding.

If the character set is a single-byte character set, an ASCII character is returned after *cvalue* mod 256.

Precautions:

- If a byte in the input *cvalue* is **0**, the output is truncated.
- If the input does not comply with the encoding rule of the current character set, an error is reported.
- If the input is **NULL** or **0**, **NULL** is returned.

Return type: text.

Example:

```
gaussdb=# SELECT chr(65);  
chr  
-----  
A  
(1 row)  
gaussdb=# CREATE DATABASE gaussdb_o WITH DBCOMPATIBILITY 'ORA';  
gaussdb=# \c gaussdb_o  
gaussdb_o=# SET a_format_version='10c';  
gaussdb_o=# SET a_format_dev_version = 's1';
```

```
gaussdb_o=# SELECT chr(16705);
chr
-----
AA
(1 row)

-- The output is truncated.
gaussdb_o=# SELECT chr(4259905);
chr
-----
A
(1 row)
gaussdb_o=# \c postgres
gaussdb=# DROP DATABASE gaussdb_o;
```

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an ORA-compatible database, the `chr` function returns a character in the collation based on the input value. If the current character set for database encoding is a multi-byte character set, the return value contains one to four bytes. If the current character set for database encoding is a single-byte character set, the return value is a single byte obtained by performing the mod 256 operation on the input value. Otherwise, if the current character set for database encoding is UTF-8, the input is encoded as Unicode and a UTF-8 character is returned. For other character sets, an ASCII character is returned.

- `nchr(cvalue int|bigint)`

Description: Returns the characters corresponding to the input parameter in the national character set. The GUC parameter **nls\_nchar\_characterset** specifies the country character set. Only AL16UTF16 and UTF8 are supported. This function is valid only when the value of the GUC parameter **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s4** in an ORA-compatible database. If **nls\_nchar\_characterset** is set to **AL16UTF16** and the input parameter exceeds two bytes, the input parameter will be truncated and the lowest two bytes will be retained. If **nls\_nchar\_characterset** is set to **UTF8** and the input parameter exceeds three bytes, the value **0** is used.

Parameter: `cvalue`. **cvalue** can be converted to the `int` or `bigint` type. The value range is  $[0, 2^{32} - 1]$ , corresponding to the range of unsigned `int`. If the input parameter contains the decimal part, the decimal part will be deleted.

Return type: `NVARCHAR2`.

 **CAUTION**

- The byte length of the return value of the function is different from that in database ORA.
- The return value of the function is restricted by the database character set. In different database character sets, if there is no mapping table for converting UTF8 to the database character set or the mapping table does not contain the UTF8 code, the current database character set does not support the UTF8 character corresponding to the input parameter. As a result, the result returned by the `nchr(cvalue int|bigint)` function is inconsistent with that in database ORA.
- If the current database character set does not support the UTF8 character corresponding to the input parameter, or the national character set is UTF8 but the input parameter does not comply with the UTF8 format, the byte array corresponding to the input parameter is returned. If a single byte is in the range of [0x00,0x7F], an ASCII character is returned. If a single byte is in the range of [0x80,0xFF], a question mark (?) is returned.
- For details about how to set and modify the character set and collation, see [Character Sets and Collations](#).

- `regexp_substr(source_char, pattern)`

Description: Extracts substrings from a regular expression. If the SQL syntax is ORA- and MySQL-compatible and the value of the GUC parameter **behavior\_compat\_options** contains **aformat\_regexp\_match**, the period (.) cannot match the '\n' character. If **aformat\_regexp\_match** is not contained, the period (.) matches the '\n' character by default.

Return type: text.

Example:

```
gaussdb=# SELECT regexp_substr('500 Hello World, Redwood Shores, CA', '[^,]+,')
"REGEXPR_SUBSTR";
REGEXPR_SUBSTR
-----
, Redwood Shores,
(1 row)
```

- `regexp_replace(string, pattern, replacement [,flags ])`

Description: Replaces substrings matching the POSIX-style regular expression. The source string is returned unchanged if there is no match to the pattern. If there is a match, the source string is returned with the replacement string substituted for the matching substring.

The replacement string can contain `\n`, where `\n` ranges from 1 to 9, to indicate that the source substring matching the *n*th parenthesized subexpression of the pattern should be inserted, and it can contain `\&` to indicate that the substring matching the entire pattern should be inserted.

The optional **flags** parameter contains zero or multiple single-letter flags that change the behavior of a function. The options supported by **flags** and description are described in [Table 7-30](#).

Return type: varchar.

Example:

```
gaussdb=# SELECT regexp_replace('Thomas', '[mN]a.', 'M');
regexp_replace
```

```
-----
ThM
(1 row)
gaussdb=# SELECT regexp_replace('foobarbaz','b(.)', E'X\1Y', 'g') AS
RESULT;
result
-----
fooXarYXazY
(1 row)
```

- `regexp_replace(string text, pattern text [, replacement text [, position int [, occurrence int [, flags text]]]])`

Description: Replaces substrings matching the POSIX-style regular expression. The source string is returned unchanged if there is no match to the pattern. If there is a match, the source string is returned with the replacement string substituted for the matching substring.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **replacement**: character string used to replace the matched substring. This parameter is optional. If no parameter value is specified or the parameter value is null, an empty string is used for replacement.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **occurrence**: sequence number of the matched substring to be replaced. This parameter is optional. The default value is **1**, indicating that the first matched substring is replaced.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are described in [Table 7-30](#).

#### NOTE

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an ORA-compatible database, the default value of **occurrence** is **0**, indicating that all matched substrings are replaced and the pattern parameter ending with a backslash (\) is valid.

Return type: text.

Example:

```
gaussdb=# SELECT regexp_replace('foobarbaz','b(.)', E'X\1Y', 2, 2, 'n') AS RESULT;
result
-----
fooXarXazY
(1 row)
```

- `concat_ws(sep text, str"any" [, str"any" [, ...] ])`

Description: Uses the first parameter as the separator, which is associated with all following parameters. The **NULL** parameter is ignored.

**NOTICE**

- If the first parameter value is **NULL**, the returned result is **NULL**.
- If the first parameter is provided but the parameter value is an empty string ('') and the SQL compatibility mode of the database is set to ORA, the returned result is **NULL**. This is because the ORA-compatible mode treats the empty string ('') as **NULL**. To resolve this problem, you can change the SQL compatibility mode of the database to MySQL, TD, or PG.

Return type: text.

Example:

```
gaussdb=# SELECT concat_ws(',', 'ABCDE', 2, NULL, 22);
concat_ws
-----
ABCDE,2,22
(1 row)
```

- `nlsort(string text, sort_method text)`

Description: Returns the encoding value of a string in the sorting mode specified by **sort\_method**. The encoding value can be used for sorting and determines the sequence of the string in the sorting mode. Currently, **sort\_method** can be set to **nls\_sort=schinese\_pinyin\_m** or **nls\_sort=generic\_m\_ci**. **nls\_sort=generic\_m\_ci** supports only the case-insensitive order for English characters.

String type: text.

sort\_method type: text

Return type: text.

Example:

```
gaussdb=# CREATE TABLE test(a text);

gaussdb=# INSERT INTO test(a) VALUES('abc');

gaussdb=# INSERT INTO test(a) VALUES('abC');

gaussdb=# INSERT INTO test(a) VALUES('abc');

gaussdb=# SELECT * FROM test ORDER BY nlsort(a,'nls_sort=schinese_pinyin_m');
 a
-----
abc
abC
abC
(3 rows)

gaussdb=# SELECT * FROM test ORDER BY nlsort(a, 'nls_sort=generic_m_ci');
 a
-----
abC
abc
abC
(3 rows)

gaussdb=# DROP TABLE test;
```

- `convert(string bytea, src_encoding name, dest_encoding name)`

Description: Converts the string to **dest\_encoding**. **src\_encoding** specifies the source code encoding. The string must be valid in this encoding.

Return type: bytea.

Example:

```
gaussdb=# SELECT convert('text_in_utf8', 'UTF8', 'GBK');
convert
-----
\x746578745f696e5f75746638
(1 row)
```

 **NOTE**

If the rule for converting between source to target encoding (for example, GBK and LATIN1) does not exist, the string is returned without conversion. See the `pg_conversion` system catalog for details. **server\_encoding** is specified during database initialization.

Example:

```
gaussdb=# SHOW server_encoding;
server_encoding
-----
LATIN1
(1 row)

gaussdb=# SELECT convert_from('some text', 'GBK');
convert_from
-----
some text
(1 row)

db_latin1=# SELECT convert_to('some text', 'GBK');
convert_to
-----
\x736f6d652074657874
(1 row)

db_latin1=# SELECT convert('some text', 'GBK', 'LATIN1');
convert
-----
\x736f6d652074657874
(1 row)
```

- `convert(expr, USING transcoding_name)`

Description: Converts a parameter, which can be a character or a number, into a character string of the `transcoding_name` type, and returns the character string.

Return type: text.

Example:

```
gaussdb=# SELECT convert('asd' using 'gbk');
convert
-----
asd
(1 row)
```

 **NOTE**

This function takes effect only in databases in MySQL compatibility mode.

- `convert_from(string bytea, src_encoding name)`

Description: Converts a string using the coding mode of the database.

**src\_encoding** specifies the source code encoding. The string must be valid in this encoding.

Return type: text.

Example:

```
gaussdb=# SELECT convert_from('text_in_utf8', 'UTF8');
convert_from
```

```
-----
text_in_utf8
(1 row)
```

- `convert_to(string text, dest_encoding name)`

Description: Converts a string to **dest\_encoding**.

Return type: bytea.

Example:

```
gaussdb=# SELECT convert_to('some text', 'UTF8');
convert_to
-----
\x736f6d652074657874
(1 row)
```

- `string [NOT] LIKE pattern [ESCAPE escape-character]`

Description: Specifies the pattern matching function.

If the pattern does not include a percentage sign (%) or an underscore (\_), this mode represents itself only. In this case, the behavior of LIKE is the same as the equal operator. The underscore (\_) in the pattern matches any single character while one percentage sign (%) matches no or multiple characters.

To match with underscores (\_) or percent signs (%), corresponding characters in **pattern** must lead escape characters. The default escape character is a backward slash (\) and can be specified using the ESCAPE clause. To match with escape characters, enter two escape characters.

Return type: Boolean.

Example:

```
gaussdb=# SELECT 'AA_BBCC' LIKE '%A@_B%' ESCAPE '@' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'AA_BBCC' LIKE '%A@_B%' AS RESULT;
result
-----
f
(1 row)
gaussdb=# SELECT 'AA@_BBCC' LIKE '%A@_B%' AS RESULT;
result
-----
t
(1 row)
```

- `REGEXP_LIKE(source_string, pattern [, match_parameter])`

Description: Indicates the mode matching function of a regular expression.

**source\_string** indicates the source string and **pattern** indicates the matching pattern of the regular expression. **match\_parameter** indicates the matching items and the values are as follows:

- 'i': case-insensitive
- 'c': case-sensitive
- 'n': allowing the metacharacter "." in a regular expression to be matched with a linefeed.
- 'm': allows **source\_string** to be regarded as multiple rows.

If **match\_parameter** is ignored, **case-sensitive** is enabled by default, "." is not matched with a linefeed, and **source\_string** is regarded as a single row.

Return type: Boolean.

Example:

```
gaussdb=# SELECT regexp_like('ABC', '[A-Z]');
regexp_like
-----
t
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[D-Z]');
regexp_like
-----
f
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[A-Z]','i');
regexp_like
-----
t
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[A-Z]');
regexp_like
-----
t
(1 row)
```

- `format(formatstr text [, str"any" [, ...] ])`

Description: Formats a string.

Return type: text.

Example:

```
gaussdb=# SELECT format('Hello %s, %1$s', 'World');
format
-----
Hello World, World
(1 row)
```

- `md5(string)`

Description: Encrypts a string in MD5 mode and returns a value in hexadecimal form.

 **NOTE**

The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

Return type: text.

Example:

```
gaussdb=# SELECT md5('ABC');
md5
-----
902fbbd2b1df0c4f70b4a5d23525e932
(1 row)
```

- `sha(string) / sha1(string)`

Description: Encrypts a string using SHA1 and returns a hexadecimal number. The sha and sha1 functions are the same.

 **NOTE**

- The SHA1 encryption algorithm is not recommended because it has lower security and poses security risks.
- This function is valid only when GaussDB is compatible with the MY type (that is, **sql\_compatibility** is set to 'MYSQL').

Return type: text.

Example:

```
gaussdb=# SELECT sha('ABC');
          sha
-----
3c01bdbb26f358bab27f267924aa2c9a03fcfdb8
(1 row)
gaussdb=# SELECT sha1('ABC');
          sha1
-----
3c01bdbb26f358bab27f267924aa2c9a03fcfdb8
(1 row)
```

- sha2(string, hash\_length)

Description: Encrypts a string in SHA2 mode and returns a value in hexadecimal form.

*hash\_length*: corresponds to an SHA2 algorithm. The value can be **0** (SHA-256), **224** (SHA-224), **256** (SHA-256), **384** (SHA-384), or **512** (SHA-512). For other values, **NULL** is returned.

 **NOTE**

- The SHA-224 encryption algorithm is not recommended because it has lower security and poses security risks.
- The SHA2 function records hash plaintext in logs. Therefore, you are advised not to use this function to encrypt sensitive information such as keys.
- This function is valid only when GaussDB is compatible with the MY type (that is, **sql\_compatibility** is set to 'MYSQL').

Return type: text.

Example:

```
gaussdb=# SELECT sha2('ABC',224);
          sha2
-----
107c5072b799c4771f328304cfe1ebb375eb6ea7f35a3aa753836fad
(1 row)
gaussdb=# SELECT sha2('ABC',256);
          sha2
-----
b5d4045c3f466fa91fe2cc6abe79232a1a57cdf104f7a26e716e0a1e2789df78
(1 row)
gaussdb=# SELECT sha2('ABC',0);
          sha2
-----
b5d4045c3f466fa91fe2cc6abe79232a1a57cdf104f7a26e716e0a1e2789df78
(1 row)
```

- decode(string text, format text)

Description: Decodes binary data from textual representation.

Return type: bytea.

Example:

```
gaussdb=# SELECT decode('MTIzAAE=', 'base64');
          decode
-----
\x3132330001
(1 row)
```

- similar\_escape(pat text, esc text)

Description: Converts a regular expression of the SQL:2008 style to the POSIX style.

Return type: text.

Example:

```
gaussdb=# SELECT similar_escape('\s+ab','2');
similar_escape
-----
^(?:\\s+ab)$
(1 row)
```

- `find_in_set(text, set)`

Description: Finds the position of a given member in a set, counting from 1. If no record is found, 0 is returned. The distributed system does not support the SET data type. An error will be reported when this function is executed.

Return type: int2

- `find_in_set(str, strlist)`

Description: Queries whether the **strlist** field contains **str**. If yes, the position of **str** in the **strlist** field is returned. The inputs are **str** and **strlist**. **str** indicates the character string to be queried. **strlist** is a set of character strings separated by commas (.). If **str** is not in **strlist** or **strlist** is an empty string, the return value is **0**.

The parameters are described as follows.

**Table 7-32** Parameter

Parameter	Type	Description
str	text	Target string
strlist	text	A set of character strings

Return type: int.

Example:

```
gaussdb=# SELECT find_in_set('ee','a,ee,c');
find_in_set
-----
2
(1 row)
```

- `encode(data bytea, format text)`

Description: Encodes binary data into a textual representation.

Return type: text.

Example:

```
gaussdb=# SELECT encode(E'123\000\001', 'base64');
encode
-----
MTIzAAE=
(1 row)
```

- `strcmp(expr1,expr2)`

Description: Compares two input strings based on the current character order. If the strings are the same, **0** is returned. If the first string is smaller than the second string, **-1** is returned. Otherwise, **1** is returned.

The parameters are described as follows.

Parameter	Type	Description
expr1/expr2	Character types: CHAR, VARCHAR, NVARCHAR2, and TEXT. Binary type: BYTEA. Numeral types: TINYING [UNSIGNED], SMALLINT [UNSIGNED], INTEGER [UNSIGNED], BIGINT [UNSIGNED], FLOAT4, FLOAT8, and NUMERIC. Date and time types: DATE, TIME WITHOUT TIME ZONE, DATETIME, and TIMESTAMPTZ.	Character string involved in comparison.

Return type: integer.

Example:

```
-- Switch to the MySQL-compatible database.
gaussdb=# CREATE DATABASE gaussdb_m dbcompatibility='MYSQL';
gaussdb=# \c gaussdb_m

-- Set the compatible version control parameter to enable the function of specifying the collation for
constant character strings.
gaussdb_m=# SET b_format_version='5.7';
gaussdb_m=# SET b_format_dev_version='s2';

gaussdb_m=# SELECT strcmp('abc', 'ABC');
strcmp
-----
0
(1 row)

gaussdb_m=# SELECT strcmp('abc ', 'abc');
strcmp
-----
0
(1 row)

gaussdb_m=# SELECT strcmp('1', 1);
strcmp
-----
0
(1 row)

gaussdb_m=# SELECT strcmp(123, 2);
strcmp
-----
-1
(1 row)
```

 NOTE

- The strcmp function is valid only when **sql\_compatibility** is set to 'MYSQL'.
- Since the version whose **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1', the sql\_mode parameter **pad\_char\_to\_full\_length** specifies whether to add spaces at the end of the char type, which affects the strcmp comparison result. For details, see [Table 7-8](#).
- Since the version whose **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1', the behavior of the character, binary, numeric, and date and time types is M-compatible, which affects the strcmp comparison result. For details, see [Data Types](#). For the floating-point type in the numeric type, the precision may be different from that in MySQL due to different connection parameter settings. Therefore, this scenario is not recommended, or the numeric type is used instead. For details, see [Connection Parameters](#).
- Since the version whose **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's2', character escape and constant character string obtaining collation are supported. The collation affects the strcmp comparison result. For details, see the SET NAMES syntax in [SET](#). For details about the rules for combining different collations of the character types, see [Rules for Combining Character Sets and Collations](#).

 NOTE

- For a string containing linefeed characters, for example, a string consisting of a linefeed character and a space, the value of **LENGTH** and **LENGTHB** in GaussDB is 2.
- In GaussDB, *n* in the CHAR(*n*) type indicates the number of characters. Therefore, for multiple-octet coded character sets, the length returned by the LENGTHB function may be longer than *n*.
- GaussDB supports multiple types of databases, including ORA, MySQL, TD, and PG. The lexical analyzer of ORA-compatible database is different from that of the other three databases. In an ORA-compatible database, an empty string is considered as **NULL**. Therefore, when an ORA-compatible database is used, if an empty string is used as a parameter in the preceding character operation function, no output is displayed. For example:

```
gaussdb=# SELECT translate('12345','123','');
translate
-----
(1 row)
```

This is because the kernel checks whether the input parameter contains **NULL** before calling the corresponding function. If the input parameter contains **NULL**, the kernel does not call the corresponding function. As a result, no output is displayed. In PG-compatible mode, the processing of character strings is the same as that of PostgreSQL. Therefore, the preceding problem does not occur.

## Extension Functions and Operators

- pkg\_bpchar\_opc()  
Description: Serves as an extension API to add the comparison operator between bpchar and text or between text and bpchar policies, so as to solve the problem that indexes cannot be matched when data of the bpchar and text types is compared. Only a system administrator can install extensions.

Example:

Compare the bpchar type with the text type (initial state, forward compatibility).

```
/*
Create a table and initialize data.
*/
```

```
gaussdb=# CREATE TABLE logs_nchar(log_id nchar(16), log_message text);
gaussdb=# INSERT INTO logs_nchar SELECT GENERATE_SERIES(1,100000),MD5(RANDOM());
gaussdb=# INSERT INTO logs_nchar VALUES ('FE306991300002 ','002');
gaussdb=# CREATE INDEX idx_nchar_logid on logs_nchar(log_id);
gaussdb=# VACUUM ANALYZE logs_nchar;

/*
The purpose is to obtain the detailed execution plan of all nodes.
*/
gaussdb=# SET max_datanode_for_plan = 1;
SET

/*
If no extension is installed, when nchar and text are compared, nchar is implicitly converted to text
because there is no bpchar or text index operator. That is, the fixed-length character type is converted
to the variable-length character type. As a result, the execution plan changes and the index cannot be
matched.
*/
gaussdb=# EXPLAIN SELECT * FROM logs_nchar WHERE log_id = RPAD(TRIM('FE306991300002 '),16,
');

```

QUERY PLAN

```
-----
Data Node Scan (cost=0.00..0.00 rows=0 width=0)
  Node/s: All datanodes

Remote SQL: SELECT log_id, log_message FROM public.logs_nchar WHERE log_id::text =
rpad(btrim('FE306991300002 '::text), 16, ' '::text)
Datanode Name: datanode1
  Seq Scan on logs_nchar (cost=0.00..2539.01 rows=500 width=50)

#### NOTE

- This solves the problem that data and indexes cannot be properly matched when equality matching is performed between the bpchar type (containing multiple spaces) and the text type.
- The UB-tree and B-tree are involved. The comparison symbols include >, >=, <, <=, and <>.
- The impact scope involves implicit conversion between character types. For example, when a variable-length data type is compared with a fixed-length data type, the variable-length data type is preferentially converted to the text type instead of the original bpchar type.
- The pkg\_bpchar\_opc extension is disabled by default. You can check whether the extension is enabled in the pg\_extension system catalog. If the extension data exists, the extension is enabled. If the extension data does not exist, the extension is disabled. When extension is disabled, forward compatibility is maintained. When extension is enabled, compatibility with database ORA is maintained. After the pkg\_bpchar\_opc extension is enabled, you need to set the **max\_datanode\_for\_plan** parameter as required. This parameter specifies the number of execution plans displayed on DNs when the FQS plan is generated. For example, to set **max\_datanode\_for\_plan** to **64**, run the following command:  
set max\_datanode\_for\_plan = 64  
The extended function is for internal use only. You are advised not to use it.
- In the example, the table structure uses **log\_id** as the index and has two columns: **log\_id** and **log\_message**. The table name is followed by the **log\_id** column type. For example, if the table name is **logs\_text**, the **log\_id** column type is text.

**Table 7-33** Functions supported by pkg\_bpchar\_opc

API	Description
pg_catalog.bpchar_text_lt	Compares the bpchar type with the text type to check whether the value on the left is less than the value on the right.
pg_catalog.bpchar_text_le	Compares the bpchar type with the text type to check whether the value on the left is less than or equal to the value on the right.
pg_catalog.bpchar_text_eq	Compares the bpchar type with the text type to check whether the value on the left is equal to the value on the right.
pg_catalog.bpchar_text_ge	Compares the bpchar type with the text type to check whether the value on the left is greater than or equal to the value on the right.
pg_catalog.bpchar_text_gt	Compares the bpchar type with the text type to check whether the value on the left is greater than the value on the right.
pg_catalog.bpchar_text_ne	Compares the bpchar type with the text type to check whether the value on the left is different from the value on the right.
pg_catalog.bpchar_text_cmp	Specifies that the index of the bpchar and text types supports comparison functions.
pg_catalog.text_bpchar_lt	Compares the text type with the bpchar type to check whether the value on the left is less than the value on the right.
pg_catalog.text_bpchar_le	Compares the text type with the bpchar type to check whether the value on the left is less than or equal to the value on the right.
pg_catalog.text_bpchar_eq	Compares the text type with the bpchar type to check whether the value on the left is equal to the value on the right.
pg_catalog.text_bpchar_ge	Compares the text type with the bpchar type to check whether the value on the left is greater than or equal to the value on the right.
pg_catalog.text_bpchar_gt	Compares the text type with the bpchar type to check whether the value on the left is greater than the value on the right.
pg_catalog.text_bpchar_ne	Compares the text type with the bpchar type to check whether the value on the left is different from the value on the right.
pg_catalog.text_bpchar_cmp	Specifies that the index of the text and bpchar types supports comparison functions.

API	Description
pg_catalog.hashbpchar text	Specifies that the hash of the bpchar and text types supports comparison functions.
pg_catalog.hashtextbp char	Specifies that the hash of the text and bpchar types supports comparison functions.

- `bpcharlikebpchar(BPCHAR, BPCHAR)`

Description: Determines whether the BPCHAR character string of the first input parameter is LIKE and whether the BPCHAR character string of the second input parameter is LIKE. It is used to add the BPCHAR type and the LIKE operator of the BPCHAR type. To enable the `~~` operator, ensure that the value of the GUC parameter **behavior\_compat\_options** contains the **enable\_bpcharlikebpchar\_compare** configuration item.

Return value type: Boolean

Value range:

- **t**: Two parameters of the BPCHAR type are matched.
- **f**: Two parameters of the BPCHAR type are not matched.

Example:

```
gaussdb=# SELECT bpcharlikebpchar('455'::BPCHAR(10), '455 '::BPCHAR);
bpcharlikebpchar
-----
f
(1 row)
gaussdb=# SELECT bpcharlikebpchar('455 '::BPCHAR(10), '455 '::BPCHAR(10));
bpcharlikebpchar
-----
t
(1 row)
gaussdb=# SELECT bpcharlikebpchar('455 '::BPCHAR(10), '455'::BPCHAR(10));
bpcharlikebpchar
-----
t
(1 row)
gaussdb=# SELECT bpcharlikebpchar('455 '::BPCHAR(10), '455'::BPCHAR(11));
bpcharlikebpchar
-----
f
(1 row)
gaussdb=# CREATE TABLE op_test (
col BPCHAR(2) DEFAULT NULL
);
CREATE TABLE
gaussdb=# CREATE INDEX op_index ON op_test(col);
CREATE INDEX
gaussdb=# INSERT INTO op_test VALUES ('a');
INSERT 0 1
gaussdb=# INSERT INTO op_test VALUES ('1');
INSERT 0 1
gaussdb=# INSERT INTO op_test VALUES ('11');
INSERT 0 1
gaussdb=# INSERT INTO op_test VALUES ('12');
INSERT 0 1
gaussdb=# INSERT INTO op_test VALUES ('sd');
INSERT 0 1
gaussdb=# INSERT INTO op_test VALUES ('aa');
INSERT 0 1
gaussdb=# SHOW behavior_compat_options;
behavior_compat_options
```

```

-----
(1 row)
-- If behavior_compat_options does not contain enable_bpcharlikebpchar_compare, the latest
bpcharlikebpchar operator is not enabled and the result set returned by the matching between
bpchars is not the same as expected (all data should be returned in normal cases).
gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM op_test WHERE col LIKE col::BPCHAR ORDER BY
col;
          QUERY PLAN
-----
Streaming (type: GATHER)
  Merge Sort Key: col
  Node/s: All datanodes
  -> Sort
    Sort Key: col
    -> Seq Scan on op_test
      Filter: (col !~~ (col)::text)

(6 rows)
gaussdb=# DROP TABLE op_test;
DROP TABLE

```

 NOTE

- `bpcharlikebpchar` can be used only when the database compatibility parameter `SQL_COMPATIBILITY` is set to `ORA` and the GUC parameter `behavior_compat_options` contains the `enable_bpcharlikebpchar_compare` column.
- If this feature is enabled, the result set and execution plan for the LIKE pattern matching of the BPCHAR types are affected.
- `SET behavior_compat_options=""`; indicates that this feature is disabled, and `SET behavior_compat_options='enable_bpcharlikebpchar_compare'` indicates that this feature is enabled.
- After the new feature is enabled, fixed-length matching is used (bpchar matches bpchar). The parameter lengths on the left and right sides must be the same. During pattern matching, ensure that the length of the pattern column is the same as the forcible conversion length to avoid the difference between the result and the expected result caused by filling spaces after the length is too long.

• `bpcharnlikebpchar(BPCHAR, BPCHAR)`

Description: Determines whether the BPCHAR character string of the first input parameter is NOT LIKE and whether the BPCHAR character string of the second input parameter is NOT LIKE. It is used to add the BPCHAR type and the NOT LIKE operator of the BPCHAR type. To enable the `~~` operator, ensure that the value of the GUC parameter `behavior_compat_options` contains the `enable_bpcharlikebpchar_compare` configuration item.

Return value type: Boolean

Value range:

- **t**: Two parameters of the BPCHAR type are matched.
- **f**: Two parameters of the BPCHAR type are not matched.

Example:

```
gaussdb=# SELECT bpcharnlikebpchar('455 '::BPCHAR(10), '455 '::BPCHAR(11));
bpcharnlikebpchar
-----
t
(1 row)

gaussdb=# SELECT bpcharnlikebpchar('455 '::BPCHAR(10), '455 '::BPCHAR(10));
bpcharnlikebpchar
-----
f
(1 row)

gaussdb=# SELECT bpcharnlikebpchar('455 '::BPCHAR(10), '455 '::BPCHAR);
bpcharnlikebpchar
-----
t
(1 row)

gaussdb=# CREATE TABLE op_test (
col BPCHAR(2) DEFAULT NULL
);
CREATE TABLE
gaussdb=# CREATE INDEX op_index ON op_test(col);
CREATE INDEX
gaussdb=# INSERT INTO op_test VALUES ('a');
INSERT 0 1
gaussdb=# INSERT INTO op_test VALUES ('1');
INSERT 0 1
gaussdb=# INSERT INTO op_test VALUES ('11');
INSERT 0 1
gaussdb=# insert into op_test VALUES ('12');
INSERT 0 1
```

```

gaussdb=# INSERT INTO op_test VALUES ('sd');
INSERT 0 1
gaussdb=# INSERT INTO op_test VALUES ('aa');
INSERT 0 1
gaussdb=# SHOW behavior_compat_options;
behavior_compat_options
-----
(1 row)
-- If behavior_compat_options does not contain enable_bpcharlikebpchar_compare, the latest
bpcharlikebpchar operator is not enabled and the result set returned by the matching between
bpchars is not the same as expected (no data record is returned in normal cases).
gaussdb=# SELECT * FROM op_test WHERE col NOT LIKE col::BPCHAR ORDER BY col;
col
-----
1
a
(2 rows)

gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM op_test WHERE col NOT LIKE col::BPCHAR ORDER
BY col;
QUERY PLAN
-----
Streaming (type: GATHER)
  Merge Sort Key: col
  Node/s: All datanodes
  -> Sort
      Sort Key: col
      -> Seq Scan on op_test
          Filter: (col !~~ (col)::text)
(7 rows)
gaussdb=# SET behavior_compat_options = 'enable_bpcharlikebpchar_compare';
SET
gaussdb=# SHOW behavior_compat_options;
behavior_compat_options
-----
enable_bpcharlikebpchar_compare
(1 row)
-- After this parameter is enabled, the latest bpcharlikebpchar operator is enabled, and the returned
behavior meets the expected behavior during matching.
gaussdb=# SELECT * FROM op_test WHERE col NOT LIKE col::BPCHAR ORDER BY col;
col
-----
(0 rows)

gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM op_test WHERE col NOT LIKE col::BPCHAR ORDER
BY col;
QUERY PLAN
-----
Streaming (type: GATHER)
  Merge Sort Key: col
  Node/s: All datanodes
  -> Sort
      Sort Key: col
      -> Seq Scan on op_test
          Filter: (col !~~ col)
(7 rows)
gaussdb=# DROP TABLE op_test;
DROP TABLE

```

 NOTE

- `bpcharlikebpchar` can be used only when the database compatibility parameter `SQL_COMPATIBILITY` is set to `ORA` and the GUC parameter `behavior_compat_options` contains the `enable_bpcharlikebpchar_compare` column.
- If this feature is enabled, the result set and execution plan for the NOT LIKE pattern matching of the BPCHAR types are affected.
- `SET behavior_compat_options=""`; indicates that this feature is disabled, and `SET behavior_compat_options='enable_bpcharlikebpchar_compare'` indicates that this feature is enabled.
- After the new feature is enabled, fixed-length matching is used (`bpchar` matches `bpchar`). The parameter lengths on the left and right sides must be the same. During pattern matching, ensure that the length of the pattern column is the same as the forcible conversion length to avoid the difference between the result and the expected result caused by filling spaces after the length is too long.

## 7.6.4 Binary String Functions and Operators

### String Operators

SQL defines some string functions that use keywords, rather than commas, to separate arguments.

- `octet_length(string)`

Description: Specifies the number of bytes in a binary string.

Return type: `int`

Example:

```
gaussdb=# SELECT octet_length(E'jo\000se'::bytea) AS RESULT;
result
-----
      5
(1 row)
```

- `overlay(string placing string from int [for int])`

Description: Replaces substrings.

Return type: `bytea`

Example:

```
gaussdb=# SELECT overlay(E'Th\000omas'::bytea placing E'\002\003'::bytea from 2 for 3) AS
RESULT;
result
-----
\x5402036d6173
(1 row)
```

- `position(substring in string)`

Description: Specifies the position of a specified substring.

Return type: `int`

Example:

```
gaussdb=# SELECT position(E'\000om'::bytea in E'Th\000omas'::bytea) AS RESULT;
result
-----
      3
(1 row)
```

- `substring(string [from int] [for int])`

Description: Truncates a substring.

Return type: bytea

Example:

```
gaussdb=# SELECT substr(E'Th\000omas'::bytea from 2 for 3) AS RESULT;
result
-----
\x68006f
(1 row)
```

- substr(bytea [from int] [for int])

Description: Truncates a substring.

Return type: bytea

Example:

```
gaussdb=# SELECT substr(E'Th\000omas'::bytea,2, 3) as result;
result
-----
\x68006f
(1 row)
```

- trim([both] bytes from string)

Description: Removes the longest string containing only **bytes** from the start and end of **string**.

Return type: bytea

Example:

```
gaussdb=# SELECT trim(E'\000'::bytea from E'\000Tom\000'::bytea) AS RESULT;
result
-----
\x546f6d
(1 row)
```

## Other Binary String Functions

GaussDB provides common syntax used for calling functions.

- btrim(string bytea,bytes bytea)

Description: Removes the longest string containing only **bytes** from the start and end of **string**.

Return type: bytea

Example:

```
gaussdb=# SELECT btrim(E'\000trim\000'::bytea, E'\000'::bytea) AS RESULT;
result
-----
\x7472696d
(1 row)
```

- get\_bit(string, offset)

Description: Extracts bits from a string.

Return type: int

Example:

```
gaussdb=# SELECT get_bit(E'Th\000omas'::bytea, 45) AS RESULT;
result
-----
1
(1 row)
```

- get\_byte(string, offset)

Description: Extracts bytes from a string.

Return type: int

Example:

```
gaussdb=# SELECT get_byte(E'Th\000omas'::bytea, 4) AS RESULT;
 result
-----
    109
(1 row)
```

- `set_bit(string,offset, newvalue)`

Description: Sets bits in a string.

Return type: bytea

Example:

```
gaussdb=# SELECT set_bit(E'Th\000omas'::bytea, 45, 0) AS RESULT;
 result
-----
\x5468006f6d4173
(1 row)
```

- `set_byte(string,offset, newvalue)`

Description: Sets bytes in a string.

Return type: bytea

Example:

```
gaussdb=# SELECT set_byte(E'Th\000omas'::bytea, 4, 64) AS RESULT;
 result
-----
\x5468006f406173
(1 row)
```

- `rawcmp(raw, raw)`

Description: Specifies the raw data type comparison function.

Parameters: raw, raw

Return type: integer

- `raweq(raw, raw)`

Description: Specifies the raw data type comparison function.

Parameters: raw, raw

Return type: Boolean

- `rawge(raw, raw)`

Description: Specifies the raw data type comparison function.

Parameters: raw, raw

Return type: Boolean

- `rawgt(raw, raw)`

Description: Specifies the raw data type comparison function.

Parameters: raw, raw

Return type: Boolean

- `rawin(cstring)`

Description: Specifies the raw data type parsing function.

Parameter: cstring

Return type: bytea

- `rawle(raw, raw)`  
Description: Specifies the raw data type parsing function.  
Parameters: raw, raw  
Return type: Boolean
- `rawlike(raw, raw)`  
Description: Specifies the raw data type parsing function.  
Parameters: raw, raw  
Return type: Boolean
- `rawlt(raw, raw)`  
Description: Specifies the raw data type parsing function.  
Parameters: raw, raw  
Return type: Boolean
- `rawne(raw, raw)`  
Description: Compares whether the raw types are the same.  
Parameters: raw, raw  
Return type: Boolean
- `rawnlike(raw, raw)`  
Description: Checks whether the raw type matches the pattern.  
Parameters: raw, raw  
Return type: Boolean
- `rawout(bytea)`  
Description: Specifies the RAW output API.  
Parameter: bytea  
Return type: cstring
- `rawsend(raw)`  
Description: Converts the bytea type to the binary type.  
Parameter: raw  
Return type: bytea
- `rawtohex(text)`  
Description: Converts the raw format to the hexadecimal format.  
Parameter: text  
Return type: text

## 7.6.5 Bit String Functions and Operators

### Bit String Operators

Aside from the usual comparison operators, the following operators can be used. Bit string operands of `&`, `|`, and `#` must be of equal length. In case of bit shifting, the original length of the string is preserved by zero padding (if necessary).

- `||`  
Description: Connects bit strings.

Example:

```
gaussdb=# SELECT B'10001' || B'011' AS RESULT;
result
-----
10001011
(1 row)
```

 **NOTE**

- A field can have a maximum of 180 consecutive internal joins. A field with excessive joins will be split into joined consecutive strings.  
Example: **str1||str2||str3||str4** is split into **(str1||str2)||(str3||str4)**.
- In ORA-compatible mode, if bit strings contain a null string, the null string is ignored and other strings are joined. In other compatibility modes, the null string is returned.  
Take **str1||NULL||str2** as an example. **str1str2** is returned in ORA-compatible mode and **NULL** is returned in other compatibility modes.

- **&**

Description: Specifies the AND operation between bit strings.

Example:

```
gaussdb=# SELECT B'10001' & B'01101' AS RESULT;
result
-----
00001
(1 row)
```

- **|**

Description: Specifies the OR operation between bit strings.

Example:

```
gaussdb=# SELECT B'10001' | B'01101' AS RESULT;
result
-----
11101
(1 row)
```

- **#**

Description: Specifies the OR operation between bit strings if they are inconsistent. If the same positions in the two bit strings are both 1 or 0, the position returns **0**.

Example:

```
gaussdb=# SELECT B'10001' # B'01101' AS RESULT;
result
-----
11100
(1 row)
```

- **~**

Description: Specifies the NOT operation between bit strings.

Example:

```
gaussdb=# SELECT ~B'10001' AS RESULT;
result
-----
01110
(1 row)
```

- **<<**

Description: Shifts left in a bit string.

Example:

```
gaussdb=# SELECT B'10001' << 3 AS RESULT;
result
-----
01000
(1 row)
```

- >>  
Description: Shifts right in a bit string.

Example:

```
gaussdb=# SELECT B'10001' >> 2 AS RESULT;
result
-----
00100
(1 row)
```

The following SQL-standard functions work on bit strings as well as strings: `length`, `bit_length`, `octet_length`, `position`, `substring`, and `overlay`.

The following functions work on bit strings as well as binary strings: `get_bit` and `set_bit`. When working with a bit string, these functions number the first (leftmost) bit of the string as bit 0.

In addition, it is possible to convert between integral values and type bit. Example:

```
gaussdb=# SELECT 44::bit(10) AS RESULT;
result
-----
0000101100
(1 row)

gaussdb=# SELECT 44::bit(3) AS RESULT;
result
-----
100
(1 row)

gaussdb=# SELECT cast(-44 as bit(12)) AS RESULT;
result
-----
111111010100
(1 row)

gaussdb=# SELECT '1110'::bit(4)::integer AS RESULT;
result
-----
14
(1 row)

gaussdb=# SELECT substring('10101111'::bit(8), 2);
substring
-----
0101111
(1 row)
```

#### NOTE

Casting to just "bit" means casting to bit(1), and so will deliver only the least significant bit of the integer.

## 7.6.6 Pattern Matching Operators

The database provides three independent methods for implementing pattern matching: SQL LIKE operator, SIMILAR TO operator, and POSIX-style regular expressions. Besides these basic operators, functions can be used to extract or replace matching substrings and to split a string at matching locations.

- LIKE

Description: Specifies whether the string matches the pattern string following LIKE. The LIKE expression returns true if the string matches the supplied pattern. (As expected, the NOT LIKE expression returns false if LIKE returns true, and vice versa.)

Matching rules:

- This operator can succeed only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.
- An underscore (\_) represents (matches) any single character. A percent sign (%) represents the wildcard character of any string.
- To match a literal underscore or percent sign, the respective character in pattern must be preceded by the escape character. The default escape character is one backslash but a different one can be selected by using the ESCAPE clause.
- To match with escape characters, enter two escape characters. For example, to write a pattern constant containing a backslash (\), you need to enter two backslashes in SQL statements.

 NOTE

When **standard\_conforming\_strings** is set to **off**, any backslashes you write in literal string constants will need to be doubled. Therefore, writing a pattern matching a single backslash is actually going to write four backslashes in the statement. You can avoid this by selecting a different escape character by using ESCAPE, so that the backslash is no longer a special character of LIKE. But the backslash is still the special character of the character text analyzer. In this case, two backslashes are required. You can also select no escape character by writing "ESCAPE". This effectively disables the escape mechanism, but it does not eliminate the special meaning of underscore and percent signs in the pattern.

- The keyword ILIKE can be used instead of LIKE to make the match case-insensitive.
- Operator ~~ is equivalent to LIKE, and operator ~~\* corresponds to ILIKE.

Example:

```
gaussdb=# SELECT 'abc' LIKE 'abc' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' LIKE 'a%' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' LIKE '_b_' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' LIKE 'c' AS RESULT;
result
-----
f
(1 row)
```

- SIMILAR TO

Description: Returns true or false depending on whether the pattern matches the given string. It is similar to LIKE, but differs in that SIMILAR TO uses the regular expression understanding pattern defined by the SQL standard.

Matching rules:

- a. Similar to LIKE, this operator succeeds only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.
- b. An underscore (\_) represents (matches) any single character. A percent sign (%) represents the wildcard character of any string.
- c. SIMILAR TO supports these pattern-matching metacharacters borrowed from POSIX-style regular expressions:

Metacharacter	Description
	Specifies alternation (either of two alternatives).
*	Specifies repetition of the previous item zero or more times.
+	Specifies repetition of the previous item one or more times.
?	Specifies repetition of the previous item zero or one time.
{m}	Specifies repetition of the previous item exactly <i>m</i> times.
{m,}	Specifies repetition of the previous item <i>m</i> or more times.
{m,n}	Specifies repetition of the previous item at least <i>m</i> times and does not exceed <i>n</i> times.
()	Specifies that parentheses () can be used to group items into a single logical item.
[...]	Specifies a character class, just as in POSIX-style regular expressions.

- d. A preamble escape character disables the special meaning of any of these metacharacters. The rules for using escape characters are the same as those for LIKE.

Regular expressions:

The **substring(string from pattern for escape)** function extracts a substring that matches an SQL regular expression pattern.

Example:

```
gaussdb=# SELECT 'abc' SIMILAR TO 'abc' AS RESULT;
result
-----
```

```

t
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO 'a' AS RESULT;
result
-----
f
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO '%(b|d)%' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO '(b|c)%' AS RESULT;
result
-----
f
(1 row)
    
```

- **POSIX-style regular expressions**

Description: A regular expression is a collation that is an abbreviated definition of a set of strings (a regular set). If a string is a member of a regular set described by a regular expression, the string matches the regular expression. POSIX-style regular expressions provide a more powerful means for pattern matching than the LIKE and SIMILAR TO operators. [Table 1 Regular expression match operators](#) lists all available operators for pattern matching using POSIX-style regular expressions.

**Table 7-34** Regular expression match operators

Operator	Description	Example
~	Matches a regular expression, which is case-sensitive.	'thomas' ~ '.*thomas.*'
~*	Matches a regular expression, which is case-insensitive.	'thomas' ~* '.*Thomas.*'
!~	Does not match a regular expression, which is case-sensitive.	'thomas' !~ '.*Thomas.*'
!~*	Does not match a regular expression, which is case-insensitive.	'thomas' !~* '.*vadim.*'

**Matching rules:**

- Unlike LIKE patterns, a regular expression is allowed to match anywhere within a string, unless the regular expression is explicitly anchored to the beginning or end of the string.
- Besides the metacharacters mentioned above, POSIX-style regular expressions also support the following pattern matching metacharacters:

Metacharacter	Description
^	Specifies the match starting with a string.
\$	Specifies the match at the end of a string.
.	Matches any single character.

Regular expressions:

POSIX-style regular expressions support the following functions:

- The **substring(string from pattern)** function provides a method for extracting a substring that matches the POSIX-style regular expression pattern.
- The **regexp\_count(string text, pattern text [, position int [, flags text]])** function provides the function of obtaining the number of substrings that match the POSIX-style regular expression pattern.
- The **regexp\_instr(string text, pattern text [, position int [, occurrence int [, return\_opt int [, flags text]]])** function is used to obtain the position of a substring that matches a POSIX-style regular expression pattern.
- The **regexp\_substr(string text, pattern text [, position int [, occurrence int [, flags text]])** function provides a method to extract a substring that matches a POSIX-style regular expression pattern.
- The **regexp\_replace(string, pattern, replacement [,flags ])** function replaces the substring that matches the POSIX-style regular expression pattern with the new text.
- The **regexp\_matches(string text, pattern text [, flags text])** function returns a text array consisting of all captured substrings that match a POSIX-style regular expression pattern.
- The **regexp\_split\_to\_table(string text, pattern text [, flags text])** function splits a string using a POSIX-style regular expression pattern as a delimiter.
- The **regexp\_split\_to\_array(string text, pattern text [, flags text ])** function behaves the same as `regexp_split_to_table`, except that `regexp_split_to_array` returns its result as an array of text.

 NOTE

The regular expression split functions ignore zero-length matches, which occur at the beginning or end of a string or after the previous match. This is contrary to the strict definition of regular expression matching. The latter is implemented by **regexp\_matches**, but the former is usually the most commonly used behavior in practice.

Example:

```
gaussdb=# SELECT 'abc' ~ 'Abc' AS RESULT;
result
-----
f
(1 row)
gaussdb=# SELECT 'abc' ~* 'Abc' AS RESULT;
result
```

```

-----
t
(1 row)
gaussdb=# SELECT 'abc' !~ 'Abc' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc'!~* 'Abc' AS RESULT;
result
-----
f
(1 row)
gaussdb=# SELECT 'abc' ~ '^a' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' ~ '(b)d)'AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' ~ '^(\b|c)'AS RESULT;
result
-----
f
(1 row)

```

Although most regular expression searches can be executed quickly, they can still be artificially processed to require any length of time and any amount of memory. It is not recommended that you accept the regular expression search pattern from the non-security pattern source. If you must do this, you are advised to add the statement timeout limit. The search with the SIMILAR TO pattern has the same security risks, as SIMILAR TO provides many capabilities that are the same as those of the POSIX-style regular expression. The LIKE search is much simpler than the other two options. Therefore, it is more secure to accept the non-secure pattern source search.

- [NOT] REGEXP/ [NOT] RLIKE

Description: The REGEXP operator is used for regular expression matching and complies with POSIX-style regular expression matching rules. **TRUE** or **FALSE** is returned based on whether the pattern matches the given string.

The following table describes the regular expression operators.

Operator Name	Description	Syntax
REGEXP	Specifies whether a string matches the regular expression.	expr REGEXP pat
RLIKE	Specifies whether a string matches the regular expression (same as REGEXP).	expr RLIKE pat
NOT REGEXP	Specifies whether a string does not match the regular expression.	expr NOT REGEXP pat

Operator Name	Description	Syntax
NOT RLIKE	Specifies whether the character string does not match the regular expression (same as NOT REGEXP).	expr NOT RLIKE pat

Matching rules:

- a. A regular expression allows you to match any position in a string unless the regular expression is explicitly concatenated at the beginning or end of the string.
- b. The pattern matching metacharacters supported by the REGEXP operator are the same as those supported by POSIX-style regular expressions.
- c. The operator supports the following escape character matching.

Escape Character	Description
\b	Backspace key.
\f	Form feed character, for example, C language.
\n	Newline character, for example, C language.
\r	Carriage return character, for example, C language.
\t	Horizontal tab character, for example, C language.
\uwxxyz	Character whose hexadecimal value is <b>0xwxxyz</b> , where <b>wxyz</b> is four hexadecimal digits.
\xhhh	Character whose hexadecimal value is <b>0xhhh</b> , where <b>hhh</b> is any sequence of hexadecimal digits.
\xy	Character whose octal value is <b>0xy</b> , where <b>xy</b> is two octal digits.
\xyz	Character whose octal value is <b>0xyz</b> , where <b>xyz</b> is three octal digits.

- d. Ranges for matching a pattern string: [a-dX] and [^a-dX].  
[a-dX] matches any characters of a, b, c, d, and X. [^a-dX] matches characters other than a, b, c, d, or X.

The hyphen (-) between two characters forms a range, indicating that all characters in the range are matched. To include a right square bracket (]), it must follow the left square bracket ([). To include a hyphen (-), it must be after the left square bracket ([) or before the right square bracket (]). Any character that does not have any special meaning enclosed in square brackets ([]) matches itself.

Example:

```
gaussdb=# SELECT 'abd' REGEXP 'a[bc]d' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'aed' REGEXP 'a[^bc]d' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'a-' REGEXP 'a[-b]' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'aX]bc' REGEXP '^[]a-dXYZ]*$' AS RESULT;
result
-----
t
(1 row)
```

- e. [.characters.] in the pattern string pat matches the collation of the element. In bracket expressions using quare brackets ([ ]), the collation used to proofread elements is matched. The character is a single character or a character name such as **space**. A complete list of character names can be found in the **regex/regc\_locale** file.

Example:

```
gaussdb=# SELECT '' REGEXP '[[.space.]]' AS RESULT;
result
-----
t
(1 row)
```

- f. Character class matching the [=character\_class=] character in the pattern string pat. It is written in the square bracket expression. [=character\_class=] indicates the equivalence class. A character matches all characters with the same sort proofreading value, including itself. For example, if o and (+) are of the same class, [[=o=]], [[=(+)=]], and [o(+)] are synonyms. The same class cannot be used as an endpoint of a range.
- g. Character class matching the [:character\_class:] character in the pattern string pat. It is written in square brackets ([ ]). [:character\_class:] is used to match the characters that match the character class. Other class names may be provided for specific regions. The character class cannot be used as an endpoint of a range. The following table lists the standard class names. If the backslash (\) is involved, set the parameters according to the description.

Character Class	Description	Character Range
alnum	Alphanumeric numeric character.	[0-9a-zA-Z]
alpha	Alphanumeric character.	[a-zA-Z]
blank	Blank character.	[\t], indicating a blank character
cntrl	Control character.	[\x01-\x1F]

Character Class	Description	Character Range
digit	Digit character.	[0-9]
graph	Graphic character.	[^\x01-\x20]
lower	Lowercase character.	[a-z]
print	Graphic character.	[^\x01-\x20]
punct	Punctuation character.	[-!"#\$%&'()*+,-./:;<=>?@[\\]^_`{ }~]
space	Spaces, tabs, new lines, and carriage returns.	[\n\r\t\x0B]
upper	Uppercase character.	[A-Z]
xdigit	Hexadecimal numeric character.	[0-9a-fA-F]

Example:

```
gaussdb=# SELECT '\n' REGEXP '[:space:]' AS RESULT;
result
-----
t
(1 row)
```

- h. Start and end matching of the [[:<:]], [[:>]] matching string in the pattern string pat.

Example:

```
gaussdb=# SELECT 'a word a' REGEXP '[:<:]word[:>:]' AS RESULT;
result
-----
t
(1 row)
```

- i. For text instances that match special characters, add two backslashes (\) before the special characters (including (, ), ., ", ^, +, and ?). To match single quotation marks, you need to write \' in the source string to match \\' in the pattern string. If the backslash (\) is involved, set the parameters according to the description.

Example:

```
gaussdb=# SELECT 'a+b' REGEXP 'a\\+b' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT '\'' REGEXP '\\\'' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT '\\\' REGEXP '\\\'' AS RESULT;
```

```
result
-----
t
(1 row)
```

- j. When the case-sensitive character set and collation are set, regular expression matching is also case-sensitive.

Example:

```
gaussdb=# SELECT 'abc' REGEXP 'ABC' COLLATE utf8mb4_bin AS RESULT;
result
-----
f
(1 row)
```

- k. If the input parameter **Expr** or **pat** is **NULL**, an empty value is returned.

```
gaussdb=# SELECT NULL REGEXP '*' AS RESULT;
result
-----
(1 row)
gaussdb=# SELECT '-' REGEXP NULL AS RESULT;
result
-----
(1 row)
```

#### NOTE

This operator is supported only in MySQL-compatible databases and is valid only when **sql\_compatibility** is set to 'MYSQL'. **b\_format\_version** is set to '5.7'. In this case, the REGEXP operator is equivalent to the ~\* operator, and the NOT REGEXP operator is equivalent to the !~\* operator.

- When **b\_format\_dev\_version** is set to **s2**, **standard\_conforming\_strings** is set to **off** and **escape\_string\_warning** is set to **off** by default. In this case, any backslash written in the string constant must be written repeatedly. Therefore, writing a pattern matching a single backslash is actually going to write four backslashes in the statement.
- This operator supports only the string type, text type, and other data types that can be implicitly converted to the string type and text type. The bytea type is not supported.

## 7.6.7 Arithmetic Functions and Operators

### Arithmetic Operators

- +

Description: Addition

Example:

```
gaussdb=# SELECT 2+3 AS RESULT;
result
-----
5
(1 row)
```

- -

Description: Subtraction

Example:

```
gaussdb=# SELECT 2-3 AS RESULT;
result
-----
-1
(1 row)
```

- \*

Description: Multiplication

Example:

```
gaussdb=# SELECT 2*3 AS RESULT;
result
-----
      6
(1 row)
```

- /

Description: Division (The result is not rounded.)

Example:

```
gaussdb=# SELECT 4/2 AS RESULT;
result
-----
      2
(1 row)
gaussdb=# SELECT 4/3 AS RESULT;
result
-----
1.3333333333333333
(1 row)
```

- +/-

Description: Positive/Negative

Example:

```
gaussdb=# SELECT -2 AS RESULT;
result
-----
     -2
(1 row)
```

- %

Description: Model (to obtain the remainder)

Example:

```
gaussdb=# SELECT 5%4 AS RESULT;
result
-----
      1
(1 row)
```

- @

Description: Absolute value

Example:

```
gaussdb=# SELECT @ -5.0 AS RESULT;
result
-----
     5.0
(1 row)
```

- ^

Description: Power (exponent calculation)

Example:

```
gaussdb=# SELECT 2.0^3.0 AS RESULT;
result
-----
8.0000000000000000
(1 row)
```

- |/

Description: Square root

Example:

```
gaussdb=# SELECT |/ 25.0 AS RESULT;  
result  
-----  
5  
(1 row)
```

- `||/`

Description: Cubic root

Example:

```
gaussdb=# SELECT ||/ 27.0 AS RESULT;  
result  
-----  
3  
(1 row)
```

- `!`

Description: Factorial

Example:

```
gaussdb=# SELECT 5! AS RESULT;  
result  
-----  
120  
(1 row)
```

- `!!`

Description: Factorial (prefix operator)

Example:

```
gaussdb=# SELECT !!5 AS RESULT;  
result  
-----  
120  
(1 row)
```

- `&`

Description: Binary AND

Example:

```
gaussdb=# SELECT 91&15 AS RESULT;  
result  
-----  
11  
(1 row)
```

- `|`

Description: Binary OR

Example:

```
gaussdb=# SELECT 32|3 AS RESULT;  
result  
-----  
35  
(1 row)
```

- `#`

Description: Binary XOR

Example:

```
gaussdb=# SELECT 17#5 AS RESULT;  
result  
-----
```

- ```
20
(1 row)
```

~

Description: Binary NOT

Example:

```
gaussdb=# SELECT ~1 AS RESULT;
result
-----
-2
(1 row)
```
- <<

Description: Binary shift left

Example:

```
gaussdb=# SELECT 1<<4 AS RESULT;
result
-----
16
(1 row)
```

- >>

Description: Binary shift right

Example:

```
gaussdb=# SELECT 8>>2 AS RESULT;
result
-----
2
(1 row)
```

## Arithmetic Functions

- abs(x)

Description: Absolute value

Return type: same as the input

Example:

```
gaussdb=# SELECT abs(-17.4);
abs
-----
17.4
(1 row)
```

- acos(x)

Description: Arc cosine

Return type: double precision

Example:

```
gaussdb=# SELECT acos(-1);
acos
-----
3.14159265358979
(1 row)
```

- asin(x)

Description: Arc sine

Return type: double precision

Example:

```
gaussdb=# SELECT asin(0.5);
asin
```

- ```
-----  
.523598775598299  
(1 row)
```

  - **atan(x)**  
Description: Arc tangent  
Return type: double precision  
Example:  

```
gaussdb=# SELECT atan(1);  
atan  
-----  
.785398163397448  
(1 row)
```
  - **atan2(y, x)**  
Description: Arc tangent of y/x  
Return type: double precision  
Example:  

```
gaussdb=# SELECT atan2(2, 1);  
atan2  
-----  
1.10714871779409  
(1 row)
```
  - **bitand(integer, integer)**  
Description: Performs the AND (&) operation on two integers.  
Return type: bigint  
Example:  

```
gaussdb=# SELECT bitand(127, 63);  
bitand  
-----  
63  
(1 row)
```
  - **cbrt(dp)**  
Description: Cubic root  
Return type: double precision  
Example:  

```
gaussdb=# SELECT cbrt(27.0);  
cbrt  
-----  
3  
(1 row)
```
  - **ceil(x)**  
Description: Minimum integer greater than or equal to the parameter  
Return type: integer  
Example:  

```
gaussdb=# SELECT ceil(-42.8);  
ceil  
-----  
-42  
(1 row)
```
  - **ceiling(dp or numeric)**  
Description: Minimum integer (alias of ceil) greater than or equal to the parameter

Return type: same as the input

Example:

```
gaussdb=# SELECT ceiling(-95.3);
 ceiling
-----
      -95
(1 row)
```

- **cos(x)**

Description: Cosine

Return type: double precision

Example:

```
gaussdb=# SELECT cos(-3.1415927);
   cos
-----
-.9999999999999999
(1 row)
```

- **cosh(x)**

Description: Hyperbolic cosine

Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

```
gaussdb=# SELECT cosh(4);
   cosh
-----
27.3082328360165
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- **cot(x)**

Description: Cotangent

Return type: double precision

Example:

```
gaussdb=# SELECT cot(1);
   cot
-----
.642092615934331
(1 row)
```

- **degrees(dp)**

Description: Converts radians to angles.

Return type: double precision

Example:

```
gaussdb=# SELECT degrees(0.5);
 degrees
-----
28.6478897565412
(1 row)
```

- **div(y numeric, x numeric)**

Description: Integer part of y/x

Return type: numeric

Example:

```
gaussdb=# SELECT div(9,4);
div
-----
 2
(1 row)
```

- **exp(x)**

Description: Natural exponent

Return type: same as the input

Example:

```
gaussdb=# SELECT exp(1.0);
exp
-----
2.7182818284590452
(1 row)
```

- **floor(x)**

Description: Not larger than the maximum integer of the parameter

Return type: same as the input

Example:

```
gaussdb=# SELECT floor(-42.8);
floor
-----
-43
(1 row)
```

- **int1(in)**

Description: Converts the input text parameter to a value of the int1 type and returns the value.

Return type: int1

Example:

```
gaussdb=# SELECT int1('123');
int1
-----
123
(1 row)
gaussdb=# SELECT int1('1.1');
int1
-----
 1
(1 row)
```

- **int2(in)**

Description: Converts the input parameter to a value of the int2 type and returns the value. The supported input parameter types include bigint, float4, float8, int16, integer, numeric, real, and text.

Return type: int2

Example:

```
gaussdb=# SELECT int2('1234');
int2
-----
1234
(1 row)
gaussdb=# SELECT int2(25.3);
int2
-----
 25
(1 row)
```

- **int4(in)**

Description: Converts the input parameter to a value of the int4 type and returns the value. The supported input parameter types include bit, boolean, char, double precision, int16, numeric, real, smallint, and text

Return type: int4

Example:

```
gaussdb=# SELECT int4('789');
int4
-----
 789
(1 row)
gaussdb=# SELECT int4(99.9);
int4
-----
 100
(1 row)
```

- **int8(in)**

Description: Converts the input parameter to a value of the int8 type and returns the value. The supported input parameter types include bit, double precision, int16, integer, numeric, oid, real, smallint, and text.

Return type: int8

Example:

```
gaussdb=# SELECT int8('789');
int8
-----
 789
(1 row)
gaussdb=# SELECT int8(99.9);
int8
-----
  99
(1 row)
```

- **float4(in)**

Description: Converts the input parameter to a value of the float4 type and returns the value. The supported input parameter types include bigint, double precision, int16, integer, numeric, smallint, and text.

Return type: float4

Example:

```
gaussdb=# SELECT float4('789');
float4
-----
 789
(1 row)
gaussdb=# SELECT float4(99.9);
float4
-----
 99.9
(1 row)
```

- **float8(in)**

Description: Converts the input parameter to a value of the float8 type and returns the value. The supported input parameter types include bigint, int16, integer, numeric, real, smallint, and text.

Return type: float8

Example:

```
gaussdb=# SELECT float8('789');
float8
-----
 789
(1 row)
```

```
gaussdb=# SELECT float8(99.9);
float8
-----
 99.9
(1 row)
```

- **int16(in)**

Description: Converts the input parameter to a value of the int16 type and returns the value. The supported input parameter types include bigint, boolean, double precision, integer, numeric, oid, real, smallint, and tinyint.

Return type: int16

Example:

```
gaussdb=# SELECT int16('789');
int16
-----
 789
(1 row)
```

```
gaussdb=# SELECT int16(99.9);
int16
-----
 100
(1 row)
```

- **numeric(in)**

Description: Converts the input parameter to a value of the numeric type and returns the value. The supported input parameter types include bigint, boolean, double precision, int16, integer, money, real, and smallint.

Return type: numeric

Example:

```
gaussdb=# SELECT "numeric"('789');
numeric
-----
 789
(1 row)
```

```
gaussdb=# SELECT "numeric"(99.9);
numeric
-----
 99.9
(1 row)
```

- **oid(in)**

Description: Converts the input parameter to a value of the oid type and returns the value. The supported input parameter types include bigint and int16.

Return type: oid

- **radians(dp)**

Description: Converts angles to radians.

Return type: double precision

Example:

```
gaussdb=# SELECT radians(45.0);
radians
```

```
-----  
.785398163397448  
(1 row)
```

- random()

Description: Random number between 0.0 and 1.0.

Return type: double precision

Example:

```
gaussdb=# SELECT random();  
random
```

```
-----  
.824823560658842  
(1 row)
```

- rand([seed])

Description: Returns a random number between 0 and 1. If seed is specified, the random value of seed is returned. There can be no input parameter or a seed input parameter of the bigint type.

Parameter: a random number seed of the bigint type.

Return type: double

Example:

```
b_compatible_db=# SELECT rand();  
rand
```

```
-----  
.327476012520492  
(1 row)
```

```
b_compatible_db=# SELECT rand(12321);  
rand
```

```
-----  
.326073104515672  
(1 row)
```

 **NOTE**

This function takes effect when the database parameter **sql\_compatibility** is set to **'MYSQL'**.

- multiply(x double precision or text, y double precision or text)

Description: product of x and y.

Return type: double precision

Example:

```
gaussdb=# SELECT multiply(9.0, '3.0');  
multiply
```

```
-----  
27  
(1 row)
```

```
gaussdb=# SELECT multiply('9.0', 3.0);  
multiply
```

```
-----  
27  
(1 row)
```

- ln(x)

Description: Natural logarithm.

Return type: same as the input

Example:

```
gaussdb=# SELECT ln(2.0);  
ln
```

```
-----  
.6931471805599453  
(1 row)
```

- **log(x)**  
Description: Logarithm with 10 as the base.  
Return type: same as the input.  
Example:

```
gaussdb=# SELECT log(100.0);  
log  
-----  
2.0000000000000000  
(1 row)
```

- **log(b numeric, x numeric)**  
Description: Logarithm with b as the base.  
Return type: numeric  
Example:

```
gaussdb=# SELECT log(2.0, 64.0);  
log  
-----  
6.0000000000000000  
(1 row)
```

- **log2(x)**  
Description: Logarithm with 2 as the base.  
Return type: double precision  
Example:

```
gaussdb=# SELECT log2(2);  
log2  
-----  
1  
(1 row)
```

 **NOTE**

This function takes effect when the database parameter **sql\_compatibility** is set to **'MYSQL'**.

- **log10(x)**  
Description: Logarithm with 10 as the base.  
Return type: double precision  
Example:

```
gaussdb=# SELECT log10(10);  
log10  
-----  
1  
(1 row)
```

 **NOTE**

This function takes effect when the database parameter **sql\_compatibility** is set to **'MYSQL'**.

- **mod(x,y)**  
Description:  
Remainder of x/y (model).  
If x equals to 0, y is returned.

Return type: same as the parameter type

Example:

```
gaussdb=# SELECT mod(9,4);
 mod
-----
  1
(1 row)
gaussdb=# SELECT mod(9,0);
 mod
-----
  9
(1 row)
```

- pi()

Description:  $\pi$  constant value.

Return type: double precision

Example:

```
gaussdb=# SELECT pi();
 pi
-----
3.14159265358979
(1 row)
```

- power(a double precision, b double precision)

Description: b power of a.

Return type: double precision

Example:

```
gaussdb=# SELECT power(9.0, 3.0);
 power
-----
729.0000000000000000
(1 row)
```

- remainder(x,y)

Description: Remainder of x/y. If y is 0, an error is reported.

Return type: same as the input (float4, float8, or numeric)

Example:

```
gaussdb=# SELECT remainder(11,4);
 remainder
-----
 -1
(1 row)
gaussdb=# SELECT remainder(9,0);
ERROR: division by zero
CONTEXT: referenced column: remainder
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- round(x)

Description: Integer closest to the input parameter.

Return type: same as the input (double precision or numeric).

Example:

```
gaussdb=# SELECT round(42.4);
 round
-----
 42
```

```
(1 row)
gaussdb=# SELECT round(42.6);
round
-----
43
(1 row)
```

 **CAUTION**

The output of the float/double type may be **-0**. (This also occurs in functions such as trunc and ceil. If the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s1** in an ORA-compatible database, the returned result is **0**. The following is an example:

```
gaussdb=# SELECT round(-0.2::float8);
round
-----
-0
(1 row)
```

- round(v numeric, s int)

Description: The number of *s* digits are kept after the decimal point, and the number is rounded off.

Return type: numeric

Example:

```
gaussdb=# SELECT round(42.4382, 2);
round
-----
42.44
(1 row)
```

 **NOTE**

- When the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s1** in an ORA-compatible database, *s* is truncated to an integer. Otherwise, *s* is rounded off to an integer.
- If the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1**, the round function supports round(timestamp, text) overloading. When **(text, text)** or **(text, '')** is used as the input parameter to call the round function, round(timestamp, text) is preferred.

- setseed(dp)

Description: Sets seed for the following random() calling (from -1.0 to 1.0, inclusive).

Return type: void

Example:

```
gaussdb=# SELECT setseed(0.54823);
setseed
-----
(1 row)
```

- sign(x)

Description: Returns symbols of this parameter.

Return type: **-1** indicates negative numbers. **0** indicates 0, and **1** indicates positive numbers.

Example:

```
gaussdb=# SELECT sign(-8.4);
sign
-----
-1
(1 row)
```

- **sin(x)**

Description: Sine

Return type: double precision

Example:

```
gaussdb=# SELECT sin(1.57079);
sin
-----
.999999999979986
(1 row)
```

- **sinh(x)**

Description: Hyperbolic sine

Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

```
gaussdb=# SELECT sinh(4);
sinh
-----
27.2899171971277
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- **sqrt(x)**

Description: Square root

Return type: same as the input.

Example:

```
gaussdb=# SELECT sqrt(2.0);
sqrt
-----
1.414213562373095
(1 row)
```

 **NOTE**

This function uses the Karatsuba sqrt square root algorithm when the GUC parameter **gs\_format\_behavior\_compat\_options** is set to **sqrt\_karatsuba**. Otherwise, this function uses the Newton iteration algorithm. The performance of the Karatsuba sqrt square root algorithm is better. In a few scenarios, the precision of the Karatsuba sqrt square root algorithm is different from that of the Newton iteration algorithm.

- **tan(x)**

Description: Tangent

Return type: double precision

Example:

```
gaussdb=# SELECT tan(20);
tan
-----
2.23716094422474
(1 row)
```

- `tanh(x)`  
Description: Hyperbolic tangent  
Return type: same as the input (double precision or numeric)

Example:

```
gaussdb=# SELECT tanh(0.1);
      tanh
-----
0.0996679946249558171183050836783521835389
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `trunc(x)`  
Description: Truncation (the integer part is retained).  
Return type: same as the input.

Example:

```
gaussdb=# SELECT trunc(42.8);
      trunc
-----
42
(1 row)
```

- `trunc(v numeric, s int)`  
Description: Truncates the last *s* digits after a decimal point.  
Return type: numeric

Example:

```
gaussdb=# SELECT trunc(42.4382, 2);
      trunc
-----
42.43
(1 row)
```

 **NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in ORA-compatible mode. If the value of **s** is a decimal, the value is truncated instead of being rounded off.

- `width_bucket(op numeric, b1 numeric, b2 numeric, count int)`  
Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.

Return type: int

Example:

```
gaussdb=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
width_bucket
-----
3
(1 row)
```

- `width_bucket(op dp, b1 dp, b2 dp, count int)`  
Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.

Return type: int

Example:

```
gaussdb=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
width_bucket
-----
          3
(1 row)
```

- `smgrne(a smgr, b smgr)`  
Description: Compares two integers of the smgr type to check whether they are different.  
Return type: Boolean
- `smgreq(a smgr, b smgr)`  
Description: Compares two integers of the smgr type to check whether they are equivalent.  
Return type: Boolean
- `int1abs(tinyint)`  
Description: Returns the absolute value of data of the uint8 type.  
Parameter: tinyint  
Return type: tinyint
- `int1and(tinyint, tinyint)`  
Description: Returns the bitwise AND result of two data records of the uint8 type.  
Parameter: tinyint, tinyint  
Return type: tinyint
- `int1cmp(tinyint, tinyint)`  
Description: Returns the comparison result of two data records of the uint8 type. If the value of the first parameter is greater, **1** is returned. If the value of the second parameter is greater, **-1** is returned. If they are the same, **0** is returned.  
Parameter: tinyint, tinyint  
Return type: integer
- `int1div(tinyint, tinyint)`  
Description: Returns the result of dividing two data records of the uint8 type. The result is of the float8 type.  
Parameter: tinyint, tinyint  
Return type: tinyint
- `int1eq(tinyint, tinyint)`  
Description: Compares two pieces of data of the uint8 type to check whether they are the same.  
Parameter: tinyint, tinyint  
Return type: Boolean
- `int1ge(tinyint, tinyint)`  
Description: Determines whether the value of the first parameter is greater than or equal to the value of the second parameter in two data records of the uint8 type.  
Parameter: tinyint, tinyint  
Return type: Boolean

- `int1gt(tinyint, tinyint)`  
Description: Performs the greater-than operation on an unsigned 1-byte integer.  
Parameter: `tinyint`, `tinyint`  
Return type: Boolean
- `int1larger(tinyint, tinyint)`  
Description: Returns the larger value of unsigned one-byte integers.  
Parameter: `tinyint`, `tinyint`  
Return type: `tinyint`
- `int1le(tinyint, tinyint)`  
Description: Determines whether the unsigned 1-byte integer is less than or equal to.  
Parameter: `tinyint`, `tinyint`  
Return type: Boolean
- `int1lt(tinyint, tinyint)`  
Description: Determines whether the unsigned 1-byte integer is less than.  
Parameter: `tinyint`, `tinyint`  
Return type: Boolean
- `int1smaller(tinyint, tinyint)`  
Description: Returns the smaller of two unsigned one-byte integers.  
Parameter: `tinyint`, `tinyint`  
Return type: `tinyint`
- `int1inc(tinyint)`  
Description: Unsigned 1-byte integer plus 1.  
Parameter: `tinyint`  
Return type: `tinyint`
- `int1mi(tinyint, tinyint)`  
Description: Performs a minus operation on an unsigned 1-byte integer.  
Parameter: `tinyint`, `tinyint`  
Return type: `tinyint`
- `int1mod(tinyint, tinyint)`  
Description: Performs a remainder operation on an unsigned 1-byte integer.  
Parameter: `tinyint`, `tinyint`  
Return type: `tinyint`
- `int1mul(tinyint, tinyint)`  
Description: Performs a multiplication operation on an unsigned 1-byte integer.  
Parameter: `tinyint`, `tinyint`  
Return type: `tinyint`
- `int1ne(tinyint, tinyint)`  
Description: Performs a not-equal-to operation on an unsigned 1-byte integer.

- Parameter: tinyint, tinyint  
Return type: Boolean
- `int1pl(tinyint, tinyint)`  
Description: Performs an addition operation on an unsigned 1-byte integer.  
Parameter: tinyint, tinyint  
Return type: tinyint
  - `int1um(tinyint)`  
Description: Returns an unsigned 2-byte integer after subtracting the opposite number from the unsigned 1-byte integer.  
Parameter: tinyint  
Return type: smallint
  - `int1xor(tinyint, tinyint)`  
Description: Performs an exclusive OR operation on an unsigned 1-byte integer.  
Parameter: tinyint, tinyint  
Return type: tinyint
  - `cash_div_int1(money, tinyint)`  
Description: Performs a division operation on the money type.  
Parameter: money, tinyint  
Return type: money
  - `cash_mul_int1(money, tinyint)`  
Description: Performs a multiplication operation on the money type.  
Parameter: money, tinyint  
Return type: money
  - `int1not(tinyint)`  
Description: Reverts binary bits of an unsigned 1-byte integer.  
Parameter: tinyint  
Return type: tinyint
  - `int1or(tinyint, tinyint)`  
Description: Performs an OR operation on an unsigned 1-byte integer.  
Parameter: tinyint, tinyint  
Return type: tinyint
  - `int1shl(tinyint, integer)`  
Description: Shifts an unsigned 1-byte integer leftwards by a specified number of bits.  
Parameter: tinyint, integer  
Return type: tinyint
  - `int1shr(tinyint, integer)`  
Description: Shifts an unsigned 1-byte integer rightwards by a specified number of bits.  
Parameter: tinyint, integer  
Return type: tinyint

- `analyze_tgtype_for_type(n smallint)`  
 Description: Parses **pg\_trigger.tgtype**, parses *n* by bit, and returns one of **before each row**, **after each row**, **before statement**, **after statement**, and **instead of**.  
 Return type: `varchar2(16)`
- `analyze_tgtype_for_event(n smallint)`  
 Description: Parses **pg\_trigger.tgtype**, parses *n* by bit, and returns one or more of **insert**, **update**, **delete**, and **truncate**.  
 Return type: `varchar2(246)`
- `nanvl(n2, n1)`  
 Description: Two parameters are entered. The parameters must be of the numeric type or a non-numeric type that can be implicitly converted to the numeric type. If the first parameter **n2** is NaN, **n1** is returned. Otherwise, **n2** is returned.  
 Return value type: input parameter with a higher priority. The priority is as follows: double precision > float4 > numeric.

Example:

```
gaussdb=# SELECT nanvl('NaN', 1.1);
 nanvl
-----
 1.1
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `numeric_eq_text(numeric, text)`  
 Description: Checks whether the numeric variable is equal to the numeric value converted from the text variable.  
 Return type: Boolean  
 Example:

```
gaussdb=# SELECT numeric_eq_text(1, '1');
 numeric_eq_text
-----
 t
(1 row)
```
- `numeric_ne_text(numeric, text)`  
 Description: Checks whether the numeric variable is not equal to the numeric value converted from the text variable.  
 Return type: Boolean
- `numeric_gt_text(numeric, text)`  
 Description: Checks whether the numeric variable is greater than the numeric value converted from the text variable.  
 Return type: Boolean
- `numeric_ge_text(numeric, text)`  
 Description: Checks whether the numeric variable is greater than or equal to the numeric value converted from the text variable.  
 Return type: Boolean

- `numeric_lt_text(numeric, text)`  
Description: Checks whether the numeric variable is smaller than the numeric value converted from the text variable.  
Return type: Boolean
- `numeric_le_text(numeric, text)`  
Description: Checks whether the numeric variable is less than or equal to the numeric value converted from the text variable.  
Return type: Boolean
- `text_eq_numeric(text, numeric)`  
Description: Checks whether the numeric value converted from a text variable is equal to the numeric variable.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT text_eq_numeric('1', 1);
text_eq_numeric
-----
t
(1 row)
```
- `text_ne_numeric(text, numeric)`  
Description: Checks whether the numeric value converted from a text variable is not equal to the numeric variable.  
Return type: Boolean
- `text_gt_numeric(text, numeric)`  
Description: Checks whether the numeric value converted from a text variable is greater than the numeric variable.  
Return type: Boolean
- `text_ge_numeric(text, numeric)`  
Description: Checks whether the numeric value converted from a text variable is greater than or equal to the numeric variable.  
Return type: Boolean
- `text_lt_numeric(text, numeric)`  
Description: Checks whether the numeric value converted from a text variable is less than the numeric variable.  
Return type: Boolean
- `text_le_numeric(text, numeric)`  
Description: Checks whether the numeric value converted from a text variable is less than or equal to the numeric variable.  
Return type: Boolean
- `bigint_eq_text(bigint, text)`  
Description: Checks whether the bigint variable is equal to the bigint value converted from a text variable.  
Return type: Boolean

```
gaussdb=# SELECT bigint_eq_text(1, '1');
bigint_eq_text
-----
t
(1 row)
```

- `bigint_ne_text(bigint, text)`  
Description: Checks whether the bigint variable is not equal to the bigint value converted from a text variable.  
Return type: Boolean
- `bigint_gt_text(bigint, text)`  
Description: Checks whether the bigint variable is greater than the bigint value converted from a text variable.  
Return type: Boolean
- `bigint_ge_text(bigint, text)`  
Description: Checks whether the bigint variable is greater than or equal to the bigint value converted from a text variable.  
Return type: Boolean
- `bigint_lt_text(bigint, text)`  
Description: Checks whether the bigint variable is smaller than the bigint value converted from a text variable.  
Return type: Boolean
- `bigint_le_text(bigint, text)`  
Description: Checks whether the bigint variable is less than or equal to the bigint value converted from a text variable.  
Return type: Boolean
- `text_eq_bigint(text, bigint)`  
Description: Checks whether the bigint value converted from a text variable is equal to the bigint variable.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT text_eq_bigint('1', 1);
text_eq_bigint
-----
t
(1 row)
```
- `text_ne_bigint(text, bigint)`  
Description: Checks whether the bigint value converted from a text variable is not equal to the bigint variable.  
Return type: Boolean
- `text_gt_bigint(text, bigint)`  
Description: Checks whether the bigint value converted from a text variable is greater than the bigint variable.  
Return type: Boolean
- `text_ge_bigint(text, bigint)`  
Description: Checks whether the bigint value converted from a text variable is greater than or equal to the bigint variable.  
Return type: Boolean
- `text_lt_bigint(text, bigint)`  
Description: Checks whether the bigint value converted from a text variable is less than the bigint variable.

- Return type: Boolean
- `text_le_bigint(text, bigint)`  
Description: Checks whether the bigint value converted from a text variable is less than or equal to the bigint variable.  
Return type: Boolean

## 7.6.8 Date and Time Processing Functions and Operators

### Date and Time Operators

**Table 7-35** describes the time and date operators.

#### NOTE

Do not use expressions similar to `'now'::date`, `'now'::timestamp`, `'now'::timestamptz` (for string constant conversion) and `text_date('now')` to obtain the current database time or use the current time as the input parameter of the function. In these scenarios, the optimizer calculates the constant time in advance, causing incorrect query results.

```
gaussdb=# EXPLAIN SELECT * FROM t1 WHERE b='now'::date;
QUERY PLAN
-----
Seq Scan on t1 (cost=0.00..13.60 rows=1 width=310)
Filter: ((b)::text = '2024-11-09 15:07:56'::text)
(2 rows)
gaussdb=# EXPLAIN SELECT * FROM t1 WHERE b=text_date('now');
QUERY PLAN
-----
Seq Scan on t1 (cost=0.00..13.60 rows=1 width=310)
Filter: ((b)::text = '2024-11-09'::text)
(2 rows)
```

You are advised to use the `now()` and `currenttimestamp()` functions to obtain the current time of the database.

```
gaussdb=# EXPLAIN SELECT * FROM t1 WHERE b=now();
QUERY PLAN
-----
Seq Scan on t1 (cost=0.00..14.80 rows=1 width=310)
Filter: ((b)::text = (now())::text)
(2 rows)
gaussdb=# EXPLAIN SELECT * FROM t1 WHERE b=text_date(now());
QUERY PLAN
-----
Seq Scan on t1 (cost=0.00..16.00 rows=1 width=310)
Filter: ((b)::text = (text_date((now())::text))::text)
(2 rows)
```

When the user uses date and time operators, explicit type prefixes are modified for corresponding operands to ensure that the operands parsed by the database are consistent with what the user expects, and no unexpected results occur.

For example, abnormal mistakes will occur in the following example without an explicit data type.

```
gaussdb=# SELECT date '2001-10-01' - '7' AS RESULT;
ERROR:
GAUSS-10416: invalid input syntax for type timestamp: "7"
SQLSTATE: 22007
LINE 1: SELECT date '2001-10-01' - '7' AS RESULT;
           ^
CONTEXT: referenced column: result
```

**Table 7-35** Date and time operators

Operator	Example
+	<pre>gaussdb=# SELECT date '2001-9-28' + integer '7' AS RESULT; result ----- 2001-10-05 (1 row)</pre> <p><b>NOTE</b> In ORA-compatible mode, the query result is 2001-10-05 00:00:00.</p>
	<pre>gaussdb=# SELECT date '2001-09-28' + interval '1 hour' AS RESULT; result ----- 2001-09-28 01:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT date '2001-09-28' + time '03:00' AS RESULT; result ----- 2001-09-28 03:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT interval '1 day' + interval '1 hour' AS RESULT; result ----- 1 day 01:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT timestamp '2001-09-28 01:00' + interval '23 hours' AS RESULT; result ----- 2001-09-29 00:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT time '01:00' + interval '3 hours' AS RESULT; result ----- 04:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT date '2001-10-01' - date '2001-09-28' AS RESULT; result ----- 3 (1 row)</pre>
-	<pre>gaussdb=# SELECT date '2001-10-01' - integer '7' AS RESULT; result ----- 2001-09-24 00:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT date '2001-09-28' - interval '1 hour' AS RESULT; result ----- 2001-09-27 23:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT time '05:00' - time '03:00' AS RESULT; result ----- 02:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT time '05:00' - time '03:00' AS RESULT; result ----- 02:00:00 (1 row)</pre>

Operator	Example
	<pre>gaussdb=# SELECT time '05:00' - interval '2 hours' AS RESULT; result ----- 03:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT timestamp '2001-09-28 23:00' - interval '23 hours' AS RESULT; result ----- 2001-09-28 00:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT interval '1 day' - interval '1 hour' AS RESULT; result ----- 23:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT timestamp '2001-09-29 03:00' - timestamp '2001-09-27 12:00' AS RESULT; result ----- 1 day 15:00:00 (1 row)</pre>
*	<pre>gaussdb=# SELECT 900 * interval '1 second' AS RESULT; result ----- 00:15:00 (1 row)</pre>
	<pre>gaussdb=# SELECT 21 * interval '1 day' AS RESULT; result ----- 21 days (1 row)</pre>
	<pre>gaussdb=# SELECT double precision '3.5' * interval '1 hour' AS RESULT; result ----- 03:30:00 (1 row)</pre>
/	<pre>gaussdb=# SELECT interval '1 hour' / double precision '1.5' AS RESULT; result ----- 00:40:00 (1 row)</pre>

## Time and Date Functions

- age(timestamp, timestamp)**  
 Description: Subtracts parameters, producing a result in YYYY-MM-DD format. If the result is negative, the returned result is also negative. The input parameters may or may not contain time zones.  
 Return type: interval  
 Example:  

```
gaussdb=# SELECT age(timestamp '2001-04-10', timestamp '1957-06-13');
age
-----
```

```
43 years 9 mons 27 days
(1 row)
```

- **age(timestamp)**

Description: Subtracts the parameter value from the system time when the current SQL statement starts to be executed. The input parameter may or may not contain a time zone.

Return type: interval

Example:

```
gaussdb=# SELECT age(timestamp '1957-06-13');
 age
-----
60 years 2 mons 18 days
(1 row)
```

- **clock\_timestamp()**

Description: Returns the timestamp of the system time when the current function is called. The volatile function obtains the latest timestamp for each scan. Therefore, the result of each call in a query is different.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT clock_timestamp();
 clock_timestamp
-----
2017-09-01 16:57:36.636205+08
(1 row)
```

- **current\_date**

Description: Returns the system date when the current SQL statement starts.

Return type: date

Example:

```
gaussdb=# SELECT current_date;
 date
-----
2017-09-01
(1 row)
-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT current_date;
 current_date
-----
2023-11-24 11:25:09
(1 row)
```

 NOTE

- This function has the following behaviors when **sql\_compatibility** is set to 'ORA' and **a\_format\_date\_timestamp** is set to **on**:
  - The timestamp of the system time is returned when the current SQL execution starts.
  - The return value type is timestamp without time zone. The value unit is seconds. The column name is **current\_date**.
  - When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2**, the return value type is timestamp.
  - If the GUC parameter **a\_format\_date\_timestamp** is disabled, the system date when the transaction starts is returned.
  - This prevents the optimizer from obtaining the constant time in advance. As a result, the obtained time is incorrect in the gplan scenario.
- This function has the following behaviors when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to **5.7**, and **b\_format\_dev\_version** is set to **s1**:
  - `current_date` can be called with parentheses.
  - The actually called function of `current_date` is `curdate`. You can run the **\df curdate** command to query the detailed input parameters and return values of the function.

- `current_time()`

Description: Specifies the system time when the current transaction starts. If **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', the system time when the current SQL execution starts is returned.

Return type: time with time zone. When **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', the return type is time without time zone.

Example:

```
gaussdb=# SELECT current_time();
          timetz
-----
16:58:07.086215+08
(1 row)
-- When the parameter is enabled in MySQL-compatible mode:
gaussdb_m=# SELECT current_time();
          current_time
-----
15:14:00
(1 row)
```

- `current_time([precision])`

Description: Returns the system time when the current SQL execution starts.

Parameter: **precision** indicates the precision (number of decimal places after the second). The value is of the int type and in the range [0,6]. The default value is **0**. If the precision is invalid, an error is reported.

Return type: time without time zone

Implementation mode: This function is mapped to the system function `curtime`.

Example:

```
gaussdb_m=# SELECT current_time();
          current_time
-----
15:14:05
```

```
(1 row)
gaussdb_m=# SELECT current_time(3);
current_time
-----
15:14:08.433
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'. The actually called function of `current_time` is `curtime`. You can run the `\df curtime` command to query the detailed input parameters and return values of the function.

- **current\_timestamp**

**Description:** Specifies the current date and time. This is a statement-level timestamp. The returned results within the same statement remain unchanged.

**Return type:** timestamp without time zone when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', or timestamp with time zone in other scenarios

**Example:**

```
gaussdb=# SELECT current_timestamp;
pg_systimestamp
-----
2017-09-01 16:58:19.22173+08
(1 row)

-- When the version is 5.7 in MySQL-compatible database:
gaussdb_m=# SELECT current_timestamp;
timestamp
-----
2023-08-21 15:08:24
(1 row)

-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT current_timestamp;
current_timestamp
-----
2023-11-24 11:31:04.895312+08
(1 row)
```

 NOTE

This function has the following behaviors when **sql\_compatibility** is set to 'ORA' and **a\_format\_date\_timestamp** is set to on:

- The timestamp of the system time is returned when the current SQL execution starts.
- The return value type is timestamp with time zone, and the column name is **current\_timestamp**.
- If the GUC parameter **a\_format\_date\_timestamp** is disabled, the system time is returned.

This function has the following behaviors when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to 5.7, and **b\_format\_dev\_version** is set to s1:

- The return type is timestamp without time zone.
- The precision of the returned result is 0.
- The timestamp of the system time is returned when the current SQL execution starts.
- This function is implemented through TYPE conversion and has no registered function. Therefore, you can run the `\df+` command of `gsql` to view the function information in other compatible modes, not the function information in version 5.7 in the MySQL-compatible mode.

- **current\_timestamp()**

Description: Returns the system time when the current SQL execution starts.

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT current_timestamp();
          timestamp
-----
2023-08-21 14:34:30
(1 row)
```

 NOTE

This function can be used only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'. In addition, this function has the following behavior:

- The return type is timestamp without time zone.
- The precision of the returned result is 0.
- The timestamp of the system time is returned when the current SQL execution starts.
- This function is implemented through TYPE conversion and has no registered function. Therefore, you can run the `\df+` command of `gsql` to view the function information in other modes, not the function information in version 5.7 in the MySQL-compatible mode.

- **current\_timestamp(precision)**

Description: Obtains the current date and time, and rounds the microseconds of the result to the specified decimal place.

Parameter: **precision** indicates the precision (number of decimal places after the second). The value is of the int type and in the range [0,6]. The default value is 0. If the value is an integer greater than 6, an alarm is generated, and the maximum precision value 6 is used to output the time. If the value is invalid, an error is reported.

Return type: timestamp without time zone when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', or timestamp with time zone in other scenarios

Example:

```
gaussdb=# SELECT current_timestamp(1);
          timestampz
-----
2017-09-01 16:58:19.2+08
(1 row)

-- When the version is 5.7 in MySQL-compatible database:
gaussdb_m=# SELECT current_timestamp(1);
          timestamp
-----
2023-08-21 15:09:35.3
(1 row)

-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT current_timestamp(6);
          current_timestamp
-----
2023-11-24 11:35:57.268592+08
(1 row)
-- If a_format_version is set to 10c and a_format_dev_version is set to s2 in an ORA-compatible
database, precision can be an integer of the numeric type.
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s2';
SET
gaussdb=# SELECT current_timestamp(6.0);
          current_timestamp
-----
2023-11-25 11:14:48.74763+08
(1 row)
```

 **NOTE**

- Zeros at the end of microseconds are not displayed. For example, 2017-09-01 10:32:19.212000 is displayed as 2017-09-01 10:32:19.212.
- This function has the following behaviors when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to 5.7, and **b\_format\_dev\_version** is set to s1:
  - The return type is timestamp without time zone.
  - The timestamp of the system time is returned when the current SQL execution starts.
  - This function is implemented through TYPE conversion and has no registered function. Therefore, you can run the **\df+** command of gsql to view the function information in other modes, not the function information in version 5.7 in the MySQL-compatible mode.
- The function has the following behaviors when **sql\_compatibility** is set to 'ORA' and **a\_format\_date\_timestamp** is set to on:
  - The return value type is timestamp with time zone, and the column name is **current\_timestamp**.
  - The timestamp of the system time is returned when the current SQL execution starts.
  - When **a\_format\_version** is set to 10c and **a\_format\_dev\_version** is set to s2, the **precision** parameter can be an integer of the numeric type. Otherwise, only the int type is supported.
  - If the GUC parameter **a\_format\_date\_timestamp** is disabled, when the input parameter is an integer without a decimal point, the returned result is the date and time of the system where the transaction is started; when the input parameter is an integer with a decimal point, the returned result is the system time.

- **pg\_systimestamp()**

Description: Current date and time (start of the current statement).

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_systimestamp();
           pg_systimestamp
-----
2015-10-14 11:21:28.317367+08
(1 row)
```

- **date\_part(text, timestamp)**

Description:

Retrieves fields such as year or hour from date/time values.

It is equivalent to **extract(field from timestamp)**.

Timestamp types: abstime, date, interval, reltime, time with time zone, time without time zone, timestamp with time zone, timestamp without time zone

Return type: double precision

Example:

```
gaussdb=# SELECT date_part('hour', timestamp '2001-02-16 20:38:40');
           date_part
-----
                20
(1 row)
```

- **date\_part(text, interval)**

Description: Obtains the month. If the value is greater than 12, obtain the remainder after it is divided by 12. It is equivalent to **extract(field from timestamp)**.

Return type: double precision

Example:

```
gaussdb=# SELECT date_part('month', interval '2 years 3 months');
date_part
-----
      3
(1 row)
```

- **date\_trunc(text, timestamp)**

Description: Truncates to the precision specified by **text**.

Return type: interval, timestamp with time zone, timestamp without time zone

Example:

```
gaussdb=# SELECT date_trunc('hour', timestamp '2001-02-16 20:38:40');
date_trunc
-----
2001-02-16 20:00:00
(1 row)
```

- **trunc(timestamp)**

Description: Truncates to day by default.

Example:

```
gaussdb=# SELECT trunc(timestamp '2001-02-16
20:38:40');
trunc
-----
2001-02-16 00:00:00
(1 row)
```

- **trunc(arg1, arg2)**

Description: Truncates to the precision specified by **arg2**.

- Type of **arg1**: interval, timestamp with time zone, timestamp without time zone

- Type of **arg2**: text

Return type: interval, timestamp with time zone, timestamp without time zone

Example:

```
gaussdb=# SELECT trunc(timestamp '2001-02-16 20:38:40',
'hour');
trunc
-----
2001-02-16 20:00:00
(1 row)
```

- **round(arg1, arg2)**

Description: Rounds off to the precision specified by **arg2**.

Type of **arg1**: timestamp without time zone

Type of **arg2**: text

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT round(timestamp '2001-02-16 20:38:40',
'hour');
```

```

round
-----
2001-02-16 21:00:00
(1 row)

```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s1** in an ORA-compatible database.

- **daterange(arg1, arg2)**

Description: Obtains time boundary information.

**arg1** type: date

**arg2** type: date

Return type: daterange

Example:

```

gaussdb=# SELECT daterange('2000-05-06','2000-08-08');
 daterange
-----
[2000-05-06,2000-08-08)
(1 row)

```

- **daterange(arg1, arg2, text)**

Description: Obtains time boundary information.

**arg1** type: date

**arg2** type: date

**text** type: text

Return type: daterange

Example:

```

gaussdb=# SELECT daterange('2000-05-06','2000-08-08','[]');
 daterange
-----
[2000-05-06,2000-08-09)
(1 row)

```

- **isfinite(date)**

Description: Checks whether a date is a finite value. If the date is a finite value, **t** is returned. Otherwise, **f** is returned.

Return type: Boolean

Example:

```

gaussdb=# SELECT isfinite(date '2001-02-16');
 isfinite
-----
t
(1 row)
gaussdb=# SELECT isfinite(date 'infinity');
 isfinite
-----
f
(1 row)

```

- **isfinite(timestamp)**

Description: Checks whether a timestamp is a finite value. If the timestamp is a finite value, **t** is returned. Otherwise, **f** is returned.

Return type: Boolean

Example:

```
gaussdb=# SELECT isfinite(timestamp '2001-02-16 21:28:30');
isfinite
-----
t
(1 row)
gaussdb=# SELECT isfinite(timestamp 'infinity');
isfinite
-----
f
(1 row)
```

- **isfinite(interval)**

Description: Checks whether the interval is a finite value. If the interval is a finite value, **t** is returned. Currently, **f** cannot be returned. If '**infinity**' is entered, an error is reported.

Return type: Boolean

Example:

```
gaussdb=# SELECT isfinite(interval '4 hours');
isfinite
-----
t
(1 row)
```

- **justify\_days(interval)**

Description: Adjusts intervals to 30-day time periods, which are represented as months.

Return type: interval

Example:

```
gaussdb=# SELECT justify_days(interval '35 days');
justify_days
-----
1 mon 5 days
(1 row)
```

- **justify\_hours(interval)**

Description: Sets the time interval in days (24 hours is one day).

Return type: interval

Example:

```
gaussdb=# SELECT JUSTIFY_HOURS(INTERVAL '27 HOURS');
justify_hours
-----
1 day 03:00:00
(1 row)
```

- **justify\_interval(interval)**

Description: Adjusts **interval** using **justify\_days** and **justify\_hours**.

Return type: interval

Example:

```
gaussdb=# SELECT JUSTIFY_INTERVAL(INTERVAL '1 MON -1 HOUR');
justify_interval
-----
29 days 23:00:00
(1 row)
```

- **localtime()**

Description: Specifies the system time when the current transaction starts. If **sql\_compatibility** is set to '**MYSQL**', **b\_format\_version** is set to '**5.7**', and **b\_format\_dev\_version** is set to '**s1**', the system date and time when the current SQL query execution starts is returned.

Return type: time. If **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', a timestamp without time zone is returned.

Example:

```
gaussdb=# SELECT localtime AS RESULT;
      result
-----
 16:05:55.664681
(1 row)
-- When the parameter is enabled in MySQL-compatible mode:
gaussdb_m=# select localtime;
      localtime
-----
2023-08-21 15:21:57
(1 row)
```

- localtime([[precision]])

Description: Returns the system date and time when the current SQL query execution starts.

Parameter: **precision** indicates the precision (number of decimal places after the second). The value is of the int type and in the range [0,6]. The default value is 0. If the value is invalid, an error is reported.

Return type: timestamp without time zone

Implementation method: Register the system function localtime.

Example:

```
gaussdb_m=# SELECT localtime();
      localtime
-----
2023-08-21 15:23:49
(1 row)
gaussdb_m=# SELECT localtime(3);
      localtime
-----
2023-08-21 15:23:51.965
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- localtimestamp

Description: Specifies the current date and time.

Return type: timestamp

Example:

```
gaussdb=# SELECT localtimestamp;
      timestamp
-----
2017-09-01 17:03:30.781902
(1 row)
-- When the parameter is enabled in MySQL-compatible mode:
gaussdb_m=# SELECT localtimestamp;
      timestamp
-----
2023-08-21 15:27:55
(1 row)
-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT localtimestamp;
```

```

localtimestamp
-----
2023-11-24 11:38:25.633231
(1 row)

```

 **NOTE**

This function has the following behaviors when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to 5.7, and **b\_format\_dev\_version** is set to s1:

- The system date and time are returned when the current SQL query execution starts.
- The return type is timestamp without time zone, and the column name is **timestamp**.

The function has the following behaviors when **sql\_compatibility** is set to 'ORA' and **a\_format\_date\_timestamp** is set to on:

- The return value type is timestamp without time zone, and the column name is **localtimestamp**.
- The timestamp of the system time is returned when the current SQL execution starts.
- If the GUC parameter **a\_format\_date\_timestamp** is disabled, the system date and time when the transaction is started is returned.

- `localtimestamp([([precision]))]`

Description: Specifies the current date and time.

Parameter: **precision** indicates the precision (number of decimal places after the second). The value is of the int type and in the range [0,6]. The default value is 0. If the value is an integer greater than 6, an alarm is generated, and the maximum precision value 6 is used to output the time. If the value is invalid, an error is reported.

Return type: timestamp without time zone

Example:

```

-- Calls with parentheses and without input parameters are supported only in MySQL-compatible mode.
gaussdb=# SELECT localtimestamp();
timestamp
-----
2023-08-21 15:27:59
(1 row)
gaussdb=# SELECT localtimestamp(3);
timestamp
-----
2023-08-21 15:28:02.445
(1 row)
-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT localtimestamp(6);
localtimestamp
-----
2023-11-24 11:41:14.086227
(1 row)
-- If a_format_version is set to 10c and a_format_dev_version is set to s2 in an ORA-compatible database, precision can be an integer of the numeric type.
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s2';
SET
gaussdb=# SELECT localtimestamp(6.0);
localtimestamp
-----
2023-11-24 11:42:45.642167
(1 row)

```

 NOTE

- Zeros at the end of microseconds are not displayed. For example, 2017-09-01 10:32:19.212000 is displayed as 2017-09-01 10:32:19.212.
- When **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to 5.7, and **b\_format\_dev\_version** is set to s1, this function returns the system date and time when the current SQL execution starts. The function can be called with parentheses without input parameters.
- This function has the following behaviors when **sql\_compatibility** is set to 'ORA' and **a\_format\_date\_timestamp** is set to on:
  - The timestamp of the system time is returned when the current SQL execution starts.
  - The return value type is timestamp without time zone, and the column name is **localtimestamp**.
  - When **a\_format\_version** is set to 10c and **a\_format\_dev\_version** is set to s2, the **precision** parameter can be an integer of the numeric type. Otherwise, only the int type is supported.
  - If the GUC parameter **a\_format\_date\_timestamp** is disabled, the system date and time when the transaction is started is returned.

- `maketime(hour, minute, second)`

Description: Generates the time (of the time type) based on the input parameters hour, minute, and second. The three input parameters are of the bigint, bigint, and numeric types, respectively.

Return type: time

Example:

```
gaussdb=# SELECT maketime(8, 15, 26.53);
 maketime
-----
08:15:26.53
(1 row)

gaussdb=# SELECT maketime(-888, 15, 26.53);
 maketime
-----
-838:59:59
(1 row)
```

 NOTE

This function can be used only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'. In addition, this function has the following behavior:

- The function returns **NULL** if any of the following conditions is met:
    - The value of the input parameter **minute** is less than 0 or greater than or equal to 60.
    - The value of the input parameter **second** is less than 0 or greater than or equal to 60.
    - The value of any parameter is **NULL**.
  - The returned result of the time type contains six decimal places. If the value of **second** contains more than six decimal places, the value is rounded off.
  - The returned value of the time type is in the range [-838:59:59,838:59:59]. If the value is out of the range, the specified boundary value is returned based on the positive and negative values of **hour**.
  - **maketime** does not support self-nesting.
- `now()`

Description: Returns the system date and time when the current transaction starts. The results returned in the same transaction are the same. Only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to 5.7, and **b\_format\_dev\_version** is set to s1, the system date and time when the current SQL query execution starts is returned.

Return type: timestamp with time zone. If **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to 5.7, and **b\_format\_dev\_version** is set to s1, a timestamp without time zone is returned.

Example:

```
gaussdb=# SELECT now();
          now
-----
2017-09-01 17:03:42.549426+08
(1 row)
-- When the compatibility parameter is enabled and set to 'MYSQL':
gaussdb_m=# SELECT now();
          timestamp
-----
2023-08-21 17:17:42
(1 row)
```

- **now(precision)**

Description: Returns the system date and time when the current SQL query execution starts.

Parameter: **precision** indicates the precision (number of decimal places after the second). The value is of the int type and in the range [0,6]. The default value is 0. If the value is an integer greater than 6, an alarm is generated, and the maximum precision value 6 is used to output the time. If the value is invalid, an error is reported.

Return type: timestamp without time zone

Implementation mode: Obtain the value using a 'now' :: text :: timestamp without time zone expression.

Example:

```
gaussdb_m=# SELECT now(3);
          timestamp
-----
2023-08-21 17:17:48.819
(1 row)
```

#### NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **timenow()**

Description: Returns the system date and time when the current SQL query execution starts.

Return type: abstime

Example:

```
gaussdb=# SELECT timenow();
          timenow
-----
2020-06-23 20:36:56+08
(1 row)
```

- **dbtimezone**

Description: Time zone of the current database.

Return type: text

Example:

```
gaussdb=# SELECT dbtimezone;
          dbtimezone
-----
PRC
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- numtodsinterval(num, interval\_unit)

Description: Converts a number to the interval type. **num** is a numeric-typed number. **interval\_unit** is a string in the following format: 'DAY' | 'HOUR' | 'MINUTE' | 'SECOND'

You can set the GUC parameter **IntervalStyle** to **ORA** to be compatible with the interval output format of the function in the Oracle database.

Return type: interval

Example:

```
gaussdb=# SELECT numtodsinterval(100, 'HOUR');
          numtodsinterval
-----
100:00:00
(1 row)

gaussdb=# SET intervalstyle = oracle;
SET
gaussdb=# SELECT numtodsinterval(100, 'HOUR');
          numtodsinterval
-----
+000000004 04:00:00.000000000
(1 row)
```

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2** in an ORA-compatible database, an error is reported if **interval\_unit** is set to **'DAY'** and **num** is set to a value greater than **1000000000**.

- numtoyminterval(num, interval\_unit)

Description: Converts a number to the interval type. **num** is a number of the numeric type, and **interval\_unit** is a string of the fixed format ('YEAR'|'MONTH').

You can set the GUC parameter **IntervalStyle** to **ORA** to be compatible with the interval output format of the function in the Oracle database.

Return type: interval

Example:

```
gaussdb=# SELECT numtoyminterval(100, 'MONTH');
          numtoyminterval
-----
8 years 4 mons
(1 row)

gaussdb=# SET intervalstyle = oracle;
SET
gaussdb=# SELECT numtodsinterval(100, 'MONTH');
          numtoyminterval
-----
```

8-4  
(1 row)

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `new_time(date, timezone1, timezone2)`

Description: Returns the date and time of the time zone specified by **timezone2** when the date and time of the time zone specified by **timezone1** are date.

Return type: timestamp

Example:

```
gaussdb=# SELECT new_time('1997-10-10','AST','EST');
new_time
-----
1997-10-09 23:00:00
(1 row)
gaussdb=# SELECT NEW_TIME(TO_TIMESTAMP ('10-Sep-02 14:10:10.123000','DD-Mon-RR
HH24:MI:SS.FF'), 'AST', 'PST');
new_time
-----
2002-09-10 10:10:10.123
(1 row)
```

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `sessiontimezone()`

Description: Returns the time zone of the current session. There is no input parameter.

Return type: text

Example:

```
gaussdb=# SELECT SESSIONTIMEZONE;
session_time_zone
-----
PST8PDT
(1 row)
gaussdb=# SELECT LOWER(SESSIONTIMEZONE);
lower
-----
@ 8 hours
(1 row)
```

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

When the value of **set session time zone** is in the GMT+08:00/GMT-08:00 format, the verification fails and an error is reported. This behavior meets the expectation. If the value is 's2' and the "ERROR:invalid value for parameter "TimeZone" : "GMT-08:00"" error is reported when you use JDBC to create a connection, the application where the driver is located sends the same time zone parameter in GMT format to GaussDB. You can use either of the following methods to solve the problem:

Method 1: Adjust the time zone of the OS on the application side and set the local time zone to the region format, for example, Asia/Shanghai.

Method 2: Use the JDBC driver that matches the version on the application side. The JDBC driver changes the GMT time zone to a time zone format that can be identified by the database.

- `sys_extract_utc(timestamp| timestamptz)`

Description: Extracts Coordinated Universal Time (UTC, also formerly known as Greenwich Mean Time) from a date-time value with a time zone offset or time zone region name. If no time zone is specified, the date and time are associated with the session time zone. The input parameter can be in timestamp or timestamptz format.

Return type: timestamp

Example:

```
gaussdb=# SELECT SYS_EXTRACT_UTC(TIMESTAMP '2000-03-28 11:30:00.00');
 sys_extract_utc
-----
2000-03-28 03:30:00
(1 row)
gaussdb=# SELECT SYS_EXTRACT_UTC(TIMESTAMPZ '2000-03-28 11:30:00.00 -08:00');
 sys_extract_utc
-----
2000-03-28 19:30:00
(1 row)
```

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- `tz_offset('time_zone_name' | '(+/-)hh:mi' | SESSIONTIMEZONE | DBTIMEZONE)`

Description: Returns the UTC offset of the time zone indicated by the input parameter. The input parameter has the preceding four formats.

Return type: text

Example:

```
gaussdb=# SELECT TZ_OFFSET('US/Pacific');
 tz_offset
-----
-08:00
(1 row)
gaussdb=# SELECT TZ_OFFSET(sessiontimezone);
 tz_offset
-----
+08:00
(1 row)
```

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s2** in an ORA-compatible database.

- **pg\_sleep(seconds)**

Description: Specifies the delay time of the server thread in unit of second. Note that when the database calls this function, the corresponding transaction snapshot is obtained, which is equivalent to a long transaction. If the input parameter time is too long, the database **oldestxmin** may fail to be executed, affecting the table recycling and query performance.

Return type: void

Example:

```
gaussdb=# SELECT pg_sleep(10);
pg_sleep
-----
(1 row)
```

- **statement\_timestamp()**

Description: Current date and time (start of the current statement).

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT statement_timestamp();
statement_timestamp
-----
2017-09-01 17:04:39.119267+08
(1 row)
```

- **sysdate**

Description: Returns the system date and time when the current SQL statement is executed.

Return type: timestamp

Example:

```
gaussdb=# SELECT sysdate;
sysdate
-----
2017-09-01 17:04:49
(1 row)
```

- **sysdate([precision])**

Description: Returns the system date and time when a function is executed.

Parameter: Indicates the time precision. The value is of the int type and in the range [0,6]. The default value is **0**.

Return type: timestamp without time zone

Example:

```
gaussdb_m=# SELECT sysdate();
sysdate()
-----
2023-08-21 17:17:42
(1 row)
gaussdb_m=# SELECT sysdate(3);
sysdate(3)
-----
2023-08-21 17:17:48.819
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **current\_sysdate()**

Description: Returns the system date and time when the current SQL query execution starts.

Return type: timestamp

Example:

```
gaussdb=# SELECT current_sysdate();
current_sysdate
-----
2023-06-20 20:09:02
(1 row)
```

- **timeofday()**

Description: Returns the timestamp (such as **clock\_timestamp**, but the return type is text) of the system time when the current function is called.

Return type: text

Example:

```
gaussdb=# SELECT timeofday();
timeofday
-----
Fri Sep 01 17:05:01.167506 2017 CST
(1 row)
```

- **transaction\_timestamp()**

Description: Specifies the system date and time when the current transaction starts.

Return type: timestamp with time zone. If **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', a timestamp without time zone is returned.

Example:

```
gaussdb=# SELECT transaction_timestamp();
transaction_timestamp
-----
2017-09-01 17:05:13.534454+08
(1 row)
-- When the compatibility parameter is enabled and set to 'MYSQL':
gaussdb=# SELECT transaction_timestamp();
transaction_timestamp
-----
2023-09-07 09:32:09.728998
(1 row)
```

- **add\_months(d,n)**

Description: Returns the time point *d* plus *n* months.

**d**: indicates the value of the timestamp type and the value that can be implicitly converted to the timestamp type.

**n**: indicates the value of the INTEGER type and the value that can be implicitly converted to the INTEGER type.

Return type: timestamp

Example:

```
gaussdb=# SELECT add_months(to_date('2017-5-29', 'yyyy-mm-dd'), 11) FROM sys_dummy;
add_months
```

```
-----
2018-04-29 00:00:00
(1 row)
```

 **NOTE**

In the scenario where this function is in an ORA-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- If the calculation result is greater than 9999, an error is reported.
  - If the value of *n* is a decimal, the value is truncated instead of being rounded off.
- **last\_day(d)**

Description: Returns the date of the last day of the month that contains *date*.

Return type: timestamp

Example:

```
gaussdb=# SELECT last_day(to_date('2017-01-01', 'YYYY-MM-DD')) AS cal_result;
cal_result
-----
2017-01-31 00:00:00
(1 row)
```

 **NOTE**

When **sql\_compatibility** is set to **'MYSQL'**, **b\_format\_version** is set to **'5.7'**, and **b\_format\_dev\_version** is set to **'s1'**, the **last\_day** function calls the built-in function **b\_db\_last\_day**. The input parameter type can be TEXT, DATE, DATETIME, or TIME. The return value is of the date type and can be a number in the datetime format.

- **months\_between(d1, d2)**

Description: Calculates the month difference between time points **d1** and **d2**. If both dates are the end of a month or are the same day, an integer is returned. Otherwise, the return value is a decimal and is calculated as 31 days per month.

Return type: numeric

Example:

```
gaussdb=# SELECT months_between(to_date('2022-10-31', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
months_between
-----
1
(1 row)

gaussdb=# SELECT months_between(to_date('2022-10-30', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
months_between
-----
1
(1 row)

gaussdb=# SELECT months_between(to_date('2022-10-29', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
months_between
-----
.96774193548387096774
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s1** in an ORA-compatible database.

- `next_day(x,y)`  
Description: Calculates the time of the next week y started from x.  
Return type: timestamp  
Example:  

```
gaussdb=# SELECT next_day(timestamp '2017-05-25 00:00:00','Sunday')AS cal_result;
           cal_result
-----
2017-05-28 00:00:00
(1 row)
```
- `tinterval(abstime, abstime)`  
Description: Creates a time interval with two pieces of absolute time.  
Return type: tinterval  
Example:  

```
gaussdb=# CALL tinterval(abstime 'May 10, 1947 23:59:12', abstime 'Mon May 1 00:30:30 1995');
           tinterval
-----
["1947-05-10 23:59:12+08" "1995-05-01 00:30:30+08"]
(1 row)
```
- `tintervalend(tinterval)`  
Description: Returns the end time of tinterval.  
Return type: abstime  
Example:  

```
gaussdb=# SELECT tintervalend(['"Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"']);
           tintervalend
-----
1983-10-04 23:59:12+08
(1 row)
```
- `tintervalrel(tinterval)`  
Description: Calculates and returns the relative time of **tinterval**.  
Return type: reltime  
Example:  

```
gaussdb=# SELECT tintervalrel(['"Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"']);
           tintervalrel
-----
1 mon
(1 row)
```
- `smalldatetime_ge(smalldatetime, smalldatetime)`  
Description: Determines whether the first parameter is greater than the second parameter.  
Parameter: smalldatetime, smalldatetime  
Return type: Boolean
- `smalldatetime_cmp(smalldatetime, smalldatetime)`  
Description: Compares two smalldatetime values to check whether they are the same.  
Parameter: smalldatetime, smalldatetime  
Return type: integer
- `smalldatetime_eq(smalldatetime, smalldatetime)`  
Description: Compares two smalldatetime values to check whether they are the same.

Parameter: smalldatetime, smalldatetime

Return type: Boolean

- `smalldatetime_gt(smalldatetime, smalldatetime)`  
Description: Determines whether the first parameter is less than the second parameter.  
Parameter: smalldatetime, smalldatetime  
Return type: Boolean
- `smalldatetime_hash(smalldatetime)`  
Description: Calculates the hash value corresponding to a timestamp.  
Parameter: smalldatetime  
Return type: integer
- `smalldatetime_in(cstring, oid, integer)`  
Description: Inputs a timestamp.  
Parameter: cstring, oid, integer  
Return type: smalldatetime
- `smalldatetime_larger(smalldatetime, smalldatetime)`  
Description: Returns a larger timestamp.  
Parameter: smalldatetime, smalldatetime  
Return type: smalldatetime
- `smalldatetime_le(smalldatetime, smalldatetime)`  
Description: Determines whether the first parameter is less than the second parameter.  
Parameter: smalldatetime, smalldatetime  
Return type: Boolean
- `smalldatetime_lt(smalldatetime, smalldatetime)`  
Description: Determines whether the first parameter is greater than the second parameter.  
Parameter: smalldatetime, smalldatetime  
Return type: Boolean
- `smalldatetime_ne(smalldatetime, smalldatetime)`  
Description: Compares two timestamps to check whether they are different.  
Parameter: smalldatetime, smalldatetime  
Return type: Boolean
- `smalldatetime_out(smalldatetime)`  
Description: Converts a timestamp into the external form.  
Parameter: smalldatetime  
Return type: cstring
- `smalldatetime_send(smalldatetime)`  
Description: Converts a timestamp to the binary format.

Parameter: smalldatetime

Return type: bytea

- `smalldatetime_smaller(smalldatetime, smalldatetime)`  
Description: Returns a smaller smalldatetime.  
Parameter: smalldatetime, smalldatetime  
Return type: smalldatetime
- `smalldatetime_to_abstime(smalldatetime)`  
Description: Converts smalldatetime to abstime.  
Parameter: smalldatetime  
Return type: abstime
- `smalldatetime_to_time(smalldatetime)`  
Description: Converts smalldatetime to time.  
Parameter: smalldatetime  
Return type: time without time zone
- `smalldatetime_to_timestamp(smalldatetime)`  
Description: Converts smalldatetime to timestamp.  
Parameter: smalldatetime  
Return type: timestamp without time zone
- `smalldatetime_to_timestampz(smalldatetime)`  
Description: Converts smalldatetime to timestampz.  
Parameter: smalldatetime  
Return type: timestamp with time zone
- `smalldatetime_to_varchar2(smalldatetime)`  
Description: Converts smalldatetime to varchar2.  
Parameter: smalldatetime  
Return type: character varying

 NOTE

There are multiple methods for obtaining the current time. Select an appropriate API based on the actual service scenario.

1. The following APIs return values based on the start time of the current transaction:

```
CURRENT_DATE CURRENT_TIME
CURRENT_TIME(precision)
CURRENT_TIMESTAMP(precision)
LOCALTIME
LOCALTIMESTAMP
LOCALTIME(precision)
LOCALTIMESTAMP(precision)
transaction_timestamp()
now()
```

The values transferred by **CURRENT\_TIME** and **CURRENT\_TIMESTAMP(precision)** contain time zone information. The values transferred by **LOCALTIME** and **LOCALTIMESTAMP** do not contain time zone information. **CURRENT\_TIME**, **LOCALTIME**, and **LOCALTIMESTAMP** can specify a precision parameter, which rounds the seconds field of the result to the decimal place. If there is no precision parameter, the result is given the full precision that can be obtained.

Because these functions all return results by the start time of the current transaction, their values do not change throughout the transaction. This can be considered as a feature with the purpose to allow a transaction to have a consistent concept at the "current" time, so that multiple modifications in the same transaction can maintain the same timestamp. **transaction\_timestamp()** is equivalent to **CURRENT\_TIMESTAMP(precision)**, indicating the start time of the transaction where the current statement is located. **now()** is equivalent to **transaction\_timestamp()**.

When a transaction starts, **sql\_compatibility** is set to 'ORA', and **a\_format\_date\_timestamp** is set to **on**, the results returned by the **CURRENT\_DATE**, **CURRENT\_TIMESTAMP(precision)**, **LOCALTIMESTAMP** and **LOCALTIMESTAMP (precision)** functions are the timestamp when the current SQL statement is started. If the GUC parameter **a\_format\_date\_timestamp** is disabled, the returned result is the transaction start date or date and time.

When **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', **CURDATE**, **CURRENT\_DATE**, **CURTIME**, **CURRENT\_TIME**, **CURRENT\_TIMESTAMP**, **NOW**, **LOCALTIME**, **LOCALTIMESTAMP**, **UTC\_TIME** and **UTC\_TIMESTAMP** all return the start time of SQL statement execution, and **SYSDATE** returns the start time of function calling. **transaction\_timestamp()** still indicates the transaction start time. The return value type is changed to timestamp without time zone.

2. The following APIs return the start time of the current statement:

```
statement_timestamp()
```

**statement\_timestamp()** returns the start time of the current statement (more accurately, the time when the last instruction is received from the client). The return values of **statement\_timestamp()** and **transaction\_timestamp()** are the same during the execution of the first instruction of a transaction, but may be different in subsequent instructions.

3. The following APIs return the actual current time when the function is called:

```
clock_timestamp()
```

```
timeofday()
```

**clock\_timestamp()** returns the actual current time, and its value changes even in the same SQL command. Similar to **clock\_timestamp()**, **timeofday()** also returns the actual current time. However, the result of **timeofday()** is a formatted text string instead of a timestamp with time zone information.

- **convert\_tz(dt, from\_tz, to\_tz)**

Description: Converts the date and time value **dt** from the **from\_tz** time zone to the **to\_tz** time zone.

Parameters: For details about the parameters, see [Table 7-36](#).

**Table 7-36** Parameters

Parameter	Type	Description	Value Range
dt	datetime, date, text, and numeric	Time and date value.	[0000-01-01 00:00:00.000000,9999-12-31 23:59:59.999999].
from_tz /to_tz	A character string in the format of ±hh:mm	Offset compared with the UTC time, for example, '+08:00'.	[-15:59,15:00]
	Named time zone	For example, 'MET' and 'UTC'.	For details, see the <a href="#">PG_TIMEZONE_NAMES</a> system view.

Return type: datetime

Example:

```

gaussdb=# SET b_format_dev_version = 's1';
SET
gaussdb=# SET b_format_version = '5.7';
SET
gaussdb=# SELECT convert_tz(cast('2023-01-01 10:10:10' as datetime), '+00:00', '+01:00');
convert_tz
-----
2023-01-01 11:10:10
(1 row)
gaussdb=# SELECT convert_tz(cast('2023-01-01' as date), '+00:00', '+01:00');
convert_tz
-----
2023-01-01 01:00:00
(1 row)
gaussdb=# SELECT convert_tz('2023-01-01 10:10:10', '+00:00', '+01:00');
convert_tz
-----
2023-01-01 11:10:10
(1 row)
gaussdb=# SELECT convert_tz('2023-01-01', '+00:00', '+01:00');
convert_tz
-----
2023-01-01 01:00:00
(1 row)
gaussdb=# SELECT convert_tz(20230101101010, '+00:00', '+01:00');
convert_tz
-----
2023-01-01 11:10:10
(1 row)
gaussdb=# SELECT convert_tz(20230101, '+00:00', '+01:00');
convert_tz
-----
2023-01-01 01:00:00
(1 row)
gaussdb=# SELECT convert_tz('2023-01-01 10:10:10', 'UTC', 'PRC');
convert_tz
-----

```

2023-01-01 18:10:10  
(1 row)

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- `sec_to_time(seconds)`

Description: Converts the number of seconds into a time of the time type.

Parameters: For details about the parameters, see [Table 7-37](#).

**Table 7-37** Parameters

Parameter	Type	Description	Value Range
seconds	numeric and text	Number of seconds	[-3020399,+3020399], corresponding to the range of the time type [-838:59:59,838:59:59]. An out-of-bounds input will be truncated to the corresponding boundary value.

Return type: time without time zone

Example:

```
gaussdb=# SET b_format_dev_version = 's1';
SET
gaussdb=# SET b_format_version = '5.7';
SET
gaussdb=# SELECT sec_to_time(2000);
sec_to_time
-----
00:33:20
(1 row)
gaussdb=# SELECT sec_to_time('-2000');
sec_to_time
-----
-00:33:20
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- `adddate(date, INTERVAL val unit)`

Description: Returns a new date by adding a certain interval to a date.

Parameters: For details about the parameters, see [Table 7-38](#).

**Table 7-38** Parameters

Parameter	Type	Description	Value Range
date	Expression of the time type, text, datetime, date, or time	Date to be added with an interval.	See the value ranges of the corresponding types.
val	Integer, floating-point number, or character string	Interval to be added.	See the value ranges of the corresponding types.
unit	Keyword	Unit of the interval.	YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, SECOND, and MICROSECOND. For details, see <a href="#">Time Interval Expressions</a> .

Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT ADDDATE('2018-05-01', INTERVAL 1 DAY);
adddate
-----
2018-05-02
(1 row)
```

 **NOTE**

1. This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
  2. In the prepare statement, the second parameter of **adddate** is an interval expression. When parameter **\$1** is used to completely replace **adddate**, the result is unexpected, for example, prepare p1 as select adddate('2023-01-01 10:00:00', \$1); execute p1(interval 13 hour). The unexpected result returned in this test case is '2023-01-01 10:00:00'.
- **adddate(expr, days)**

Description: Returns a new date by adding a certain number of days to a date.

Parameters:

- **expr**: specifies the start date and time. The value type can be expression of the time type, TEXT, DATE, DATETIME, or TIME.
- **days**: specifies the number of days to be added. The value is of the int type.

Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT ADDDATE('2018-05-01', 1);
adddate
-----
```

```
2018-05-02
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **curdate()**

Description: Returns the system date when the local function calling starts. The time zone can be changed within the same connection. The returned date is affected by the time zone.

Return type: date

Example:

```
gaussdb=# SELECT curdate();
 curdate
-----
2023-08-10
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **curtime([precision])**

Description: Returns the system time when the SQL query call starts.

Parameter: **precision** indicates the precision (number of decimal places after the second). The value is of the int type and in the range [0,6]. The default value is 0. If the value can be converted into an integer within the range, the time value of the corresponding precision can be output. If the value is invalid, an error is reported.

Return type: time without time zone

Implementation method: Register the system function curtime.

Example:

```
gaussdb=# SELECT curtime(3);
 curtime
-----
16:59:57.203
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **date\_add(date,INTERVAL val unit)**

Description: Adds a period of time to a specified date and returns the calculation result.

Parameters: For details about the parameters, see [Table 7-39](#).

**Table 7-39** Parameters

Parameter	Type	Description	Value Range
date	Expression of the time type, text, datetime, date, or time	Date to be added with an interval.	See the value ranges of the corresponding types.
val	Integer, floating-point number, or character string	Interval to be added.	See the value ranges of the corresponding types.
unit	Keyword	Unit of the interval.	YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, SECOND, and MICROSECOND. For details, see <a href="#">Time Interval Expressions</a> .

Return value type: a single return value. For details, see [Table 7-40](#).

**Table 7-40** Return value types

Return Type	Description
TEXT	The <b>date</b> input parameter is of the text type.
DATE	The <b>date</b> input parameter is of the date type, and the value of the <b>unit</b> input parameter is greater than or equal to <b>day</b> (for example, <b>week</b> or <b>month</b> ).
TIME WITHOUT TIMEZONE	The <b>date</b> input parameter is of the time type.
DATETIME	The <b>date</b> input parameter is of the datetime type, or the <b>date</b> input parameter and the value of the <b>unit</b> input parameter is less than <b>day</b> (for example, <b>hour</b> or <b>second</b> ).

Example:

```
gaussdb=# SELECT DATE_ADD('2018-05-01', INTERVAL 1 DAY);
date_add
-----
2018-05-02
(1 row)
```

 NOTE

1. This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
  2. In the prepare statement, the second parameter of **date\_add** is an interval expression and cannot be replaced by \$1, for example, prepare p1 as select date\_add('2023-01-01 10:00:00', \$1).
- **date\_add(expr, days)**

Description: Returns a new date by adding a certain number of days to a date.

Parameters:

- **expr**: specifies the start date and time. The value type can be expression of the time type, TEXT, DATE, DATETIME, or TIME.
- **days**: specifies the number of days to be added. The value is of the int type.

Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT DATE_ADD('2018-05-01', 1);
date_add
-----
2018-05-02
(1 row)
```

 NOTE

- This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
- **date\_format(date, format)**

Description: Outputs the date and time in the specified format.

Parameters: For details about the parameters, see [Table 7-41](#).

**Table 7-41** Parameters

Parameter	Type	Description	Value Range
date	Time expression, TEXT, DATETIME, DATE, or TIME	Date to be formatted.	See the value ranges of the corresponding types.
format	text	A formatted string.	For details, see <a href="#">Table 7-42</a> .

[Table 7-42](#) lists the format parameters.

**Table 7-42** Values and meanings of format

Value	Description
%a	Abbreviation of a week (Sun, ..., Sat)
%b	Abbreviation of a month (Jan, ..., Dec)
%c	Month number (0, ..., 12)
%D	Every day in a month with an English prefix (0th, 1st, 2nd, 3rd, ...)
%d	Two-digit representation of every day in a month (00, ..., 31)
%e	Sequence number of every day in a month (0, ..., 31)
%f	Microsecond (000000, ..., 999999)
%H	Hour (00, ..., 23)
%h	Hour (01, ..., 12)
%l	Hour (01, ..., 12)
%i	Minute (00, ..., 59)
%j	Every day in a year (001, ..., 366)
%k	Hours (0, ..., 23)
%l	Hour (1, ..., 12)
%M	Month name (January, ..., December)
%m	Two-digit month (00, ..., 12)
%p	AM or PM
%r	12-hour time (hh:mm:ss followed by AM or PM).
%S	Second (00, ..., 59)
%s	Second (00, ..., 59)
%T	24-hour time (hh:mm:ss)
%U	Week of a year (00, ..., 53). Each week starts from Sunday.
%u	Week of a year (00, ..., 53). Each week starts from Monday.
%V	Week of a year (01, ..., 53). Each week starts from Sunday.
%v	Week of a year (01, ..., 53). Each week starts from Monday.

Value	Description
%W	Name of a week (Sunday, ..., Saturday)
%w	Every day in a week (0 = Sunday, ..., 6 = Saturday)
%X	Week of a year. Each week starts from Sunday. The value is a four-digit number and is used for %V.
%x	Week of a year. Each week starts from Monday. The value is a four-digit number and is used for %v.
%Y	Four-digit year
%y	Two-digit year

Return type: text

Example:

```
gaussdb=# SELECT date_format('2023-10-11 12:13:14.151617','%b %c %M %m');
date_format
-----
Oct 10 October 10
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **date\_sub**(date, INTERVAL val unit)

Description: Returns a new date by subtracting a certain interval from a date.

Parameters: For details about the parameters, see [Table 7-43](#).

**Table 7-43** Parameters

Parameter	Type	Description	Value Range
date	Expression of the time type, text, datetime, date, or time	Date to be added with an interval.	See the value ranges of the corresponding types.
val	Integer, floating-point number, or character string	Interval to be added.	See the value ranges of the corresponding types.
unit	Keyword	Unit of the interval.	YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, SECOND, and MICROSECOND. For details, see <a href="#">Time Interval Expressions</a> .

Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT DATE_SUB('2018-05-01', INTERVAL 1 YEAR);
date_sub
-----
2017-05-01
(1 row)
```

 NOTE

1. This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
  2. In the prepare statement, the second parameter of **date\_sub** is an interval expression and cannot be replaced by \$1, for example, prepare p1 as select date\_sub('2023-01-01 10:00:00', \$1).
- **date\_sub(expr, days)**

Description: Specifies the start date and time and the number of days to be subtracted from the start date and time, and returns the subtraction result.

Parameters:

- **expr**: specifies the start date and time. The value type can be expression of the time type, TEXT, DATE, DATETIME, or TIME.
- **days**: specifies the number of days to be subtracted. The value is of the int type.

Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT DATE_SUB('2023-1-1', 20);
date_sub
-----
2022-12-12
(1 row)
```

 NOTE

- This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
- **datediff(expr1, expr2)**

Description: Returns the number of days between two time expressions.

Parameter: Expression of the time type, text, datetime, date, or time

Return type: int

Example:

```
gaussdb=# SELECT datediff('2021-11-12','2021-11-13');
datediff
-----
-1
(1 row)
```

 NOTE

- This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
- **day()/dayofmonth()**
- Description: Extracts the number of days in a date and time expression and returns the result. **dayofmonth()** is the alias of **day()** and has the same function.

Parameter: The input parameter is the date and time to be extracted, which can be an expression of the time type, or of the text, datetime, date, or time type.

Return type: int

Example:

```
gaussdb=# SELECT day('2023-01-02');
 day
-----
  2
(1 row)
gaussdb=# SELECT dayofmonth('23-05-22');
 dayofmonth
-----
      22
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **dayname()**

Description: Returns the name of a day in a week.

Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME.

Return type: text

Example:

```
gaussdb=# SELECT dayname('2023-10-11');
 dayname
-----
Wednesday
(1 row)
```

 **NOTE**

- This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
- The language used by the return value is specified by the GUC parameter **lc\_time\_names**.

- **dayofweek()**

Description: Returns the working day index of a date (1 = Sunday, 2 = Monday, ..., 7 = Saturday).

Parameter: Expression of the time type, text, datetime, date, or time

Return type: bigint

Example:

```
gaussdb=# SELECT dayofweek('2023-04-16');
 dayofweek
-----
      1
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **dayofyear()**

Description: Returns the number of a day in the year.

Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME.

Return type: int; value range: 1 to 366.

Example:

```
gaussdb=# SELECT dayofyear('2000-12-31');
 dayofyear
-----
       366
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- extract(unit FROM date)

Description: Extracts part of the time. This function can be used in other modes, but the behavior varies greatly. When **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1', the function is described as follows:

Parameters:

- **unit**: text type. For details about the value types, see [Table 7-44](#).
- **date**: expression of the time type, such as date, time, datetime, and text.

Return type: bigint

**Table 7-44** Values and meanings of unit

Value of UNIT	Description
MICROSECOND	Microsecond
SECOND	Second
MINUTE	Minute
HOUR	Hour
DAY	Day
WEEK	Week
MONTH	Month
QUARTER	Quarter
YEAR	Year
SECOND_MICROSECOND	Concatenated value of second and microsecond
MINUTE_MICROSECOND	Concatenated value of minute, second, and microsecond
MINUTE_SECOND	Concatenated value of minute and second

Value of UNIT	Description
HOUR_MICROSECOND	Concatenated value of hour, minute, second, and microsecond
HOUR_SECOND	Concatenated value of hour, minute, and second
HOUR_MINUTE	Concatenated value of hour and minute
DAY_MICROSECOND	Concatenated value of day, hour, minute, second, and microsecond
DAY_SECOND	Concatenated value of day, hour, minute, and second
DAY_MINUTE	Concatenated value of day and minute
DAY_HOUR	Concatenated value of day and hour
YEAR_MONTH	Concatenated value of year and month
EPOCH	Total number of seconds or interval since 1970-01-01 00:00:00-00 UTC

**Example:**

```

gaussdb=# SELECT extract(YEAR FROM '2023-10-11');
extract
-----
 2023
(1 row)

gaussdb=# SELECT extract(QUARTER FROM '2023-10-11');
extract
-----
    4
(1 row)

gaussdb=# SELECT extract(MONTH FROM '2023-10-11');
extract
-----
   10
(1 row)

gaussdb=# SELECT extract(WEEK FROM '2023-10-11');
extract
-----
   41
(1 row)

gaussdb=# SELECT extract(DAY FROM '2023-10-11');
extract
-----
   11
(1 row)

gaussdb=# SELECT extract(HOUR FROM '2023-10-11 12:13:14');
extract

```

```
-----
      12
(1 row)
```

 **NOTE**

When `sql_compatibility` is set to 'MYSQL', `b_format_version` is set to 5.7, and `b_format_dev_version` is set to s1, the called function is registered as `b_extract`. In other cases, the actually registered function is `date_part`. You can use commands such as `\df b_extract` to query the detailed input parameter and return value of a function.

The GUC parameter `default_week_format` is used to process special week issues. The default value is 0. For details, see [Table 7-45](#).

**Table 7-45** default\_week\_format

default_week_format	First Day of a Week	Range	Which Week is the First Week
0	Sunday	0-53	Week containing Sunday in this year
1	Monday	0-53	Week containing four or more days in this year
2	Sunday	1-53	Week containing Sunday in this year
3	Monday	1-53	Week containing four or more days in this year
4	Sunday	0-53	Week containing four or more days in this year
5	Monday	0-53	Week containing Monday in this year
6	Sunday	1-53	Week containing four or more days in this year
7	Monday	1-53	Week containing Monday in this year

- `from_days(days)`

Description: Returns the corresponding date value given a number of days.

Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME.

Return type: date

Example:

```
gaussdb=# SELECT from_days(36524);--0099-12-31
from_days
-----
0099-12-31
(1 row)
```

 NOTE

- This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
  - Null characters and zeros are processed as 0. For input parameters that cannot be correctly converted to bigint, an error is reported.
  - If the input parameter is less than 366, the return date is 0000-00-00.
- `from_unixtime(unix_timestamp[,format])`

Description: Converts a Unix timestamp to the date and time format. A Unix timestamp is the number of seconds from 08:00:00 UTC on January 1, 1970 to a specified time.

Parameters:

- **unix\_timestamp**: Unix timestamp, which is of the numeric type.
- **format**: time format. The value is of the text type.

Return type: text/datetime

Example:

```
gaussdb=# SELECT from_unixtime(1111885200);
 from_unixtime
-----
2005-03-27 09:00:00
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- `get_format({DATE | TIME | DATETIME | TIMESTAMP}, {'EUR' | 'USA' | 'JIS' | 'ISO' | 'INTERNAL'})`

Description: Converts a date, time, or datetime into a string in a specified time format, that is, the year, month, day, hour, minute, and second formats and sorting standards of different regions.

Parameters:

- **DATE|TIME|DATETIME|TIMESTAMP**: time type, which are keywords.
- **'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'**: five time formats, which are of the text type.

Return type: text

Example:

```
gaussdb=# SELECT get_format(date, 'eur');
 get_format
-----
%d.%m.%y
(1 row)
gaussdb=# SELECT get_format(date, 'usa');
 get_format
-----
%m.%d.%y
(1 row)
```

 NOTE

1. This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
2. In the prepare statement, the first parameter of **get\_format** is a keyword and cannot be replaced by \$1, for example, prepare p1 as select get\_format(\$1, 'usa').

- **hour()**  
Description: Returns the hour part of a time after you enter a time type.  
Parameter: Expression of the time type, text, datetime, date, or time  
Return type: bigint

Example:

```
gaussdb=# SELECT HOUR('10:10:10.1');
hour
-----
10
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **makedate(year,dayofyear)**  
Description: Returns a date based on the given year and day.  
Parameters:
  - **year**: bigint.
  - **dayofyear**: bigint, indicating the number of days in the year. The value can cross years. If the value is less than or equal to **0**, **null** is returned.

Return type: date

Example:

```
gaussdb=# SELECT makedate(2000, 60);
makedate
-----
2000-02-29
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **microsecond()**  
Description: Returns the microsecond part of a time after you enter a time type.  
Parameter: Expression of the time type, text, datetime, date, or time  
Return type: bigint

Example:

```
gaussdb=# SELECT MICROSECOND('2023-5-5 10:10:10.24485');
microsecond
-----
244850
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **minute()**  
Description: Returns the minute part of a time after you enter a time type.  
Parameter: Expression of the time type, text, datetime, date, or time  
Return type: bigint

Example:

```
gaussdb=# SELECT MINUTE(time'10:10:10');
minute
-----
      10
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **month()**

Description: Returns the month starting from a past date.

Parameter: The input parameter is the date and time to be extracted, which can be an expression of the time type, or of the TEXT, DATETIME, DATE, or TIME type.

Return type: int

Example:

```
gaussdb=# SELECT month('2021-11-30');
month
-----
     11
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- **monthname()**

Description: Returns the full month name of a date.

Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME.

Return type: text

Example:

```
gaussdb=# SELECT monthname('2023-02-28');
monthname
-----
February
(1 row)
```

 **NOTE**

- This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
- The language used by the return value is controlled by the value of the **lc\_time\_names** system variable.

- **period\_add(period, month\_number)**

Description: Adds a specified number of months to a specified time segment and returns the result as a time segment.

Parameters:

- **period**: bigint, which is a date in the format of YYYYMM or YYMM.
- **month\_number**: bigint, indicating the number of months to be added. The value can be a negative number.

Return type: bigint, which is a date in YYYYMM format.

Example:

```
gaussdb=# SELECT period_add(202205, -12);
period_add
-----
202105
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- `period_diff(p1,p2)`

Description: Calculates the month difference between two time points.

Parameters: **P1** and **P2** are periods in YYMM or YYYYMM format and are of the bigint type.

Return type: bigint (month difference)

Example:

```
gaussdb=# SELECT period_diff('202101', '202102');
period_diff
-----
-1
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- `second()`

Description: Returns the second part of a time after you enter a time type.

Parameter: Expression of the time type, text, datetime, date, or time

Return type: bigint

Example:

```
gaussdb=# SELECT SECOND('2023-5-5 10:10:10');
second
-----
10
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- `quarter()`

Description: Returns the quarter part of a date after you enter a date type.

Parameter: The input parameter is the date and time to be extracted, which can be an expression of the time type, or of the TEXT, DATETIME, DATE, or TIME type.

Return type: bigint

Example:

```
gaussdb=# SELECT QUARTER('2012-1-1');
quarter
-----
1
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- str\_to\_date(str, format)

Description: Converts a specified character string to a date/time based on the specified date format.

Parameters:

- **str**: text type, which is the character string to be formatted into a date.
- **format**: text type, indicating the target format.
- [Table 7-46](#) lists the format parameters.

**Table 7-46** Values and meanings of format

Value	Description
%a	Abbreviation of a week (Sun, ..., Sat)
%b	Abbreviation of a month (Jan, ..., Dec)
%c	Month number (0, ..., 12)
%D	Every day in a month with an English prefix (0th, 1st, 2nd, 3rd, ...)
%d	Two-digit representation of every day in a month (00, ..., 31)
%e	Sequence number of every day in a month (0, ..., 31)
%f	Microsecond (000000, ..., 999999)
%H	Hour (00, ..., 23)
%h	Hour (01, ..., 12)
%l	Hour (01, ..., 12)
%i	Minute (00, ..., 59)
%j	Every day in a year (001, ..., 366)
%k	Hours (0, ..., 23)
%l	Hour (1, ..., 12)
%M	Month name (January, ..., December)
%m	Two-digit month (00, ..., 12)
%p	AM or PM
%r	12-hour time (hh:mm:ss followed by AM or PM).
%S	Second (00, ..., 59)

Value	Description
%s	Second (00, ..., 59)
%T	24-hour time (hh:mm:ss)
%U	Week of a year (00, ..., 53). Each week starts from Sunday.
%u	Week of a year (00, ..., 53). Each week starts from Monday.
%V	Week of a year (01, ..., 53). Each week starts from Sunday.
%v	Week of a year (01, ..., 53). Each week starts from Monday.
%W	Name of a week (Sunday, ..., Saturday)
%w	Every day in a week (0 = Sunday, ..., 6 = Saturday)
%X	Week of a year. Each week starts from Sunday. The value is a four-digit number and is used for %V.
%x	Week of a year. Each week starts from Monday. The value is a four-digit number and is used for %v.
%Y	Four-digit year
%y	Two-digit year

Return type: text

Example:

```
gaussdb=# SELECT str_to_date('May 1, 2013','%M %d,%Y');--2013-05-01
str_to_date
-----
2013-05-01
(1 row)
```

 **NOTE**

- This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
- Only the time in YYYY-MM-DD format can be returned.
- If the time contains 0 year, 0 month, and 0 day or contains only hour, minute, and second, an alarm is generated and **NULL** is returned.
- **subdate(expr, days)**  
Description: Specifies the start date and time and the number of days to be subtracted from the start date and time, and returns the subtraction result.  
Parameters:  
– **expr**: specifies the start date and time. The value type can be expression of the time type, TEXT, DATE, DATETIME, or TIME.

- **days**: specifies the number of days to be subtracted. The value is of the int type.

Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT SUBDATE('2023-1-1', 20);
subdate
-----
2022-12-12
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- subdate(expr,INTERVAL val unit)

Description: Specifies the start date and time and the interval to be subtracted from the start date and time, and returns the subtraction result.

Parameters: For details about the parameters, see [Table 7-47](#).

**Table 7-47** Parameters

Parameter	Type	Description	Value Range
expr	Expression of the time type, text, datetime, date, or time	Specifies the start date and time.	See the value ranges of the corresponding types.
val	Integer, floating-point number, or character string	Specifies the interval to be subtracted.	See the value ranges of the corresponding types.
unit	Keyword		YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, SECOND, and MICROSECOND. For details, see <a href="#">Time Interval Expressions</a> .

Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT SUBDATE('2018-05-01', INTERVAL 1 YEAR);
subdate
-----
2017-05-01
(1 row)
```

 NOTE

1. This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
2. In the prepare statement, the second parameter of **subdate** is an interval expression. When parameter **\$1** is used to completely replace **subdate**, the result is unexpected, for example, prepare p1 as select subdate('2023-01-01 10:00:00', \$1); execute p1(interval 13 hour). The unexpected result returned in this test case is '2023-01-01 10:00:00'.

- subtime(expr1,expr2)

Description: Returns the difference between **expr1** and **expr2**.

Parameters:

- **expr1** is an expression of the TIMESTAMP WITHOUT TIME ZONE or TIME type, and **expr2** is a time expression.
- The return value type is related to the **expr1** type. If the two input parameters are of the TEXT type, the return value type is TEXT. If the two input parameters are parsed as TIMESTAMP WITHOUT TIME ZONE, the return value type is TIMESTAMP WITHOUT TIME ZONE. If the two input parameters are parsed as TIME, the return value type is TIME.

Return type: TEXT, TIMESTAMP WITHOUT TIME ZONE, or TIME

Example:

```
gaussdb=# SELECT subtime('2000-03-01 20:59:59', '22:58');
 subtime
-----
2000-02-29 22:01:59
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- addtime(expr1,expr2)

Description: Returns the sum of **expr1** and **expr2**. The format of the return value is the same as that of **expr1**.

Parameters:

- **expr1** is an expression of the timestamp without time zone or time type, and **expr2** is a time expression.
- The return value type is related to the type of **expr1**. If it is parsed as timestamp without time zone, the return value type is timestamp without time zone. If it is parsed as time, the return value type is time.

Return type: text, timestamp without time zone, or time.

Example:

```
gaussdb=# SELECT addtime('2000-03-01 20:59:59', '00:00:01');
 addtime
-----
2000-03-01 21:00:00
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- `time_format(time, format)`  
Description: Formats the **time** input parameter based on the format specified by **format**.  
Parameters:
  - The value type of **time** is expression of the time type, text, datetime, date, or time
  - **format** is of the text type. [Table 7-48](#) lists the supported formats.

**Table 7-48** Values and meanings of format

Value	Description
%f	Microsecond (000000-999999)
%H	Hour (00 to 23)
%h, %l	Hour (00 to 12)
%l	Hour (0 to 12)
%k	Hour (0 to 838)
%i	Minute (00 to 59)
%p	AM or PM
%r	Time in 12-hour AM or PM format (hh:mm:ss AM/PM)
%S, %s	Second (00 to 59)
%T	Time in 24-hour format (hh:mm:ss)
%a, %b, %D, %j, %M, %U, %u, %V, %v, %W, %w, %X, %x	NULL.
%c, %e	0
%d, %m, %y	00
%Y	0000
<i>%Other characters/Other characters, for example, %A/A</i>	The character itself is returned, for example, A.
<i>%Single character + string s</i>	<i>%Single character</i> is parsed and then concatenated with <i>s</i> .

Return type: text

Example:

```
gaussdb=# SELECT TIME_FORMAT('25:30:30', '%T|%r|%H|%h|%l|%i|%S|%f|%p|%k');
time_format
-----
25:30:30|01:30:30 AM|25|01|01|30|30|000000|AM|25
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- `time_to_sec()`

Description: Converts the input parameter of the time type to the number of seconds.

Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME. The time expression is parsed as TIME.

Return type: int

Example:

```
gaussdb=# SELECT time_to_sec('00:00:01');
time_to_sec
-----
1
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- `timediff()`

Description: Calculates the difference between two time points and returns an interval.

Parameter: There are two parameters, which are of the time expression, text, datetime, date, or time type.

Return type: TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT timediff(date'2022-12-30',20221229);
timediff
-----
24:00:00
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- `timestampadd(unit,interval,datetime_expr)`

Description: Returns a new timestamp calculated by adding multiple intervals of a unit to **datetime\_expr**.

Parameters: For details about the parameters, see [Table 7-49](#).

**Table 7-49** Parameters

Parameter	Type	Description	Value Range
unit	Keyword	Unit of the interval.	YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, SECOND, MICROSECOND, Y, MM (month), D, H, M (minute), S, US, YRS, QTR, MON, HRS, MIN, YEARS, WEEKS, or HOURS.
interval	numeric	Interval.	See the value ranges of the corresponding types.
datetime_expr	Expression of the time type, text, datetime, date, or time	Date and time to be changed. If the value is of the text type, the return value type is text. If the value is of the time type, the return value type is time. In other cases, the return value type is datetime.	See the value ranges of the corresponding types.

Return type: DATETIME, TEXT, TIME WITHOUT TIMEZONE

Example:

```
gaussdb=# SELECT TIMESTAMPADD(DAY,-2,'2022-07-27');
timestampadd
-----
2022-07-25
(1 row)
```

 **NOTE**

- This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.
- The actually registered function of timestampadd is timestamp\_add. You can run commands such as `\df timestamp_add` to query the detailed input parameter and return value of the function.
- In the prepare statement, the first parameter of **timestampadd** is a keyword and cannot be replaced by **\$1**, for example, prepare p1 as select timestampadd(\$1, -2, '2023-01-01');
- to\_days()

Description: Returns the number of days from year 0 of a specified date.

Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME. The time expression is parsed as DATE.

Return type: bigint

Example:

```
gaussdb=# SELECT to_days('2000-1-1');
to_days
-----
730485
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- to\_seconds()

Description: Returns the number of seconds since the year 0 A.D.

Parameter: The input parameter is a time expression, TEXT, DATETIME, DATE, or TIME. The time expression is parsed as datetime.

Return type: bigint

Example:

```
gaussdb=# SELECT TO_SECONDS('2009-11-29 13:43:32');
to_seconds
-----
63426721412
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- unix\_timestamp([date])

Description: Returns a Unix timestamp representing the number of seconds since "1970-01-01 08:00" UTC. If there is no input parameter, the default value is the datetime timestamp when the function is called.

Parameter: Expression of the time type, text, datetime, date, or time

Return type: numeric

Example:

```
gaussdb=# SELECT UNIX_TIMESTAMP('2022-12-22');
unix_timestamp
-----
1671638400
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1'.

- utc\_date()

Description: Returns the current UTC date of function execution as a value in YYYY-MM-DD format.

Return type: date

Example:

```
gaussdb=# SELECT utc_date();
utc_date
-----
2023-08-10
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1'.

- `utc_time()`

Description: Returns the current UTC time of function execution as a value in HH:MM:SS format.

Parameter: Indicates the time precision. The value is of the int type and in the range [0,6]. The default value is 0.

Return type: time without time zone

Example:

```
gaussdb=# SELECT utc_time();
 utc_time
-----
11:47:53
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1'.

- `utc_timestamp()`

Description: Returns the current UTC timestamp of function execution as a value in YYYY-MM-DD HH:MM:SS format.

Parameter: Indicates the time precision. The value is of the int type and in the range [0,6]. The default value is 0.

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT utc_timestamp();
 utc_timestamp
-----
2023-08-21 11:51:19
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1'.

- `week(date[, mode])`

Description: Returns the number of weeks of a date.

Parameters:

- **date**: specifies the date and time, which is of the time expression, text, datetime, date, or time type.
- **Table 7-50** describes the optional parameter **mode**. The default value is 0.

**Table 7-50** Description of mode

mode	First Day of a Week	Range	Which Week is the First Week
0	Sunday	0-53	Week containing Sunday in this year
1	Monday	0-53	Week containing four or more days in this year
2	Sunday	1-53	Week containing Sunday in this year
3	Monday	1-53	Week containing four or more days in this year
4	Sunday	0-53	Week containing four or more days in this year
5	Monday	0-53	Week containing Monday in this year
6	Sunday	1-53	Week containing four or more days in this year
7	Monday	1-53	Week containing Monday in this year

Return type: bigint

Example:

```
gaussdb=# SELECT week(date'2000-01-01', 1);
week
-----
0
(1 row)
```

```
gaussdb=# SELECT week('2000-01-01', 2);
week
-----
52
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1'.

- weekday()**

Description: Returns the working day index of a date, that is, Monday is 0, Tuesday is 1, Wednesday is 2, Thursday is 3, Friday is 4, Saturday is 5, and Sunday is 6.

Parameter: Expression of the time type, text, datetime, date, or time

Return type: bigint

Example:

```
gaussdb=# SELECT weekday('1970-01-01 12:00:00');
weekday
-----
      3
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1'.

- weekofyear(date)

Description: Returns the calendar week of the date and time. The value ranges from 1 to 53. It is equivalent to week(date, 3).

Parameters:

- **date**: specifies the date and time, which is of the time expression, text, datetime, date, or time type.
- This function is equivalent to week(date, 3). For details, see [week\(date\[, mode\]\)](#).

Return type: bigint

Example:

```
gaussdb=# SELECT weekofyear('1970-05-22');
weekofyear
-----
      21
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1'.

- year()

Description: Extracts the year part of the date and time and returns the result.

Parameter: The input parameter is the date and time to be extracted, which can be an expression of the time type, or of the text, datetime, date, or time type.

Return type: int

Example:

```
gaussdb=# SELECT year('23-05-22');
year
-----
2023
(1 row)
```

 NOTE

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1'.

- yearweek(date[, mode])

Description: Returns the year and week of a date.

Parameters:

- **date**: specifies the date and time.

- The value of **date** can be DATE, DATETIME, TIMESTAMP, TIME, TEXT or NUMERIC.
- **Table 7-51** describes the optional parameter **mode**. The default value is **0**.

**Table 7-51** Description of mode

mode	First Day of a Week	Range	Which Week is the First Week
0	Sunday	0-53	Week containing Sunday in this year
1	Monday	0-53	Week containing four or more days in this year
2	Sunday	1-53	Week containing Sunday in this year
3	Monday	1-53	Week containing four or more days in this year
4	Sunday	0-53	Week containing four or more days in this year
5	Monday	0-53	Week containing Monday in this year
6	Sunday	1-53	Week containing four or more days in this year
7	Monday	1-53	Week containing Monday in this year

Return type: bigint

Example:

```
gaussdb=# SELECT yearweek(datetime'2000-01-01', 3);
yearweek
-----
199952
(1 row)
```

 **NOTE**

This function is valid only when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1'.

**Table 7-52** shows the templates for truncating date/time values.

**Table 7-52** Truncating date/time values

Item	Format	Description
Microsecond	MICROSECON	Truncates date/time values, accurate to the microsecond (000000–999999).
	US	
	USEC	
	USECOND	
Millisecond	MILLISECON	Truncates date/time values, accurate to the millisecond (000–999).
	MS	
	MSEC	
	MSECOND	
Second	S	Truncates date/time values, accurate to the second (00–59).
	SEC	
	SECOND	
Minute	M	Truncates date/time values, accurate to the minute (00–59).
	MI	
	MIN	
	MINUTE	
Hour	H	Truncates date/time values, accurate to the hour (00–23).
	HH	
	HOUR	
	HR	
Day	D	Truncates date/time values, accurate to the day (01-01 to 12-31)
	DAY	
	DD	
	DDD	
	J	
Week	W	Truncates date/time values, accurate to the week (the first day of the current week).
	WEEK	
Month	MM	Truncates date/time values, accurate to the month (the first day of the current month).
	MON	
	MONTH	

Item	Format	Description
Quarter	Q	Truncates date/time values, accurate to the quarter (the first day of the current quarter).
	QTR	
	QUARTER	
Year	Y	Truncates date/time values, accurate to the year (the first day of the current year).
	YEAR	
	YR	
	YYYY	
Decade	DEC	Truncates date/time values, accurate to the decade (the first day of the current decade).
	DECADE	
Century	C	Truncates date/time values, accurate to the century (the first day of the current century).
	CC	
	CENT	
	CENTURY	
Millennium	MIL	Truncates date/time values, accurate to the millennium (the first day of the current millennium).
	MILLENNIA	
	MILLENNIUM	

**Table 7-53** Parameters for time truncation and rounding

Item	Format	Description
Minute	M	Truncated or rounded off, accurate to minute (00–59).
	MI	
	MIN	
	MINUTE	
Hour	H	Truncated or rounded off, accurate to hour (00–23).
	HH	
	HOUR	
	HR	
	HH12	
	HH24	

Item	Format	Description
Day	DD	Truncated or rounded off, accurate to day (01-01 to 12-31).
	DDD	
	J	
ISO week	IW	Truncated or rounded off, accurate to week (the first day of the week is Monday).
Week	DAY	Truncated or rounded off, accurate to week (the first day of the week is Sunday).
	DY	
	D	
Week of the month	W	Truncated or rounded off, accurate to week (the first day of the week is the first day of the month).
Week of the year	WW	Truncated or rounded off, accurate to week (the first day of the week is the first day of the year).
Month	MM	Truncated or rounded off, accurate to month (the first day of the month).
	MON	
	MONTH	
	RM	
Quarter	Q	Truncated or rounded off, accurate to quarter (the first day of the quarter).
	QTR	
	QUARTER	
Year	Y	Truncated or rounded off, accurate to year (the first day of the current year).
	YEAR	
	YR	
	YYYY	
	SYYYY	
	YYY	
	YY	
	SYEAR	
Decade	DEC	Truncated or rounded off, accurate to decade (the first day of the current decade).
	DECADE	

Item	Format	Description
Century	C	Truncated or rounded off, accurate to the century (the first day of the century).
	CC	
	CENT	
	CENTURY	
	SCC	
Millennium	MIL	Truncated or rounded off, accurate to millennium (the first day of the millennium).
	MILLENNIA	
	MILLENNIUM	

 **NOTE**

The behaviors of [Table 7-53](#) are valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s1** in an ORA-compatible database.

- `timestamp_diff(text, timestamp, timestamp)`  
Description: Calculates the difference between two timestamps and truncates the difference to the precision specified by text.

Return type: bigint

Example:

```
gaussdb=# SELECT timestamp_diff('year','2018-01-01','2020-04-01');
timestamp_diff
-----
          2
(1 row)
gaussdb=# SELECT timestamp_diff('month','2018-01-01','2020-04-01');
timestamp_diff
-----
         27
(1 row)
gaussdb=# SELECT timestamp_diff('quarter','2018-01-01','2020-04-01');
timestamp_diff
-----
          9
(1 row)
gaussdb=# SELECT timestamp_diff('week','2018-01-01','2020-04-01');
timestamp_diff
-----
        117
(1 row)
gaussdb=# SELECT timestamp_diff('day','2018-01-01','2020-04-01');
timestamp_diff
-----
        821
(1 row)
gaussdb=# SELECT timestamp_diff('hour','2018-01-01 10:10:10','2018-01-01 12:12:12');
timestamp_diff
-----
          2
(1 row)
gaussdb=# SELECT timestamp_diff('minute','2018-01-01 10:10:10','2018-01-01 12:12:12');
timestamp_diff
-----
```

```

122
(1 row)
gaussdb=# SELECT timestamp_diff('second','2018-01-01 10:10:10','2018-01-01 10:12:12');
timestamp_diff
-----
122
(1 row)
gaussdb=# SELECT timestamp_diff('microsecond','2018-01-01 10:10:10','2018-01-01 10:12:12');
timestamp_diff
-----
122000000
(1 row)

```

## TIMESTAMPDIFF

- **TIMESTAMPDIFF**(*unit* , *timestamp\_expr1*, *timestamp\_expr2*)

Description: Returns the result of **timestamp\_expr2** – **timestamp\_expr1** in the specified unit. This function is equivalent to **timestamp\_diff(text, timestamp, timestamp)**.

Parameters: **timestamp\_expr1** and **timestamp\_expr2** are of the time expression, text, datetime, date, or time type. **unit** specifies the unit of the difference between two dates.

Return type: bigint

### NOTE

- This function takes effect only in databases in MySQL compatibility mode.
- When **sql\_compatibility** is set to **'MYSQL'**, **b\_format\_version** is set to **5.7**, and **b\_format\_dev\_version** is set to **s1**, the called function is registered as **b\_timestampdiff**. If the GUC parameter is not enabled in a database in MySQL-compatible mode, the called function is registered as **timestamp\_diff**. You can run the **\df b\_timestampdiff** command to query the detailed input parameter and return value of the function.

- year

Year.

```

gaussdb=# SELECT TIMESTAMPDIFF(YEAR, '2018-01-01', '2020-01-01');
timestamp_diff
-----
2
(1 row)

```

- quarter

Quarter.

```

gaussdb=# SELECT TIMESTAMPDIFF(QUARTER, '2018-01-01', '2020-01-01');
timestamp_diff
-----
8
(1 row)

```

- month

Month.

```

gaussdb=# SELECT TIMESTAMPDIFF(MONTH, '2018-01-01', '2020-01-01');
timestamp_diff
-----
24
(1 row)

```

- week

Week.

```
gaussdb=# SELECT TIMESTAMPDIFF(WEEK, '2018-01-01', '2020-01-01');
timestamp_diff
-----
          104
(1 row)
```

- day

Day.

```
gaussdb=# SELECT TIMESTAMPDIFF(DAY, '2018-01-01', '2020-01-01');
timestamp_diff
-----
          730
(1 row)
```

- hour

Hour.

```
gaussdb=# SELECT TIMESTAMPDIFF(HOUR, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
timestamp_diff
-----
              1
(1 row)
```

- minute

Minute.

```
gaussdb=# SELECT TIMESTAMPDIFF(MINUTE, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
timestamp_diff
-----
              61
(1 row)
```

- second

Second.

```
gaussdb=# SELECT TIMESTAMPDIFF(SECOND, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
timestamp_diff
-----
          3661
(1 row)
```

- microseconds

The second field, including fractional parts, is multiplied by 1,000,000.

```
gaussdb=# SELECT TIMESTAMPDIFF(MICROSECOND, '2020-01-01 10:10:10.000000', '2020-01-01
10:10:10.111111');
timestamp_diff
-----
         111111
(1 row)
```

## EXTRACT

- **EXTRACT(*field* FROM *source*)**

The **extract** function retrieves fields such as year or hour from date/time values. **source** must be a value expression of type **timestamp**, **time**, or **interval**. (Expressions of type **date** are cast to **timestamp** and can therefore be used as well.) **field** is an identifier or string that selects what field to extract from the source value. The extract function returns a value of the double precision type. The following are valid **field** names:

- century  
Century.

The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0. You go from **-1** century to **1** century.

```
gaussdb=# SELECT EXTRACT(CENTURY FROM TIMESTAMP '2000-12-16 12:21:13');
date_part
-----
      20
(1 row)
```

- **day**

- **Day (1–31) of the month for **timestamp**.**

```
gaussdb=# SELECT EXTRACT(DAY FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
      16
(1 row)
```

- **Number of days for **interval**.**

```
gaussdb=# SELECT EXTRACT(DAY FROM INTERVAL '40 days 1 minute');
date_part
-----
      40
(1 row)
```

- **decade**

Year divided by 10

```
gaussdb=# SELECT EXTRACT(DECADE FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
     200
(1 row)
```

- **dow**

Day of the week as Sunday (**0**) to Saturday (**6**)

```
gaussdb=# SELECT EXTRACT(DOW FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
      5
(1 row)
```

- **doy**

Day of the year (1–365 or 366)

```
gaussdb=# SELECT EXTRACT(DOY FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
      47
(1 row)
```

- **epoch**

- For **timestamp with time zone** values, the number of seconds since 1970-01-01 00:00:00-00 UTC (can be negative).

For **date** and **timestamp** values, the number of seconds since 1970-01-01 00:00:00-00 local time.

For **interval** values, the total number of seconds in the interval.

```
gaussdb=# SELECT EXTRACT(EPOCH FROM TIMESTAMP WITH TIME ZONE '2001-02-16
20:38:40.12-08');
date_part
-----
982384720.12
(1 row)
gaussdb=# SELECT EXTRACT(EPOCH FROM INTERVAL '5 days 3 hours');
date_part
```

```
-----
442800
(1 row)
```

– Way to convert an epoch value back to a timestamp

```
gaussdb=# SELECT TIMESTAMP WITH TIME ZONE 'epoch' + 982384720.12 * INTERVAL '1
second' AS RESULT;
          result
-----
2001-02-17 12:38:40.12+08
(1 row)
```

- hour

Hour (0–23)

```
gaussdb=# SELECT EXTRACT(HOUR FROM TIMESTAMP '2001-02-16 20:38:40');
          date_part
-----
20
(1 row)
```

- isodow

Day of the week (1–7)

Monday is 1 and Sunday is 7.

 **NOTE**

This is identical to **dow** except for Sunday.

```
gaussdb=# SELECT EXTRACT(ISODOW FROM TIMESTAMP '2001-02-18 20:38:40');
          date_part
-----
7
(1 row)
```

- isoyear

The ISO 8601 year that the date falls in (not applicable to intervals).

Each ISO year begins with the Monday of the week containing January 4, so in early January or late December the ISO year may be different from the Gregorian year. See [week](#) for more information.

```
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
          date_part
-----
2005
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-01 00:00:40');
          date_part
-----
52
(1 row)
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
          date_part
-----
2006
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-02 00:00:40');
          date_part
-----
1
(1 row)
```

- microseconds

The second field, including fractional parts, is multiplied by 1,000,000.

```
gaussdb=# SELECT EXTRACT(MICROSECONDS FROM TIME '17:12:28.5');
          date_part
-----
```

```
28500000
(1 row)
```

- millennium

Millennium.

Years in the 1900s are in the second millennium. The third millennium started from January 1, 2001.

```
gaussdb=# SELECT EXTRACT(MILLENNIUM FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
3
(1 row)
```

- milliseconds

Second field, including fractional parts, is multiplied by 1000. Note that this includes full seconds.

```
gaussdb=# SELECT EXTRACT(MILLISECONDS FROM TIME '17:12:28.5');
date_part
-----
28500
(1 row)
```

- minute

Minute (0–59).

```
gaussdb=# SELECT EXTRACT(MINUTE FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
38
(1 row)
```

- month

For **timestamp** values, the specific month in the year (1–12).

```
gaussdb=# SELECT EXTRACT(MONTH FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
2
(1 row)
```

For **interval** values, the number of months, modulo 12 (0–11).

```
gaussdb=# SELECT EXTRACT(MONTH FROM INTERVAL '2 years 13 months');
date_part
-----
1
(1 row)
```

- quarter

Quarter of the year (1–4) that the date is in.

```
gaussdb=# SELECT EXTRACT(QUARTER FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
1
(1 row)
```

- second

Second field, including fractional parts (0–59).

```
gaussdb=# SELECT EXTRACT(SECOND FROM TIME '17:12:28.5');
date_part
-----
28.5
(1 row)
```

- timezone

Time zone offset from UTC, measured in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.

- `timezone_hour`  
Hour component of the time zone offset.
- `timezone_minute`  
Minute component of the time zone offset.
- `week`  
Number of the week of the year that the day is in. By definition (ISO 8601), the first week of a year contains January 4 of that year. (The ISO-8601 week starts on Monday.) In other words, the first Thursday of a year is in week 1 of that year.

Because of this, it is possible for early January dates to be part of the 52nd or 53rd week of the previous year, and late December dates to be part of the 1st week of the next year. For example, 2006-01-01 is the 52nd week of 2005, and 2006-01-02 is the first week of 2006. You are advised to use the columns [isoyear](#) and [week](#) together to ensure consistency.

```
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
date_part
-----
      2005
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-01 00:00:40');
date_part
-----
       52
(1 row)
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
date_part
-----
      2006
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-02 00:00:40');
date_part
-----
        1
(1 row)
```

- `year`  
Year field.

```
gaussdb=# SELECT EXTRACT(YEAR FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
      2001
(1 row)
```

## date\_part

The `date_part` function is modeled on the traditional Ingres equivalent to the SQL-standard function `extract`:

**date\_part**('field', source)

Note that here the **field** parameter needs to be a string value, not a name. The valid field names are the same as those for **extract**. For details, see [EXTRACT](#).

Example:

```
gaussdb=# SELECT date_part('day', TIMESTAMP '2001-02-16 20:38:40');
date_part
```

```

-----
      16
(1 row)
gaussdb=# SELECT date_part('hour', INTERVAL '4 hours 3 minutes');
date_part
-----
      4
(1 row)

```

**Table 7-54** specifies the formats for formatting date and time values.

**Table 7-54** Formats for formatting date and time

Category	Format	Description
Hour	HH	Number of hours in one day (01-12)
	HH12	Number of hours in one day (01-12)
	HH24	Number of hours in one day (00-23)
Minute	MI	Minute (00-59)
Second	SS	Second (00-59)
	FF	Microsecond (000000-999999)
	FF1	Microsecond (0-9)
	FF2	Microsecond (00-99)
	FF3	Microsecond (000-999)
	FF4	Microsecond (0000-9999)
	FF5	Microsecond (00000-99999)
	FF6	Microsecond (000000-999999)
	SSSSS	Second after midnight (0-86399)
Morning and afternoon	AM or A.M.	Morning identifier
	PM or P.M.	Afternoon identifier
Year	Y,YYY	Year with comma (with four digits or more)
	YYYY	Year with four digits BC
	YYYY	Year (with four digits or more)
	YYY	Last three digits of a year
	YY	Last two digits of a year
	Y	Last one digit of a year
	IYYY	ISO year (with four digits or more)
	IYY	Last three digits of an ISO year
	IY	Last two digits of an ISO year

Category	Format	Description
	I	Last one digit of an ISO year
	RR	Last two digits of a year (A year of the 20th century can be stored in the 21st century.)
	RRRR	Capable of receiving a year with four digits or two digits. If there are 2 digits, the value is the same as the returned value of RR. If there are 4 digits, the value is the same as YYYY.
	<ul style="list-style-type: none"> <li>• BC or B.C.</li> <li>• AD or A.D.</li> </ul>	Era indicator BC or AD
Month	MONTH	Full name of a month in uppercase (9 characters are filled in if the value is empty.)
	MON	Month in abbreviated format in uppercase (with three characters)
	MM	Month (01-12)
	RM	Month in Roman numerals (I-XII; I=JAN) and uppercase
Day	DAY	Full name of a date in uppercase (9 characters are filled in if the value is empty.)
	DY	Day in abbreviated format in uppercase (with three characters)
	DDD	Day in a year (001-366)
	DD	Day in a month (01-31)
	D	Day in a week (1-7).
Week	W	Week in a month (1-5) (The first week starts from the first day of the month.)
	WW	Week in a year (1-53) (The first week starts from the first day of the year.)
	IW	Week in an ISO year (The first Thursday is in the first week.)
Century	CC	Century (with two digits) (The 21st century starts from 2001-01-01.)
Julian date	J	Julian date (starting from January 1 of 4712 BC)
Quarter	Q	Quarter

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an ORA-compatible database, the date and time will be formatted in the specified format.

**Table 7-55** New formats for formatting date and time

Item	Format	Description
Century	SCC	Century. A hyphen (-) will be displayed before BC years.
Year	SYYYY	Returns a numeric year. A hyphen (-) will be displayed before BC years.
	RR	Returns the two-digit year of a date.
	RRRR	Returns the four-digit year of a date.
	YEAR	Returns the year of the character type.
	SYEAR	Returns the year of the character type. A hyphen (-) will be displayed before BC years.
Date Format	DL	Returns the date in the specified long date format.
	DS	Returns the date in the specified short date format.
	TS	Returns the time in the specified time format.
Second	FF7	Microsecond (0000000-9999990)
	FF8	Microsecond (00000000-99999900)
	FF9	Microsecond (000000000-999999000)

 **NOTE**

The rules for RR to calculate years are as follows:

- If the range of the input two-digit year is between 00 and 49:
  - If the last two digits of the current year are between 00 and 49, the first two digits of the returned year are the same as the first two digits of the current year.
  - If the last two digits of the current year are between 50 and 99, the first two digits of the returned year equal to the first two digits of the current year plus 1.
- If the range of the input two-digit year is between 50 and 99:
  - If the last two digits of the current year are between 00 and 49, the first two digits of the returned year are equal to the first two digits of the current year minus 1.
  - If the last two digits of the current year are between 50 and 99, the first two digits of the returned year are the same as the first two digits of the current year.

 NOTE

In the scenario where this function is in an ORA-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- The **to\_date** and **to\_timestamp** functions support the FX pattern (the input strictly corresponds to a pattern) and the X pattern (decimal point).
- The input pattern can appear only once, indicating that the patterns of the same information cannot appear at the same time. For example, SYYYY and BC cannot be used together.
- The pattern is case-insensitive.
- You are advised to use a separator between the input and the pattern. Otherwise, the behavior may not be compatible with database O.

## 7.6.9 Type Conversion Functions

### Type Conversion Functions

- `cash_words(money)`

Description: Type conversion function, which converts money into text.

Example:

```
gaussdb=# SELECT cash_words('1.23');
          cash_words
-----
One dollar and twenty three cents
(1 row)
```

- `convert(expr, type)`

Description: Converts **expr** to the type specified by **type**.

Parameter: The first parameter is an arbitrary value, and the second parameter is the type name.

Return value type: The return value type is the same as that of the input.

Example:

```
gaussdb=# SELECT convert(12.5, text);
          text
-----
12.5
(1 row)
```

 NOTE

This function takes effect only in databases in MySQL compatibility mode.

- `cast(x as y [DEFAULT z ON CONVERSION ERROR][,fmt])`

Description: Converts *x* into the type specified by *y*. When **sql\_compatibility** is set to **'MYSQL'**, **b\_format\_version** is set to **'5.7'**, and **b\_format\_dev\_version** is set to **'s1'**, if *y* is of the char type, this function converts *x* to the varchar type.

- **DEFAULT z ON CONVERSION ERROR**: This parameter is optional. If the attempt to convert *x* to type *y* fails, *z* is converted to type *y* by default.
- *fmt*: This parameter is optional, which can be specified when *y* is one of the following data types:
  - int1/int2/int4/int8/int16/float4/float8/numeric: The function of the optional parameter *fmt* is the same as that in the `to_number(expr [,fmt])` function.

- date/timestamp/timestamp with time zone: The function of the optional parameter *fmt* is the same as that in the to\_date(string [,*fmt*])/to\_timestamp(string [,*fmt*])/to\_timestamp\_tz(string [,*fmt*]) function.

Example:

```
gaussdb=# SELECT cast('22-oct-1997' as timestamp);
          timestamp
-----
1997-10-22 00:00:00
(1 row)

gaussdb=# SELECT cast('22-ocX-1997' as timestamp DEFAULT '22-oct-1997' ON CONVERSION
ERROR, 'DD-Mon-YYYY');
          timestamp
-----
1997-10-22 00:00:00
(1 row)

gaussdb=# CREATE DATABASE gaussdb_m WITH dbcompatibility 'MYSQL';
gaussdb=# \c gaussdb_m
-- Set compatible version control parameters.
gaussdb_m=# SET b_format_version='5.7';
gaussdb_m=# SET b_format_dev_version='s1';
gaussdb_m=# SELECT cast('aaa' as char);
          varchar
-----
aaa
(1 row)
```

#### NOTE

The DEFAULT z ON CONVERSION ERROR and *fmt* syntaxes are supported only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

- cast(x AS {SIGNED | UNSIGNED} [INT | INTEGER])

Description: Converts *x* to the BIGINT SIGNED or BIGINT UNSIGNED type.

Return type: BIGINT SIGNED or BIGINT UNSIGNED

Example:

```
gaussdb=# SELECT CAST(12 AS UNSIGNED);
          uint8
-----
12
(1 row)
```

- hextoraw(text)

Description: Converts a string in hexadecimal format into raw type.

Return type: raw

Example:

```
gaussdb=# SELECT hextoraw('7D');
          hextoraw
-----
7D
(1 row)
```

- numtoday(numeric)

Description: Converts values of the number type into the timestamp of the specified type.

Return type: timestamp

Example:

```
gaussdb=# SELECT numtoday(2);
          numtoday
-----
```

```
2 days
(1 row)
```

- `rawtohex(string)`

Description: Converts a string in binary format into hexadecimal format.  
The result is the ACSII code of the input characters in hexadecimal format.

Return type: `varchar`

Example:

```
gaussdb=# SELECT rawtohex('1234567');
 rawtohex
-----
31323334353637
(1 row)
```

- `to_blob(raw)`

Description: Converts the RAW type to the BLOB type.

Return type: `BLOB`

Example:

```
gaussdb=# SELECT to_blob('0AADD343CDBBD'::RAW(10));
 to_blob
-----
00AADD343CDBBD
(1 row)
```

 **NOTE**

The `to_blob` function is supported only when the value of `a_format_version` is `10c` and the value of `a_format_dev_version` is `s2`.

- `to_bigint(varchar)`

Description: Converts the character type to the bigint type.

Return type: `bigint`

Example:

```
gaussdb=# SELECT to_bigint('123364545554455');
 to_bigint
-----
123364545554455
(1 row)
```

- `to_binary_double(expr)`

Description: Converts an expression to a value of the float8 type.

**expr**: supports the number, float4, and float8 data types and character strings that can be implicitly converted to numeric types.

Return type: `float8`

Example:

```
gaussdb=# SELECT to_binary_double('12345678');
 to_binary_double
-----
12345678
(1 row)
```

 **NOTE**

The `to_binary_double` function is supported only when the value of `a_format_version` is `10c` and the value of `a_format_dev_version` is `s2`.

- `to_binary_double(expr, fmt)`

Description: Converts an expression to a value of the float8 type after format matching.

**expr/fmt**: supports character strings of the char, nchar, varchar2, and nvarchar2 types. The **expr** also supports numeric types that can be implicitly converted to character string types.

Return type: float8

Example:

```
gaussdb=# SELECT to_binary_double('1,2,3', '9,9,9');
to_binary_double
-----
          123
(1 row)
```

 **NOTE**

The **to\_binary\_double** function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- to\_binary\_double(expr default return\_value on conversion error)

Description: Converts an expression to a value of the float8 type. If the conversion fails, the default value **return\_value** is returned.

**expr**: supports the number, float4, and float8 data types and numeric types that can be implicitly converted to character strings. If **expr** is not of the numeric or character string type, an error message is displayed.

Return type: float8

Example:

```
gaussdb=# SELECT to_binary_double(1e2 default 12 on conversion error);
to_binary_double
-----
          100
(1 row)

gaussdb=# SELECT to_binary_double('aa' default 12 on conversion error);
to_binary_double
-----
           12
(1 row)
```

 **NOTE**

The **to\_binary\_double** function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- to\_binary\_double(expr default return\_value on conversion error, fmt)

Description: Converts an expression to a value of the float8 type after format matching. If the expression fails to be converted, the default value **return\_value** is returned.

**expr/fmt**: supports character strings of the char, nchar, varchar2, and nvarchar2 types. The **expr** also supports numeric types that can be implicitly converted to character string types.

Return type: float8

Example:

```
gaussdb=# SELECT to_binary_double('12-' default 10 on conversion error, '99S');
to_binary_double
-----
          -12
(1 row)
```

```
gaussdb=# SELECT to_binary_double('aa-' default 12 on conversion error, '99S');
to_binary_double
-----
12
(1 row)
```

 **NOTE**

The **to\_binary\_double** function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- **to\_binary\_float(expr)**

Description: Converts an expression to a value of the float4 type.

**expr**: supports the number, float4, and float8 data types and character strings that can be implicitly converted to numeric types.

Return type: float4

Example:

```
gaussdb=# SELECT to_binary_float('12345678');
to_binary_float
-----
1.23457e+07
(1 row)
```

 **NOTE**

The **to\_binary\_float** function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- **to\_binary\_float(expr, fmt)**

Description: Converts an expression to a value of the float4 type after format matching.

**expr/fmt**: supports character strings of the char, nchar, varchar2, and nvarchar2 types. The **expr** also supports numeric types that can be implicitly converted to character string types.

Return type: float4

Example:

```
gaussdb=# SELECT to_binary_float('1,2,3', '9,9,9');
to_binary_float
-----
123
(1 row)
```

 **NOTE**

The **to\_binary\_float** function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- **to\_binary\_float(expr default return\_value on conversion error)**

Description: Converts an expression to a value of the float4 type. If the conversion fails, the default value **return\_value** is returned.

**expr**: Supports the number, float4, and float8 numeric types and numeric types that can be implicitly converted to character strings. If **expr** is of a non-numeric or non-character string type, an error message is displayed.

Return type: float4

Example:

```
gaussdb=# SELECT to_binary_float(1e2 default 12 on conversion error);
to_binary_float
```

```

-----
          100
(1 row)

gaussdb=# SELECT to_binary_float('aa' default 12 on conversion error);
to_binary_float
-----
          12
(1 row)

```

 **NOTE**

The **to\_binary\_float** function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- **to\_binary\_float**(expr default return\_value on conversion error, fmt)  
Description: Converts an expression to a value of the float4 type after format matching. If the expression fails to be converted, the default value **return\_value** is returned.

**expr/fmt**: supports character strings of the char, nchar, varchar2, and nvarchar2 types. The **expr** also supports numeric types that can be implicitly converted to character string types.

Return type: float4

Example:

```

gaussdb=# SELECT to_binary_float('12-' default 10 on conversion error, '99S');
to_binary_float
-----
        -12
(1 row)

gaussdb=# SELECT to_binary_float('aa-' default 12 on conversion error, '99S');
to_binary_float
-----
          12
(1 row)

```

 **NOTE**

The **to\_binary\_float** function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- **to\_char**(datetime/interval [, fmt])  
Description: Converts a DATETIME or INTERVAL value of the DATE/TIMESTAMP/TIMESTAMP WITH TIME ZONE/TIMESTAMP WITH LOCAL TIME ZONE type into the VARCHAR type according to the format specified by **fmt**.
  - The optional parameter **fmt** allows for the following types: date, time, week, quarter, and century. Each type has a unique template. The templates can be combined together. Common templates include HH, MI, SS, YYYY, MM, and DD. For details, see [Table 7-54](#).
  - A template may have a modification word. FM is a common modification word and is used to suppress the preceding zero or the following blank spaces.

Return type: varchar

Example:

```

gaussdb=# SELECT to_char(current_timestamp,'HH12:MI:SS');
to_char
-----
10:19:26
(1 row)

```

```
gaussdb=# SELECT to_char(current_timestamp,'FMHH12:FMMI:FMSS');
to_char
-----
10:19:46
(1 row)
```

- `to_char(double precision/real, text)`

Description: Converts the values of the floating point type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(125.8::real, '999D99');
to_char
-----
125.80
(1 row)
```

- `to_char (numeric/smallint/integer/bigint/double precision/real[, fmt])`

Descriptions: Converts an integer or a value in floating point format into a string in specified format.

- The optional parameter *fmt* allows for the following types: decimal point, group (thousand) separator, positive/negative sign and currency sign. Each type has a unique template. The templates can be combined together. Common templates include: 9, 0, millesimal sign (.), and decimal point (.). For details, see [Table 7-56](#).
- A template can have a modification word, similar to FM. However, FM does not suppress 0 which is output according to the template.
- Use the template X or x to convert an integer value into a string in hexadecimal format.

Return type: varchar

Example:

```
gaussdb=# SELECT to_char(1485,'9,999');
to_char
-----
1,485
(1 row)
gaussdb=# SELECT to_char( 1148.5,'9,999.999');
to_char
-----
1,148.500
(1 row)
gaussdb=# SELECT to_char(148.5,'990999.909');
to_char
-----
0148.500
(1 row)
gaussdb=# SELECT to_char(123,'XXX');
to_char
-----
7B
(1 row)
```

**Table 7-56** *fmt* parameter of the number type

Pattern	Description
, (comma)	Group (thousand) separator

Pattern	Description
.	Decimal point
\$	\$ output to the specified position
0	Value with leading zeros
9	Value with specified digits
B	Space returned when the integer part is 0
C	Currency symbol (depending on the locale setting)
D	Decimal point (depending on the locale setting)
EEEE	Scientific notation
G	Group separator (depending on the locale setting)
L	Currency symbol (depending on the locale setting)
MI	Minus sign in the specified position (if the number is less than 0)
PR	Negative values in angle brackets
RN	Roman numeral (ranging from 1 to 3999)
S	Signed number (depending on the locale setting)
TM	Standard number in scientific notation
TM9	Standard number in scientific notation
TME	Standard number in scientific notation
U	Currency symbol (depending on the locale setting)
V	Decimal with specified number of digits shifted
PL	Plus sign in the specified position (if the number is greater than 0)
SG	Plus or minus sign in the specified position
TH or th	Ordinal number suffix

 **NOTE**

This function supports the \$, C, TM, TM9, TME and U patterns when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**. In addition, the **fmt** parameter cannot be set to **TH**, **PL**, or **SG** in this case.

- **to\_char(interval, text)**  
Description: Converts the values of the time interval type into the strings in the specified format.  
Return type: text  
Example:

```
gaussdb=# SELECT to_char(interval '15h 2m 12s', 'HH24:MI:SS');
to_char
-----
15:02:12
(1 row)
```
- **to\_char(integer, text)**  
Description: Converts the values of the integer type into the strings in the specified format.  
Return type: text  
Example:

```
gaussdb=# SELECT to_char(125, '999');
to_char
-----
125
(1 row)
```
- **to\_char(set)**  
Description: Converts a value of the SET type to a string. The distributed system does not support the SET data type.  
Return value: text
- **to\_char(numeric, text)**  
Description: Converts the values of the numeric type into the strings in the specified format.  
Return type: text  
Example:

```
gaussdb=# SELECT to_char(-125.8, '999D99S');
to_char
-----
125.80-
(1 row)
```
- **to\_char (string)**  
Description: Converts the CHAR/VARCHAR/VARCHAR2/CLOB type into the VARCHAR type.  
If this function is used to convert data of the CLOB type, and the value to be converted exceeds the value range of the target type, an error is returned.  
Return type: varchar  
Example:

```
gaussdb=# SELECT to_char('01110');
to_char
-----
01110
(1 row)
```
- **to\_nvarchar2(numeric)**  
Description: Converts to the nvarchar2 type.  
Parameter: numeric  
Return type: nvarchar2

- `to_char(timestamp, text)`

Description: Converts the values of the timestamp type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(current_timestamp, 'HH12:MI:SS');
to_char
-----
10:55:59
(1 row)
```

 **NOTE**

- When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, the `to_char` function reports an error for the incorrect format (**fmt**).
  - In non-compatible mode, the `to_char` function outputs the incorrect format (**fmt**) without change. For example, if the **fmt** is **FF10**, FF1 is matched for formatted output, and then **0** is output without change.
- `to_nchar (datetime/interval [, fmt])`

Description: Converts a DATETIME or INTERVAL value of the DATE/TIMESTAMP/TIMESTAMP WITH TIME ZONE/TIMESTAMP WITH LOCAL TIME ZONE type into the TEXT type according to the format specified by **fmt**.

- The optional parameter **fmt** allows for the following types: date, time, week, quarter, and century. Each type has a unique template. The templates can be combined together. Common templates include HH, MI, SS, YYYY, MM, and DD. For details, see [Table 7-54](#).
- A template may have a modification word. FM is a common modification word and is used to suppress the preceding zero or the following blank spaces.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(current_timestamp, 'HH12:MI:SS');
to_nchar
-----
10:19:26
(1 row)
gaussdb=# SELECT to_nchar(current_timestamp, 'FMHH12:FM MI:FMSS');
to_nchar
-----
10:19:46
(1 row)
```

- `to_nchar(double precision/real, text)`

Description: Converts the values of the floating point type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(125.8::real, '999D99');
to_nchar
-----
125.80
(1 row)
```

- `to_nchar (numeric/smallint/integer/bigint/double precision/real[, fmt])`

Descriptions: Converts an integer or a value in floating point format into a string in specified format.

- The optional parameter *fmt* allows for the following types: decimal point, group (thousand) separator, positive/negative sign and currency sign. Each type has a unique template. The templates can be combined together. Common templates include: 9, 0, millesimal sign (,), and decimal point (.). For details, see [Table 7-56](#).
- A template can have a modification word, similar to FM. However, FM does not suppress 0 which is output according to the template.
- Use the template X or x to convert an integer value into a string in hexadecimal format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(1485,'9,999');
to_nchar
-----
1,485
(1 row)
gaussdb=# SELECT to_nchar( 1148.5,'9,999.999');
to_nchar
-----
1,148.500
(1 row)
gaussdb=# SELECT to_nchar(148.5,'990999.909');
to_nchar
-----
0148.500
(1 row)
gaussdb=# SELECT to_nchar(123,'XXX');
to_nchar
-----
7B
(1 row)
```

#### NOTE

This function supports the \$, C, TM, TM9, TME and U patterns when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**. In addition, the **fmt** parameter cannot be set to **TH**, **PL**, or **SG** in this case.

- **to\_nchar(interval, text)**

Description: Converts the values of the time interval type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(interval '15h 2m 12s', 'HH24:MI:SS');
to_nchar
-----
15:02:12
(1 row)
```

- **to\_nchar(integer, text)**

Description: Converts the values of the integer type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(125, '999');
to_nchar
-----
125
(1 row)
```

- **to\_nchar(set)**  
Description: Converts a value of the SET type to a string. The distributed system does not support the SET data type.  
Return value: text
- **to\_nchar(numeric, text)**  
Description: Converts the values of the numeric type into the strings in the specified format.  
Return type: text  
Example:

```
gaussdb=# SELECT to_nchar(-125.8, '999D99S');
to_nchar
-----
125.80-
(1 row)
```
- **to\_nchar (string)**  
Description: Converts the CHAR/VARCHAR/VARCHAR2/CLOB type into the TEXT type.  
If this function is used to convert data of the CLOB type, and the value to be converted exceeds the value range of the target type, an error is returned.  
Return type: text  
Example:

```
gaussdb=# SELECT to_nchar('01110');
to_nchar
-----
01110
(1 row)
```
- **to\_nchar(timestamp, text)**  
Description: Converts the values of the timestamp type into the strings in the specified format.  
Return type: text  
Example:

```
gaussdb=# SELECT to_nchar(current_timestamp, 'HH12:MI:SS');
to_nchar
-----
10:55:59
(1 row)
```
- **to\_clob(char/nchar/varchar/nvarchar/varchar2/nvarchar2/text/raw)**  
Description: Converts the raw type or text character set type CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR, NVARCHAR2, or TEXT to the CLOB type.  
Return type: CLOB  
Example:

```
gaussdb=# SELECT to_clob('ABCDEF'::RAW(10));
to_clob
-----
ABCDEF
(1 row)
gaussdb=# SELECT to_clob('hello111'::CHAR(15));
to_clob
-----
hello111
(1 row)
gaussdb=# SELECT to_clob('gauss123'::NCHAR(10));
to_clob
```

```

-----
gauss123
(1 row)
gaussdb=# SELECT to_clob('gauss234'::VARCHAR(10));
to_clob
-----
gauss234
(1 row)
gaussdb=# SELECT to_clob('gauss345'::VARCHAR2(10));
to_clob
-----
gauss345
(1 row)
gaussdb=# SELECT to_clob('gauss456'::NVARCHAR2(10));
to_clob
-----
gauss456
(1 row)
gaussdb=# SELECT to_clob('World222!'::TEXT);
to_clob
-----
World222!
(1 row)

```

- `to_date(text)`

Description: Converts values of the text type into the timestamp in the specified format.

- Format 1: Date without separators, for example, 20150814. The value must contain the complete year, month, and day.
- Format 2: Date with separators, for example, 2014-08-14. The separator can be any non-digit character.

Return type: timestamp without time zone

Example:

```

gaussdb=# SELECT to_date('2015-08-14');
to_date
-----
2015-08-14 00:00:00
(1 row)

```

 **NOTE**

Case execution environment: The value of **a\_format\_version** is **10c**, the value of **a\_format\_dev\_version** is **s1**, and the value of **nls\_timestamp\_format** is **YYYY-MM-DD HH24:MI:SS**.

- `to_date(text, text)`

Description: Converts the values of the string type into the dates in the specified format.

Return type: timestamp without time zone

Example:

```

gaussdb=# SELECT to_date('05 Dec 2000', 'DD Mon YYYY');
to_date
-----
2000-12-05 00:00:00
(1 row)

```

- `to_date(text [DEFAULT return_value ON CONVERSION ERROR [, fmt]])`

Description: Converts a string *text* into a value of the DATE type according to the format specified by *fmt*. If *fmt* is not specified, **a\_format\_version** is set to **10c**, and **a\_format\_dev\_version** is set to **s1**, the format specified by

**nlstamp\_format** is used for conversion. Otherwise, the fixed format (fmt = 'yyyy-mm-dd hh24-mi-ss') is used for conversion.

- **text**: any expression that can be calculated to CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT string. If null is entered, null is returned.
- **DEFAULT return\_value ON CONVERSION ERROR**: This parameter is optional, which can be used to specify the return value when *text* fails to be converted to the DATE type. The value of *return\_value* can be an expression or a bound variable that can be converted to the CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT type or null. The method of converting *return\_value* to the DATE type is the same as that of converting *text* to the DATE type. If *return\_value* fails to be converted to the DATE type, an error is reported.
- **fmt**: This parameter is optional, which specifies the date and time model format of *text*. By default, *text* must comply with the default date format. If *fmt* is set to *J*, *text* must be an integer.

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT to_date('2015-08-14');
to_date
-----
2015-08-14 00:00:00
(1 row)
gaussdb=# SELECT to_date('05 Dec 2000', 'DD Mon YYYY');
to_date
-----
2000-12-05 00:00:00
(1 row)
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s1';
SET
gaussdb=# SHOW nls_timestamp_format;
nls_timestamp_format
-----
DD-Mon-YYYY HH:MI:SS.FF AM
(1 row)
gaussdb=# SELECT to_date('12-jan-2022' default '12-apr-2022' on conversion error);
to_date
-----
2022-01-12 00:00:00
(1 row)
gaussdb=# SELECT to_date('12-ja-2022' default '12-apr-2022' on conversion error);
to_date
-----
2022-04-12 00:00:00
(1 row)
gaussdb=# SELECT to_date('2022-12-12' default '2022-01-01' on conversion error, 'yyyy-mm-dd');
to_date
-----
2022-12-12 00:00:00
(1 row)
```

 CAUTION

- The DEFAULT *return\_value* ON CONVERSION ERROR syntax is supported only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.
- When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, the system may not report an error if the entered year exceeds 9999. For example, the result of **to\_date('9999-12-12', 'yyyy-mm-dd hh24:mi:ss')** is **9999-09-12 12:00:00**. If the value of year exceeds 9999, the number following 9999 will be parsed as the next **fmt**. This restriction also applies to **to\_timestamp**.

- **to\_number ( expr [, fmt])**

Description: Converts **expr** into a value of the NUMBER type according to the specified format.

For details about the type conversion formats, see [Table 7-58](#).

If a hexadecimal string is converted into a decimal number, the hexadecimal string can include a maximum of 16 bytes if it is to be converted into a sign-free number.

During the conversion from a hexadecimal string to a decimal digit, the format string cannot have a character other than x or X. Otherwise, an error is reported.

Return type: number

Example:

```
gaussdb=# SELECT to_number('12,454.8-', '99G999D9S');
to_number
-----
-12454.8
(1 row)
```

- **to\_number(text, text)**

Description: Converts the values of the string type into the numbers in the specified format.

Return type: numeric

Example:

```
gaussdb=# SELECT to_number('12,454.8-', '99G999D9S');
to_number
-----
-12454.8
(1 row)
```

- **to\_number(expr [DEFAULT return\_value ON CONVERSION ERROR [, fmt]])**

Description: Converts a string *expr* to a value of the numeric type based on the format specified by *fmt*. If *fmt* is not specified, *text* must be a character string that can be directly converted to numeric, for example, '123', '1e2'.

For details about the type conversion formats, see [Table 7-59](#).

- **expr**: an expression that can be converted into a CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT/INT/FLOAT string. If null is entered, null is returned.
- **DEFAULT return\_value ON CONVERSION ERROR**: This parameter is optional, which can be used to specify the return value when *expr* fails to

be converted to the numeric type. Similar to *expr*, *return\_value* can be any type that can be converted to a character string. Similar to *expr*, *return\_value* is converted based on the format specified by *fmt*. The system checks whether *return\_value* fails to be converted. If *return\_value* fails to be converted, the function reports an error.

- *fmt*: This parameter is optional, which specifies the conversion format of *expr*.

If any input parameter is **NULL**, **NULL** is returned.

Return type: numeric

Example:

```
gaussdb=# SET a_format_version='10c';
gaussdb=# SET a_format_dev_version='s1';

gaussdb=# SELECT to_number('1e2');
to_number
-----
      100
(1 row)

gaussdb=# SELECT to_number('123.456');
to_number
-----
  123.456
(1 row)

gaussdb=# SELECT to_number('123', '999');
to_number
-----
      123
(1 row)

gaussdb=# SELECT to_number('123-', '999MI');
to_number
-----
     -123
(1 row)

gaussdb=# SELECT to_number('123' default '456-' on conversion error, '999MI');
to_number
-----
     -456
(1 row)
```

 **NOTE**

The DEFAULT *return\_value* ON CONVERSION ERROR syntax is supported only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

- **to\_timestamp(double precision)**

Description: Converts a UNIX century into a timestamp.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT to_timestamp(1284352323);
to_timestamp
-----
2010-09-13 12:32:03+08
(1 row)
```

- **to\_timestamp(string [,fmt])**

Description: Converts a string into a value of the timestamp type according to the format specified by **fmt**. When **fmt** is not specified, perform the conversion according to the format specified by **nls\_timestamp\_format**.

In **to\_timestamp** in GaussDB:

- If the input year *YYYY* is 0, an error will be reported.
- If the input year *YYYY* is less than 0, specify *SYYY* in **fmt**. The year with the value of *n* (an absolute value) BC will be output correctly.

Characters in the **fmt** must match the schema for formatting the data and time. Otherwise, an error is reported.

Return type: timestamp without time zone

Example:

```
gaussdb=# SHOW nls_timestamp_format;
nls_timestamp_format
-----
DD-Mon-YYYY HH:MI:SS.FF AM
(1 row)

gaussdb=# SELECT to_timestamp('12-sep-2014');
to_timestamp
-----
2014-09-12 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('12-Sep-10 14:10:10.123000','DD-Mon-YY HH24:MI:SS.FF');
to_timestamp
-----
2010-09-12 14:10:10.123
(1 row)
gaussdb=# SELECT to_timestamp('-1','SYYY');
to_timestamp
-----
0001-01-01 00:00:00 BC
(1 row)
gaussdb=# SELECT to_timestamp('98','RR');
to_timestamp
-----
1998-01-01 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('01','RR');
to_timestamp
-----
2001-01-01 00:00:00
(1 row)
```

 **NOTE**

1. When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, **fmt** supports FF[7-9]. When FF[7-9] is used, and the length of the corresponding position in the string is less than or equal to the number following FF, then, the number can be converted. However, the maximum length of the final conversion result is six digits.
  2. The result returned by the `current_timestamp` function cannot be used as a string parameter.
- `to_timestamp(text [DEFAULT return_value ON CONVERSION ERROR [, fmt]])`  
Description: Converts a string *text* into a value of the DATE type according to the format specified by *fmt*. If *fmt* is not specified, **a\_format\_version** is set to **10c**, and **a\_format\_dev\_version** is set to **s1**, the format specified by **nls\_timestamp\_format** is used for conversion. Otherwise, the fixed format (**fmt** = 'yyyy-mm-dd hh24-mi-ss') is used for conversion.
    - *text*: any expression that can be calculated to CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT string. If null is entered, null is returned.
    - **DEFAULT return\_value ON CONVERSION ERROR**: This parameter is optional, which can be used to specify the return value when *text* fails to

be converted to the DATE type. The value of *return\_value* can be an expression or a bound variable that can be converted to the CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT type or null. The method of converting *return\_value* to the timestamp type is the same as that of converting *text* to the timestamp type. If *return\_value* fails to be converted to the timestamp type, an error is reported.

- *fmt*: This parameter is optional, which specifies the date and time model format of *text*. By default, *text* must comply with the default date format. If *fmt* is set to *J*, *text* must be an integer.

Return type: timestamp without time zone

Example:

```
gaussdb=# set a_format_version='10c';
SET
gaussdb=# set a_format_dev_version='s1';
SET
gaussdb=# SELECT to_timestamp('11-Sep-11' DEFAULT '12-Sep-10 14:10:10.123000' ON
CONVERSION ERROR,'DD-Mon-YY HH24:MI:SS.FF');
 to_timestamp
-----
2011-09-11 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('12-Sep-10 14:10:10.123000','DD-Mon-YY HH24:MI:SSXFF');
 to_timestamp
-----
2010-09-12 14:10:10.123
(1 row)
```

#### NOTE

The DEFAULT *return\_value* ON CONVERSION ERROR syntax is supported only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

- `to_timestamp(text, text)`

Description: Converts values of the string type into the timestamp of the specified type.

Return type: timestamp

Example:

```
gaussdb=# SELECT to_timestamp('05 Dec 2000', 'DD Mon YYYY');
 to_timestamp
-----
2000-12-05 00:00:00
(1 row)
```

- `to_timestamp_tz(string [DEFAULT return_value ON CONVERSION ERROR] [,fmt])`

Description: Converts a string into a value of the timestamp type with the time zone according to the format specified by **fmt**. When **fmt** is not specified, perform the conversion according to the format specified by **nls\_timestamp\_tz\_format**.

**DEFAULT return\_value ON CONVERSION ERROR**: This parameter is optional, If *string* fails to be converted to the timestamp type with time zone, *return\_value* is converted to the timestamp type with time zone.

*fmt*: This parameter is optional, which specifies the date and time model format of *string*. The setting of this parameter is the same as that in the `to_timestamp` function.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT to_timestamp_tz('05 DeX 2000' DEFAULT '05 Dec 2001' ON CONVERSION ERROR,
'DD Mon YYYY');
 to_timestamp_tz
-----
2001-12-05 00:00:00+08:00
(1 row)
```

 **NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

- to\_timestamp\_tz(string [DEFAULT return\_value ON CONVERSION ERROR], fmt, nlsparam)

Description: Converts a string into a value of the timestamp type with the time zone according to the format specified by **fmt**. If *string* fails to be converted to the timestamp type with time zone, *return\_value* is converted to the timestamp type with time zone. **nlsparam** specifies the language of the month and day in the time character string. The format is '**nls\_date\_language=language**'. Currently, **language** supports only **ENGLISH** and **AMERICAN**. Currently, the result of correctly using the **nlsparam** parameter is the same as that of omitting the **nlsparam** parameter. For details, see [Table 7-57](#).

Return type: timestamp with time zone

**Table 7-57** Parameters

Parameter	Type	Description
string	text	Converts to a string of the timestamp with time zone type.
return_value	text	If a string fails to be converted to the timestamp type with time zone, <b>return_value</b> is converted to the timestamp type with time zone.
fmt	text	Specifies the date and time model format of the <b>string</b> parameter.
nlsparam	text	Specifies the language of the month and day in the <b>string</b> parameter.

Example:

```
gaussdb=# SELECT to_timestamp_tz('05 DeX 2000' DEFAULT '05 Dec 2001' ON CONVERSION ERROR,
'DD Mon YYYY','nls_date_language=AMERICAN');
 to_timestamp_tz
-----
2001-12-05 00:00:00+08:00
(1 row)
```

 **NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s4**.

- `to_dsinterval(text)`  
Description: Converts characters to the interval type. SQL-compatible and ISO formats are supported.

Return type: interval

Example:

```
gaussdb=# SELECT to_dsinterval('12 1:2:3.456');
 to_dsinterval
-----
12 days 01:02:03.456
(1 row)

gaussdb=# SELECT to_dsinterval('P3DT4H5M6S');
 to_dsinterval
-----
3 days 04:05:06
(1 row)
```

 **NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2**.

- `to_ymininterval(text)`  
Description: Converts characters to the interval type. SQL-compatible and ISO formats are supported.

Return type: interval

Example:

```
gaussdb=# SELECT to_ymininterval('1-1');
 to_ymininterval
-----
1 year 1 mon
(1 row)

gaussdb=# SELECT to_ymininterval('P13Y3M4DT4H2M5S');
 to_ymininterval
-----
13 years 3 mons
(1 row)
```

 **NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2**.

**Table 7-58** Template patterns for numeric formatting

Pattern	Description
9	Value with specified digits
0	Values with leading zeros
Period (.)	Decimal point
Comma (,)	Group (thousand) separator
PR	Negative values in angle brackets
S	Signed number (depending on the locale setting)

Pattern	Description
L	Currency symbol (depending on the locale setting)
D	Decimal point (depending on the locale setting)
G	Group separator (depending on the locale setting)
MI	Minus sign in the specified position (if the number is less than 0)
PL	Plus sign in the specified position (if the number is greater than 0)
SG	Plus or minus sign in the specified position
RN	Roman numeral (ranging from 1 to 3999)
TH or th	Ordinal number suffix
V	Decimal with specified number of digits shifted
x or X	Hexadecimal-to-decimal conversion identifier

**Table 7-59** Template patterns for to\_number formatting

Pattern	Description
9	Matches a digit. The number of digits "9" can be greater than or equal to that in the corresponding position in <i>expr</i> .
0	Strictly matches a digit. The number of digits "0" must be equal to that in <i>expr</i> .
5	Matches digit 0 or 5.
Period (.)	Decimal point in the specified position
Comma (,)	Group (thousand) separator in the specified position. Multiple commas can be specified in <i>fmt</i> .
B	No leading sign
PR	A negative value in angle brackets, or a positive value with no leading sign
S	A negative value with the leading minus sign (-) or a positive value with the leading plus sign (+)
MI	A negative value with the leading minus sign (-) or a positive value with no leading sign
\$	Leading dollar sign
L	Local currency symbol

Pattern	Description
C	Symbol of currency in the specified position (complying with the ISO standard)
U	Dual-currency symbol
D	Decimal point (uses locale)
G	Group separator (complying with the ISO standard). Multiple commas can be specified in <i>fmt</i> .
RN / rn	Roman numeral (ranging from 1 to 3999). <code>to_number</code> does not support this format.
V	<code>to_number</code> does not support this format.
X / x	Conversion between hexadecimal and decimal
TM	<code>to_number</code> does not support this format.
FM	This format can be used only at the beginning of <i>fmt</i> .
EEEE	Conversion based on the scientific notation model

 NOTE

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, refer to this table for the setting of *fmt*. Otherwise, refer to the previous table. The *fmt* setting complying with the ISO standard is affected by the values of **LC\_MONETARY** and **LC\_NUMERIC** parameters.

- `cast_varchar2_to_raw_for_histogram(varchar2)`  
Description: Converts from the varchar2 type to the raw type.  
Return type: raw
- `abstime_text(abstime)`  
Description: Converts abstime to text.  
Parameter: abstime  
Return type: text
- `abstime_to_smalldatetime(abstime)`  
Description: Converts abstime to smalldatetime.  
Parameter: abstime  
Return type: smalldatetime
- `bigint_tid(bigint)`  
Description: Converts bigint to tid.  
Parameter: bigint  
Return type: tid
- `bool_int1(boolean)`  
Description: Converts Boolean to int1.  
Parameter: Boolean

- Return type: tinyint
- `bool_int2(boolean)`  
Description: Converts Boolean to int2.  
Parameter: Boolean  
Return type: smallint
  - `bool_int8(boolean)`  
Description: Converts Boolean to int8.  
Parameter: Boolean  
Return type: bigint
  - `bpchar_date(character)`  
Description: Converts a string to a date.  
Parameter: character  
Return type: date
  - `bpchar_float4(character)`  
Description: Converts a string to float4.  
Parameter: character  
Return type: real
  - `bpchar_float8(character)`  
Description: Converts a string to float8.  
Parameter: character  
Return type: double precision
  - `bpchar_int4(character)`  
Description: Converts a string to int4.  
Parameter: character  
Return type: integer
  - `bpchar_int8(character)`  
Description: Converts a string to int8.  
Parameter: character  
Return type: bigint
  - `bpchar_numeric(character)`  
Description: Converts a string to numeric.  
Parameter: character  
Return type: numeric
  - `bpchar_timestamp(character)`  
Description: Converts a string to a timestamp.  
Parameter: character  
Return type: timestamp without time zone
  - `bpchar_to_smalldatetime(character)`  
Description: Converts a string to smalldatetime.  
Parameter: character  
Return type: smalldatetime

- `complex_array_in(cstring, oid, int2vector)`  
Description: Converts the external `complex_array` type to the internal `anyarray` array type.  
Parameter: `cstring`, `oid`, `int2vector`  
Return type: `anyarray`
- `date_bpchar(date)`  
Description: Converts the `date` type to `bpchar`.  
Parameter: `date`  
Return type: `character`
- `date_text(date)`  
Description: Converts `date` to `text`.  
Parameter: `date`  
Return type: `text`
- `date_varchar(date)`  
Description: Converts `date` to `varchar`.  
Parameter: `date`  
Return type: `character varying`
- `f4toi1(real)`  
Description: Forcibly converts `float4` to `uint8`.  
Parameter: `real`  
Return type: `tinyint`
- `f8toi1(double precision)`  
Description: Forcibly converts `float8` to `uint8`.  
Parameter: `double precision`  
Return type: `tinyint`
- `float4_bpchar(real)`  
Description: Converts `float4` to `bpchar`.  
Parameter: `real`  
Return type: `character`
- `float4_text(real)`  
Description: Converts `float4` to `text`.  
Parameter: `real`  
Return type: `text`
- `float4_varchar(real)`  
Description: Converts `float4` to `varchar`.  
Parameter: `real`  
Return type: `character varying`
- `float8_bpchar(double precision)`  
Description: Converts `float8` to `bpchar`.  
Parameter: `double precision`  
Return type: `character`

- float8\_interval(double precision)  
Description: Converts float8 to interval.  
Parameter: double precision  
Return type: interval
- float8\_text(double precision)  
Description: Converts float8 to text.  
Parameter: double precision  
Return type: text
- float8\_varchar(double precision)  
Description: Converts float8 to varchar.  
Parameter: double precision  
Return type: character varying
- i1tof4(tinyint)  
Description: Converts uint8 to float4.  
Parameter: tinyint  
Return type: real
- i1tof8(tinyint)  
Description: Converts uint8 to float8.  
Parameter: tinyint  
Return type: double precision
- i1toi2(tinyint)  
Description: Converts uint8 to int16.  
Parameter: tinyint  
Return type: smallint
- i1toi4(tinyint)  
Description: Converts uint8 to int32.  
Parameter: tinyint  
Return type: integer
- i1toi8(tinyint)  
Description: Converts uint8 to int64.  
Parameter: tinyint  
Return type: bigint
- i2toi1(smallint)  
Description: Converts int16 to uint8.  
Parameter: smallint  
Return type: tinyint
- i4toi1(integer)  
Description: Converts int32 to uint8.  
Parameter: integer  
Return type: tinyint

- `i8toi1(bigint)`  
Description: Converts int64 to uint8.  
Parameter: bigint  
Return type: tinyint
- `int1_avg_accum(bigint[], tinyint)`  
Description: Adds the second parameter of the uint8 type to the first parameter. The first parameter is an array of the bigint type.  
Parameter: bigint[], tinyint  
Return type: bigint[]
- `int1_bool(tinyint)`  
Description: Converts uint8 to Boolean.  
Parameter: tinyint  
Return type: Boolean
- `int1_bpchar(tinyint)`  
Description: Converts uint8 to bpchar.  
Parameter: tinyint  
Return type: character
- `int1_mul_cash(tinyint, money)`  
Description: Returns the product of a parameter of the int8 type and a parameter of the cash type. The return type is cash.  
Parameter: tinyint, money  
Return type: money
- `int1_numeric(tinyint)`  
Description: Converts uint8 to numeric.  
Parameter: tinyint  
Return type: numeric
- `int1_nvarchar2(tinyint)`  
Description: Converts uint8 to nvarchar2.  
Parameter: tinyint  
Return type: nvarchar2
- `int1_text(tinyint)`  
Description: Converts uint8 to text.  
Parameter: tinyint  
Return type: text
- `int1_varchar(tinyint)`  
Description: Converts uint8 to varchar.  
Parameter: tinyint  
Return type: character varying
- `int1in(cstring)`  
Description: Converts a string into an unsigned 1-byte integer.  
Parameter: cstring

- Return type: tinyint
- `int1out(tinyint)`  
Description: Converts an unsigned 1-byte integer into a string.  
Parameter: tinyint  
Return type: cstring
  - `int1up(tinyint)`  
Description: Converts an input integer to an unsigned 1-byte integer.  
Parameter: tinyint  
Return type: tinyint
  - `int2_bool(smallint)`  
Description: Converts a signed two-byte integer to the bool type.  
Parameter: smallint  
Return type: Boolean
  - `int2_bpchar(smallint)`  
Description: Converts a signed two-byte integer to the bpchar type.  
Parameter: smallint  
Return type: character
  - `int2_text(smallint)`  
Description: Converts a signed two-byte integer to the text type.  
Parameter: smallint  
Return type: text
  - `int2_varchar(smallint)`  
Description: Converts a signed two-byte integer to the varchar type.  
Parameter: smallint  
Return type: character varying
  - `int4_bpchar(integer)`  
Description: Converts a signed four-byte integer to bpchar.  
Parameter: integer  
Return type: character
  - `int4_text(integer)`  
Description: Converts a signed four-byte integer to the text type.  
Parameter: integer  
Return type: text
  - `int4_varchar(integer)`  
Description: Converts a signed four-byte integer into varchar.  
Parameter: integer  
Return type: character varying
  - `int8_bool(bigint)`  
Description: Converts an eight-byte signed integer to a Boolean value.  
Parameter: bigint  
Return type: Boolean

- `int8_bpchar(bigint)`  
Description: Converts an 8-byte signed integer to bpchar.  
Parameter: bigint  
Return type: character
- `int8_text(bigint)`  
Description: Converts an eight-byte signed integer to the text type.  
Parameter: bigint  
Return type: text
- `int8_varchar(bigint)`  
Description: Converts an eight-byte signed integer to varchar.  
Parameter: bigint  
Return type: character varying
- `intervaltonum(interval)`  
Description: Converts the internal date type to numeric.  
Parameter: interval  
Return type: numeric
- `numeric_bpchar(numeric)`  
Description: Converts numeric to bpchar.  
Parameter: numeric  
Return type: character
- `numeric_int1(numeric)`  
Description: Converts numeric to a signed one-byte integer.  
Parameter: numeric  
Return type: tinyint
- `numeric_text(numeric)`  
Description: Converts numeric to text.  
Parameter: numeric  
Return type: text
- `numeric_varchar(numeric)`  
Description: Converts numeric to varchar.  
Parameter: numeric  
Return type: character varying
- `nvarchar2in(cstring, oid, integer)`  
Description: Converts c string to varchar.  
Parameter: cstring, oid, integer  
Return type: nvarchar2
- `nvarchar2out(nvarchar2)`  
Description: Converts text into a c string.  
Parameter: nvarchar2  
Return type: cstring

- `nvarchar2send(nvarchar2)`  
Description: Converts varchar to binary.  
Parameter: `nvarchar2`  
Return type: `bytea`
- `oidvectorin_extend(cstring)`  
Description: Converts a string to oidvector.  
Parameter: `cstring`  
Return type: `oidvector_extend`
- `oidvectorout_extend(oidvector_extend)`  
Description: Converts oidvector to a string.  
Parameter: `oidvector_extend`  
Return type: `cstring`
- `oidvectorseend_extend(oidvector_extend)`  
Description: Converts oidvector to a string.  
Parameter: `oidvector_extend`  
Return type: `bytea`
- `reltime_text(reltime)`  
Description: Converts reltime to text.  
Parameter: `reltime`  
Return type: `text`
- `text_date(text)`  
Description: Converts the text type to the date type.  
Parameter: `text`  
Return type: `date`
- `text_float4(text)`  
Description: Converts text to float4.  
Parameter: `text`  
Return type: `real`
- `text_float8(text)`  
Description: Converts the text type to float8.  
Parameter: `text`  
Return type: `double precision`
- `text_int1(text)`  
Description: Converts the text type to int1.  
Parameter: `text`  
Return type: `tinyint`
- `text_int2(text)`  
Description: Converts the text type to the int2 type.  
Parameter: `text`  
Return type: `smallint`

- `text_int4(text)`  
Description: Converts the text type to int4.  
Parameter: text  
Return type: integer
- `text_int8(text)`  
Description: Converts the text type to the int8 type.  
Parameter: text  
Return type: bigint
- `text_numeric(text)`  
Description: Converts the text type to the numeric type.  
Parameter: text  
Return type: numeric
- `text_timestamp(text)`  
Description: Converts the text type to the timestamp type.  
Parameter: text  
Return type: timestamp without time zone
- `time_text(time without time zone)`  
Description: Converts the time type to the text type.  
Parameter: time without time zone  
Return type: text
- `timestamp_text(timestamp without time zone)`  
Description: Converts the timestamp type to the text type.  
Parameter: timestamp without time zone  
Return type: text
- `timestamp_to_smalldatetime(timestamp without time zone)`  
Description: Converts the timestamp type to the smalldatetime type.  
Parameter: timestamp without time zone  
Return type: smalldatetime
- `timestamp_varchar(timestamp without time zone)`  
Description: Converts the timestamp type to varchar.  
Parameter: timestamp without time zone  
Return type: character varying
- `timestamptz_to_smalldatetime(timestamp with time zone)`  
Description: Converts timestamptz to smalldatetime.  
Parameter: timestamp with time zone  
Return type: smalldatetime
- `timestampzone_text(timestamp with time zone)`  
Description: Converts the timestampzone type to the text type.  
Parameter: timestamp with time zone  
Return type: text

- `timetz_text`(time with time zone)  
Description: Converts the `timetz` type to the `text` type.  
Parameter: time with time zone  
Return type: `text`
- `to_integer`(character varying)  
Description: Converts data to the integer type.  
Parameter: character varying  
Return type: `integer`
- `to_interval`(character varying)  
Description: Converts to the interval type.  
Parameter: character varying  
Return type: `interval`
- `to_numeric`(character varying)  
Description: Converts to the numeric type.  
Parameter: character varying  
Return type: `numeric`
- `to_text`(smallint)  
Description: Converts to the `text` type.  
Parameter: `smallint`  
Return type: `text`
- `to_ts`(character varying)  
Description: Converts to the `ts` type.  
Parameter: character varying  
Return type: `timestamp without time zone`
- `to_varchar2`(timestamp without time zone)  
Description: Converts to the `varchar2` type.  
Parameter: `timestamp without time zone`  
Return type: `character varying`
- `varchar_date`(character varying)  
Description: Converts `varchar` to `date`.  
Parameter: character varying  
Return type: `date`
- `varchar_float4`(character varying)  
Description: Converts `varchar` to `float4`.  
Parameter: character varying  
Return type: `real`
- `varchar_float8`(character varying)  
Description: Converts the `varchar` type to the `float8` type.  
Parameter: character varying  
Return type: `double precision`

- `varchar_int4(character varying)`  
Description: Converts the type from `varchar` to `int4`.  
Parameter: `character varying`  
Return type: `integer`
- `varchar_int8(character varying)`  
Description: Converts the `varchar` type to the `int8` type.  
Parameter: `character varying`  
Return type: `bigint`
- `varchar_numeric(character varying)`  
Description: Converts `varchar` to `numeric`.  
Parameter: `character varying`  
Return type: `numeric`
- `varchar_timestamp(character varying)`  
Description: Converts `varchar` to `timestamp`.  
Parameter: `character varying`  
Return type: `timestamp without time zone`
- `varchar2_to_smlldatetime(character varying)`  
Description: Converts `varchar2` to `smlldatetime`.  
Parameter: `character varying`  
Return type: `smalldatetime`
- `xidout4(xid32)`  
Description: The `xid` output is a four-byte number.  
Parameter: `xid32`  
Return type: `cstring`
- `xidsend4(xid32)`  
Description: Converts `xid` to the binary format.  
Parameter: `xid32`  
Return type: `bytea`
- `treat(expr AS [JSON | REF] schema.type)`  
Description: Converts `expr` to the type (`JSON` or user-defined type) specified by the keyword after `AS`.  
Return value type: `JSON` or user-defined type.

Example:

```
gaussdb=# CREATE TABLE json_doc(data CLOB);
gaussdb=# INSERT INTO json_doc values('{"name":"a"}');
gaussdb=# SELECT treat(data as json) FROM json_doc;
      json
-----
{"name":"a"}
(1 row)
gaussdb=# DROP TABLE json_doc;
DROP TABLE
```

## Encoding Type Conversion

- `convert_to_nocase(text, text)`  
Description: Converts a string into a specified encoding type.

Return type: bytea

Example:

```
gaussdb=# SELECT convert_to_nocase('12345', 'GBK');
convert_to_nocase
-----
\x3132333435
(1 row)
```

## 7.6.10 Geometric Functions and Operators

### Geometric Operators

- `+`  
Description: Translation  
Example:  

```
gaussdb=# SELECT box '((0,0),(1,1))' + point '(2.0,0)' AS RESULT;
result
-----
(3,1),(2,0)
(1 row)
```
- `-`  
Description: Translation  
Example:  

```
gaussdb=# SELECT box '((0,0),(1,1))' - point '(2.0,0)' AS RESULT;
result
-----
(-1,1),(-2,0)
(1 row)
```
- `*`  
Description: Scaling out/Rotation  
Example:  

```
gaussdb=# SELECT box '((0,0),(1,1))' * point '(2.0,0)' AS RESULT;
result
-----
(2,2),(0,0)
(1 row)
```
- `/`  
Description: Scaling in/Rotation  
Example:  

```
gaussdb=# SELECT box '((0,0),(2,2))' / point '(2.0,0)' AS RESULT;
result
-----
(1,1),(0,0)
(1 row)
```
- `#`  
Description: Intersection of two figures  
Example:

```
gaussdb=# SELECT box '((1,-1),(-1,1))' # box '((1,1),(-2,-2))' AS RESULT;
result
```

- ```
-----
(1,1),(-1,-1)
(1 row)
```
- #

Description: Number of paths or polygon vertexes

Example:

```
gaussdb=# SELECT # path '((1,0),(0,1),(-1,0))' AS RESULT;
result
-----
3
(1 row)
```
- @-@

Description: Length or circumference

Example:

```
gaussdb=# SELECT @-@ path '((0,0),(1,0))' AS RESULT;
result
-----
2
(1 row)
```
- @@

Description: Center of box

Example:

```
gaussdb=# SELECT @@ circle '((0,0),10)' AS RESULT;
result
-----
(0,0)
(1 row)
```
- <->

Description: Distance between the two figures

Example:

```
gaussdb=# SELECT circle '((0,0),1)' <-> circle '((5,0),1)' AS RESULT;
result
-----
3
(1 row)
```
- &&

Description: Overlaps? (One point in common makes this true.)

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' && box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```
- <<

Description: Is strictly left of (no common horizontal coordinate)?

Example:

```
gaussdb=# SELECT circle '((0,0),1)' << circle '((5,0),1)' AS RESULT;
result
-----
t
(1 row)
```
- >>

Description: Is strictly right of (no common horizontal coordinate)?

Example:

```
gaussdb=# SELECT circle '((5,0),1)' >> circle '((0,0),1)' AS RESULT;
result
-----
t
(1 row)
```

- &<

Description: Does not extend to the right of?

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' &< box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```

- &>

Description: Does not extend to the left of?

Example:

```
gaussdb=# SELECT box '((0,0),(3,3))' &> box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```

- <<|

Description: Is strictly below (no common horizontal coordinate)?

Example:

```
gaussdb=# SELECT box '((0,0),(3,3))' <<| box '((3,4),(5,5))' AS RESULT;
result
-----
t
(1 row)
```

- |>>

Description: Is strictly above (no common horizontal coordinate)?

Example:

```
gaussdb=# SELECT box '((3,4),(5,5))' |>> box '((0,0),(3,3))' AS RESULT;
result
-----
t
(1 row)
```

- &<|

Description: Does not extend above?

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' &<| box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```

- |&>

Description: Does not extend below?

Example:

```
gaussdb=# SELECT box '((0,0),(3,3))' |&> box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```

- <^

Description: Is below (allows touching)?

Example:

```
gaussdb=# SELECT box '((0,0),(-3,-3))' <^ box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```
- >^

Description: Is above (allows touching)?

Example:

```
gaussdb=# SELECT box '((0,0),(2,2))' >^ box '((0,0),(-3,-3))' AS RESULT;
result
-----
t
(1 row)
```
- ?#

Description: Intersect?

Example:

```
gaussdb=# SELECT lseg '((-1,0),(1,0))' ?# box '((-2,-2),(2,2))' AS RESULT;
result
-----
t
(1 row)
```
- ?-

Description: Is horizontal?

Example:

```
gaussdb=# SELECT ?- lseg '((-1,0),(1,0))' AS RESULT;
result
-----
t
(1 row)
```
- ?-

Description: Are horizontally aligned?

Example:

```
gaussdb=# SELECT point '(1,0)' ?- point '(0,0)' AS RESULT;
result
-----
t
(1 row)
```
- ?|

Description: Is vertical?

Example:

```
gaussdb=# SELECT ?| lseg '((-1,0),(1,0))' AS RESULT;
result
-----
f
(1 row)
```
- ?|

Description: Are vertically aligned?

Example:

```
gaussdb=# SELECT point '(0,1)' ?| point '(0,0)' AS RESULT;
result
```

- ```
-----
t
(1 row)
```
- ?-|

Description: Are perpendicular?

Example:

```
gaussdb=# SELECT lseg '((0,0),(0,1))' ?-| lseg '((0,0),(1,0))' AS RESULT;
result
-----
t
(1 row)
```
  - ?||

Description: Are parallel?

Example:

```
gaussdb=# SELECT lseg '((-1,0),(1,0))' ?|| lseg '((-1,2),(1,2))' AS RESULT;
result
-----
t
(1 row)
```
  - @>

Description: Contains?

Example:

```
gaussdb=# SELECT circle '((0,0),2)' @> point '(1,1)' AS RESULT;
result
-----
t
(1 row)
```
  - <@

Description: Contained in or on?

Example:

```
gaussdb=# SELECT point '(1,1)' <@ circle '((0,0),2)' AS RESULT;
result
-----
t
(1 row)
```
  - ~=

Description: Specifies whether two figures are the same.

Example:

```
gaussdb=# SELECT polygon '((0,0),(1,1))' ~= polygon '((1,1),(0,0))' AS RESULT;
result
-----
t
(1 row)
```

## Geometric Functions

- area(object)

Description: Area calculation

Return type: double precision

Example:

```
gaussdb=# SELECT area(box '((0,0),(1,1))') AS RESULT;
result
-----
```

- 1  
(1 row)

  - **center(object)**  
Description: Figure center calculation  
Return type: point  
Example:  

```
gaussdb=# SELECT center(box '((0,0),(1,2)')) AS RESULT;  
result  
-----  
(0.5,1)  
(1 row)
```
  - **diameter(circle)**  
Description: Circle diameter calculation  
Return type: double precision  
Example:  

```
gaussdb=# SELECT diameter(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
4  
(1 row)
```
  - **height(box)**  
Description: Vertical size of box  
Return type: double precision  
Example:  

```
gaussdb=# SELECT height(box '((0,0),(1,1)')) AS RESULT;  
result  
-----  
1  
(1 row)
```
  - **isclosed(path)**  
Description: A closed path?  
Return type: Boolean  
Example:  

```
gaussdb=# SELECT isclosed(path '((0,0),(1,1),(2,0)')) AS RESULT;  
result  
-----  
t  
(1 row)
```
  - **isopen(path)**  
Description: An open path?  
Return type: Boolean  
Example:  

```
gaussdb=# SELECT isopen(path '[(0,0),(1,1),(2,0)]') AS RESULT;  
result  
-----  
t  
(1 row)
```
  - **length(object)**  
Description: Length calculation  
Return type: double precision  
Example:

```
gaussdb=# SELECT length(path '((-1,0),(1,0))') AS RESULT;
result
-----
      4
(1 row)
```

- **npoints(path)**

Description: Number of points in path

Return type: int

Example:

```
gaussdb=# SELECT npoints(path '((0,0),(1,1),(2,0))') AS RESULT;
result
-----
      3
(1 row)
```

- **npoints(polygon)**

Description: Number of points in polygon

Return type: int

Example:

```
gaussdb=# SELECT npoints(polygon '((1,1),(0,0))') AS RESULT;
result
-----
      2
(1 row)
```

- **pclose(path)**

Description: Converts path to closed.

Return type: path

Example:

```
gaussdb=# SELECT pclose(path '((0,0),(1,1),(2,0))') AS RESULT;
result
-----
((0,0),(1,1),(2,0))
(1 row)
```

- **popen(path)**

Description: Converts path to open.

Return type: path

Example:

```
gaussdb=# SELECT popen(path '((0,0),(1,1),(2,0))') AS RESULT;
result
-----
[(0,0),(1,1),(2,0)]
(1 row)
```

- **radius(circle)**

Description: Circle diameter calculation

Return type: double precision

Example:

```
gaussdb=# SELECT radius(circle '((0,0),2.0)') AS RESULT;
result
-----
      2
(1 row)
```

- **width(box)**

Description: Horizontal size of box

Return type: double precision

Example:

```
gaussdb=# SELECT width(box '((0,0),(1,1)')) AS RESULT;
result
-----
      1
(1 row)
```

## Geometric Type Conversion Functions

- `box(circle)`

Description: Circle to box

Return type: box

Example:

```
gaussdb=# SELECT box(circle '((0,0),2.0)') AS RESULT;
result
-----
(1.41421356237309,1.41421356237309),(-1.41421356237309,-1.41421356237309)
(1 row)
```

- `box(point, point)`

Description: Points to box

Return type: box

Example:

```
gaussdb=# SELECT box(point '(0,0)', point '(1,1)') AS RESULT;
result
-----
(1,1),(0,0)
(1 row)
```

- `box(polygon)`

Description: Polygon to box

Return type: box

Example:

```
gaussdb=# SELECT box(polygon '((0,0),(1,1),(2,0)')) AS RESULT;
result
-----
(2,1),(0,0)
(1 row)
```

- `circle(box)`

Description: Box to circle

Return type: circle

Example:

```
gaussdb=# SELECT circle(box '((0,0),(1,1)')) AS RESULT;
result
-----
<(0.5,0.5),0.707106781186548>
(1 row)
```

- `circle(point, double precision)`

Description: Center and radius to circle

Return type: circle

Example:

```
gaussdb=# SELECT circle(point '(0,0)', 2.0) AS RESULT;
result
```

- ```
-----
<(0,0),2>
(1 row)
```
- circle(polygon)**  
Description: Polygon to circle  
Return type: circle  
Example:  
gaussdb=# SELECT circle(polygon '((0,0),(1,1),(2,0)')) AS RESULT;  
result  
-----  
<(1,0.3333333333333333),0.924950591148529>  
(1 row)
  - lseg(box)**  
Description: Box diagonal to line segment  
Return type: lseg  
Example:  
gaussdb=# SELECT lseg(box '((-1,0),(1,0)')) AS RESULT;  
result  
-----  
[(1,0),(-1,0)]  
(1 row)
  - lseg(point, point)**  
Description: Points to line segment  
Return type: lseg  
Example:  
gaussdb=# SELECT lseg(point '(-1,0)', point '(1,0)') AS RESULT;  
result  
-----  
[(-1,0),(1,0)]  
(1 row)
  - slope(point, point)**  
Description: Calculates the slope of a straight line formed by two points.  
Return type: double  
Example:  
gaussdb=# SELECT slope(point '(1,1)', point '(0,0)') AS RESULT;  
result  
-----  
1  
(1 row)
  - path(polygon)**  
Description: Polygon to path  
Return type: path  
Example:  
gaussdb=# SELECT path(polygon '((0,0),(1,1),(2,0)')) AS RESULT;  
result  
-----  
((0,0),(1,1),(2,0))  
(1 row)
  - point(double precision, double precision)**  
Description: Points  
Return type: point

Example:

```
gaussdb=# SELECT point(23.4, -44.5) AS RESULT;  
result  
-----  
(23.4,-44.5)  
(1 row)
```

- **point(box)**

Description: Center of box

Return type: point

Example:

```
gaussdb=# SELECT point(box '((-1,0),(1,0))') AS RESULT;  
result  
-----  
(0,0)  
(1 row)
```

- **point(circle)**

Description: Center of circle

Return type: point

Example:

```
gaussdb=# SELECT point(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
(0,0)  
(1 row)
```

- **point(lseg)**

Description: Center of a line segment

Return type: point

Example:

```
gaussdb=# SELECT point(lseg '((-1,0),(1,0))') AS RESULT;  
result  
-----  
(0,0)  
(1 row)
```

- **point(polygon)**

Description: Center of a polygon

Return type: point

Example:

```
gaussdb=# SELECT point(polygon '((0,0),(1,1),(2,0))') AS RESULT;  
result  
-----  
(1,0.3333333333333333)  
(1 row)
```

- **polygon(box)**

Description: Box to 4-point polygon

Return type: polygon

Example:

```
gaussdb=# SELECT polygon(box '((0,0),(1,1))') AS RESULT;  
result  
-----  
((0,0),(0,1),(1,1),(1,0))  
(1 row)
```

- **polygon(circle)**  
Description: Circle to 12-point polygon  
Return type: polygon

Example:

```
gaussdb=# SELECT polygon(circle '((0,0),2.0)') AS RESULT;
```

```
result
```

```
-----  
-----  
((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),  
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),  
(1.73205080756888,-0.9999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),  
(-0.9999999999999999,-1.73205080756888),(-1.73205080756888,-1))  
(1 row)
```

- **polygon(npts, circle)**  
Description: Circle to npts-point polygon  
Return type: polygon

Example:

```
gaussdb=# SELECT polygon(12, circle '((0,0),2.0)') AS RESULT;
```

```
result
```

```
-----  
-----  
((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),  
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),  
(1.73205080756888,-0.9999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),  
(-0.9999999999999999,-1.73205080756888),(-1.73205080756888,-1))  
(1 row)
```

- **polygon(path)**  
Description: Path to polygon  
Return type: polygon

Example:

```
gaussdb=# SELECT polygon(path '((0,0),(1,1),(2,0)')) AS RESULT;
```

```
result
```

```
-----  
-----  
((0,0),(1,1),(2,0))  
(1 row)
```

## 7.6.11 Network Address Functions and Operators

### cidr and inet Operators

The operators <<, <<=, >>, and >>= test for subnet inclusion. They consider only the network parts of the two addresses (ignoring any host part) and determine whether one network is identical to or a subnet of the other.

- <
- Description: Is less than

Example:

```
gaussdb=# SELECT inet '192.168.1.5' < inet '192.168.1.6' AS RESULT;
```

```
result
```

Example:

```
gaussdb=# SELECT inet '192.168.1/24' <<= inet '192.168.1/24' AS RESULT;  
result  
-----  
t  
(1 row)
```

- >>

Description: Contains

Example:

```
gaussdb=# SELECT inet '192.168.1/24' >> inet '192.168.1.5' AS RESULT;  
result  
-----  
t  
(1 row)
```

- >>=

Description: Contains or equals

Example:

```
gaussdb=# SELECT inet '192.168.1/24' >>= inet '192.168.1/24' AS RESULT;  
result  
-----  
t  
(1 row)
```

- ~

Description: Bitwise NOT

Example:

```
gaussdb=# SELECT ~ inet '192.168.1.6' AS RESULT;  
result  
-----  
63.87.254.249  
(1 row)
```

- &

Description: Performs an AND operation on each bit of the two network addresses.

Example:

```
gaussdb=# SELECT inet '192.168.1.6' & inet '10.0.0.0' AS RESULT;  
result  
-----  
0.0.0.0  
(1 row)
```

- |

Description: Performs an OR operation on each bit of the two network addresses.

Example:

```
gaussdb=# SELECT inet '192.168.1.6' | inet '10.0.0.0' AS RESULT;  
result  
-----  
202.168.1.6  
(1 row)
```

- +

Description: Addition

Example:

```
gaussdb=# SELECT inet '192.168.1.6' + 25 AS RESULT;  
result
```

- ```
-----  
192.168.1.31  
(1 row)
```
- Description: Subtraction  
Example:  

```
gaussdb=# SELECT inet '192.168.1.43' - 36 AS RESULT;  
result  
-----  
192.168.1.7  
(1 row)
```
- Description: Subtraction  
Example:  

```
gaussdb=# SELECT inet '192.168.1.43' - inet '192.168.1.19' AS RESULT;  
result  
-----  
24  
(1 row)
```

## cidr and inet Functions

The abbrev, host, and text functions are primarily intended to offer alternative display formats.

- abbrev(inet)  
Description: Abbreviated display format as text  
Return type: text  
Example:  

```
gaussdb=# SELECT abbrev(inet '10.1.0.0/16') AS RESULT;  
result  
-----  
10.1.0.0/16  
(1 row)
```
- abbrev(cidr)  
Description: Abbreviated display format as text  
Return type: text  
Example:  

```
gaussdb=# SELECT abbrev(cidr '10.1.0.0/16') AS RESULT;  
result  
-----  
10.1/16  
(1 row)
```
- broadcast(inet)  
Description: Broadcast address for networks  
Return type: inet  
Example:  

```
gaussdb=# SELECT broadcast('192.168.1.5/24') AS RESULT;  
result  
-----  
192.168.1.255/24  
(1 row)
```

- **family(inet)**  
Description: Extracts address families. **4** indicates IPv4 addresses.  
Return type: int  
Example:

```
gaussdb=# SELECT family('127.0.0.1') AS RESULT;
result
-----
      4
(1 row)
```
- **host(inet)**  
Description: Extracts IP addresses as text.  
Return type: text  
Example:

```
gaussdb=# SELECT host('192.168.1.5/24') AS RESULT;
result
-----
192.168.1.5
(1 row)
```
- **hostmask(inet)**  
Description: Constructs the host mask for a network.  
Return type: inet  
Example:

```
gaussdb=# SELECT hostmask('192.168.23.20/30') AS RESULT;
result
-----
0.0.0.3
(1 row)
```
- **masklen(inet)**  
Description: Extracts subnet mask length.  
Return type: int  
Example:

```
gaussdb=# SELECT masklen('192.168.1.5/24') AS RESULT;
result
-----
      24
(1 row)
```
- **netmask(inet)**  
Description: Constructs the subnet mask for a network.  
Return type: inet  
Example:

```
gaussdb=# SELECT netmask('192.168.1.5/24') AS RESULT;
result
-----
255.255.255.0
(1 row)
```
- **network(inet)**  
Description: Extracts the network part of an address.  
Return type: cidr  
Example:

```
gaussdb=# SELECT network('192.168.1.5/24') AS RESULT;
result
```

```
-----  
192.168.1.0/24  
(1 row)
```

- `set_masklen(inet, int)`

Description: Sets subnet mask length for the **inet** value.

Return type: `inet`

Example:

```
gaussdb=# SELECT set_masklen('192.168.1.5/24', 16) AS RESULT;  
result  
-----  
192.168.1.5/16  
(1 row)
```

- `set_masklen(cidr, int)`

Description: Sets subnet mask length for the **cidr** value.

Return type: `cidr`

Example:

```
gaussdb=# SELECT set_masklen('192.168.1.0/24::cidr', 16) AS RESULT;  
result  
-----  
192.168.0.0/16  
(1 row)
```

- `text(inet)`

Description: Extracts IP addresses and subnet mask length as text.

Return type: `text`

Example:

```
gaussdb=# SELECT text(inet '192.168.1.5') AS RESULT;  
result  
-----  
192.168.1.5/32  
(1 row)
```

Any **cidr** value can be cast to **inet** implicitly or explicitly; therefore, the functions shown above as operating on **inet** also work on **cidr** values. An **inet** value can be cast to **cidr**. After the conversion, any bits to the right of the subnet mask are silently zeroed to create a valid **cidr** value. In addition, you can cast a text string to **inet** or **cidr** using normal casting syntax. For example, **inet(expression)** or **colname::cidr**.

## macaddr Functions

The `trunc(macaddr)` function returns a MAC address with the last 3 bytes set to zero.

`trunc(macaddr)`

Description: Sets last 3 bytes to zero.

Return type: `macaddr`

Example:

```
gaussdb=# SELECT trunc(macaddr '12:34:56:78:90:ab') AS RESULT;  
result  
-----  
12:34:56:00:00:00  
(1 row)
```

The macaddr type also supports the standard relational operators (such as > and <=) for lexicographical ordering, and the bitwise arithmetic operators (~, & and |) for NOT, AND and OR.

## 7.6.12 Text Search Functions and Operators

### Text Search Operators

- @@

Description: Specifies whether the tsvector-typed words match the tsquery-typed words.

Example:

```
gaussdb=# SELECT to_tsvector('fat cats ate rats') @@ to_tsquery('cat & rat') AS RESULT;
result
-----
t
(1 row)
```

- @@@

Description: Synonym for @@

Example:

```
gaussdb=# SELECT to_tsvector('fat cats ate rats') @@@ to_tsquery('cat & rat') AS RESULT;
result
-----
t
(1 row)
```

- ||

Description: Connects two tsvector-typed words.

Example:

```
gaussdb=# SELECT 'a:1 b:2'::tsvector || 'c:1 d:2 b:3'::tsvector AS RESULT;
result
-----
'a:1 'b':2,5 'c':3 'd':4
(1 row)
```

- &&

Description: Performs the AND operation on two tsquery-typed words.

Example:

```
gaussdb=# SELECT 'fat | rat'::tsquery && 'cat'::tsquery AS RESULT;
result
-----
( 'fat' | 'rat' ) & 'cat'
(1 row)
```

- ||

Description: Performs the OR operation on two tsquery-typed words.

Example:

```
gaussdb=# SELECT 'fat | rat'::tsquery || 'cat'::tsquery AS RESULT;
result
-----
( 'fat' | 'rat' ) | 'cat'
(1 row)
```

- !!

Description: Not a tsquery-typed word.

Example:

```
gaussdb=# SELECT !! 'cat'::tsquery AS RESULT;
result
-----
!'cat'
(1 row)
```

- **@>**  
Description: Specifies whether a tsquery-typed word contains another tsquery-typed word.

Example:

```
gaussdb=# SELECT 'cat'::tsquery @> 'cat & rat'::tsquery AS RESULT;
result
-----
f
(1 row)
```

- **<@**  
Description: Specifies whether a tsquery-typed word is contained in another tsquery-typed word.

Example:

```
gaussdb=# SELECT 'cat'::tsquery <@ 'cat & rat'::tsquery AS RESULT;
result
-----
t
(1 row)
```

In addition to the preceding operators, the ordinary B-tree comparison operators (including = and <) are defined for types tsvector and tsquery.

## Text Search Functions

- **get\_current\_ts\_config()**  
Description: Obtains default text search configurations.  
Return type: regconfig

Example:

```
gaussdb=# SELECT get_current_ts_config();
get_current_ts_config
-----
english
(1 row)
```

- **length(tsvector)**  
Description: Specifies the number of tsvector-typed words.  
Return type: integer

Example:

```
gaussdb=# SELECT length('fat:2,4 cat:3 rat:5A'::tsvector);
length
-----
3
(1 row)
```

- **numnode(tsquery)**  
Description: Specifies the number of tsquery-typed words plus operators.  
Return type: integer

Example:

```
gaussdb=# SELECT numnode('(fat & rat) | cat'::tsquery);
numnode
-----
```

- ```

5
(1 row)

```
- plainto\_tsquery([ config regconfig , ] query text)**  
 Description: Generates tsquery-typed words without punctuations.  
 Return type: tsquery  
 Example:

```

gaussdb=# SELECT plainto_tsquery('english', 'The Fat Rats');
plainto_tsquery
-----
'fat' & 'rat'
(1 row)

```
  - querytree(query tsquery)**  
 Description: Obtains the indexable part of a tsquery-typed word.  
 Return type: text  
 Example:

```

gaussdb=# SELECT querytree('foo & ! bar::tsquery');
querytree
-----
'foo'
(1 row)

```
  - setweight(tsvector, "char")**  
 Description: Assigns weight to each element of tsvector.  
 Return type: tsvector  
 Example:

```

gaussdb=# SELECT setweight('fat:2,4 cat:3 rat:5B::tsvector, 'A');
setweight
-----
'cat':3A 'fat':2A,4A 'rat':5A
(1 row)

```
  - strip(tsvector)**  
 Description: Removes positions and weights from tsvector.  
 Return type: tsvector  
 Example:

```

gaussdb=# SELECT strip('fat:2,4 cat:3 rat:5A::tsvector');
strip
-----
'cat' 'fat' 'rat'
(1 row)

```
  - to\_tsquery([ config regconfig , ] query text)**  
 Description: Normalizes words and converts them to tsquery.  
 Return type: tsquery  
 Example:

```

gaussdb=# SELECT to_tsquery('english', 'The & Fat & Rats');
to_tsquery
-----
'fat' & 'rat'
(1 row)

```
  - to\_tsvector([ config regconfig , ] document text)**  
 Description: Reduces document text to tsvector.  
 Return type: tsvector  
 Example:

```
gaussdb=# SELECT to_tsvector('english', 'The Fat Rats');
 to_tsvector
-----
'fat':2 'rat':3
(1 row)
```

- `to_tsvector_for_batch([ config regconfig , ] document text)`

Description: Reduces document text to tsvector.

Return type: tsvector

Example:

```
gaussdb=# SELECT to_tsvector_for_batch('english', 'The Fat Rats');
 to_tsvector
-----
'fat':2 'rat':3
(1 row)
```

- `ts_headline([ config regconfig, ] document text, query tsquery [, options text ])`

Description: Highlights a query match.

Return type: text

Example:

```
gaussdb=# SELECT ts_headline('x y z', 'z'::tsquery);
 ts_headline
-----
x y <b>z</b>
(1 row)
```

- `ts_rank([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ])`

Description: Ranks document for query.

Return type: float4

Example:

```
gaussdb=# SELECT ts_rank('hello world'::tsvector, 'world'::tsquery);
 ts_rank
-----
.0607927
(1 row)
```

- `ts_rank_cd([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ])`

Description: Ranks document for query using cover density.

Return type: float4

Example:

```
gaussdb=# SELECT ts_rank_cd('hello world'::tsvector,'world'::tsquery);
 ts_rank_cd
-----
0
(1 row)
```

- `ts_rewrite(query tsquery, target tsquery, substitute tsquery)`

Description: Replaces tsquery-typed word.

Return type: tsquery

Example:

```
gaussdb=# SELECT ts_rewrite('a & b'::tsquery, 'a'::tsquery, 'foo|bar'::tsquery);
 ts_rewrite
-----
'b' & ( 'foo' | 'bar' )
(1 row)
```

- `ts_rewrite(query tsquery, select text)`  
Description: Replaces tsquery data in the target with the result of a **SELECT** command.

Return type: tsquery

Example:

```
gaussdb=# SELECT ts_rewrite('world::tsquery, 'select "world"::tsquery, "hello"::tsquery');
ts_rewrite
-----
'hello'
(1 row)
```

## Text Search Debugging Functions

- `ts_debug([ config regconfig, ] document text, OUT alias text, OUT description text, OUT token text, OUT dictionaries regdictionary[], OUT dictionary regdictionary, OUT lexemes text[])`

Description: Tests a configuration.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_debug('english', 'The Brightest supernovaes');
ts_debug
-----
(asciiword,"Word, all ASCII",The,{english_stem},english_stem,{})
(blank,"Space symbols", " ",{},{,})
(asciiword,"Word, all ASCII",Brightest,{english_stem},english_stem,{brightest})
(blank,"Space symbols", " ",{},{,})
(asciiword,"Word, all ASCII",supernovaes,{english_stem},english_stem,{supernova})
(5 rows)
```

- `ts_lexize(dict regdictionary, token text)`

Description: Tests a data dictionary.

Return type: text[]

Example:

```
gaussdb=# SELECT ts_lexize('english_stem', 'stars');
ts_lexize
-----
{star}
(1 row)
```

- `ts_parse(parser_name text, document text, OUT tokid integer, OUT token text)`

Description: Tests a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_parse('default', 'foo - bar');
ts_parse
-----
(1,foo)
(12," ")
(12,"- ")
(1,bar)
(4 rows)
```

- `ts_parse(parser_oid oid, document text, OUT tokid integer, OUT token text)`

Description: Tests a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_parse(3722, 'foo - bar');
ts_parse
-----
(1,foo)
(12," ")
(12,"- ")
(1,bar)
(4 rows)
```

- **ts\_token\_type**(parser\_name text, OUT tokid integer, OUT alias text, OUT description text)

Description: Obtains token types defined by a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_token_type('default');
ts_token_type
-----
(1,asciiword,"Word, all ASCII")
(2,word,"Word, all letters")
(3,numword,"Word, letters and digits")
(4,email,"Email address")
(5,url,URL)
(6,host,Host)
(7,sfloat,"Scientific notation")
(8,version,"Version number")
(9,hword_numpart,"Hyphenated word part, letters and digits")
(10,hword_part,"Hyphenated word part, all letters")
(11,hword_asciipart,"Hyphenated word part, all ASCII")
(12,blank,"Space symbols")
(13,tag,"XML tag")
(14,protocol,"Protocol head")
(15,numhword,"Hyphenated word, letters and digits")
(16,asciihword,"Hyphenated word, all ASCII")
(17,hword,"Hyphenated word, all letters")
(18,url_path,"URL path")
(19,file,"File or path name")
(20,float,"Decimal notation")
(21,int,"Signed integer")
(22,uint,"Unsigned integer")
(23,entity,"XML entity")
(23 rows)
```

- **ts\_token\_type**(parser\_oid oid, OUT tokid integer, OUT alias text, OUT description text)

Description: Obtains token types defined by a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_token_type(3722);
ts_token_type
-----
(1,asciiword,"Word, all ASCII")
(2,word,"Word, all letters")
(3,numword,"Word, letters and digits")
(4,email,"Email address")
(5,url,URL)
(6,host,Host)
(7,sfloat,"Scientific notation")
(8,version,"Version number")
(9,hword_numpart,"Hyphenated word part, letters and digits")
(10,hword_part,"Hyphenated word part, all letters")
(11,hword_asciipart,"Hyphenated word part, all ASCII")
(12,blank,"Space symbols")
(13,tag,"XML tag")
```

```
(14,protocol,"Protocol head")
(15,numhword,"Hyphenated word, letters and digits")
(16,asciihword,"Hyphenated word, all ASCII")
(17,hword,"Hyphenated word, all letters")
(18,url_path,"URL path")
(19,file,"File or path name")
(20,float,"Decimal notation")
(21,int,"Signed integer")
(22,uint,"Unsigned integer")
(23,entity,"XML entity")
(23 rows)
```

- `ts_stat(sqlquery text, [ weights text, ] OUT word text, OUT ndoc integer, OUT nentry integer)`

Description: Obtains statistics of a tsvector column.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_stat('select "hello world"::tsvector');
 ts_stat
-----
(world,1,1)
(hello,1,1)
(2 rows)
```

## 7.6.13 JSON/JSONB Functions and Operators

For details about the JSON/JSONB data type, see [JSON/JSONB Types](#). For details about the operator information, see [Table 7-60](#) and [Table 7-61](#).

**Table 7-60** JSON/JSONB common operators

| Operator | Left Operand Type | Right Operand Type | Return Type | Description                                                                                  | Example                                                                                           |
|----------|-------------------|--------------------|-------------|----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| ->       | Array-json(b)     | int                | json(b)     | Obtains the <b>array-json</b> element. If the index does not exist, <b>NULL</b> is returned. | SELECT '{"a":"foo"},"b":"bar"}, {"c":"baz"}::json->2; ?column?<br>-----<br>{"c":"baz"}<br>(1 row) |
| ->       | object-json(b)    | text               | json(b)     | Obtains the value by a key. If no record is found, <b>NULL</b> is returned.                  | SELECT '{"a": {"b":"foo"}}::json->'a'; ?column?<br>-----<br>{"b":"foo"}<br>(1 row)                |
| ->>      | Array-json(b)     | int                | text        | Obtains the JSON array element. If the index does not exist, <b>NULL</b> is returned.        | SELECT '[1,2,3]::json->>2; ?column?<br>-----<br>3<br>(1 row)                                      |
| ->>      | object-json(b)    | text               | text        | Obtains the value by a key. If no record is found, <b>NULL</b> is returned.                  | SELECT '{"a":1,"b":2}::json->>'b'; ?column?<br>-----<br>2<br>(1 row)                              |

| Operators | Left Operand Type | Right Operand Type | Return Type | Description                                                                                         | Example                                                                                            |
|-----------|-------------------|--------------------|-------------|-----------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| #>        | contains-json (b) | text[]             | json(b)     | Obtains the JSON object in the specified path. If the path does not exist, <b>NULL</b> is returned. | <pre>SELECT '{"a":{"b":{"c":"foo"}}}::json #&gt;'{a,b}'; ?column? ----- {"c": "foo"} (1 row)</pre> |
| #>>       | contains-json (b) | text[]             | text        | Obtains the JSON object in the specified path. If the path does not exist, <b>NULL</b> is returned. | <pre>SELECT '{"a":[1,2,3],"b":[4,5,6]}::json #&gt;&gt;'{a,2}'; ?column? ----- 3 (1 row)</pre>      |

 **CAUTION**

For the #> and #>> operators, if no data can be found in the specified path, no error is reported and a **NULL** value is returned.

**Table 7-61** Additional JSONB support for operators

| Operators | Right Operand Type | Description                                                                                                           | Example                                                   |
|-----------|--------------------|-----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| @>        | jsonb              | Specifies whether the top layer of the JSON on the left contains all items of the top layer of the JSON on the right. | <pre>'{"a":1, "b":2}'::jsonb @&gt; '{"b":2}'::jsonb</pre> |
| <@        | jsonb              | Specifies whether all items in the JSON file on the left exist at the top layer of the JSON file on the right.        | <pre>'{"b":2}'::jsonb &lt;@ '{"a":1, "b":2}'::jsonb</pre> |
| ?         | text               | Specifies whether the string of the key or element exists at the top layer of the JSON value.                         | <pre>'{"a":1, "b":2}'::jsonb ? 'b'</pre>                  |

| Operators | Right Operand Type | Description                                                                                            | Example                                           |
|-----------|--------------------|--------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| ?         | text[]             | Specifies whether any of these array strings exists as top-layer keys.                                 | '{"a":1, "b":2, "c":3}'::jsonb ?  array['b', 'c'] |
| ?&        | text[]             | Specifies whether all these array strings exist as top-layer keys.                                     | '["a", "b"]'::jsonb ? & array['a', 'b']           |
| =         | jsonb              | Determines the size between two <b>JSONB</b> files, which is the same as the <b>jsonb_eq</b> function. | /                                                 |
| <>        | jsonb              | Determines the size between two <b>JSONB</b> files, which is the same as the <b>jsonb_ne</b> function. | /                                                 |
| <         | jsonb              | Determines the size between two <b>JSONB</b> files, which is the same as the <b>jsonb_lt</b> function. | /                                                 |
| >         | jsonb              | Determines the size between two <b>JSONB</b> files, which is the same as the <b>jsonb_gt</b> function. | /                                                 |
| <=        | jsonb              | Determines the size between two <b>JSONB</b> files, which is the same as the <b>jsonb_le</b> function. | /                                                 |
| >=        | jsonb              | Determines the size between two <b>JSONB</b> files, which is the same as the <b>jsonb_ge</b> function. | /                                                 |

## Functions Supported by JSON/JSONB

- `array_to_json(anyarray [, pretty_bool])`

Description: Returns the array as JSON. It combines a multi-dimensional array into a JSON array. Line feeds will be added between one-dimensional elements if **pretty\_bool** is **true**.

Return type: json

Example:

```
gaussdb=# SELECT array_to_json('{{1,5},{99,100}}'::int[]);
array_to_json
-----
[[1,5],[99,100]]
(1 row)
```

- `row_to_json(record [, pretty_bool])`

Description: Returns the row as JSON. Line feeds will be added between level-1 elements if **pretty\_bool** is **true**.

Return type: json

Example:

```
gaussdb=# SELECT row_to_json(row(1,'foo'));
row_to_json
-----
{"f1":1,"f2":"foo"}
(1 row)
```

- `json_array_element(array-json, integer), jsonb_array_element(array-jsonb, integer)`

Description: Same as the operator ``->``, which returns the element with the specified index in the array.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_array_element('[1,true,[1,[2,3]],null]',2);
json_array_element
-----
[1,[2,3]]
(1 row)
```

- `json_array_element_text(array-json, integer), jsonb_array_element_text(array-jsonb, integer)`

Description: Same as the operator ``->>``, which returns the element with the specified index in the array.

Return type: text, text

Example:

```
gaussdb=# SELECT json_array_element_text('[1,true,[1,[2,3]],null]',2);
json_array_element_text
-----
[1,[2,3]]
(1 row)
```

- `json_object_field(object-json, text), jsonb_object_field(object-jsonb, text)`

Description: Same as the operator ``->``, which returns the value of a specified key in an object.

Return type: json, json

Example:

```
gaussdb=# SELECT json_object_field('{\"a\": {\"b\": \"foo\"}}', 'a');
json_object_field
-----
{\"b\": \"foo\"}
(1 row)
```

- `json_object_field_text(object-json, text)`, `jsonb_object_field_text(object-jsonb, text)`

Description: Same as the operator ``->``, which returns the value of a specified key in an object.

Return type: text, text

Example:

```
gaussdb=# SELECT json_object_field_text('{\"a\": {\"b\": \"foo\"}}', 'a');
json_object_field_text
-----
{\"b\": \"foo\"}
(1 row)
```

- `json_extract_path(json, VARIADIC text[])`, `jsonb_extract_path((jsonb, VARIADIC text[])`

Description: Equivalent to the operator ``#>`` searches for JSON based on the path specified by `$2` and returns the result.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_extract_path('{\"f2\": {\"f3\": 1}, \"f4\": {\"f5\": 99, \"f6\": \"stringy\"}}', 'f4', 'f6');
json_extract_path
-----
\"stringy\"
(1 row)
```

- `json_extract_path_op(json, text[])`, `jsonb_extract_path_op(jsonb, text[])`

Description: Same as the operator ``#>``, searches for JSON based on the path specified by `$2` and returns the result.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_extract_path_op('{\"f2\": {\"f3\": 1}, \"f4\": {\"f5\": 99, \"f6\": \"stringy\"}}', ARRAY['f4', 'f6']);
json_extract_path_op
-----
\"stringy\"
(1 row)
```

- `json_extract_path_text(json, VARIADIC text[])`, `jsonb_extract_path_text((jsonb, VARIADIC text[])`

Description: Equivalent to the operator ``#>``, searches for JSON based on the path specified by `$2` and return the result.

Return type: text, text

Example:

```
gaussdb=# SELECT json_extract_path_text('{\"f2\": {\"f3\": 1}, \"f4\": {\"f5\": 99, \"f6\": \"stringy\"}}', 'f4', 'f6');
json_extract_path_text
-----
stringy
(1 row)
```

- `json_extract_path_text_op(json, text[])`, `jsonb_extract_path_text_op(jsonb, text[])`

Description: Same as the operator ``#>``, searches for JSON based on the path specified by `$2` and return the result.

Return type: text, text

Example:

```
gaussdb=# SELECT json_extract_path_text_op('{ "f2":{ "f3":1}, "f4":{ "f5":99, "f6":"stringy"} }',
ARRAY['f4','f6']);
 json_extract_path_text_op
-----
stringy
(1 row)
```

- `json_array_elements(array-json)`, `jsonb_array_elements(array-jsonb)`

Description: Splits an array. Each element returns a row.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_array_elements('[1,true,[1,[2,3]],null]');
 json_array_elements
-----
1
true
[1,[2,3]]
null
(4 rows)
```

- `json_array_elements_text(array-json)`, `jsonb_array_elements_text(array-jsonb)`

Description: Splits an array. Each element returns a row.

Return type: text, text

Example:

```
gaussdb=# SELECT * FROM json_array_elements_text('[1,true,[1,[2,3]],null]');
 value
-----
1
true
[1,[2,3]]
(4 rows)
```

- `json_array_length(array-json)`, `jsonb_array_length(array-jsonb)`

Description: Returns the array length.

Return type: integer

Example:

```
gaussdb=# SELECT json_array_length('[1,2,3,{"f1":1,"f2":[5,6]},4,null]');
 json_array_length
-----
6
(1 row)
```

- `json_each(object-json)`, `jsonb_each(object-jsonb)`

Description: Splits each key-value pair of an object into one row and two columns.

Return type: `setof(key text, value json)`, `setof(key text, value jsonb)`

Example:

```
gaussdb=# SELECT * FROM json_each('{ "f1":[1,2,3], "f2":{ "f3":1}, "f4":null }');
 key | value
-----+-----
f1  | [1,2,3]
f2  | { "f3":1}
f4  | null
(3 rows)
```

- `json_each_text(object-json)`, `jsonb_each_text(object-jsonb)`

Description: Splits each key-value pair of an object into one row and two columns.

Return type: setof(key text, value text), setof(key text, value text)

Example:

```
gaussdb=# SELECT * FROM json_each_text({'f1':[1,2,3],"f2":{"f3":1},"f4":null});
 key | value
-----+-----
 f1  | [1,2,3]
 f2  | {"f3":1}
 f4  |
(3 rows)
```

- `json_object_keys(object-json)`, `jsonb_object_keys(object-jsonb)`

Description: Returns all keys at the top layer of the object.

Return type: SETOF text

Example:

```
gaussdb=# SELECT json_object_keys({'f1':"abc","f2":{"f3":"a"}, "f4":"b"}, "f1':"abcd'});
 json_object_keys
-----
 f1
 f2
 f1
(3 rows)
```

- JSONB deduplication operations:

```
gaussdb=# SELECT jsonb_object_keys({'f1':"abc","f2":{"f3":"a"}, "f4":"b"}, "f1':"abcd'});
 jsonb_object_keys
-----
 f1
 f2
(2 rows)
```

- `json_populate_record(anyelement, object-json [, bool])`,  
`jsonb_populate_record(anyelement, object-jsonb [, bool])`

Description: *\$1* must be a compound parameter. Each key-value in the **object-json** file is split. The key is used as the column name to match the column name in *\$1* and fill in the *\$1* format.

Return type: anyelement, anyelement

Example:

```
gaussdb=# CREATE TYPE jpop AS (a text, b int, c bool);
CREATE TYPE
gaussdb=# SELECT * FROM json_populate_record(null::jpop,{'a':"blurfl","x":43.2});
 a | b | c
-----+---
 blurfl | |
(1 row)
```

```
gaussdb=# SELECT * FROM json_populate_record((1,1,null)::jpop,{'a':"blurfl","x":43.2});
 a | b | c
-----+---
 blurfl | 1 |
(1 row)
gaussdb=# DROP TYPE jpop;
DROP TYPE
```

- `json_populate_record_set(anyelement, array-json [, bool])`,  
`jsonb_populate_record_set(anyelement, array-jsonb [, bool])`

Description: Performs the preceding operations on each element in the *\$2* array by referring to the **json\_populate\_record** and **jsonb\_populate\_record** functions. Therefore, each element in the *\$2* array must be of the **object-json** type.

Return type: setof anyelement, setof anyelement

Example:

```
gaussdb=# CREATE TYPE jpop AS (a text, b int, c bool);
CREATE TYPE
gaussdb=# SELECT * FROM json_populate_recordset(null::jpop, '{"a":1,"b":2},{"a":3,"b":4}');
 a | b | c
---+---+---
 1 | 2 |
 3 | 4 |
(2 rows)
gaussdb=# DROP TYPE jpop;
DROP TYPE
```

- `json_typeof(json)`, `jsonb_typeof(jsonb)`

Description: Checks the JSON type.

Return type: text, text

Example:

```
gaussdb=# SELECT value, json_typeof(value) FROM (values (json '123.4'), (json '"foo"'), (json 'true'),
(json 'null'), (json '[1, 2, 3]'), (json '{"x":"foo", "y":123}'), (NULL::json)) AS data(value);
 value | json_typeof
-----+-----
 123.4 | number
 "foo" | string
 true  | boolean
 null  | null
 [1, 2, 3] | array
 {"x":"foo", "y":123} | object
(7 rows)
```

- `json_build_array( [VARIADIC "any"] )`

Description: Constructs a JSON array from a variable parameter list.

Return type: array-json

Example:

```
gaussdb=# SELECT json_build_array('a',1,'b',1.2,'c',true,'d',null,'e',json '{"x": 3, "y": [1,2,3]}');
 json_build_array
-----
["a", 1, "b", 1.2, "c", true, "d", null, "e", {"x": 3, "y": [1,2,3]}, null]
(1 row)
```

- `json_build_object( [VARIADIC "any"] )`

Description: Constructs a JSON object from a variable parameter list. The number of input parameters must be an even number. Every two input parameters form a key-value pair. Note that the value of a key cannot be null.

Return type: object-json

Example:

```
gaussdb=# SELECT json_build_object(1,2);
 json_build_object
-----
{"1": 2}
(1 row)
```

- `jsonb_build_object( [VARIADIC "any"] )`

Description: Constructs a JSONB object from a variable parameter list. The number of input parameters must be an even number. Every two input parameters form a key-value pair. Note that the key value cannot be **NULL**.

Return type: object-jsonb

**NOTICE**

- When an element in the variable parameter list contains an empty string ("), if the SQL compatibility mode of the database is A, the return result of the corresponding element is **NULL**; if the SQL compatibility mode of the database is PG, the return result of the corresponding element is an empty string. This is because empty strings are treated as **NULL** in A compatibility mode.
- When an element in the variable parameter list is of the DATE type, if the SQL compatibility mode of the database is A, the return result of the corresponding element contains hour, minute, and second; if the SQL compatibility mode of the database is PG, the return result of the corresponding element does not contain hour, minute, and second. This is because DATE will be replaced by **TIMESTAMP(0) WITHOUT TIME ZONE** in A compatibility mode.

Example:

```
gaussdb=# SELECT jsonb_build_object('a',1,'b',1.2,'c',true,'d',null,'e',json '{"x": 3, "y": [1,2,3]}');
           jsonb_build_object
```

```
-----
{"a": 1, "b": 1.2, "c": true, "d": null, "e": {"x": 3, "y": [1, 2, 3]}}
(1 row)
```

```
gaussdb=# SELECT jsonb_build_object();
           jsonb_build_object
```

```
-----
{}
(1 row)
```

- `json_to_record(object-json, bool), json_to_record(object-json)`

Description: Like all functions that return **record**, the caller must explicitly define the structure of the record with an AS clause. The key-value pair of **object-json** is split and reassembled. The key is used as a column name to match and fill in the structure of the record specified by the **AS** clause. The **bool** input parameter of overload 1 specifies whether object nesting is allowed. The value **true** indicates yes and the value **false** indicates no. If there is only one input parameter, object nesting is allowed by default. If there is only one input parameter, the nested JSON object can be converted to the row type and arrays in square brackets can be parsed. Dates of the time type are equivalent to `timestamp(0)` in ORA compatibility mode. Compared with that in the PG compatibility mode, the value also displays the 00:00:00 (hour, minute, and second) character string.

Return type: record

Example:

```
gaussdb=# SELECT * FROM json_to_record('{"a":1,"b":"foo","c":"bar"}',true) AS x(a int, b text, d text);
   a | b | d
-----+-----+-----
   1 | foo |
(1 row)
```

```
gaussdb=# SELECT * FROM json_to_record('{"a": {"x": 1, "y": 2},"b":"foo","c":[1, 2]}') AS x(a json, b text, c int[]);
```

```
   a | b | c
-----+-----+-----
{"x": 1, "y": 2} | foo | {1,2}
(1 row)
```

- `json_to_recordset(array-json, bool)`

Description: Executes the preceding function on each element in the array by referring to the `json_to_record` function. Therefore, each element in the array must be object-json. For **bool**, refer to the `json_to_record` function. **true** indicates that nested objects can be parsed, and **false** indicates that nested objects cannot be parsed, that is, whether the value of an element in a JSON object can be a JSON object.

Return type: set of record

Example:

```
gaussdb=# SELECT * FROM json_to_recordset(['{"a":1,"b":"foo","d":false},
{"a":2,"b":"bar","c":true}'],false) AS x(a int, b text, c boolean);
 a | b | c
---+-----+---
 1 | foo |
 2 | bar | t
(2 rows)
```

- `json_object(text[], json_object(text[], text[]))`

Description: Constructs an **object-json** from a text array. This is an overloaded function. When the input parameter is a text array, the array length must be an even number, and members are considered as alternate key-value pairs. When two text arrays are used, the first array is considered as a key, and the second array a value. The lengths of the two arrays must be the same. Note that the value of a key cannot be null.

Return type: object-json

Example:

```
gaussdb=# SELECT json_object('{a,1,b,2,3,NULL,"d e f","a b c"}');
          json_object
-----
{"a" : "1", "b" : "2", "3" : null, "d e f" : "a b c"}
(1 row)
gaussdb=# SELECT json_object('{a,b,"a b c"}', '{a,1,1}');
          json_object
-----
{"a" : "a", "b" : "1", "a b c" : "1"}
(1 row)
```

- `json_object([VARIADIC "any"] )`

Description: Constructs a JSON object from a variable parameter list. The number of input parameters must be an even number. Every two input parameters form a key-value pair. If the key-value pair is null, an error is reported. If the parameter is in the odd format, an error is reported.

Parameter: variable parameter list. The input parameter is a combination of one or more key-value pairs.

Return type: json

Example:

```
gaussdb=# SELECT json_object('d',2,'c','name','b',true,'a',2,'a',NULL,'d',1);
          json_object
-----
{"a": 2, "b": true, "c": "name", "d": 2}
(1 row)
gaussdb=# SELECT json_object('d',2,true,'name','b',true,'a',2,'aa', current_timestamp);
          json_object
-----
{"1": "name", "a": 2, "b": true, "d": 2, "aa": "2023-08-12 11:28:13.385958"}
(1 row)
```

 NOTE

This function takes effect when **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1' in the MySQL-compatible database. When this function takes effect, the original json\_object behavior is replaced.

- json\_append/json\_array\_append(json, [VARIADIC "any"])

Description: Constructs several json\_path-value pairs from a variable parameter list, adds a value to the path specified by **json**, and returns the modified JSON value. json\_append is the same as json\_array\_append. If any parameter is null, **null** is returned. If the JSON format is incorrect, **json\_path** is an invalid path expression, or **json\_path** contains \* or \*\*, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

Parameter: The first input parameter must be in JSON format, and the second input parameter is a variable parameter list. The json\_path-value pair is constructed from the variable parameter list. For details, see [Table 7-62](#).

**Table 7-62** Parameters

| Parameter        | Type               | Description                                                          | Value Range                                                                          |
|------------------|--------------------|----------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| json             | json               | JSON value to be modified.                                           | The value must be in JSON format.                                                    |
| [VARIADIC "any"] | Variable any array | A variable parameter list, including variable json_path-value pairs. | <b>json_path</b> must be a valid path expression, and <b>value</b> can be any value. |

Return type: json

Example:

```
gaussdb=# SELECT json_array_append('[1, [2, 3]]', '$[1]', 4, '$[0]', false, '$[0]', null, '$[0]',
current_timestamp);
          json_array_append
-----
[[1, false, null, "2023-08-12 14:27:16.142355+08"], [2, 3, 4]]
(1 row)
```

- json\_array([VARIADIC "any"])

Description: Constructs an array from a variable parameter list and returns a JSON array. If the function does not have any parameters, an empty JSON array is returned.

Parameter: The input parameter is a variable parameter list. The values in the list can be of any type.

Return type: json

Example:

```
-- If no input parameter is entered, an empty JSON array is returned.
gaussdb=# SELECT json_array();
          json_array
-----
```

```

[]
(1 row)

-- The input parameter can be of any type.
gaussdb=# SELECT json_array(TRUE, FALSE, NULL, 114, 'text', current_timestamp);
           json_array
-----
[true, false, null, 114, "text", "2023-08-12 15:17:34.979294+08"]
(1 row)

```

- json\_array\_insert(json, [VARIADIC "any"])**  
 Description: Constructs one or more json\_path-value pairs from a variable parameter list, inserts a value into the array path specified by the **json\_path** in **json**, and returns a new JSON value. If there is already an existing value on the specified path, the value is inserted on the path and the existing value is moved backward. If **json** or **json\_path** is null, **null** is returned. If the JSON format is incorrect, **json\_path** is an invalid path expression, or **json\_path** contains \* or \*\*, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

Parameters: See [Table 4 Parameters](#).

**Table 7-63** Parameters

| Parameter        | Type               | Description                                                            | Value Range                                                                          |
|------------------|--------------------|------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| json             | json               | JSON value to be modified.                                             | The value must be in JSON format.                                                    |
| [VARIADIC "any"] | Variable any array | Variable parameter list, containing one or more json_path-value pairs. | <b>json_path</b> must be a valid path expression, and <b>value</b> can be any value. |

Return type: json

Example:

```

-- Example of containing one json_path-value pair
gaussdb=# SELECT json_array_insert('[1, [2, 3]]', '$[1]', 4);
           json_array_insert
-----
[1, 4, [2, 3]]
(1 row)

-- Example of containing multiple json_path-value pairs
gaussdb=# SELECT json_array_insert('{"x": 1, "y": [1, 2]}', '$.y[0]', NULL, '$.y[0]', 123, '$.y[3]',
           current_timestamp);
           json_array_insert
-----
{"x": 1, "y": [123, null, 1, "2023-08-14 14:54:12.85087+08", 2]}
(1 row)

```

- json\_contains(target\_json, candidate\_json[, json\_path])**  
 Description: The input parameters are two JSON objects and an optional path specified by **json\_path**. If **json\_path** is not specified, the system checks whether **target\_json** contains **candidate\_json**. If **json\_path** is specified, the system checks whether **candidate\_json** is contained in the JSON path

specified by **json\_path** in **target\_json**. If **json** or **json\_path** is null, **null** is returned. If the JSON format is incorrect, **json\_path** is an invalid path expression, or **json\_path** contains \* or \*\*, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

Parameters: See [Table 7-64](#).

**Table 7-64** Parameters

| Parameter      | Type | Description                                                                                                                                                                                    | Value Range                                       |
|----------------|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| target_json    | json | Target JSON object, which is used to check whether <b>candidate_json</b> is contained in the JSON object.                                                                                      | The value must be in JSON format.                 |
| candidate_json | json | JSON subobject, which is used to check whether it is contained in <b>target_json</b> .                                                                                                         | The value must be in JSON format.                 |
| json_path      | text | Specified JSON path. This parameter is optional. If this parameter is specified, the path specified by <b>json_path</b> in <b>target_json</b> is used to determine the inclusion relationship. | <b>json_path</b> must be a valid path expression. |

Return type: bigint. If there is an inclusion relationship, **1** is returned. If there is no inclusion relationship, **0** is returned.

**Example:**

```
-- No path is specified.
gaussdb=# SELECT json_contains('[1, 2, {"x": 3}], {"x":3}');
json_contains
-----
1
(1 row)

-- A path is specified.
gaussdb=# SELECT json_contains('[1, 2, {"x": 3],[1,2,3,4]]', '2','$[1]');
json_contains
-----
1
(1 row)

gaussdb=# SELECT json_contains('[1, 2, {"x": 3],[1,2,3,4]]', '1','$[1]');
json_contains
-----
0
(1 row)
```

- json\_contains\_path(json, mode\_str, [VARIADIC text])**  
 Description: Checks whether a JSON object has a value on the specified path. There can be multiple paths. The first input parameter is a JSON object, and the second input parameter can be **one** or **all**, specifying whether to check all paths. The third input parameter is a variable parameter list. All JSON paths are constructed from the variable parameter list. According to the mode, if a path value exists, **1** is returned. If no path value exists, **0** is returned. If **json** or **json\_path** is null, **null** is returned. If the JSON format is incorrect, or **json\_path** is an invalid path expression, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.  
 Parameters: See [Table 7-65](#).

**Table 7-65** Parameters

| Parameter       | Type                | Description                                                                                                                                                                                                                                               | Value Range                                                             |
|-----------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| json            | json                | JSON object to be transferred.                                                                                                                                                                                                                            | The value must be in JSON format.                                       |
| mode_str        | text                | The value can be <b>one</b> or <b>all</b> . If the value is <b>one</b> and one path exists, <b>1</b> is returned; otherwise, <b>0</b> is returned. If the value is <b>all</b> and all paths exist, <b>1</b> is returned; otherwise, <b>0</b> is returned. | The value must be <b>one</b> or <b>all</b> , which is case-insensitive. |
| [VARIADIC text] | Variable text array | Variable parameter list from which all JSON paths are constructed.                                                                                                                                                                                        | <b>json_path</b> must be a valid path expression.                       |

Return type: bigint

Example:

```
-- In the all scenario, all paths must exist.
gaussdb=# SELECT json_contains_path('[1, 2, {"x": 3}]', 'all', '$[0]', '$[1]', '$[2]');
json_contains_path
-----
1
(1 row)

gaussdb=# SELECT json_contains_path('[1, 2, {"x": 3}]', 'all', '$[0]', '$[1]', '$[6]');
json_contains_path
-----
0
(1 row)

-- In the one scenario, at least one path must exist.
gaussdb=# SELECT json_contains_path('[1, 2, {"x": 3}]', 'one', '$[0]', '$[1]', '$[5]');
json_contains_path
-----
1
(1 row)
```

- `json_depth(json)`

Description: The input parameter is a JSON object. This function is used to return the maximum depth of the JSON object. If the input parameter is null, **null** is returned.

Parameter: The input parameter is a JSON string whose depth needs to be queried. If the input parameter is not in valid JSON format, an error is reported.

Return type: int

Example:

```
-- The depth of an empty array is 1.
gaussdb=# SELECT json_depth('[]');
json_depth
-----
         1
(1 row)

gaussdb=# SELECT json_depth('{ "s":1, "x":2,"y":[1]}');
json_depth
-----
         3
(1 row)
```

- `json_extract(json, [VARIADIC text])`

Description: The input parameters are a JSON object and several JSON paths. The JSON paths are constructed from the variable parameter list. This function extracts data of the specified JSON path from **json**, combines the data into a JSON array, and returns the JSON array. If **json** or **json\_path** is null, **null** is returned. If the JSON format is incorrect, or **json\_path** is an invalid path expression, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

Parameters: See [Table 7-66](#).

**Table 7-66** Parameters

| Parameter                    | Type                | Description                                                 | Value Range                                       |
|------------------------------|---------------------|-------------------------------------------------------------|---------------------------------------------------|
| <code>json</code>            | json                | JSON value from which paths are to be extracted.            | The value must be in JSON format.                 |
| <code>[VARIADIC text]</code> | Variable text array | Variable parameter list, containing one or more JSON paths. | <b>json_path</b> must be a valid path expression. |

Return type: json

Example:

```
-- One path is extracted.
gaussdb=# SELECT json_extract('[1, 2, {"x": 3}]', '$[2]');
json_extract
-----
{"x": 3}
(1 row)
```

```
-- Multiple paths are extracted.
gaussdb=# SELECT json_extract(['a', ['b', 'c'], 'd'], '$[1]', '$[2]', '$[3]');
 json_extract
-----
[["b", "c"], "d"]
(1 row)
```

- `json_insert(json, [VARIADIC any])`

Description: The input parameter is a JSON object, multiple JSON paths, and values to be inserted. JSON paths and values must be paired. This function inserts **value** at the position specified by **json\_path** in **json**. This function can only insert data to a position where no path exists. If the specified path already exists in **json**, no data will be inserted. If **json** or **json\_path** is null, **null** is returned. In addition, **json\_path** cannot contain wildcard characters \* or \*\*. Otherwise, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

Parameters: See [Table 7-67](#).

**Table 7-67** Parameters

| Parameter      | Type               | Description                                                            | Value Range                                                                          |
|----------------|--------------------|------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| json           | json               | JSON object to which a value is to be inserted.                        | The value must be in JSON format.                                                    |
| [VARIADIC any] | Variable any array | Variable parameter list, containing one or more json_path-value pairs. | <b>json_path</b> must be a valid path expression, and <b>value</b> can be any value. |

Return type: json

Example:

```
gaussdb=# SELECT json_insert([1, [2, 3], {'a': [4, 5]}], '$[3]', 2);
 json_insert
-----
[1, [2, 3], {'a': [4, 5]}, 2]
(1 row)

gaussdb=# SELECT json_insert([1, [2, 3], {'a': [4, 5]}], '$[10]', 10; '$[5]', 5);
 json_insert
-----
[1, [2, 3], {'a': [4, 5]}, 10, 5]
(1 row)
```

- `json_keys(json[, json_path])`

Description: The input parameters are a JSON object and an optional JSON path. If no JSON path is transferred, this function returns a JSON array of member key values of the top-layer object in the JSON object. If a JSON path is transferred, this function returns the JSON array of the top-layer member key values in the JSON object corresponding to the path. If **json** or **json\_path** is null, **null** is returned. If the JSON format is incorrect, **json\_path** is an invalid path expression, or **json\_path** contains \* or \*\*, an error is reported.

Parameters: See [Table 9 Parameters](#).

**Table 7-68** Parameters

| Parameter | Type | Description                     | Value Range                                       |
|-----------|------|---------------------------------|---------------------------------------------------|
| json      | json | A JSON value.                   | The value must be in JSON format.                 |
| json_path | text | A JSON path, which is optional. | <b>json_path</b> must be a valid path expression. |

Return type: json

Example:

```
gaussdb=# SELECT json_keys('{ "x": 1, "y": 2, "z": 3 }');
 json_keys
-----
["x", "y", "z"]
(1 row)
```

```
gaussdb=# SELECT json_keys('[1,2,3,{"name":"Tom"}]',$[3]);
 json_keys
-----
["name"]
(1 row)
```

- `json_length(json[, json_path])`

Description: The input parameters are a JSON object and an optional JSON path. If no JSON path is transferred, this function returns the length of the transferred JSON object. If a JSON path is transferred, this function returns the length of the JSON object corresponding to the path. If **json** or **json\_path** is null, **null** is returned. If the JSON format is incorrect, **json\_path** is an invalid path expression, or **json\_path** contains \* or \*\*, an error is reported.

Parameters: See [Table 7-69](#).

**Table 7-69** Parameters

| Parameter | Type | Description                     | Value Range                                       |
|-----------|------|---------------------------------|---------------------------------------------------|
| json      | json | A JSON value.                   | The value must be in JSON format.                 |
| json_path | text | A JSON path, which is optional. | <b>json_path</b> must be a valid path expression. |

Return type: int

Example:

```
gaussdb=# SELECT json_length('[1,2,3,4,5]');
 json_length
-----
5
```

```
(1 row)

gaussdb=# SELECT json_length({'name':'Tom', 'age':24, 'like':'football'});
 json_length
-----
          3
(1 row)
```

- `json_merge([VARIADIC any])`

Description: The input parameters are of the JSON type and the number of input parameters is greater than or equal to 2. The JSON objects are constructed from the variable parameter list. This function combines all input JSON parameters and returns the combination result. If the input parameter is null, **null** is returned. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

Parameter: a variable parameter list. Multiple JSON objects are constructed from this list.

Return type: json

Example:

```
gaussdb=# SELECT json_merge('[1, 2]','[2]');
 json_merge
-----
 [1, 2, 2]
(1 row)

gaussdb=# SELECT json_merge({'b':"2"},{'a':"1"},[1,2]);
 json_merge
-----
 [{"a": "1", "b": "2"}, 1, 2]
(1 row)
```

- `json_quote(text)`

Description: The input parameter is of the text type. This function uses double quotation marks (") to enclose the input parameter into a JSON string and returns the string.

Parameter: The input parameter is the character string to be enclosed.

Return type: json

Example:

```
gaussdb=# SELECT json_quote('gauss');
 json_quote
-----
 "gauss"
(1 row)
```

- `json_unquote(json)`

Description: The input parameter is a JSON object. This function cancels the quotation marks of the input parameter and returns the character string.

Return type: object-json

Return type: text

Example:

```
gaussdb=# SELECT json_unquote('"gauss"');
 json_unquote
-----
 gauss
(1 row)
```

- json\_remove(json, [VARIADIC text])**  
 Description: The input parameters are a JSON object and several JSON paths to be deleted. These JSON paths are constructed from the variable parameter list. This function deletes the value of **json\_path** in **json** and returns the JSON object after deletion. If **json** or **json\_path** is null, **null** is returned. If the JSON format is incorrect, **json\_path** is an invalid path expression, or **json\_path** contains \* or \*\*, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.  
 Parameters: See [Table 7-70](#).

**Table 7-70** Parameters

| Parameter       | Type                | Description                                                 | Value Range                                       |
|-----------------|---------------------|-------------------------------------------------------------|---------------------------------------------------|
| json            | json                | A JSON value.                                               | The value must be in JSON format.                 |
| [VARIADIC text] | Variable text array | Variable parameter list, containing one or more JSON paths. | <b>json_path</b> must be a valid path expression. |

Return type: json

Example:

```
gaussdb=# SELECT json_remove('[0, 1, 2, [3, 4]]', '$[0]', '$[2]');
json_remove
-----
[1, 2]
(1 row)

gaussdb=# SELECT json_remove('[0, 1, 2, [3, 4]]', '$[0]', '$[0]','$[0]');
json_remove
-----
[[3, 4]]
(1 row)
```

- json\_replace(json, [VARIADIC any])**  
 Description: The input parameter is a JSON object, multiple JSON paths, and values to be replaced. The JSON paths and values must be in pairs. This function replaces data in a path specified by **json\_path** in **json** with a specified value and returns the modified JSON object. If **json** or **json\_path** is null, **null** is returned. If the JSON format is incorrect, **json\_path** is an invalid path expression, or **json\_path** contains \* or \*\*, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.  
 Parameters: See [Table 7-71](#).

**Table 7-71** Parameters

| Parameter      | Type                         | Description                                                            | Value Range                                                                          |
|----------------|------------------------------|------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| json           | json                         | A JSON value.                                                          | The value must be in JSON format.                                                    |
| [VARIABLE ANY] | Variable any input parameter | Variable parameter list, containing one or more json_path-value pairs. | <b>json_path</b> must be a valid path expression, and <b>value</b> can be any value. |

Return type: json

Example:

```
gaussdb=# SELECT json_replace('{\"x\": 1}', '$.x', 'true');
json_replace
```

```
-----
{\"x\": \"true\"}
(1 row)
```

```
gaussdb=# SELECT json_replace('{\"x\": 1}', '$.x', true, '$.x', 123, '$.x', 'asd', '$.x', null);
json_replace
```

```
-----
{\"x\": null}
(1 row)
```

- `json_search(json, mode_str, search_str, escape_char, json_path)`

Description: Returns the path of a given string in **json**. It returns a path string or an array of multiple paths. If any of **json**, **search\_str**, and **json\_path** is null, **null** is returned. If the JSON format is incorrect or **json\_path** is not a valid path expression, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

Parameters: See [Table 13 Parameters](#).

**Table 7-72** Parameters

| Parameter | Type | Description                                                                                                                                                                    | Value Range                                                             |
|-----------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| json      | json | Target JSON object.                                                                                                                                                            | The value must be in JSON format.                                       |
| mode_str  | text | The value can be <b>one</b> or <b>all</b> . If the value is <b>one</b> , only the first matched path is obtained. If the value is <b>all</b> , all matched paths are obtained. | The value must be <b>one</b> or <b>all</b> , which is case-insensitive. |

| Parameter   | Type | Description                                                                                                                                                                                                                                                     | Value Range                                       |
|-------------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| search_str  | text | Character string to be searched for. In normal cases, the entire character string is matched. However, the wildcard % can be used to match any number of characters, and _ can be used to match any character.                                                  | -                                                 |
| escape_char | text | If <b>search_str</b> contains a wildcard, this parameter is defined as an escape character for the wildcard. This parameter is optional. The default value is '\'. If the character is added before the wildcard, the wildcard is not considered as a wildcard. | The value can be any single character.            |
| json_path   | text | If <b>json_path</b> is specified, the search is performed in the path. This parameter is optional.                                                                                                                                                              | <b>json_path</b> must be a valid path expression. |

Return type: text

Example:

```
-- In the all mode:
gaussdb=# SELECT json_search('{"a":"abc","b":"abc"}','all','abc');
json_search
-----
["$a", "$b"]
(1 row)

-- In the one mode:
gaussdb=# SELECT json_search('{"a":"abc","b":"abc"}','one','abc');
json_search
-----
"$a"
(1 row)

-- The default escape character is used.
gaussdb=# SELECT json_search('{"a":"abc","b":"a%c"}','one','a%c');
json_search
-----
"$b"
(1 row)
```

- `json_set(json, [VARIADIC any])`

Description: The input parameter is a JSON object, multiple JSON paths, and values to be set. The JSON paths and values must be in pairs. This function

uses the specified value to update the data in the path specified by **json\_path** in **json** and returns the modified JSON object. If the specified path does not have any value, the value is inserted into the corresponding path. If **json** or **json\_path** is null, **null** is returned. If the JSON format is incorrect, **json\_path** is an invalid path expression, or **json\_path** contains \* or \*\*, an error is reported. If the variable parameter list contains null values and has format error, the exceptions are processed based on the exception sequence. If a null value exists first, **null** is returned first. If a format error occurs first, an error is reported first.

Parameters: See [Table 14 Parameters](#).

**Table 7-73** Parameters

| Parameter      | Type               | Description                                                            | Value Range                                                                          |
|----------------|--------------------|------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| json           | json               | A JSON value.                                                          | The value must be in JSON format.                                                    |
| [VARIABLE any] | Variable any array | Variable parameter list, containing one or more json_path-value pairs. | <b>json_path</b> must be a valid path expression, and <b>value</b> can be any value. |

Return type: json

Example:

```
gaussdb=# SELECT json_set('{\"s\":3}', '$s','d');
 json_set
-----
{"s": "d"}
(1 row)
```

```
gaussdb=# SELECT json_set('{\"s\":3}', '$a','d','$a','1');
 json_set
-----
{"a": "1", "s": 3}
(1 row)
```

- **json\_type(json)**

Description: The input parameter is a JSON object. This function returns a string, which represents the type of the given JSON value. If the input parameter is null, **null** is returned.

Parameter: a JSON value. For details, see [Table 7-74](#).

Return type: text

**Table 7-74** Return value of json\_type

| Input Parameter Type          | Return Value |
|-------------------------------|--------------|
| JSON value of the array type  | ARRAY        |
| JSON value of the object type | OBJECT       |

| Input Parameter Type                    | Return Value |
|-----------------------------------------|--------------|
| JSON value of the character string type | STRING       |
| JSON value of the numeric type          | NUMBER       |
| JSON value of the Boolean type          | BOOLEAN      |
| NULL                                    | NULL         |

**Example:**

```
gaussdb=# SELECT json_type('{\"w\":{\"2\":3},\"2\":4}');
json_type
-----
OBJECT
(1 row)
```

```
gaussdb=# SELECT json_type('[1,2,2,3,3,4,4,4,4,4,4]');
json_type
-----
ARRAY
(1 row)
```

- **json\_valid(json)**

Description: Returns **0** or **1** to indicate whether the given parameter is a valid JSON object. If the input parameter is null, **null** is returned.

Return type: object-json

Return type: bigint

**Example:**

```
gaussdb=# SELECT json_valid('{\"name\":\"Tom\"}');
json_valid
-----
1
(1 row)
```

```
gaussdb=# SELECT json_valid('[1,23,4,5,5]');
json_valid
-----
1
(1 row)
```

```
gaussdb=# SELECT json_valid('[1,23,4,5,5]');
json_valid
-----
0
(1 row)
```

- **json\_agg(any)**

Description: Aggregates values into a JSON array.

Return type: array-json

**Example:**

```
gaussdb=# CREATE TABLE classes(name varchar, score int);
CREATE TABLE
gaussdb=# INSERT INTO classes VALUES('A',2);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('A',3);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',5);
```

```

INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',null);
INSERT 0 1
gaussdb=# SELECT * FROM classes;
 name | score
-----+-----
 A   |    2
 A   |    3
 D   |    5
 D   |
(4 rows)

gaussdb=# SELECT name, json_agg(score) score FROM classes GROUP BY name ORDER BY name;
 name | score
-----+-----
 A   | [2, 3]
 D   | [5, null]
(2 rows)

gaussdb=# DROP TABLE classes;
DROP TABLE

```

- **json\_object\_agg(any, any)**

Description: Aggregates values into a JSON object.

Return type: object-json

Example:

```

gaussdb=# CREATE TABLE classes(name varchar, score int);
CREATE TABLE
gaussdb=# INSERT INTO classes VALUES('A',2);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('A',3);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',5);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',null);
INSERT 0 1
gaussdb=# SELECT * FROM classes;
 name | score
-----+-----
 A   |    2
 A   |    3
 D   |    5
 D   |
(4 rows)

gaussdb=# SELECT json_object_agg(name, score) FROM classes GROUP BY name ORDER BY name;
 json_object_agg
-----
 { "A" : 2, "A" : 3 }
 { "D" : 5, "D" : null }
(2 rows)

gaussdb=# DROP TABLE classes;
DROP TABLE

```

- **jsonb\_contained(jsonb, jsonb)**

Description: Same as the operator `<@`, determines whether all elements in \$1 exist at the top layer of \$2.

Return type: Boolean

Example:

```

gaussdb=# SELECT jsonb_contained('[1,2,3]', '[1,2,3,4]');
 jsonb_contained
-----
 t
(1 row)

```

- jsonb\_contains(jsonb, jsonb)**

Description: Same as the operator `@>`, checks whether all top-layer elements in `$1` are contained in `$2`.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_contains('[1,2,3,4]', '[1,2,3]');
 jsonb_contains
-----
t
(1 row)
```
- jsonb\_exists(jsonb, text)**

Description: Same as the operator `?`, determines whether all elements in the string array `$2` exist at the top layer of `$1` in the form of **key\elem\scalar**.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_exists('["1",2,3]', '1');
 jsonb_exists
-----
t
(1 row)
```
- jsonb\_exists\_all(jsonb, text[])**

Description: Same as the operator `?&`, checks whether all elements in the string array `$2` exist at the top layer of `$1` in the form of **key\elem\scalar**.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_exists_all('["1","2",3]', '{1, 2}');
 jsonb_exists_all
-----
t
(1 row)
```
- jsonb\_exists\_any(jsonb, text[])**

Description: Same as the operator `?|`, checks whether all elements in the string array `$2` exist at the top layer of `$1` in the form of **key\elem\scalar**.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_exists_any('["1","2",3]', '{1, 2, 4}');
 jsonb_exists_any
-----
t
(1 row)
```
- jsonb\_cmp(jsonb, jsonb)**

Description: Compares values. A positive value indicates greater than, a negative value indicates less than, and **0** indicates equal.

Return type: integer

Example:

```
gaussdb=# SELECT jsonb_cmp('["a", "b"]', '{"a":1, "b":2}');
 jsonb_cmp
-----
-1
(1 row)
```
- jsonb\_eq(jsonb, jsonb)**

Description: Same as the operator `=`, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_eq(['a', 'b'], '{"a":1, "b":2}');
 jsonb_eq
-----
f
(1 row)
```

- `jsonb_ne(jsonb, jsonb)`

Description: Same as the operator ``<>``, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_ne(['a', 'b'], '{"a":1, "b":2}');
 jsonb_ne
-----
t
(1 row)
```

- `jsonb_gt(jsonb, jsonb)`

Description: Same as the operator ``>``, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_gt(['a', 'b'], '{"a":1, "b":2}');
 jsonb_gt
-----
f
(1 row)
```

- `jsonb_ge(jsonb, jsonb)`

Description: Same as the operator ``>=``, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_ge(['a', 'b'], '{"a":1, "b":2}');
 jsonb_ge
-----
f
(1 row)
```

- `jsonb_lt(jsonb, jsonb)`

Description: Same as the operator ``<``, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_lt(['a', 'b'], '{"a":1, "b":2}');
 jsonb_lt
-----
t
(1 row)
```

- `jsonb_le(jsonb, jsonb)`

Description: Same as the operator ``<=``, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_le(['a', 'b'], '{"a":1, "b":2}');
 jsonb_le
-----
t
(1 row)
```

- `to_json(anyelement)`

Description: Converts parameters to `json`.

Return type: json

Example:

```
gaussdb=# SELECT to_json('{1,5}::text[]);  
to_json  
-----  
["1","5"]  
(1 row)
```

- `to_jsonb(anelement)`

Description: Converts the input `anelement` parameter to the JSONB type.

Return type: jsonb

#### NOTICE

- When the parameter is an empty string (""), if the SQL compatibility mode of the database is A, **NULL** is returned; if the SQL compatibility mode of the database is PG, an empty string is returned. This is because empty strings are treated as **NULL** in A compatibility mode.
- When the parameter is of the DATE type, if the database SQL compatibility mode is A, the returned result contains hour, minute, and second; if the database SQL compatibility mode is PG, the returned result does not contain hour, minute, and second. This is because DATE will be replaced by `TIMESTAMP(0) WITHOUT TIME ZONE` in A compatibility mode.

Example:

```
gaussdb=# SELECT to_jsonb(ARRAY[1, 2, 3, 4]);  
to_jsonb  
-----  
[1, 2, 3, 4]  
(1 row)
```

- `jsonb_hash(jsonb)`

Description: Performs the hash operation on JSONB.

Return type: integer

Example:

```
gaussdb=# SELECT jsonb_hash('[1,2,3]');  
jsonb_hash  
-----  
-559968547  
(1 row)
```

- Other Functions

```
json_agg_transfn  
json_agg_finalfn  
json_object_agg_transfn  
json_object_agg_finalfn
```

## 7.6.14 HLL Functions and Operators

### Hash Functions

- `hll_hash_boolean(bool)`

Description: Hashes data of the Boolean type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_boolean(FALSE);
 hll_hash_boolean
-----
-5451962507482445012
(1 row)
```

- `hll_hash_boolean(bool, int32)`

Description: Configures a hash seed (that is, changes the hash policy) and hashes data of the Boolean type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_boolean(FALSE, 10);
 hll_hash_boolean
-----
-1169037589280886076
(1 row)
```

- `hll_hash_smallint(smallint)`

Description: Hashes data of the smallint type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_smallint(100::smallint);
 hll_hash_smallint
-----
962727970174027904
(1 row)
```

 **NOTE**

If parameters with the same numeric value are hashed using different data types, the data will differ, because hash functions select different calculation policies for each type.

- `hll_hash_smallint(smallint, int32)`

Description: Configures a hash seed (that is, changes the hash policy) and hashes data of the smallint type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_smallint(100::smallint, 10);
 hll_hash_smallint
-----
-9056177146160443041
(1 row)
```

- `hll_hash_integer(integer)`

Description: Hashes data of the integer type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_integer(0);
 hll_hash_integer
-----
5156626420896634997
(1 row)
```

- `hll_hash_integer(integer, int32)`

Description: Hashes data of the integer type and configures a hash seed (that is, changes the hash policy).

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_integer(0, 10);
 hll_hash_integer
-----
-5035020264353794276
(1 row)
```

- **hll\_hash\_bigint(bigint)**

Description: Hashes data of the bigint type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_bigint(100::bigint);
 hll_hash_bigint
-----
-2401963681423227794
(1 row)
```

- **hll\_hash\_bigint(bigint, int32)**

Description: Hashes data of the bigint type and configures a hash seed (that is, changes the hash policy).

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_bigint(100::bigint, 10);
 hll_hash_bigint
-----
-2305749404374433531
(1 row)
```

- **hll\_hash\_bytea(bytea)**

Description: Hashes data of the bytea type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_bytea(E'\x');
 hll_hash_bytea
-----
0
(1 row)
```

- **hll\_hash\_bytea(bytea, int32)**

Description: Hashes data of the bytea type and configures a hash seed (that is, changes the hash policy).

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_bytea(E'\x', 10);
 hll_hash_bytea
-----
7233188113542599437
(1 row)
```

- **hll\_hash\_text(text)**

Description: Hashes data of the text type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_text('AB');
 hll_hash_text
-----
```

```
-----  
-5666002586880275174  
(1 row)
```

- **hll\_hash\_text(text, int32)**

Description: Hashes data of the text type and configures a hash seed (that is, changes the hash policy).

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_text('AB', 10);  
hll_hash_text
```

```
-----  
-2215507121143724132  
(1 row)
```

- **hll\_hash\_any(anytype)**

Description: Hashes data of any type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_any(1);  
hll_hash_any
```

```
-----  
-1316670585935156930  
(1 row)
```

```
gaussdb=# SELECT hll_hash_any('08:00:2b:01:02:03'::macaddr);  
hll_hash_any
```

```
-----  
-3719950434455589360  
(1 row)
```

- **hll\_hash\_any(anytype, int32)**

Description: Hashes data of any type and configures a hash seed (that is, changes the hash policy).

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_any(1, 10);  
hll_hash_any
```

```
-----  
7048553517657992351  
(1 row)
```

- **hll\_hashval\_eq(hll\_hashval, hll\_hashval)**

Description: Compares two pieces of data of the hll\_hashval type to check whether they are the same.

Return type: Boolean

Example:

```
gaussdb=# SELECT hll_hashval_eq(hll_hash_integer(1), hll_hash_integer(1));  
hll_hashval_eq
```

```
-----  
t  
(1 row)
```

- **hll\_hashval\_ne(hll\_hashval, hll\_hashval)**

Description: Compares two pieces of data of the hll\_hashval type to check whether they are different.

Return type: Boolean

Example:

```
gaussdb=# SELECT hll_hashval_ne(hll_hash_integer(1), hll_hash_integer(1));
hll_hashval_ne
-----
f
(1 row)
```

## HLL Functions

There are three HLL modes: explicit, sparse, and full. When the data size is small, the explicit mode is used. In this mode, distinct values are calculated without errors. As the number of distinct values increases, the HLL mode is switched to the sparse and full modes in sequence. The two modes have no difference in the calculation result, but vary in the calculation efficiency of HLL functions and the storage space of HLL objects. The following functions can be used to view some HLL parameters:

- `hll_print(hll)`

Description: Prints some debugging parameters of an HLL.

Example:

```
gaussdb=# SELECT hll_print(hll_empty());
hll_print
-----
type=1(HLL_EMPTY), log2m=14, log2explicit=10, log2sparse=12, duplicatecheck=0
(1 row)
```

- `hll_type(hll)`

Description: Checks the type of the current HLL. The return values are described as follows: **0** indicates **HLL\_UNINIT**, an HLL object that is not initialized. **1** indicates **HLL\_EMPTY**, an empty HLL object. **2** indicates **HLL\_EXPLICIT**, an HLL object in explicit mode. **3** indicates **HLL\_SPARSE**, an HLL object in sparse mode. **4** indicates **HLL\_FULL**, an HLL object in full mode. **5** indicates **HLL\_UNDEFINED**, an invalid HLL object.

Example:

```
gaussdb=# SELECT hll_type(hll_empty());
hll_type
-----
1
(1 row)
```

- `hll_log2m(hll)`

Description: Checks the value of **log2m** in the current HLL data structure. **log2m** is the logarithm of the number of buckets. This value affects the error rate of calculating distinct values by HLL. The error rate =  $\pm 1.04/\sqrt{2^{\log 2m}}$ . When the value of **log2m** is explicitly set a value ranges from 10 to 16, HLL sets the number of buckets to  $2^{\log 2m}$ . When the value of **log2explicit** is explicitly set to **-1**, the built-in default value is used.

Example:

```
gaussdb=# SELECT hll_log2m(hll_empty());
hll_log2m
-----
14
(1 row)

gaussdb=# SELECT hll_log2m(hll_empty(10));
hll_log2m
-----
10
(1 row)
```

```
gaussdb=# SELECT hll_log2m(hll_empty(-1));
hll_log2m
-----
      14
(1 row)
```

- **hll\_log2explicit(hll)**

Description: Queries the value of **log2explicit** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can change the value of **log2explicit** to change the policy. For example, if the value of **log2explicit** is **0**, the HLL will skip the explicit mode and directly enter the sparse mode. When the value of **log2explicit** is explicitly set to a value ranging from 1 to 12, the HLL will switch to the sparse mode when the length of the data segment exceeds  $2^{\text{log2explicit}}$ . When the value of **log2explicit** is explicitly set to **-1**, the built-in default value is used.

Example:

```
gaussdb=# SELECT hll_log2explicit(hll_empty());
hll_log2explicit
-----
          10
(1 row)
```

```
gaussdb=# SELECT hll_log2explicit(hll_empty(12, 8));
hll_log2explicit
-----
           8
(1 row)
```

```
gaussdb=# SELECT hll_log2explicit(hll_empty(12, -1));
hll_log2explicit
-----
          10
(1 row)
```

- **hll\_log2sparse(hll)**

Description: Queries the value of **log2sparse** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can adjust the value of **log2sparse** to change the policy. For example, if the value of **log2sparse** is **0**, the system skips the sparse mode and directly enters the full mode. If the value of **log2sparse** is explicitly set to a value ranging from 1 to 14, the HLL will switch to the full mode when the length of the data segment exceeds  $2^{\text{log2sparse}}$ . When the value of **log2sparse** is explicitly set to **-1**, the built-in default value is used.

Example:

```
gaussdb=# SELECT hll_log2sparse(hll_empty());
hll_log2sparse
-----
          12
(1 row)
```

```
gaussdb=# SELECT hll_log2sparse(hll_empty(12, 8, 10));
hll_log2sparse
-----
          10
(1 row)
```

```
gaussdb=# SELECT hll_log2sparse(hll_empty(12, 8, -1));
```

Description: Performs the UNION operation on two HLL data structures to obtain one HLL.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_union(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
          hll_union
-----
\x484c4c10002000002b0900000000000000004000000000000000b3ccc49320cca1ae3e2921ff133fba
ed00
(1 row)
```

## Aggregate Functions

- `hll_add_agg(hll_hashval)`

Description: Groups hashed data into HLL.

Return type: HLL

Example:

```
-- Prepare data:
gaussdb=# CREATE TABLE t_id(id int);
gaussdb=# INSERT INTO t_id VALUES(generate_series(1,500));
gaussdb=# CREATE TABLE t_data(a int, c text);
gaussdb=# INSERT INTO t_data SELECT mod(id,2), id FROM t_id;

-- Create a table and specify an HLL column:
gaussdb=# CREATE TABLE t_a_c_hll(a int, c hll);

-- Use GROUP BY on column a to group data, and insert the data to the HLL:
gaussdb=# INSERT INTO t_a_c_hll SELECT a, hll_add_agg(hll_hash_text(c)) FROM t_data GROUP BY a;

-- Calculate the number of distinct values for each group in the HLL:
gaussdb=# SELECT a, #c AS cardinality FROM t_a_c_hll ORDER BY a;
 a | cardinality
---+-----
 0 | 247.862354346299
 1 | 250.908710610377
(2 rows)
```

- `hll_add_agg(hll_hashval, int32 log2m)`

Description: Groups hashed data into HLL and specifies the **log2m** parameter. The value ranges from 10 to 16. If the input is **-1** or **NULL**, the built-in default value is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), 12)) FROM t_data;
 hll_cardinality
-----
497.965240179228
(1 row)
```

- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit)`

Description: Groups hashed data into HLL and specifies the **log2m** and **log2explicit** parameters in sequence. The value of **log2explicit** ranges from 0 to 12. The value **0** indicates that the explicit mode is skipped. This parameter is used to set the threshold of the explicit mode. When the length of the data segment reaches  $2^{\text{log2explicit}}$ , the mode is switched to the sparse or full mode. If the input is **-1** or **NULL**, the built-in default value of **log2explicit** is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 1)) FROM t_data;
hll_cardinality
-----
498.496062953313
(1 row)
```

- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse)`

Description: Groups hashed data into HLL and sets the **log2m**, **log2explicit**, and **log2sparse** parameters in sequence. The value of **log2sparse** ranges from 0 to 14. The value **0** indicates that the sparse mode is skipped. This parameter is used to set the threshold of the sparse mode. When the length of the data segment reaches  $2^{\text{log2sparse}}$ , the mode is switched to the full mode. If the input is **-1** or **NULL**, the built-in default value of **log2sparse** is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10)) FROM t_data;
hll_cardinality
-----
498.496062953313
(1 row)
```

- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse, int32 duplicatecheck)`

Description: Groups hashed data into HLL and sets the **log2m**, **log2explicit**, **log2sparse**, and **duplicatecheck** parameters. The value of **duplicatecheck** can be **0** or **1**, indicating whether to enable this mode. By default, this mode is disabled. If the input is **-1** or **NULL**, the built-in default value of **duplicatecheck** is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10, -1)) FROM t_data;
hll_cardinality
-----
498.496062953313
(1 row)
```

- `hll_union_agg(hll)`

Description: Performs the UNION operation on multiple pieces of data of the HLL type to obtain one HLL.

Return type: HLL

Example:

```
-- Perform the UNION operation on data of the HLL type in each group to obtain one HLL, and
calculate the number of distinct values:
gaussdb=# SELECT #hll_union_agg(c) AS cardinality FROM t_a_c_hll;
cardinality
-----
498.496062953313
(1 row)
```

#### NOTE

To perform the UNION operation on data in multiple HLLs, ensure that the HLLs have the same precision. Otherwise, **UNION** cannot be performed. This constraint also applies to the **hll\_union(hll, hll)** function.

## Obsolete Functions

Some old HLL functions are discarded due to version upgrade. You can replace them with similar functions.

- `hll_schema_version(hll)`  
Description: Checks the schema version in the current HLL. In earlier versions, the schema version is fixed at **1**, which is used to verify the header of the HLL field. After refactoring, the HLL field is added to the header for verification. The schema version is no longer used.
- `hll_regwidth(hll)`  
Description: Queries the bucket size in the HLL data structure. In earlier versions, the value of **regwidth** ranges from 1 to 5, which has a large error and limits the upper limit of the cardinality estimation. After refactoring, the value of **regwidth** is fixed at **6** and the variable is not used.
- `hll_expthresh(hll)`  
Description: Obtains the value of **expthresh** in the current HLL. The `hll_log2explicit(hll)` function is used to replace similar functions.
- `hll_sparseon(hll)`  
Description: Specifies whether the sparse mode is enabled. Use `hll_log2sparse(hll)` to replace similar functions. The value **0** indicates that the sparse mode is disabled.

## Built-In Functions

HLL has a series of built-in functions for internal data processing. Generally, users do not need to know how to use these functions. For details, see [Table 7-75](#).

**Table 7-75** Built-in functions

| Function                    | Description                                                 |
|-----------------------------|-------------------------------------------------------------|
| <code>hll_in</code>         | Receives HLL data in string format.                         |
| <code>hll_out</code>        | Sends HLL data in string format.                            |
| <code>hll_recv</code>       | Receives HLL data in bytea format.                          |
| <code>hll_send</code>       | Sends HLL data in bytea format.                             |
| <code>hll_trans_in</code>   | Receives <code>hll_trans_type</code> data in string format. |
| <code>hll_trans_out</code>  | Sends <code>hll_trans_type</code> data in string format.    |
| <code>hll_trans_recv</code> | Receives <code>hll_trans_type</code> data in bytea format.  |
| <code>hll_trans_send</code> | Sends <code>hll_trans_type</code> data in bytea format.     |
| <code>hll_typmod_in</code>  | Receives <code>typmod</code> data.                          |
| <code>hll_typmod_out</code> | Sends <code>typmod</code> data.                             |
| <code>hll_hashval_in</code> | Receives <code>hll_hashval</code> data.                     |

| Function          | Description                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hll_hashval_out   | Sends hll_hashval data.                                                                                                                                                   |
| hll_add_trans0    | Works similar to hll_add. No input parameter is specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.      |
| hll_add_trans1    | Works similar to hll_add. An input parameter is specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.      |
| hll_add_trans2    | Works similar to hll_add. Two input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.   |
| hll_add_trans3    | Works similar to hll_add. Three input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations. |
| hll_add_trans4    | Works similar to hll_add. Four input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.  |
| hll_union_trans   | Works similar to hll_union and is used on the first phase of DNs in distributed aggregation operations.                                                                   |
| hll_union_collect | Works similar to hll_union and is used on the second phase of CNs in distributed aggregation operations to summarize the results of each DN.                              |
| hll_pack          | Is used on the third phase of CNs in distributed aggregation operations to convert a user-defined type hll_trans_type to the HLL type.                                    |
| hll               | Converts an HLL type to another HLL type. Input parameters can be specified.                                                                                              |
| hll_hashval       | Converts the bigint type to the hll_hashval type.                                                                                                                         |
| hll_hashval_int4  | Converts the int4 type to the hll_hashval type.                                                                                                                           |

## Operators

- =  
 Description: Compares the values of the HLL or hll\_hashval type to check whether they are the same.  
 Return type: Boolean  
 Example:  

```
--hll
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) = (hll_empty() || hll_hash_integer(1));
column
-----
t
(1 row)
```

```
--hll_hashval
gaussdb=# SELECT hll_hash_integer(1) = hll_hash_integer(1);
?column?
-----
t
(1 row)
```

- <> or !=

Description: Compares the values of the HLL or hll\_hashval type to check whether they are different.

Return type: Boolean

Example:

```
--hll
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) <> (hll_empty() || hll_hash_integer(2));
?column?
-----
t
(1 row)
```

```
--hll_hashval
gaussdb=# SELECT hll_hash_integer(1) <> hll_hash_integer(2);
?column?
-----
t
(1 row)
```

- ||

Description: Represents the functions of hll\_add, hll\_union, and hll\_add\_rev.

Return type: HLL

Example:

```
--hll_add
gaussdb=# SELECT hll_empty() || hll_hash_integer(1);
?column?
-----
\x484c4c08000002002b090000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)
```

```
--hll_add_rev
gaussdb=# SELECT hll_hash_integer(1) || hll_empty();
?column?
-----
\x484c4c08000002002b090000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)
```

```
--hll_union
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) || (hll_empty() || hll_hash_integer(2));
?column?
-----
\x484c4c10002000002b0900000000000000400000000000000b3ccc49320cca1ae3e2921ff133fbaed00
(1 row)
```

- #

Description: Calculates the number of distinct values of an HLL. It works the same as the hll\_cardinality function.

Return type: int

Example:

```
gaussdb=# SELECT #(hll_empty() || hll_hash_integer(1));
?column?
-----
```

```
1  
(1 row)
```

## 7.6.15 SEQUENCE Functions

The sequence functions provide a simple method to ensure security of multiple users for users to obtain sequence values from sequence objects.

- `nextval(regclass)`

Description: Specifies an increasing sequence and returns a new value.

### NOTE

- To avoid blocking of concurrent transactions that obtain numbers from the same sequence, a `nextval` operation is never rolled back; that is, once a value is fetched, it is considered used, even if the transaction that did the `nextval` later aborts. This means that aborted transactions may leave unused "holes" in the sequence of assigned values. Therefore, the GaussDB sequence object cannot be used to obtain "holeless" sequences.
- If the `nextval` function is pushed to DNs, each DN will automatically connect to the GTM and requests the next value. For example, in the **`insert into t1 select xxx`** statement, a column in table **`t1`** needs to call the `nextval` function. If the maximum number of connections on the GTM is 8192, this type of pushed statements occupies too many GTM connections. Therefore, the number of concurrent connections for these statements is limited to 7000 divided by the number of clusterDNs. The other connections are reserved for other statements.

Return type: numeric

The `nextval` function can be called in either of the following ways (In example 2, the ORA syntax is supported. Currently, the sequence name cannot contain a dot.):

```
gaussdb=# CREATE SEQUENCE seqDemo;  
  
-- Example 1:  
gaussdb=# SELECT nextval('seqDemo');  
nextval  
-----  
1  
(1 row)  
  
-- Example 2:  
gaussdb=# SELECT seqDemo.nextval;  
nextval  
-----  
2  
(1 row)  
gaussdb=# DROP SEQUENCE seqDemo;
```

- `currval(regclass)`

Description: Returns the last value of **`nextval`** in the current session. If `nextval` has not been called for the specified sequence in the current session, an error is reported when `currval` is called. By default, **`currval`** is disabled. To enable it, set **`enable_beta_features`** to **`true`**. After **`enable_beta_features`** is set to **`true`**, **`nextval`** will not be pushed down.

Return type: numeric

The `currval` function can be called in either of the following ways (In example 2, the ORA syntax is supported. Currently, the sequence name cannot contain a dot.):

```
gaussdb=# CREATE SEQUENCE seq1;  
gaussdb=# SELECT nextval('seq1');
```

```
gaussdb=# SET enable_beta_features = on;

-- Example 1:
gaussdb=# SELECT currval('seq1');
currval
-----
      1
(1 row)

-- Example 2:
gaussdb=# SELECT seq1.currval seq1;
seq1
-----
      1
(1 row)
gaussdb=# DROP SEQUENCE seq1;
```

- **lastval()**

Returns the last value of **nextval** in the current session. This function is equivalent to **currval**, except that it does not use sequence names as parameters. It fetches the sequence used by **nextval** last time in the current session. If **nextval** has not been called in the current session, an error is reported when **lastval** is called.

By default, **lastval** is disabled. To enable it, set **enable\_beta\_features** or **lastval\_supported** to **true**. After **lastval** is enabled, **nextval()** will not be pushed down.

Return type: numeric

Example:

```
gaussdb=# CREATE SEQUENCE seq1;
gaussdb=# SELECT nextval('seq1');
gaussdb=# SET enable_beta_features = on;
gaussdb=# SELECT lastval();
lastval
-----
      1
(1 row)
gaussdb=# DROP SEQUENCE seq1;
```

- **setval(regclass, bigint)**

Description: Sets the current value of a sequence.

Return type: numeric

Example:

```
gaussdb=# CREATE SEQUENCE seqDemo;
gaussdb=# SELECT nextval('seqDemo');
gaussdb=# SELECT setval('seqDemo',3);
setval
-----
      3
(1 row)
gaussdb=# DROP SEQUENCE seqDemo;
```

- **setval(regclass, numeric, Boolean)**

Sets the current value of a sequence and the **is\_called** sign.

Return type: numeric

Example:

```
gaussdb=# CREATE SEQUENCE seqDemo;
gaussdb=# SELECT nextval('seqDemo');
gaussdb=# SELECT setval('seqDemo',5,true);
setval
-----
```

```
5
(1 row)
gaussdb=# DROP SEQUENCE seqDemo;
```

 **NOTE**

The current session and GTM will take effect immediately after setval is performed. If other sessions have buffered sequence values, setval will take effect only after the values are used up. Therefore, to prevent sequence value conflicts, you are advised to perform setval with caution.

Because the sequence is non-transactional, changes made by setval will not be canceled when a transaction rolled back.

- `pg_sequence_last_value(sequence_oid oid, OUT cache_value int16, OUT last_value int16)`

Description: Obtains the parameters of a specified sequence, including the cache value and current value.

Return type: int16, int16

## 7.6.16 Array Functions and Operators

### Array Operators

- =

Description: Specifies whether two arrays are equal.

Example:

```
gaussdb=# SELECT ARRAY[1,1,2,1,3,1]::int[] = ARRAY[1,2,3] AS RESULT ;
result
-----
t
(1 row)
```

- <>

Description: Specifies whether two arrays are not equal.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] <> ARRAY[1,2,4] AS RESULT;
result
-----
t
(1 row)
```

- <

Description: Specifies whether an array is less than another.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] < ARRAY[1,2,4] AS RESULT;
result
-----
t
(1 row)
```

- >

Description: Specifies whether an array is greater than another.

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] > ARRAY[1,2,4] AS RESULT;
result
-----
t
(1 row)
```

- <=

Description: Specifies whether an array is less than another.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] <= ARRAY[1,2,3] AS RESULT;
result
-----
t
(1 row)
```
- >=

Description: Specifies whether an array is greater than or equal to another.

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] >= ARRAY[1,4,3] AS RESULT;
result
-----
t
(1 row)
```
- @>

Description: Specifies whether an array contains another.

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] @> ARRAY[3,1] AS RESULT;
result
-----
t
(1 row)
```
- <@

Description: Specifies whether an array is contained in another.

Example:

```
gaussdb=# SELECT ARRAY[2,7] <@ ARRAY[1,7,4,2,6] AS RESULT;
result
-----
t
(1 row)
```
- &&

Description: Specifies whether an array overlaps another (have common elements).

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] && ARRAY[2,1] AS RESULT;
result
-----
t
(1 row)
```
- ||

Description: Array-to-array concatenation.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] || ARRAY[4,5,6] AS RESULT;
result
-----
{1,2,3,4,5,6}
(1 row)
gaussdb=# SELECT ARRAY[1,2,3] || ARRAY[[4,5,6],[7,8,9]] AS RESULT;
result
-----
{{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

- ||  
Description: Element-to-array concatenation.

Example:

```
gaussdb=# SELECT 3 || ARRAY[4,5,6] AS RESULT;  
result  
-----  
{3,4,5,6}  
(1 row)
```

- ||  
Description: Array-to-element concatenation.

Example:

```
gaussdb=# SELECT ARRAY[4,5,6] || 7 AS RESULT;  
result  
-----  
{4,5,6,7}  
(1 row)
```

Array comparisons compare the array contents element-by-element, using the default B-tree comparison function for the element data type. In multidimensional arrays, the elements are accessed in row-major order. If the contents of two arrays are equal but the dimensionality is different, the first difference in the dimensionality information determines the sort order.

## Array Functions

- `array_append(anyarray, anyelement)`

Description: Appends an element to the end of an array, and only supports dimension-1 arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_append(ARRAY[1,2], 3) AS RESULT;  
result  
-----  
{1,2,3}  
(1 row)
```

- `array_prepend(anyelement, anyarray)`

Description: Appends an element to the beginning of an array, and only supports dimension-1 arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_prepend(1, ARRAY[2,3]) AS RESULT;  
result  
-----  
{1,2,3}  
(1 row)
```

- `array_cat(anyarray, anyarray)`

Description: Concatenates two arrays, and supports multi-dimensional arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_cat(ARRAY[1,2,3], ARRAY[4,5]) AS RESULT;  
result  
-----  
{1,2,3,4,5}
```

```
(1 row)

gaussdb=# SELECT array_cat(ARRAY[[1,2],[4,5]], ARRAY[6,7]) AS RESULT;
      result
-----
{{1,2},{4,5},{6,7}}
(1 row)
```

- `array_union(anyarray, anyarray)`

Description: Concatenates two arrays. Only one-dimensional arrays are supported. If an input parameter is **NULL**, another input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_union(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
      result
-----
{1,2,3,3,4,5}
(1 row)

gaussdb=# SELECT array_union(ARRAY[1,2,3], NULL) AS RESULT;
      result
-----
{1,2,3}
(1 row)
```

- `array_union_distinct(anyarray, anyarray)`

Description: Concatenates two arrays and deduplicates them. Only one-dimensional arrays are supported. If an input parameter is **NULL**, another input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_union_distinct(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
      result
-----
{1,2,3,4,5}
(1 row)

gaussdb=# SELECT array_union_distinct(ARRAY[1,2,3], NULL) AS RESULT;
      result
-----
{1,2,3}
(1 row)
```

- `array_intersect(anyarray, anyarray)`

Description: Intersects two arrays. Only one-dimensional arrays are supported. If any input parameter is **NULL**, **NULL** is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_intersect(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
      result
-----
{3}
(1 row)

gaussdb=# SELECT array_intersect(ARRAY[1,2,3], NULL) AS RESULT;
      result
-----
(1 row)
```

- `array_intersect_distinct(anyarray, anyarray)`

Description: Intersects two arrays and deduplicates them. Only one-dimensional arrays are supported. If any input parameter is **NULL**, **NULL** is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_intersect_distinct(ARRAY[1,2,2], ARRAY[2,2,4,5]) AS RESULT;
result
-----
{2}
(1 row)

gaussdb=# SELECT array_intersect_distinct(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
(1 row)
```

- `array_except(anyarray, anyarray)`

Description: Calculates the difference between two arrays. Only one-dimensional arrays are supported. If the first input parameter is **NULL**, **NULL** is returned. If the second input parameter is **NULL**, the first input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_except(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
result
-----
{1,2}
(1 row)

gaussdb=# SELECT array_except(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
{1,2,3}
(1 row)

gaussdb=# SELECT array_except(NULL, ARRAY[3,4,5]) AS RESULT;
result
-----
(1 row)
```

- `array_except_distinct(anyarray, anyarray)`

Description: Calculates the difference between two arrays and deduplicates them. Only one-dimensional arrays are supported. If the first input parameter is **NULL**, **NULL** is returned. If the second input parameter is **NULL**, the first input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_except_distinct(ARRAY[1,2,2,3], ARRAY[3,4,5]) AS RESULT;
result
-----
{1,2}
(1 row)

gaussdb=# SELECT array_except_distinct(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
{1,2,3}
```

```
(1 row)
gaussdb=# SELECT array_except_distinct(NULL, ARRAY[3,4,5]) AS RESULT;
result
-----
(1 row)
```

- `array_ndims(anyarray)`

Description: Returns the number of dimensions of an array.

Return type: int

Example:

```
gaussdb=# SELECT array_ndims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
result
-----
      2
(1 row)
```

- `array_dims(anyarray)`

Description: Returns a text representation of array's dimensions.

Return type: text

Example:

```
gaussdb=# SELECT array_dims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
result
-----
[1:2][1:3]
(1 row)
```

- `array_length(anyarray, int)`

Description: Returns the length of the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_length(array[1,2,3], 1) AS RESULT;
result
-----
      3
(1 row)
```

- `array_lower(anyarray, int)`

Description: Returns lower bound of the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_lower('[0:2]={1,2,3}::int[]', 1) AS RESULT;
result
-----
      0
(1 row)
```

- `array_sort(anyarray)`

Description: Returns an array in ascending order. Only one-dimensional array of the anyarray type supports sorting. Multidimensional arrays return **NULL**. Currently, the record, XML, XMLtype, and JSON arrays cannot be sorted.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_sort(ARRAY[5,1,3,6,2,7]) AS RESULT;
result
-----
{1,2,3,5,6,7}
```

```
(1 row)
gaussdb=# SELECT array_sort(array[array[1,23], array[1,34]]);
array_sort
-----
{NULL,NULL}
(1 row)
```

- `array_upper(anyarray, int)`

Description: Returns upper bound of the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_upper(ARRAY[1,8,3,7], 1) AS RESULT;
result
-----
4
(1 row)
```

- `array_to_string(anyarray, text [, text])`

Description: Uses the first **text** as the new delimiter and the second **text** to replace **NULL** values.

Return type: text

Example:

```
gaussdb=# SELECT array_to_string(ARRAY[1, 2, 3, NULL, 5], ',', '*') AS RESULT;
result
-----
1,2,3*,5
(1 row)
```

- `array_delete(anyarray)`

Description: Clears elements in an array and returns an empty array of the same type.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_delete(ARRAY[1,8,3,7]) AS RESULT;
result
-----
{}
(1 row)
```

- `array_deleteidx(anyarray, int)`

Description: Deletes specified index elements from an array and returns an array consisting of the remaining elements.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_deleteidx(ARRAY[1,2,3,4,5], 1) AS RESULT;
result
-----
{2,3,4,5}
(1 row)
```

#### NOTE

**array\_deleteidx(anyarray, int)**: This function is disabled when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1**.

- `array_extendnull(anyarray, int)`

Description: Adds a specified number of null elements to the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_extendnull(ARRAY[1,8,3,7],1) AS RESULT;
result
-----
{1,8,3,7,null}
(1 row)
```

- `array_extendnull(anyarray, int, int)`

Description: Adds a specified number of elements with a specified index to the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_extendnull(ARRAY[1,8,3,7],2,2) AS RESULT;
result
-----
{1,8,3,7,8,8}
(1 row)
```

 **NOTE**

**array\_extendnull(anyarray, int, int):** This function takes effect when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1**.

- `array_trim(anyarray, int)`

Description: Deletes a specified number of elements from the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_trim(ARRAY[1,8,3,7],1) AS RESULT;
result
-----
{1,8,3}
(1 row)
```

- `array_exists(anyarray, int)`

Description: Checks whether the second parameter is a valid index of an array.

Return type: Boolean

Example:

```
gaussdb=# SELECT array_exists(ARRAY[1,8,3,7],1) AS RESULT;
result
-----
t
(1 row)
```

- `array_next(anyarray, int)`

Description: Returns the index of the element following a specified index in an array based on the second input parameter.

Return type: int

Example:

```
gaussdb=# SELECT array_next(ARRAY[1,8,3,7],1) AS RESULT;
result
-----
2
(1 row)
```

- `array_prior(anyarray, int)`

Description: Returns the index of the element followed by a specified index in an array based on the second input parameter.

Return type: int

Example:

```
gaussdb=# SELECT array_prior(ARRAY[1,8,3,7],2) AS RESULT;
result
-----
1
(1 row)
```

- `string_to_array(text, text, [text])`

Description: Uses the second **text** as the new delimiter and the third **text** as the substring to be replaced by **NULL** values. A substring can be replaced by **NULL** values only when it is the same as the third **text**.

Return type: `text[]`

Example:

```
gaussdb=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'yy') AS RESULT;
result
-----
{xx,NULL,zz}
(1 row)
gaussdb=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'y') AS RESULT;
result
-----
{xx,yy,zz}
(1 row)
```

In **string\_to\_array**, if the delimiter parameter is **NULL**, each character in the input string will become a separate element in the resulting array. If the delimiter is an empty string, then the entire input string is returned as a one-element array. Otherwise, the input string is split at each occurrence of the delimiter string.

In **string\_to\_array**, if the null-string parameter is omitted or **NULL**, none of the substrings of the input will be replaced by **NULL**.

In **array\_to\_string**, if the null-string parameter is omitted or **NULL**, any null elements in the array are simply skipped and not represented in the output string.

- `unnest(anyarray)`

Description: Expands an array to a set of rows.

Return type: `setof anyelement`

Example:

```
gaussdb=# SELECT unnest(ARRAY[1,2]) AS RESULT;
result
-----
1
2
(2 rows)
```

- `_pg_keysequal`

Description: Checks whether two smallint arrays are the same.

Parameter: `smallint[], smallint[]`

Return type: Boolean

 **NOTE**

This function exists in the `information_schema` namespace.

- `cardinality(anyarray)`

Description: Returns the total number of elements in each dimension of an array. If the array is empty, **0** is returned.

Return type: integer

Example:

```
gaussdb=# SELECT cardinality(array[[1, 2], [3, 4]]);
cardinality
-----
4
(1 row)
```

- `array_positions(anyarray, anyelement)`

Description: Returns an array of indexes of all second parameters that appear in the array given as the first parameter.

Return type: `int[]`

Example:

```
gaussdb=# SELECT array_positions(array[1, 2, 3, 1], 1) AS RESULT;
result
-----
{1,4}
(1 row)
```

 **NOTE**

- The array must be one-dimensional.
- The second parameter can be set to **NULL**.
- If no second parameter is found in the array, an empty array is returned.

## 7.6.17 Range Functions and Operators

### Range Operators

- =

Description: Equals

Example:

```
gaussdb=# SELECT int4range(1,5) = '[1,4]::int4range AS RESULT;
result
-----
t
(1 row)
```

- <>

Description: Does not equal

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) <> numrange(1.1,2.3) AS RESULT;
result
-----
t
(1 row)
```

- <

Description: Is less than

Example:

```
gaussdb=# SELECT int4range(1,10) < int4range(2,3) AS RESULT;
result
-----
t
(1 row)
```

- >

Description: Is greater than

Example:

```
gaussdb=# SELECT int4range(1,10) > int4range(1,5) AS RESULT;  
result  
-----  
t  
(1 row)
```

- <=

Description: Is less than or equals

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) <= numrange(1.1,2.2) AS RESULT;  
result  
-----  
t  
(1 row)
```

- >=

Description: Is greater than or equals

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) >= numrange(1.1,2.0) AS RESULT;  
result  
-----  
t  
(1 row)
```

- @>

Description: Contains range

Example:

```
gaussdb=# SELECT int4range(2,4) @> int4range(2,3) AS RESULT;  
result  
-----  
t  
(1 row)
```

- @>

Description: Contains element

Example:

```
gaussdb=# SELECT '[2011-01-01,2011-03-01)::tsrange @> '2011-01-10)::timestamp AS RESULT;  
result  
-----  
t  
(1 row)
```

- <@

Description: Range is contained by

Example:

```
gaussdb=# SELECT int4range(2,4) <@ int4range(1,7) AS RESULT;  
result  
-----  
t  
(1 row)
```

- <@

Description: Element is contained by

Example:

```
gaussdb=# SELECT 42 <@ int4range(1,7) AS RESULT;  
result  
-----
```

- ```
f
(1 row)
```

  - **&&**  
Description: Overlap (have points in common)  
Example:  

```
gaussdb=# SELECT int8range(3,7) && int8range(4,12) AS RESULT;
result
-----
t
(1 row)
```
  - **<<**  
Description: Strictly left of  
Example:  

```
gaussdb=# SELECT int8range(1,10) << int8range(100,110) AS RESULT;
result
-----
t
(1 row)
```
  - **>>**  
Description: Strictly right of  
Example:  

```
gaussdb=# SELECT int8range(50,60) >> int8range(20,30) AS RESULT;
result
-----
t
(1 row)
```
  - **&<**  
Description: Does not extend to the right of  
Example:  

```
gaussdb=# SELECT int8range(1,20) &< int8range(18,20) AS RESULT;
result
-----
t
(1 row)
```
  - **&>**  
Description: Does not extend to the left of  
Example:  

```
gaussdb=# SELECT int8range(7,20) &> int8range(5,10) AS RESULT;
result
-----
t
(1 row)
```
  - **-|-**  
Description: Is adjacent to  
Example:  

```
gaussdb=# SELECT numrange(1.1,2.2) -|- numrange(2.2,3.3) AS RESULT;
result
-----
t
(1 row)
```
  - **+**  
Description: Union  
Example:

```
gaussdb=# SELECT numrange(5,15) + numrange(10,20) AS RESULT;
result
-----
[5,20)
(1 row)
```

- \*

Description: Intersection

Example:

```
gaussdb=# SELECT int8range(5,15) * int8range(10,20) AS RESULT;
result
-----
[10,15)
(1 row)
```

- -

Description: Difference

Example:

```
gaussdb=# SELECT int8range(5,15) - int8range(10,20) AS RESULT;
result
-----
[5,10)
(1 row)
```

The simple comparison operators `<`, `>`, `<=`, and `>=` compare the lower bounds first, and only if those are equal, compare the upper bounds.

The `<<`, `>>`, and `-|-` operators always return false when an empty range is involved; that is, an empty range is not considered to be either before or after any other range.

The union and difference operators will fail if the resulting range would need to contain two disjoint sub-ranges.

## Range Functions

The lower and upper functions return null if the range is empty or the requested bound is infinite. The `lower_inc`, `upper_inc`, `lower_inf`, and `upper_inf` functions all return false for an empty range.

- `numrange(numeric, numeric, [text])`

Description: Specifies a range.

Return type: range's element type

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) AS RESULT;
result
-----
[1.1,2.2)
(1 row)
gaussdb=# SELECT numrange(1.1,2.2, '(') AS RESULT;
result
-----
(1.1,2.2)
(1 row)
```

- `lower(anyrange)`

Description: Lower bound of range

Return type: range's element type

Example:

```
gaussdb=# SELECT lower(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
1.1  
(1 row)
```

- **upper(anyrange)**  
Description: Upper bound of range  
Return type: range's element type  
Example:

```
gaussdb=# SELECT upper(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
2.2  
(1 row)
```

- **isempty(anyrange)**  
Description: Is the range empty?  
Return type: Boolean  
Example:

```
gaussdb=# SELECT isempty(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
f  
(1 row)
```

- **lower\_inc(anyrange)**  
Description: Is the lower bound inclusive?  
Return type: Boolean  
Example:

```
gaussdb=# SELECT lower_inc(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
t  
(1 row)
```

- **upper\_inc(anyrange)**  
Description: Is the upper bound inclusive?  
Return type: Boolean  
Example:

```
gaussdb=# SELECT upper_inc(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
f  
(1 row)
```

- **lower\_inf(anyrange)**  
Description: Is the lower bound infinite?  
Return type: Boolean  
Example:

```
gaussdb=# SELECT lower_inf('(,):daterange) AS RESULT;  
result  
-----  
t  
(1 row)
```

- **upper\_inf(anyrange)**  
Description: Is the upper bound infinite?

Return type: Boolean

Example:

```
gaussdb=# SELECT upper_inf('::daterange') AS RESULT;
result
-----
t
(1 row)
```

- `elem_contained_by_range(anyelement, anyrange)`

Description: Determines whether an element is within the range.

Return type: Boolean

Example:

```
gaussdb=# SELECT elem_contained_by_range('2', numrange(1.1,2.2));
elem_contained_by_range
-----
t
(1 row)
```

## 7.6.18 Aggregate Functions

### Aggregate Functions

- `sum(expression)`

Description: Sum of expression across all input values

Return type:

Generally, same as the argument data type. In the following cases, type conversion occurs:

- BIGINT for SMALLINT or INT arguments
- NUMBER for BIGINT arguments
- DOUBLE PRECISION for floating-point arguments

Example:

```
gaussdb=# CREATE TABLE tab(a int);
CREATE TABLE
gaussdb=# INSERT INTO tab values(1);
INSERT 0 1
gaussdb=# INSERT INTO tab values(2);
INSERT 0 1
gaussdb=# SELECT sum(a) FROM tab;
sum
----
3
(1 row)
gaussdb=# DROP TABLE tab;
```

- `max(expression)`

Description: Specifies the maximum value of expression across all input values.

Parameter type: any array, numeric, string, or date/time type

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE max_t1(a int, b int);
gaussdb=# INSERT INTO max_t1 VALUES(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT MAX(a) FROM max_t1;
```

```
max
-----
4
(1 row)
```

```
gaussdb=# DROP TABLE max_t1;
```

- **min(expression)**

Description: Minimum value of expression across all input values

Parameter type: any array, numeric, string, or date/time type

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE min_t1(a int, b int);
```

```
gaussdb=# INSERT INTO min_t1 VALUES(1,2),(2,3),(3,4),(4,5);
```

```
gaussdb=# SELECT MIN(a) FROM min_t1;
```

```
min
-----
1
(1 row)
```

```
gaussdb=# DROP TABLE min_t1;
```

- **avg(expression)**

Description: Average (arithmetic mean) of all input values

Return type:

NUMBER for any integer-type argument.

DOUBLE PRECISION for floating-point parameters.

otherwise the same as the argument data type.

Example:

```
gaussdb=# CREATE TABLE avg_t1(a int, b int);
```

```
gaussdb=# INSERT INTO avg_t1 VALUES(1,2),(2,3),(3,4),(4,5);
```

```
gaussdb=# SELECT AVG(a) FROM avg_t1;
```

```
avg
-----
2.5000000000000000
(1 row)
```

```
gaussdb=# DROP TABLE avg_t1;
```

- **count(expression)**

Description: Returns the number of input rows for which the value of expression is not null.

Return type: bigint

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE count_t1(a int, b int);
```

```
gaussdb=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
```

```
gaussdb=# SELECT COUNT(a) FROM count_t1;
```

```
count
-----
4
(1 row)
```

```
gaussdb=# DROP TABLE count_t1;
```

- **count(\*)**

Description: Returns the number of input rows.

Return type: bigint

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE count_t1(a int, b int);
gaussdb=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT COUNT(*) FROM count_t1;
count
-----
      5
(1 row)
gaussdb=# DROP TABLE count_t1;
```

- **default(column\_name)**

Description: Obtains the default value of a table column.

Return type: text

Example:

```
-- Create a MySQL-compatible database.
gaussdb=# CREATE DATABASE gaussdb_m WITH DBCOMPATIBILITY 'MYSQL';
gaussdb=# \c gaussdb_m
gaussdb_m=# CREATE TABLE t1(id int DEFAULT 100, name varchar(20) DEFAULT 'tt');
gaussdb_m=# INSERT INTO t1 VALUES(1,'test');
-- Execute the query.
gaussdb_m=# SELECT default(id), default(name) FROM t1;
default | default
-----+-----
      100 | tt
(1 row)
-- Delete the database.
gaussdb_m=# \c postgres
gaussdb=# DROP DATABASE gaussdb_m;
```

 **NOTE**

- The default function takes effect only when **sql\_compatibility** is set to 'MYSQL'.
- If a table column does not have a default value, the default function returns a null value.
- If a table column is a hidden column (such as **xmin** or **cmin**), the default function returns a null value.
- If a table column is an auto-increment column, the default function returns **0**.
- GaussDB supports default values of partitioned tables, temporary tables, and multi-table join query.
- GaussDB supports the query of nodes whose column names contain character string values (indicating names) and A\_Star nodes (indicating that asterisks (\*) appear), for example, **default(tt.t4.id)** and **default(tt.t4.\*)**.
- When the default value of a column is created in GaussDB, the range of the column type is not verified. As a result, an error may be reported when the default function is used.
- If the default value of a column is a function expression, the default function in GaussDB returns the calculated value of the default expression of the column during table creation.

- **array\_agg(expression)**

Description: Input values, including nulls, concatenated into an array

Return type: array of the parameter type

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE array_agg_t1(a int, b int);
gaussdb=# INSERT INTO array_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT ARRAY_AGG(a) FROM array_agg_t1;
array_agg
-----
{NULL,1,2,3,4}
(1 row)

gaussdb=# DROP TABLE array_agg_t1;
```

- **string\_agg(expression, delimiter)**

Description: Input values concatenated into a string, separated by delimiter

Return type: same as the parameter data type.

Operations on XML data that is explicitly converted to the character type are supported.

Example:

```
gaussdb=# CREATE TABLE string_agg_t1(a int, b int);
gaussdb=# INSERT INTO string_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT STRING_AGG(a,;) FROM string_agg_t1;
string_agg
-----
1;2;3;4
(1 row)

gaussdb=# DROP TABLE string_agg_t1;
```

- **listagg(expression [, delimiter]) WITHIN GROUP(ORDER BY order-list)**

Description: Aggregation column data sorted according to the mode specified by WITHIN GROUP, and concatenated to a string using the specified delimiter

- **expression:** Required. It specifies an aggregation column name or a column-based, valid expression. It does not support the DISTINCT keyword and the parameters of VARIADIC.
- **delimiter:** Optional. It specifies a delimiter, which can be a string constant or a deterministic expression based on a group of columns. The default value is empty.
- **order-list:** Required. It specifies the sorting mode in a group.

Return type: text

 **NOTE**

listagg is a column-to-row aggregate function, compatible with Oracle Database 11g Release 2. You can specify the OVER clause as a window function. When listagg is used as a window function, the OVER clause does not support the window sorting or framework of ORDER BY, to avoid ambiguity in listagg and ORDER BY of the WITHIN GROUP clause.

Example:

The aggregation column is of the text character set type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b text);
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'a1'),(1,'b2'),(1,'c3'),(2,'d4'),(2,'e5'),(3,'f6');
gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
-----+-----
1 | b2;c3
2 | d4;e5
3 | f6
  | a1
(4 rows)

gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the integer type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b int);
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
-----+-----
1 | 2;3
2 | 4;5
3 | 6
  | 1
(4 rows)

gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the floating point type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b float);
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,1.111),(1,2.222),(1,3.333),(2,4.444),(2,5.555),
(3,6.666);
gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
-----+-----
1 | 2.222000;3.333000
2 | 4.444000;5.555000
3 | 6.666000
  | 1.111000
(4 rows)
```

```
gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the time type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b timestamp);
```

```
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'2000-01-01'),(1,'2000-02-02'),(1,'2000-03-03'),
(2,'2000-04-04'),(2,'2000-05-05'),(3,'2000-06-06');
```

```
gaussdb=# SELECT a,LISTAGG(b,;) WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
```

```
a | listagg
-----+-----
1 | 2000-02-02 00:00:00;2000-03-03 00:00:00
2 | 2000-04-04 00:00:00;2000-05-05 00:00:00
3 | 2000-06-06 00:00:00
   | 2000-01-01 00:00:00
(4 rows)
```

```
gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the time interval type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');
```

```
gaussdb=# SELECT a,LISTAGG(b,;) WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
```

```
a | listagg
-----+-----
1 | 2 days;3 days
2 | 4 days;5 days
3 | 6 days
   | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE listagg_t1;
```

By default, the delimiter is empty.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');
```

```
gaussdb=# SELECT a,LISTAGG(b) WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
```

```
a | listagg
-----+-----
1 | 2 days3 days
2 | 4 days5 days
3 | 6 days
   | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE listagg_t1;
```

When listagg is used as a window function, the OVER clause does not support the window sorting of ORDER BY, and the listagg column is an ordered aggregation of the corresponding groups.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');
```

```
gaussdb=# SELECT a,LISTAGG(b) WITHIN GROUP(ORDER BY b) OVER(PARTITION BY a) FROM
listagg_t1;
```

```
a | listagg
-----+-----
1 | 2 days3 days
1 | 2 days3 days
2 | 4 days5 days
```

```
2 | 4 days5 days
3 | 6 days
  | 1 day
(6 rows)
```

```
gaussdb=# DROP TABLE listagg_t1;
```

- `group_concat`([**DISTINCT** | **ALL**] expression [,expression ...] [**ORDER BY** { expression [ [ **ASC** | **DESC** | **USING** operator ] | `nlssort_expression_clause` ] [ **NULLS** { **FIRST** | **LAST** } ] } [,...]) [**SEPARATOR** str\_val])

Description: The number of parameters is not fixed. Multiple columns can be concatenated. Aggregation columns are sorted based on the value of **ORDER BY** and concatenated into a character string using the specified separator. This function cannot be used as a window function.

- **DISTINCT**: Optional. It deduplicates the results after each row is concatenated.
- **expression**: Required. It specifies the aggregation column name or a valid column-based expression.
- **ORDER BY**: Optional. It is followed by a variable number of expressions and sorting rule. The `group_concat` function does not support the (**ORDER BY** + number) format.
- **SEPARATOR**: Optional. It is followed by a character or string. This separator is used to concatenate the expression results of two adjacent lines in a group. If it is not specified, the comma (,) is used by default.
- When both **DISTINCT** and **ORDER BY** are specified, all **ORDER BY** expressions must be in **DISTINCT** expressions. Otherwise, an error is reported.

Return type: text

Example:

Set **separator** to ';':

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b int);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT a,group_concat(b separator ';') FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
-----+-----
1 | 2;3
2 | 4;5
3 | 6
  | 1
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

By default, the separator is a comma (,).

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b int);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT a,group_concat(a,b) FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
-----+-----
1 | 12,13
2 | 24,25
3 | 36
  |
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the text character set type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b text);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'a1'),(1,'b2'),(1,'c3'),(2,'d4'),(2,'e5'),(3,'f6');
gaussdb=# SELECT a,group_concat(a,b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | 1b2,1c3
2 | 2d4,2e5
3 | 3f6
|
(4 rows)
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the integer type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b int);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | 2,3
2 | 4,5
3 | 6
| 1
(4 rows)
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the floating point type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b float);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1.11),(1,2.22),(1,3.33),(2,4.44),(2,5.55),
(3,6.66);
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | 3,2,2,3
2 | 6,4,5,4
3 | 7,6
| 1,1
(4 rows)
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the time type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b timestamp);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'2000-01-01'),(1,'2000-02-02'),
(1,'2000-03-03'),(2,'2000-04-04'),(2,'2000-05-05'),(3,'2000-06-06');
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | 2000-02-02 00:00:00,2000-03-03 00:00:00
2 | 2000-04-04 00:00:00,2000-05-05 00:00:00
3 | 2000-06-06 00:00:00
| 2000-01-01 00:00:00
(4 rows)
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the binary type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b bytea);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1'),(1,'2'),(1,'3'),(2,'4'),(2,'5'),(3,'6');
```

```
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
-----+-----
1 | \x32,\x33
2 | \x34,\x35
3 | \x36
  | \x31
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the time interval type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),
(2,'5 days'),(3,'6 days');
```

```
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
-----+-----
1 | 2 days,3 days
2 | 4 days,5 days
3 | 6 days
  | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

Set **distinct** to deduplicate data.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'2 days'),(1,'3 days'),
(1,'3 days'),(2,'4 days'),(2,'5 days'),(3,'6 days');
```

```
gaussdb=# SELECT a,group_concat(distinct b) FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
-----+-----
1 | 2 days,3 days
2 | 4 days,5 days
3 | 6 days
  | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

Set **ORDER BY** to sort data.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),
(2,'5 days'),(3,'6 days');
```

```
gaussdb=# SELECT a,group_concat(b ORDER BY b desc) FROM group_concat_t1 GROUP BY a ORDER
BY a;
```

```
a | group_concat
-----+-----
1 | 3 days,2 days
2 | 5 days,4 days
3 | 6 days
  | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

- **wm\_concat(expression)**

Description: Concatenates column data into a string separated by commas (,).

Return type: same as the parameter data type.

 NOTE

**wm\_concat** is an ORA compatibility requirement. Currently, this function has been canceled in the latest ORA version and replaced by the listagg function. You can also use the string\_agg function. For details, see the description of the two functions.

- covar\_pop(Y, X)

Description: Overall covariance

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE covar_pop_t1(a int, b int);
gaussdb=# INSERT INTO covar_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT COVAR_POP(a,b) FROM covar_pop_t1;
 covar_pop
-----
      100
(1 row)
gaussdb=# DROP TABLE covar_pop_t1;
```

- covar\_samp(Y, X)

Description: Sample covariance

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE covar_samp_t1(a int, b int);
gaussdb=# INSERT INTO covar_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT COVAR_SAMP(a,b) FROM covar_samp_t1;
 covar_samp
-----
      125
(1 row)
gaussdb=# DROP TABLE covar_samp_t1;
```

- stddev\_pop(expression)

Description: Overall standard difference

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE stddev_pop_t1(a int, b int);
gaussdb=# INSERT INTO stddev_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT STDDEV_POP(a) FROM stddev_pop_t1;
 stddev_pop
-----
7.4833147735478828
(1 row)
gaussdb=# DROP TABLE stddev_pop_t1;
```

- stddev\_samp(expression)

Description: Sample standard deviation of the input values

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE stddev_samp_t1(a int, b int);
gaussdb=# INSERT INTO stddev_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT STDDEV_SAMP(a) FROM stddev_samp_t1;
      stddev_samp
-----
8.3666002653407555
(1 row)
gaussdb=# DROP TABLE stddev_samp_t1;
```

- **var\_pop(expression)**

Description: Specifies the population variance of the input values (square of the population standard deviation).

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE var_pop_t1(a int, b int);
gaussdb=# INSERT INTO var_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT VAR_POP(a) FROM var_pop_t1;
      var_pop
-----
56.0000000000000000
(1 row)
gaussdb=# DROP TABLE var_pop_t1;
```

- **var\_samp(expression)**

Description: Specifies the sample variance of the input values (square of the sample standard deviation).

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE var_samp_t1(a int, b int);
gaussdb=# INSERT INTO var_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT VAR_SAMP(a) FROM var_samp_t1;
      var_samp
-----
70.0000000000000000
(1 row)
gaussdb=# DROP TABLE var_samp_t1;
```

- **bit\_and(expression)**

Description: The bitwise AND of all non-null input values, or null if none

Return type: same as the parameter data type.

Example:

```
gaussdb=# CREATE TABLE bit_and_t1(a int, b int);
gaussdb=# INSERT INTO bit_and_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT BIT_AND(a) FROM bit_and_t1;
      bit_and
-----
0
(1 row)
```

```
gaussdb=# DROP TABLE bit_and_t1;
```

- **bit\_or(expression)**

Description: The bitwise OR of all non-null input values, or null if none

Return type: same as the parameter data type.

Example:

```
gaussdb=# CREATE TABLE bit_or_t1(a int, b int);
```

```
gaussdb=# INSERT INTO bit_or_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT BIT_OR(a) FROM bit_or_t1;
```

```
bit_or
-----
      3
(1 row)
```

```
gaussdb=# DROP TABLE bit_or_t1;
```

- **bool\_and(expression)**

Description: Its value is **true** if all input values are **true**, otherwise **false**.

Return type: Boolean

Example:

```
gaussdb=# SELECT bool_and(100 <2500);
```

```
bool_and
-----
      t
(1 row)
```

- **bool\_or(expression)**

Description: Its value is **true** if at least one input value is **true**, otherwise **false**.

Return type: Boolean

Example:

```
gaussdb=# SELECT bool_or(100 <2500);
```

```
bool_or
-----
      t
(1 row)
```

- **corr(Y, X)**

Description: Specifies the correlation coefficient.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE corr_t1(a int, b int);
```

```
gaussdb=# INSERT INTO corr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT CORR(a,b) FROM corr_t1;
```

```
corr
-----
.944911182523068
(1 row)
```

```
gaussdb=# DROP TABLE corr_t1;
```

- **every(expression)**

Description: Equivalent to **bool\_and**

Return type: Boolean

Example:

```
gaussdb=# SELECT every(100 <2500);
every
-----
t
(1 row)
```

- **rank(expression)**

Description: The tuples in different groups are sorted non-consecutively by **expression**.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE rank_t1(a int, b int);
gaussdb=# INSERT INTO rank_t1 VALUES(NULL,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,RANK() OVER(PARTITION BY a ORDER BY b) FROM rank_t1;
a | b | rank
---+---+-----
1 | 2 | 1
1 | 3 | 2
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
| 1 | 1
(6 rows)
gaussdb=# DROP TABLE rank_t1;
```

- **regr\_avgx(Y, X)**

Description: Specifies the average of the independent variable (**sum(X)/Y**).

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_t1(a int, b int);
gaussdb=# INSERT INTO regr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_AVGX(a,b) FROM regr_t1;
regr_avgx
-----
4
(1 row)
gaussdb=# DROP TABLE regr_t1;
```

- **regr\_avgy(Y, X)**

Description: Specifies the average of the dependent variable (**sum(Y)/X**).

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_avgy_t1(a int, b int);
gaussdb=# INSERT INTO regr_avgy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_AVGY(a,b) FROM regr_avgy_t1;
regr_avgy
-----
1.8
(1 row)
gaussdb=# DROP TABLE regr_avgy_t1;
```

- **regr\_count(Y, X)**

Description: Specifies the number of input rows in which both expressions are non-null.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE regr_count_t1(a int, b int);
gaussdb=# INSERT INTO regr_count_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_COUNT(a,b) FROM regr_count_t1;
regr_count
-----
          5
(1 row)
gaussdb=# DROP TABLE regr_count_t1;
```

- **regr\_intercept(Y, X)**

Description: y-intercept of the least-squares-fit linear equation determined by the (X, Y) pairs

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_intercept_t1(a int, b int);
gaussdb=# INSERT INTO regr_intercept_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_INTERCEPT(b,a) FROM regr_intercept_t1;
regr_intercept
-----
.785714285714286
(1 row)
gaussdb=# DROP TABLE regr_intercept_t1;
```

- **regr\_r2(Y, X)**

Description: Specifies the square of the correlation coefficient.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_r2_t1(a int, b int);
gaussdb=# INSERT INTO regr_r2_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_R2(b,a) FROM regr_r2_t1;
regr_r2
-----
.892857142857143
(1 row)
gaussdb=# DROP TABLE regr_r2_t1;
```

- **regr\_slope(Y, X)**

Description: Slope of the least-squares-fit linear equation determined by the (X, Y) pairs

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_slope_t1(a int, b int);
gaussdb=# INSERT INTO regr_slope_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_SLOPE(b,a) FROM regr_slope_t1;
regr_slope
```

```
-----
1.78571428571429
(1 row)
```

```
gaussdb=# DROP TABLE regr_slope_t1;
```

- **regr\_sxx(Y, X)**

Description:  **$\sum(Y^2) - \sum(X)^2/N$**  (sum of squares of the independent variables)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_sxx_t1(a int, b int);
```

```
gaussdb=# INSERT INTO regr_sxx_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT REGR_SXX(b,a) FROM regr_sxx_t1;
regr_sxx
```

```
-----
2.8
(1 row)
```

```
gaussdb=# DROP TABLE regr_sxx_t1;
```

- **regr\_sxy(Y, X)**

Description:  **$\sum(X*Y) - \sum(X) * \sum(Y)/N$**  (sum of products of independent times dependent variable)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_sxy_t1(a int, b int);
```

```
gaussdb=# INSERT INTO regr_sxy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT REGR_SXY(b,a) FROM regr_sxy_t1;
regr_sxy
```

```
-----
5
(1 row)
```

```
gaussdb=# DROP TABLE regr_sxy_t1;
```

- **regr\_syy(Y, X)**

Description:  **$\sum(Y^2) - \sum(X)^2/N$**  ("sum of squares" of the dependent variable)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_syy_t1(a int, b int);
```

```
gaussdb=# INSERT INTO regr_syy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT REGR_SYY(b,a) FROM regr_syy_t1;
regr_syy
```

```
-----
10
(1 row)
```

```
gaussdb=# DROP TABLE regr_syy_t1;
```

- **stddev(expression)**

Description: Alias of **stddev\_samp**

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

**Example:**

```
gaussdb=# CREATE TABLE stddev_t1(a int, b int);
gaussdb=# INSERT INTO stddev_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT STDDEV(a) FROM stddev_t1;
         stddev
-----
.83666002653407554798
(1 row)
gaussdb=# DROP TABLE stddev_t1;
```

- **variance(expression,ression)**

Description: Alias of **var\_samp**

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

**Example:**

```
gaussdb=# CREATE TABLE variance_t1(a int, b int);
gaussdb=# INSERT INTO variance_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT VARIANCE(a) FROM variance_t1;
         variance
-----
.70000000000000000000000000000000
(1 row)
gaussdb=# DROP TABLE variance_t1;
```

- **spread()**

Description: Calculates the difference between the maximum value and minimum value in a certain period.

Parameter: **real**

Return type: real

- **pivot\_func(anelement)**

Description: Returns the only non-null value in a column. If there are two or more non-null values, an error is reported. **value** is an input parameter and can be of any type.

Return type: same as the input parameter type

**NOTE**

This aggregate function is mainly used inside the pivot syntax.

```
gaussdb=# CREATE TABLE pivot_func_t1(a int, b int);
gaussdb=# INSERT INTO pivot_func_t1 VALUES (NULL,11),(1,2);
gaussdb=# SELECT PIVOT_FUNC(a) FROM pivot_func_t1;
         pivot_func
-----
1
(1 row)
gaussdb=# DROP TABLE pivot_func_t1;
```

- **checksum(expression)**

Description: Returns the CHECKSUM value of all input values. This function can be used to check whether the data in the tables is the same before and after the backup, restoration, or migration of the GaussDB database

(databases other than GaussDB are not supported). Before and after database backup, database restoration, or data migration, you need to manually run SQL commands to obtain the execution results. Compare the obtained execution results to check whether the data in the tables before and after the backup or migration is the same.

#### NOTE

- For large tables, the execution of CHECKSUM function may take a long time.
  - If the CHECKSUM values of two tables are different, it indicates that the contents of the two tables are different. Using the hash function in the CHECKSUM function may incur conflicts. There is low possibility that two tables with different contents may have the same CHECKSUM value. The same problem may occur when CHECKSUM is used for columns.
  - If the time type is timestamp, timestamptz, or smalldatetime, ensure that the time zone settings are the same when calculating the CHECKSUM value.
- If the CHECKSUM value of a column is calculated and the column type can be changed to TEXT by default, set *expression* to the column name.
  - If the CHECKSUM value of a column is calculated and the column type cannot be converted to TEXT by default, set *expression* to *Column name::TEXT*.
  - If the CHECKSUM value of all columns is calculated, set *expression* to *Table name::TEXT*.

The following types of data can be converted into the TEXT type by default: char, name, int8, int2, int1, int4, raw, pg\_node\_tree, float4, float8, bpchar, varchar, nvarchar2, date, timestamp, timestamptz, numeric, and smalldatetime. Other types (for example, XML) need to be forcibly converted to TEXT.

Return type: numeric

Example:

The following shows the CHECKSUM value of a column that can be converted to the TEXT type by default:

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(a) FROM checksum_t1;
checksum
-----
18126842830
(1 row)

gaussdb=# DROP TABLE checksum_t1;
```

The following shows the CHECKSUM value of a column that cannot be converted to the TEXT type by default. Note that the CHECKSUM parameter is set to *Column name::TEXT*.

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(a::TEXT) FROM checksum_t1;
checksum
-----
18126842830
(1 row)

gaussdb=# DROP TABLE checksum_t1;
```

The following shows the CHECKSUM value of all columns in a table. Note that the CHECKSUM parameter is set to *Table name::TEXT*. The table name is not modified by its schema.

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(checksum_t1::TEXT) FROM checksum_t1;
checksum
-----
1116052226
(1 row)
gaussdb=# DROP TABLE checksum_t1;
```

## Aggregate Function Nesting

Description: Performs another aggregate function operation on the grouping calculation result of the aggregate function.

Generally, it can be described as follows:

```
SELECT AGG1(AGG2(column_name1)) FROM table_name GROUP BY column_name2;
```

It is equivalent to:

```
SELECT AGG1(value) FROM (SELECT AGG2(column_name1) value FROM table_name GROUP BY column_name2);
```

In the preceding information:

- **AGG1()**: outer aggregate function.
- **AGG2()**: inner aggregate function.
- **table\_name**: table name.
- **column\_name1** and **column\_name2**: column names.
- **value**: alias of the result of the inner aggregate function.

The overall meaning can be described as follows: The grouping calculation result of the inner aggregate function AGG2() is used as the input of the outer aggregate function AGG1() for recalculation.

### NOTE

1. The nested aggregate function is located between SELECT and FROM. Otherwise, it is meaningless.
2. The SELECT statement that uses a nested aggregate function contains a GROUP BY clause.
3. Only the nested aggregate functions or constant expressions can be selected together with another nested aggregate function.
4. The aggregate function supports only one nesting operation.
5. Currently, the following aggregate functions can be nested: avg, max, min, sum, var\_pop, var\_samp, variance, stddev\_pop, stddev\_samp, stddev, median, regr\_sxx, regr\_syy, regr\_sxy, regr\_avgx, regr\_avgy, regr\_r2, regr\_slope, regr\_intercept, covar\_pop, covar\_samp, corr, and listagg.
6. The return type of the inner aggregate function must comply with the parameter type of the outer aggregate function.

Example:

```
gaussdb=# CREATE TABLE test1 (id INT,val INT);
CREATE TABLE
gaussdb=# INSERT INTO test1 VALUES (1, 1);
INSERT 0 1
gaussdb=# INSERT INTO test1 VALUES (1, null);
INSERT 0 1
gaussdb=# INSERT INTO test1 VALUES (2, 10);
INSERT 0 1
gaussdb=# INSERT INTO test1 VALUES (2, 55);
INSERT 0 1

gaussdb=# SELECT SUM(MIN(val)) FROM test1 GROUP BY id;
 sum
-----
  11
(1 row)

gaussdb=# DROP TABLE test1;
DROP TABLE
```

## 7.6.19 Window Functions

### Window Functions

This statement is used together with the window function. The OVER clause is used for grouping data and sorting the elements in a group. Window functions are used for generating sequence numbers for the values in the group.

#### NOTE

**order by** in a window function must be followed by a column name. If it is followed by a number, the number is processed as a constant value and the target column is not ranked.

If a parent query contains filter criteria of a window function in a subquery, the filter criteria in the parent query can be pushed down to the subquery.

---

#### CAUTION

1. Only the <, <=, and = filter criteria of window functions in parent queries can be pushed down to subqueries.
2. The upper boundary of a restriction condition range can be a constant, constant expression, parameter, non-VOLATILE function, or non-correlated sublink.
3. Only the ROW\_NUMB, [ROW\\_NUMBER\(\)](#), [RANK\(\)](#), and [DENSE\\_RANK\(\)](#) window functions are supported.

---

#### Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t2 (c1 INT, c2 INT);
-- Import data.
gaussdb=# INSERT INTO t2 SELECT generate_series, generate_series FROM generate_series(1, 1000000);
-- Execute the query. The query is normal, no error is reported, and the execution result is correct.
gaussdb=# EXPLAIN ANALYZE SELECT nc1 FROM (
SELECT row_number() over() rid,
t2.c1 nc1
FROM t2
) WHERE rid BETWEEN 1 AND (1 + 10 - 1);
QUERY PLAN
```

```

-----

        Spawn on: All datanodes
        -> WindowAgg (cost=0.00..10.25 rows=16 width=4) (actual time=[1.759,1.815]..
[1.786,1.844], rows=20)
          row_number_filter: (row_number() OVER () <= 10)
          -> Seq Scan on t2 (cost=0.00..13.13 rows=20 width=4) (actual time=[1.711,1.716]..
[1.743,1.747], rows=22)
        Total runtime: 13.428 ms
      (12 rows)
    -- Clear the environment to prevent data leakage.
    gaussdb=# DROP TABLE t2;

```

- **RANK()**

Description: The RANK function is used for generating non-consecutive sequence numbers for the values in each group. The same values have the same sequence number.

Return type: bigint

Example:

```

gaussdb=# CREATE TABLE rank_t1(a int, b int);

gaussdb=# INSERT INTO rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,RANK() OVER(PARTITION BY a ORDER BY b) FROM rank_t1;
 a | b | rank
-----+-----
 1 | 1 | 1
 1 | 1 | 1
 1 | 2 | 3
 1 | 3 | 4
 2 | 4 | 1
 2 | 5 | 2
 3 | 6 | 1
(7 rows)

gaussdb=# DROP TABLE rank_t1;

```

- **ROW\_NUMBER()**

Description: The ROW\_NUMBER function is used for generating consecutive sequence numbers for the values in each group. The same values have different sequence numbers.

Return type: bigint

Example:

```

gaussdb=# CREATE TABLE row_number_t1(a int, b int);

gaussdb=# INSERT INTO row_number_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,ROW_NUMBER() OVER(PARTITION BY a ORDER BY b) FROM row_number_t1;
 a | b | row_number
-----+-----
 1 | 1 | 1
 1 | 1 | 2
 1 | 2 | 3
 1 | 3 | 4

```

```
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
(7 rows)
```

```
gaussdb=# DROP TABLE row_number_t1;
```

- **DENSE\_RANK()**

Description: The DENSE\_RANK function is used for generating consecutive sequence numbers for the values in each group. The same values have the same sequence number.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE dense_rank_t1(a int, b int);
```

```
gaussdb=# INSERT INTO dense_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,DENSE_RANK() OVER(PARTITION BY a ORDER BY b) FROM dense_rank_t1;
```

```
a | b | dense_rank
```

```
-----
```

```
1 | 1 | 1
1 | 1 | 1
1 | 2 | 2
1 | 3 | 3
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
(7 rows)
```

```
gaussdb=# DROP TABLE dense_rank_t1;
```

- **PERCENT\_RANK()**

Description: The PERCENT\_RANK function is used for generating corresponding sequence numbers for the values in each group. That is, the function calculates the value according to the formula: Sequence number =  $(\text{rank} - 1) / (\text{totalrows} - 1)$ . **rank** is the corresponding sequence number generated based on the **RANK** function for the value and **totalrows** is the total number of elements in a group.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE percent_rank_t1(a int, b int);
```

```
gaussdb=# INSERT INTO percent_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,PERCENT_RANK() OVER(PARTITION BY a ORDER BY b) FROM percent_rank_t1;
```

```
a | b | percent_rank
```

```
-----
```

```
1 | 1 | 0
1 | 1 | 0
1 | 2 | .6666666666666667
1 | 3 | 1
2 | 4 | 0
2 | 5 | 1
3 | 6 | 0
(7 rows)
```

```
gaussdb=# DROP TABLE percent_rank_t1;
```

- **CUME\_DIST()**

Description: The CUME\_DIST function is used for generating accumulative distribution sequence numbers for the values in each group. That is, the

function calculates the value according to the following formula: Sequence number = Number of rows preceding or peer with current row/Total rows.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE cume_dist_t1(a int, b int);

gaussdb=# INSERT INTO cume_dist_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,CUME_DIST() OVER(PARTITION BY a ORDER BY b) FROM cume_dist_t1;
 a | b | cume_dist
---+---+-----
 1 | 1 |      .5
 1 | 1 |      .5
 1 | 2 |     .75
 1 | 3 |      1
 2 | 4 |      .5
 2 | 5 |      1
 3 | 6 |      1
(7 rows)

gaussdb=# DROP TABLE cume_dist_t1;
```

- **NTILE(num\_buckets integer)**

Description: The NTILE function is used for equally allocating sequential data sets to the buckets whose quantity is specified by **num\_buckets** according to **num\_buckets integer** and allocating the bucket number to each row. Divide the partition as evenly as possible.

Return type: integer

Example:

```
gaussdb=# CREATE TABLE ntile_t1(a int, b int);

gaussdb=# INSERT INTO ntile_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,NTILE(2) OVER(PARTITION BY a ORDER BY b) FROM ntile_t1;
 a | b | ntile
---+---+-----
 1 | 1 |    1
 1 | 1 |    1
 1 | 2 |    2
 1 | 3 |    2
 2 | 4 |    1
 2 | 5 |    2
 3 | 6 |    1
(7 rows)

gaussdb=# DROP TABLE ntile_t1;
```

- **LAG**

Description: The LAG function is used for generating lag values for the corresponding values in each group. That is, the value of the row obtained by moving forward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row does not exist after the moving, the result value is the default value. If not specified, **offset** defaults to **1** and **default** to **NULL**. The type of the **default** value must be the same as that of the **value** value.

Syntax:

```
LAG(value any [, offset integer [, default any ]])
LAG(value any ignore|respect nulls [, offset integer [, default any ]])
LAG(value any [, offset integer [, default any ]]) ignore|respect nulls
```

**ignore|respect nulls** determines whether NULL is included in the forward offset value. If not specified, the default value **respect nulls** is used. If **ignore nulls** is specified and the **value** is set to **NULL**, NULL is not included in the forward offset value. If **ignore nulls** is specified, the function performance deteriorates.

Return type: same as the parameter type

Example 1: Disable **ignore nulls** and set **offset** to **3** and **default** to **null**.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE ta1 (hire_date date, last_name varchar(20), department_id int);
CREATE TABLE
gaussdb=# INSERT INTO ta1 values('07-DEC-02', 'Raphaely', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-JUL-05', 'Tobias', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-DEC-05', 'Baida', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('18-MAY-03', 'Khoo', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('15-NOV-06', 'Himuro', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-AUG-07', 'Colmenares', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-07', 'yq', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-08', 'zi', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('', 'yq1', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, 'yq2', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-DEC-07', 'yq3', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1

-- Call LAG and set offset to 3 and default to null.
gaussdb=# SELECT hire_date, last_name, department_id, lag(hire_date, 3, null) OVER (PARTITION BY
department_id ORDER BY last_name) AS "NextHired" FROM ta1 ORDER BY department_id;
 hire_date | last_name | department_id | NextHired
-----+-----+-----+-----
2007-05-10 00:00:00 | yq | 11 |
2008-05-10 00:00:00 | zi | 11 |
| | 11 |
| | 11 | 2007-05-10 00:00:00
2005-12-24 00:00:00 | Baida | 30 |
2007-08-10 00:00:00 | Colmenares | 30 |
2006-11-15 00:00:00 | Himuro | 30 |
2003-05-18 00:00:00 | Khoo | 30 | 2005-12-24 00:00:00
2002-12-07 00:00:00 | Raphaely | 30 | 2007-08-10 00:00:00
2005-07-24 00:00:00 | Tobias | 30 | 2006-11-15 00:00:00

	yq1	30	2003-05-18 00:00:00
	yq2	30	2003-05-18 00:00:00
2007-12-10 00:00:00	yq3	30	2003-05-18 00:00:00

(13 rows)

```
-- Delete the table.
gaussdb=# DROP TABLE ta1;
DROP TABLE
```

- **LEAD**

Description: The LEAD function is used for generating leading values for the corresponding values in each group. That is, the value of the row obtained by moving backward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row after the moving exceeds the total number of rows for the current group, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **NULL**. The type of the **default** value must be the same as that of the **value** value.

Syntax:

```
LEAD(value any [, offset integer [, default any ]])
LEAD(value any ignore|respect nulls [, offset integer [, default any ]])
LEAD(value any [, offset integer [, default any ]]) ignore|respect nulls
```

**ignore|respect nulls** determines whether NULL is included in the backward offset value. If not specified, the default value **respect nulls** is used. If **ignore nulls** is specified and the **value** is set to **NULL**, NULL is not included in the backward offset value. If **ignore nulls** is specified, the function performance deteriorates.

Return type: same as the parameter type

Example 1: Disable **ignore nulls**, set **offset** to **2**, and do not specify **default**.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE ta1 (hire_date date, last_name varchar(20), department_id int);
CREATE TABLE
```

```

gaussdb=# INSERT INTO ta1 values('07-DEC-02', 'Raphaely', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-JUL-05', 'Tobias', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-DEC-05', 'Baida', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('18-MAY-03', 'Khoo', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('15-NOV-06', 'Himuro', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-AUG-07', 'Colmenares', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-07', 'yq', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-08', 'zi', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('', 'yq1', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, 'yq2', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-DEC-07', 'yq3', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);

(13 rows)

```

```
-- Delete the table.
gaussdb=# DROP TABLE ta1;
DROP TABLE
```

- **FIRST\_VALUE(value any)**

Description: Returns the first value of each group.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE first_value_t1(a int, b int);
gaussdb=# INSERT INTO first_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,FIRST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM first_value_t1;
a | b | first_value
---+---+-----
1 | 1 |          1
1 | 1 |          1
1 | 2 |          1
1 | 3 |          1
2 | 4 |          4
2 | 5 |          4
3 | 6 |          6
(7 rows)

gaussdb=# DROP TABLE first_value_t1;
```

- **LAST\_VALUE(value any)**

Description: Returns the last value of each group.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE last_value_t1(a int, b int);
gaussdb=# INSERT INTO last_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,LAST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM last_value_t1;
a | b | last_value
---+---+-----
1 | 1 |          1
1 | 1 |          1
1 | 2 |          2
1 | 3 |          3
2 | 4 |          4
2 | 5 |          5
3 | 6 |          6
(7 rows)

gaussdb=# DROP TABLE last_value_t1;
```

- **NTH\_VALUE(value any, nth integer)**

Description: The *n*th row for a group is the returned value. If the row does not exist, **NULL** is returned by default.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE nth_value_t1(a int, b int);
gaussdb=# INSERT INTO nth_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,NTH_VALUE(b, 2) OVER(PARTITION BY a order by b) FROM nth_value_t1;
a | b | nth_value
---+---+-----
1 | 1 |          1
1 | 1 |          1
1 | 2 |          1
```

```
1 | 3 | 1
2 | 4 |
2 | 5 | 5
3 | 6 |
(7 rows)
```

```
gaussdb=# DROP TABLE nth_value_t1;
```

- **delta**

Description: Returns the difference between the current row and the previous row.

Parameter: numeric

Return type: numeric

- **spread**

Description: Calculates the difference between the maximum value and minimum value in a certain period.

Parameter: real

Return type: real

- **RATIO\_TO\_REPORT(column\_name)**

Description: Calculates the ratio of the value in a column to the total value in the group to which the column belongs.

Parameter: numeric type, or any type that can be implicitly converted to the numeric type.

Return type: For input parameter types float4 and float8, the return type is of the same value type. For other input parameter types, the return type is numeric.

 **NOTE**

When RATIO\_TO\_REPORT(column\_name) is used together with OVER(), the input parameters of OVER() support only **PRTITION BY** and **NULL**.

**Example 1:**

```
gaussdb=# CREATE TABLE ratio_to_report_t1(a int, b int);
```

```
gaussdb=# INSERT INTO ratio_to_report_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,RATIO_TO_REPORT(b) OVER(PARTITION BY a) FROM ratio_to_report_t1;
```

```
a | b | ratio_to_report
---+---+-----
1 | 1 | .14285714285714285714
1 | 1 | .14285714285714285714
1 | 2 | .28571428571428571429
1 | 3 | .42857142857142857143
2 | 4 | .44444444444444444444
2 | 5 | .55555555555555555556
3 | 6 | 1.00000000000000000000
(7 rows)
```

```
gaussdb=# DROP TABLE ratio_to_report_t1;
```

**Example 2: Nest this function with other functions.**

```
gaussdb=# CREATE TABLE ratio_to_report_t1(a int, b int);
```

```
gaussdb=# INSERT INTO ratio_to_report_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,TO_CHAR(RATIO_TO_REPORT(b) OVER(PARTITION BY a), '$999eeee') FROM
```

```
ratio_to_report_t1;
a | b | to_char
---+---+-----
```

```
1 | 1 | 1e-01
1 | 1 | 1e-01
1 | 2 | 3e-01
1 | 3 | 4e-01
2 | 4 | 4e-01
2 | 5 | 6e-01
3 | 6 | 1e+00
(7 rows)

gaussdb=# DROP TABLE ratio_to_report_t1;

Example 3: Invoke a stored procedure.

gaussdb=# CREATE TABLE ratio_to_report_t1(a int, b int);

gaussdb=# INSERT INTO ratio_to_report_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# CREATE OR REPLACE PROCEDURE ratio_to_report_proc IS CURSOR cur_1 IS SELECT
a,b,RATIO_TO_REPORT(b) OVER(PARTITION BY a) FROM ratio_to_report_t1;
BEGIN
FOR cur IN cur_1 LOOP
RAISE INFO '%', cur.ratio_to_report;
END LOOP;
END;
/

gaussdb=# CALL RATIO_TO_REPORT_PROC();

ratio_to_report_proc
-----
(1 row)

gaussdb=# DROP PROCEDURE ratio_to_report_proc;

gaussdb=# DROP TABLE ratio_to_report_t1;
```

## 7.6.20 Security Functions

### Security Functions

- `gs_encrypt_aes128(encryptstr,keyststr)`

Description: Encrypts **encryptstr** strings using the key derived from **keyststr** and returns encrypted strings. The value of **keyststr** ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters. Currently, the following types of data can be encrypted: numerals supported in the database; character type; RAW in binary type; and DATE, TIMESTAMP, and SMALLDATETIME in date/time type.

Return type: text

Length of the return value: At least 92 bytes and no more than  $(4 * [Len / 3] + 68)$  bytes, where *Len* indicates the length of the data before encryption (unit: byte).

Example:

```
gaussdb=# SELECT gs_encrypt_aes128('MPPDB','1234@abc');
gs_encrypt_aes128
-----
```

```
OF1g3+70oeqFfyKiWlpxfYxPnpeitNc6+7nAe02Ttt37fZF8Q+bbEYhdw/YG+0c9tHKRWM6OcTzIB3HnqvX+1d8Bflo=
(1 row)
```

**NOTE**

A password is required during the execution of this function. For security purposes, the `gsql` tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in `gsql` by paging up and down.

- `gs_decrypt_aes128(encryptstr,keyst)`

Description: Decrypts **decrypt** strings using the key derived from **keyst** and returns decrypted strings. The **keyst** used for decryption must be consistent with that used for encryption. **keyst** cannot be empty.

**NOTE**

This function needs to be used with the `gs_encrypt_aes128` encryption function.

Return type: text

Example:

```
gaussdb=# SELECT gs_decrypt_aes128('OF1g3+70oeqFfyKiWlpxfYxPnpeitNc6+7nAe02Ttt37fZF8Q+bbEYhdw/YG+0c9tHKRWM6OcTzIB3HnqvX+1d8Bflo=', '1234@abc');
gs_decrypt_aes128
```

```
-----
MPPDB
(1 row)
```

**NOTE**

A password is required during the execution of this function. For security purposes, the `gsql` tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in `gsql` by paging up and down.

- `aes_encrypt(str, key_str, init_vector)`

Description: Encrypts the string **str** using the encryption password **key\_str** and initialization vector **init\_vector** based on the AES algorithm.

Parameters in the command above are as follows:

- **str**: character string to be encrypted. If **str** is set to **NULL**, the function returns **NULL**.
- **key\_str**: encryption password. If **key\_str** is set to **NULL**, the function returns **NULL**. For security purposes, you are advised to use a 128-bit, 192-bit, or 256-bit secure random number as the key character string if the key length is 128 bits, 192 bits, or 256 bits (determined by the value of **block\_encryption\_mode**).
- **init\_vector**: An initialization variable is provided for the required block encryption mode. The length is greater than or equal to 16 bytes. Bytes greater than 16 bytes are automatically ignored. If neither **str** nor **key\_str** is **NULL**, this parameter cannot be **NULL**. Otherwise, an error is reported. For security purposes, you are advised to ensure that the IV for each encryption is unique in OFB mode and that the IV for each encryption is unpredictable in CBC or CFB mode.

Return type: text

Example:

```
gaussdb=# SELECT aes_encrypt('huwei123','123456vfhex4dyu,vdaladhjsadad','1234567890123456');
aes_encrypt
```

```
-----  
u*8\x05c?0  
(1 row)
```

**NOTE**

- This function is valid only when GaussDB is compatible with MySQL (that is, **sql\_compatibility** is set to 'MYSQL').
  - An encryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.
  - Do not call this function during operations related to stored procedures, preventing the risk of sensitive information disclosure. In addition, when using the stored procedure that contains the function, you are advised to filter the parameter information of the function before providing the information for external maintenance personnel to locate the fault. Delete the logs after using them.
  - Do not call the function when **debug\_print\_plan** is set to **on**, preventing the risk of sensitive information disclosure. You are advised to filter parameter information of the function in the log files generated when **debug\_print\_plan** is set to **on** before providing the log files to external maintenance engineers for fault locating. After you finish using the logs, delete them as soon as possible.
  - The SQL\_ASCII setting performs quite differently from other settings. If the character set of the server is SQL\_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL\_ASCII, no code conversion occurs. When this function calls the third-party OpenSSL library, the returned data is non-ASCII data. Therefore, when the character set of the database server is set to SQL\_ASCII, the encoding of the client must also be set to SQL\_ASCII. Otherwise, an error is reported. The database does not convert or verify non-ASCII characters.
- **aes\_decrypt(pass\_str, key\_str, init\_vector)**

Description: Decrypts the string **str** using the decryption password **key\_str** and initialization vector **init\_vector** based on the AES algorithm.

Parameters in the command above are as follows:

- **pass\_str**: character string to be decrypted. If **pass\_str** is set to **NULL**, the function returns **NULL**.
- **key\_str**: decryption password. If **key\_str** is set to **NULL**, the function returns **NULL**. For security purposes, you are advised to use a 128-bit, 192-bit, or 256-bit secure random number as the key character string if the key length is 128 bits, 192 bits, or 256 bits (determined by the value of **block\_encryption\_mode**).
- **init\_vector**: An initialization variable is provided for the required block decryption mode. The length is greater than or equal to 16 bytes. Bytes greater than 16 bytes are automatically ignored. If neither **pass\_str** nor **key\_str** is **NULL**, this parameter cannot be **NULL**. Otherwise, an error is reported. For security purposes, you are advised to ensure that the IV for each encryption is unique in OFB mode and that the IV for each encryption is unpredictable in CBC or CFB mode.

Return type: text

Example:

```
gaussdb=# SELECT  
aes_decrypt(aes_encrypt('huwei123','123456vfhex4dyu,vdaladhjsadad','1234567890123456'),'123456vf  
hex4dyu,vdaladhjsadad','1234567890123456');  
aes_decrypt
```

```
-----
huwei123
(1 row)
```

 **NOTE**

- This function is valid only when GaussDB is compatible with MySQL (that is, **sql\_compatibility** is set to 'MYSQL').
- A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.
- Do not call this function during operations related to stored procedures, preventing the risk of sensitive information disclosure. In addition, when using the stored procedure that contains the function, you are advised to filter the parameter information of the function before providing the information for external maintenance personnel to locate the fault. Delete the logs after using them.
- Do not call the function when **debug\_print\_plan** is set to **on**, preventing the risk of sensitive information disclosure. You are advised to filter parameter information of the function in the log files generated when **debug\_print\_plan** is set to **on** before providing the log files to external maintenance engineers for fault locating. After you finish using the logs, delete them as soon as possible.
- To ensure successful decryption, ensure that the values of **block\_encryption\_mode**, **key\_str** and IV are the same as those during encryption.
- Due to encoding differences, encrypted data cannot be directly copied from the gsql client for decryption. In this scenario, the decryption result may not be the character string before encryption.
- The SQL\_ASCII setting performs quite differently from other settings. If the character set of the server is SQL\_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL\_ASCII, no code conversion occurs. When this function calls the third-party OpenSSL library, the returned data is non-ASCII data. Therefore, when the character set of the database server is set to SQL\_ASCII, the encoding of the client must also be set to SQL\_ASCII. Otherwise, an error is reported. The database does not convert or verify non-ASCII characters.

- **gs\_digest(input\_string, hash\_algorithm)**

Description: Hashes the input string using the specified hash algorithm and returns a hexadecimal number.

Parameters in the command above are as follows:

- **input\_string**: character string to be hashed. The value cannot be **NULL**.
- **hash\_algorithm**: specifies the hash algorithm. Currently, SHA-256, SHA-384, SHA-512, and SM3 are supported. Both uppercase and lowercase letters are supported. If an unsupported hash algorithm is used, an error is reported.

Return type: text

Example:

```
gaussdb=# SELECT pg_catalog.gs_digest('gaussdb', 'sha256');
           gs_digest
-----
4dc50d746f4e04f9b446986b34a0050e358fbfb8bc1fba314c54b52a417b0b8e
(1 row)
```

- **gs\_password\_deadline()**

Description: Indicates the number of remaining days before the password of the current user expires.

Return type: interval

Example:

```
gaussdb=# SELECT gs_password_deadline();
gs_password_deadline
-----
83 days 17:44:32.196094
(1 row)
```

- `gs_password_notifytime()`

Description: Specifies the number of days prior to password expiration that a user will receive a reminder.

Return type: int32

- `login_audit_messages(BOOLEAN)`

Description: Queries login information about a login user.

Return type: tuple

Example:

- Check the date, time, and IP address of the last successful login.

```
gaussdb=> SELECT * FROM login_audit_messages(true);
username | database | logintime      | mytype | result | client_conninfo
-----+-----+-----+-----+-----+-----
omm      | postgres | 2020-06-29 21:56:40+08 | login_success | ok | gsql@[local]
(1 row)
```

- Check the number, date, and time of failed attempts since the previous successful login.

```
gaussdb=> SELECT * FROM login_audit_messages(false);
username | database | logintime      | mytype | result | client_conninfo
-----+-----+-----+-----+-----+-----
omm      | postgres | 2020-06-29 21:57:55+08 | login_failed | failed | [unknown]@[local]
omm      | postgres | 2020-06-29 21:57:53+08 | login_failed | failed | [unknown]@[local]
(2 rows)
```

- `login_audit_messages_pid()`

Description: Queries login information about a login user. Different from **login\_audit\_messages**, this function queries login information based on **backendid**. Information about subsequent logins of the same user does not alter the query result of previous logins and cannot be found using this function.

Return type: tuple

 **NOTE**

When the thread pool is enabled, the **backendid** obtained in the same session may change due to thread switchover. As a result, the return values are different when the function is called for multiple times. You are advised not to call this function when the thread pool is enabled.

Example:

- Check the date, time, and IP address of the last successful login.

```
gaussdb=> SELECT * FROM login_audit_messages_pid(true);
username | database | logintime      | mytype | result | client_conninfo | backendid
-----+-----+-----+-----+-----+-----+-----
omm      | postgres | 2020-06-29 21:56:40+08 | login_success | ok | gsql@[local] | 139823109633792
(1 row)
```

- Check the number, date, and time of failed attempts since the previous successful login.

```
gaussdb=> SELECT * FROM login_audit_messages_pid(false);
username | database | logintime      | mytype | result | client_conninfo | backendid
```

Name	Type	Description
database	text	Database name
client_conninfo	text	Client connection information
object_name	text	Object name
detail_info	text	Operation details
node_name	text	Node name
thread_id	text	Thread ID
local_port	text	Local port
remote_port	text	Remote port

- pgxc\_query\_audit()**  
 Description: Displays audit logs of all CNs.  
 Return type: record  
 The return fields of this function are the same as those of the `pg_query_audit` function.
- pg\_delete\_audit()**  
 Description: Deletes audit logs in a specified period.  
 Return type: void
- alldigitsmasking()**  
 Description: Specifies the internal function of the masking policy, which is used to anonymize all characters.  
 Parameter: col text, letter character default '0'  
 Return type: text
- creditcardmasking()**  
 Description: Specifies the internal function of the masking policy, which is used to anonymize all credit card information.  
 Parameter: col text, letter character default 'x'  
 Return type: text
- randommasking()**  
 Description: Specifies the internal function of the masking policy. The random policy is used.  
 Parameter: col text  
 Return type: text
- fullemailmasking()**  
 Description: Specifies the internal function of the masking policy, which is used to anonymize the text (except @) before the last period (.).  
 Parameter: col text, letter character default 'x'  
 Return type: text

- basicemailmasking()**

Description: Specifies the internal function of the masking policy, which is used to anonymize the text before the first at sign (@).

Parameter: col text, letter character default 'x'

Return type: text
- shufflemasking()**

Description: Specifies the internal function of the masking policy, which is used to sort characters out of order.

Parameter: col text

Return type: text
- regexprmasking()**

Description: Specifies the internal function of the masking policy, which is used to replace characters using a regular expression.

Parameter: col text, reg text, replace\_text text, pos INTEGER default 0, reg\_len INTEGER default -1

Return type: text
- gs\_encrypt(encryptstr, keystr, encrypttype)**

Description: Encrypts **encryptstr** strings using **keystr** as the key and returns encrypted strings based on **encrypttype**.

Return type: text

Parameter	Type	Description	Value Range
encryptstr	text	Data to be encrypted	-
keystr	text	Encryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.
encrypttype	text	Encryption/Decryption type (case-insensitive)	aes128, sm4, aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

**Example:**

```
gaussdb=# SELECT gs_encrypt('MPPDB', 'Asdf1234', 'sm4');
gs_encrypt
-----
ZBzOmaGA4Bb+coyucJ0B8AkIShqc
(1 row)
```

 **NOTE**

An encryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in **gsql** by paging up and down.

**aes128** and **sm4** are compatible with earlier versions. The **aes128** encryption and decryption algorithm in CBC mode is used for AES-128 encryption and decryption, and **SHA1** is used for integrity check. The **sm4** encryption and decryption algorithm uses the SM4 CTR mode and does not perform integrity check.

- `gs_decrypt(decryptstr, keystr, decrypttype)`

Description: Decrypts **decrypt** strings using **keystr** as the decryption password and returns decrypted strings based on **decrypttype**. **decrypttype** and **keystr** used for decryption must be consistent with **encrypttype** and **keystr** used for encryption. **keystr** cannot be empty.

This function needs to be used with the `gs_encrypt` encryption function.

Return type: text

Parameter	Type	Description	Value Range
decryptstr	text	Data to be decrypted	-
keystr	text	Decryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.
decrypttype	text	Encryption/Decryption type (case-insensitive)	aes128, sm4, aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

**Example:**

```
gaussdb=# SELECT gs_decrypt('ZBzOmaGA4Bb+coyucJ0B8AkIshqc', 'Asdf1234', 'sm4');
gs_decrypt
-----
MPPDB
(1 row)
```

 **NOTE**

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in `gsql` by paging up and down.

**aes128** and **sm4** are compatible with earlier versions. The **aes128** encryption and decryption algorithm in CBC mode is used for AES128 encryption and decryption, and **SHA1** is used for integrity check. The **sm4** encryption and decryption algorithm uses the SM4 CTR mode and does not perform integrity check.

- `gs_encrypt_bytea(encryptstr, keystr, encrypttype)`  
Description: Encrypts **encryptstr** strings using **keystr** as the encryption password and returns encrypted strings based on **encrypttype**.

Return type: bytea

Parameter	Type	Description	Value Range
encryptstr	text	Data to be encrypted	-
keystr	text	Encryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.
encrypttype	text	Encryption/Decryption type (case-insensitive)	aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

Example:

```
gaussdb=# SELECT gs_encrypt_bytea('MPPDB', 'Asdf1234', 'sm4_ctr_sm3');
gs_encrypt_bytea
```

```
-----
\x90e286971c2c70410def0a2814af4ac44c737926458b66271d9d1547bc937395ca018d7755672fa9dc3c
dc6ec4a76001dc0e137f3bc5c8a5c51143561f1d09a848bfdebfe5e
(1 row)
```

 **NOTE**

An encryption password is required during the execution of this function. For security purposes, the `gsqr` tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in `gsqr` by paging up and down.

- `gs_decrypt_bytea(decryptstr, keystr, decrypttype)`  
Description: Decrypts **decryptstr** strings using **keystr** as the decryption password and returns decrypted strings based on **decrypttype**. **decrypttype** and **keystr** used for decryption must be consistent with **encrypttype** and **keystr** used for encryption. **keystr** cannot be empty.

This function needs to be used with the `gs_encrypt_bytea` encryption function.

Return type: text

Parameter	Type	Description	Value Range
decryptstr	bytea	Data to be decrypted	-

Parameter	Type	Description	Value Range
keystr	text	Decryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.
decrypttype	text	Encryption/Decryption type (case-insensitive)	aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

Example:

```
gaussdb=# SELECT
gs_decrypt_bytea('\x90e286971c2c70410def0a2814af4ac44c737926458b66271d9d1547bc937395ca018
d7755672fa9dc3cdc6ec4a76001dc0e137f3bc5c8a5c51143561f1d09a848bfdefbec5e', 'Asdf1234',
'sm4_ctr_sm3');
gs_decrypt_bytea
-----
MPPDB
(1 row)
```

 **NOTE**

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

## 7.6.21 Ledger Database Functions

- get\_dn\_hist\_rehash(text, text)**

Description: Returns the hash value of table-level data in a specified tamper-proof user table. This function can be invoked only between distributed nodes. A message indicating insufficient permission is displayed when all users invoke this function.

Parameter type: text

Return type: hash16
- ledger\_hist\_check(text, text)**

Description: Verifies the consistency between the hash value of table-level data in a specified tamper-proof user table and that in the corresponding history table.

Parameter type: text

Return type: Boolean

Example:

```
-- Create a schema.
gaussdb=# CREATE SCHEMA ledgernsp WITH BLOCKCHAIN;
-- Create a table.
gaussdb=# CREATE TABLE ledgernsp.tab(a int, b text);
-- Insert data.
```

```
gaussdb=# INSERT INTO ledgernsp.tab values(generate_series(1, 10000), 'test');
gaussdb=# SELECT ledger_hist_check('ledgernsp','tab');
ledger_hist_check
-----
t
(1 row)
```

- `ledger_hist_repair(text, text)`

Description: Restores the hash value of the history table corresponding to the specified tamper-proof user table to be the same as that of the user table, and returns the hash difference.

Parameter type: text

Return type: hash16

Example:

```
gaussdb=# SELECT ledger_hist_repair('ledgernsp','tab');
ledger_hist_repair
-----
0000000000000000
(1 row)
```

- `ledger_hist_archive(text, text)`

Description: Archives the history table corresponding to a specified tamper-proof user table to the **hist\_back** folder in the audit log directory.

Parameter type: text

Return type: Boolean

Example:

```
gaussdb=# EXECUTE DIRECT ON (datanode1) 'select pg_catalog.ledger_hist_archive("ledgernsp",
"tab");';
ledger_hist_archive
-----
t
(1 row)
```

- `ledger_gchain_check(text, text)`

Description: Verifies the consistency between the history table hash corresponding to the specified tamper-proof user table and the **relhash** corresponding to the global history table.

Parameter type: text

Return type: Boolean

Example:

```
gaussdb=# SELECT ledger_gchain_check('ledgernsp','tab');
ledger_gchain_check
-----
t
(1 row)
```

- `ledger_gchain_repair(text, text)`

Description: Restores **relhash** of a specified tamper-proof user table in the global history table so that the hash is the same as that in the history table, and returns the total hash value of the specified table.

Parameter type: text

Return type: hash16

Example:

```
gaussdb=# SELECT ledger_gchain_repair('ledgernsp','tab');
ledger_gchain_repair
-----
```

```
da30c1260af5be50  
(1 row)
```

- `ledger_gchain_archive(void)`  
Description: Archives global history tables to the **hist\_back** folder in the audit log directory.  
Parameter type: void  
Return type: Boolean  
Example:  

```
gaussdb=# SELECT ledger_gchain_archive();  
ledger_gchain_archive  
-----  
t  
(1 row)
```
- `hash16in(cstring)`  
Description: Converts the input hexadecimal string into the internal hash16 format.  
Parameter type: cstring  
Return type: hash16
- `hash16out(hash16)`  
Description: Converts internal hash16 data to hexadecimal cstring data.  
Parameter type: hash16  
Return type: cstring
- `hash32in(cstring)`  
Description: Converts the input hexadecimal string (32 characters) into the internal type hash32.  
Parameter type: cstring  
Return type: hash32
- `hash32out(hash32)`  
Description: Converts internal hash32 data to hexadecimal cstring data.  
Parameter type: hash32  
Return type: cstring

## 7.6.22 Encrypted Functions and Operators

- `byteawwithoutorderwithequalcolin(cstring)`  
Description: Converts input data to the internal `byteawwithoutorderwithequalcol` format.  
Parameter type: cstring  
Return type: `byteawwithoutorderwithequalcol`
- `byteawwithoutorderwithequalcolout(byteawwithoutorderwithequalcol)`  
Description: Converts internal data of the `byteawwithoutorderwithequalcol` type to data of the cstring type.  
Parameter type: `byteawwithoutorderwithequalcol`  
Return type: cstring
- `byteawwithoutorderwithequalcolsend(byteawwithoutorderwithequalcol)`

Description: Converts data of the `byteawithoutorderwithequalcol` type to data of the `bytea` type.

Parameter type: `byteawithoutorderwithequalcol`

Return type: `bytea`

- `byteawithoutorderwithequalcolrecv(internal)`

Description: Converts data of the `internal` type to data of the `byteawithoutorderwithequalcol` type.

Parameter type: `internal`

Return type: `byteawithoutorderwithequalcol`

- `byteawithoutorderwithequalcoltypmodin(cstring[])`

Description: Converts data of the `cstring[]` type to data of the `byteawithoutorderwithequalcol` type.

Parameter type: `cstring[]`

Return type: `int4`

- `byteawithoutorderwithequalcoltypmodout(int4)`

Description: Converts data of the `int4` type into data of the `cstring` type.

Parameter type: `int4`

Return type: `cstring`

- `byteawithoutordercolin(cstring)`

Description: Converts input data to the internal `byteawithoutordercolin` format.

Parameter type: `cstring`

Return type: `byteawithoutordercol`

- `byteawithoutordercolout(byteawithoutordercol)`

Description: Converts internal data of the `byteawithoutordercol` type to data of the `cstring` type.

Parameter type: `byteawithoutordercol`

Return type: `cstring`

- `byteawithoutordercolsend(byteawithoutordercol)`

Description: Converts data of the `byteawithoutordercol` type to data of the `bytea` type.

Parameter type: `byteawithoutordercol`

Return type: `bytea`

- `byteawithoutordercolrecv(internal)`

Description: Converts data of the `internal` type to data of the `byteawithoutordercol` type.

Parameter type: `internal`

Return type: `byteawithoutordercol`

- `byteawithoutorderwithequalcolcmp(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`

Description: Compares two `byteawithoutorderwithequalcol` data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: byteawithoutorderwithequalcol,  
byteawithoutorderwithequalcol

Return type: int4

- byteawithoutorderwithequalcolcmpbytear(byteawithoutorderwithequalcol,  
bytea)

Description: Compares the byteawithoutorderwithequalcol and bytea data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: byteawithoutorderwithequalcol, bytea

Return type: int4

- byteawithoutorderwithequalcolcmpbyteal(bytea,  
byteawithoutorderwithequalcol)

Description: Compares the bytea and byteawithoutorderwithequalcol data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: bytea, byteawithoutorderwithequalcol

Return type: int4

- byteawithoutorderwithequalcoleq(byteawithoutorderwithequalcol,  
byteawithoutorderwithequalcol)

Description: Compares two byteawithoutorderwithequalcol data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: byteawithoutorderwithequalcol,  
byteawithoutorderwithequalcol

Return type: Boolean

- byteawithoutorderwithequalcoleqbyteal(bytea,  
byteawithoutorderwithequalcol)

Description: Compares the bytea and byteawithoutorderwithequalcol data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: bytea, byteawithoutorderwithequalcol

Return type: Boolean

- byteawithoutorderwithequalcoleqbytear(byteawithoutorderwithequalcol,  
bytea)

Description: Compares the byteawithoutorderwithequalcol and bytea data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: byteawithoutorderwithequalcol, bytea

Return type: Boolean

- byteawithoutorderwithequalcolne(byteawithoutorderwithequalcol,  
byteawithoutorderwithequalcol)

Description: Compares two byteawithoutorderwithequalcol data records. If they are different, **true** is returned. Otherwise, **false** is returned.

Parameter type: byteawithoutorderwithequalcol,  
byteawithoutorderwithequalcol

Return type: Boolean

- `byteawithoutorderwithequalcolnebyteal(bytea, byteawithoutorderwithequalcol)`  
Description: Compares the `bytea` and `byteawithoutorderwithequalcol` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.  
Parameter type: `bytea`, `byteawithoutorderwithequalcol`  
Return type: Boolean
- `byteawithoutorderwithequalcolnebytear(byteawithoutorderwithequalcol, bytea)`  
Description: Compares the `byteawithoutorderwithequalcol` and `bytea` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.  
Parameter type: `byteawithoutorderwithequalcol`, `bytea`  
Return type: Boolean
- `hll_hash_byteawithoutorderwithequalcol(byteawithoutorderwithequalcol)`  
Description: Returns the hll hash value of `byteawithoutorderwithequalcol`.  
Parameter type: `byteawithoutorderwithequalcol`  
Return type: `hll_hashval`
- `tee_lt(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`  
Description: Checks whether a value of the `byteawithoutorderwithequalcol` type is less than another value of the `byteawithoutorderwithequalcol` type. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.  
Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`  
Return type: Boolean
- `tee_gt(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`  
Description: Checks whether a value of the `byteawithoutorderwithequalcol` type is greater than another value of the `byteawithoutorderwithequalcol` type. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.  
Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`  
Return type: Boolean
- `tee_le(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`  
Description: Checks whether a value of the `byteawithoutorderwithequalcol` type is less than or equal to another value of the `byteawithoutorderwithequalcol` type. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.  
Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`  
Return type: Boolean
- `tee_ge(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`  
Description: Checks whether a value of the `byteawithoutorderwithequalcol` type is greater than or equal to another value of the `byteawithoutorderwithequalcol` type. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.

Parameter type: byteawithoutorderwithequalcol,  
byteawithoutorderwithequalcol

Return type: Boolean

- tee\_like(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)  
Description: Checks whether byteawithoutorderwithequalcol data meets fuzzy match. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.

Parameter type: byteawithoutorderwithequalcol,  
byteawithoutorderwithequalcol

Return type: Boolean

- tee\_nlike(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)  
Description: Checks whether byteawithoutorderwithequalcol data does not meet fuzzy match. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.

Parameter type: byteawithoutorderwithequalcol,  
byteawithoutorderwithequalcol

Return type: Boolean

- tee\_calculation(byteawithoutorderwithequalcol,  
byteawithoutorderwithequalcol)  
Description: General function for mathematical operations between byteawithoutorderwithequalcol types. This function is not supported in distributed mode.

Parameter type: byteawithoutorderwithequalcol,  
byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- tee\_sortsupport(internal)  
Description: Function used to support sorting, which is internally invoked during sorting and is not supported in the current version.

Parameter type: internal

Return type: void

- teegtssel(internal, oid, internal, integer)  
Description: Selectivity of ciphertext greater than and greater than or equal to. The default value **0.3333333333333333** is returned. This function cannot be invoked by common users.

Parameter type: internal, oid, internal, integer

Return type: double precision

- teeltsel(internal, oid, internal, integer)  
Description: Selectivity of ciphertext less than and less than or equal to. The default value **0.3333333333333333** is returned. This function cannot be invoked by common users.

Parameter type: internal, oid, internal, integer

Return type: double precision

- teelikesel(internal, oid, internal, integer)  
Description: Selectivity of ciphertext fuzzy match. The default value **0.005** is returned. This function cannot be invoked by common users.

Parameter type: internal, oid, internal, integer

Return type: double precision

- teenlikesel(internal, oid, internal, integer)

Description: Selectivity of ciphertext non-fuzzy-match. The default value **0.005** is returned. This function cannot be invoked by common users.

Parameter type: internal, oid, internal, integer

Return type: double precision

- sum(byteawithoutorderwithequalcol)

Description: Aggregates the ciphertext sum. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- avg(byteawithoutorderwithequalcol)

Description: Aggregates the ciphertext average value. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- min(byteawithoutorderwithequalcol)

Description: Aggregates the ciphertext minimum value. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- max(byteawithoutorderwithequalcol)

Description: Aggregates the ciphertext maximum value. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- stddev\_samp(byteawithoutorderwithequalcol)

Description: Aggregates the standard deviation of ciphertext samples. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- stddev\_pop(byteawithoutorderwithequalcol)

Description: Aggregates the total standard deviation of ciphertext. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- var\_samp(byteawithoutorderwithequalcol)

Description: Aggregates the variance of ciphertext samples. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- `var_pop(byteawithoutorderwithequalcol)`  
Description: Aggregates the total variance of ciphertext. It is not supported in the current version.  
Parameter type: `byteawithoutorderwithequalcol`  
Return type: `byteawithoutorderwithequalcol`
- `tee_trans(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`  
Description: Aggregates the internal processing function for ciphertext. This function cannot be invoked by common users.  
Parameter type: `byteawithoutorderwithequalcol`,  
`byteawithoutorderwithequalcol`  
Return type: `byteawithoutorderwithequalcol`
- `tee_collect(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`  
Description: Aggregates the internal processing function for ciphertext. This function cannot be invoked by common users.  
Parameter type: `byteawithoutorderwithequalcol`,  
`byteawithoutorderwithequalcol`  
Return type: `byteawithoutorderwithequalcol`
- `tee_final(byteawithoutorderwithequalcol)`  
Description: Aggregates the internal processing function for ciphertext. This function cannot be invoked by common users.  
Parameter type: `byteawithoutorderwithequalcol`  
Return type: `byteawithoutorderwithequalcol`
- `security_tee_process()`  
Description: Manages the computational state in a secret trusted domain. It is not supported in the current version.  
Parameter type: `int`  
Return type: `Boolean`
- `ce_encrypt_deterministic(text, oid)`  
Description: Encrypts the plaintext of the TEXT type to the encrypted equivalent structure. The key OID is the value of **column\_key\_distributed\_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.  
Parameter type: `text`, `oid`  
Return type: `byteawithoutorderwithequalcol`
- `ce_encrypt_deterministic(int1, oid)`  
Description: Encrypts the plaintext of the int1 type to the encrypted equivalent structure. The key OID is the value of **column\_key\_distributed\_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.  
Parameter type: `int1`, `oid`  
Return type: `byteawithoutorderwithequalcol`
- `ce_encrypt_deterministic(int2, oid)`  
Description: Encrypts the plaintext of the int2 type to the encrypted equivalent structure. The key OID is the value of **column\_key\_distributed\_id**

in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `int2`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(int4, oid)`

Description: Encrypts the plaintext of the `int4` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `int4`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(int8, oid)`

Description: Encrypts the plaintext of the `int8` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `int8`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(float4, oid)`

Description: Encrypts the plaintext of the `float4` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `float4`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(float8, oid)`

Description: Encrypts the plaintext of the `float8` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `float8`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(numeric, oid)`

Description: Encrypts the plaintext of the `numeric` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `numeric`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(clob, oid)`

Description: Encrypts the plaintext of the `CLOB` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `clob`, `oid`

Return type: byteawithoutorderwithequalcol

- `ce_encrypt_deterministic(varchar, oid)`

Description: Encrypts the plaintext of the `varchar` type to the encrypted equivalent structure. The key OID is the value of **column\_key\_distributed\_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `varchar, oid`

Return type: byteawithoutorderwithequalcol

- `ce_encrypt_deterministic(nvarchar2, oid)`

Description: Encrypts the plaintext of the `nvarchar2` type to the encrypted equivalent structure. The key OID is the value of **column\_key\_distributed\_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `nvarchar2, oid`

Return type: byteawithoutorderwithequalcol

- `ce_encrypt_deterministic(bpchar, oid)`

Description: Encrypts the plaintext of the `bpchar` type to the encrypted equivalent structure. The key OID is the value of **column\_key\_distributed\_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `bpchar, oid`

Return type: byteawithoutorderwithequalcol

- `ce_encrypt_deterministic(nvarchar2, oid)`

Description: Encrypts the plaintext of the `nvarchar2` type to the encrypted equivalent structure. The key OID is the value of **column\_key\_distributed\_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `nvarchar2, oid`

Return type: byteawithoutorderwithequalcol

- `ce_encrypt_deterministic(bytea, oid)`

Description: Encrypts the plaintext of the `bytea` type to the encrypted equivalent structure. The key OID is the value of **column\_key\_distributed\_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `bytea, oid`

Return type: byteawithoutorderwithequalcol

- `ce_decrypt_deterministic(byteawithoutorderwithequalcol, oid)`

Description: Decrypts the ciphertext of the encrypted equivalent structure to the plaintext data of the `text` type. The key OID is the value of **column\_key\_distributed\_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `byteawithoutorderwithequalcol, oid`

Return type: `text`

 **NOTE**

The following functions starting with `ce_encrypt/ce_decrypt` exist in the `pg_catalog` namespace.

- `ce_encrypt_text(text, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: text, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_varchar(varchar, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: varchar, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_nvarchar2(nvarchar2, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: nvarchar2, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_bpchar(bpchar, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: bpchar, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_int1(int1, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: int1, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_int2(int2, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: int2, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_int4(int4, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: int4, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_int8(int8, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: int8, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol

- `ce_encrypt_float4(float4, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: float4, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_float8(float8, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: float8, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_numeric(numeric, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: numeric, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_bytea(bytea, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: bytea, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_clob(clob, int4, boolean, int4, internal)`  
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: clob, int4, boolean, int4, internal  
Return type: byteawithoutorderwithequalcol
- `ce_decrypt_text(byteawithoutorderwithequalcol, int4, boolean, int4, internal)`  
Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal  
Return type: text
- `ce_decrypt_varchar(byteawithoutorderwithequalcol, int4, boolean, int4, internal)`  
Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal  
Return type: varchar
- `ce_decrypt_nvarchar2(byteawithoutorderwithequalcol, int4, boolean, int4, internal)`  
Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.  
Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal  
Return type: nvarchar2
- `ce_decrypt_bpchar(byteawithoutorderwithequalcol, int4, boolean, int4, internal)`

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: bpchar

- ce\_decrypt\_int1(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: int1

- ce\_decrypt\_int2(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: int2

- ce\_decrypt\_int4(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: int4

- ce\_decrypt\_int8(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: int8

- ce\_decrypt\_float4(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: float4

- ce\_decrypt\_float8(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: float8

- ce\_decrypt\_numeric(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: numeric

- ce\_decrypt\_bytea(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

```
gaussdb=# SELECT * FROM
byteawithoutorderwithequalcolrecv('\x9072190199999999999912381298461289346129'::byteawithoutorde
rwithequalcol);

## 7.6.23 Set Returning Functions

### Series Generating Functions

- `generate_series(start, stop)`  
Description: Generates a series of values, from **start** to **stop** with a step size of one.  
Parameter type: int, bigint, numeric  
Return type: setof int, setof bigint, setof numeric (same as the parameter type)
- `generate_series(start, stop, step)`  
Description: Generates a series of values, from **start** to **stop** with a step size of **step**.  
Parameter type: int, bigint, numeric  
Return type: setof int, setof bigint, setof numeric (same as the parameter type)
- `generate_series(start, stop, step interval)`  
Description: Generates a series of values, from **start** to **stop** with a step size of **step**.  
Parameter type: timestamp or timestamp with time zone  
Return type: setof timestamp or setof timestamp with time zone (same as parameter type)

When **step** is positive, zero rows are returned if **start** is greater than **stop**. Conversely, when **step** is negative, zero rows are returned if **start** is less than **stop**. Zero rows are also returned for **NULL** inputs. It is an error for **step** to be zero.

Example:

```
gaussdb=# SELECT * FROM generate_series(2,4);
generate_series
-----
         2
         3
         4
(3 rows)

gaussdb=# SELECT * FROM generate_series(5,1,-2);
generate_series
-----
         5
         3
         1
(3 rows)
```

```
gaussdb=# SELECT * FROM generate_series(4,3);
generate_series
-----
(0 rows)

-- This example applies to the date-plus-integer operator.
gaussdb=# SELECT current_date + s.a AS dates FROM generate_series(0,14,7) AS s(a);
dates
-----
2017-06-02
2017-06-09
2017-06-16
(3 rows)

gaussdb=# SELECT * FROM generate_series('2008-03-01 00:00'::timestamp, '2008-03-04 12:00', '10 hours');
generate_series
-----
2008-03-01 00:00:00
2008-03-01 10:00:00
2008-03-01 20:00:00
2008-03-02 06:00:00
2008-03-02 16:00:00
2008-03-03 02:00:00
2008-03-03 12:00:00
2008-03-03 22:00:00
2008-03-04 08:00:00
(9 rows)
```

- `gs_search_function_with_name(funcname)`  
Description: Obtains the OID of the funcname function.  
Parameter type: cstring  
Return type: SETOF oid

```
-- Basic usage
CREATE OR REPLACE FUNCTION proc_plpgsql(a int,b int, c int)
RETURNS int AS $BODY$
DECLARE
BEGIN
RETURN $1 + $2;
END;
$BODY$ language plpgsql;
CREATE OR REPLACE FUNCTION proc_plpgsql(int,int)
RETURNS int AS $BODY$
DECLARE
BEGIN
RETURN $1 + $2;
END;
$BODY$ language plpgsql;
gaussdb=# SELECT gs_search_function_with_name('proc_plpgsql');
gs_search_function_with_name
-----
16776
24576
(2 rows)
```

## Subscript Generating Functions

- `generate_subscripts(array anyarray, dim int)`  
Description: Generates a series comprising the given array's subscripts.  
Return type: setof int
- `generate_subscripts(array anyarray, dim int, reverse boolean)`  
Description: Generates a series comprising the given array's subscripts. When **reverse** is true, the series is returned in reverse order.  
Return type: setof int

**generate\_subscripts** is a function that generates the set of valid subscripts for the specified dimension of the given array. Zero rows are returned for arrays that do not have the requested dimension, or for NULL arrays (but valid subscripts are returned for NULL array elements). Example:

```
-- Basic usage
gaussdb=# SELECT generate_subscripts('{NULL,1,NULL,2}'::int[], 1) AS s;
s
-----
1
2
3
4
(4 rows)
-- Unnest a 2D array.
gaussdb=# CREATE OR REPLACE FUNCTION unnest2(anyarray)
RETURNS SETOF anyelement AS $$
SELECT $1[i][j]
FROM generate_subscripts($1,1) g1(i),
generate_subscripts($1,2) g2(j);
$$ LANGUAGE sql IMMUTABLE;

gaussdb=# SELECT * FROM unnest2(ARRAY[[1,2],[3,4]]);
unnest2
-----
1
2
3
4
(4 rows)

-- Delete the function.
gaussdb=# DROP FUNCTION unnest2;
```

## 7.6.24 Conditional Expression Functions

### Conditional Expression Functions

- `coalesce(expr1, expr2, ..., exprn)`

Description:

Returns the first non-NULL value in the parameter list.

**COALESCE(expr1, expr2)** is equivalent to **CASE WHEN expr1 IS NOT NULL THEN expr1 ELSE expr2 END**.

Example:

```
gaussdb=# SELECT coalesce(NULL,'hello');
coalesce
-----
hello
(1 row)
```

Note:

- **NULL** is returned only if all parameters are **NULL**.
  - It is often used to replace **NULL** with the default value.
  - Like a **CASE** expression, **COALESCE** only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first non-NULL parameter are not evaluated.
- `decode(base_expr, compare1, value1, Compare2,value2, ... default)`

Description: Compares **base\_expr** with each **compare(n)** and **returns value(n)** if they are matched. If no matching result is found, the default value is returned.

Example:

```
gaussdb=# SELECT decode('A','A',1,'B',2,0);
case
-----
1
(1 row)
```

Note: Operations on the XML data are not supported.

- **nullif(expr1, expr2)**

Description: Returns **NULL** only when **expr1** is equal to **expr2**. Otherwise, **expr1** is returned.

**nullif(expr1, expr2)** is equivalent to **CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END**.

 **NOTE**

The **nullif(expr1, expr2)** function is a mapping function. Therefore, the corresponding function definition cannot be found in the **pg\_proc** system catalog.

Example:

```
gaussdb=# SELECT nullif('hello','world');
nullif
-----
hello
(1 row)
```

Note: Operations on the XML data are not supported.

Assume the two parameter data types are different:

- If implicit conversion exists between the two data types, implicitly convert the parameter of lower priority to this data type using the data type of higher priority. If the conversion succeeds, computation is performed.

Otherwise, an error is reported. Example:

```
gaussdb=# SELECT nullif('1234'::VARCHAR,123::INT4);
nullif
-----
1234
(1 row)
gaussdb=# SELECT nullif('1234'::VARCHAR,'2012-12-24'::DATE);
ERROR:  invalid input syntax for type timestamp: "1234"
```

- If implicit conversion is not applied between two data types, an error is displayed. Example:

```
gaussdb=# SELECT nullif(1::bit, '1'::MONEY);
ERROR:  operator does not exist: bit = money
LINE 1: SELECT nullif(1::bit, '1'::MONEY);
           ^
HINT:  No operator matches the given name and argument type(s). You might need to add explicit type casts.
CONTEXT:  referenced column: nullif
```

- **nv( expr1 , expr2 )**

Description:

- If the value of **expr1** is **NULL**, the value of **expr2** is returned.
- If the value of **expr1** is not **NULL**, the value of **expr1** is returned.

Example:

```
gaussdb=# SELECT nv('hello','world');
nv
```

```
-----
hello
(1 row)
```

Parameters **expr1** and **expr2** can be of any data type. If **expr1** and **expr2** are of different data types, NVL checks whether **expr2** can be implicitly converted to **expr1**. If it can, the **expr1** data type is returned. If **expr2** cannot be implicitly converted to **expr1** but **expr1** can be implicitly converted to **expr2**, the **expr2** data type is returned. If no implicit type conversion exists between the two parameters and the parameters are different data types, an error is reported.

- `nvl2(expr1, expr2, expr3)`

Description:

- If *expr1* is **NULL**, *expr3* is returned.
- If *expr1* is not **NULL**, *expr2* is returned.

 **NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

Example:

```
gaussdb=# SELECT nvl2('hello','world','other');
 case
-----
world
(1 row)
```

Note: The *expr2* and *expr3* parameters can be of any type. If the last two parameters of NVL2 are of different types, check whether *expr3* can be implicitly converted to *expr2*. If *expr3* cannot be implicitly converted to *expr2*, an error is returned. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- `greatest(expr1 [, ...])`

Description: Selects the largest value from a list of any number of expressions.

Return type:

Example:

```
gaussdb=# SELECT greatest(1*2,2-3,4-1);
 greatest
-----
        3
(1 row)
gaussdb=# SELECT greatest('HARRY', 'HARRIOT', 'HAROLD');
 greatest
-----
HARRY
(1 row)
```

Note: Operations on the XML data are not supported.

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**:

1. If the value of any parameter is null, the function returns null.
2. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- **least(expr1 [, ...])**

Description: Selects the smallest value from a list of any number of expressions.

Example:

```
gaussdb=# SELECT least(1*2,2-3,4-1);
least
-----
-1
(1 row)
gaussdb=# SELECT least('HARRY','HARRIOT','HAROLD');
least
-----
HAROLD
(1 row)
```

Note: Operations on the XML data are not supported.

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**:

1. If the value of any parameter is null, the function returns null.
2. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- **EMPTY\_BLOB()**

Description: Initiates a BLOB variable in an INSERT or an UPDATE statement to a **NULL** value.

Return type: BLOB

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE blob_tb(b blob,id int) DISTRIBUTE BY REPLICATION;
-- Insert data.
gaussdb=# INSERT INTO blob_tb VALUES (empty_blob(),1);
-- Drop the table.
gaussdb=# DROP TABLE blob_tb;
```

Note: The length is 0 obtained using DBE\_LOB.GET\_LENGTH.

- **EMPTY\_CLOB()**

Description: Initiates a CLOB variable in an INSERT or UPDATE statement to a null value.

 **NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

Return type: CLOB

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE clob_tb(c clob,id int);
-- Insert data.
gaussdb=# INSERT INTO clob_tb VALUES (empty_clob(),1);
-- Drop the table.
gaussdb=# DROP TABLE clob_tb;
```

Note: The length is 0 obtained using DBE\_LOB.GET\_LENGTH.

- **lnnvl(condition)**

Description: Checks the condition in the WHERE clause of a query statement. If the condition is true, **false** is returned. If the condition is unknown or false, **true** is returned.

**condition:** The value must be a logical expression. However, it cannot be used in composite conditions with keywords such as AND, OR, and BETWEEN.

Return type: Boolean

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE student_demo (name VARCHAR2(20), grade NUMBER(10,2));
CREATE TABLE

-- Insert data.
gaussdb=# INSERT INTO student_demo VALUES ('name0',0);
INSERT 0 1
gaussdb=# INSERT INTO student_demo VALUES ('name1',1);
INSERT 0 1
gaussdb=# INSERT INTO student_demo VALUES ('name2',2);
INSERT 0 1

-- Invoke lnnvl.
gaussdb=# SELECT * FROM student_demo WHERE LNNVL(name = 'name1');
 name | grade
-----+-----
name0 | 0.00
name2 | 2.00
(2 rows)
```

 **NOTE**

The lnnvl function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- **isnull(expr)**

Description: Checks whether **expr** is **NULL**. If **expr** is **NULL**, **true** is returned. Otherwise, **false** is returned. The isnull function is the mapping of the is null expression. isnull(expr) is equivalent to the expr is null expression. The isnull function is compatible in full mode.

Parameter: Any type of input is supported.

Return type: Boolean

Example:

```
gaussdb=# SELECT isnull(null);
?column?
-----
t
(1 row)

gaussdb=# SELECT isnull(1);
?column?
```

```
-----
f
(1 row)
```

 **NOTE**

The `isnull(expr)` function is a mapping function. Therefore, the corresponding function definition cannot be found in the `pg_proc` system catalog.

- `if(expr1, expr2, expr3)`

Description: Checks the value of **expr1**. If **expr1** is **true**, **expr2** is returned. Otherwise, **expr3** is returned.

`if(expr1, expr2, expr3)` is logically equivalent to `CASE WHEN expr1 THEN expr2 ELSE expr3 END`.

Parameters: See [Table 7-76](#).

**Table 7-76** Parameter types

Parameter	Valid Input Parameter Type	Description
<code>expr1</code>	boolean	Determines the return value of the <code>if()</code> function.
<code>expr2</code>	Any type	If <b>expr1</b> is <b>true</b> , <b>expr2</b> is returned.
<code>expr3</code>	Any type	If <b>expr1</b> is <b>false</b> , <b>expr3</b> is returned.

Return value type: related to the input parameter type. For details about the output rules, see the description.

 NOTE

- `if(expr1, expr2, expr3)` is supported only in MySQL compatibility mode.
- When the compatibility parameters `b_format_version` is set to "" and `b_format_dev_version` is set to "", the output result type of the `if(expr1, expr2, expr3)` function is the same as that of the `CASE WHEN expr1 THEN expr2 ELSE expr3 END` function. When the compatibility parameters `b_format_version` is set to '5.7' and `b_format_dev_version` is set to 's1', the return value type is deduced according to the following rules in descending order:
  - If the two input parameters are of the same type, the return value type is the same as the input parameter type.
  - If one of the input parameters is of the SET type, the return value is of the TEXT type.
  - If one of the input parameters is of the BLOB type, the return value is of the BLOB type.
  - If one of the input parameters is of the TEXT type, the return value is of the TEXT type.
  - If one of the input parameters is of the STRING type, the return value is of the TEXT type.
  - If the two input parameters are of the time type, the return value is of the TIMESTAMPTZ type; if one of the input parameters is of the time type but the other is not, the return value is of the TEXT type.
  - If both input parameters are signed integers and one input parameter is of the BIGINT type, the return value is of the BIGINT type; otherwise, the return value is of the INT type.
  - If both input parameters are unsigned integers and one input parameter is of the UNSIGNED BIGINT type, the return value is of the UNSIGNED BIGINT type; otherwise, the return value is of the UNSIGNED INT type.
  - If the two input parameters are of the floating point type and integer type respectively, the return value is of the floating point type.
  - Except the preceding NUMERIC type combinations, the return value for other NUMERIC type combinations is of the NUMERIC type.
  - If no implicit conversion function exists between the input parameter type and return value type, an error is reported.
- If the input parameter `expr1` is **NULL**, the returned result is the same as that when `expr1` is **FALSE**.
- The `if(expr1, expr2, expr3)` function is a mapping function. Therefore, the corresponding function definition cannot be found in the `pg_proc` system catalog.

## Example:

```
-- expr1 is an expression.
gaussdb=# select if(2>3, 'true', 'false');
 case
-----
 false
(1 row)

-- If the input parameter expr1 is NULL, the result is the same as that when expr1 is false, and the
value of expr2 is returned.
gaussdb=# select if(null, 'not null', 'is null');
 case
-----
 is null
(1 row)
```

- `ifnull(expr1, expr2)`

Description: Returns the value of `expr2` if `expr1` is **NULL**; otherwise, returns the value of `expr1`.

ifnull(expr1, expr2) is logically equivalent to nvl(expr1, expr2).

Parameter: any type.

Return value type: related to the input parameter type. For details about the output rules, see the description.

#### NOTE

- ifnull(expr1, expr2) is supported only in MySQL compatibility mode.
- When the compatibility parameters **b\_format\_version** is set to "" and **b\_format\_dev\_version** is set to "", the output result type of the ifnull(expr1, expr2) function is the same as that of the nvl(expr1, expr2) function. When the compatibility parameters **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1', the return value type is deduced according to the following rules in descending order:
  - If the two input parameters are of the same type, the return value type is the same as the input parameter type.
  - If one of the input parameters is of the SET type, the return value is of the TEXT type.
  - If one of the input parameters is of the BLOB type, the return value is of the BLOB type.
  - If one of the input parameters is of the TEXT type, the return value is of the TEXT type.
  - If one of the input parameters is of the STRING type, the return value is of the TEXT type.
  - If the two input parameters are of the time type, the return value is of the TIMESTAMPTZ type; if one of the input parameters is of the time type but the other is not, the return value is of the TEXT type.
  - If one input parameter is of the FLOAT4 type and the other is of any numeric type, the return type is DOUBLE.
  - If both input parameters are of the NUMERIC type, the return value is of the type with higher precision. For example, if the input parameter types are TINYINT and INT, the return value type is INT.
  - If no implicit conversion function exists between the input parameter type and return value type, an error is reported.
- If both input parameters are **NULL**, the return value is **NULL**; otherwise, the first value that is not **NULL** is returned.
- The ifnull(expr1, expr2) function is a mapping function. Therefore, the corresponding function definition cannot be found in the pg\_proc system catalog.

Example:

```
-- If the input parameter is an empty string, the output is an empty string instead of NULL.
gaussdb=# SELECT ifnull("", null) is null as a;
a
---
f
(1 row)

-- If both input parameters are NULL, the output is NULL.
gaussdb=# SELECT ifnull(null, null) is null as a;
a
---
t
(1 row)

-- If the input parameters are NULL and a character string, the output is the first non-null value.
gaussdb=# SELECT ifnull(null, 'A') as a;
a
---
```

```
A  
(1 row)
```

## 7.6.25 System Information Functions

### Session Information Functions

- `SYS_CONTEXT()`

Description: Returns the value of the parameter associated with the context namespace at the current time.

Return type: text

Example:

```
SELECT SYS_CONTEXT('userenv','NLS_CURRENCY');  
sys_context  
-----  
$  
(1 row)  
  
SELECT SYS_CONTEXT('userenv','NLS_DATE_FORMAT');  
sys_context  
-----  
ISO, MDY  
(1 row)  
  
SELECT SYS_CONTEXT('userenv','NLS_DATE_LANGUAGE');  
sys_context  
-----  
en_US.UTF-8  
(1 row)
```

- `current_catalog()`

Description: Name of the current database (called "catalog" in the SQL standard)

Return type: name

Example:

```
testdb=# SELECT current_catalog;  
current_database  
-----  
testdb  
(1 row)
```

- `current_database()`

Description: Name of the current database

Return type: name

Example:

```
testdb=# SELECT current_database();  
current_database  
-----  
testdb  
(1 row)
```

- `current_query()`

Description: Text of the currently executing query committed by the client (which might contain more than one statement)

Return type: text

Example:

```
gaussdb=# SELECT current_query();  
current_query
```

```
-----
SELECT current_query();
(1 row)
```

- `current_schema()`

Description: Name of the current schema

Return type: name

Example:

```
gaussdb=# SELECT current_schema();
current_schema
-----
public
(1 row)
```

Note: **current\_schema** returns the first valid schema name in the search path. (If the search path is empty or contains no valid schema name, **NULL** is returned.) This is the schema that will be used for any tables or other named objects that are created without specifying a target schema.

- `current_schemas(Boolean)`

Description: Name of a schema in the search path

Return type: name[]

Example:

```
gaussdb=# SELECT current_schemas(true);
current_schemas
-----
{pg_catalog,public}
(1 row)
```

Note:

**current\_schemas(Boolean)** returns an array of the names of all schemas in the search path. The Boolean option specifies whether implicitly included system schemas such as `pg_catalog` are included in the returned search path.

#### NOTE

The search path can be altered at the run time. The command is as follows:

```
SET search_path TO schema [, schema, ...]
```

- `database()`

Description: Returns the name of the current schema.

Parameter: none

Return type: name

Example:

```
gaussdb=# SELECT database();
database
-----
public
(1 row)
```

#### NOTE

This function is valid in a MySQL-compatible database when **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's1'.

- `current_user()`

Description: Username of current execution context

Return type: name

Example:

```
gaussdb=# SELECT current_user;  
current_user  
-----  
omm  
(1 row)
```

Note: **current\_user** is the user identifier used for permission check. Generally, it indicates a session user, which can be modified by **SET ROLE**. During function execution, it is affected by the SECURITY DEFINER attribute.

- definer\_current\_user

Description: Username of current execution context

Return type: name

Example:

```
gaussdb=# SELECT definer_current_user();  
definer_current_user  
-----  
omm  
(1 row)
```

Note: Generally, the results of **definer\_current\_user** and **current\_user** are the same. However, when this function is executed in a stored procedure, the name of user who defines the current stored procedure is returned.

- pg\_current\_sessionid()

Description: Session ID in the current execution environment.

Return type: text

Example:

```
gaussdb=# SELECT pg_current_sessionid();  
pg_current_sessionid  
-----  
1579228402.140190434944768  
(1 row)
```

Note: **pg\_current\_sessionid()** is used to obtain the session ID in the current operating environment. The format of the value is *Timestamp.Session ID*. When **enable\_thread\_pool** is disabled, the actual session ID is the thread ID.

- pg\_current\_sessid()

Description: Session ID in the current operating environment.

Return type: text

Example:

```
gaussdb=# select pg_current_sessid();  
pg_current_sessid  
-----  
140308875015936  
(1 row)
```

Note: In thread pool mode, the session ID of the current session is obtained. In non-thread pool mode, the backend thread ID of the current session is obtained.

- pg\_current\_userid()

Description: Current user ID

Return type: text

Example:

```
gaussdb=# SELECT pg_current_userid();  
pg_current_userid
```

```
-----  
10  
(1 row)
```

- `tablespace_oid_name(oid)`

Description: Queries the tablespace name based on the tablespace OID.

Return type: text

Example:

```
gaussdb=# select tablespace_oid_name(1663);  
tablespace_oid_name
```

```
-----  
pg_default  
(1 row)
```

- `inet_client_addr()`

Description: Remote connection address. **inet\_client\_addr** returns the IP address of the current client.

 **NOTE**

It is available only in remote connection mode.

Return type: inet

Example:

```
gaussdb=# SELECT inet_client_addr();  
inet_client_addr
```

```
-----  
10.10.0.50  
(1 row)
```

- `inet_client_port()`

Description: Remote connection port. **inet\_client\_port** returns the port number of the current client.

 **NOTE**

This function is valid only in remote connection mode.

Return type: int

Example:

```
gaussdb=# SELECT inet_client_port();  
inet_client_port
```

```
-----  
33143  
(1 row)
```

- `inet_server_addr()`

Description: Local connection address. **inet\_server\_addr** returns the IP address on which the server accepts the current connection.

 **NOTE**

It is available only in remote connection mode.

Return type: inet

Example:

```
gaussdb=# SELECT inet_server_addr();  
inet_server_addr
```

```
-----  
10.10.0.13  
(1 row)
```

- `inet_server_port()`

Description: Local connection port. **inet\_server\_port** returns the number of the port receiving the current connection. All these functions return **NULL** if the current connection is via a UDS.

 **NOTE**

This function is valid only in remote connection mode.

Return type: int

Example:

```
gaussdb=# SELECT inet_server_port();
inet_server_port
-----
          8000
(1 row)
```

- `pg_backend_pid()`

Description: Thread ID of the service thread connected to the current session.

Return type: int

Example:

```
gaussdb=# SELECT pg_backend_pid();
pg_backend_pid
-----
140229352617744
(1 row)
```

- `pg_conf_load_time()`

Description: Configures load time. **pg\_conf\_load\_time** returns the timestamp when the server configuration files were last loaded.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_conf_load_time();
pg_conf_load_time
-----
2017-09-01 16:05:23.89868+08
(1 row)
```

- `pg_my_temp_schema()`

Description: OID of the temporary schema of a session. The value is **0** if the OID does not exist.

Return type: OID

Example:

```
gaussdb=# SELECT pg_my_temp_schema();
pg_my_temp_schema
-----
          0
(1 row)
```

Note: **pg\_my\_temp\_schema** returns the OID of the current session's temporary schema, or **0** if it has no temporary schemas (because no temporary tables are created). **pg\_is\_other\_temp\_schema** returns **true** if the given OID is the OID of another session's temporary schema.

- `pg_is_other_temp_schema(oid)`

Description: Specifies whether the schema is the temporary schema of another session.

Return type: Boolean

Example:

```
gaussdb=# SELECT pg_is_other_temp_schema(25356);
pg_is_other_temp_schema
-----
f
(1 row)
```

- `pg_listening_channels()`

Description: Name of the channel that the session is currently listening to.

Return type: setof text

Example:

```
gaussdb=# SELECT pg_listening_channels();
pg_listening_channels
-----
(0 rows)
```

Note: **pg\_listening\_channels** returns a set of names of channels that the current session is currently listening to.

- `pg_postmaster_start_time()`

Description: Server start time. **pg\_postmaster\_start\_time** returns the timestamp with time zone when the server is started.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_postmaster_start_time();
pg_postmaster_start_time
-----
2017-08-30 16:02:54.99854+08
(1 row)
```

- `sessionid2pid()`

Description: Obtains PID information from a session ID (for example, the **sessid** column in **pv\_session\_stat**).

Return type: int8

Example:

```
gaussdb=# select sessionid2pid(sessid::cstring) from pv_session_stat limit 2;
sessionid2pid
-----
139973107902208
139973107902208
(2 rows)
```

- `session_context( 'namespace' , 'parameter')`

Description: Obtains and returns the parameter values of a specified namespace.

Return type: VARCHAR

Example:

```
gaussdb=# SELECT session_context('USERENV', 'CURRENT_SCHEMA');
session_context
-----
public
(1 row)
```

The result varies according to the current actual schema.

Note: Currently, only the `SESSION_CONTEXT('USERENV', 'CURRENT_SCHEMA')` and `SESSION_CONTEXT('USERENV', 'CURRENT_USER')` formats are supported.

- `pg_trigger_depth()`  
Description: Nesting level of triggers.  
Return type: int  
Example:

```
gaussdb=# SELECT pg_trigger_depth();
pg_trigger_depth
-----
          0
(1 row)
```
- `opengauss_version()`  
Description: Referenced openGauss kernel version.  
Return type: text  
The following is an example. Replace *x.x.x* in the query result with the actual value.

```
gaussdb=# SELECT opengauss_version();
opengauss_version
-----
          x.x.x
(1 row)
```
- `gs_deployment()`  
Description: Deployment mode of the current system. For a distributed system, **Distribute** is returned.  
Return type: text  
Example:

```
gaussdb=# SELECT gs_deployment();
gs_deployment
-----
Distribute
(1 row)
```
- `session_user`  
Description: Session username.  
Return type: name  
Example:

```
gaussdb=# SELECT session_user;
session_user
-----
omm
(1 row)
```

Note: **session\_user** usually specifies the initial user connected to the current database, but the system administrator can change this setting by using **SET SESSION AUTHORIZATION**.
- `user`  
Description: Equivalent to `current_user`.  
Return type: name  
Example:

```
gaussdb=# SELECT user;
current_user
-----
omm
(1 row)
```
- `get_shard_oids_byname()`

Description: Returns the OID of the node when the node name is entered.

Return type: OID

Example:

```
gaussdb=# SELECT get_shard_oids_byname('datanode1');
get_shard_oids_byname
-----
{16385}
(1 row)
```

- `getpgusername()`

Description: Obtains the database username.

Return type: name

Example:

```
gaussdb=# SELECT getpgusername();
getpgusername
-----
GaussDB_userna
(1 row)
```

- `getdatabaseencoding()`

Description: Obtains the database encoding mode.

Return type: name

Example:

```
gaussdb=# SELECT getdatabaseencoding();
getdatabaseencoding
-----
SQL_ASCII
(1 row)
```

- `version()`

Description: version information. **version** returns a string describing a server's version.

Return type: text

Example:

```
gaussdb=# SELECT version();
version
-----
gaussdb (GaussDB XXX.XXX.XXX build f521c606) compiled at 2021-09-16 14:55:22 commit 2935 last
mr 6385 release
(1 row)
```

- `working_version_num()`

Description: version number. It returns a version number related to system compatibility.

Return type: int

Example:

```
gaussdb=# SELECT working_version_num();
working_version_num
-----
92231
(1 row)
```

- `get_hostname()`

Description: Returns the host name of the current node.

Return type: text

Example:

```
gaussdb=# SELECT get_hostname();
get_hostname
-----
linux-user
(1 row)
```

- `get_nodename()`

Description: Returns the name of the current node.

Return type: text

Example:

```
gaussdb=# SELECT get_nodename();
get_nodename
-----
coordinator1
(1 row)
```

- `get_nodeinfo(text)`

Description: Returns the value of the corresponding node information based on the search attribute. Currently, the search attributes include **node\_name** and **node\_type**.

Return type: text

Example:

```
gaussdb=# SELECT get_nodeinfo('node_type');
get_nodeinfo
-----
DIS_CN
(1 row)
gaussdb=# SELECT get_nodeinfo('node_name');
get_nodeinfo
-----
coordinator1
(1 row)
```

- `get_schema_oid(cstring)`

Description: Returns the OID of the queried schema.

Return type: OID

Example:

```
gaussdb=# SELECT get_schema_oid('public');
get_schema_oid
-----
2200
(1 row)
```

- `pgxc_parse_clog(OUT xid int8, OUT nodename text, OUT status text)`

Description: Returns the status of all transactions in the current cluster.

Return type: SETOF record

Example:

```
gaussdb=# SELECT pgxc_parse_clog();
pgxc_parse_clog
-----
(0,dn_6004_6005_6006,INPROGRESS)
(1,dn_6004_6005_6006,COMMITTED)
(2,dn_6004_6005_6006,INPROGRESS)
(3 row)
```

- `pgxc_parse_clog(IN int2 bucketid, OUT xid int8, OUT nodename text, OUT status text)`

Description: Returns the statuses of all transactions with the specified bucket IDs in the current cluster. The input parameter is the bucket IDs of the hash bucket table. The value range is [-1,1023]. For an ordinary table, the value is **-1**.

Return type: SETOF record

Example:

```
gaussdb=# SELECT pgxc_parse_clog('-1');
pgxc_parse_clog
-----
(0,dn_6004_6005_6006,INPROGRESS)
(1,dn_6004_6005_6006,COMMITTED)
(2,dn_6004_6005_6006,INPROGRESS)
(3 row)
```

- `pgxc_prepared_xact()`

Description: Returns the list of transaction GIDs at the prepared stage in the cluster.

Return type: set of text

Example:

```
gaussdb=# SELECT pgxc_prepared_xact();
pgxc_prepared_xact
-----
(0 row)
```

- `pgxc_xacts_iscommitted()`

Description: Returns the status of the transaction with the specified XID in the cluster. **t** indicates the committed state, **f** indicates the aborted state, and **null** indicates other states. To execute this function, you must have the **sysadmin** or **monadmin** permission.

Return type: SETOF record

Example:

```
gaussdb=# SELECT pgxc_xacts_iscommitted(1);
pgxc_xacts_iscommitted
-----
(dn_6004_6005_6006,t)
(cn_5001,t)
(cn_5002,t)
(dn_6001_6002_6003,t)
(4 row)
```

- `pgxc_total_memory_detail()`

Description: Displays the memory usage in the cluster. To execute this function, you must have the **sysadmin** or **monadmin** permission.

 **NOTE**

If the GUC parameter **enable\_memory\_limit** is set to **off**, this function cannot be used.

Return type: set of `pv_total_memory_detail`

Example:

```
gaussdb=# SELECT pgxc_total_memory_detail();
pgxc_total_memory_detail
-----
(dn_6004_6005_6006,max_process_memory,81920)
(dn_6004_6005_6006,process_used_memory,72747)
(dn_6004_6005_6006,max_dynamic_memory,12096)
(dn_6004_6005_6006,dynamic_used_memory,1530)
(4 row)
```

- `pv_total_memory_detail()`

Description: Collects statistics on memory usage of the current database node in the unit of MB.

 **NOTE**

If the GUC parameter `enable_memory_limit` is set to `off`, this function cannot be used.

Return type: record

**Table 7-77** Return value description

Name	Type	Description
nodename	text	Node name
memorytype	text	Memory type. The value must be one of the following: <ul style="list-style-type: none"> <li>• <b>max_process_memory</b>: memory occupied by a GaussDB cluster instance</li> <li>• <b>process_used_memory</b>: memory occupied by a GaussDB thread</li> <li>• <b>max_dynamic_memory</b>: maximum dynamic memory</li> <li>• <b>dynamic_used_memory</b>: used dynamic memory</li> <li>• <b>dynamic_peak_memory</b>: dynamic peak memory</li> <li>• <b>dynamic_used_shrctx</b>: maximum dynamic shared memory context</li> <li>• <b>dynamic_peak_shrctx</b>: dynamic peak value of the shared memory context</li> <li>• <b>max_shared_memory</b>: maximum shared memory</li> <li>• <b>shared_used_memory</b>: used shared memory</li> <li>• <b>max_sctpcomm_memory</b>: maximum memory allowed for the communications library</li> <li>• <b>sctpcomm_used_memory</b>: memory used by the communications library</li> <li>• <b>sctpcomm_peak_memory</b>: memory peak of the communications library</li> <li>• <b>other_used_memory</b>: other used memory</li> </ul>
memorybytes	integer	Size of allocated memory-typed memory

- `get_client_info()`

Description: Returns client information.  
Return type: record

## Access Permission Query Functions

The DDL permissions, including ALTER, DROP, COMMENT, INDEX, and VACUUM, are inherent permissions implicitly owned by the owner.

The following access permission query function only indicates whether a user has a certain permission on an object. That is, the permission on the object recorded in the **acl** column of the system catalog is returned.

- `has_any_column_privilege(user, table, privilege)`

Description: Queries whether a specified user has permissions on any column of a table.

**Table 7-78** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
table	text, oid	Tables	Table name or ID
privilege	text	Permissions	<ul style="list-style-type: none"> <li>• <b>SELECT</b>: allows the SELECT statement to be executed on any column of a specified table.</li> <li>• <b>INSERT</b>: allows the INSERT statement to be executed on any column of a specified table.</li> <li>• <b>UPDATE</b>: allows the UPDATE statement to be executed on any column of a specified table.</li> <li>• <b>REFERENCES</b>: allows a foreign key constraint (not supported in distributed mode).</li> <li>• <b>COMMENT</b>: allows the COMMENT statement to be executed on any column of a specified table.</li> </ul>

Return type: Boolean

- `has_any_column_privilege(table, privilege)`

Description: Queries whether the current user has the permission to access any column of a table. For details about the valid parameter types, see [Table 7-78](#).

Return type: Boolean

Note: **has\_any\_column\_privilege** checks whether a user can access any column of a table in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**, except that the desired access permission type must be some combination of SELECT, INSERT, UPDATE, or REFERENCES.

 **NOTE**

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table. Therefore, **has\_any\_column\_privilege** always returns **true** if **has\_table\_privilege** has the same parameters. But "success" is also returned if there is a column-level grant of the permission for at least one column.

- **has\_column\_privilege**(user, table, column, privilege)

Description: Specifies whether a specified user has the permission to access columns.

**Table 7-79** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
table	text, oid	Table name	Table name or ID
column	text, smallint	Column name	Name or attribute number of a column
privilege	text	Permissions	<ul style="list-style-type: none"> <li>• <b>SELECT</b>: allows the SELECT statement to be executed on specified columns of a table.</li> <li>• <b>INSERT</b>: allows the INSERT statement to be executed on specified columns of a table.</li> <li>• <b>UPDATE</b>: allows the UPDATE statement to be executed on specified columns of a table.</li> <li>• <b>REFERENCES</b>: allows a foreign key constraint (not supported in distributed mode).</li> <li>• <b>COMMENT</b>: allows the COMMENT statement to be executed on specified columns of a table.</li> </ul>

Return type: Boolean

- **has\_column\_privilege**(table, column, privilege)

Description: Specifies whether the current user has the permission to access columns. For details about the valid parameter types, see [Table 7-79](#).

Return type: Boolean

**has\_column\_privilege** checks whether a user can access a column in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. Columns can be added either by name or by attribute number. The desired access permission type must be some combination of SELECT, INSERT, UPDATE, or REFERENCES.

 **NOTE**

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table.

- **has\_cek\_privilege**(user, cek, privilege)

Description: Specifies whether a specified user has permissions on CEKs.

**Table 7-80** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
cek	text, oid	CEK	Name or ID of a CEK
privilege	text	Permission	<ul style="list-style-type: none"> <li>• <b>USAGE</b>: allows users to use the specified CEK.</li> <li>• <b>DROP</b>: allows users to delete the specified CEK.</li> </ul>

Return type: Boolean

- **has\_cmk\_privilege**(user, cmk, privilege)

Description: Specifies whether a specified user has permissions on CMKs.

**Table 7-81** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
cmk	text, oid	CMK	Name or ID of the CMK
privilege	text	Permission	<ul style="list-style-type: none"> <li>• <b>USAGE</b>: allows users to use the specified CMK.</li> <li>• <b>DROP</b>: allows users to delete the specified CMK.</li> </ul>

Return type: Boolean

- `has_database_privilege(user, database, privilege)`

Description: Specifies whether a specified user has permissions on databases.

**Table 7-82** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
database	text, oid	Database	Database name or ID
privilege	text	Permission	<ul style="list-style-type: none"> <li>• <b>CREATE</b>: For databases, allows new schemas to be created within the database.</li> <li>• <b>TEMPORARY</b>: allows users to create temporary tables when the database is used.</li> <li>• <b>TEMP</b>: allows users to create temporary tables when the database is used.</li> <li>• <b>CONNECT</b>: allows users to access specified databases.</li> <li>• <b>ALTER</b>: allows users to modify the attributes of a specified object.</li> <li>• <b>DROP</b>: allows users to delete a specified object.</li> <li>• <b>COMMENT</b>: allows users to define or modify comments of a specified object.</li> </ul>

Return type: Boolean

- `has_database_privilege(database, privilege)`

Description: Queries whether the current user has the permission to access a database. For details about the valid parameter types, see [Table 7-82](#).

Return type: Boolean

Note: **has\_database\_privilege** checks whether a user can access a database in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The desired access permission type must be some combination of CREATE, CONNECT, TEMPORARY, or TEMP (which is equivalent to TEMPORARY).

- `has_directory_privilege(user, directory, privilege)`

**Table 7-83** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
directory	text, oid	Directory	Directory name or OID
privilege	text	Permission	<ul style="list-style-type: none"> <li>• <b>READ</b>: allows read operations on the directory.</li> <li>• <b>WRITE</b>: allows write operations on the directory.</li> </ul>

Description: Specifies whether a specified user has permissions on directories.

Return type: Boolean

- `has_directory_privilege(directory, privilege)`

Description: Queries whether the current user has the permission to access a directory. For details about the valid parameter types, see [Table 7-83](#).

Return type: Boolean

- `has_foreign_data_wrapper_privilege(user, fdw, privilege)`

**Table 7-84** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
fdw	text, oid	Foreign data wrapper	Name or ID of the foreign data wrapper
privilege	text	Permission	<b>USAGE</b> : allows access to the foreign data wrapper.

Description: Specifies whether a specified user has permissions on foreign data wrappers.

Return type: Boolean

- `has_foreign_data_wrapper_privilege(fdw, privilege)`

Description: Queries whether the current user has permissions on foreign data wrappers. For details about the valid parameter types, see [Table 7-84](#).

Return type: Boolean

Note: **has\_foreign\_data\_wrapper\_privilege** checks whether a user can access a foreign data wrapper in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The desired access permission type must evaluate to USAGE.

- `has_function_privilege(user, function, privilege)`

**Table 7-85** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
function	text, oid	Function	Function name or ID
privilege	text	Permission	<p><b>EXECUTE:</b> allows users to use specified functions and the operators that are realized by the functions.</p> <ul style="list-style-type: none"> <li>• <b>ALTER:</b> allows users to modify the attributes of a specified object.</li> <li>• <b>DROP:</b> allows users to delete a specified object.</li> <li>• <b>COMMENT:</b> allows users to define or modify comments of a specified object.</li> </ul>

Description: Specifies whether a specified user has permissions on functions.

Return type: Boolean

- `has_function_privilege(function, privilege)`

Description: Specifies whether the current user has permissions on functions. For details about valid parameter types, see [Table 7-85](#).

Return type: Boolean

Note: **has\_function\_privilege** checks whether a user can access a function in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. When a function is specified by a text string rather than by an OID, the allowed input is the same as that for the regprocedure data type (see [Object Identifier Types](#)). The desired access permission type must be EXECUTE.

- `has_language_privilege(user, language, privilege)`

**Table 7-86** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID

Parameter	Valid Input Parameter Type	Description	Value Range
language	text, oid	Language	Language name or ID
privilege	text	Permission	<b>USAG:</b> allows users to specify a procedural language when creating a function.

Description: Specifies whether a specified user has permissions on languages.

Return type: Boolean

- has\_language\_privilege(language, privilege)

Description: Specifies whether the current user has permissions on languages. For details about valid parameter types, see [Table 7-86](#).

Return type: Boolean

Note: **has\_language\_privilege** checks whether a user can access a procedural language in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The desired access permission type must evaluate to USAGE.

- has\_nodegroup\_privilege(user, nodegroup, privilege)

Description: Checks whether a user has permission to access a cluster node.

Return type: Boolean

**Table 7-87** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Existing username or ID
nodegroup	text, oid	Cluster node	Existing cluster node

Parameter	Valid Input Parameter Type	Description	Value Range
privilege	text	Permission	<ul style="list-style-type: none"> <li>• <b>USAGE</b>: For sub-clusters, allows users who can access objects contained in the schema to access tables in the sub-cluster.</li> <li>• <b>CREATE</b>: For sub-clusters, allows users to create tables within the sub-cluster.</li> <li>• <b>COMPUTE</b>: allows elastic computing in the sub-cluster.</li> <li>• <b>ALTER</b>: allows users to modify the attributes of a specified object.</li> <li>• <b>DROP</b>: allows users to delete a specified object.</li> </ul>

- `has_nodegroup_privilege(nodegroup, privilege)`  
Description: Checks whether a user has permission to access a cluster node.  
Return type: Boolean
- `has_schema_privilege(user, schema, privilege)`  
Description: Specifies whether a specified user has permissions on schemas.  
Return type: Boolean
- `has_schema_privilege(schema, privilege)`  
Description: Specifies whether the current user has permissions on schemas.  
Return type: Boolean  
Note: **has\_schema\_privilege** checks whether a user can access a schema in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The desired access permission type must be a combination among CREATE, USAGE, ALTER, DROP, and COMMENT. If the check type contains the CREATE permission and the checked schema is a schema with the same name as the user, the function returns **TRUE** only when the user has the OWNER permission for the schema due to the special constraint of the schema with the same name.
- `has_sequence_privilege(user, sequence, privilege)`  
Description: Queries whether a specified user has permissions on sequences.  
Return type: Boolean

**Table 7-88** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Existing username or ID

Parameter	Valid Input Parameter Type	Description	Value Range
sequence	text, oid	Sequence	Existing sequence name or ID
privilege	text	Permission	<ul style="list-style-type: none"> <li>• <b>USAGE</b>: For sequences, allows users to use the nextval function.</li> <li>• <b>SELECT</b>: allows users to create a sequence.</li> <li>• <b>UPDATE</b>: allows users to execute the <b>UPDATE</b> statement.</li> <li>• <b>ALTER</b>: allows users to modify the attributes of a specified object.</li> <li>• <b>DROP</b>: allows users to delete a specified object.</li> <li>• <b>COMMENT</b>: allows users to define or modify comments of a specified object.</li> </ul>

- `has_sequence_privilege(sequence, privilege)`  
Description: Queries whether the current user has permissions on sequences.  
Return type: Boolean
- `has_server_privilege(user, server, privilege)`  
Description: Specifies whether a specified user has permissions on foreign servers.  
Return type: Boolean
- `has_server_privilege(server, privilege)`  
Description: Specifies whether the current user has permissions on foreign servers.  
Return type: Boolean  
Note: **has\_server\_privilege** checks whether a user can access a foreign server in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The access permission type must be USAGE, ALTER, DROP, or COMMENT.
- `has_table_privilege(user, table, privilege)`  
Description: Specifies whether a specified user has permissions on tables.  
Return type: Boolean
- `has_table_privilege(table, privilege)`  
Description: Specifies whether the current user has permissions on tables.  
Return type: Boolean  
Note: **has\_table\_privilege** checks whether a user can access a table in a particular way. The user can be specified by name or by OID (**pg\_authid.oid**),

or be set to **public** which indicates public pseudo roles. If this parameter is omitted, **current\_user** is used. The table can be specified by name or by OID. When it is specified by name, the name can be schema-qualified if necessary. If the desired access permission type is specified by a text string, the text string must be one of the values **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE**, **REFERENCETRIGGER**, **ALTER**, **DROP**, **COMMENT**, **INDEX**, or **VACUUM**. Optionally, **WITH GRANT OPTION** can be added to a permission type to test whether the permission is held with the grant option. Also, multiple permission types can be separated by commas (,), in which case the result will be **true** if any of the listed permissions is held.

Example:

```
gaussdb=# SELECT has_table_privilege('tpcds.web_site', 'select');
has_table_privilege
-----
t
(1 row)

gaussdb=# SELECT has_table_privilege('omm', 'tpcds.web_site', 'select,INSERT WITH GRANT OPTION ');
has_table_privilege
-----
t
(1 row)
```

- **has\_tablespace\_privilege**(user, tablespace, privilege)  
Description: Specifies whether a specified user has permissions on tablespaces.  
Return type: Boolean
- **has\_tablespace\_privilege**(tablespace, privilege)  
Description: Specifies whether the current user has permissions on tablespaces.  
Return type: Boolean  
Note: **has\_tablespace\_privilege** checks whether a user can access a tablespace in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The access permission type must be CREATE, ALTER, DROP, or COMMENT.
- **pg\_has\_role**(user, role, privilege)  
Description: Specifies whether a specified user has permissions on roles.  
Return type: Boolean
- **pg\_has\_role**(role, privilege)  
Description: Specifies whether the current user has permissions on roles.  
Return type: Boolean  
Note: **pg\_has\_role** checks whether a user can access a role in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**, except that **public** cannot be used as a username. The desired access permission type must be some combination of MEMBER or USAGE. MEMBER denotes direct or indirect membership in the role (that is, permission SET ROLE), while USAGE denotes the usage permission on the role that is available without the SET ROLE permission.
- **has\_any\_privilege**(user, privilege)  
Description: Queries whether a specified user has certain ANY permission. If multiple permissions are queried at the same time, **true** is returned as long as one permission is obtained.

Return type: Boolean

**Table 7-89** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name	Users	Existing username
privilege	text	ANY permission	Available values: <ul style="list-style-type: none"> <li>• CREATE ANY TABLE [WITH ADMIN OPTION]</li> <li>• ALTER ANY TABLE [WITH ADMIN OPTION]</li> <li>• DROP ANY TABLE [WITH ADMIN OPTION]</li> <li>• SELECT ANY TABLE [WITH ADMIN OPTION]</li> <li>• INSERT ANY TABLE [WITH ADMIN OPTION]</li> <li>• UPDATE ANY TABLE [WITH ADMIN OPTION]</li> <li>• DELETE ANY TABLE [WITH ADMIN OPTION]</li> <li>• CREATE ANY SEQUENCE [WITH ADMIN OPTION]</li> <li>• CREATE ANY INDEX [WITH ADMIN OPTION]</li> <li>• CREATE ANY FUNCTION [WITH ADMIN OPTION]</li> <li>• EXECUTE ANY FUNCTION [WITH ADMIN OPTION]</li> <li>• CREATE ANY TYPE [WITH ADMIN OPTION]</li> </ul>

## Schema Visibility Query Functions

Each function performs the visibility check on one type of database objects. For functions and operators, an object in the search path is visible if there is no object of the same name and parameter data type earlier in the path. For operator classes, both name and associated index access methods are considered.

All these functions require OIDs to identify the objects to be checked. If you want to test an object by name, it is convenient to use the OID alias type (regclass, regtype, regprocedure, regoperator, regconfig, or regdictionary).

For example, a table is said to be visible if the schema where the table is located is in the search path and no table of the same name appears earlier in the search

path. This is equivalent to the statement that the table can be referenced by name without explicit schema qualification. To list the names of all visible tables, run the following command:

```
gaussdb=# SELECT relname FROM pg_class WHERE pg_table_is_visible(oid);
```

- `pg_collation_is_visible(collation_oid)`  
Description: Specifies whether the collation is visible in the search path.  
Return type: Boolean
- `pg_conversion_is_visible(conversion_oid)`  
Description: Specifies whether the conversion is visible in the search path.  
Return type: Boolean
- `pg_function_is_visible(function_oid)`  
Description: Specifies whether the function is visible in the search path.  
Return type: Boolean
- `pg_opclass_is_visible(opclass_oid)`  
Description: Specifies whether the operator class is visible in the search path.  
Return type: Boolean
- `pg_operator_is_visible(operator_oid)`  
Description: Specifies whether the operator is visible in the search path.  
Return type: Boolean
- `pg_opfamily_is_visible(opclass_oid)`  
Description: Specifies whether the operator family is visible in the search path.  
Return type: Boolean
- `pg_table_is_visible(table_oid)`  
Description: Specifies whether the table is visible in the search path.  
Return type: Boolean
- `pg_ts_config_is_visible(config_oid)`  
Description: Specifies whether the text search configuration is visible in the search path.  
Return type: Boolean
- `pg_ts_dict_is_visible(dict_oid)`  
Description: Specifies whether the text search dictionary is visible in the search path.  
Return type: Boolean
- `pg_ts_parser_is_visible(parser_oid)`  
Description: Specifies whether the text search parser is visible in the search path.  
Return type: Boolean
- `pg_ts_template_is_visible(template_oid)`  
Description: Specifies whether the text search template is visible in the search path.  
Return type: Boolean
- `pg_type_is_visible(type_oid)`

Description: Specifies whether the type (or domain) is visible in the search path.

Return type: Boolean

## System Catalog Information Functions

- `format_type(type_oid, typemod)`

Description: Obtains the SQL name of a data type.

Return type: text

Note: **format\_type** returns the SQL name of a data type based on the OID of the data type and possible modifiers. If the specific modifier is unknown, pass **NULL** at the position of the modifier. Modifiers are generally meaningful only for data types with length restrictions. The SQL name returned by **format\_type** contains the length of the data type, which can be calculated by taking `sizeof(int32)` from actual storage length [actual storage len - `sizeof(int32)`] in the unit of bytes. 32-bit space is required to store the customized length set by users. Therefore, the actual storage length contains 4 bytes more than the customized length. In the following example, the SQL name returned by **format\_type** is `character varying(6)`, indicating the length of the `varchar` type is 6 bytes. Therefore, the actual storage length of the `varchar` type is 10 bytes.

```
gaussdb=# SELECT format_type((SELECT oid FROM pg_type WHERE typename='varchar'), 10);
format_type
-----
character varying(6)
(1 row)
```

- `pg_check_authid(role_oid)`

Description: Checks whether a role name with given OID exists.

Return type: Boolean

```
gaussdb=# select pg_check_authid(1);
pg_check_authid
-----
f
(1 row)
```

- `pg_describe_object(catalog_id, object_id, object_sub_id)`

Description: Obtains the description of a database object.

Return type: text

Note: **pg\_describe\_object** returns the description of a database object specified by a catalog OID, an object OID, and a (possibly zero) sub-object ID. This is useful to determine the identity of an object stored in the `pg_depend` catalog.

- `pg_get_constraintdef(constraint_oid)`

Description: Obtains definition of a constraint.

Return type: text

- `pg_get_constraintdef(constraint_oid, pretty_bool)`

Description: Obtains definition of a constraint.

Return type: text

Note: **pg\_get\_constraintdef** and **pg\_get\_indexdef** respectively reconstruct the creation command for a constraint and an index.

- `pg_get_expr(pg_node_tree, relation_oid)`  
 Description: Decompiles the internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.  
 Return type: text
- `pg_get_expr(pg_node_tree, relation_oid, pretty_bool)`  
 Description: Decompiles the internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.  
 Return type: text  
 Note: **pg\_get\_expr** decompiles the internal form of an individual expression, such as the default value of a column. This helps to check the content of system catalogs. If the expression contains keywords, specify the OID of the relationship that the keywords refer to as the second parameter; if no keywords are contained, use zero.
- `pg_get_functiondef(func_oid)`  
 Description: Obtains the definition of a function.  
 Return type: text  
 Example:  

```
gaussdb=# SELECT * FROM pg_get_functiondef(598);
headerlines |          definition
-----+-----
4 | CREATE OR REPLACE FUNCTION pg_catalog.abbrev(inet)+
| RETURNS text +
| LANGUAGE internal +
| IMMUTABLE STRICT NOT FENCED NOT SHIPPABLE +
| AS $function$inet_abbrev$function$ +
(1 row)
```
- `pg_get_function_arguments(func_oid)`  
 Description: Obtains argument list of function's definition (with default values).  
 Return type: text  
 Note: **pg\_get\_function\_arguments** returns the parameter list of a function, in the form it would need to appear in CREATE FUNCTION.
- `pg_get_function_identity_arguments(func_oid)`  
 Description: Obtains the parameter list to identify a function (without default values).  
 Return type: text  
 Note: **pg\_get\_function\_identity\_arguments** returns the parameter list necessary to identify a function, in the form it would need to appear in within ALTER FUNCTION. This form omits default values.
- `pg_get_function_result(func_oid)`  
 Description: Obtains the RETURNS clause for a function.  
 Return type: text  
 Note: **pg\_get\_function\_result** returns the appropriate RETURNS clause for the function.
- `pg_get_indexdef(index_oid)`  
 Description: Obtains the **CREATE INDEX** command for an index.  
 Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_indexdef(16416);
           pg_get_indexdef
-----
CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
```

- `pg_get_indexdef(index_oid, dump_schema_only)`

Description: Obtains the **CREATE INDEX** command for indexes in dump scenarios. In the current version, the value of **dump\_schema\_only** does not affect the function output.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_indexdef(16416, true);
           pg_get_indexdef
-----
CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
```

- `pg_get_indexdef(index_oid, column_no, pretty_bool)`

Description: Obtains the **CREATE INDEX** command for an index, or definition of just one index column when the value of **column\_no** is not zero.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_indexdef(16416, 0, false);
           pg_get_indexdef
-----
CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
gaussdb=# SELECT * FROM pg_get_indexdef(16416, 1, false);
           pg_get_indexdef
-----
b
(1 row)
```

Note: **pg\_get\_functiondef** returns a complete CREATE OR REPLACE FUNCTION statement for a function.

- `pg_get_keywords()`

Description: Obtains the list of SQL keywords and their categories.

Return type: SETOF record

Note: **pg\_get\_keywords** returns a set of records describing the SQL keywords recognized by the server. The **word** column contains the keywords. The **catcode** column contains a category code: **U** for unreserved, **C** for column name, **T** for type or function name, or **R** for reserved. The **catdesc** column contains a possibly-localized string describing the category.

- `pg_get_ruledef(rule_oid)`

Description: Obtains the **CREATE RULE** command for a rule.

Return type: text

- `pg_get_ruledef(rule_oid, pretty_bool)`

Description: Obtains the **CREATE RULE** command for a rule.

Return type: text

- `pg_get_userbyid(role_oid)`

Description: Obtains the role name with a given OID.

Return type: name

Note: **pg\_get\_userbyid** extracts a role's name given its OID.

- **pg\_check\_authid(role\_id)**

Description: Checks whether a user exists based on **role\_id**.

Return type: text

```
gaussdb=# SELECT pg_check_authid(20);
pg_check_authid
-----
f
(1 row)
```

- **pg\_get\_viewdef(view\_name)**

Description: Obtains the underlying **SELECT** command for a view.

Return type: text

- **pg\_get\_viewdef(view\_name, pretty\_bool)**

Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to 80 columns if **pretty\_bool** is set to **true**.

Return type: text

Note: **pg\_get\_viewdef** reconstructs the SELECT query that defines a view. Most of these functions come in two forms. When the function has the **pretty\_bool** parameter and the value is **true**, it can optionally "pretty-print" the result. The pretty-printed format is more readable. The other one is the default format which is more likely to be interpreted in the same way by future versions. Avoid using pretty-printed output for dump purposes. Passing **false** to the pretty-print parameter generates the same result as a variant without this parameter.

- **pg\_get\_viewdef(view\_oid)**

Description: Obtains the underlying **SELECT** command for a view.

Return type: text

- **pg\_get\_viewdef(view\_oid, pretty\_bool)**

Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to 80 columns if **pretty\_bool** is set to **true**.

Return type: text

- **pg\_get\_viewdef(view\_oid, wrap\_column\_int)**

Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to the specified number of columns and printing is implicit.

Return type: text

- **pg\_get\_tabledef(table\_oid)**

Description: Obtains the definition of a table based on **table\_oid**.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_tabledef(16384);
pg_get_tabledef
-----
SET search_path = public;          +
CREATE TABLE t1 (                  +
    c1 bigint DEFAULT nextval('serial'::regclass)  +
)                                     +
WITH (orientation=row,compression=no)  +
DISTRIBUTE BY HASH(c1)              +
```

```

TO GROUP group1;
ILM Security Policies:
  POLICY "p4" TABLE
  ROW STORE COMPRESS ADVANCED ROW AFTER 1 DAYS OF NO MODIFICATION
  STATUS: ENABLED DELETED: NO
(1 row)

```

- `pg_get_tabledef(table_name)`

Description: Obtains the definition of a table based on **table\_name**.

Return type: text

Example:

```

gaussdb=# SELECT * FROM pg_get_tabledef('t1');
pg_get_tabledef
-----
SET search_path = public;
CREATE TABLE t1 (
  c1 bigint DEFAULT nextval('serial'::regclass)
)
WITH (orientation=row, compression=no)
DISTRIBUTE BY HASH(c1)
TO GROUP group1;
ILM Security Policies:
  POLICY "p4" TABLE
  ROW STORE COMPRESS ADVANCED ROW AFTER 1 DAYS OF NO MODIFICATION
  STATUS: ENABLED DELETED: NO
(1 row)

```

Note: **pg\_get\_tabledef** reconstructs the CREATE statement of the definition of the table, including the table definition, index information, comments, and ILM policy. You need to create the group, schema, tablespace, and server information on which the table object depends.

- `pg_options_to_table(reloptions)`

Description: Obtains the set of storage option name/value pairs.

Return type: SETOF record

Note: **pg\_options\_to\_table** returns the set of storage option name/value pairs (**option\_name/option\_value**) when **pg\_class.reloptions** or **pg\_attribute.attoptions** is passed.

- `pg_tablespace_databases(tablespace_oid)`

Description: Obtains the set of database OIDs that have objects in the specified tablespace.

Return type: setof oid

Note: **pg\_tablespace\_databases** allows a tablespace to be checked. It returns the set of OIDs of databases that have objects stored in the tablespace. If this function returns any rows of data, the tablespace is not empty and cannot be dropped. To display the specific objects in the tablespace, you need to connect to the databases identified by **pg\_tablespace\_databases** and query their **pg\_class** catalogs.

- `pg_tablespace_location(tablespace_oid)`

Description: Obtains the path in the file system that this tablespace is located in.

Return type: text

- `pg_typeof(any)`

Description: Obtains the data type of any value.

Return type: regtype

Note: **pg\_typeof** returns the OID of the data type of the value that is passed to it. This can be helpful for troubleshooting or dynamically constructing SQL queries. It is declared that the function returns regtype, which is an OID alias type (see [Object Identifier Types](#)). This means that it is the same as an OID for comparison purposes but displays as a type name.

Example:

```
gaussdb=# SELECT pg_typeof(33);
 pg_typeof
-----
integer
(1 row)

gaussdb=# SELECT typlen FROM pg_type WHERE oid = pg_typeof(33);
 typlen
-----
      4
(1 row)
```

- collation for (any)

Description: Obtains the collation of the parameter.

Return type: text

Note: The expression COLLATION FOR returns the collation of the value that is passed to it. Example:

```
gaussdb=# SELECT collation for (description) FROM pg_description LIMIT 1;
 pg_collation_for
-----
"default"
(1 row)
```

The value might be quoted and schema-qualified. If no collation is derived for the parameter expression, then a null value is returned. If the argument is not of a collatable data type, then an error message is displayed.

- getdistributekey(table\_name)

Description: Gets a distribution key for a hash table.

Return type: text

Example:

```
gaussdb=# SELECT getdistributekey('item');
 getdistributekey
-----
i_item_sk
(1 row)
```

- pg\_extension\_update\_paths(name)

Description: Returns the version update path of the specified extension. This function can be called only by the system administrator.

Return type: text (source text), text (target text), text (path text)

- pg\_get\_serial\_sequence(tablename, colname)

Description: Obtains the sequence of the corresponding table name and column name.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_serial_sequence('t1', 'c1');
 pg_get_serial_sequence
-----
public.serial
(1 row)
```

- pg\_sequence\_parameters(sequence\_oid)**

Description: Obtains the parameters of a specified sequence, including the start value, minimum value, maximum value, and incremental value.

Return type: int16, int16, int16, int16, Boolean

Example:

```
gaussdb=# SELECT * FROM pg_sequence_parameters(16420);
 start_value | minimum_value | maximum_value | increment | cycle_option
-----+-----+-----+-----+-----
          101 |              1 | 9223372036854775807 |          1 | f
(1 row)
```
- pgxc\_get\_variable\_info( )**

Description: Obtains variable values on the node, including **nodeName**, **nextOid**, **nextXid**, **oldestXid**, **xidVacLimit**, **oldestXidDB**, **lastExtendCSNLogpage**, **startExtendCSNLogpage**, **nextCommitSeqNo**, **latestCompleteXid**, and **startupMaxXid**.

Return type: set of pg\_variable\_info

Example:

```
gaussdb=# SELECT pgxc_get_variable_info( );
 pgxc_get_variable_info
-----
(dn_6004_6005_6006,25617,141396349,2073,20000002073,15808,138111,0,127154152,141396348,104433004)
(1 row)
```
- gs\_get\_index\_status(schema\_name, index\_name)**

Description: Obtains the index status information on all nodes, including whether an index can be inserted and whether an index is available. This function is mainly used to check the index status during online index creation or when the index creation fails. The return values include **node\_name**, **indisready**, and **indisvalid**. Only when **indisready** and **indisvalid** of indexes on all nodes are set to **true** and the index state is not changed to unusable, the current index is available.

Return type: text, Boolean, Boolean

Example:

```
gaussdb=# SELECT * FROM gs_get_index_status('public', 'index1');
 node_name | indisready | indisvalid
-----+-----+-----
 datanode1 | t          | t
 datanode2 | t          | t
 coordinator1 | t        | t
(3 row)
```

## Comment Information Functions

- col\_description(table\_oid, column\_number)**

Description: Obtains the comment for a table column.

Return type: text

Note: **col\_description** returns the comment for a table column, which is specified by the OID of its table and its column number.
- obj\_description(object\_oid, catalog\_name)**

Description: Obtains the comment for a database object.

Return type: text

Note: The two-parameter form of **obj\_description** returns the comment for a database object specified by its OID and the name of the system catalog to

which it belongs. For example, **obj\_description(123456,'pg\_class')** would retrieve the comment for the table with OID 123456. The one-parameter form of **obj\_description** requires only the OID.

**obj\_description** cannot be used for table columns since columns do not have OIDs of their own.

- **obj\_description(object\_oid)**  
Description: Obtains the comment for a database object.  
Return type: text
- **shobj\_description(object\_oid, catalog\_name)**  
Description: Obtains the comment for a shared database object.  
Return type: text

Note: **shobj\_description** is used just like **obj\_description**, except that the former is used for shared objects. Some system catalogs are global to all databases in the cluster, and the comments for objects in them are stored globally as well.

## XIDs and Snapshots

Internal XIDs are 64 bits. **txid\_snapshot**, data type used by these functions, stores information about XID visibility at a particular moment in time. [Table 7-90](#) describes the components.

**Table 7-90** Snapshot components

Name	Description
xmin	Earliest XID ( <b>txid</b> ) that is still active. All earlier transactions will either be committed and visible, or rolled back.
xmax	First as-yet-unassigned <b>txid</b> . All txids greater than or equal to this are not yet started as of the time of the snapshot, so they are invisible.
xip_list	Active <b>txids</b> at the time of the snapshot. The list includes only those active <b>txids</b> between <b>xmin</b> and <b>xmax</b> ; there might be active <b>txids</b> higher than <b>xmax</b> . A <b>txid</b> that is greater than or equal to <b>xmin</b> and less than <b>xmax</b> and that is not in this list was already completed at the time of the snapshot, and is either visible or rolled back according to its commit status. The list does not include <b>txids</b> of subtransactions.

The textual representation of **txid\_snapshot** is **xmin:xmax:xip\_list**.

For example, **10:20:10,14,15** means **xmin=10, xmax=20, xip\_list=10, 14, 15**.

The following functions provide server transaction information in an exportable form. These functions are mainly used to determine which transactions were committed between two snapshots.

- **pgxc\_is\_committed(transaction\_id)**  
Description: Specifies whether the given XID is committed or ignored. **NULL** indicates the unknown status (it can be running, ready, frozen, or other

status). In maintenance mode (when the GUC parameter **xc\_maintenance\_mode** is set to **on**), the statuses of all transactions with the specified bucket IDs and ordinary tables are traversed. If a status conflict occurs, for example, the status of the same transaction is **committed** in bucket 1 and **rolled back** in bucket 2, an error is reported. Exercise caution when enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.

Return type: Boolean

- `pgxc_is_committed(transaction_id, bucketid)`  
Description: Commits or ignores the given transaction (gxid) if **bucketid** is specified. **NULL** indicates that the status is unknown (running, ready, or frozen). **bucketid** is the physical bucket ID of the hash bucket table. The value is **-1** for an ordinary table. In maintenance mode (when the GUC parameter **xc\_maintenance\_mode** is set to **on**), if **bucketid** is set to **-1**, the statuses of all transactions with the specified bucket IDs and ordinary tables are traversed. If a status conflict occurs, for example, the status of the same transaction is **committed** in bucket 1 and **rolled back** in bucket 2, an error is reported. Exercise caution when enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.

Return type: Boolean

- `txid_current()`  
Description: Obtains the current XID.  
Return type: bigint
- `gs_txid_oldestxmin()`  
Description: Obtains the minimum XID (specified by **oldesxmin**).  
Return type: bigint
- `txid_current_snapshot()`  
Description: Obtains the current snapshot.  
Return type: txid\_snapshot
- `txid_snapshot_xip(txid_snapshot)`  
Description: Obtains in-progress XIDs in a snapshot.  
Return type: setof bigint
- `txid_snapshot_xmax(txid_snapshot)`  
Description: Obtains **xmax** of snapshots.  
Return type: bigint
- `txid_snapshot_xmin(txid_snapshot)`  
Description: Obtains **xmin** of snapshots.  
Return type: bigint
- `txid_visible_in_snapshot(bigint, txid_snapshot)`  
Description: Specifies whether the XID is visible in a snapshot (do not use subtransaction IDs).  
Return type: Boolean
- `get_local_prepared_xact()`

Description: Obtains the two-phase residual transaction information of the current node, including the XID, GID of the two-phase transaction, prepared time, owner OID, database OID, and node name of the current node.

Return type: xid, text, timestamptz, oid, text

- `get_remote_prepared_xacts()`

Description: Obtains the two-phase residual transaction information of all remote nodes, including the XID, GID of the two-phase transaction, prepared time, owner name, database name, and node name.

Return type: xid, text, timestamptz, name, text

- `global_clean_prepared_xacts(text, text)`

Description: Concurrently cleans two-phase residual transactions. Only the `gs_clean` tool can call this function for cleaning. In other situations, **false** is returned.

Return type: Boolean

- `pgxc_stat_get_wal_senders()`

Description: Returns the sent logs of all primary DN's and the received logs of their corresponding standby DN's in the cluster. Only users with the system admin or monitor admin permission can use this function.

For details about the return values, see [Table 7-91](#).

**Table 7-91** `pgxc_stat_get_wal_senders` parameters

Column	Description
<code>nodename</code>	Instance name.
<code>sender_pid</code>	PID of the thread for sending logs.
<code>local_role</code>	Instance role.
<code>peer_role</code>	Role of the instance on the receiver.
<code>peer_state</code>	Status of the instance on the receiver.
<code>state</code>	Synchronization status between instances.
<code>sender_sent_location</code>	Location where the sender sends logs.
<code>sender_write_location</code>	Location where the sender writes logs.
<code>sender_flush_location</code>	Location where the sender flushes logs to disks.
<code>sender_replay_location</code>	Location of the instance logs. If the DN is a primary DN, the location is the value of <b>sender_flush_location</b> . Otherwise, the location where the current instance log is replayed is used.
<code>receiver_received_location</code>	Location where the receiver receives logs.

Column	Description
receiver_write_location	Location where the receiver writes logs.
receiver_flush_location	Location where the receiver flushes logs to disks.
receiver_replay_location	Location where the receiver replays logs.

- pgxc\_stat\_get\_wal\_senders\_status()**  
 Description: Returns the receiving status of transaction logs on all nodes. Only users with the system admin or monitor admin permission can use this function.

For details about the return values, see [Table 7-92](#).

**Table 7-92** pgxc\_stat\_get\_wal\_senders\_status parameters

Column	Description
nodename	Name of the primary node
source_ip	IP address of the primary node
source_port	Port of the primary node
dest_ip	IP address of the standby node
dest_port	Port of the standby node
sender_pid	PID of the sending thread
local_role	Type of the primary node
peer_role	Type of the standby node
peer_state	Status of the standby node
state	WAL sender status
sender_sent_location	Sending position of the primary node
sender_write_location	Writing position of the primary node
sender_replay_location	Redo position of the primary node
receiver_received_location	Receiving position of the standby node
receiver_write_location	Writing position of the standby node
receiver_flush_location	Flushing location of the standby node
receiver_replay_location	Redo location of the standby node

- gs\_get\_next\_xid\_csn()**

Description: Returns the values of **next\_xid** and **next\_csn** on all nodes globally.

For details about the return values, see [Table 7-93](#).

**Table 7-93** gs\_get\_next\_xid\_csn parameters

Column	Description
nodename	Node name
next_xid	ID of the next transaction on the current node.
next_csn	Next CSN of the current node.

- `pg_control_system()`  
Description: Returns the status of the system control file.  
Return type: SETOF record
- `pg_control_checkpoint()`  
Description: Returns the system checkpoint status  
Return type: SETOF record
- `get_prepared_pending_xid()`  
Description: Returns **nextxid** when restoration is complete.  
Parameter: nan  
Return type: text
- `pg_clean_region_info()`  
Description: Clears the region map.  
Parameter: nan  
Return type: character varying
- `pg_get_replication_slot_name()`  
Description: Obtains the slot name.  
Parameter: nan  
Return type: text
- `pg_get_running_xacts()`  
Description: Obtains running **xact**.  
Parameter: nan  
Return type: handle integer, gxid xid, state tinyint, node text, xmin xid, vacuum boolean, timeline bigint, prepare\_xid xid, pid bigint, next\_xid xid
- `pg_get_variable_info()`  
Description: Obtains the shared memory variable cache.  
Parameter: nan  
Return type: node\_name text, nextOid oid, nextXid xid, oldestXid xid, xidVacLimit xid, oldestXidDB oid, lastExtendCSNLogpage xid, startExtendCSNLogpage xid, nextCommitSeqNo xid, latestCompletedXid xid, and startupMaxXid xid

- `pg_get_xidlimit()`  
Description: Obtains XID information from the shared memory.  
Parameter: nan  
Return type: nextXid xid, oldestXid xid, xidVacLimit xid, xidWarnLimit xid, xidStopLimit xid, xidWrapLimit xid, oldestXidDB oid
- `pg_relation_compression_ratio()`  
Description: Queries the compression rate of a table. By default, **1.0** is returned.  
Parameter: text  
Return type: real
- `pg_relation_with_compression()`  
Description: Specifies whether a table is compressed.  
Parameter: text  
Return type: Boolean
- `pg_stat_file_recursive()`  
Description: Lists all files in a path.  
Parameter: location text  
Return type: path text, filename text, size bigint, isdir boolean
- `pg_stat_get_activity_for temptable()`  
Description: Returns records of backend threads related to the temporary table.  
Parameter: nan  
Return type: datid oid, timelineid integer, tempid integer, and sessionid bigint
- `pg_stat_get_activity_ng()`  
Description: Returns records of backend threads related to nodegroup.  
Parameter: pid bigint  
Return type: datid oid, pid bigint, sessionid bigint, and node\_group text
- `pg_stat_get_cgroup_info()`  
Description: Returns Cgroup information.  
Parameter: nan  
Return type: cgroup\_name text, percent integer, usage\_percent integer, shares bigint, usage bigint, cpuset text, relpath text, valid text, node\_group text
- `pg_stat_get_realtime_info_internal()`  
Description: Returns real-time information. Currently, this API is unavailable. **FailedToGetSessionInfo** is returned.  
Parameter: oid, oid, bigint, cstring, oid  
Return type: text
- `pg_stat_get_wlm_session_iostat_info()`  
Description: Returns the session load I/O information.  
Parameter: nan  
Return type: threadid bigint, maxcurr\_iops integer, mincurr\_iops integer, maxpeak\_iops integer, minpeak\_iops integer, iops\_limits integer, io\_priority integer, and curr\_io\_limits integer

- `pg_test_err_contain_err()`  
Description: Tests the error type and return information.  
Parameter: integer  
Return type: void
- `pv_session_memory_detail_tp()`  
Description: Returns the memory usage of the session. For details, see [pv\\_session\\_memory\\_detail](#).  
Parameter: nan  
Return type: sessid text, sesstype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint
- `gs_get_table_distribution()`  
Description: Returns the distribution of table data on each DN.  
Parameter: table\_name text, schema\_name text  
Return type: text
- `pv_builtin_functions()`  
Description: Displays information about all built-in system functions.  
Parameter: nan  
Return type: proname name, pronamespace oid, proowner oid, prolang oid, procost real, prorows real, provariadic oid, protransform regproc, proisagg boolean, proiswindow boolean, proscdef boolean, proleakproof boolean, proisstrict boolean, proretset boolean, provolatile "char", pronargs smallint, pronargdefaults smallint, prorettype oid, proargtypes oidvector, proallargtypes integer[], proargmodes "char"[], proargnames text[], proargdefaults pg\_node\_tree, prosrc text, probin text, proconfig text[], proacl aclitem[], prodefaultargpos int2vector, fencedmode boolean, proshippable boolean, propackage boolean, oid oid
- `pv_thread_memory_detail()`  
Description: Returns the memory information of each thread.  
Parameter: nan  
Return type: threadid text, tid bigint, thrdtype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint
- `pg_shared_memory_detail()`  
Description: Returns usage information about all generated shared memory contexts. For details about each column, see [SHARED\\_MEMORY\\_DETAIL](#).  
Parameter: nan  
Return type: contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint
- `pgxc_get_running_xacts()`  
Description: Returns information about running transactions on each node in the cluster. The field content is the same as that in [PGXC\\_RUNNING\\_XACTS](#). Only users with the system admin or monitor admin permission can view the information.  
Parameter: nan  
Return type: setof record

- `pgxc_snapshot_status()`

Description: Returns the status of key memory information in the GTM in GTM mode for fault locating. GTM-Free and GTM-Lite do not support this function.

Parameter: nan

Return type: xmin xid, xmax xid, xcnt int, oldestxmin xid, next\_xid xid, timeline int, active\_thread\_num int, max\_active\_thread\_num int, snapshot\_num int, snapshot\_totalsize bigint

For details about the return values, see [Table 7-94](#).

**Table 7-94** get\_gtm\_lite\_status return parameters

Column	Description
xmin	Minimum active XID in the GTM.
xmax	Largest XID committed in the GTM plus 1. Transactions whose IDs are greater than or equal to this value are active.
xcnt	Number of active transactions in the GTM.
oldestxmin	ID of the earliest accessed transaction in the GTM.
next_xid	ID of the next transaction allocated by the GTM.
timeline	Current time line in the GTM.
active_thread_num	Number of active worker threads in the GTM.
max_active_thread_num	Peak number of worker threads in the GTM within one minute.
snapshot_num	Number of snapshots delivered by the GTM within one minute.
snapshot_totalsize	Total size of snapshots delivered by the GTM within one minute.

- `get_gtm_lite_status()`

Description: Returns the backup XID and CSN in the GTM for fault locating. This system function is not supported in GTM-Free mode.

For details about the return values, see [Table 7-95](#).

**Table 7-95** get\_gtm\_lite\_status return parameters

Column	Description
backup_xid	Backup XID in the GTM.
csn	Latest CSN issued by the GTM.

- `adm_hist_snapshot_func()`  
Description: Returns information about the snapshot execution time. To access this function, set the **enable\_wdr\_snapshot** parameter to **on** and obtain the permission to access the **snapshot schema**, **snapshot table**, and **tables\_snap\_timestamp** tables.  
Parameter: nan  
Return type: `snap_id` bigint, `dbid` oid, `begin_interval_time` timestamp(3), `end_interval_time` timestamp(3), `flush_elapsed` interval day(5) to second(1), `begin_interval_time_tz` timestamp(3) with time zone, `end_interval_time_tz` timestamp(3) with time zone
- `global_sql_patch_func()`  
Description: SQL patch information on each global node, which is used to return the result of the `global_sql_patch` view.  
For details about the return values, see [Table 7-96](#).

**Table 7-96** `global_sql_patch_func` return parameters

Name	Type	Description
<code>node_name</code>	text	Name of the node where the SQL patch is located.
<code>patch_name</code>	name	Patch name.
<code>unique_sql_id</code>	bigint	Global unique query ID.
<code>owner</code>	oid	ID of the user who creates the patch.
<code>enable</code>	boolean	Determines whether the patch takes effect.
<code>status</code>	"char"	Patch status (reserved field).
<code>abort</code>	boolean	Determines whether the value is <b>AbortHint</b> .
<code>hint_string</code>	text	Hint text.
<code>description</code>	text	Patch description.
<code>parent_unique_sql_id</code>	bigint	Globally unique ID of the outer statement of the SQL statement for which the patch takes effect. The value of this parameter is <b>0</b> for statements outside a stored procedure. For statements inside the stored procedure, the value of this parameter is the globally unique ID of the statement that calls the stored procedure.

- `gs_get_current_version()`  
Description: Returns the current compilation mode based on the current compilation macro. 'M' is returned.  
Parameter: nan  
Return type: char
- `gs_get_kernel_info()`  
Description: Global transaction information on each primary CN and DN.  
For details about the return values, see [Table 7-97](#).

**Table 7-97** `gs_get_kernel_info` parameter description

Name	Type	Description
node_name	text	Node name.
module	text	Module name, including: <ul style="list-style-type: none"><li>• <b>XACT</b> (transaction module)</li><li>• <b>STANDBY</b> (standby module)</li><li>• <b>UNDO</b> (undo module)</li><li>• <b>HOTPATH</b> (hot patch module)</li></ul>

Name	Type	Description
name	text	<p>Name of the key data in the memory state, including:</p> <ul style="list-style-type: none"> <li>• <b>startup_max_xid</b> (maximum XID when a thread is started)</li> <li>• <b>recent_local_xmin</b> (minimum XID of a local active transaction)</li> <li>• <b>recent_global_xmin</b> (minimum XID of a global active transaction)</li> <li>• <b>standby_xmin</b> (minimum XID of an active transaction on the standby node)</li> <li>• <b>standby_redo_cleanup_xmin</b> (minimum XID of cleanup logs during redo on the standby node)</li> <li>• <b>standby_redo_cleanup_xmin_lsn</b> (LSN of the minimum XID of cleanup logs during redo on the standby node)</li> <li>• <b>local_csn_min</b> (minimum CSN of a local active transaction)</li> <li>• <b>replication_slot_xmin</b> (minimum XID of a replication slot)</li> <li>• <b>replication_slot_catalog_xmin</b> (minimum XID of a catalog replication slot)</li> <li>• <b>global_recycle_xid</b> (minimum XID of a global undo recycling transaction)</li> <li>• <b>global_frozen_xid</b> (minimum XID of a globally frozen transaction)</li> <li>• <b>recent_xmin</b> (minimum XID of active transactions in the current session)</li> <li>• <b>next_csn</b> (CSN of the next transaction)</li> <li>• <b>hotpatch_additional_info</b> (reserved column for hot patches)</li> <li>• <b>stmt_session_discard_records</b> (data volume discarded by full SQL statements due to full slots supported by the kernel)</li> <li>• <b>stmt_shm_flush_discard_records</b> (data volume discarded by full SQL statements due to full ringbuf supported by the kernel)</li> </ul>
value	text	Value of the key data in the memory state.

Example:

```
gaussdb=# SELECT * FROM gs_get_kernel_info();
node_name | module | name | value
-----+-----+-----+-----
```

```

coordinator1 | XACT | startup_max_xid | 16488
coordinator1 | XACT | recent_local_xmin | 16504
coordinator1 | XACT | recent_global_xmin | 16503
coordinator1 | STANDBY | standby_xmin | 0
coordinator1 | STANDBY | standby_redo_cleanup_xmin | 0
coordinator1 | STANDBY | standby_redo_cleanup_xmin_lsn | 0/0
coordinator1 | XACT | local_csn_min | 6014225
coordinator1 | XACT | replication_slot_xmin | 0
coordinator1 | XACT | replication_slot_catalog_xmin | 0
coordinator1 | UNDO | global_recycle_xid | 16501
coordinator1 | XACT | global_frozen_xid | 0
coordinator1 | XACT | recent_xmin | 16504
coordinator1 | XACT | next_csn | 6014226
coordinator1 | HOTPATH | hotpatch_additional_info |
coordinator1 | FULL_SQL | stmt_session_discard_records | 0
coordinator1 | FULL_SQL | stmt_shm_flush_discard_records | 0
datanode1 | XACT | startup_max_xid | 16488
datanode1 | XACT | recent_local_xmin | 15805
datanode1 | XACT | recent_global_xmin | 15805
datanode1 | STANDBY | standby_xmin | 0
datanode1 | STANDBY | standby_redo_cleanup_xmin | 0
datanode1 | STANDBY | standby_redo_cleanup_xmin_lsn | 0/0
datanode1 | XACT | local_csn_min | 6014225
datanode1 | XACT | replication_slot_xmin | 0
datanode1 | XACT | replication_slot_catalog_xmin | 0
datanode1 | UNDO | global_recycle_xid | 15805
datanode1 | XACT | global_frozen_xid | 0
datanode1 | XACT | recent_xmin | 15805
datanode1 | XACT | next_csn | 6014226
datanode1 | HOTPATH | hotpatch_additional_info |
datanode1 | FULL_SQL | stmt_session_discard_records | 0
datanode1 | FULL_SQL | stmt_shm_flush_discard_records | 0
(32 row)

```

## 7.6.26 System Administration Functions

### 7.6.26.1 Configuration Setting Functions

Configuration setting functions are used for querying and modifying GUC parameters during running.

- `current_setting(setting_name)`

Description: Specifies the current setting.

Return type: text

Note: **current\_setting** obtains the current setting of **setting\_name** by query. It is equivalent to the **SHOW** statement. For example:

```

gaussdb=# SELECT current_setting('datestyle');
current_setting
-----
ISO, MDY
(1 row)

```

- `set_working_grand_version_num_manually(tmp_version)`

Description: Upgrades new features of GaussDB by switching the authorization version.

Return type: void

- `shell_in(type)`

Description: Inputs a route for the shell type that has not yet been filled.

Return type: void

- `shell_out(type)`  
Description: Outputs a route for the shell type that has not yet been filled.  
Return type: void
- `set_config(setting_name, new_value, is_local)`  
Description: Sets the parameter and returns a new value.  
Return type: text  
Note: **set\_config** sets the parameter **setting\_name** to **new\_value**. If **is\_local** is **true**, **new\_value** will only apply to the current transaction. If you want **new\_value** to apply to the current session, use **false** instead. This function is equivalent to the SQL statement SET.

Example:

```
gaussdb=# SELECT set_config('log_statement_stats', 'off', false);
 set_config
-----
 off
(1 row)
```

### 7.6.26.2 Universal File Access Functions

Universal file access functions provide local access interfaces for files on a database server. Only files in the database cluster directory and the **log\_directory** directory can be accessed. A relative path is used for files in the cluster directory, and a path matching the **log\_directory** configuration setting is used for log files. Only database initialization users can use these functions.

- `pg_ls_dir(dirname text)`  
Description: Lists files in a directory.  
Return type: setof text  
Note: **pg\_ls\_dir** returns all the names in the specified directory, except the special entries "." and "..".

Example:

```
gaussdb=# SELECT pg_ls_dir('./');
 pg_ls_dir
-----
 .gaussdb.conf.swp
 gaussdb.conf
 pg_tblspc
 PG_VERSION
 gs_ident.conf
 core
 server.crt
 pg_serial
 pg_twophase
 gaussdb.conf.lock
 pg_stat_tmp
 pg_notify
 pg_subtrans
 pg_ctl.lock
 pg_xlog
 pg_clog
 base
 pg_snapshots
 postmaster.opts
 postmaster.pid
 server.key.rand
 server.key.cipher
```

```
pg_multixact
pg_errorinfo
server.key
gs_hba.conf
pg_replslot
.gs_hba.conf.swp
cacert.pem
gs_hba.conf.lock
global
gaussdb.state
(32 rows)
```

- `pg_read_file(filename text, offset bigint, length bigint)`

Description: Returns the content of a text file.

Return type: text

Note: **pg\_read\_file** returns part of a text file. It can return a maximum of *length* bytes from *offset*. The actual size of fetched data is less than *length* if the end of the file is reached first. If *offset* is negative, it is the length rolled back from the file end. If *offset* and *length* are omitted, the entire file is returned.

Example:

```
gaussdb=# SELECT pg_read_file('postmaster.pid',0,100);
           pg_read_file
```

```
-----
53078          +
/srv/BigData/testdir/data1/coordinator+
1500022474     +
8000          +
/var/run/FusionInsight      +
localhost      +
2
(1 row)
```

- `pg_read_binary_file(filename text [, offset bigint, length bigint,missing_ok boolean])`

Description: Returns the content of a binary file.

Return type: bytea

Note: **pg\_read\_binary\_file** is similar to **pg\_read\_file**, except that the result is a **bytea** value; accordingly, no encoding checks are performed. In combination with the `convert_from` function, this function can be used to read a file in a specified encoding.

```
gaussdb=# SELECT convert_from(pg_read_binary_file('filename'), 'UTF8');
```

- `pg_stat_file(filename text)`

Description: Returns status information about a file.

Return type: record

Note: **pg\_stat\_file** returns a record containing the file size, last access timestamp, last modification timestamp, last file status change timestamp, and a **Boolean** value indicating if it is a directory. Typical usages are as follows:

```
gaussdb=# SELECT * FROM pg_stat_file('filename');
gaussdb=# SELECT (pg_stat_file('filename')).modification;
```

Example:

```
gaussdb=# SELECT convert_from(pg_read_binary_file('postmaster.pid'), 'UTF8');
           convert_from
```

```
-----
4881          +
/srv/BigData/gaussdb/data1/coordinator+
```

```
1496308688      +
25108           +
/opt/huawei/Bigdata/gaussdb/gaussdb_tmp +
*              +
25108001 43352069      +

(1 row)
gaussdb=# SELECT * FROM pg_stat_file('postmaster.pid');

size |      access      |      modification      |      change
| creation | isdir
-----+-----+-----+-----
117 | 2017-06-05 11:06:34+08 | 2017-06-01 17:18:08+08 | 2017-06-01 17:18:08+08
|      | f
(1 row)
gaussdb=# SELECT (pg_stat_file('postmaster.pid')).modification;
modification
-----
2017-06-01 17:18:08+08
(1 row)
```

### 7.6.26.3 Server Signal Functions

Server signal functions send control signals to other server threads. Only the system administrator has the permission to execute the following functions:

- `pg_cancel_backend(pid int)`  
Description: Cancels a statement that is being executed by a backend thread.  
Return type: Boolean  
Note: `pg_cancel_backend` sends a query cancellation (SIGINT) signal to the backend thread identified by **pid**. The PID of an active backend thread can be found in the **pid** column of the `pg_stat_activity` view, or can be found by listing the database thread using `ps` on the server. A user with the SYSADMIN permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits permissions of the built-in role `gs_role_signal_backend` can use this function.
- `pg_cancel_session(pid bigint, sessionid bigint)`  
Description: Cancels the statement that is being executed by an active session in thread pool mode.  
Return type: Boolean  
Note: The input parameters of `pg_cancel_session` can be queried using the **pid** and **sessionid** columns in `pg_stat_activity`. The input parameters can be used to cancel the statements that are being executed by active sessions in thread pool mode. When the input parameters **pid** and **sessionid** are the same and both are thread IDs, the function of `pg_cancel_backend` is the same as that of `pg_cancel_backend`.
- `pg_cancel_invalid_query()`  
Description: Cancels the invalid query of a backend.  
Return type: Boolean  
Note: Only the system administrator has the permission to cancel queries that are running in the backend of a degraded GTM.
- `pg_reload_conf()`  
Description: Causes all server threads to overload their configuration files.

Return type: Boolean

Note: `pg_reload_conf` sends a `SIGHUP` signal to the server. As a result, all server threads reload their configuration files.

- `pg_rotate_logfile()`

Description: Rotates the log files of the server.

Return type: Boolean

Note: `pg_rotate_logfile` sends a signal to the log file manager, instructing the manager to immediately switch to a new output file. This function works only when `redirect_stderr` is used for log output. Otherwise, no log file manager sub-thread is generated.

- `pg_terminate_session(pid bigint, sessionid bigint)`

Description: Terminates a backend session in thread pool mode.

Return type: Boolean

Note: The input parameters of this function can be queried using the **pid** and **sessionid** fields in `pg_stat_activity`. A user with the `SYSADMIN` permission, the owner of the database connected to the session, the owner of the session, or a user who inherits permissions of the built-in role `gs_role_signal_backend` has the permission to use this function.

---

#### NOTICE

When the input parameters **pid** and **sessionid** are the same and both are thread IDs, this function can terminate non-thread pool threads and active thread pool threads.

When the input parameters **pid** and **sessionid** are different, this function can terminate active sessions or close inactive sessions and the socket connection of the client.

- 
- `pg_terminate_active_session_socket(pid int64, sessionid int64)`

Description: Closes the socket connection between an active session and the client.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. This function can be used only by initial users.

- `pg_terminate_backend(pid int)`

Description: Terminates a backend thread. Only the system administrator and thread owner can use this function.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the `SYSADMIN` permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits permissions of the built-in role `gs_role_signal_backend` can use this function.

**NOTICE**

This function can terminate non-thread pool threads and active thread pool threads, but cannot terminate inactive thread pool threads.

Example:

```
gaussdb=# SELECT pid from pg_stat_activity;
 pid
-----
140657876268816
(1 rows)

gaussdb=# SELECT pg_terminate_backend(140657876268816);
 pg_terminate_backend
-----
t
(1 row)
```

## 7.6.26.4 Backup and Restoration Control Functions

### Backup Control Functions

Backup control functions help with online backup.

- `pg_create_restore_point(name text)`

Description: Creates a named point for performing a restore (requires an administrator role).

Return type: text

Note: **pg\_create\_restore\_point** creates a named transaction log record that can be used as a restoration target, and returns the corresponding transaction log location. The given name can then be used with **recovery\_target\_name** to specify the point up to which restoration will proceed. Avoid creating multiple restoration points with the same name, since restoration will stop at the first one whose name matches the restoration target.

- `pg_current_xlog_location()`

Description: Obtains the write position of the current transaction log.

Return type: text

Note: **pg\_current\_xlog\_location** displays the write position of the current transaction log in the same format as those of the previous functions. Read-only operations do not require permissions of the system administrator.

- `pg_current_xlog_insert_location()`

Description: Obtains the insert position of the current transaction log.

Return type: text

Note: **pg\_current\_xlog\_insert\_location** displays the insert position of the current transaction log. The insertion point is the logical end of the transaction log at any instant, while the write location is the end of what has been written out from the server's internal buffers. The write position is the end that can be detected externally from the server. This operation can be performed to archive only some of completed transaction log files. The insert position is mainly used for commissioning the server. Read-only operations do not require permissions of the system administrator.

- `gs_current_xlog_insert_end_location()`  
Description: Obtains the insert position of the current transaction log.  
Return type: text  
Note: **gs\_current\_xlog\_insert\_end\_location** displays the insert position of the current transaction log.
- `pg_start_backup(label text [, fast boolean ])`  
Description: Starts to perform online backup. (An administrator, replication role, or O&M administrator must enable **operation\_mode**.) Label strings starting with **gs\_roach** are reserved and can be used only by the internal backup tool GaussRoach.  
Return type: text  
Note: `pg_start_backup` receives a user-defined backup label (usually the name of the position where the backup dump file is stored). This function writes a backup label file to the data directory of the database cluster and then returns the starting position of backed up transaction logs in text mode. This function must be used together with `pg_stop_backup()`. If this function is called independently, `backup_label` remains. During WAL replay, the checkpoint is read based on `backup_label`. If the WAL file corresponding to the checkpoint has been reclaimed, the database cannot be started.  

```
gaussdb=# SELECT pg_start_backup('label_goes_here',true);
pg_start_backup
-----
0/3000020
(1 row)
```
- `pg_stop_backup()`  
Description: Completes online backup An administrator, replication role, or O&M administrator must enable **operation\_mode**.  
Return type: text  
Note: **pg\_stop\_backup** deletes the label file created by **pg\_start\_backup** and creates a backup history file in the transaction log archive area. The history file includes the label given to **pg\_start\_backup**, the start and end transaction log locations for the backup, and the start and end time of the backup. The return value is the backup's ending transaction log location. After the end position is calculated, the insert position of the current transaction log automatically goes ahead to the next transaction log file. The ended transaction log file can be immediately archived so that backup is complete.
- `pg_switch_xlog()`  
Description: Switches to a new transaction log file An administrator or O&M administrator must enable **operation\_mode**.  
Return type: text  
Note: **pg\_switch\_xlog** moves to the next transaction log file so that the current log file can be archived (if continuous archive is used). The return value is the ending transaction log location + 1 within the just-completed transaction log file. If there has been no transaction log activity since the last transaction log switchover, `pg_switch_xlog` does not move but returns the start location of the transaction log file currently in use.
- `pg_xlogfile_name(location text)`  
Description: Converts the position string in a transaction log to a file name.  
Return type: text

Note: **pg\_xlogfile\_name** extracts only the transaction log file name. If the given transaction log position is the transaction log file border, a transaction log file name will be returned for both the two functions. This is usually the desired behavior for managing transaction log archiving, since the preceding file is the last one that currently needs to be archived.

- **pg\_xlogfile\_name\_offset**(location text)

Description: Converts the position string in a transaction log to a file name and returns the byte offset in the file.

Return type: text, integer

Note: **pg\_xlogfile\_name\_offset** can extract transaction log file names and byte offsets from the returned results of the preceding functions. Example:

```
gaussdb=# SELECT * FROM pg_xlogfile_name_offset(pg_stop_backup());
NOTICE: pg_stop_backup cleanup done, waiting for required WAL segments to be archived
NOTICE: pg_stop_backup complete, all required WAL segments have been archived
  file_name          | file_offset
-----+-----
000000010000000000000003 |      272
(1 row)
```

- **pg\_xlog\_location\_diff**(location text, location text)

Description: Calculates the difference in bytes between two transaction log locations.

Return type: numeric

- **pg\_cbm\_start\_tracked\_location**()

Description: Queries the start LSN parsed by CBM.

Return type: text

- **pg\_cbm\_tracked\_location**()

Description: Queries the LSN location parsed by CBM.

Return type: text

- **pg\_cbm\_get\_merged\_file**(startLSNArg text, endLSNArg text)

Description: Combines CBM files within the specified LSN range into one and returns the name of the combined file.

Return type: text

Note: Only the system administrator or O&M administrator can obtain the CBM combination file.

- **pg\_cbm\_get\_changed\_block**(startLSNArg text, endLSNArg text)

Description: Combines CBM files within the specified LSN range into a table and return records of this table.

Return type: record

Note: The table columns returned by **pg\_cbm\_get\_changed\_block** include the start LSN, end LSN, tablespace OID, database OID, table relfilenode, table fork number, whether the table is a system catalog, whether the table is deleted, whether the table is created, whether the table is truncated, number of pages in the truncated table, number of modified pages, and list of modified page numbers.

- **pg\_cbm\_recycle\_file**(targetLSNArg text)

Description: Deletes the CBM files that are no longer used and returns the first LSN after the deletion.

- Return type: text
- `pg_cbm_force_track(targetLSNArg text,timeOut int)`  
Description: Forcibly executes the CBM trace to the specified Xlog position and returns the Xlog position of the actual trace end point.  
Return type: text
  - `pg_enable_delay_ddl_recycle()`  
Description: Enables DDL delay and returns the Xlog position of the enabling point. An administrator or O&M administrator must enable **operation\_mode**.  
Return type: text
  - `pg_disable_delay_ddl_recycle(barrierLSNArg text, isForce bool)`  
Description: Disables DDL delay and returns the Xlog range where DDL delay takes effect. An administrator or O&M administrator must enable **operation\_mode**.  
Return type: record
  - `pg_enable_delay_xlog_recycle()`  
Description: Enables the Xlog recycling delay function for CN recovery. An administrator or O&M administrator must enable **operation\_mode**.  
Return type: void
  - `pg_disable_delay_xlog_recycle()`  
Description: Disables the Xlog recycling delay function for CN recovery. An administrator or O&M administrator must enable **operation\_mode**.  
Return type: void
  - `pg_cbm_rotate_file(rotate_lsn text)`  
Description: Forcibly switches the file after the CBM parses **rotate\_lsn**. This function is called during the build process.  
Return type: void
  - `gs_roach_stop_backup(backupid text)`  
Description: Stops a backup started by the internal backup tool GaussRoach. It is similar to the **pg\_stop\_backup system** function but is more lightweight.  
Return type: text. The content is the insertion position of the current log.
  - `gs_roach_enable_delay_ddl_recycle(backupid name)`  
Description: Enables DDL delay and returns the log location of the enabling point. It is similar to the **pg\_enable\_delay\_ddl\_recycle** system function but is more lightweight. In addition, different **backupid** values can be used to concurrently open DDL statements with delay.  
Return type: text. The content is the log location of the start point.
  - `gs_roach_disable_delay_ddl_recycle(backupid text)`  
Description: Disables DDL delay, returns the range of logs on which DDL delay takes effect. It is similar to the **pg\_enable\_delay\_ddl\_recycle** system function but is more lightweight. In addition, the DDL delay function can be disabled concurrently by specifying different backupid values.  
Return type: record. The content is the range of logs for which DDL is delayed to take effect.
  - `gs_roach_switch_xlog(request_ckpt bool)`

Description: Switches the currently used log segment file and triggers a full checkpoint if **request\_ckpt** is set to **true**.

Return type: text. The content is the location of the segment log.

- `gs_block_dw_io(timeout int, identifier text)`

Description: Blocks doublewrite page flushing.

Parameter description:

- `timeout`

Block duration.

Value range: [0,3600], in seconds. The value **0** indicates that the block duration is 0s.

- `identifier`

ID of the operation.

Value range: a string, supporting only uppercase letters, lowercase letters, digits, and underscores (\_).

Return type: Boolean

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**.

- `gs_is_dw_io_blocked()`

Description: Checks whether disk flushing on the current doublewrite page is blocked. If disk flushing is blocked, **true** is returned.

Return type: Boolean

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**.

- `gs_pitr_advance_last_updated_barrier()`

Description: In PITR mode, forcibly updates the global maximum archived recovery point uploaded to OBS/NAS last time to the current point. No input parameter is required.

Return type: text

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**. This parameter is valid only on the first normal CN in a distributed system. The return value is the latest local maximum archived recovery point.

- `gs_pitr_clean_local_barrier_files('delete_timestamp')`

Description: Clears locally cached barrier record files.

Value range: The **delete\_timestamp** parameter is of the text type. It is a Linux timestamp and contains 10 characters.

Return type: text

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**. The returned result is the start timestamp of the earliest barrier file on the local host after the deletion.

- `gs_get_barrier_lsn(barrier_name text)`

Description: Obtains the LSN corresponding to the barrier created using a backup.

Return type: text

Note: Currently, only **gs\_roach\_full** and **gs\_roach\_inc** are supported. To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**.

- **gs\_gbr\_relation\_associated\_filenode**(schemaName name, tableName name)

Description: Returns the relfilenode of all indexes, sequences, partitions, toasts, and toast indexes related to the input table.

Return type: record

Note: The table columns returned by **gs\_gbr\_relation\_associated\_filenode** include the file type relkind, namespace where the file is located, relation name corresponding to the file, OID of the database where the file is located, OID of the tablespace where the file is located, and relfilenode of the file.

- **pg\_create\_physical\_replication\_slot\_extern**(slotname text, dummy\_standby bool, extra\_content text, need\_recycle\_xlog bool)

Description: Creates an OBS or a NAS archive slot. **slotname** indicates the name of the archive slot or recovery slot. The primary and standby slots must use the same slot name. **dummy\_standby** is a reserved parameter.

**extra\_content** contains some information about the archive slot. For an OBS archive slot, the format is

**OBS;obs\_server\_ip;obs\_bucket\_name;obs\_ak;obs\_sk;archive\_path;is\_recovery;is\_vote\_replicate**, in which **OBS** indicates the archive media of the archive slot, **obs\_server\_ip** indicates the IP address of OBS, **obs\_bucket\_name** indicates the bucket name, **obs\_ak** indicates the AK of OBS, **obs\_sk** indicates the SK of OBS, **archive\_path** indicates the archive path, and **is\_recovery** specifies whether the slot is an archive slot or a recovery slot (**0**: archive slot; **1**: recovery slot). **is\_vote\_replicate** indicates whether the voting copy is archived first. The value **0** indicates that the synchronous standby server is archived first, and the value **1** indicates that the voting copy is archived first.

This field is reserved in the current version and is not adapted yet. For a NAS archive slot, the format is **NAS;archive\_path;is\_recovery;is\_vote\_replicate**. Compared with the OBS archive slot, the NAS archive slot does not have the OBS configuration information, while the meanings of other fields are the same.

If the media is not OBS or NAS, the OBS archive slot is used by default. The **extra\_content** format is

**obs\_server\_ip;obs\_bucket\_name;obs\_ak;obs\_sk;archive\_path;is\_recovery;is\_vote\_replicate**.

**need\_recycle\_xlog** specifies whether to recycle old archived logs when creating an archive slot. The value **true** indicates that old archived logs are recycled, and the value **false** indicates that old archive logs are not recycled.

Return type: record contains slotname and xlog\_position

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit permissions of the built-in role **gs\_role\_replication**. Currently, multiple archive slots cannot be created.

Examples:

Create an OBS archive slot.

```
gaussdb=# SELECT * FROM pg_create_physical_replication_slot_extern('uuid', false, 'OBS;obs.cn-north-7.ulanqab.huawei.com;dyk;19D772JBCACXX3KWS51D;*****;gaussdb_uuid/dn1;0', false);
 slotname | xlog_position
-----+-----
 uuid    |
(1 row)
```

Create a NAS archive slot.

```
gaussdb=# SELECT * FROM pg_create_physical_replication_slot_extern('uuid', false, 'NAS:/data/nas/
media/gaussdb_uuid/dn1;0;0', false);
 slotname | xlog_position
-----+-----
 uuid    |
```

- `gs_set_obs_delete_location(delete_location text)`

Description: Sets the location where OBS archive logs can be deleted. The value of **delete\_location** is an LSN. The logs before this location have been replayed and flushed to disks and can be deleted on OBS.

Return type: `xlog_file_name` text, indicating the file name of the logs that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

```
gaussdb=# SELECT gs_set_obs_delete_location('0/54000000');
 gs_set_obs_delete_location
-----
 0000000100000000000000054_00
(1 row)
```

- `gs_set_obs_delete_location_with_slotname(cstring, cstring )`

Description: Sets the location where OBS archive logs in a specified archive slot can be deleted. The first parameter indicates the LSN. The logs before this location have been replayed and flushed to disks and can be deleted on OBS. The second parameter indicates the name of the archive slot.

Return type: `xlog_file_name` text, indicating the file name of the logs that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

- `gs_get_global_barrier_status()`

Description: `gs_get_global_barrier_status` is used to query the latest global barrier archived in OBS.

Return type: text

**global\_barrier\_id**: globally latest barrier ID.

**global\_achive\_barrier\_id**: globally latest archived barrier ID.

- `gs_get_global_barriers_status()`

Description: `gs_get_global_barriers_status` is used to query the latest global barrier archived in OBS.

Return type: text

**slot\_name**: slot name.

**global\_barrier\_id**: globally latest barrier ID.

**global\_achive\_barrier\_id**: globally latest archived barrier ID.

## Restoration Control Functions

Restoration control functions provide information about the status of standby nodes. These functions may be executed both during restoration and in normal running.

- `pg_is_in_recovery()`

Description: Returns **true** if restoration is still in progress.

Return type: Boolean

- `pg_last_xlog_receive_location()`  
Description: Obtains the last transaction log location received and synchronized to disk by streaming replication. While streaming replication is in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received and synchronized to disk during restoration. If streaming replication is disabled or if it has not yet started, the function returns a null value.  
Return type: text
- `pg_last_xlog_replay_location()`  
Description: Obtains last transaction log location replayed during restoration. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. When the server has been started normally without restoration, the function returns a null value.  
Return type: text
- `pg_last_xact_replay_timestamp()`  
Description: Obtains the timestamp of last transaction replayed during restoration. This is the time to commit a transaction or abort a WAL record on the primary node. If no transactions have been replayed during restoration, this function will return a null value. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. If the server normally starts without manual intervention, this function will return a null value.  
Return type: timestamp with time zone

Restoration control functions control restoration threads. These functions may be executed only during restoration.

- `pg_is_xlog_replay_paused()`  
Description: Returns **true** if restoration is paused.  
Return type: Boolean
- `pg_xlog_replay_pause()`  
Description: Pauses restoration immediately.  
Return type: void
- `pg_xlog_replay_resume()`  
Description: Restarts restoration if it was paused.  
Return type: void
- `gs_get_active_archiving_standby()`  
Description: Queries information about archive standby nodes in the same shard. The standby node name, archive location, and number of archived logs are returned.  
Return type: text, int
- `gs_pitr_get_warning_for_xlog_force_recycle()`
