| Input Parameter Type          | Return Value |
|-------------------------------|--------------|
| JSON value of the array type  | ARRAY        |
| JSON value of the object type | OBJECT       |

| Input Parameter Type                    | Return Value |
|-----------------------------------------|--------------|
| JSON value of the character string type | STRING       |
| JSON value of the numeric type          | NUMBER       |
| JSON value of the Boolean type          | BOOLEAN      |
| NULL                                    | NULL         |

**Example:**

```
gaussdb=# SELECT json_type('{\"w\":{\"2\":3},\"2\":4}');
json_type

OBJECT
(1 row)
```

```
gaussdb=# SELECT json_type('[1,2,2,3,3,4,4,4,4,4,4]');
json_type

ARRAY
(1 row)
```

- **json\_valid(json)**

Description: Returns **0** or **1** to indicate whether the given parameter is a valid JSON object. If the input parameter is null, **null** is returned.

Return type: object-json

Return type: bigint

**Example:**

```
gaussdb=# SELECT json_valid('{\"name\":\"Tom\"}');
json_valid

1
(1 row)
```

```
gaussdb=# SELECT json_valid('[1,23,4,5,5]');
json_valid

1
(1 row)
```

```
gaussdb=# SELECT json_valid('[1,23,4,5,5]');
json_valid

0
(1 row)
```

- **json\_agg(any)**

Description: Aggregates values into a JSON array.

Return type: array-json

**Example:**

```
gaussdb=# CREATE TABLE classes(name varchar, score int);
CREATE TABLE
gaussdb=# INSERT INTO classes VALUES('A',2);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('A',3);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',5);
```

```

INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',null);
INSERT 0 1
gaussdb=# SELECT * FROM classes;
 name | score
-----+-----
 A | 2
 A | 3
 D | 5
 D |
(4 rows)

gaussdb=# SELECT name, json_agg(score) score FROM classes GROUP BY name ORDER BY name;
 name | score
-----+-----
 A | [2, 3]
 D | [5, null]
(2 rows)

gaussdb=# DROP TABLE classes;
DROP TABLE

```

- **json\_object\_agg(any, any)**

Description: Aggregates values into a JSON object.

Return type: object-json

Example:

```

gaussdb=# CREATE TABLE classes(name varchar, score int);
CREATE TABLE
gaussdb=# INSERT INTO classes VALUES('A',2);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('A',3);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',5);
INSERT 0 1
gaussdb=# INSERT INTO classes VALUES('D',null);
INSERT 0 1
gaussdb=# SELECT * FROM classes;
 name | score
-----+-----
 A | 2
 A | 3
 D | 5
 D |
(4 rows)

gaussdb=# SELECT json_object_agg(name, score) FROM classes GROUP BY name;
 json_object_agg

 { "A" : 2, "A" : 3 }
 { "D" : 5, "D" : null }
(2 rows)

gaussdb=# DROP TABLE classes;
DROP TABLE

```

- **jsonb\_contained(jsonb, jsonb)**

Description: Same as the operator `<@`, determines whether all elements in \$1 exist at the top layer of \$2.

Return type: Boolean

Example:

```

gaussdb=# SELECT jsonb_contained('[1,2,3]', '[1,2,3,4]');
 jsonb_contained

 t
(1 row)

```

- `jsonb_contains(jsonb, jsonb)`  
Description: Same as the operator `@>`, checks whether all top-layer elements in `$1` are contained in `$2`.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT jsonb_contains('[1,2,3,4]', '[1,2,3]');
 jsonb_contains

t
(1 row)
```
- `jsonb_exists(jsonb, text)`  
Description: Same as the operator `?>`, determines whether all elements in the string array `$2` exist at the top layer of `$1` in the form of `key\elem\scalar`.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT jsonb_exists('["1",2,3]', '1');
 jsonb_exists

t
(1 row)
```
- `jsonb_exists_all(jsonb, text[])`  
Description: Same as the operator `?&`, checks whether all elements in the string array `$2` exist at the top layer of `$1` in the form of `key\elem\scalar`.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT jsonb_exists_all('["1","2",3]', '{1, 2}');
 jsonb_exists_all

t
(1 row)
```
- `jsonb_exists_any(jsonb, text[])`  
Description: Same as the operator `?|`, checks whether all elements in the string array `$2` exist at the top layer of `$1` in the form of `key\elem\scalar`.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT jsonb_exists_any('["1","2",3]', '{1, 2, 4}');
 jsonb_exists_any

t
(1 row)
```
- `jsonb_cmp(jsonb, jsonb)`  
Description: Compares values. A positive value indicates greater than, a negative value indicates less than, and `0` indicates equal.  
Return type: integer  
Example:

```
gaussdb=# SELECT jsonb_cmp('["a", "b"]', '{"a":1, "b":2}');
 jsonb_cmp

-1
(1 row)
```
- `jsonb_eq(jsonb, jsonb)`  
Description: Same as the operator `=`, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_eq(['a', 'b'], '{"a":1, "b":2}');
 jsonb_eq

f
(1 row)
```

- `jsonb_ne(jsonb, jsonb)`

Description: Same as the operator ``<>``, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_ne(['a', 'b'], '{"a":1, "b":2}');
 jsonb_ne

t
(1 row)
```

- `jsonb_gt(jsonb, jsonb)`

Description: Same as the operator ``>``, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_gt(['a', 'b'], '{"a":1, "b":2}');
 jsonb_gt

f
(1 row)
```

- `jsonb_ge(jsonb, jsonb)`

Description: Same as the operator ``>=``, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_ge(['a', 'b'], '{"a":1, "b":2}');
 jsonb_ge

f
(1 row)
```

- `jsonb_lt(jsonb, jsonb)`

Description: Same as the operator ``<``, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_lt(['a', 'b'], '{"a":1, "b":2}');
 jsonb_lt

t
(1 row)
```

- `jsonb_le(jsonb, jsonb)`

Description: Same as the operator ``<=``, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_le(['a', 'b'], '{"a":1, "b":2}');
 jsonb_le

t
(1 row)
```

- `to_json(anyelement)`

Description: Converts parameters to `json`.

Return type: json

Example:

```
gaussdb=# SELECT to_json('{1,5}::text[]);
to_json

[["1","5"]]
(1 row)
```

- `to_jsonb(anelement)`

Description: Converts the input `anelement` parameter to the JSONB type.

Return type: jsonb

#### NOTICE

- When the parameter is an empty string (""), if the SQL compatibility mode of the database is A, **NULL** is returned; if the SQL compatibility mode of the database is PG, an empty string is returned. This is because empty strings are treated as **NULL** in A compatibility mode.
- When the parameter is of the DATE type, if the database SQL compatibility mode is A, the returned result contains hour, minute, and second; if the database SQL compatibility mode is PG, the returned result does not contain hour, minute, and second. This is because DATE will be replaced by `TIMESTAMP(0) WITHOUT TIME ZONE` in A compatibility mode.

Example:

```
gaussdb=# SELECT to_jsonb(ARRAY[1, 2, 3, 4]);
to_jsonb

[1, 2, 3, 4]
(1 row)
```

- `jsonb_hash(jsonb)`

Description: Performs the hash operation on JSONB.

Return type: integer

Example:

```
gaussdb=# SELECT jsonb_hash('[1,2,3]');
jsonb_hash

-559968547
(1 row)
```

- Other Functions

```
json_agg_transfn
json_agg_finalfn
json_object_agg_transfn
json_object_agg_finalfn
```

## 7.6.14 HLL Functions and Operators

### Hash Functions

- `hll_hash_boolean(bool)`

Description: Hashes data of the Boolean type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_boolean(FALSE);
 hll_hash_boolean

-5451962507482445012
(1 row)
```

- `hll_hash_boolean(bool, int32)`

Description: Configures a hash seed (that is, changes the hash policy) and hashes data of the Boolean type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_boolean(FALSE, 10);
 hll_hash_boolean

-1169037589280886076
(1 row)
```

- `hll_hash_smallint(smallint)`

Description: Hashes data of the smallint type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_smallint(100::smallint);
 hll_hash_smallint

962727970174027904
(1 row)
```

 **NOTE**

If parameters with the same numeric value are hashed using different data types, the data will differ, because hash functions select different calculation policies for each type.

- `hll_hash_smallint(smallint, int32)`

Description: Configures a hash seed (that is, changes the hash policy) and hashes data of the smallint type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_smallint(100::smallint, 10);
 hll_hash_smallint

-9056177146160443041
(1 row)
```

- `hll_hash_integer(integer)`

Description: Hashes data of the integer type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_integer(0);
 hll_hash_integer

5156626420896634997
(1 row)
```

- `hll_hash_integer(integer, int32)`

Description: Hashes data of the integer type and configures a hash seed (that is, changes the hash policy).

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_integer(0, 10);
 hll_hash_integer

-5035020264353794276
(1 row)
```

- **hll\_hash\_bigint(bigint)**

Description: Hashes data of the bigint type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_bigint(100::bigint);
 hll_hash_bigint

-2401963681423227794
(1 row)
```

- **hll\_hash\_bigint(bigint, int32)**

Description: Hashes data of the bigint type and configures a hash seed (that is, changes the hash policy).

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_bigint(100::bigint, 10);
 hll_hash_bigint

-2305749404374433531
(1 row)
```

- **hll\_hash\_bytea(bytea)**

Description: Hashes data of the bytea type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_bytea(E'\x');
 hll_hash_bytea

0
(1 row)
```

- **hll\_hash\_bytea(bytea, int32)**

Description: Hashes data of the bytea type and configures a hash seed (that is, changes the hash policy).

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_bytea(E'\x', 10);
 hll_hash_bytea

7233188113542599437
(1 row)
```

- **hll\_hash\_text(text)**

Description: Hashes data of the text type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_text('AB');
 hll_hash_text
```

```

-5666002586880275174
(1 row)
```

- **hll\_hash\_text(text, int32)**

Description: Hashes data of the text type and configures a hash seed (that is, changes the hash policy).

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_text('AB', 10);
hll_hash_text
```

```

-2215507121143724132
(1 row)
```

- **hll\_hash\_any(anytype)**

Description: Hashes data of any type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_any(1);
hll_hash_any
```

```

-1316670585935156930
(1 row)
```

```
gaussdb=# SELECT hll_hash_any('08:00:2b:01:02:03':macaddr);
hll_hash_any
```

```

-3719950434455589360
(1 row)
```

- **hll\_hash\_any(anytype, int32)**

Description: Hashes data of any type and configures a hash seed (that is, changes the hash policy).

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_any(1, 10);
hll_hash_any
```

```

7048553517657992351
(1 row)
```

- **hll\_hashval\_eq(hll\_hashval, hll\_hashval)**

Description: Compares two pieces of data of the hll\_hashval type to check whether they are the same.

Return type: Boolean

Example:

```
gaussdb=# SELECT hll_hashval_eq(hll_hash_integer(1), hll_hash_integer(1));
hll_hashval_eq
```

```

t
(1 row)
```

- **hll\_hashval\_ne(hll\_hashval, hll\_hashval)**

Description: Compares two pieces of data of the hll\_hashval type to check whether they are different.

Return type: Boolean

Example:

```
gaussdb=# SELECT hll_hashval_ne(hll_hash_integer(1), hll_hash_integer(1));
hll_hashval_ne

f
(1 row)
```

## HLL Functions

There are three HLL modes: explicit, sparse, and full. When the data size is small, the explicit mode is used. In this mode, distinct values are calculated without errors. As the number of distinct values increases, the HLL mode is switched to the sparse and full modes in sequence. The two modes have no difference in the calculation result, but vary in the calculation efficiency of HLL functions and the storage space of HLL objects. The following functions can be used to view some HLL parameters:

- `hll_print(hll)`

Description: Prints some debugging parameters of an HLL.

Example:

```
gaussdb=# SELECT hll_print(hll_empty());
hll_print

type=1(HLL_EMPTY), log2m=14, log2explicit=10, log2sparse=12, duplicatecheck=0
(1 row)
```

- `hll_type(hll)`

Description: Checks the type of the current HLL. The return values are described as follows: **0** indicates **HLL\_UNINIT**, an HLL object that is not initialized. **1** indicates **HLL\_EMPTY**, an empty HLL object. **2** indicates **HLL\_EXPLICIT**, an HLL object in explicit mode. **3** indicates **HLL\_SPARSE**, an HLL object in sparse mode. **4** indicates **HLL\_FULL**, an HLL object in full mode. **5** indicates **HLL\_UNDEFINED**, an invalid HLL object.

Example:

```
gaussdb=# SELECT hll_type(hll_empty());
hll_type

1
(1 row)
```

- `hll_log2m(hll)`

Description: Checks the value of **log2m** in the current HLL data structure. **log2m** is the logarithm of the number of buckets. This value affects the error rate of calculating distinct values by HLL. The error rate =  $\pm 1.04/\sqrt{2^{\log 2m}}$ . When the value of **log2m** is explicitly set a value ranges from 10 to 16, HLL sets the number of buckets to  $2^{\log 2m}$ . When the value of **log2explicit** is explicitly set to **-1**, the built-in default value is used.

Example:

```
gaussdb=# SELECT hll_log2m(hll_empty());
hll_log2m

14
(1 row)

gaussdb=# SELECT hll_log2m(hll_empty(10));
hll_log2m

10
(1 row)
```

```
gaussdb=# SELECT hll_log2m(hll_empty(-1));
hll_log2m

 14
(1 row)
```

- **hll\_log2explicit(hll)**

Description: Queries the value of **log2explicit** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can change the value of **log2explicit** to change the policy. For example, if the value of **log2explicit** is **0**, the HLL will skip the explicit mode and directly enter the sparse mode. When the value of **log2explicit** is explicitly set to a value ranging from 1 to 12, the HLL will switch to the sparse mode when the length of the data segment exceeds  $2^{\text{log2explicit}}$ . When the value of **log2explicit** is explicitly set to **-1**, the built-in default value is used.

Example:

```
gaussdb=# SELECT hll_log2explicit(hll_empty());
hll_log2explicit

 10
(1 row)
```

```
gaussdb=# SELECT hll_log2explicit(hll_empty(12, 8));
hll_log2explicit

 8
(1 row)
```

```
gaussdb=# SELECT hll_log2explicit(hll_empty(12, -1));
hll_log2explicit

 10
(1 row)
```

- **hll\_log2sparse(hll)**

Description: Queries the value of **log2sparse** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can adjust the value of **log2sparse** to change the policy. For example, if the value of **log2sparse** is **0**, the system skips the sparse mode and directly enters the full mode. If the value of **log2sparse** is explicitly set to a value ranging from 1 to 14, the HLL will switch to the full mode when the length of the data segment exceeds  $2^{\text{log2sparse}}$ . When the value of **log2sparse** is explicitly set to **-1**, the built-in default value is used.

Example:

```
gaussdb=# SELECT hll_log2sparse(hll_empty());
hll_log2sparse

 12
(1 row)
```

```
gaussdb=# SELECT hll_log2sparse(hll_empty(12, 8, 10));
hll_log2sparse

 10
(1 row)
```

```
gaussdb=# SELECT hll_log2sparse(hll_empty(12, 8, -1));
```

Description: Performs the UNION operation on two HLL data structures to obtain one HLL.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_union(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
 hll_union

\x484c4c10002000002b090000000000000004000000000000000b3ccc49320cca1ae3e2921ff133fba
ed00
(1 row)
```

## Aggregate Functions

- `hll_add_agg(hll_hashval)`

Description: Groups hashed data into HLL.

Return type: HLL

Example:

```
-- Prepare data:
gaussdb=# CREATE TABLE t_id(id int);
gaussdb=# INSERT INTO t_id VALUES(generate_series(1,500));
gaussdb=# CREATE TABLE t_data(a int, c text);
gaussdb=# INSERT INTO t_data SELECT mod(id,2), id FROM t_id;

-- Create a table and specify an HLL column:
gaussdb=# CREATE TABLE t_a_c_hll(a int, c hll);

-- Use GROUP BY on column a to group data, and insert the data to the HLL:
gaussdb=# INSERT INTO t_a_c_hll SELECT a, hll_add_agg(hll_hash_text(c)) FROM t_data GROUP BY a;

-- Calculate the number of distinct values for each group in the HLL:
gaussdb=# SELECT a, #c AS cardinality FROM t_a_c_hll ORDER BY a;
 a | cardinality
---+-----
 0 | 247.862354346299
 1 | 250.908710610377
(2 rows)
```

- `hll_add_agg(hll_hashval, int32 log2m)`

Description: Groups hashed data into HLL and specifies the **log2m** parameter. The value ranges from 10 to 16. If the input is **-1** or **NULL**, the built-in default value is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), 12)) FROM t_data;
 hll_cardinality

497.965240179228
(1 row)
```

- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit)`

Description: Groups hashed data into HLL and specifies the **log2m** and **log2explicit** parameters in sequence. The value of **log2explicit** ranges from 0 to 12. The value **0** indicates that the explicit mode is skipped. This parameter is used to set the threshold of the explicit mode. When the length of the data segment reaches  $2^{\text{log2explicit}}$ , the mode is switched to the sparse or full mode. If the input is **-1** or **NULL**, the built-in default value of **log2explicit** is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 1)) FROM t_data;
 hll_cardinality

498.496062953313
(1 row)
```

- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse)`

Description: Groups hashed data into HLL and sets the **log2m**, **log2explicit**, and **log2sparse** parameters in sequence. The value of **log2sparse** ranges from 0 to 14. The value **0** indicates that the sparse mode is skipped. This parameter is used to set the threshold of the sparse mode. When the length of the data segment reaches  $2^{\text{log2sparse}}$ , the mode is switched to the full mode. If the input is **-1** or **NULL**, the built-in default value of **log2sparse** is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10)) FROM t_data;
 hll_cardinality

498.496062953313
(1 row)
```

- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse, int32 duplicatecheck)`

Description: Groups hashed data into HLL and sets the **log2m**, **log2explicit**, **log2sparse**, and **duplicatecheck** parameters. The value of **duplicatecheck** can be **0** or **1**, indicating whether to enable this mode. By default, this mode is disabled. If the input is **-1** or **NULL**, the built-in default value of **duplicatecheck** is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10, -1)) FROM t_data;
 hll_cardinality

498.496062953313
(1 row)
```

- `hll_union_agg(hll)`

Description: Performs the UNION operation on multiple pieces of data of the HLL type to obtain one HLL.

Return type: HLL

Example:

```
-- Perform the UNION operation on data of the HLL type in each group to obtain one HLL, and
-- calculate the number of distinct values:
gaussdb=# SELECT #hll_union_agg(c) AS cardinality FROM t_a_c_hll;
 cardinality

498.496062953313
(1 row)
```

 **NOTE**

To perform the UNION operation on data in multiple HLLs, ensure that the HLLs have the same precision. Otherwise, **UNION** cannot be performed. This constraint also applies to the **hll\_union(hll, hll)** function.

## Obsolete Functions

Some old HLL functions are discarded due to version upgrade. You can replace them with similar functions.

- `hll_schema_version(hll)`  
Description: Checks the schema version in the current HLL. In earlier versions, the schema version is fixed at **1**, which is used to verify the header of the HLL field. After refactoring, the HLL field is added to the header for verification. The schema version is no longer used.
- `hll_regwidth(hll)`  
Description: Queries the bucket size in the HLL data structure. In earlier versions, the value of **regwidth** ranges from 1 to 5, which has a large error and limits the upper limit of the cardinality estimation. After refactoring, the value of **regwidth** is fixed at **6** and the variable is not used.
- `hll_expthresh(hll)`  
Description: Obtains the value of **expthresh** in the current HLL. The `hll_log2explicit(hll)` function is used to replace similar functions.
- `hll_sparseon(hll)`  
Description: Specifies whether the sparse mode is enabled. Use `hll_log2sparse(hll)` to replace similar functions. The value **0** indicates that the sparse mode is disabled.

## Built-In Functions

HLL has a series of built-in functions for internal data processing. Generally, users do not need to know how to use these functions. For details, see [Table 7-75](#).

**Table 7-75** Built-in functions

| Function                    | Description                                                 |
|-----------------------------|-------------------------------------------------------------|
| <code>hll_in</code>         | Receives HLL data in string format.                         |
| <code>hll_out</code>        | Sends HLL data in string format.                            |
| <code>hll_recv</code>       | Receives HLL data in bytea format.                          |
| <code>hll_send</code>       | Sends HLL data in bytea format.                             |
| <code>hll_trans_in</code>   | Receives <code>hll_trans_type</code> data in string format. |
| <code>hll_trans_out</code>  | Sends <code>hll_trans_type</code> data in string format.    |
| <code>hll_trans_recv</code> | Receives <code>hll_trans_type</code> data in bytea format.  |
| <code>hll_trans_send</code> | Sends <code>hll_trans_type</code> data in bytea format.     |
| <code>hll_typmod_in</code>  | Receives <code>typmod</code> data.                          |
| <code>hll_typmod_out</code> | Sends <code>typmod</code> data.                             |
| <code>hll_hashval_in</code> | Receives <code>hll_hashval</code> data.                     |

| Function          | Description                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hll_hashval_out   | Sends hll_hashval data.                                                                                                                                                   |
| hll_add_trans0    | Works similar to hll_add. No input parameter is specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.      |
| hll_add_trans1    | Works similar to hll_add. An input parameter is specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.      |
| hll_add_trans2    | Works similar to hll_add. Two input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.   |
| hll_add_trans3    | Works similar to hll_add. Three input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations. |
| hll_add_trans4    | Works similar to hll_add. Four input parameters are specified during initialization. It is usually used in the first phase of DNs in distributed aggregation operations.  |
| hll_union_trans   | Works similar to hll_union and is used on the first phase of DNs in distributed aggregation operations.                                                                   |
| hll_union_collect | Works similar to hll_union and is used on the second phase of CNs in distributed aggregation operations to summarize the results of each DN.                              |
| hll_pack          | Is used on the third phase of CNs in distributed aggregation operations to convert a user-defined type hll_trans_type to the HLL type.                                    |
| hll               | Converts an HLL type to another HLL type. Input parameters can be specified.                                                                                              |
| hll_hashval       | Converts the bigint type to the hll_hashval type.                                                                                                                         |
| hll_hashval_int4  | Converts the int4 type to the hll_hashval type.                                                                                                                           |

## Operators

- =  
 Description: Compares the values of the HLL or hll\_hashval type to check whether they are the same.  
 Return type: Boolean  
 Example:  

```
--hll
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) = (hll_empty() || hll_hash_integer(1));
column

t
(1 row)
```

```
--hll_hashval
gaussdb=# SELECT hll_hash_integer(1) = hll_hash_integer(1);
?column?

t
(1 row)
```

- <> or !=

Description: Compares the values of the HLL or hll\_hashval type to check whether they are different.

Return type: Boolean

Example:

```
--hll
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) <> (hll_empty() || hll_hash_integer(2));
?column?

t
(1 row)

--hll_hashval
gaussdb=# SELECT hll_hash_integer(1) <> hll_hash_integer(2);
?column?

t
(1 row)
```

- ||

Description: Represents the functions of hll\_add, hll\_union, and hll\_add\_rev.

Return type: HLL

Example:

```
--hll_add
gaussdb=# SELECT hll_empty() || hll_hash_integer(1);
?column?

\x484c4c08000002002b090000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_add_rev
gaussdb=# SELECT hll_hash_integer(1) || hll_empty();
?column?

\x484c4c08000002002b090000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_union
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) || (hll_empty() || hll_hash_integer(2));
?column?

\x484c4c10002000002b0900000000000000400000000000000b3ccc49320cca1ae3e2921ff133fbaed00
(1 row)
```

- #

Description: Calculates the number of distinct values of an HLL. It works the same as the hll\_cardinality function.

Return type: int

Example:

```
gaussdb=# SELECT #(hll_empty() || hll_hash_integer(1));
?column?

```

```
1
(1 row)
```

## 7.6.15 SEQUENCE Functions

The sequence functions provide a simple method to ensure security of multiple users for users to obtain sequence values from sequence objects.

- `nextval(regclass)`

Description: Specifies an increasing sequence and returns a new value.

### NOTE

- To avoid blocking of concurrent transactions that obtain numbers from the same sequence, a `nextval` operation is never rolled back; that is, once a value is fetched, it is considered used, even if the transaction that did the `nextval` later aborts. This means that aborted transactions may leave unused "holes" in the sequence of assigned values. Therefore, the GaussDB sequence object cannot be used to obtain "holeless" sequences.
- If the `nextval` function is pushed to DNs, each DN will automatically connect to the GTM and requests the next value. For example, in the **`insert into t1 select xxx`** statement, a column in table **`t1`** needs to call the `nextval` function. If the maximum number of connections on the GTM is 8192, this type of pushed statements occupies too many GTM connections. Therefore, the number of concurrent connections for these statements is limited to 7000 divided by the number of clusterDNs. The other connections are reserved for other statements.

Return type: numeric

The `nextval` function can be called in either of the following ways (In example 2, the ORA syntax is supported. Currently, the sequence name cannot contain a dot.):

```
gaussdb=# CREATE SEQUENCE seqDemo;

-- Example 1:
gaussdb=# SELECT nextval('seqDemo');
nextval

1
(1 row)

-- Example 2:
gaussdb=# SELECT seqDemo.nextval;
nextval

2
(1 row)
gaussdb=# DROP SEQUENCE seqDemo;
```

- `currval(regclass)`

Description: Returns the last value of **`nextval`** in the current session. If `nextval` has not been called for the specified sequence in the current session, an error is reported when `currval` is called. By default, **`currval`** is disabled. To enable it, set **`enable_beta_features`** to **`true`**. After **`enable_beta_features`** is set to **`true`**, **`nextval`** will not be pushed down.

Return type: numeric

The `currval` function can be called in either of the following ways (In example 2, the ORA syntax is supported. Currently, the sequence name cannot contain a dot.):

```
gaussdb=# CREATE SEQUENCE seq1;
gaussdb=# SELECT nextval('seq1');
```

```

gaussdb=# SET enable_beta_features = on;

-- Example 1:
gaussdb=# SELECT currval('seq1');
currval

 1
(1 row)

-- Example 2:
gaussdb=# SELECT seq1.currval seq1;
seq1

 1
(1 row)
gaussdb=# DROP SEQUENCE seq1;

```

- **lastval()**

Returns the last value of **nextval** in the current session. This function is equivalent to **currval**, except that it does not use sequence names as parameters. It fetches the sequence used by **nextval** last time in the current session. If **nextval** has not been called in the current session, an error is reported when **lastval** is called.

By default, **lastval** is disabled. To enable it, set **enable\_beta\_features** or **lastval\_supported** to **true**. After **lastval** is enabled, **nextval()** will not be pushed down.

Return type: numeric

Example:

```

gaussdb=# CREATE SEQUENCE seq1;
gaussdb=# SELECT nextval('seq1');
gaussdb=# SET enable_beta_features = on;
gaussdb=# SELECT lastval();
lastval

 1
(1 row)
gaussdb=# DROP SEQUENCE seq1;

```

- **setval(regclass, bigint)**

Description: Sets the current value of a sequence.

Return type: numeric

Example:

```

gaussdb=# CREATE SEQUENCE seqDemo;
gaussdb=# SELECT nextval('seqDemo');
gaussdb=# SELECT setval('seqDemo',3);
setval

 3
(1 row)
gaussdb=# DROP SEQUENCE seqDemo;

```

- **setval(regclass, numeric, Boolean)**

Sets the current value of a sequence and the **is\_called** sign.

Return type: numeric

Example:

```

gaussdb=# CREATE SEQUENCE seqDemo;
gaussdb=# SELECT nextval('seqDemo');
gaussdb=# SELECT setval('seqDemo',5,true);
setval

```

```
5
(1 row)
gaussdb=# DROP SEQUENCE seqDemo;
```

 **NOTE**

The current session and GTM will take effect immediately after setval is performed. If other sessions have buffered sequence values, setval will take effect only after the values are used up. Therefore, to prevent sequence value conflicts, you are advised to perform setval with caution.

Because the sequence is non-transactional, changes made by setval will not be canceled when a transaction rolled back.

- `pg_sequence_last_value(sequence_oid oid, OUT cache_value int16, OUT last_value int16)`

Description: Obtains the parameters of a specified sequence, including the cache value and current value.

Return type: int16, int16

## 7.6.16 Array Functions and Operators

### Array Operators

- =

Description: Specifies whether two arrays are equal.

Example:

```
gaussdb=# SELECT ARRAY[1,1,2,1,3,1]::int[] = ARRAY[1,2,3] AS RESULT ;
result

t
(1 row)
```

- <>

Description: Specifies whether two arrays are not equal.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] <> ARRAY[1,2,4] AS RESULT;
result

t
(1 row)
```

- <

Description: Specifies whether an array is less than another.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] < ARRAY[1,2,4] AS RESULT;
result

t
(1 row)
```

- >

Description: Specifies whether an array is greater than another.

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] > ARRAY[1,2,4] AS RESULT;
result

t
(1 row)
```

- <=

Description: Specifies whether an array is less than another.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] <= ARRAY[1,2,3] AS RESULT;
result

t
(1 row)
```
- >=

Description: Specifies whether an array is greater than or equal to another.

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] >= ARRAY[1,4,3] AS RESULT;
result

t
(1 row)
```
- @>

Description: Specifies whether an array contains another.

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] @> ARRAY[3,1] AS RESULT;
result

t
(1 row)
```
- <@

Description: Specifies whether an array is contained in another.

Example:

```
gaussdb=# SELECT ARRAY[2,7] <@ ARRAY[1,7,4,2,6] AS RESULT;
result

t
(1 row)
```
- &&

Description: Specifies whether an array overlaps another (have common elements).

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] && ARRAY[2,1] AS RESULT;
result

t
(1 row)
```
- ||

Description: Array-to-array concatenation.

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] || ARRAY[4,5,6] AS RESULT;
result

{1,2,3,4,5,6}
(1 row)
gaussdb=# SELECT ARRAY[1,2,3] || ARRAY[[4,5,6],[7,8,9]] AS RESULT;
result

{{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

- ||  
Description: Element-to-array concatenation.

Example:

```
gaussdb=# SELECT 3 || ARRAY[4,5,6] AS RESULT;
result

{3,4,5,6}
(1 row)
```

- ||  
Description: Array-to-element concatenation.

Example:

```
gaussdb=# SELECT ARRAY[4,5,6] || 7 AS RESULT;
result

{4,5,6,7}
(1 row)
```

Array comparisons compare the array contents element-by-element, using the default B-tree comparison function for the element data type. In multidimensional arrays, the elements are accessed in row-major order. If the contents of two arrays are equal but the dimensionality is different, the first difference in the dimensionality information determines the sort order.

## Array Functions

- `array_append(anyarray, anyelement)`

Description: Appends an element to the end of an array, and only supports dimension-1 arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_append(ARRAY[1,2], 3) AS RESULT;
result

{1,2,3}
(1 row)
```

- `array_prepend(anyelement, anyarray)`

Description: Appends an element to the beginning of an array, and only supports dimension-1 arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_prepend(1, ARRAY[2,3]) AS RESULT;
result

{1,2,3}
(1 row)
```

- `array_cat(anyarray, anyarray)`

Description: Concatenates two arrays, and supports multi-dimensional arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_cat(ARRAY[1,2,3], ARRAY[4,5]) AS RESULT;
result

{1,2,3,4,5}
```

```
(1 row)

gaussdb=# SELECT array_cat(ARRAY[[1,2],[4,5]], ARRAY[6,7]) AS RESULT;
 result

{{1,2},{4,5},{6,7}}
(1 row)
```

- `array_union(anyarray, anyarray)`

Description: Concatenates two arrays. Only one-dimensional arrays are supported. If an input parameter is **NULL**, another input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_union(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
 result

{1,2,3,3,4,5}
(1 row)

gaussdb=# SELECT array_union(ARRAY[1,2,3], NULL) AS RESULT;
 result

{1,2,3}
(1 row)
```

- `array_union_distinct(anyarray, anyarray)`

Description: Concatenates two arrays and deduplicates them. Only one-dimensional arrays are supported. If an input parameter is **NULL**, another input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_union_distinct(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
 result

{1,2,3,4,5}
(1 row)

gaussdb=# SELECT array_union_distinct(ARRAY[1,2,3], NULL) AS RESULT;
 result

{1,2,3}
(1 row)
```

- `array_intersect(anyarray, anyarray)`

Description: Intersects two arrays. Only one-dimensional arrays are supported. If any input parameter is **NULL**, **NULL** is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_intersect(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
 result

{3}
(1 row)

gaussdb=# SELECT array_intersect(ARRAY[1,2,3], NULL) AS RESULT;
 result

(1 row)
```

- `array_intersect_distinct(anyarray, anyarray)`

Description: Intersects two arrays and deduplicates them. Only one-dimensional arrays are supported. If any input parameter is **NULL**, **NULL** is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_intersect_distinct(ARRAY[1,2,2], ARRAY[2,2,4,5]) AS RESULT;
result

{2}
(1 row)

gaussdb=# SELECT array_intersect_distinct(ARRAY[1,2,3], NULL) AS RESULT;
result

(1 row)
```

- `array_except(anyarray, anyarray)`

Description: Calculates the difference between two arrays. Only one-dimensional arrays are supported. If the first input parameter is **NULL**, **NULL** is returned. If the second input parameter is **NULL**, the first input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_except(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
result

{1,2}
(1 row)

gaussdb=# SELECT array_except(ARRAY[1,2,3], NULL) AS RESULT;
result

{1,2,3}
(1 row)

gaussdb=# SELECT array_except(NULL, ARRAY[3,4,5]) AS RESULT;
result

(1 row)
```

- `array_except_distinct(anyarray, anyarray)`

Description: Calculates the difference between two arrays and deduplicates them. Only one-dimensional arrays are supported. If the first input parameter is **NULL**, **NULL** is returned. If the second input parameter is **NULL**, the first input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_except_distinct(ARRAY[1,2,2,3], ARRAY[3,4,5]) AS RESULT;
result

{1,2}
(1 row)

gaussdb=# SELECT array_except_distinct(ARRAY[1,2,3], NULL) AS RESULT;
result

{1,2,3}
```

```
(1 row)
gaussdb=# SELECT array_except_distinct(NULL, ARRAY[3,4,5]) AS RESULT;
result

```

```
(1 row)
```

- `array_ndims(anyarray)`

Description: Returns the number of dimensions of an array.

Return type: int

Example:

```
gaussdb=# SELECT array_ndims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
result

 2
(1 row)
```

- `array_dims(anyarray)`

Description: Returns a text representation of array's dimensions.

Return type: text

Example:

```
gaussdb=# SELECT array_dims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
result

[1:2][1:3]
(1 row)
```

- `array_length(anyarray, int)`

Description: Returns the length of the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_length(array[1,2,3], 1) AS RESULT;
result

 3
(1 row)
```

- `array_lower(anyarray, int)`

Description: Returns lower bound of the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_lower(''[0:2]={1,2,3}::int[], 1) AS RESULT;
result

 0
(1 row)
```

- `array_sort(anyarray)`

Description: Returns an array in ascending order. Only one-dimensional array of the anyarray type supports sorting. Multidimensional arrays return **NULL**. Currently, the record, XML, XMLtype, and JSON arrays cannot be sorted.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_sort(ARRAY[5,1,3,6,2,7]) AS RESULT;
result

{1,2,3,5,6,7}
```

```
(1 row)
gaussdb=# SELECT array_sort(array[array[1,23], array[1,34]]);
array_sort

{NULL,NULL}
(1 row)
```

- `array_upper(anyarray, int)`

Description: Returns upper bound of the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_upper(ARRAY[1,8,3,7], 1) AS RESULT;
result

4
(1 row)
```

- `array_to_string(anyarray, text [, text])`

Description: Uses the first **text** as the new delimiter and the second **text** to replace **NULL** values.

Return type: text

Example:

```
gaussdb=# SELECT array_to_string(ARRAY[1, 2, 3, NULL, 5], ',', '**') AS RESULT;
result

1,2,3**,5
(1 row)
```

- `array_delete(anyarray)`

Description: Clears elements in an array and returns an empty array of the same type.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_delete(ARRAY[1,8,3,7]) AS RESULT;
result

{}
(1 row)
```

- `array_deleteidx(anyarray, int)`

Description: Deletes specified index elements from an array and returns an array consisting of the remaining elements.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_deleteidx(ARRAY[1,2,3,4,5], 1) AS RESULT;
result

{2,3,4,5}
(1 row)
```

#### NOTE

**array\_deleteidx(anyarray, int)**: This function is disabled when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1**.

- `array_extendnull(anyarray, int)`

Description: Adds a specified number of null elements to the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_extendnull(ARRAY[1,8,3,7],1) AS RESULT;
result

{1,8,3,7,null}
(1 row)
```

- `array_extendnull(anyarray, int, int)`

Description: Adds a specified number of elements with a specified index to the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_extendnull(ARRAY[1,8,3,7],2,2) AS RESULT;
result

{1,8,3,7,8,8}
(1 row)
```

 NOTE

**array\_extendnull(anyarray, int, int):** This function takes effect when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1**.

- `array_trim(anyarray, int)`

Description: Deletes a specified number of elements from the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_trim(ARRAY[1,8,3,7],1) AS RESULT;
result

{1,8,3}
(1 row)
```

- `array_exists(anyarray, int)`

Description: Checks whether the second parameter is a valid index of an array.

Return type: Boolean

Example:

```
gaussdb=# SELECT array_exists(ARRAY[1,8,3,7],1) AS RESULT;
result

t
(1 row)
```

- `array_next(anyarray, int)`

Description: Returns the index of the element following a specified index in an array based on the second input parameter.

Return type: int

Example:

```
gaussdb=# SELECT array_next(ARRAY[1,8,3,7],1) AS RESULT;
result

2
(1 row)
```

- `array_prior(anyarray, int)`

Description: Returns the index of the element followed by a specified index in an array based on the second input parameter.

Return type: int

Example:

```
gaussdb=# SELECT array_prior(ARRAY[1,8,3,7],2) AS RESULT;
result

1
(1 row)
```

- `string_to_array(text, text, [text])`

Description: Uses the second **text** as the new delimiter and the third **text** as the substring to be replaced by **NULL** values. A substring can be replaced by **NULL** values only when it is the same as the third **text**.

Return type: `text[]`

Example:

```
gaussdb=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'yy') AS RESULT;
result

{xx,NULL,zz}
(1 row)
gaussdb=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'y') AS RESULT;
result

{xx,yy,zz}
(1 row)
```

In **string\_to\_array**, if the delimiter parameter is **NULL**, each character in the input string will become a separate element in the resulting array. If the delimiter is an empty string, then the entire input string is returned as a one-element array. Otherwise, the input string is split at each occurrence of the delimiter string.

In **string\_to\_array**, if the null-string parameter is omitted or **NULL**, none of the substrings of the input will be replaced by **NULL**.

In **array\_to\_string**, if the null-string parameter is omitted or **NULL**, any null elements in the array are simply skipped and not represented in the output string.

- `unnest(anyarray)`

Description: Expands an array to a set of rows.

Return type: `setof anyelement`

Example:

```
gaussdb=# SELECT unnest(ARRAY[1,2]) AS RESULT;
result

1
2
(2 rows)
```

- `_pg_keysequal`

Description: Checks whether two smallint arrays are the same.

Parameter: `smallint[], smallint[]`

Return type: Boolean

 **NOTE**

This function exists in the `information_schema` namespace.

- `cardinality(anyarray)`

Description: Returns the total number of elements in each dimension of an array. If the array is empty, **0** is returned.

Return type: integer

Example:

```
gaussdb=# SELECT cardinality(array[[1, 2], [3, 4]]);
cardinality

4
(1 row)
```

- `array_positions(anyarray, anyelement)`

Description: Returns an array of indexes of all second parameters that appear in the array given as the first parameter.

Return type: `int[]`

Example:

```
gaussdb=# SELECT array_positions(array[1, 2, 3, 1], 1) AS RESULT;
result

{1,4}
(1 row)
```

 **NOTE**

- The array must be one-dimensional.
- The second parameter can be set to **NULL**.
- If no second parameter is found in the array, an empty array is returned.

## 7.6.17 Range Functions and Operators

### Range Operators

- `=`

Description: Equals

Example:

```
gaussdb=# SELECT int4range(1,5) = '[1,4]::int4range AS RESULT;
result

t
(1 row)
```

- `<>`

Description: Does not equal

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) <> numrange(1.1,2.3) AS RESULT;
result

t
(1 row)
```

- `<`

Description: Is less than

Example:

```
gaussdb=# SELECT int4range(1,10) < int4range(2,3) AS RESULT;
result

t
(1 row)
```

- `>`

Description: Is greater than

Example:

```
gaussdb=# SELECT int4range(1,10) > int4range(1,5) AS RESULT;
result

t
(1 row)
```

- <=

Description: Is less than or equals

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) <= numrange(1.1,2.2) AS RESULT;
result

t
(1 row)
```

- >=

Description: Is greater than or equals

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) >= numrange(1.1,2.0) AS RESULT;
result

t
(1 row)
```

- @>

Description: Contains range

Example:

```
gaussdb=# SELECT int4range(2,4) @> int4range(2,3) AS RESULT;
result

t
(1 row)
```

- @>

Description: Contains element

Example:

```
gaussdb=# SELECT '[2011-01-01,2011-03-01)::tsrange @> '2011-01-10)::timestamp AS RESULT;
result

t
(1 row)
```

- <@

Description: Range is contained by

Example:

```
gaussdb=# SELECT int4range(2,4) <@ int4range(1,7) AS RESULT;
result

t
(1 row)
```

- <@

Description: Element is contained by

Example:

```
gaussdb=# SELECT 42 <@ int4range(1,7) AS RESULT;
result

```

- ```
f
(1 row)
```

 - **&&**
Description: Overlap (have points in common)
Example:

```
gaussdb=# SELECT int8range(3,7) && int8range(4,12) AS RESULT;
result
-----
t
(1 row)
```
 - **<<**
Description: Strictly left of
Example:

```
gaussdb=# SELECT int8range(1,10) << int8range(100,110) AS RESULT;
result
-----
t
(1 row)
```
 - **>>**
Description: Strictly right of
Example:

```
gaussdb=# SELECT int8range(50,60) >> int8range(20,30) AS RESULT;
result
-----
t
(1 row)
```
 - **&<**
Description: Does not extend to the right of
Example:

```
gaussdb=# SELECT int8range(1,20) &< int8range(18,20) AS RESULT;
result
-----
t
(1 row)
```
 - **&>**
Description: Does not extend to the left of
Example:

```
gaussdb=# SELECT int8range(7,20) &> int8range(5,10) AS RESULT;
result
-----
t
(1 row)
```
 - **-|-**
Description: Is adjacent to
Example:

```
gaussdb=# SELECT numrange(1.1,2.2) -|- numrange(2.2,3.3) AS RESULT;
result
-----
t
(1 row)
```
 - **+**
Description: Union
Example:

```
gaussdb=# SELECT numrange(5,15) + numrange(10,20) AS RESULT;
result
-----
[5,20)
(1 row)
```

- *

Description: Intersection

Example:

```
gaussdb=# SELECT int8range(5,15) * int8range(10,20) AS RESULT;
result
-----
[10,15)
(1 row)
```

- -

Description: Difference

Example:

```
gaussdb=# SELECT int8range(5,15) - int8range(10,20) AS RESULT;
result
-----
[5,10)
(1 row)
```

The simple comparison operators `<`, `>`, `<=`, and `>=` compare the lower bounds first, and only if those are equal, compare the upper bounds.

The `<<`, `>>`, and `-|-` operators always return false when an empty range is involved; that is, an empty range is not considered to be either before or after any other range.

The union and difference operators will fail if the resulting range would need to contain two disjoint sub-ranges.

Range Functions

The lower and upper functions return null if the range is empty or the requested bound is infinite. The `lower_inc`, `upper_inc`, `lower_inf`, and `upper_inf` functions all return false for an empty range.

- `numrange(numeric, numeric, [text])`

Description: Specifies a range.

Return type: range's element type

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) AS RESULT;
result
-----
[1.1,2.2)
(1 row)
gaussdb=# SELECT numrange(1.1,2.2, '(') AS RESULT;
result
-----
(1.1,2.2)
(1 row)
```

- `lower(anyrange)`

Description: Lower bound of range

Return type: range's element type

Example:

```
gaussdb=# SELECT lower(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
1.1  
(1 row)
```

- **upper(anyrange)**
Description: Upper bound of range
Return type: range's element type
Example:

```
gaussdb=# SELECT upper(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
2.2  
(1 row)
```

- **isempty(anyrange)**
Description: Is the range empty?
Return type: Boolean
Example:

```
gaussdb=# SELECT isempty(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
f  
(1 row)
```

- **lower_inc(anyrange)**
Description: Is the lower bound inclusive?
Return type: Boolean
Example:

```
gaussdb=# SELECT lower_inc(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
t  
(1 row)
```

- **upper_inc(anyrange)**
Description: Is the upper bound inclusive?
Return type: Boolean
Example:

```
gaussdb=# SELECT upper_inc(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
f  
(1 row)
```

- **lower_inf(anyrange)**
Description: Is the lower bound infinite?
Return type: Boolean
Example:

```
gaussdb=# SELECT lower_inf('(,):daterange) AS RESULT;  
result  
-----  
t  
(1 row)
```

- **upper_inf(anyrange)**
Description: Is the upper bound infinite?

Return type: Boolean

Example:

```
gaussdb=# SELECT upper_inf('::daterange') AS RESULT;
result
-----
t
(1 row)
```

- `elem_contained_by_range(anyelement, anyrange)`

Description: Determines whether an element is within the range.

Return type: Boolean

Example:

```
gaussdb=# SELECT elem_contained_by_range('2', numrange(1.1,2.2));
elem_contained_by_range
-----
t
(1 row)
```

7.6.18 Aggregate Functions

Aggregate Functions

- `sum(expression)`

Description: Sum of expression across all input values

Return type:

Generally, same as the argument data type. In the following cases, type conversion occurs:

- BIGINT for SMALLINT or INT arguments
- NUMBER for BIGINT arguments
- DOUBLE PRECISION for floating-point arguments

Example:

```
gaussdb=# CREATE TABLE tab(a int);
CREATE TABLE
gaussdb=# INSERT INTO tab values(1);
INSERT 0 1
gaussdb=# INSERT INTO tab values(2);
INSERT 0 1
gaussdb=# SELECT sum(a) FROM tab;
sum
----
3
(1 row)
gaussdb=# DROP TABLE tab;
```

- `max(expression)`

Description: Specifies the maximum value of expression across all input values.

Parameter type: any array, numeric, string, or date/time type

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE max_t1(a int, b int);
gaussdb=# INSERT INTO max_t1 VALUES(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT MAX(a) FROM max_t1;
```

```
max
-----
4
(1 row)

gaussdb=# DROP TABLE max_t1;
```

- **min(expression)**

Description: Minimum value of expression across all input values

Parameter type: any array, numeric, string, or date/time type

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE min_t1(a int, b int);

gaussdb=# INSERT INTO min_t1 VALUES(1,2),(2,3),(3,4),(4,5);

gaussdb=# SELECT MIN(a) FROM min_t1;
min
-----
1
(1 row)

gaussdb=# DROP TABLE min_t1;
```

- **avg(expression)**

Description: Average (arithmetic mean) of all input values

Return type:

NUMBER for any integer-type argument.

DOUBLE PRECISION for floating-point parameters.

otherwise the same as the argument data type.

Example:

```
gaussdb=# CREATE TABLE avg_t1(a int, b int);

gaussdb=# INSERT INTO avg_t1 VALUES(1,2),(2,3),(3,4),(4,5);

gaussdb=# SELECT AVG(a) FROM avg_t1;
avg
-----
2.5000000000000000
(1 row)

gaussdb=# DROP TABLE avg_t1;
```

- **count(expression)**

Description: Returns the number of input rows for which the value of expression is not null.

Return type: bigint

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE count_t1(a int, b int);

gaussdb=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);

gaussdb=# SELECT COUNT(a) FROM count_t1;
count
-----
4
(1 row)

gaussdb=# DROP TABLE count_t1;
```

- **count(*)**

Description: Returns the number of input rows.

Return type: bigint

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE count_t1(a int, b int);
gaussdb=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT COUNT(*) FROM count_t1;
count
-----
      5
(1 row)
gaussdb=# DROP TABLE count_t1;
```

- **default(column_name)**

Description: Obtains the default value of a table column.

Return type: text

Example:

```
-- Create a MySQL-compatible database.
gaussdb=# CREATE DATABASE gaussdb_m WITH DBCOMPATIBILITY 'MYSQL';
gaussdb=# \c gaussdb_m
gaussdb_m=# CREATE TABLE t1(id int DEFAULT 100, name varchar(20) DEFAULT 'tt');
gaussdb_m=# INSERT INTO t1 VALUES(1,'test');
-- Execute the query.
gaussdb_m=# SELECT default(id), default(name) FROM t1;
default | default
-----+-----
      100 | tt
(1 row)
-- Delete the database.
gaussdb_m=# \c postgres
gaussdb=# DROP DATABASE gaussdb_m;
```

 **NOTE**

- The default function takes effect only when **sql_compatibility** is set to 'MYSQL'.
- If a table column does not have a default value, the default function returns a null value.
- If a table column is a hidden column (such as **xmin** or **cmin**), the default function returns a null value.
- If a table column is an auto-increment column, the default function returns **0**.
- GaussDB supports default values of partitioned tables, temporary tables, and multi-table join query.
- GaussDB supports the query of nodes whose column names contain character string values (indicating names) and A_Star nodes (indicating that asterisks (*) appear), for example, **default(tt.t4.id)** and **default(tt.t4.*)**.
- When the default value of a column is created in GaussDB, the range of the column type is not verified. As a result, an error may be reported when the default function is used.
- If the default value of a column is a function expression, the default function in GaussDB returns the calculated value of the default expression of the column during table creation.

- **array_agg(expression)**

Description: Input values, including nulls, concatenated into an array

Return type: array of the parameter type

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE array_agg_t1(a int, b int);
gaussdb=# INSERT INTO array_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT ARRAY_AGG(a) FROM array_agg_t1;
array_agg
-----
{NULL,1,2,3,4}
(1 row)

gaussdb=# DROP TABLE array_agg_t1;
```

- **string_agg(expression, delimiter)**

Description: Input values concatenated into a string, separated by delimiter

Return type: same as the parameter data type.

Operations on XML data that is explicitly converted to the character type are supported.

Example:

```
gaussdb=# CREATE TABLE string_agg_t1(a int, b int);
gaussdb=# INSERT INTO string_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT STRING_AGG(a,;) FROM string_agg_t1;
string_agg
-----
1;2;3;4
(1 row)

gaussdb=# DROP TABLE string_agg_t1;
```

- **listagg(expression [, delimiter]) WITHIN GROUP(ORDER BY order-list)**

Description: Aggregation column data sorted according to the mode specified by WITHIN GROUP, and concatenated to a string using the specified delimiter

- **expression:** Mandatory. It specifies an aggregation column name or a column-based, valid expression. It does not support the DISTINCT keyword and the parameters of VARIADIC.
- **delimiter:** Optional. It specifies a delimiter, which can be a string constant or a deterministic expression based on a group of columns. The default value is empty.
- **order-list:** Mandatory. It specifies the sorting mode in a group.

Return type: text

 **NOTE**

listagg is a column-to-row aggregation function, compatible with Oracle Database 11g Release 2. You can specify the OVER clause as a window function. When listagg is used as a window function, the OVER clause does not support the window sorting or framework of ORDER BY, to avoid ambiguity in listagg and ORDER BY of the WITHIN GROUP clause.

Example:

The aggregation column is of the text character set type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b text);
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'a1'),(1,'b2'),(1,'c3'),(2,'d4'),(2,'e5'),(3,'f6');
gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
-----+-----
1 | b2;c3
2 | d4;e5
3 | f6
  | a1
(4 rows)

gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the integer type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b int);
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
-----+-----
1 | 2;3
2 | 4;5
3 | 6
  | 1
(4 rows)

gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the floating point type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b float);
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,1.111),(1,2.222),(1,3.333),(2,4.444),(2,5.555),
(3,6.666);
gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
-----+-----
1 | 2.222000;3.333000
2 | 4.444000;5.555000
3 | 6.666000
  | 1.111000
(4 rows)
```

```
gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the time type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b timestamp);
```

```
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'2000-01-01'),(1,'2000-02-02'),(1,'2000-03-03'),
(2,'2000-04-04'),(2,'2000-05-05'),(3,'2000-06-06');
```

```
gaussdb=# SELECT a,LISTAGG(b,;) WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
```

```
a | listagg
-----+-----
1 | 2000-02-02 00:00:00;2000-03-03 00:00:00
2 | 2000-04-04 00:00:00;2000-05-05 00:00:00
3 | 2000-06-06 00:00:00
   | 2000-01-01 00:00:00
(4 rows)
```

```
gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the time interval type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');
```

```
gaussdb=# SELECT a,LISTAGG(b,;) WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
```

```
a | listagg
-----+-----
1 | 2 days;3 days
2 | 4 days;5 days
3 | 6 days
   | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE listagg_t1;
```

By default, the delimiter is empty.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');
```

```
gaussdb=# SELECT a,LISTAGG(b) WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
```

```
a | listagg
-----+-----
1 | 2 days3 days
2 | 4 days5 days
3 | 6 days
   | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE listagg_t1;
```

When listagg is used as a window function, the OVER clause does not support the window sorting of ORDER BY, and the listagg column is an ordered aggregation of the corresponding groups.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');
```

```
gaussdb=# SELECT a,LISTAGG(b) WITHIN GROUP(ORDER BY b) OVER(PARTITION BY a) FROM
listagg_t1;
```

```
a | listagg
-----+-----
1 | 2 days3 days
1 | 2 days3 days
2 | 4 days5 days
```

```
2 | 4 days5 days
3 | 6 days
  | 1 day
(6 rows)
```

```
gaussdb=# DROP TABLE listagg_t1;
```

- `group_concat`([**DISTINCT** | **ALL**] expression [,expression ...] [**ORDER BY** { expression [[**ASC** | **DESC** | **USING** operator] | `nlssort_expression_clause`] [**NULLS** { **FIRST** | **LAST** }] } [,...]) [**SEPARATOR** str_val])

Description: The number of parameters is not fixed. Multiple columns can be concatenated. Aggregation columns are sorted based on the value of **ORDER BY** and concatenated into a character string using the specified separator. This function cannot be used as a window function.

- **DISTINCT**: Optional. It deduplicates the results after each row is concatenated.
- **expression**: Mandatory. It specifies the aggregation column name or a valid column-based expression.
- **ORDER BY**: Optional. It is followed by a variable number of expressions and sorting rule. The `group_concat` function does not support the (ORDER BY + number) format.
- **SEPARATOR**: Optional. It is followed by a character or string. This separator is used to concatenate the expression results of two adjacent lines in a group. If it is not specified, the comma (,) is used by default.
- When both **DISTINCT** and **ORDER BY** are specified, all **ORDER BY** expressions must be in **DISTINCT** expressions. Otherwise, an error is reported.

Return type: text

Example:

Set **separator** to ';':

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b int);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT a,group_concat(b separator ';') FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
-----+-----
1 | 2;3
2 | 4;5
3 | 6
  | 1
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

By default, the separator is a comma (,).

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b int);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT a,group_concat(a,b) FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
-----+-----
1 | 12,13
2 | 24,25
3 | 36
  |
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the text character set type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b text);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'a1'),(1,'b2'),(1,'c3'),(2,'d4'),(2,'e5'),(3,'f6');
gaussdb=# SELECT a,group_concat(a,b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | 1b2,1c3
2 | 2d4,2e5
3 | 3f6
|
(4 rows)
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the integer type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b int);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | 2,3
2 | 4,5
3 | 6
| 1
(4 rows)
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the floating point type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b float);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1.11),(1,2.22),(1,3.33),(2,4.44),(2,5.55),
(3,6.66);
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | 3,2,2,3
2 | 6,4,5,4
3 | 7,6
| 1,1
(4 rows)
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the time type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b timestamp);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'2000-01-01'),(1,'2000-02-02'),
(1,'2000-03-03'),(2,'2000-04-04'),(2,'2000-05-05'),(3,'2000-06-06');
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | 2000-02-02 00:00:00,2000-03-03 00:00:00
2 | 2000-04-04 00:00:00,2000-05-05 00:00:00
3 | 2000-06-06 00:00:00
| 2000-01-01 00:00:00
(4 rows)
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the binary type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b bytea);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1'),(1,'2'),(1,'3'),(2,'4'),(2,'5'),(3,'6');
```

```
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
---+-----
1 | \x32,\x33
2 | \x34,\x35
3 | \x36
  | \x31
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the time interval type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),
(2,'5 days'),(3,'6 days');
```

```
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
---+-----
1 | 2 days,3 days
2 | 4 days,5 days
3 | 6 days
  | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

Set **distinct** to deduplicate data.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'2 days'),(1,'3 days'),
(1,'3 days'),(2,'4 days'),(2,'5 days'),(3,'6 days');
```

```
gaussdb=# SELECT a,group_concat(distinct b) FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
---+-----
1 | 2 days,3 days
2 | 4 days,5 days
3 | 6 days
  | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

Set **ORDER BY** to sort data.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),
(2,'5 days'),(3,'6 days');
```

```
gaussdb=# SELECT a,group_concat(b ORDER BY b desc) FROM group_concat_t1 GROUP BY a ORDER
BY a;
```

```
a | group_concat
---+-----
1 | 3 days,2 days
2 | 5 days,4 days
3 | 6 days
  | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

- **wm_concat(expression)**

Description: Concatenates column data into a string separated by commas (,).

Return type: same as the parameter data type.

 NOTE

wm_concat is an ORA compatibility requirement. Currently, this function has been canceled in the latest ORA version and replaced by the listagg function. You can also use the string_agg function. For details, see the description of the two functions.

- covar_pop(Y, X)

Description: Overall covariance

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE covar_pop_t1(a int, b int);
gaussdb=# INSERT INTO covar_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT COVAR_POP(a,b) FROM covar_pop_t1;
 covar_pop
-----
      100
(1 row)
gaussdb=# DROP TABLE covar_pop_t1;
```

- covar_samp(Y, X)

Description: Sample covariance

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE covar_samp_t1(a int, b int);
gaussdb=# INSERT INTO covar_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT COVAR_SAMP(a,b) FROM covar_samp_t1;
 covar_samp
-----
      125
(1 row)
gaussdb=# DROP TABLE covar_samp_t1;
```

- stddev_pop(expression)

Description: Overall standard difference

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE stddev_pop_t1(a int, b int);
gaussdb=# INSERT INTO stddev_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT STDDEV_POP(a) FROM stddev_pop_t1;
 stddev_pop
-----
7.4833147735478828
(1 row)
gaussdb=# DROP TABLE stddev_pop_t1;
```

- stddev_samp(expression)

Description: Sample standard deviation of the input values

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE stddev_samp_t1(a int, b int);
gaussdb=# INSERT INTO stddev_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT STDDEV_SAMP(a) FROM stddev_samp_t1;
   stddev_samp
-----
8.3666002653407555
(1 row)
gaussdb=# DROP TABLE stddev_samp_t1;
```

- **var_pop(expression)**

Description: Specifies the population variance of the input values (square of the population standard deviation).

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE var_pop_t1(a int, b int);
gaussdb=# INSERT INTO var_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT VAR_POP(a) FROM var_pop_t1;
   var_pop
-----
56.0000000000000000
(1 row)
gaussdb=# DROP TABLE var_pop_t1;
```

- **var_samp(expression)**

Description: Specifies the sample variance of the input values (square of the sample standard deviation).

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE var_samp_t1(a int, b int);
gaussdb=# INSERT INTO var_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT VAR_SAMP(a) FROM var_samp_t1;
   var_samp
-----
70.0000000000000000
(1 row)
gaussdb=# DROP TABLE var_samp_t1;
```

- **bit_and(expression)**

Description: The bitwise AND of all non-null input values, or null if none

Return type: same as the parameter data type.

Example:

```
gaussdb=# CREATE TABLE bit_and_t1(a int, b int);
gaussdb=# INSERT INTO bit_and_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT BIT_AND(a) FROM bit_and_t1;
   bit_and
-----
0
(1 row)
```

```
gaussdb=# DROP TABLE bit_and_t1;
```

- **bit_or(expression)**

Description: The bitwise OR of all non-null input values, or null if none

Return type: same as the parameter data type.

Example:

```
gaussdb=# CREATE TABLE bit_or_t1(a int, b int);
```

```
gaussdb=# INSERT INTO bit_or_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT BIT_OR(a) FROM bit_or_t1;
```

```
bit_or
-----
      3
(1 row)
```

```
gaussdb=# DROP TABLE bit_or_t1;
```

- **bool_and(expression)**

Description: Its value is **true** if all input values are **true**, otherwise **false**.

Return type: Boolean

Example:

```
gaussdb=# SELECT bool_and(100 <2500);
```

```
bool_and
-----
      t
(1 row)
```

- **bool_or(expression)**

Description: Its value is **true** if at least one input value is **true**, otherwise **false**.

Return type: Boolean

Example:

```
gaussdb=# SELECT bool_or(100 <2500);
```

```
bool_or
-----
      t
(1 row)
```

- **corr(Y, X)**

Description: Specifies the correlation coefficient.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE corr_t1(a int, b int);
```

```
gaussdb=# INSERT INTO corr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT CORR(a,b) FROM corr_t1;
```

```
corr
-----
.944911182523068
(1 row)
```

```
gaussdb=# DROP TABLE corr_t1;
```

- **every(expression)**

Description: Equivalent to **bool_and**

Return type: Boolean

Example:

```
gaussdb=# SELECT every(100 <2500);
every
-----
t
(1 row)
```

- **rank(expression)**

Description: The tuples in different groups are sorted non-consecutively by **expression**.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE rank_t1(a int, b int);
gaussdb=# INSERT INTO rank_t1 VALUES(NULL,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,RANK() OVER(PARTITION BY a ORDER BY b) FROM rank_t1;
a | b | rank
---+---+-----
1 | 2 | 1
1 | 3 | 2
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
 | 1 | 1
(6 rows)
gaussdb=# DROP TABLE rank_t1;
```

- **regr_avgx(Y, X)**

Description: Specifies the average of the independent variable (**sum(X)/Y**).

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_t1(a int, b int);
gaussdb=# INSERT INTO regr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_AVGX(a,b) FROM regr_t1;
regr_avgx
-----
4
(1 row)
gaussdb=# DROP TABLE regr_t1;
```

- **regr_avgy(Y, X)**

Description: Specifies the average of the dependent variable (**sum(Y)/X**).

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_avgy_t1(a int, b int);
gaussdb=# INSERT INTO regr_avgy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_AVGY(a,b) FROM regr_avgy_t1;
regr_avgy
-----
1.8
(1 row)
gaussdb=# DROP TABLE regr_avgy_t1;
```

- **regr_count(Y, X)**

Description: Specifies the number of input rows in which both expressions are non-null.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE regr_count_t1(a int, b int);
gaussdb=# INSERT INTO regr_count_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_COUNT(a,b) FROM regr_count_t1;
regr_count
-----
          5
(1 row)
gaussdb=# DROP TABLE regr_count_t1;
```

- **regr_intercept(Y, X)**

Description: y-intercept of the least-squares-fit linear equation determined by the (X, Y) pairs

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_intercept_t1(a int, b int);
gaussdb=# INSERT INTO regr_intercept_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_INTERCEPT(b,a) FROM regr_intercept_t1;
regr_intercept
-----
.785714285714286
(1 row)
gaussdb=# DROP TABLE regr_intercept_t1;
```

- **regr_r2(Y, X)**

Description: Specifies the square of the correlation coefficient.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_r2_t1(a int, b int);
gaussdb=# INSERT INTO regr_r2_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_R2(b,a) FROM regr_r2_t1;
regr_r2
-----
.892857142857143
(1 row)
gaussdb=# DROP TABLE regr_r2_t1;
```

- **regr_slope(Y, X)**

Description: Slope of the least-squares-fit linear equation determined by the (X, Y) pairs

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_slope_t1(a int, b int);
gaussdb=# INSERT INTO regr_slope_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_SLOPE(b,a) FROM regr_slope_t1;
regr_slope
```

```
-----
1.78571428571429
(1 row)
```

```
gaussdb=# DROP TABLE regr_slope_t1;
```

- **regr_sxx(Y, X)**

Description: **$\sum(Y^2) - \sum(X)^2/N$** (sum of squares of the independent variables)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_sxx_t1(a int, b int);
```

```
gaussdb=# INSERT INTO regr_sxx_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT REGR_SXX(b,a) FROM regr_sxx_t1;
regr_sxx
```

```
-----
2.8
(1 row)
```

```
gaussdb=# DROP TABLE regr_sxx_t1;
```

- **regr_sxy(Y, X)**

Description: **$\sum(X*Y) - \sum(X) * \sum(Y)/N$** (sum of products of independent times dependent variable)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_sxy_t1(a int, b int);
```

```
gaussdb=# INSERT INTO regr_sxy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT REGR_SXY(b,a) FROM regr_sxy_t1;
regr_sxy
```

```
-----
5
(1 row)
```

```
gaussdb=# DROP TABLE regr_sxy_t1;
```

- **regr_syy(Y, X)**

Description: **$\sum(Y^2) - \sum(X)^2/N$** ("sum of squares" of the dependent variable)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_syy_t1(a int, b int);
```

```
gaussdb=# INSERT INTO regr_syy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
```

```
gaussdb=# SELECT REGR_SYY(b,a) FROM regr_syy_t1;
regr_syy
```

```
-----
10
(1 row)
```

```
gaussdb=# DROP TABLE regr_syy_t1;
```

- **stddev(expression)**

Description: Alias of **stddev_samp**

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE stddev_t1(a int, b int);
gaussdb=# INSERT INTO stddev_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT STDDEV(a) FROM stddev_t1;
         stddev
-----
.83666002653407554798
(1 row)
gaussdb=# DROP TABLE stddev_t1;
```

- `variance(expression,ression)`

Description: Alias of **var_samp**

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE variance_t1(a int, b int);
gaussdb=# INSERT INTO variance_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT VARIANCE(a) FROM variance_t1;
         variance
-----
.70000000000000000000000000000000
(1 row)
gaussdb=# DROP TABLE variance_t1;
```

- `spread()`

Description: Calculates the difference between the maximum value and minimum value in a certain period.

Parameter: **real**

Return type: real

- `pivot_func(anelement)`

Description: Returns the only non-null value in a column. If there are two or more non-null values, an error is reported. **value** is an input parameter and can be of any type.

Return type: same as the input parameter type

 **NOTE**

This aggregate function is mainly used inside the pivot syntax.

```
gaussdb=# CREATE TABLE pivot_func_t1(a int, b int);
gaussdb=# INSERT INTO pivot_func_t1 VALUES (NULL,11),(1,2);
gaussdb=# SELECT PIVOT_FUNC(a) FROM pivot_func_t1;
         pivot_func
-----
1
(1 row)
gaussdb=# DROP TABLE pivot_func_t1;
```

- `checksum(expression)`

Description: Returns the CHECKSUM value of all input values. This function can be used to check whether the data in the tables is the same before and after the backup, restoration, or migration of the GaussDB database

(databases other than GaussDB are not supported). Before and after database backup, database restoration, or data migration, you need to manually run SQL commands to obtain the execution results. Compare the obtained execution results to check whether the data in the tables before and after the backup or migration is the same.

NOTE

- For large tables, the execution of CHECKSUM function may take a long time.
 - If the CHECKSUM values of two tables are different, it indicates that the contents of the two tables are different. Using the hash function in the CHECKSUM function may incur conflicts. There is low possibility that two tables with different contents may have the same CHECKSUM value. The same problem may occur when CHECKSUM is used for columns.
 - If the time type is timestamp, timestampz, or smalldatetime, ensure that the time zone settings are the same when calculating the CHECKSUM value.
- If the CHECKSUM value of a column is calculated and the column type can be changed to TEXT by default, set *expression* to the column name.
 - If the CHECKSUM value of a column is calculated and the column type cannot be converted to TEXT by default, set *expression* to *Column name::TEXT*.
 - If the CHECKSUM value of all columns is calculated, set *expression* to *Table name::TEXT*.

The following types of data can be converted into the TEXT type by default: char, name, int8, int2, int1, int4, raw, pg_node_tree, float4, float8, bpchar, varchar, nvarchar2, date, timestamp, timestampz, numeric, and smalldatetime. Other types (for example, XML) need to be forcibly converted to TEXT.

Return type: numeric

Example:

The following shows the CHECKSUM value of a column that can be converted to the TEXT type by default:

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(a) FROM checksum_t1;
checksum
-----
18126842830
(1 row)

gaussdb=# DROP TABLE checksum_t1;
```

The following shows the CHECKSUM value of a column that cannot be converted to the TEXT type by default. Note that the CHECKSUM parameter is set to *Column name::TEXT*.

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(a::TEXT) FROM checksum_t1;
checksum
-----
18126842830
(1 row)

gaussdb=# DROP TABLE checksum_t1;
```

The following shows the CHECKSUM value of all columns in a table. Note that the CHECKSUM parameter is set to *Table name::TEXT*. The table name is not modified by its schema.

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(checksum_t1::TEXT) FROM checksum_t1;
checksum
-----
1116052226
(1 row)
gaussdb=# DROP TABLE checksum_t1;
```

Aggregate Function Nesting

Description: Performs another aggregate function operation on the grouping calculation result of the aggregate function.

Generally, it can be described as follows:

```
SELECT AGG1(AGG2(column_name1)) FROM table_name GROUP BY column_name2;
```

It is equivalent to:

```
SELECT AGG1(value) FROM (SELECT AGG2(column_name1) value FROM table_name GROUP BY column_name2);
```

In the preceding information:

- **AGG1()**: outer aggregate function.
- **AGG2()**: inner aggregate function.
- **table_name**: table name.
- **column_name1** and **column_name2**: column names.
- **value**: alias of the result of the inner aggregate function.

The overall meaning can be described as follows: The grouping calculation result of the inner aggregate function AGG2() is used as the input of the outer aggregate function AGG1() for recalculation.

NOTE

1. The nested aggregate function is located between SELECT and FROM. Otherwise, it is meaningless.
2. The SELECT statement that uses a nested aggregate function contains a GROUP BY clause.
3. Only the nested aggregate functions or constant expressions can be selected together with another nested aggregate function.
4. The aggregate function supports only one nesting operation.
5. Currently, the following aggregate functions can be nested: avg, max, min, sum, var_pop, var_samp, variance, stddev_pop, stddev_samp, stddev, median, regr_sxx, regr_syy, regr_sxy, regr_avgx, regr_avgy, regr_r2, regr_slope, regr_intercept, covar_pop, covar_samp, corr, and listagg.
6. The return type of the inner aggregate function must comply with the parameter type of the outer aggregate function.

Example:

```
gaussdb=# CREATE TABLE test1 (id INT,val INT);
CREATE TABLE
gaussdb=# INSERT INTO test1 VALUES (1, 1);
INSERT 0 1
gaussdb=# INSERT INTO test1 VALUES (1, null);
INSERT 0 1
gaussdb=# INSERT INTO test1 VALUES (2, 10);
INSERT 0 1
gaussdb=# INSERT INTO test1 VALUES (2, 55);
INSERT 0 1

gaussdb=# SELECT SUM(MIN(val)) FROM test1 GROUP BY id;
 sum
-----
  11
(1 row)

gaussdb=# DROP TABLE test1;
DROP TABLE
```

7.6.19 Window Functions

Window Functions

This statement is used together with the window function. The OVER clause is used for grouping data and sorting the elements in a group. Window functions are used for generating sequence numbers for the values in the group.

NOTE

order by in a window function must be followed by a column name. If it is followed by a number, the number is processed as a constant value and the target column is not ranked.

If a parent query contains filter criteria of a window function in a subquery, the filter criteria in the parent query can be pushed down to the subquery.

CAUTION

1. Only the <, <=, and = filter criteria of window functions in parent queries can be pushed down to subqueries.
2. The upper boundary of a restriction condition range can be a constant, constant expression, parameter, non-VOLATILE function, or non-correlated sublink.
3. Only the ROW_NUMB, **ROW_NUMBER()**, **RANK()**, and **DENSE_RANK()** window functions are supported.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t2 (c1 INT, c2 INT);
-- Import data.
gaussdb=# INSERT INTO t2 SELECT generate_series, generate_series FROM generate_series(1, 1000000);
-- Execute the query. The query is normal, no error is reported, and the execution result is correct.
gaussdb=# EXPLAIN ANALYZE SELECT nc1 FROM (
SELECT row_number() over() rid,
t2.c1 nc1
FROM t2
) WHERE rid BETWEEN 1 AND (1 + 10 - 1);
QUERY PLAN
```

```

-----
Streaming (type: GATHER) (cost=0.12..10.64 rows=5 width=4) (actual time=10.201..12.766 rows=10
loops=1)
  Node/s: All datanodes
  -> Subquery Scan on __unnamed_subquery__ (cost=0.00..10.45 rows=5 width=4) (actual
time=[5.310,6.092]..[5.310,6.092], rows=10)
    Filter: (__unnamed_subquery__._rid >= 1)
    -> WindowAgg (cost=0.00..10.25 rows=16 width=4) (actual time=[5.262,5.873]..[5.262,5.873],
rows=10)
      row_number_filter: (row_number() OVER () <= 10)
      -> Streaming(type: BROADCAST) (cost=0.00..10.29 rows=32 width=4) (actual
time=[5.162,5.682]..[5.162,5.682], rows=11)
        Spawn on: All datanodes
        -> WindowAgg (cost=0.00..10.25 rows=16 width=4) (actual time=[1.759,1.815]..
[1.786,1.844], rows=20)
          row_number_filter: (row_number() OVER () <= 10)
          -> Seq Scan on t2 (cost=0.00..13.13 rows=20 width=4) (actual time=[1.711,1.716]..
[1.743,1.747], rows=22)
        Total runtime: 13.428 ms
      (12 rows)
    -- Clear the environment to prevent data leakage.
    gaussdb=# DROP TABLE t2;

```

- **RANK()**

Description: The RANK function is used for generating non-consecutive sequence numbers for the values in each group. The same values have the same sequence number.

Return type: bigint

Example:

```

gaussdb=# CREATE TABLE rank_t1(a int, b int);

gaussdb=# INSERT INTO rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,RANK() OVER(PARTITION BY a ORDER BY b) FROM rank_t1;
 a | b | rank
-----+-----
 1 | 1 |  1
 1 | 1 |  1
 1 | 2 |  3
 1 | 3 |  4
 2 | 4 |  1
 2 | 5 |  2
 3 | 6 |  1
(7 rows)

gaussdb=# DROP TABLE rank_t1;

```

- **ROW_NUMBER()**

Description: The ROW_NUMBER function is used for generating consecutive sequence numbers for the values in each group. The same values have different sequence numbers.

Return type: bigint

Example:

```

gaussdb=# CREATE TABLE row_number_t1(a int, b int);

gaussdb=# INSERT INTO row_number_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,ROW_NUMBER() OVER(PARTITION BY a ORDER BY b) FROM row_number_t1;
 a | b | row_number
-----+-----
 1 | 1 |  1
 1 | 1 |  2
 1 | 2 |  3
 1 | 3 |  4

```

```
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
(7 rows)
```

```
gaussdb=# DROP TABLE row_number_t1;
```

- **DENSE_RANK()**

Description: The DENSE_RANK function is used for generating consecutive sequence numbers for the values in each group. The same values have the same sequence number.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE dense_rank_t1(a int, b int);
```

```
gaussdb=# INSERT INTO dense_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,DENSE_RANK() OVER(PARTITION BY a ORDER BY b) FROM dense_rank_t1;
```

```
a | b | dense_rank
```

```
-----
```

```
1 | 1 | 1
1 | 1 | 1
1 | 2 | 2
1 | 3 | 3
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
(7 rows)
```

```
gaussdb=# DROP TABLE dense_rank_t1;
```

- **PERCENT_RANK()**

Description: The PERCENT_RANK function is used for generating corresponding sequence numbers for the values in each group. That is, the function calculates the value according to the formula: Sequence number = $(\text{rank} - 1) / (\text{totalrows} - 1)$. **rank** is the corresponding sequence number generated based on the **RANK** function for the value and **totalrows** is the total number of elements in a group.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE percent_rank_t1(a int, b int);
```

```
gaussdb=# INSERT INTO percent_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,PERCENT_RANK() OVER(PARTITION BY a ORDER BY b) FROM percent_rank_t1;
```

```
a | b | percent_rank
```

```
-----
```

```
1 | 1 | 0
1 | 1 | 0
1 | 2 | .6666666666666667
1 | 3 | 1
2 | 4 | 0
2 | 5 | 1
3 | 6 | 0
(7 rows)
```

```
gaussdb=# DROP TABLE percent_rank_t1;
```

- **CUME_DIST()**

Description: The CUME_DIST function is used for generating accumulative distribution sequence numbers for the values in each group. That is, the

function calculates the value according to the following formula: Sequence number = Number of rows preceding or peer with current row/Total rows.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE cume_dist_t1(a int, b int);

gaussdb=# INSERT INTO cume_dist_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,CUME_DIST() OVER(PARTITION BY a ORDER BY b) FROM cume_dist_t1;
 a | b | cume_dist
---+---+-----
 1 | 1 |      .5
 1 | 1 |      .5
 1 | 2 |     .75
 1 | 3 |      1
 2 | 4 |      .5
 2 | 5 |      1
 3 | 6 |      1
(7 rows)

gaussdb=# DROP TABLE cume_dist_t1;
```

- NTILE(num_buckets integer)

Description: The NTILE function is used for equally allocating sequential data sets to the buckets whose quantity is specified by **num_buckets** according to **num_buckets integer** and allocating the bucket number to each row. Divide the partition as evenly as possible.

Return type: integer

Example:

```
gaussdb=# CREATE TABLE ntile_t1(a int, b int);

gaussdb=# INSERT INTO ntile_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,NTILE(2) OVER(PARTITION BY a ORDER BY b) FROM ntile_t1;
 a | b | ntile
---+---+-----
 1 | 1 |      1
 1 | 1 |      1
 1 | 2 |      2
 1 | 3 |      2
 2 | 4 |      1
 2 | 5 |      2
 3 | 6 |      1
(7 rows)

gaussdb=# DROP TABLE ntile_t1;
```

- LAG

Description: The LAG function is used for generating lag values for the corresponding values in each group. That is, the value of the row obtained by moving forward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row does not exist after the moving, the result value is the default value. If not specified, **offset** defaults to **1** and **default** to **NULL**. The type of the **default** value must be the same as that of the **value** value.

Syntax:

```
LAG(value any [, offset integer [, default any ]])
LAG(value any ignore|respect nulls [, offset integer [, default any ]])
LAG(value any [, offset integer [, default any ]]) ignore|respect nulls
```

ignore|respect nulls determines whether NULL is included in the forward offset value. If not specified, the default value **respect nulls** is used. If **ignore nulls** is specified and the **value** is set to **NULL**, NULL is not included in the forward offset value. If **ignore nulls** is specified, the function performance deteriorates.

Return type: same as the parameter type

Example 1: Disable **ignore nulls** and set **offset** to **3** and **default** to **null**.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE ta1 (hire_date date, last_name varchar(20), department_id int);
CREATE TABLE
gaussdb=# INSERT INTO ta1 values('07-DEC-02', 'Raphaely', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-JUL-05', 'Tobias', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-DEC-05', 'Baida', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('18-MAY-03', 'Khoo', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('15-NOV-06', 'Himuro', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-AUG-07', 'Colmenares', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-07', 'yq', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-08', 'zi', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('', 'yq1', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, 'yq2', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-DEC-07', 'yq3', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1

-- Call LAG and set offset to 3 and default to null.
gaussdb=# SELECT hire_date, last_name, department_id, lag(hire_date, 3, null) OVER (PARTITION BY
department_id ORDER BY last_name) AS "NextHired" FROM ta1 ORDER BY department_id;
  hire_date | last_name | department_id | NextHired

(13 rows)

```
-- Delete the table.
gaussdb=# DROP TABLE ta1;
DROP TABLE
```

- LEAD

Description: The LEAD function is used for generating leading values for the corresponding values in each group. That is, the value of the row obtained by moving backward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row after the moving exceeds the total number of rows for the current group, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **NULL**. The type of the **default** value must be the same as that of the **value** value.

Syntax:

```
LEAD(value any [, offset integer [, default any ]])
LEAD(value any ignore|respect nulls [, offset integer [, default any ]])
LEAD(value any [, offset integer [, default any ]]) ignore|respect nulls
```

ignore|respect nulls determines whether NULL is included in the backward offset value. If not specified, the default value **respect nulls** is used. If **ignore nulls** is specified and the **value** is set to **NULL**, NULL is not included in the backward offset value. If **ignore nulls** is specified, the function performance deteriorates.

Return type: same as the parameter type

Example 1: Disable **ignore nulls**, set **offset** to **2**, and do not specify **default**.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE ta1 (hire_date date, last_name varchar(20), department_id int);
CREATE TABLE
```

```

gaussdb=# INSERT INTO ta1 values('07-DEC-02', 'Raphaely', 30);

(13 rows)

```

```
-- Delete the table.
gaussdb=# DROP TABLE ta1;
DROP TABLE
```

- **FIRST_VALUE(value any)**

Description: Returns the first value of each group.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE first_value_t1(a int, b int);
gaussdb=# INSERT INTO first_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,FIRST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM first_value_t1;
a | b | first_value
---+---+-----
1 | 1 |          1
1 | 1 |          1
1 | 2 |          1
1 | 3 |          1
2 | 4 |          4
2 | 5 |          4
3 | 6 |          6
(7 rows)

gaussdb=# DROP TABLE first_value_t1;
```

- **LAST_VALUE(value any)**

Description: Returns the last value of each group.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE last_value_t1(a int, b int);
gaussdb=# INSERT INTO last_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,LAST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM last_value_t1;
a | b | last_value
---+---+-----
1 | 1 |          1
1 | 1 |          1
1 | 2 |          2
1 | 3 |          3
2 | 4 |          4
2 | 5 |          5
3 | 6 |          6
(7 rows)

gaussdb=# DROP TABLE last_value_t1;
```

- **NTH_VALUE(value any, nth integer)**

Description: The *n*th row for a group is the returned value. If the row does not exist, **NULL** is returned by default.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE nth_value_t1(a int, b int);
gaussdb=# INSERT INTO nth_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,NTH_VALUE(b, 2) OVER(PARTITION BY a order by b) FROM nth_value_t1;
a | b | nth_value
---+---+-----
1 | 1 |          1
1 | 1 |          1
1 | 2 |          1
```

```
1 | 3 | 1
2 | 4 |
2 | 5 | 5
3 | 6 |
(7 rows)
```

```
gaussdb=# DROP TABLE nth_value_t1;
```

- **delta**

Description: Returns the difference between the current row and the previous row.

Parameter: numeric

Return type: numeric

- **spread**

Description: Calculates the difference between the maximum value and minimum value in a certain period.

Parameter: real

Return type: real

- **RATIO_TO_REPORT(column_name)**

Description: Calculates the ratio of the value in a column to the total value in the group to which the column belongs.

Parameter: numeric type, or any type that can be implicitly converted to the numeric type.

Return type: For input parameter types float4 and float8, the return type is of the same value type. For other input parameter types, the return type is numeric.

 **NOTE**

When RATIO_TO_REPORT(column_name) is used together with OVER(), the input parameters of OVER() support only **PRTITION BY** and **NULL**.

Example 1:

```
gaussdb=# CREATE TABLE ratio_to_report_t1(a int, b int);
```

```
gaussdb=# INSERT INTO ratio_to_report_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,RATIO_TO_REPORT(b) OVER(PARTITION BY a) FROM ratio_to_report_t1;
```

```
a | b | ratio_to_report
---+---+-----
1 | 1 | .14285714285714285714
1 | 1 | .14285714285714285714
1 | 2 | .28571428571428571429
1 | 3 | .42857142857142857143
2 | 4 | .44444444444444444444
2 | 5 | .55555555555555555556
3 | 6 | 1.00000000000000000000
(7 rows)
```

```
gaussdb=# DROP TABLE ratio_to_report_t1;
```

Example 2: Nest this function with other functions.

```
gaussdb=# CREATE TABLE ratio_to_report_t1(a int, b int);
```

```
gaussdb=# INSERT INTO ratio_to_report_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,TO_CHAR(RATIO_TO_REPORT(b) OVER(PARTITION BY a), '$999eeee') FROM
```

```
ratio_to_report_t1;
a | b | to_char
---+---+-----
```

```
1 | 1 | 1e-01
1 | 1 | 1e-01
1 | 2 | 3e-01
1 | 3 | 4e-01
2 | 4 | 4e-01
2 | 5 | 6e-01
3 | 6 | 1e+00
(7 rows)
```

```
gaussdb=# DROP TABLE ratio_to_report_t1;
```

Example 3: Invoke a stored procedure.

```
gaussdb=# CREATE TABLE ratio_to_report_t1(a int, b int);
```

```
gaussdb=# INSERT INTO ratio_to_report_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# CREATE OR REPLACE PROCEDURE ratio_to_report_proc IS CURSOR cur_1 IS SELECT
a,b,RATIO_TO_REPORT(b) OVER(PARTITION BY a) FROM ratio_to_report_t1;
BEGIN
FOR cur IN cur_1 LOOP
RAISE INFO '%', cur.ratio_to_report;
END LOOP;
END;
/
```

```
gaussdb=# CALL RATIO_TO_REPORT_PROC();
```

```

```
gaussdb=# DROP PROCEDURE ratio_to_report_proc;
```

```
gaussdb=# DROP TABLE ratio_to_report_t1;
```

7.6.20 Security Functions

Security Functions

- `gs_encrypt_aes128(encryptstr,keyststr)`

Description: Encrypts **encryptstr** strings using the key derived from **keyststr** and returns encrypted strings. The value of **keyststr** ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters. Currently, the following types of data can be encrypted: numerals supported in the database; character type; RAW in binary type; and DATE, TIMESTAMP, and SMALLDATETIME in date/time type.

Return type: text

Length of the return value: At least 92 bytes and no more than $(4 * [Len / 3] + 68)$ bytes, where *Len* indicates the length of the data before encryption (unit: byte).

Example:

```
gaussdb=# SELECT gs_encrypt_aes128('MPPDB','1234@abc');
gs_encrypt_aes128
-----
```

```
OF1g3+70oeqFfyKiWlpxfYxPnpeitNc6+7nAe02Ttt37fZF8Q+bbEYhdw/YG+0c9tHKRWM6OcTzIB3HnqvX+1d8Bflo=
(1 row)
```

NOTE

A password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- `gs_decrypt_aes128(encryptstr,keyst)`

Description: Decrypts **decrypt** strings using the key derived from **keyst** and returns decrypted strings. The **keyst** used for decryption must be consistent with that used for encryption. **keyst** cannot be empty.

NOTE

This function needs to be used with the **gs_encrypt_aes128** encryption function.

Return type: text

Example:

```
gaussdb=# SELECT gs_decrypt_aes128('OF1g3+70oeqFfyKiWlpxfYxPnpeitNc6+7nAe02Ttt37fZF8Q+bbEYhdw/YG+0c9tHKRWM6OcTzIB3HnqvX+1d8Bflo=', '1234@abc');
gs_decrypt_aes128
```

```
-----
MPPDB
(1 row)
```

NOTE

A password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- `aes_encrypt(str, key_str, init_vector)`

Description: Encrypts the string **str** using the encryption password **key_str** and initialization vector **init_vector** based on the AES algorithm.

Parameters in the command above are as follows:

- **str**: character string to be encrypted. If **str** is set to **NULL**, the function returns **NULL**.
- **key_str**: encryption password. If **key_str** is set to **NULL**, the function returns **NULL**. For security purposes, you are advised to use a 128-bit, 192-bit, or 256-bit secure random number as the key character string if the key length is 128 bits, 192 bits, or 256 bits (determined by the value of **block_encryption_mode**).
- **init_vector**: An initialization variable is provided for the required block encryption mode. The length is greater than or equal to 16 bytes. Bytes greater than 16 bytes are automatically ignored. If neither **str** nor **key_str** is **NULL**, this parameter cannot be **NULL**. Otherwise, an error is reported. For security purposes, you are advised to ensure that the IV value for each encryption is unique in OFB mode and that the IV value for each encryption is unpredictable in CBC or CFB mode.

Return type: text

Example:

```
gaussdb=# SELECT aes_encrypt('huwei123','123456vfhex4dyu,vdaladhjsadad','1234567890123456');
aes_encrypt
```

```
-----  
u*8\x05c?0  
(1 row)
```

NOTE

- This function is valid only when GaussDB is compatible with MySQL (that is, **sql_compatibility** is set to 'MYSQL').
 - An encryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.
 - Do not call this function during operations related to stored procedures, preventing the risk of sensitive information disclosure. In addition, when using the stored procedure that contains the function, you are advised to filter the parameter information of the function before providing the information for external maintenance personnel to locate the fault. Delete the logs after using them.
 - Do not call the function when **debug_print_plan** is set to **on**, preventing the risk of sensitive information disclosure. You are advised to filter parameter information of the function in the log files generated when **debug_print_plan** is set to **on** before providing the log files to external maintenance engineers for fault locating. After you finish using the logs, delete them as soon as possible.
 - The SQL_ASCII setting performs quite differently from other settings. If the character set of the server is SQL_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL_ASCII, no code conversion occurs. When this function calls the third-party OpenSSL library, the returned data is non-ASCII data. Therefore, when the character set of the database server is set to SQL_ASCII, the encoding of the client must also be set to SQL_ASCII. Otherwise, an error is reported. The database does not convert or verify non-ASCII characters.
- **aes_decrypt(pass_str, key_str, init_vector)**

Description: Decrypts the string **str** using the decryption password **key_str** and initialization vector **init_vector** based on the AES algorithm.

Parameters in the command above are as follows:

- **pass_str**: character string to be decrypted. If **pass_str** is set to **NULL**, the function returns **NULL**.
- **key_str**: decryption password. If **key_str** is set to **NULL**, the function returns **NULL**. For security purposes, you are advised to use a 128-bit, 192-bit, or 256-bit secure random number as the key character string if the key length is 128 bits, 192 bits, or 256 bits (determined by the value of **block_encryption_mode**).
- **init_vector**: An initialization variable is provided for the required block decryption mode. The length is greater than or equal to 16 bytes. Bytes greater than 16 bytes are automatically ignored. If neither **pass_str** nor **key_str** is **NULL**, this parameter cannot be **NULL**. Otherwise, an error is reported. For security purposes, you are advised to ensure that the IV value for each encryption is unique in OFB mode and that the IV value for each encryption is unpredictable in CBC or CFB mode.

Return type: text

Example:

```
gaussdb=# SELECT  
aes_decrypt(aes_encrypt('huwei123','123456vfhex4dyu,vdaladhjsadad','1234567890123456'),'123456vf  
hex4dyu,vdaladhjsadad','1234567890123456');  
aes_decrypt
```

```
-----
huwei123
(1 row)
```

 **NOTE**

- This function is valid only when GaussDB is compatible with MySQL (that is, **sql_compatibility** is set to 'MYSQL').
- A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.
- Do not call this function during operations related to stored procedures, preventing the risk of sensitive information disclosure. In addition, when using the stored procedure that contains the function, you are advised to filter the parameter information of the function before providing the information for external maintenance personnel to locate the fault. Delete the logs after using them.
- Do not call the function when **debug_print_plan** is set to **on**, preventing the risk of sensitive information disclosure. You are advised to filter parameter information of the function in the log files generated when **debug_print_plan** is set to **on** before providing the log files to external maintenance engineers for fault locating. After you finish using the logs, delete them as soon as possible.
- To ensure successful decryption, ensure that the values of **block_encryption_mode**, **key_str** and IV are the same as those during encryption.
- Due to encoding differences, encrypted data cannot be directly copied from the gsql client for decryption. In this scenario, the decryption result may not be the character string before encryption.
- The SQL_ASCII setting performs quite differently from other settings. If the character set of the server is SQL_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL_ASCII, no code conversion occurs. When this function calls the third-party OpenSSL library, the returned data is non-ASCII data. Therefore, when the character set of the database server is set to SQL_ASCII, the encoding of the client must also be set to SQL_ASCII. Otherwise, an error is reported. The database does not convert or verify non-ASCII characters.

- **gs_digest(input_string, hash_algorithm)**

Description: Hashes the input string using the specified hash algorithm and returns a hexadecimal number.

Parameters in the command above are as follows:

- **input_string**: character string to be hashed. The value cannot be **NULL**.
- **hash_algorithm**: specifies the hash algorithm. Currently, SHA-256, SHA-384, SHA-512, and SM3 are supported. Both uppercase and lowercase letters are supported. If an unsupported hash algorithm is used, an error is reported.

Return type: text

Example:

```
gaussdb=# SELECT pg_catalog.gs_digest('gaussdb', 'sha256');
           gs_digest
-----
4dc50d746f4e04f9b446986b34a0050e358fbfb8bc1fba314c54b52a417b0b8e
(1 row)
```

- **gs_password_deadline()**

Description: Indicates the number of remaining days before the password of the current user expires.

Return type: interval

Example:

```
gaussdb=# SELECT gs_password_deadline();
gs_password_deadline
-----
83 days 17:44:32.196094
(1 row)
```

- `gs_password_notifytime()`

Description: Specifies the number of days prior to password expiration that a user will receive a reminder.

Return type: int32

- `login_audit_messages(BOOLEAN)`

Description: Queries login information about a login user.

Return type: tuple

Example:

- Check the date, time, and IP address of the last successful login.

```
gaussdb=> SELECT * FROM login_audit_messages(true);
username | database | logintime      | mytype | result | client_conninfo
-----+-----+-----+-----+-----+-----
omm      | postgres | 2020-06-29 21:56:40+08 | login_success | ok | gsql@[local]
(1 row)
```

- Check the number, date, and time of failed attempts since the previous successful login.

```
gaussdb=> SELECT * FROM login_audit_messages(false);
username | database | logintime      | mytype | result | client_conninfo
-----+-----+-----+-----+-----+-----
omm      | postgres | 2020-06-29 21:57:55+08 | login_failed | failed | [unknown]@[local]
omm      | postgres | 2020-06-29 21:57:53+08 | login_failed | failed | [unknown]@[local]
(2 rows)
```

- `login_audit_messages_pid()`

Description: Queries login information about a login user. Different from **login_audit_messages**, this function queries login information based on **backendid**. Information about subsequent logins of the same user does not alter the query result of previous logins and cannot be found using this function.

Return type: tuple

 **NOTE**

When the thread pool is enabled, the **backendid** obtained in the same session may change due to thread switchover. As a result, the return values are different when the function is called for multiple times. You are not advised to call this function when the thread pool is enabled.

Example:

- Check the date, time, and IP address of the last successful login.

```
gaussdb=> SELECT * FROM login_audit_messages_pid(true);
username | database | logintime      | mytype | result | client_conninfo | backendid
-----+-----+-----+-----+-----+-----+-----
omm      | postgres | 2020-06-29 21:56:40+08 | login_success | ok | gsql@[local] | 139823109633792
(1 row)
```

- Check the number, date, and time of failed attempts since the previous successful login.

```
gaussdb=> SELECT * FROM login_audit_messages_pid(false);
username | database | logintime      | mytype | result | client_conninfo | backendid
```

Name	Type	Description
database	text	Database name
client_conninfo	text	Client connection information
object_name	text	Object name
detail_info	text	Operation details
node_name	text	Node name
thread_id	text	Thread ID
local_port	text	Local port
remote_port	text	Remote port

- pgxc_query_audit()**
 Description: Displays audit logs of all CNs.
 Return type: record
 The return fields of this function are the same as those of the `pg_query_audit` function.
- pg_delete_audit()**
 Description: Deletes audit logs in a specified period.
 Return type: void
- alldigitsmasking()**
 Description: Specifies the internal function of the masking policy, which is used to anonymize all characters.
 Parameter: col text, letter character default '0'
 Return type: text
- creditcardmasking()**
 Description: Specifies the internal function of the masking policy, which is used to anonymize all credit card information.
 Parameter: col text, letter character default 'x'
 Return type: text
- randommasking()**
 Description: Specifies the internal function of the masking policy. The random policy is used.
 Parameter: col text
 Return type: text
- fullemailmasking()**
 Description: Specifies the internal function of the masking policy, which is used to anonymize the text (except @) before the last period (.).
 Parameter: col text, letter character default 'x'
 Return type: text

- basicemailmasking()**

Description: Specifies the internal function of the masking policy, which is used to anonymize the text before the first at sign (@).

Parameter: col text, letter character default 'x'

Return type: text
- shufflemasking()**

Description: Specifies the internal function of the masking policy, which is used to sort characters out of order.

Parameter: col text

Return type: text
- regexprmasking()**

Description: Specifies the internal function of the masking policy, which is used to replace characters using a regular expression.

Parameter: col text, reg text, replace_text text, pos INTEGER default 0, reg_len INTEGER default -1

Return type: text
- gs_encrypt(encryptstr, keystr, encrypttype)**

Description: Encrypts **encryptstr** strings using **keystr** as the key and returns encrypted strings based on **encrypttype**.

Return type: text

Parameter	Type	Description	Value Range
encryptstr	text	Data to be encrypted	-
keystr	text	Encryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.
encrypttype	text	Encryption/Decryption type (case-insensitive)	aes128, sm4, aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

Example:

```
gaussdb=# SELECT gs_encrypt('MPPDB', 'Asdf1234', 'sm4');
gs_encrypt
-----
ZBzOmaGA4Bb+coyucJOB8AkIShqc
(1 row)
```

 **NOTE**

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in **gsql** by paging up and down.

aes128 and **sm4** are compatible with earlier versions. The **aes128** encryption and decryption algorithm in CBC mode is used for AES128 encryption and decryption, and **SHA1** is used for integrity check. The **sm4** encryption and decryption algorithm uses the SM4 CTR mode and does not perform integrity check.

- `gs_decrypt(decryptstr, keystr, decrypttype)`

Description: Decrypts **decrypt** strings using **keystr** as the decryption password and returns decrypted strings based on **decrypttype**. **decrypttype** and **keystr** used for decryption must be consistent with **encrypttype** and **keystr** used for encryption. **keystr** cannot be empty.

This function needs to be used with the `gs_encrypt` encryption function.

Return type: text

Parameter	Type	Description	Value Range
decryptstr	text	Data to be encrypted	-
keystr	text	Decryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.
decrypttype	text	Encryption/Decryption type (case-insensitive)	aes128, sm4, aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

Example:

```
gaussdb=# SELECT gs_decrypt('ZBzOmaGA4Bb+coyucJ0B8AkIshqc', 'Asdf1234', 'sm4');
gs_decrypt
-----
MPPDB
(1 row)
```

 **NOTE**

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in `gsql` by paging up and down.

aes128 and **sm4** are compatible with earlier versions. The **aes128** encryption and decryption algorithm in CBC mode is used for AES128 encryption and decryption, and **SHA1** is used for integrity check. The **sm4** encryption and decryption algorithm uses the SM4 CTR mode and does not perform integrity check.

- `gs_encrypt_bytea(encryptstr, keystr, encrypttype)`
Description: Encrypts **encryptstr** strings using **keystr** as the encryption password and returns encrypted strings based on **encrypttype**.

Return type: bytea

Parameter	Type	Description	Value Range
encryptstr	text	Data to be encrypted	-
keystr	text	Encryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.
encrypttype	text	Encryption/Decryption type (case-insensitive)	aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

Example:

```
gaussdb=# SELECT gs_encrypt_bytea('MPPDB', 'Asdf1234', 'sm4_ctr_sm3');
gs_encrypt_bytea
```

```
-----
\x90e286971c2c70410def0a2814af4ac44c737926458b66271d9d1547bc937395ca018d7755672fa9dc3c
dc6ec4a76001dc0e137f3bc5c8a5c51143561f1d09a848bfdebefec5e
(1 row)
```

 **NOTE**

An encryption password is required during the execution of this function. For security purposes, the `gsqr` tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in `gsqr` by paging up and down.

- `gs_decrypt_bytea(decryptstr, keystr, decrypttype)`
Description: Decrypts **decryptstr** strings using **keystr** as the decryption password and returns decrypted strings based on **decrypttype**. **decrypttype** and **keystr** used for decryption must be consistent with **encrypttype** and **keystr** used for encryption. **keystr** cannot be empty.

This function needs to be used with the `gs_encrypt_bytea` encryption function.

Return type: text

Parameter	Type	Description	Value Range
decryptstr	bytea	Data to be encrypted	-

Parameter	Type	Description	Value Range
keystr	text	Decryption password	The value ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.
decrypttype	text	Encryption/Decryption type (case-insensitive)	aes128_cbc_sha256, aes256_cbc_sha256, aes128_gcm_sha256, aes256_gcm_sha256, and sm4_ctr_sm3

Example:

```
gaussdb=# SELECT
gs_decrypt_bytea('\x90e286971c2c70410def0a2814af4ac44c737926458b66271d9d1547bc937395ca018
d7755672fa9dc3cdc6ec4a76001dc0e137f3bc5c8a5c51143561f1d09a848bfdefbec5e', 'Asdf1234',
'sm4_ctr_sm3');
gs_decrypt_bytea
-----
MPPDB
(1 row)
```

 **NOTE**

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

7.6.21 Ledger Database Functions

- get_dn_hist_rehash(text, text)**

Description: Returns the hash value of table-level data in a specified tamper-proof user table. This function can be invoked only between distributed nodes. A message indicating insufficient permission is displayed when all users invoke this function.

Parameter type: text

Return type: hash16
- ledger_hist_check(text, text)**

Description: Verifies the consistency between the hash value of table-level data in a specified tamper-proof user table and that in the corresponding history table.

Parameter type: text

Return type: Boolean

Example:

```
-- Create a schema.
gaussdb=# CREATE SCHEMA ledgernsp WITH BLOCKCHAIN;
-- Create a table.
gaussdb=# CREATE TABLE ledgernsp.tab(a int, b text);
-- Insert data.
```

```
gaussdb=# INSERT INTO ledgernsp.tab values(generate_series(1, 10000), 'test');
gaussdb=# SELECT ledger_hist_check('ledgernsp','tab');
ledger_hist_check
-----
t
(1 row)
```

- **ledger_hist_repair(text, text)**

Description: Restores the hash value of the history table corresponding to the specified tamper-proof user table to be the same as that of the user table, and returns the hash difference.

Parameter type: text

Return type: hash16

Example:

```
gaussdb=# SELECT ledger_hist_repair('ledgernsp','tab');
ledger_hist_repair
-----
0000000000000000
(1 row)
```

- **ledger_hist_archive(text, text)**

Description: Archives the history table corresponding to a specified tamper-proof user table to the **hist_back** folder in the audit log directory.

Parameter type: text

Return type: Boolean

Example:

```
gaussdb=# EXECUTE DIRECT ON (datanode1) 'select pg_catalog.ledger_hist_archive("ledgernsp",
"tab");';
ledger_hist_archive
-----
t
(1 row)
```

- **ledger_gchain_check(text, text)**

Description: Verifies the consistency between the history table hash corresponding to the specified tamper-proof user table and the **relhash** corresponding to the global history table.

Parameter type: text

Return type: Boolean

Example:

```
gaussdb=# SELECT ledger_gchain_check('ledgernsp','tab');
ledger_gchain_check
-----
t
(1 row)
```

- **ledger_gchain_repair(text, text)**

Description: Restores **relhash** of a specified tamper-proof user table in the global history table so that the hash is the same as that in the history table, and returns the total hash value of the specified table.

Parameter type: text

Return type: hash16

Example:

```
gaussdb=# SELECT ledger_gchain_repair('ledgernsp','tab');
ledger_gchain_repair
-----
```

```
da30c1260af5be50  
(1 row)
```

- `ledger_gchain_archive(void)`
Description: Archives global history tables to the **hist_back** folder in the audit log directory.
Parameter type: void
Return type: Boolean
Example:

```
gaussdb=# SELECT ledger_gchain_archive();  
ledger_gchain_archive  
-----  
t  
(1 row)
```
- `hash16in(cstring)`
Description: Converts the input hexadecimal string into the internal hash16 format.
Parameter type: cstring
Return type: hash16
- `hash16out(hash16)`
Description: Converts internal hash16 data to hexadecimal cstring data.
Parameter type: hash16
Return type: cstring
- `hash32in(cstring)`
Description: Converts the input hexadecimal string (32 characters) into the internal type hash32.
Parameter type: cstring
Return type: hash32
- `hash32out(hash32)`
Description: Converts internal hash32 data to hexadecimal cstring data.
Parameter type: hash32
Return type: cstring

7.6.22 Encrypted Functions and Operators

- `byteawwithoutorderwithequalcolin(cstring)`
Description: Converts input data to the internal `byteawwithoutorderwithequalcol` format.
Parameter type: cstring
Return type: `byteawwithoutorderwithequalcol`
- `byteawwithoutorderwithequalcolout(byteawwithoutorderwithequalcol)`
Description: Converts internal data of the `byteawwithoutorderwithequalcol` type to data of the cstring type.
Parameter type: `byteawwithoutorderwithequalcol`
Return type: cstring
- `byteawwithoutorderwithequalcolsend(byteawwithoutorderwithequalcol)`

Description: Converts data of the `byteawithoutorderwithequalcol` type to data of the `bytea` type.

Parameter type: `byteawithoutorderwithequalcol`

Return type: `bytea`

- `byteawithoutorderwithequalcolrecv(internal)`

Description: Converts data of the `internal` type to data of the `byteawithoutorderwithequalcol` type.

Parameter type: `internal`

Return type: `byteawithoutorderwithequalcol`

- `byteawithoutorderwithequalcoltypmodin(cstring[])`

Description: Converts data of the `cstring[]` type to data of the `byteawithoutorderwithequalcol` type.

Parameter type: `cstring[]`

Return type: `int4`

- `byteawithoutorderwithequalcoltypmodout(int4)`

Description: Converts data of the `int4` type into data of the `cstring` type.

Parameter type: `int4`

Return type: `cstring`

- `byteawithoutordercolin(cstring)`

Description: Converts input data to the internal `byteawithoutordercolin` format.

Parameter type: `cstring`

Return type: `byteawithoutordercol`

- `byteawithoutordercolout(byteawithoutordercol)`

Description: Converts internal data of the `byteawithoutordercol` type to data of the `cstring` type.

Parameter type: `byteawithoutordercol`

Return type: `cstring`

- `byteawithoutordercolsend(byteawithoutordercol)`

Description: Converts data of the `byteawithoutordercol` type to data of the `bytea` type.

Parameter type: `byteawithoutordercol`

Return type: `bytea`

- `byteawithoutordercolrecv(internal)`

Description: Converts data of the `internal` type to data of the `byteawithoutordercol` type.

Parameter type: `internal`

Return type: `byteawithoutordercol`

- `byteawithoutorderwithequalcolcmp(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`

Description: Compares two `byteawithoutorderwithequalcol` data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: `byteawithoutorderwithequalcol`,
`byteawithoutorderwithequalcol`

Return type: `int4`

- `byteawithoutorderwithequalcolcmpbytear(byteawithoutorderwithequalcol, bytea)`

Description: Compares the `byteawithoutorderwithequalcol` and `bytea` data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: `byteawithoutorderwithequalcol`, `bytea`

Return type: `int4`

- `byteawithoutorderwithequalcolcmpbyteal(bytea, byteawithoutorderwithequalcol)`

Description: Compares the `bytea` and `byteawithoutorderwithequalcol` data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: `bytea`, `byteawithoutorderwithequalcol`

Return type: `int4`

- `byteawithoutorderwithequalcoleq(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`

Description: Compares two `byteawithoutorderwithequalcol` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: `byteawithoutorderwithequalcol`,
`byteawithoutorderwithequalcol`

Return type: `Boolean`

- `byteawithoutorderwithequalcoleqbyteal(bytea, byteawithoutorderwithequalcol)`

Description: Compares the `bytea` and `byteawithoutorderwithequalcol` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: `bytea`, `byteawithoutorderwithequalcol`

Return type: `Boolean`

- `byteawithoutorderwithequalcoleqbytear(byteawithoutorderwithequalcol, bytea)`

Description: Compares the `byteawithoutorderwithequalcol` and `bytea` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: `byteawithoutorderwithequalcol`, `bytea`

Return type: `Boolean`

- `byteawithoutorderwithequalcolne(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`

Description: Compares two `byteawithoutorderwithequalcol` data records. If they are different, **true** is returned. Otherwise, **false** is returned.

Parameter type: `byteawithoutorderwithequalcol`,
`byteawithoutorderwithequalcol`

Return type: `Boolean`

- `byteawithoutorderwithequalcolnebyteal(bytea, byteawithoutorderwithequalcol)`
Description: Compares the `bytea` and `byteawithoutorderwithequalcol` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.
Parameter type: `bytea`, `byteawithoutorderwithequalcol`
Return type: Boolean
- `byteawithoutorderwithequalcolnebytear(byteawithoutorderwithequalcol, bytea)`
Description: Compares the `byteawithoutorderwithequalcol` and `bytea` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.
Parameter type: `byteawithoutorderwithequalcol`, `bytea`
Return type: Boolean
- `hll_hash_byteawithoutorderwithequalcol(byteawithoutorderwithequalcol)`
Description: Returns the hll hash value of `byteawithoutorderwithequalcol`.
Parameter type: `byteawithoutorderwithequalcol`
Return type: `hll_hashval`
- `tee_lt(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`
Description: Checks whether a value of the `byteawithoutorderwithequalcol` type is less than another value of the `byteawithoutorderwithequalcol` type. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.
Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`
Return type: Boolean
- `tee_gt(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`
Description: Checks whether a value of the `byteawithoutorderwithequalcol` type is greater than another value of the `byteawithoutorderwithequalcol` type. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.
Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`
Return type: Boolean
- `tee_le(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`
Description: Checks whether a value of the `byteawithoutorderwithequalcol` type is less than or equal to another value of the `byteawithoutorderwithequalcol` type. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.
Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`
Return type: Boolean
- `tee_ge(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`
Description: Checks whether a value of the `byteawithoutorderwithequalcol` type is greater than or equal to another value of the `byteawithoutorderwithequalcol` type. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.

Parameter type: byteawithoutorderwithequalcol,
byteawithoutorderwithequalcol

Return type: Boolean

- tee_like(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)

Description: Checks whether byteawithoutorderwithequalcol data meets fuzzy match. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.

Parameter type: byteawithoutorderwithequalcol,
byteawithoutorderwithequalcol

Return type: Boolean

- tee_nlike(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)

Description: Checks whether byteawithoutorderwithequalcol data does not meet fuzzy match. If yes, **true** is returned. Otherwise, **false** is returned. This function is not supported in distributed mode.

Parameter type: byteawithoutorderwithequalcol,
byteawithoutorderwithequalcol

Return type: Boolean

- tee_calculation(byteawithoutorderwithequalcol,
byteawithoutorderwithequalcol)

Description: General function for mathematical operations between byteawithoutorderwithequalcol types. This function is not supported in distributed mode.

Parameter type: byteawithoutorderwithequalcol,
byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- tee_sortsupport(internal)

Description: Function used to support sorting, which is internally invoked during sorting and is not supported in the current version.

Parameter type: internal

Return type: void

- teegtssel(internal, oid, internal, integer)

Description: Selectivity of ciphertext greater than and greater than or equal to. The default value **0.3333333333333333** is returned. This function cannot be invoked by common users.

Parameter type: internal, oid, internal, integer

Return type: double precision

- teeltsel(internal, oid, internal, integer)

Description: Selectivity of ciphertext less than and less than or equal to. The default value **0.3333333333333333** is returned. This function cannot be invoked by common users.

Parameter type: internal, oid, internal, integer

Return type: double precision

- teelikesel(internal, oid, internal, integer)

Description: Selectivity of ciphertext fuzzy match. The default value **0.005** is returned. This function cannot be invoked by common users.

Parameter type: internal, oid, internal, integer

Return type: double precision

- teenlikesel(internal, oid, internal, integer)

Description: Selectivity of ciphertext non-fuzzy-match. The default value **0.005** is returned. This function cannot be invoked by common users.

Parameter type: internal, oid, internal, integer

Return type: double precision

- sum(byteawithoutorderwithequalcol)

Description: Aggregates the ciphertext sum. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- avg(byteawithoutorderwithequalcol)

Description: Aggregates the ciphertext average value. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- min(byteawithoutorderwithequalcol)

Description: Aggregates the ciphertext minimum value. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- max(byteawithoutorderwithequalcol)

Description: Aggregates the ciphertext maximum value. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- stddev_samp(byteawithoutorderwithequalcol)

Description: Aggregates the standard deviation of ciphertext samples. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- stddev_pop(byteawithoutorderwithequalcol)

Description: Aggregates the total standard deviation of ciphertext. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- var_samp(byteawithoutorderwithequalcol)

Description: Aggregates the variance of ciphertext samples. It is not supported in the current version.

Parameter type: byteawithoutorderwithequalcol

Return type: byteawithoutorderwithequalcol

- `var_pop(byteawithoutorderwithequalcol)`
Description: Aggregates the total variance of ciphertext. It is not supported in the current version.
Parameter type: `byteawithoutorderwithequalcol`
Return type: `byteawithoutorderwithequalcol`
- `tee_trans(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`
Description: Aggregates the internal processing function for ciphertext. This function cannot be invoked by common users.
Parameter type: `byteawithoutorderwithequalcol`,
`byteawithoutorderwithequalcol`
Return type: `byteawithoutorderwithequalcol`
- `tee_collect(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`
Description: Aggregates the internal processing function for ciphertext. This function cannot be invoked by common users.
Parameter type: `byteawithoutorderwithequalcol`,
`byteawithoutorderwithequalcol`
Return type: `byteawithoutorderwithequalcol`
- `tee_final(byteawithoutorderwithequalcol)`
Description: Aggregates the internal processing function for ciphertext. This function cannot be invoked by common users.
Parameter type: `byteawithoutorderwithequalcol`
Return type: `byteawithoutorderwithequalcol`
- `security_tee_process()`
Description: Manages the computational state in a secret trusted domain. It is not supported in the current version.
Parameter type: `int`
Return type: `Boolean`
- `ce_encrypt_deterministic(text, oid)`
Description: Encrypts the plaintext of the TEXT type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.
Parameter type: `text`, `oid`
Return type: `byteawithoutorderwithequalcol`
- `ce_encrypt_deterministic(int1, oid)`
Description: Encrypts the plaintext of the int1 type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.
Parameter type: `int1`, `oid`
Return type: `byteawithoutorderwithequalcol`
- `ce_encrypt_deterministic(int2, oid)`
Description: Encrypts the plaintext of the int2 type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id**

in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `int2`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(int4, oid)`

Description: Encrypts the plaintext of the `int4` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `int4`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(int8, oid)`

Description: Encrypts the plaintext of the `int8` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `int8`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(float4, oid)`

Description: Encrypts the plaintext of the `float4` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `float4`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(float8, oid)`

Description: Encrypts the plaintext of the `float8` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `float8`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(numeric, oid)`

Description: Encrypts the plaintext of the `numeric` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `numeric`, `oid`

Return type: `bytea` without order with equal col

- `ce_encrypt_deterministic(clob, oid)`

Description: Encrypts the plaintext of the `CLOB` type to the encrypted equivalent structure. The key OID is the value of `column_key_distributed_id` in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `clob`, `oid`

Return type: byteawithoutorderwithequalcol

- `ce_encrypt_deterministic(varchar, oid)`

Description: Encrypts the plaintext of the `varchar` type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `varchar, oid`

Return type: `byteawithoutorderwithequalcol`

- `ce_encrypt_deterministic(nvarchar2, oid)`

Description: Encrypts the plaintext of the `nvarchar2` type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `nvarchar2, oid`

Return type: `byteawithoutorderwithequalcol`

- `ce_encrypt_deterministic(bpchar, oid)`

Description: Encrypts the plaintext of the `bpchar` type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `bpchar, oid`

Return type: `byteawithoutorderwithequalcol`

- `ce_encrypt_deterministic(nvarchar2, oid)`

Description: Encrypts the plaintext of the `nvarchar2` type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `nvarchar2, oid`

Return type: `byteawithoutorderwithequalcol`

- `ce_encrypt_deterministic(bytea, oid)`

Description: Encrypts the plaintext of the `bytea` type to the encrypted equivalent structure. The key OID is the value of **column_key_distributed_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `bytea, oid`

Return type: `byteawithoutorderwithequalcol`

- `ce_decrypt_deterministic(byteawithoutorderwithequalcol, oid)`

Description: Decrypts the ciphertext of the encrypted equivalent structure to the plaintext data of the `text` type. The key OID is the value of **column_key_distributed_id** in the `gs_column_keys` system catalog. This function is not supported in the current version.

Parameter type: `byteawithoutorderwithequalcol, oid`

Return type: `text`

 **NOTE**

The following functions starting with `ce_encrypt/ce_decrypt` exist in the `pg_catalog` namespace.

- `ce_encrypt_text(text, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: text, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_varchar(varchar, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: varchar, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_nvarchar2(nvarchar2, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: nvarchar2, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_bpchar(bpchar, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: bpchar, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_int1(int1, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: int1, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_int2(int2, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: int2, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_int4(int4, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: int4, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_int8(int8, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: int8, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol

- `ce_encrypt_float4(float4, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: float4, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_float8(float8, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: float8, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_numeric(numeric, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: numeric, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_bytea(bytea, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: bytea, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_encrypt_clob(clob, int4, boolean, int4, internal)`
Description: Encryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: clob, int4, boolean, int4, internal
Return type: byteawithoutorderwithequalcol
- `ce_decrypt_text(byteawithoutorderwithequalcol, int4, boolean, int4, internal)`
Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal
Return type: text
- `ce_decrypt_varchar(byteawithoutorderwithequalcol, int4, boolean, int4, internal)`
Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal
Return type: varchar
- `ce_decrypt_nvarchar2(byteawithoutorderwithequalcol, int4, boolean, int4, internal)`
Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.
Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal
Return type: nvarchar2
- `ce_decrypt_bpchar(byteawithoutorderwithequalcol, int4, boolean, int4, internal)`

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: bpchar

- ce_decrypt_int1(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: int1

- ce_decrypt_int2(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: int2

- ce_decrypt_int4(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: int4

- ce_decrypt_int8(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: int8

- ce_decrypt_float4(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: float4

- ce_decrypt_float8(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: float8

- ce_decrypt_numeric(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

Description: Decryption function for fully-encrypted type conversion. This function cannot be invoked by common users.

Parameter type: byteawithoutorderwithequalcol, int4, boolean, int4, internal

Return type: numeric

- ce_decrypt_bytea(byteawithoutorderwithequalcol, int4, boolean, int4, internal)

```
gaussdb=# SELECT * FROM
byteawithoutorderwithequalcolrecv('\x9072190199999999999912381298461289346129'::byteawithoutorde
rwithequalcol);

7.6.23 Set Returning Functions

Series Generating Functions

- `generate_series(start, stop)`
Description: Generates a series of values, from **start** to **stop** with a step size of one.
Parameter type: int, bigint, numeric
Return type: setof int, setof bigint, setof numeric (same as the parameter type)
- `generate_series(start, stop, step)`
Description: Generates a series of values, from **start** to **stop** with a step size of **step**.
Parameter type: int, bigint, numeric
Return type: setof int, setof bigint, setof numeric (same as the parameter type)
- `generate_series(start, stop, step interval)`
Description: Generates a series of values, from **start** to **stop** with a step size of **step**.
Parameter type: timestamp or timestamp with time zone
Return type: setof timestamp or setof timestamp with time zone (same as parameter type)

When **step** is positive, zero rows are returned if **start** is greater than **stop**. Conversely, when **step** is negative, zero rows are returned if **start** is less than **stop**. Zero rows are also returned for **NULL** inputs. It is an error for **step** to be zero.

Example:

```
gaussdb=# SELECT * FROM generate_series(2,4);
generate_series
-----
         2
         3
         4
(3 rows)

gaussdb=# SELECT * FROM generate_series(5,1,-2);
generate_series
-----
         5
         3
         1
(3 rows)
```

```

gaussdb=# SELECT * FROM generate_series(4,3);
generate_series
-----
(0 rows)

-- This example applies to the date-plus-integer operator.
gaussdb=# SELECT current_date + s.a AS dates FROM generate_series(0,14,7) AS s(a);
dates
-----
2017-06-02
2017-06-09
2017-06-16
(3 rows)

gaussdb=# SELECT * FROM generate_series('2008-03-01 00:00'::timestamp, '2008-03-04 12:00', '10 hours');
generate_series
-----
2008-03-01 00:00:00
2008-03-01 10:00:00
2008-03-01 20:00:00
2008-03-02 06:00:00
2008-03-02 16:00:00
2008-03-03 02:00:00
2008-03-03 12:00:00
2008-03-03 22:00:00
2008-03-04 08:00:00
(9 rows)

```

- gs_search_function_with_name(funcname)**
 Description: Obtains the OID of the funcname function.
 Parameter type:cstring
 Return type: SETOF oid

```

-- Basic usage
CREATE OR REPLACE FUNCTION proc_plpgsql(a int,b int, c int)
RETURNS int AS $BODY$
DECLARE
BEGIN
RETURN $1 + $2;
END;
$BODY$ language plpgsql;
CREATE OR REPLACE FUNCTION proc_plpgsql(int,int)
RETURNS int AS $BODY$
DECLARE
BEGIN
RETURN $1 + $2;
END;
$BODY$ language plpgsql;
gaussdb=# SELECT gs_search_function_with_name('proc_plpgsql');
gs_search_function_with_name
-----
16776
24576
(2 rows)

```

Subscript Generating Functions

- generate_subscripts(array anyarray, dim int)**
 Description: Generates a series comprising the given array's subscripts.
 Return type: setof int
- generate_subscripts(array anyarray, dim int, reverse boolean)**
 Description: Generates a series comprising the given array's subscripts. When **reverse** is true, the series is returned in reverse order.
 Return type: setof int

generate_subscripts is a function that generates the set of valid subscripts for the specified dimension of the given array. Zero rows are returned for arrays that do not have the requested dimension, or for NULL arrays (but valid subscripts are returned for NULL array elements). Example:

```
-- Basic usage
gaussdb=# SELECT generate_subscripts('{NULL,1,NULL,2}'::int[], 1) AS s;
s
-----
1
2
3
4
(4 rows)
-- Unnest a 2D array.
gaussdb=# CREATE OR REPLACE FUNCTION unnest2(anyarray)
RETURNS SETOF anyelement AS $$
SELECT $1[i][j]
FROM generate_subscripts($1,1) g1(i),
generate_subscripts($1,2) g2(j);
$$ LANGUAGE sql IMMUTABLE;

gaussdb=# SELECT * FROM unnest2(ARRAY[[1,2],[3,4]]);
unnest2
-----
1
2
3
4
(4 rows)

-- Delete the function.
gaussdb=# DROP FUNCTION unnest2;
```

7.6.24 Conditional Expression Functions

Conditional Expression Functions

- `coalesce(expr1, expr2, ..., exprn)`

Description:

Returns the first non-NULL value in the parameter list.

COALESCE(expr1, expr2) is equivalent to **CASE WHEN expr1 IS NOT NULL THEN expr1 ELSE expr2 END**.

Example:

```
gaussdb=# SELECT coalesce(NULL,'hello');
coalesce
-----
hello
(1 row)
```

Note:

- **NULL** is returned only if all parameters are **NULL**.
 - It is often used to replace **NULL** with the default value.
 - Like a **CASE** expression, **COALESCE** only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first non-NULL parameter are not evaluated.
- `decode(base_expr, compare1, value1, Compare2,value2, ... default)`

Description: Compares **base_expr** with each **compare(n)** and **returns value(n)** if they are matched. If no matching result is found, the default value is returned.

Example:

```
gaussdb=# SELECT decode('A','A',1,'B',2,0);
case
-----
1
(1 row)
```

Note: Operations on the XML data are not supported.

- **nullif(expr1, expr2)**

Description: Returns **NULL** only when **expr1** is equal to **expr2**. Otherwise, **expr1** is returned.

nullif(expr1, expr2) is equivalent to **CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END**.

NOTE

The **nullif(expr1, expr2)** function is a mapping function. Therefore, the corresponding function definition cannot be found in the **pg_proc** system catalog.

Example:

```
gaussdb=# SELECT nullif('hello','world');
nullif
-----
hello
(1 row)
```

Note: Operations on the XML data are not supported.

Assume the two parameter data types are different:

- If implicit conversion exists between the two data types, implicitly convert the parameter of lower priority to this data type using the data type of higher priority. If the conversion succeeds, computation is performed.

Otherwise, an error is reported. Example:

```
gaussdb=# SELECT nullif('1234'::VARCHAR,123::INT4);
nullif
-----
1234
(1 row)
gaussdb=# SELECT nullif('1234'::VARCHAR,'2012-12-24'::DATE);
ERROR:  invalid input syntax for type timestamp: "1234"
```

- If implicit conversion is not applied between two data types, an error is displayed. Example:

```
gaussdb=# SELECT nullif(1::bit, '1'::MONEY);
ERROR:  operator does not exist: bit = money
LINE 1: SELECT nullif(1::bit, '1'::MONEY);
           ^
HINT:  No operator matches the given name and argument type(s). You might need to add explicit type casts.
CONTEXT:  referenced column: nullif
```

- **nv(expr1 , expr2)**

Description:

- If the value of **expr1** is **NULL**, the value of **expr2** is returned.
- If the value of **expr1** is not **NULL**, the value of **expr1** is returned.

Example:

```
gaussdb=# SELECT nv('hello','world');
nv
```

```
-----
hello
(1 row)
```

Parameters **expr1** and **expr2** can be of any data type. If **expr1** and **expr2** are of different data types, NVL checks whether **expr2** can be implicitly converted to **expr1**. If it can, the **expr1** data type is returned. If **expr2** cannot be implicitly converted to **expr1** but **expr1** can be implicitly converted to **expr2**, the **expr2** data type is returned. If no implicit type conversion exists between the two parameters and the parameters are different data types, an error is reported.

- `nvl2(expr1, expr2, expr3)`

Description:

- If *expr1* is **NULL**, *expr3* is returned.
- If *expr1* is not **NULL**, *expr2* is returned.

 **NOTE**

This function is valid only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**.

Example:

```
gaussdb=# SELECT nvl2('hello','world','other');
 case
-----
world
(1 row)
```

Note: The *expr2* and *expr3* parameters can be of any type. If the last two parameters of NVL2 are of different types, check whether *expr3* can be implicitly converted to *expr2*. If *expr3* cannot be implicitly converted to *expr2*, an error is returned. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- `greatest(expr1 [, ...])`

Description: Selects the largest value from a list of any number of expressions.

Return type:

Example:

```
gaussdb=# SELECT greatest(1*2,2-3,4-1);
 greatest
-----
        3
(1 row)
gaussdb=# SELECT greatest('HARRY', 'HARRIOT', 'HAROLD');
 greatest
-----
HARRY
(1 row)
```

Note: Operations on the XML data are not supported.

 NOTE

When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**:

1. If the value of any parameter is null, the function returns null.
2. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- **least(expr1 [, ...])**

Description: Selects the smallest value from a list of any number of expressions.

Example:

```
gaussdb=# SELECT least(1*2,2-3,4-1);
least
-----
-1
(1 row)
gaussdb=# SELECT least('HARRY','HARRIOT','HAROLD');
least
-----
HAROLD
(1 row)
```

Note: Operations on the XML data are not supported.

 NOTE

When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**:

1. If the value of any parameter is null, the function returns null.
2. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- **EMPTY_BLOB()**

Description: Initiates a BLOB variable in an INSERT or an UPDATE statement to a **NULL** value.

Return type: BLOB

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE blob_tb(b blob,id int) DISTRIBUTE BY REPLICATION;
-- Insert data.
gaussdb=# INSERT INTO blob_tb VALUES (empty_blob(),1);
-- Drop the table.
gaussdb=# DROP TABLE blob_tb;
```

Note: The length is 0 obtained using DBE_LOB.GET_LENGTH.

- **EMPTY_CLOB()**

Description: Initiates a CLOB variable in an INSERT or UPDATE statement to a null value.

 NOTE

This function is valid only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**.

Return type: CLOB

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE clob_tb(c clob,id int);
-- Insert data.
gaussdb=# INSERT INTO clob_tb VALUES (empty_clob(),1);
-- Drop the table.
gaussdb=# DROP TABLE clob_tb;
```

Note: The length is 0 obtained using DBE_LOB.GET_LENGTH.

- **lnnvl(condition)**

Description: Checks the condition in the WHERE clause of a query statement. If the condition is true, **false** is returned. If the condition is unknown or false, **true** is returned.

condition: The value must be a logical expression. However, it cannot be used in composite conditions with keywords such as AND, OR, and BETWEEN.

Return type: Boolean

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE student_demo (name VARCHAR2(20), grade NUMBER(10,2));
CREATE TABLE

-- Insert data.
gaussdb=# INSERT INTO student_demo VALUES ('name0',0);
INSERT 0 1
gaussdb=# INSERT INTO student_demo VALUES ('name1',1);
INSERT 0 1
gaussdb=# INSERT INTO student_demo VALUES ('name2',2);
INSERT 0 1

-- Invoke lnnvl.
gaussdb=# SELECT * FROM student_demo WHERE LNNVL(name = 'name1');
 name | grade
-----+-----
name0 | 0.00
name2 | 2.00
(2 rows)
```

 **NOTE**

The lnnvl function is supported only when the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s2**.

- **isnull(expr)**

Description: Checks whether **expr** is **NULL**. If **expr** is **NULL**, **true** is returned. Otherwise, **false** is returned. The isnull function is the mapping of the is null expression. isnull(expr) is equivalent to the expr is null expression. The isnull function is compatible in full mode.

Parameter: Any type of input is supported.

Return type: Boolean

Example:

```
gaussdb=# SELECT isnull(null);
?column?
-----
t
(1 row)

gaussdb=# SELECT isnull(1);
?column?
```

```
-----
f
(1 row)
```

 **NOTE**

The `isnull(expr)` function is a mapping function. Therefore, the corresponding function definition cannot be found in the `pg_proc` system catalog.

- `if(expr1, expr2, expr3)`

Description: Checks the value of **expr1**. If **expr1** is **true**, **expr2** is returned. Otherwise, **expr3** is returned.

`if(expr1, expr2, expr3)` is logically equivalent to `CASE WHEN expr1 THEN expr2 ELSE expr3 END`.

Parameters: See [Table 7-76](#).

Table 7-76 Parameter types

Parameter	Valid Input Parameter Type	Description
<code>expr1</code>	boolean	Determines the return value of the <code>if()</code> function.
<code>expr2</code>	Any type	If expr1 is true , expr2 is returned.
<code>expr3</code>	Any type	If expr1 is false , expr3 is returned.

Return value type: related to the input parameter type. For details about the output rules, see the description.

 NOTE

- `if(expr1, expr2, expr3)` is supported only in MySQL compatibility mode.
- When the compatibility parameters `b_format_version` is set to "" and `b_format_dev_version` is set to "", the output result type of the `if(expr1, expr2, expr3)` function is the same as that of the `CASE WHEN expr1 THEN expr2 ELSE expr3 END` function. When the compatibility parameters `b_format_version` is set to '5.7' and `b_format_dev_version` is set to 's1', the return value type is deduced according to the following rules in descending order:
 - If the two input parameters are of the same type, the return value type is the same as the input parameter type.
 - If one of the input parameters is of the SET type, the return value is of the TEXT type.
 - If one of the input parameters is of the BLOB type, the return value is of the BLOB type.
 - If one of the input parameters is of the TEXT type, the return value is of the TEXT type.
 - If one of the input parameters is of the STRING type, the return value is of the TEXT type.
 - If the two input parameters are of the time type, the return value is of the TIMESTAMPTZ type; if one of the input parameters is of the time type but the other is not, the return value is of the TEXT type.
 - If both input parameters are signed integers and one input parameter is of the BIGINT type, the return value is of the BIGINT type; otherwise, the return value is of the INT type.
 - If both input parameters are unsigned integers and one input parameter is of the UNSIGNED BIGINT type, the return value is of the UNSIGNED BIGINT type; otherwise, the return value is of the UNSIGNED INT type.
 - If the two input parameters are of the floating point type and integer type respectively, the return value is of the floating point type.
 - Except the preceding NUMERIC type combinations, the return value for other NUMERIC type combinations is of the NUMERIC type.
 - If no implicit conversion function exists between the input parameter type and return value type, an error is reported.
- If the input parameter `expr1` is **NULL**, the returned result is the same as that when `expr1` is **FALSE**.
- The `if(expr1, expr2, expr3)` function is a mapping function. Therefore, the corresponding function definition cannot be found in the `pg_proc` system catalog.

Example:

```
-- expr1 is an expression.
gaussdb=# select if(2>3, 'true', 'false');
 case
-----
 false
(1 row)

-- If the input parameter expr1 is NULL, the result is the same as that when expr1 is false, and the
value of expr2 is returned.
gaussdb=# select if(null, 'not null', 'is null');
 case
-----
 is null
(1 row)
```

- `ifnull(expr1, expr2)`

Description: Returns the value of `expr2` if `expr1` is **NULL**; otherwise, returns the value of `expr1`.

ifnull(expr1, expr2) is logically equivalent to nvl(expr1, expr2).

Parameter: any type.

Return value type: related to the input parameter type. For details about the output rules, see the description.

NOTE

- ifnull(expr1, expr2) is supported only in MySQL compatibility mode.
- When the compatibility parameters **b_format_version** is set to "" and **b_format_dev_version** is set to "", the output result type of the ifnull(expr1, expr2) function is the same as that of the nvl(expr1, expr2) function. When the compatibility parameters **b_format_version** is set to '5.7' and **b_format_dev_version** is set to 's1', the return value type is deduced according to the following rules in descending order:
 - If the two input parameters are of the same type, the return value type is the same as the input parameter type.
 - If one of the input parameters is of the SET type, the return value is of the TEXT type.
 - If one of the input parameters is of the BLOB type, the return value is of the BLOB type.
 - If one of the input parameters is of the TEXT type, the return value is of the TEXT type.
 - If one of the input parameters is of the STRING type, the return value is of the TEXT type.
 - If the two input parameters are of the time type, the return value is of the TIMESTAMPTZ type; if one of the input parameters is of the time type but the other is not, the return value is of the TEXT type.
 - If one input parameter is of the FLOAT4 type and the other is of any numeric type, the return type is DOUBLE.
 - If both input parameters are of the NUMERIC type, the return value is of the type with higher precision. For example, if the input parameter types are TINYINT and INT, the return value type is INT.
 - If no implicit conversion function exists between the input parameter type and return value type, an error is reported.
- If both input parameters are **NULL**, the return value is **NULL**; otherwise, the first value that is not **NULL** is returned.
- The ifnull(expr1, expr2) function is a mapping function. Therefore, the corresponding function definition cannot be found in the pg_proc system catalog.

Example:

```
-- If the input parameter is an empty string, the output is an empty string instead of NULL.
gaussdb=# SELECT ifnull("", null) is null as a;
a
---
f
(1 row)

-- If both input parameters are NULL, the output is NULL.
gaussdb=# SELECT ifnull(null, null) is null as a;
a
---
t
(1 row)

-- If the input parameters are NULL and a character string, the output is the first non-null value.
gaussdb=# SELECT ifnull(null, 'A') as a;
a
---
```

```
A  
(1 row)
```

7.6.25 System Information Functions

Session Information Functions

- `SYS_CONTEXT()`

Description: Returns the value of the parameter associated with the context namespace at the current time.

Return type: text

Example:

```
SELECT SYS_CONTEXT('userenv','NLS_CURRENCY');  
sys_context  
-----  
$  
(1 row)  
  
SELECT SYS_CONTEXT('userenv','NLS_DATE_FORMAT');  
sys_context  
-----  
ISO, MDY  
(1 row)  
  
SELECT SYS_CONTEXT('userenv','NLS_DATE_LANGUAGE');  
sys_context  
-----  
en_US.UTF-8  
(1 row)
```

- `current_catalog()`

Description: Name of the current database (called "catalog" in the SQL standard)

Return type: name

Example:

```
testdb=# SELECT current_catalog;  
current_database  
-----  
testdb  
(1 row)
```

- `current_database()`

Description: Name of the current database

Return type: name

Example:

```
testdb=# SELECT current_database();  
current_database  
-----  
testdb  
(1 row)
```

- `current_query()`

Description: Text of the currently executing query committed by the client (which might contain more than one statement)

Return type: text

Example:

```
gaussdb=# SELECT current_query();  
current_query
```

```
-----
SELECT current_query();
(1 row)
```

- `current_schema()`

Description: Name of the current schema

Return type: name

Example:

```
gaussdb=# SELECT current_schema();
current_schema
-----
public
(1 row)
```

Note: **current_schema** returns the first valid schema name in the search path. (If the search path is empty or contains no valid schema name, **NULL** is returned.) This is the schema that will be used for any tables or other named objects that are created without specifying a target schema.

- `current_schemas(Boolean)`

Description: Name of a schema in the search path

Return type: name[]

Example:

```
gaussdb=# SELECT current_schemas(true);
current_schemas
-----
{pg_catalog,public}
(1 row)
```

Note:

current_schemas(Boolean) returns an array of the names of all schemas in the search path. The Boolean option specifies whether implicitly included system schemas such as `pg_catalog` are included in the returned search path.

NOTE

The search path can be altered at the run time. The command is as follows:

```
SET search_path TO schema [, schema, ...]
```

- `database()`

Description: Returns the name of the current schema.

Parameter: none

Return type: name

Example:

```
gaussdb=# SELECT database();
database
-----
public
(1 row)
```

NOTE

This function is valid in a MySQL-compatible database when **b_format_version** is set to '5.7' and **b_format_dev_version** is set to 's1'.

- `current_user()`

Description: Username of current execution context

Return type: name

Example:

```
gaussdb=# SELECT current_user;  
current_user  
-----  
omm  
(1 row)
```

Note: **current_user** is the user identifier used for permission check. Generally, it indicates a session user, which can be modified by **SET ROLE**. During function execution, it is affected by the SECURITY DEFINER attribute.

- definer_current_user

Description: Username of current execution context

Return type: name

Example:

```
gaussdb=# SELECT definer_current_user();  
definer_current_user  
-----  
omm  
(1 row)
```

Note: Generally, the results of **definer_current_user** and **current_user** are the same. However, when this function is executed in a stored procedure, the name of user who defines the current stored procedure is returned.

- pg_current_sessionid()

Description: Session ID in the current execution environment.

Return type: text

Example:

```
gaussdb=# SELECT pg_current_sessionid();  
pg_current_sessionid  
-----  
1579228402.140190434944768  
(1 row)
```

Note: **pg_current_sessionid()** is used to obtain the session ID in the current execution environment. The format of the value is *Timestamp.Session ID*. When **enable_thread_pool** is disabled, the actual session ID is the thread ID.

- pg_current_sessid()

Description: Session ID in the current execution environment.

Return type: text

Example:

```
gaussdb=# select pg_current_sessid();  
pg_current_sessid  
-----  
140308875015936  
(1 row)
```

Note: In thread pool mode, the session ID of the current session is obtained. In non-thread pool mode, the backend thread ID of the current session is obtained.

- pg_current_userid()

Description: Current user ID

Return type: text

Example:

```
gaussdb=# SELECT pg_current_userid();  
pg_current_userid
```

```
-----  
10  
(1 row)
```

- `tablespace_oid_name(oid)`

Description: Queries the tablespace name based on the tablespace OID.

Return type: text

Example:

```
gaussdb=# select tablespace_oid_name(1663);  
tablespace_oid_name  
-----  
pg_default  
(1 row)
```

- `inet_client_addr()`

Description: Remote connection address. **inet_client_addr** returns the IP address of the current client.

 **NOTE**

It is available only in remote connection mode.

Return type: inet

Example:

```
gaussdb=# SELECT inet_client_addr();  
inet_client_addr  
-----  
10.10.0.50  
(1 row)
```

- `inet_client_port()`

Description: Remote connection port. **inet_client_port** returns the port number of the current client.

 **NOTE**

This function is valid only in remote connection mode.

Return type: int

Example:

```
gaussdb=# SELECT inet_client_port();  
inet_client_port  
-----  
33143  
(1 row)
```

- `inet_server_addr()`

Description: Local connection address. **inet_server_addr** returns the IP address on which the server accepts the current connection.

 **NOTE**

It is available only in remote connection mode.

Return type: inet

Example:

```
gaussdb=# SELECT inet_server_addr();  
inet_server_addr  
-----  
10.10.0.13  
(1 row)
```

- `inet_server_port()`

Description: Local connection port. **inet_server_port** returns the number of the port receiving the current connection. All these functions return **NULL** if the current connection is via a Unix-domain socket.

 **NOTE**

This function is valid only in remote connection mode.

Return type: int

Example:

```
gaussdb=# SELECT inet_server_port();
inet_server_port
-----
          8000
(1 row)
```

- `pg_backend_pid()`

Description: Thread ID of the service thread connected to the current session.

Return type: int

Example:

```
gaussdb=# SELECT pg_backend_pid();
pg_backend_pid
-----
140229352617744
(1 row)
```

- `pg_conf_load_time()`

Description: Configures load time. **pg_conf_load_time** returns the timestamp when the server configuration files were last loaded.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_conf_load_time();
pg_conf_load_time
-----
2017-09-01 16:05:23.89868+08
(1 row)
```

- `pg_my_temp_schema()`

Description: OID of the temporary schema of a session. The value is **0** if the OID does not exist.

Return type: OID

Example:

```
gaussdb=# SELECT pg_my_temp_schema();
pg_my_temp_schema
-----
          0
(1 row)
```

Note: **pg_my_temp_schema** returns the OID of the current session's temporary schema, or **0** if it has no temporary schemas (because no temporary tables are created). **pg_is_other_temp_schema** returns **true** if the given OID is the OID of another session's temporary schema.

- `pg_is_other_temp_schema(oid)`

Description: Specifies whether the schema is the temporary schema of another session.

Return type: Boolean

Example:

```
gaussdb=# SELECT pg_is_other_temp_schema(25356);
pg_is_other_temp_schema
-----
f
(1 row)
```

- `pg_listening_channels()`

Description: Name of the channel that the session is currently listening to.

Return type: setof text

Example:

```
gaussdb=# SELECT pg_listening_channels();
pg_listening_channels
-----
(0 rows)
```

Note: **pg_listening_channels** returns a set of names of channels that the current session is currently listening to.

- `pg_postmaster_start_time()`

Description: Server start time. **pg_postmaster_start_time** returns the timestamp with time zone when the server is started.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_postmaster_start_time();
pg_postmaster_start_time
-----
2017-08-30 16:02:54.99854+08
(1 row)
```

- `sessionid2pid()`

Description: Obtains PID information from a session ID (for example, the **sessid** column in **pv_session_stat**).

Return type: int8

Example:

```
gaussdb=# select sessionid2pid(sessid::cstring) from pv_session_stat limit 2;
sessionid2pid
-----
139973107902208
139973107902208
(2 rows)
```

- `session_context('namespace', 'parameter')`

Description: Obtains and returns the parameter values of a specified namespace.

Return type: VARCHAR

Example:

```
gaussdb=# SELECT session_context('USERENV', 'CURRENT_SCHEMA');
session_context
-----
public
(1 row)
```

The result varies according to the current actual schema.

Note: Currently, only the `SESSION_CONTEXT('USERENV', 'CURRENT_SCHEMA')` and `SESSION_CONTEXT('USERENV', 'CURRENT_USER')` formats are supported.

- `pg_trigger_depth()`
Description: Nesting level of triggers.
Return type: int
Example:

```
gaussdb=# SELECT pg_trigger_depth();
pg_trigger_depth
-----
          0
(1 row)
```
- `opengauss_version()`
Description: Referenced openGauss kernel version.
Return type: text
The following is an example. Replace *x.x.x* in the query result with the actual value.

```
gaussdb=# SELECT opengauss_version();
opengauss_version
-----
          x.x.x
(1 row)
```
- `gs_deployment()`
Description: Deployment mode of the current system. For a distributed system, **Distribute** is returned.
Return type: text
Example:

```
gaussdb=# SELECT gs_deployment();
gs_deployment
-----
Distribute
(1 row)
```
- `session_user`
Description: Session username.
Return type: name
Example:

```
gaussdb=# SELECT session_user;
session_user
-----
omm
(1 row)
```

Note: **session_user** usually specifies the initial user connected to the current database, but the system administrator can change this setting by using **SET SESSION AUTHORIZATION**.
- `user`
Description: Equivalent to `current_user`.
Return type: name
Example:

```
gaussdb=# SELECT user;
current_user
-----
omm
(1 row)
```
- `get_shard_oids_byname()`

Description: Returns the OID of the node when the node name is entered.

Return type: OID

Example:

```
gaussdb=# SELECT get_shard_oids_byname('datanode1');
get_shard_oids_byname
-----
{16385}
(1 row)
```

- `getpgusername()`

Description: Obtains the database username.

Return type: name

Example:

```
gaussdb=# SELECT getpgusername();
getpgusername
-----
GaussDB_userna
(1 row)
```

- `getdatabaseencoding()`

Description: Obtains the database encoding mode.

Return type: name

Example:

```
gaussdb=# SELECT getdatabaseencoding();
getdatabaseencoding
-----
SQL_ASCII
(1 row)
```

- `version()`

Description: version information. **version** returns a string describing a server's version.

Return type: text

Example:

```
gaussdb=# SELECT version();
version
-----
gaussdb (GaussDB XXX.XXX.XXX build f521c606) compiled at 2021-09-16 14:55:22 commit 2935 last
mr 6385 release
(1 row)
```

- `working_version_num()`

Description: version number. It returns a version number related to system compatibility.

Return type: int

Example:

```
gaussdb=# SELECT working_version_num();
working_version_num
-----
92231
(1 row)
```

- `get_hostname()`

Description: Returns the host name of the current node.

Return type: text

Example:

```
gaussdb=# SELECT get_hostname();
get_hostname
-----
linux-user
(1 row)
```

- `get_nodename()`

Description: Returns the name of the current node.

Return type: text

Example:

```
gaussdb=# SELECT get_nodename();
get_nodename
-----
coordinator1
(1 row)
```

- `get_nodeinfo(text)`

Description: Returns the value of the corresponding node information based on the search attribute. Currently, the search attributes include **node_name** and **node_type**.

Return type: text

Example:

```
gaussdb=# SELECT get_nodeinfo('node_type');
get_nodeinfo
-----
DIS_CN
(1 row)
gaussdb=# SELECT get_nodeinfo('node_name');
get_nodeinfo
-----
coordinator1
(1 row)
```

- `get_schema_oid(cstring)`

Description: Returns the OID of the queried schema.

Return type: OID

Example:

```
gaussdb=# SELECT get_schema_oid('public');
get_schema_oid
-----
2200
(1 row)
```

- `pgxc_parse_clog(OUT xid int8, OUT nodename text, OUT status text)`

Description: Returns the status of all transactions in the current cluster.

Return type: SETOF record

Example:

```
gaussdb=# SELECT pgxc_parse_clog();
pgxc_parse_clog
-----
(0,dn_6004_6005_6006,INPROGRESS)
(1,dn_6004_6005_6006,COMMITTED)
(2,dn_6004_6005_6006,INPROGRESS)
(3 row)
```

- `pgxc_parse_clog(IN int2 bucketid, OUT xid int8, OUT nodename text, OUT status text)`

Description: Returns the statuses of all transactions with the specified bucket IDs in the current cluster. The input parameter is the bucket IDs of the hash bucket table. The value range is [-1,1023]. For an ordinary table, the value is -1.

Return type: SETOF record

Example:

```
gaussdb=# SELECT pgxc_parse_clog('-1');
pgxc_parse_clog
-----
(0,dn_6004_6005_6006,INPROGRESS)
(1,dn_6004_6005_6006,COMMITTED)
(2,dn_6004_6005_6006,INPROGRESS)
(3 row)
```

- `pgxc_prepared_xact()`

Description: Returns the list of transaction GIDs at the prepared stage in the cluster.

Return type: set of text

Example:

```
gaussdb=# SELECT pgxc_prepared_xact();
pgxc_prepared_xact
-----
(0 row)
```

- `pgxc_xacts_iscommitted()`

Description: Returns the status of the transaction with the specified XID in the cluster. **t** indicates the committed state, **f** indicates the aborted state, and **null** indicates other states. To execute this function, you must have the **sysadmin** or **monadmin** permission.

Return type: SETOF record

Example:

```
gaussdb=# SELECT pgxc_xacts_iscommitted(1);
pgxc_xacts_iscommitted
-----
(dn_6004_6005_6006,t)
(cn_5001,t)
(cn_5002,t)
(dn_6001_6002_6003,t)
(4 row)
```

- `pgxc_total_memory_detail()`

Description: Displays the memory usage in the cluster. To execute this function, you must have the **sysadmin** or **monadmin** permission.

 **NOTE**

If the GUC parameter **enable_memory_limit** is set to **off**, this function cannot be used.

Return type: set of `pv_total_memory_detail`

Example:

```
gaussdb=# SELECT pgxc_total_memory_detail();
pgxc_total_memory_detail
-----
(dn_6004_6005_6006,max_process_memory,81920)
(dn_6004_6005_6006,process_used_memory,72747)
(dn_6004_6005_6006,max_dynamic_memory,12096)
(dn_6004_6005_6006,dynamic_used_memory,1530)
(4 row)
```

- `pv_total_memory_detail()`

Description: Collects statistics on memory usage of the current database node in the unit of MB.

 **NOTE**

If the GUC parameter `enable_memory_limit` is set to `off`, this function cannot be used.

Return type: record

Table 7-77 Return value description

Name	Type	Description
nodename	text	Node name
memorytype	text	Memory type. The value must be one of the following: <ul style="list-style-type: none"> • max_process_memory: memory occupied by a GaussDB cluster instance • process_used_memory: memory occupied by a GaussDB thread • max_dynamic_memory: maximum dynamic memory • dynamic_used_memory: used dynamic memory • dynamic_peak_memory: dynamic peak memory • dynamic_used_shrctx: maximum dynamic shared memory context • dynamic_peak_shrctx: dynamic peak value of the shared memory context • max_shared_memory: maximum shared memory • shared_used_memory: used shared memory • max_sctpcomm_memory: maximum memory allowed for the communications library • sctpcomm_used_memory: memory used by the communications library • sctpcomm_peak_memory: memory peak of the communications library • other_used_memory: other used memory
memorybytes	integer	Size of allocated memory-typed memory

- `get_client_info()`

Description: Returns client information.
Return type: record

Access Permission Query Functions

The DDL permissions, including ALTER, DROP, COMMENT, INDEX, and VACUUM, are inherent permissions implicitly owned by the owner.

The following access permission query function only indicates whether a user has a certain permission on an object. That is, the permission on the object recorded in the **acl** column of the system catalog is returned.

- `has_any_column_privilege(user, table, privilege)`

Description: Queries whether a specified user has permissions on any column of a table.

Table 7-78 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
table	text, oid	Tables	Table name or ID
privilege	text	Permissions	<ul style="list-style-type: none"> • SELECT: allows the SELECT statement to be executed on any column of a specified table. • INSERT: allows the INSERT statement to be executed on any column of a specified table. • UPDATE: allows the UPDATE statement to be executed on any column of a specified table. • REFERENCES: allows a foreign key constraint (not supported in distributed mode). • COMMENT: allows the COMMENT statement to be executed on any column of a specified table.

Return type: Boolean

- `has_any_column_privilege(table, privilege)`

Description: Queries whether the current user has the permission to access any column of a table. For details about the valid parameter types, see [Table 7-78](#).

Return type: Boolean

Note: **has_any_column_privilege** checks whether a user can access any column of a table in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**, except that the desired access permission type must be some combination of SELECT, INSERT, UPDATE, or REFERENCES.

 **NOTE**

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table. Therefore, **has_any_column_privilege** always returns **true** if **has_table_privilege** has the same parameters. But "success" is also returned if there is a column-level grant of the permission for at least one column.

- **has_column_privilege**(user, table, column, privilege)

Description: Specifies whether a specified user has the permission to access columns.

Table 7-79 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
table	text, oid	Table name	Table name or ID
column	text, smallint	Column name	Name or attribute number of a column
privilege	text	Permissions	<ul style="list-style-type: none"> • SELECT: allows the SELECT statement to be executed on specified columns of a table. • INSERT: allows the INSERT statement to be executed on specified columns of a table. • UPDATE: allows the UPDATE statement to be executed on specified columns of a table. • REFERENCES: allows a foreign key constraint (not supported in distributed mode). • COMMENT: allows the COMMENT statement to be executed on specified columns of a table.

Return type: Boolean

- **has_column_privilege**(table, column, privilege)

Description: Specifies whether the current user has the permission to access columns. For details about the valid parameter types, see [Table 7-79](#).

Return type: Boolean

has_column_privilege checks whether a user can access a column in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. Columns can be added either by name or by attribute number. The desired access permission type must be some combination of SELECT, INSERT, UPDATE, or REFERENCES.

 **NOTE**

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table.

- `has_cek_privilege(user, cek, privilege)`

Description: Specifies whether a specified user has permissions on CEKs.

Table 7-80 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
cek	text, oid	CEK	Name or ID of a CEK
privilege	text	Permission	<ul style="list-style-type: none"> • USAGE: allows users to use the specified CEK. • DROP: allows users to delete the specified CEK.

Return type: Boolean

- `has_cmk_privilege(user, cmk, privilege)`

Description: Specifies whether a specified user has permissions on CMKs.

Table 7-81 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
cmk	text, oid	CMK	Name or ID of the CMK
privilege	text	Permission	<ul style="list-style-type: none"> • USAGE: allows users to use the specified CMK. • DROP: allows users to delete the specified CMK.

Return type: Boolean

- `has_database_privilege(user, database, privilege)`

Description: Specifies whether a specified user has permissions on databases.

Table 7-82 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
database	text, oid	Database	Database name or ID
privilege	text	Permission	<ul style="list-style-type: none"> • CREATE: For databases, allows new schemas to be created within the database. • TEMPORARY: allows users to create temporary tables when the database is used. • TEMP: allows users to create temporary tables when the database is used. • CONNECT: allows users to access specified databases. • ALTER: allows users to modify the attributes of a specified object. • DROP: allows users to delete a specified object. • COMMENT: allows users to define or modify comments of a specified object.

Return type: Boolean

- `has_database_privilege(database, privilege)`

Description: Queries whether the current user has the permission to access a database. For details about the valid parameter types, see [Table 7-82](#).

Return type: Boolean

Note: **has_database_privilege** checks whether a user can access a database in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The desired access permission type must be some combination of CREATE, CONNECT, TEMPORARY, or TEMP (which is equivalent to TEMPORARY).

- `has_directory_privilege(user, directory, privilege)`

Table 7-83 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
directory	text, oid	Directory	Directory name or OID
privilege	text	Permission	<ul style="list-style-type: none"> • READ: allows read operations on the directory. • WRITE: allows write operations on the directory.

Description: Specifies whether a specified user has permissions on directories.

Return type: Boolean

- `has_directory_privilege(directory, privilege)`

Description: Queries whether the current user has the permission to access a directory. For details about the valid parameter types, see [Table 7-83](#).

Return type: Boolean

- `has_foreign_data_wrapper_privilege(user, fdw, privilege)`

Table 7-84 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
fdw	text, oid	Foreign data wrapper	Name or ID of the foreign data wrapper
privilege	text	Permission	USAGE : allows access to the foreign data wrapper.

Description: Specifies whether a specified user has permissions on foreign data wrappers.

Return type: Boolean

- `has_foreign_data_wrapper_privilege(fdw, privilege)`

Description: Queries whether the current user has permissions on foreign data wrappers. For details about the valid parameter types, see [Table 7-84](#).

Return type: Boolean

Note: **has_foreign_data_wrapper_privilege** checks whether a user can access a foreign data wrapper in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The desired access permission type must evaluate to USAGE.

- `has_function_privilege(user, function, privilege)`

Table 7-85 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
function	text, oid	Function	Function name or ID
privilege	text	Permission	<p>EXECUTE: allows users to use specified functions and the operators that are realized by the functions.</p> <ul style="list-style-type: none"> • ALTER: allows users to modify the attributes of a specified object. • DROP: allows users to delete a specified object. • COMMENT: allows users to define or modify comments of a specified object.

Description: Specifies whether a specified user has permissions on functions.

Return type: Boolean

- `has_function_privilege(function, privilege)`

Description: Specifies whether the current user has permissions on functions. For details about valid parameter types, see [Table 7-85](#).

Return type: Boolean

Note: **has_function_privilege** checks whether a user can access a function in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. When a function is specified by a text string rather than by an OID, the allowed input is the same as that for the regprocedure data type (see [Object Identifier Types](#)). The desired access permission type must be EXECUTE.

- `has_language_privilege(user, language, privilege)`

Table 7-86 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID

Parameter	Valid Input Parameter Type	Description	Value Range
language	text, oid	Language	Language name or ID
privilege	text	Permission	USAG: allows users to specify a procedural language when creating a function.

Description: Specifies whether a specified user has permissions on languages.

Return type: Boolean

- `has_language_privilege(language, privilege)`

Description: Specifies whether the current user has permissions on languages. For details about valid parameter types, see [Table 7-86](#).

Return type: Boolean

Note: **has_language_privilege** checks whether a user can access a procedural language in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The desired access permission type must evaluate to USAGE.

- `has_nodegroup_privilege(user, nodegroup, privilege)`

Description: Checks whether a user has permission to access a cluster node.

Return type: Boolean

Table 7-87 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Existing username or ID
nodegroup	text, oid	Cluster node	Existing cluster node

Parameter	Valid Input Parameter Type	Description	Value Range
privilege	text	Permission	<ul style="list-style-type: none"> • USAGE: For sub-clusters, allows users who can access objects contained in the schema to access tables in the sub-cluster. • CREATE: For sub-clusters, allows users to create tables within the sub-cluster. • COMPUTE: allows elastic computing in the sub-cluster. • ALTER: allows users to modify the attributes of a specified object. • DROP: allows users to delete a specified object.

- `has_nodegroup_privilege(nodegroup, privilege)`
Description: Checks whether a user has permission to access a cluster node.
Return type: Boolean
- `has_schema_privilege(user, schema, privilege)`
Description: Specifies whether a specified user has permissions on schemas.
Return type: Boolean
- `has_schema_privilege(schema, privilege)`
Description: Specifies whether the current user has permissions on schemas.
Return type: Boolean
Note: **has_schema_privilege** checks whether a user can access a schema in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The desired access permission type must be a combination among CREATE, USAGE, ALTER, DROP, and COMMENT. If the check type contains the CREATE permission and the checked schema is a schema with the same name as the user, the function returns **TRUE** only when the user has the OWNER permission for the schema due to the special constraint of the schema with the same name.
- `has_sequence_privilege(user, sequence, privilege)`
Description: Queries whether a specified user has permissions on sequences.
Return type: Boolean

Table 7-88 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Existing username or ID

Parameter	Valid Input Parameter Type	Description	Value Range
sequence	text, oid	Sequence	Existing sequence name or ID
privilege	text	Permission	<ul style="list-style-type: none"> • USAGE: For sequences, allows users to use the nextval function. • SELECT: allows users to create a sequence. • UPDATE: allows users to execute the UPDATE statement. • ALTER: allows users to modify the attributes of a specified object. • DROP: allows users to delete a specified object. • COMMENT: allows users to define or modify comments of a specified object.

- `has_sequence_privilege(sequence, privilege)`
Description: Queries whether the current user has permissions on sequences.
Return type: Boolean
- `has_server_privilege(user, server, privilege)`
Description: Specifies whether a specified user has permissions on foreign servers.
Return type: Boolean
- `has_server_privilege(server, privilege)`
Description: Specifies whether the current user has permissions on foreign servers.
Return type: Boolean
Note: **has_server_privilege** checks whether a user can access a foreign server in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The access permission type must be USAGE, ALTER, DROP, or COMMENT.
- `has_table_privilege(user, table, privilege)`
Description: Specifies whether a specified user has permissions on tables.
Return type: Boolean
- `has_table_privilege(table, privilege)`
Description: Specifies whether the current user has permissions on tables.
Return type: Boolean
Note: **has_table_privilege** checks whether a user can access a table in a particular way. The user can be specified by name or by OID (**pg_authid.oid**),

or be set to **public** which indicates public pseudo roles. If this parameter is omitted, **current_user** is used. The table can be specified by name or by OID. When it is specified by name, the name can be schema-qualified if necessary. If the desired access permission type is specified by a text string, the text string must be one of the values **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE**, **REFERENCETRIGGER**, **ALTER**, **DROP**, **COMMENT**, **INDEX**, or **VACUUM**. Optionally, **WITH GRANT OPTION** can be added to a permission type to test whether the permission is held with the grant option. Also, multiple permission types can be separated by commas (,), in which case the result will be **true** if any of the listed permissions is held.

Example:

```
gaussdb=# SELECT has_table_privilege('tpcds.web_site', 'select');
 has_table_privilege
-----
t
(1 row)

gaussdb=# SELECT has_table_privilege('omm', 'tpcds.web_site', 'select,INSERT WITH GRANT OPTION ');
 has_table_privilege
-----
t
(1 row)
```

- **has_tablespace_privilege**(user, tablespace, privilege)
Description: Specifies whether a specified user has permissions on tablespaces.
Return type: Boolean
- **has_tablespace_privilege**(tablespace, privilege)
Description: Specifies whether the current user has permissions on tablespaces.
Return type: Boolean
Note: **has_tablespace_privilege** checks whether a user can access a tablespace in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**. The access permission type must be CREATE, ALTER, DROP, or COMMENT.
- **pg_has_role**(user, role, privilege)
Description: Specifies whether a specified user has permissions on roles.
Return type: Boolean
- **pg_has_role**(role, privilege)
Description: Specifies whether the current user has permissions on roles.
Return type: Boolean
Note: **pg_has_role** checks whether a user can access a role in a particular way. Its parameter possibilities are analogous to those of **has_table_privilege**, except that **public** cannot be used as a username. The desired access permission type must be some combination of MEMBER or USAGE. MEMBER denotes direct or indirect membership in the role (that is, permission SET ROLE), while USAGE denotes the usage permission on the role that is available without the SET ROLE permission.
- **has_any_privilege**(user, privilege)
Description: Queries whether a specified user has certain ANY permission. If multiple permissions are queried at the same time, **true** is returned as long as one permission is obtained.

Return type: Boolean

Table 7-89 Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name	Users	Existing username
privilege	text	ANY permission	Available values: <ul style="list-style-type: none"> • CREATE ANY TABLE [WITH ADMIN OPTION] • ALTER ANY TABLE [WITH ADMIN OPTION] • DROP ANY TABLE [WITH ADMIN OPTION] • SELECT ANY TABLE [WITH ADMIN OPTION] • INSERT ANY TABLE [WITH ADMIN OPTION] • UPDATE ANY TABLE [WITH ADMIN OPTION] • DELETE ANY TABLE [WITH ADMIN OPTION] • CREATE ANY SEQUENCE [WITH ADMIN OPTION] • CREATE ANY INDEX [WITH ADMIN OPTION] • CREATE ANY FUNCTION [WITH ADMIN OPTION] • EXECUTE ANY FUNCTION [WITH ADMIN OPTION] • CREATE ANY TYPE [WITH ADMIN OPTION]

Schema Visibility Query Functions

Each function performs the visibility check on one type of database objects. For functions and operators, an object in the search path is visible if there is no object of the same name and parameter data type earlier in the path. For operator classes, both name and associated index access methods are considered.

All these functions require OIDs to identify the objects to be checked. If you want to test an object by name, it is convenient to use the OID alias type (regclass, regtype, regprocedure, regoperator, regconfig, or regdictionary).

For example, a table is said to be visible if the schema where the table is located is in the search path and no table of the same name appears earlier in the search

path. This is equivalent to the statement that the table can be referenced by name without explicit schema qualification. To list the names of all visible tables, run the following command:

```
gaussdb=# SELECT relname FROM pg_class WHERE pg_table_is_visible(oid);
```

- `pg_collation_is_visible(collation_oid)`
Description: Specifies whether the collation is visible in the search path.
Return type: Boolean
- `pg_conversion_is_visible(conversion_oid)`
Description: Specifies whether the conversion is visible in the search path.
Return type: Boolean
- `pg_function_is_visible(function_oid)`
Description: Specifies whether the function is visible in the search path.
Return type: Boolean
- `pg_opclass_is_visible(opclass_oid)`
Description: Specifies whether the operator class is visible in the search path.
Return type: Boolean
- `pg_operator_is_visible(operator_oid)`
Description: Specifies whether the operator is visible in the search path.
Return type: Boolean
- `pg_opfamily_is_visible(opclass_oid)`
Description: Specifies whether the operator family is visible in the search path.
Return type: Boolean
- `pg_table_is_visible(table_oid)`
Description: Specifies whether the table is visible in the search path.
Return type: Boolean
- `pg_ts_config_is_visible(config_oid)`
Description: Specifies whether the text search configuration is visible in the search path.
Return type: Boolean
- `pg_ts_dict_is_visible(dict_oid)`
Description: Specifies whether the text search dictionary is visible in the search path.
Return type: Boolean
- `pg_ts_parser_is_visible(parser_oid)`
Description: Specifies whether the text search parser is visible in the search path.
Return type: Boolean
- `pg_ts_template_is_visible(template_oid)`
Description: Specifies whether the text search template is visible in the search path.
Return type: Boolean
- `pg_type_is_visible(type_oid)`

Description: Specifies whether the type (or domain) is visible in the search path.

Return type: Boolean

System Catalog Information Functions

- `format_type(type_oid, typemod)`

Description: Obtains the SQL name of a data type.

Return type: text

Note: **format_type** returns the SQL name of a data type based on the OID of the data type and possible modifiers. If the specific modifier is unknown, pass **NULL** at the position of the modifier. Modifiers are generally meaningful only for data types with length restrictions. The SQL name returned by **format_type** contains the length of the data type, which can be calculated by taking `sizeof(int32)` from actual storage length [actual storage len - `sizeof(int32)`] in the unit of bytes. 32-bit space is required to store the customized length set by users. Therefore, the actual storage length contains 4 bytes more than the customized length. In the following example, the SQL name returned by **format_type** is `character varying(6)`, indicating the length of the `varchar` type is 6 bytes. Therefore, the actual storage length of the `varchar` type is 10 bytes.

```
gaussdb=# SELECT format_type((SELECT oid FROM pg_type WHERE typename='varchar'), 10);
format_type
-----
character varying(6)
(1 row)
```

- `pg_check_authid(role_oid)`

Description: Checks whether a role name with given OID exists.

Return type: Boolean

```
gaussdb=# select pg_check_authid(1);
pg_check_authid
-----
f
(1 row)
```

- `pg_describe_object(catalog_id, object_id, object_sub_id)`

Description: Obtains the description of a database object.

Return type: text

Note: **pg_describe_object** returns the description of a database object specified by a catalog OID, an object OID, and a (possibly zero) sub-object ID. This is useful to determine the identity of an object stored in the `pg_depend` catalog.

- `pg_get_constraintdef(constraint_oid)`

Description: Obtains definition of a constraint.

Return type: text

- `pg_get_constraintdef(constraint_oid, pretty_bool)`

Description: Obtains definition of a constraint.

Return type: text

Note: **pg_get_constraintdef** and **pg_get_indexdef** respectively reconstruct the creation command for a constraint and an index.

- pg_get_expr(pg_node_tree, relation_oid)**
 Description: Decompiles the internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.
 Return type: text
- pg_get_expr(pg_node_tree, relation_oid, pretty_bool)**
 Description: Decompiles the internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.
 Return type: text
 Note: **pg_get_expr** decompiles the internal form of an individual expression, such as the default value of a column. This helps to check the content of system catalogs. If the expression contains keywords, specify the OID of the relationship that the keywords refer to as the second parameter; if no keywords are contained, use zero.
- pg_get_functiondef(func_oid)**
 Description: Obtains the definition of a function.
 Return type: text
 Example:

```
gaussdb=# SELECT * FROM pg_get_functiondef(598);
headerlines |          definition
-----+-----
4 | CREATE OR REPLACE FUNCTION pg_catalog.abbrev(inet)+
| RETURNS text +
| LANGUAGE internal +
| IMMUTABLE STRICT NOT FENCED NOT SHIPPABLE +
| AS $function$inet_abbrev$function$ +
(1 row)
```
- pg_get_function_arguments(func_oid)**
 Description: Obtains argument list of function's definition (with default values).
 Return type: text
 Note: **pg_get_function_arguments** returns the parameter list of a function, in the form it would need to appear in CREATE FUNCTION.
- pg_get_function_identity_arguments(func_oid)**
 Description: Obtains the parameter list to identify a function (without default values).
 Return type: text
 Note: **pg_get_function_identity_arguments** returns the parameter list necessary to identify a function, in the form it would need to appear in within ALTER FUNCTION. This form omits default values.
- pg_get_function_result(func_oid)**
 Description: Obtains the RETURNS clause for a function.
 Return type: text
 Note: **pg_get_function_result** returns the appropriate RETURNS clause for the function.
- pg_get_indexdef(index_oid)**
 Description: Obtains the **CREATE INDEX** command for an index.
 Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_indexdef(16416);
           pg_get_indexdef
-----
CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
```

- `pg_get_indexdef(index_oid, dump_schema_only)`

Description: Obtains the **CREATE INDEX** command for indexes in dump scenarios. In the current version, the value of **dump_schema_only** does not affect the function output.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_indexdef(16416, true);
           pg_get_indexdef
-----
CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
```

- `pg_get_indexdef(index_oid, column_no, pretty_bool)`

Description: Obtains the **CREATE INDEX** command for an index, or definition of just one index column when the value of **column_no** is not zero.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_indexdef(16416, 0, false);
           pg_get_indexdef
-----
CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
gaussdb=# SELECT * FROM pg_get_indexdef(16416, 1, false);
           pg_get_indexdef
-----
b
(1 row)
```

Note: **pg_get_functiondef** returns a complete CREATE OR REPLACE FUNCTION statement for a function.

- `pg_get_keywords()`

Description: Obtains the list of SQL keywords and their categories.

Return type: SETOF record

Note: **pg_get_keywords** returns a set of records describing the SQL keywords recognized by the server. The **word** column contains the keywords. The **catcode** column contains a category code: **U** for unreserved, **C** for column name, **T** for type or function name, or **R** for reserved. The **catdesc** column contains a possibly-localized string describing the category.

- `pg_get_ruledef(rule_oid)`

Description: Obtains the **CREATE RULE** command for a rule.

Return type: text

- `pg_get_ruledef(rule_oid, pretty_bool)`

Description: Obtains the **CREATE RULE** command for a rule.

Return type: text

- `pg_get_userbyid(role_oid)`

Description: Obtains the role name with a given OID.

Return type: name

Note: **pg_get_userbyid** extracts a role's name given its OID.

- **pg_check_authid(role_id)**

Description: Checks whether a user exists based on **role_id**.

Return type: text

```
gaussdb=# SELECT pg_check_authid(20);
pg_check_authid
-----
f
(1 row)
```

- **pg_get_viewdef(view_name)**

Description: Obtains the underlying **SELECT** command for a view.

Return type: text

- **pg_get_viewdef(view_name, pretty_bool)**

Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to 80 columns if **pretty_bool** is set to **true**.

Return type: text

Note: **pg_get_viewdef** reconstructs the SELECT query that defines a view. Most of these functions come in two forms. When the function has the **pretty_bool** parameter and the value is **true**, it can optionally "pretty-print" the result. The pretty-printed format is more readable. The other one is the default format which is more likely to be interpreted in the same way by future versions. Avoid using pretty-printed output for dump purposes. Passing **false** to the pretty-print parameter generates the same result as a variant without this parameter.

- **pg_get_viewdef(view_oid)**

Description: Obtains the underlying **SELECT** command for a view.

Return type: text

- **pg_get_viewdef(view_oid, pretty_bool)**

Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to 80 columns if **pretty_bool** is set to **true**.

Return type: text

- **pg_get_viewdef(view_oid, wrap_column_int)**

Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to the specified number of columns and printing is implicit.

Return type: text

- **pg_get_tabledef(table_oid)**

Description: Obtains the definition of a table based on **table_oid**.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_tabledef(16384);
pg_get_tabledef
-----
SET search_path = public;          +
CREATE TABLE t1 (                  +
    c1 bigint DEFAULT nextval('serial'::regclass)  +
)                                     +
WITH (orientation=row,compression=no)  +
DISTRIBUTE BY HASH(c1)                +
```

```

TO GROUP group1;
ILM Security Policies:
  POLICY "p4" TABLE
    ROW STORE COMPRESS ADVANCED ROW AFTER 1 DAYS OF NO MODIFICATION
    STATUS: ENABLED DELETED: NO
(1 row)

```

- `pg_get_tabledef(table_name)`

Description: Obtains the definition of a table based on **table_name**.

Return type: text

Example:

```

gaussdb=# SELECT * FROM pg_get_tabledef('t1');
pg_get_tabledef
-----
SET search_path = public;
CREATE TABLE t1 (
  c1 bigint DEFAULT nextval('serial'::regclass)
)
WITH (orientation=row, compression=no)
DISTRIBUTE BY HASH(c1)
TO GROUP group1;
ILM Security Policies:
  POLICY "p4" TABLE
    ROW STORE COMPRESS ADVANCED ROW AFTER 1 DAYS OF NO MODIFICATION
    STATUS: ENABLED DELETED: NO
(1 row)

```

Note: **pg_get_tabledef** reconstructs the CREATE statement of the definition of the table, including the table definition, index information, comments, and ILM policy. You need to create the group, schema, tablespace, and server information on which the table object depends.

- `pg_options_to_table(reloptions)`

Description: Obtains the set of storage option name/value pairs.

Return type: SETOF record

Note: **pg_options_to_table** returns the set of storage option name/value pairs (**option_name/option_value**) when **pg_class.reloptions** or **pg_attribute.attoptions** is passed.

- `pg_tablespace_databases(tablespace_oid)`

Description: Obtains the set of database OIDs that have objects in the specified tablespace.

Return type: setof oid

Note: **pg_tablespace_databases** allows a tablespace to be checked. It returns the set of OIDs of databases that have objects stored in the tablespace. If this function returns any rows of data, the tablespace is not empty and cannot be dropped. To display the specific objects in the tablespace, you need to connect to the databases identified by **pg_tablespace_databases** and query their **pg_class** catalogs.

- `pg_tablespace_location(tablespace_oid)`

Description: Obtains the path in the file system that this tablespace is located in.

Return type: text

- `pg_typeof(any)`

Description: Obtains the data type of any value.

Return type: regtype

Note: **pg_typeof** returns the OID of the data type of the value that is passed to it. This can be helpful for troubleshooting or dynamically constructing SQL queries. It is declared that the function returns regtype, which is an OID alias type (see [Object Identifier Types](#)). This means that it is the same as an OID for comparison purposes but displays as a type name.

Example:

```
gaussdb=# SELECT pg_typeof(33);
 pg_typeof
-----
integer
(1 row)

gaussdb=# SELECT typlen FROM pg_type WHERE oid = pg_typeof(33);
 typlen
-----
      4
(1 row)
```

- collation for (any)

Description: Obtains the collation of the parameter.

Return type: text

Note: The expression COLLATION FOR returns the collation of the value that is passed to it. Example:

```
gaussdb=# SELECT collation for (description) FROM pg_description LIMIT 1;
 pg_collation_for
-----
"default"
(1 row)
```

The value might be quoted and schema-qualified. If no collation is derived for the parameter expression, then a null value is returned. If the argument is not of a collatable data type, then an error message is displayed.

- getdistributekey(table_name)

Description: Gets a distribution key for a hash table.

Return type: text

Example:

```
gaussdb=# SELECT getdistributekey('item');
 getdistributekey
-----
i_item_sk
(1 row)
```

- pg_extension_update_paths(name)

Description: Returns the version update path of the specified extension. This function can be called only by the system administrator.

Return type: text (source text), text (target text), text (path text)

- pg_get_serial_sequence(tablename, colname)

Description: Obtains the sequence of the corresponding table name and column name.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_serial_sequence('t1', 'c1');
 pg_get_serial_sequence
-----
public.serial
(1 row)
```

- pg_sequence_parameters(sequence_oid)**

Description: Obtains the parameters of a specified sequence, including the start value, minimum value, maximum value, and incremental value.

Return type: int16, int16, int16, int16, Boolean

Example:

```
gaussdb=# SELECT * FROM pg_sequence_parameters(16420);
 start_value | minimum_value | maximum_value | increment | cycle_option
-----+-----+-----+-----+-----
          101 |              1 | 9223372036854775807 |          1 | f
(1 row)
```
- pgxc_get_variable_info()**

Description: Obtains variable values on the node, including **nodeName**, **nextOid**, **nextXid**, **oldestXid**, **xidVacLimit**, **oldestXidDB**, **lastExtendCSNLogpage**, **startExtendCSNLogpage**, **nextCommitSeqNo**, **latestCompleteXid**, and **startupMaxXid**.

Return type: set of pg_variable_info

Example:

```
gaussdb=# SELECT pgxc_get_variable_info( );
 pgxc_get_variable_info
-----
(dn_6004_6005_6006,25617,141396349,2073,20000002073,15808,138111,0,127154152,141396348,104433004)
(1 row)
```
- gs_get_index_status(schema_name, index_name)**

Description: Obtains the index status information on all nodes, including whether an index can be inserted and whether an index is available. This function is mainly used to check the index status during online index creation or when the index creation fails. The return values include **node_name**, **indisready**, and **indisvalid**. Only when **indisready** and **indisvalid** of indexes on all nodes are set to **true** and the index state is not changed to unusable, the current index is available.

Return type: text, Boolean, Boolean

Example:

```
gaussdb=# SELECT * FROM gs_get_index_status('public', 'index1');
 node_name | indisready | indisvalid
-----+-----+-----
 datanode1 | t          | t
 datanode2 | t          | t
 coordinator1 | t        | t
(3 row)
```

Comment Information Functions

- col_description(table_oid, column_number)**

Description: Obtains the comment for a table column.

Return type: text

Note: **col_description** returns the comment for a table column, which is specified by the OID of its table and its column number.
- obj_description(object_oid, catalog_name)**

Description: Obtains the comment for a database object.

Return type: text

Note: The two-parameter form of **obj_description** returns the comment for a database object specified by its OID and the name of the system catalog to

which it belongs. For example, **obj_description(123456,'pg_class')** would retrieve the comment for the table with OID 123456. The one-parameter form of **obj_description** requires only the OID.

obj_description cannot be used for table columns since columns do not have OIDs of their own.

- **obj_description(object_oid)**
Description: Obtains the comment for a database object.
Return type: text
- **shobj_description(object_oid, catalog_name)**
Description: Obtains the comment for a shared database object.
Return type: text

Note: **shobj_description** is used just like **obj_description**, except that the former is used for shared objects. Some system catalogs are global to all databases in the cluster, and the comments for objects in them are stored globally as well.

XIDs and Snapshots

Internal XIDs are 64 bits. **txid_snapshot**, data type used by these functions, stores information about XID visibility at a particular moment in time. [Table 7-90](#) describes the components.

Table 7-90 Snapshot components

Name	Description
xmin	Earliest XID (txid) that is still active. All earlier transactions will either be committed and visible, or rolled back.
xmax	First as-yet-unassigned txid . All txids greater than or equal to this are not yet started as of the time of the snapshot, so they are invisible.
xip_list	Active txids at the time of the snapshot. The list includes only those active txids between xmin and xmax ; there might be active txids higher than xmax . A txid that is greater than or equal to xmin and less than xmax and that is not in this list was already completed at the time of the snapshot, and is either visible or rolled back according to its commit status. The list does not include txids of subtransactions.

The textual representation of **txid_snapshot** is **xmin:xmax:xip_list**.

For example, **10:20:10,14,15** means **xmin=10, xmax=20, xip_list=10, 14, 15**.

The following functions provide server transaction information in an exportable form. These functions are mainly used to determine which transactions were committed between two snapshots.

- **pgxc_is_committed(transaction_id)**
Description: Specifies whether the given XID is committed or ignored. **NULL** indicates the unknown status (it can be running, ready, frozen, or other

status). In maintenance mode (when the GUC parameter **xc_maintenance_mode** is set to **on**), the statuses of all transactions with the specified bucket IDs and ordinary tables are traversed. If a status conflict occurs, for example, the status of the same transaction is **committed** in bucket 1 and **rolled back** in bucket 2, an error is reported. Exercise caution when enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.

Return type: Boolean

- `pgxc_is_committed(transaction_id, bucketid)`
Description: Commits or ignores the given transaction (gxid) if **bucketid** is specified. **NULL** indicates that the status is unknown (running, ready, or frozen). **bucketid** is the physical bucket ID of the hash bucket table. The value is **-1** for an ordinary table. In maintenance mode (when the GUC parameter **xc_maintenance_mode** is set to **on**), if **bucketid** is set to **-1**, the statuses of all transactions with the specified bucket IDs and ordinary tables are traversed. If a status conflict occurs, for example, the status of the same transaction is **committed** in bucket 1 and **rolled back** in bucket 2, an error is reported. Exercise caution when enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.

Return type: Boolean

- `txid_current()`
Description: Obtains the current XID.
Return type: bigint
- `gs_txid_oldestxmin()`
Description: Obtains the minimum XID (specified by **oldesxmin**).
Return type: bigint
- `txid_current_snapshot()`
Description: Obtains the current snapshot.
Return type: txid_snapshot
- `txid_snapshot_xip(txid_snapshot)`
Description: Obtains in-progress XIDs in a snapshot.
Return type: setof bigint
- `txid_snapshot_xmax(txid_snapshot)`
Description: Obtains **xmax** of snapshots.
Return type: bigint
- `txid_snapshot_xmin(txid_snapshot)`
Description: Obtains **xmin** of snapshots.
Return type: bigint
- `txid_visible_in_snapshot(bigint, txid_snapshot)`
Description: Specifies whether the XID is visible in a snapshot (do not use subtransaction IDs).
Return type: Boolean
- `get_local_prepared_xact()`

Description: Obtains the two-phase residual transaction information of the current node, including the XID, GID of the two-phase transaction, prepared time, owner OID, database OID, and node name of the current node.

Return type: xid, text, timestamptz, oid, text

- `get_remote_prepared_xacts()`

Description: Obtains the two-phase residual transaction information of all remote nodes, including the XID, GID of the two-phase transaction, prepared time, owner name, database name, and node name.

Return type: xid, text, timestamptz, name, text

- `global_clean_prepared_xacts(text, text)`

Description: Concurrently cleans two-phase residual transactions. Only the `gs_clean` tool can call this function for cleaning. In other situations, **false** is returned.

Return type: Boolean

- `pgxc_stat_get_wal_senders()`

Description: Returns the sent logs of all primary DN's and the received logs of their corresponding standby DN's in the cluster. Only users with the system admin or monitor admin permission can use this function.

For details about the return values, see [Table 7-91](#).

Table 7-91 `pgxc_stat_get_wal_senders` parameters

Column	Description
<code>nodename</code>	Instance name.
<code>sender_pid</code>	PID of the thread for sending logs.
<code>local_role</code>	Instance role.
<code>peer_role</code>	Role of the instance on the receiver.
<code>peer_state</code>	Status of the instance on the receiver.
<code>state</code>	Synchronization status between instances.
<code>sender_sent_location</code>	Location where the sender sends logs.
<code>sender_write_location</code>	Location where the sender writes logs.
<code>sender_flush_location</code>	Location where the sender flushes logs to disks.
<code>sender_replay_location</code>	Location of the instance logs. If the DN is a primary DN, the location is the value of sender_flush_location . Otherwise, the location where the current instance log is replayed is used.
<code>receiver_received_location</code>	Location where the receiver receives logs.

Column	Description
receiver_write_location	Location where the receiver writes logs.
receiver_flush_location	Location where the receiver flushes logs to disks.
receiver_replay_location	Location where the receiver replays logs.

- pgxc_stat_get_wal_senders_status()**
 Description: Returns the receiving status of transaction logs on all nodes. Only users with the system admin or monitor admin permission can use this function.

For details about the return values, see [Table 7-92](#).

Table 7-92 pgxc_stat_get_wal_senders_status parameters

Column	Description
nodename	Name of the primary node
source_ip	IP address of the primary node
source_port	Port of the primary node
dest_ip	IP address of the standby node
dest_port	Port of the standby node
sender_pid	PID of the sending thread
local_role	Type of the primary node
peer_role	Type of the standby node
peer_state	Status of the standby node
state	WAL sender status
sender_sent_location	Sending position of the primary node
sender_write_location	Writing position of the primary node
sender_replay_location	Redo position of the primary node
receiver_received_location	Receiving position of the standby node
receiver_write_location	Writing position of the standby node
receiver_flush_location	Flushing location of the standby node
receiver_replay_location	Redo location of the standby node

- gs_get_next_xid_csn()**

Description: Returns the values of **next_xid** and **next_csn** on all nodes globally.

For details about the return values, see [Table 7-93](#).

Table 7-93 gs_get_next_xid_csn parameters

Column	Description
nodename	Node name
next_xid	ID of the next transaction on the current node.
next_csn	Next CSN of the current node.

- `pg_control_system()`
Description: Returns the status of the system control file.
Return type: SETOF record
- `pg_control_checkpoint()`
Description: Returns the system checkpoint status
Return type: SETOF record
- `get_prepared_pending_xid()`
Description: Returns **nextxid** when restoration is complete.
Parameter: nan
Return type: text
- `pg_clean_region_info()`
Description: Clears the region map.
Parameter: nan
Return type: character varying
- `pg_get_replication_slot_name()`
Description: Obtains the slot name.
Parameter: nan
Return type: text
- `pg_get_running_xacts()`
Description: Obtains running **xact**.
Parameter: nan
Return type: handle integer, gxid xid, state tinyint, node text, xmin xid, vacuum boolean, timeline bigint, prepare_xid xid, pid bigint, next_xid xid
- `pg_get_variable_info()`
Description: Obtains the shared memory variable cache.
Parameter: nan
Return type: node_name text, nextOid oid, nextXid xid, oldestXid xid, xidVacLimit xid, oldestXidDB oid, lastExtendCSNLogpage xid, startExtendCSNLogpage xid, nextCommitSeqNo xid, latestCompletedXid xid, and startupMaxXid xid

- `pg_get_xidlimit()`
Description: Obtains XID information from the shared memory.
Parameter: nan
Return type: nextXid xid, oldestXid xid, xidVacLimit xid, xidWarnLimit xid, xidStopLimit xid, xidWrapLimit xid, oldestXidDB oid
- `pg_relation_compression_ratio()`
Description: Queries the compression rate of a table. By default, **1.0** is returned.
Parameter: text
Return type: real
- `pg_relation_with_compression()`
Description: Specifies whether a table is compressed.
Parameter: text
Return type: Boolean
- `pg_stat_file_recursive()`
Description: Lists all files in a path.
Parameter: location text
Return type: path text, filename text, size bigint, isdir boolean
- `pg_stat_get_activity_for temptable()`
Description: Returns records of backend threads related to the temporary table.
Parameter: nan
Return type: datid oid, timelineid integer, tempid integer, and sessionid bigint
- `pg_stat_get_activity_ng()`
Description: Returns records of backend threads related to nodegroup.
Parameter: pid bigint
Return type: datid oid, pid bigint, sessionid bigint, and node_group text
- `pg_stat_get_cgroup_info()`
Description: Returns Cgroup information.
Parameter: nan
Return type: cgroup_name text, percent integer, usage_percent integer, shares bigint, usage bigint, cpuset text, relpath text, valid text, node_group text
- `pg_stat_get_realtime_info_internal()`
Description: Returns real-time information. Currently, this API is unavailable. **FailedToGetSessionInfo** is returned.
Parameter: oid, oid, bigint, cstring, oid
Return type: text
- `pg_stat_get_wlm_session_iostat_info()`
Description: Returns the session load I/O information.
Parameter: nan
Return type: threadid bigint, maxcurr_iops integer, mincurr_iops integer, maxpeak_iops integer, minpeak_iops integer, iops_limits integer, io_priority integerw, and curr_io_limits integer

- `pg_test_err_contain_err()`
Description: Tests the error type and return information.
Parameter: integer
Return type: void
- `pv_session_memory_detail_tp()`
Description: Returns the memory usage of the session. For details, see [pv_session_memory_detail](#).
Parameter: nan
Return type: sessid text, sesstype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint
- `gs_get_table_distribution()`
Description: Returns the distribution of table data on each DN.
Parameter: table_name text, schema_name text
Return type: text
- `pv_builtin_functions()`
Description: Displays information about all built-in system functions.
Parameter: nan
Return type: proname name, pronamespace oid, proowner oid, prolang oid, procost real, prorows real, provariadic oid, protransform regproc, proisagg boolean, proiswindow boolean, proscdef boolean, proleakproof boolean, proisstrict boolean, proretset boolean, provolatile "char", pronargs smallint, pronargdefaults smallint, prorettype oid, proargtypes oidvector, proallargtypes integer[], proargmodes "char"[], proargnames text[], proargdefaults pg_node_tree, prosrc text, probin text, proconfig text[], proacl aclitem[], prodefaultargpos int2vector, fencedmode boolean, proshippable boolean, propackage boolean, oid oid
- `pv_thread_memory_detail()`
Description: Returns the memory information of each thread.
Parameter: nan
Return type: threadid text, tid bigint, thrdtype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint
- `pg_shared_memory_detail()`
Description: Returns usage information about all generated shared memory contexts. For details about each column, see [SHARED_MEMORY_DETAIL](#).
Parameter: nan
Return type: contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint
- `pgxc_get_running_xacts()`
Description: Returns information about running transactions on each node in the cluster. The field content is the same as that in [PGXC_RUNNING_XACTS](#). Only users with the system admin or monitor admin permission can view the information.
Parameter: nan
Return type: setof record

- `pgxc_snapshot_status()`

Description: Returns the status of key memory information in the GTM in GTM mode for fault locating. GTM-Free and GTM-Lite do not support this function.

Parameter: nan

Return type: xmin xid, xmax xid, xcnt int, oldestxmin xid, next_xid xid, timeline int, active_thread_num int, max_active_thread_num int, snapshot_num int, snapshot_totalsize bigint

For details about the return values, see [Table 7-94](#).

Table 7-94 get_gtm_lite_status return parameters

Column	Description
xmin	Minimum active XID in the GTM.
xmax	Largest XID committed in the GTM plus 1. Transactions whose IDs are greater than or equal to this value are active.
xcnt	Number of active transactions in the GTM.
oldestxmin	ID of the earliest accessed transaction in the GTM.
next_xid	ID of the next transaction allocated by the GTM.
timeline	Current time line in the GTM.
active_thread_num	Number of active worker threads in the GTM.
max_active_thread_num	Peak number of worker threads in the GTM within one minute.
snapshot_num	Number of snapshots delivered by the GTM within one minute.
snapshot_totalsize	Total size of snapshots delivered by the GTM within one minute.

- `get_gtm_lite_status()`

Description: Returns the backup XID and CSN in the GTM for fault locating. This system function is not supported in GTM-Free mode.

For details about the return values, see [Table 7-95](#).

Table 7-95 get_gtm_lite_status return parameters

Column	Description
backup_xid	Backup XID in the GTM.
csn	Latest CSN issued by the GTM.

- adm_hist_snapshot_func()**

Description: Returns information about the snapshot execution time. To access this function, set the **enable_wdr_snapshot** parameter to **on** and obtain the permission to access the **snapshot schema**, **snapshot table**, and **tables_snap_timestamp** tables.

Parameter: nan

Return type: snap_id bigint, dbid oid, begin_interval_time timestamp(3), end_interval_time timestamp(3), flush_elapsed interval day(5) to second(1), begin_interval_time_tz timestamp(3) with time zone, end_interval_time_tz timestamp(3) with time zone
- global_sql_patch_func()**

Description: SQL patch information on each global node, which is used to return the result of the global_sql_patch view.

For details about the return values, see [Table 7-96](#).

Table 7-96 global_sql_patch_func return parameters

Name	Type	Description
node_name	text	Name of the node where the SQL patch is located.
patch_name	name	Patch name.
unique_sql_id	bigint	Global unique query ID.
owner	oid	ID of the user who creates the patch.
enable	boolean	Determines whether the patch takes effect.
status	"char"	Patch status (reserved field).
abort	boolean	Determines whether the value is AbortHint .
hint_string	text	Hint text.
description	text	Patch description.
parent_unique_sql_id	bigint	Globally unique ID of the outer statement of the SQL statement for which the patch takes effect. The value of this parameter is 0 for statements outside a stored procedure. For statements inside the stored procedure, the value of this parameter is the globally unique ID of the statement that calls the stored procedure.

- `gs_get_current_version()`
Description: Returns the current compilation mode based on the current compilation macro. 'M' is returned.
Parameter: nan
Return type: char
- `gs_get_kernel_info()`
Description: Global transaction information on each primary CN and DN.
For details about the return values, see [Table 7-97](#).

Table 7-97 `gs_get_kernel_info` parameter description

Name	Type	Description
node_name	text	Node name.
module	text	Module name, including: <ul style="list-style-type: none">• XACT (transaction module)• STANDBY (standby module)• UNDO (undo module)• HOTPATH (hot patch module)

Name	Type	Description
name	text	<p>Name of the key data in the memory state, including:</p> <ul style="list-style-type: none"> • startup_max_xid (maximum XID when a thread is started) • recent_local_xmin (minimum XID of a local active transaction) • recent_global_xmin (minimum XID of a global active transaction) • standby_xmin (minimum XID of an active transaction on the standby node) • standby_redo_cleanup_xmin (minimum XID of cleanup logs during redo on the standby node) • standby_redo_cleanup_xmin_lsn (LSN of the minimum XID of cleanup logs during redo on the standby node) • local_csn_min (minimum CSN of a local active transaction) • replication_slot_xmin (minimum XID of a replication slot) • replication_slot_catalog_xmin (minimum XID of a catalog replication slot) • global_recycle_xid (minimum XID of a global undo recycling transaction) • global_frozen_xid (minimum XID of a globally frozen transaction) • recent_xmin (minimum XID of active transactions in the current session) • next_csn (CSN of the next transaction) • hotpatch_additional_info (reserved column for hot patches) • stmt_session_discard_records (data volume discarded by full SQL statements due to full slots supported by the kernel) • stmt_shm_flush_discard_records (data volume discarded by full SQL statements due to full ringbuf supported by the kernel)
value	text	Value of the key data in the memory state.

Example:

```
gaussdb=# SELECT * FROM gs_get_kernel_info();
node_name | module | name | value
-----+-----+-----+-----
```

```

coordinator1 | XACT | startup_max_xid | 16488
coordinator1 | XACT | recent_local_xmin | 16504
coordinator1 | XACT | recent_global_xmin | 16503
coordinator1 | STANDBY | standby_xmin | 0
coordinator1 | STANDBY | standby_redo_cleanup_xmin | 0
coordinator1 | STANDBY | standby_redo_cleanup_xmin_lsn | 0/0
coordinator1 | XACT | local_csn_min | 6014225
coordinator1 | XACT | replication_slot_xmin | 0
coordinator1 | XACT | replication_slot_catalog_xmin | 0
coordinator1 | UNDO | global_recycle_xid | 16501
coordinator1 | XACT | global_frozen_xid | 0

7.6.26 System Administration Functions

7.6.26.1 Configuration Setting Functions

Configuration setting functions are used for querying and modifying GUC parameters during running.

- `current_setting(setting_name)`

Description: Specifies the current setting.

Return type: text

Note: **current_setting** obtains the current setting of **setting_name** by query. It is equivalent to the **SHOW** statement. For example:

```
gaussdb=# SELECT current_setting('datestyle');
```

```

current_setting
-----
ISO, MDY
(1 row)

```

- `set_working_grand_version_num_manually(tmp_version)`

Description: Upgrades new features of GaussDB by switching the authorization version.

Return type: void

- `shell_in(type)`

Description: Inputs a route for the shell type that has not yet been filled.

Return type: void

- `shell_out(type)`
Description: Outputs a route for the shell type that has not yet been filled.
Return type: void
- `set_config(setting_name, new_value, is_local)`
Description: Sets the parameter and returns a new value.
Return type: text
Note: **set_config** sets the parameter **setting_name** to **new_value**. If **is_local** is **true**, **new_value** will only apply to the current transaction. If you want **new_value** to apply to the current session, use **false** instead. This function is equivalent to the SQL statement SET.

Example:

```
gaussdb=# SELECT set_config('log_statement_stats', 'off', false);
 set_config
-----
off
(1 row)
```

7.6.26.2 Universal File Access Functions

Universal file access functions provide local access interfaces for files on a database server. Only files in the database cluster directory and the **log_directory** directory can be accessed. A relative path is used for files in the cluster directory, and a path matching the **log_directory** configuration setting is used for log files. Only database initialization users can use these functions.

- `pg_ls_dir(dirname text)`
Description: Lists files in a directory.
Return type: setof text
Note: **pg_ls_dir** returns all the names in the specified directory, except the special entries "." and "..".

Example:

```
gaussdb=# SELECT pg_ls_dir('./');
 pg_ls_dir
-----
.gaussdb.conf.swp
gaussdb.conf
pg_tblspc
PG_VERSION
gs_ident.conf
core
server.crt
pg_serial
pg_twophase
gaussdb.conf.lock
pg_stat_tmp
pg_notify
pg_subtrans
pg_ctl.lock
pg_xlog
pg_clog
base
pg_snapshots
postmaster.opts
postmaster.pid
server.key.rand
server.key.cipher
```

```
pg_multixact
pg_errorinfo
server.key
gs_hba.conf
pg_replslot
.gs_hba.conf.swp
cacert.pem
gs_hba.conf.lock
global
gaussdb.state
(32 rows)
```

- `pg_read_file(filename text, offset bigint, length bigint)`

Description: Returns the content of a text file.

Return type: text

Note: **pg_read_file** returns part of a text file. It can return a maximum of *length* bytes from *offset*. The actual size of fetched data is less than *length* if the end of the file is reached first. If *offset* is negative, it is the length rolled back from the file end. If *offset* and *length* are omitted, the entire file is returned.

Example:

```
gaussdb=# SELECT pg_read_file('postmaster.pid',0,100);
           pg_read_file
-----
53078      +
/srv/BigData/testdir/data1/coordinator+
1500022474 +
8000      +
/var/run/FusionInsight      +
localhost      +
2
(1 row)
```

- `pg_read_binary_file(filename text [, offset bigint, length bigint,missing_ok boolean])`

Description: Returns the content of a binary file.

Return type: bytea

Note: **pg_read_binary_file** is similar to **pg_read_file**, except that the result is a **bytea** value; accordingly, no encoding checks are performed. In combination with the `convert_from` function, this function can be used to read a file in a specified encoding.

```
gaussdb=# SELECT convert_from(pg_read_binary_file('filename'), 'UTF8');
```

- `pg_stat_file(filename text)`

Description: Returns status information about a file.

Return type: record

Note: **pg_stat_file** returns a record containing the file size, last access timestamp, last modification timestamp, last file status change timestamp, and a **Boolean** value indicating if it is a directory. Typical usages are as follows:

```
gaussdb=# SELECT * FROM pg_stat_file('filename');
gaussdb=# SELECT (pg_stat_file('filename')).modification;
```

Example:

```
gaussdb=# SELECT convert_from(pg_read_binary_file('postmaster.pid'), 'UTF8');
           convert_from
-----
4881      +
/srv/BigData/gaussdb/data1/coordinator+
```

```
1496308688      +
25108           +
/opt/huawei/Bigdata/gaussdb/gaussdb_tmp +
*              +
25108001 43352069      +

(1 row)
gaussdb=# SELECT * FROM pg_stat_file('postmaster.pid');

size |      access      |      modification      |      change
| creation | isdir
-----+-----+-----+-----
117 | 2017-06-05 11:06:34+08 | 2017-06-01 17:18:08+08 | 2017-06-01 17:18:08+08
|      | f
(1 row)
gaussdb=# SELECT (pg_stat_file('postmaster.pid')).modification;
modification
-----
2017-06-01 17:18:08+08
(1 row)
```

7.6.26.3 Server Signal Functions

Server signal functions send control signals to other server threads. Only the system administrator has the permission to execute the following functions:

- `pg_cancel_backend(pid int)`
Description: Cancels a statement that is being executed by a backend thread.
Return type: Boolean
Note: `pg_cancel_backend` sends a query cancellation (SIGINT) signal to the backend thread identified by **pid**. The PID of an active backend thread can be found in the **pid** column of the `pg_stat_activity` view, or can be found by listing the database thread using `ps` on the server. A user with the SYSADMIN permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits the built-in role permission `gs_role_signal_backend` can use this function.
- `pg_cancel_session(pid bigint, sessionid bigint)`
Description: Cancels the statement that is being executed by an active session in thread pool mode.
Return type: Boolean
Note: The input parameters of `pg_cancel_session` can be queried using the **pid** and **sessionid** columns in `pg_stat_activity`. The input parameters can be used to cancel the statements that are being executed by active sessions in thread pool mode. When the input parameters **pid** and **sessionid** are the same and both are thread IDs, the function of `pg_cancel_backend` is the same as that of `pg_cancel_backend`.
- `pg_cancel_invalid_query()`
Description: Cancels the invalid query of a backend.
Return type: Boolean
Note: Only the system administrator has the permission to cancel queries that are running in the backend of a degraded GTM.
- `pg_reload_conf()`
Description: Causes all server threads to overload their configuration files.

Return type: Boolean

Note: `pg_reload_conf` sends a `SIGHUP` signal to the server. As a result, all server threads reload their configuration files.

- `pg_rotate_logfile()`

Description: Rotates the log files of the server.

Return type: Boolean

Note: `pg_rotate_logfile` sends a signal to the log file manager, instructing the manager to immediately switch to a new output file. This function works only when `redirect_stderr` is used for log output. Otherwise, no log file manager sub-thread is generated.

- `pg_terminate_session(pid bigint, sessionid bigint)`

Description: Terminates a backend session in thread pool mode.

Return type: Boolean

Note: The input parameters of this function can be queried using the **pid** and **sessionid** fields in `pg_stat_activity`. A user with the `SYSADMIN` permission, the owner of the database connected to the session, the owner of the session, or a user who inherits the built-in role permission `gs_role_signal_backend` has the permission to use this function.

NOTICE

When the input parameters **pid** and **sessionid** are the same and both are thread IDs, this function can terminate non-thread pool threads and active thread pool threads.

When the input parameters **pid** and **sessionid** are different, this function can terminate active sessions or close inactive sessions and the socket connection of the client.

-
- `pg_terminate_active_session_socket(pid int64, sessionid int64)`

Description: Closes the socket connection between an active session and the client.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. This function can be used only by initial users.

- `pg_terminate_backend(pid int)`

Description: Terminates a backend thread. Only the system administrator and thread owner can use this function.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the `SYSADMIN` permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits the built-in role permission `gs_role_signal_backend` can use this function.

NOTICE

This function can terminate non-thread pool threads and active thread pool threads, but cannot terminate inactive thread pool threads.

Example:

```
gaussdb=# SELECT pid from pg_stat_activity;
 pid
-----
140657876268816
(1 rows)

gaussdb=# SELECT pg_terminate_backend(140657876268816);
 pg_terminate_backend
-----
t
(1 row)
```

7.6.26.4 Backup and Restoration Control Functions

Backup Control Functions

Backup control functions help with online backup.

- `pg_create_restore_point(name text)`

Description: Creates a named point for performing a restore (requires an administrator role).

Return type: text

Note: **pg_create_restore_point** creates a named transaction log record that can be used as a restoration target, and returns the corresponding transaction log location. The given name can then be used with **recovery_target_name** to specify the point up to which restoration will proceed. Avoid creating multiple restoration points with the same name, since restoration will stop at the first one whose name matches the restoration target.

- `pg_current_xlog_location()`

Description: Obtains the write position of the current transaction log.

Return type: text

Note: **pg_current_xlog_location** displays the write position of the current transaction log in the same format as those of the previous functions. Read-only operations do not require permissions of the system administrator.

- `pg_current_xlog_insert_location()`

Description: Obtains the insert position of the current transaction log.

Return type: text

Note: **pg_current_xlog_insert_location** displays the insert position of the current transaction log. The insertion point is the logical end of the transaction log at any instant, while the write location is the end of what has been written out from the server's internal buffers. The write position is the end that can be detected externally from the server. This operation can be performed to archive only some of completed transaction log files. The insert position is mainly used for commissioning the server. Read-only operations do not require permissions of the system administrator.

- `gs_current_xlog_insert_end_location()`
Description: Obtains the insert position of the current transaction log.
Return type: text
Note: **gs_current_xlog_insert_end_location** displays the insert position of the current transaction log.
- `pg_start_backup(label text [, fast boolean])`
Description: Starts to perform online backup. (An administrator, replication role, or O&M administrator must enable **operation_mode**.) Label strings starting with **gs_roach** are reserved and can be used only by the internal backup tool GaussRoach.
Return type: text
Note: `pg_start_backup` receives a user-defined backup label (usually the name of the position where the backup dump file is stored). This function writes a backup label file to the data directory of the database cluster and then returns the starting position of backed up transaction logs in text mode. This function must be used together with `pg_stop_backup()`. If this function is called independently, `backup_label` remains. During WAL replay, the checkpoint is read based on `backup_label`. If the WAL file corresponding to the checkpoint has been reclaimed, the database cannot be started.

```
gaussdb=# SELECT pg_start_backup('label_goes_here',true);
pg_start_backup
-----
0/3000020
(1 row)
```
- `pg_stop_backup()`
Description: Completes online backup An administrator, replication role, or O&M administrator must enable **operation_mode**.
Return type: text
Note: **pg_stop_backup** deletes the label file created by **pg_start_backup** and creates a backup history file in the transaction log archive area. The history file includes the label given to **pg_start_backup**, the start and end transaction log locations for the backup, and the start and end time of the backup. The return value is the backup's ending transaction log location. After the end position is calculated, the insert position of the current transaction log automatically goes ahead to the next transaction log file. The ended transaction log file can be immediately archived so that backup is complete.
- `pg_switch_xlog()`
Description: Switches to a new transaction log file An administrator or O&M administrator must enable **operation_mode**.
Return type: text
Note: **pg_switch_xlog** moves to the next transaction log file so that the current log file can be archived (if continuous archive is used). The return value is the ending transaction log location + 1 within the just-completed transaction log file. If there has been no transaction log activity since the last transaction log switchover, `pg_switch_xlog` does not move but returns the start location of the transaction log file currently in use.
- `pg_xlogfile_name(location text)`
Description: Converts the position string in a transaction log to a file name.
Return type: text

Note: **pg_xlogfile_name** extracts only the transaction log file name. If the given transaction log position is the transaction log file border, a transaction log file name will be returned for both the two functions. This is usually the desired behavior for managing transaction log archiving, since the preceding file is the last one that currently needs to be archived.

- **pg_xlogfile_name_offset**(location text)

Description: Converts the position string in a transaction log to a file name and returns the byte offset in the file.

Return type: text, integer

Note: **pg_xlogfile_name_offset** can extract transaction log file names and byte offsets from the returned results of the preceding functions. Example:

```
gaussdb=# SELECT * FROM pg_xlogfile_name_offset(pg_stop_backup());
NOTICE: pg_stop_backup cleanup done, waiting for required WAL segments to be archived
NOTICE: pg_stop_backup complete, all required WAL segments have been archived
  file_name          | file_offset
-----+-----
000000010000000000000003 |      272
(1 row)
```

- **pg_xlog_location_diff**(location text, location text)

Description: Calculates the difference in bytes between two transaction log locations.

Return type: numeric

- **pg_cbm_start_tracked_location**()

Description: Queries the start LSN parsed by CBM.

Return type: text

- **pg_cbm_tracked_location**()

Description: Queries the LSN location parsed by CBM.

Return type: text

- **pg_cbm_get_merged_file**(startLSNArg text, endLSNArg text)

Description: Combines CBM files within the specified LSN range into one and returns the name of the combined file.

Return type: text

Note: Only the system administrator or O&M administrator can obtain the CBM combination file.

- **pg_cbm_get_changed_block**(startLSNArg text, endLSNArg text)

Description: Combines CBM files within the specified LSN range into a table and return records of this table.

Return type: record

Note: The table columns returned by **pg_cbm_get_changed_block** include the start LSN, end LSN, tablespace OID, database OID, table relfilenode, table fork number, whether the table is a system catalog, whether the table is deleted, whether the table is created, whether the table is truncated, number of pages in the truncated table, number of modified pages, and list of modified page numbers.

- **pg_cbm_recycle_file**(targetLSNArg text)

Description: Deletes the CBM files that are no longer used and returns the first LSN after the deletion.

- Return type: text
- `pg_cbm_force_track(targetLSNArg text,timeOut int)`
Description: Forcibly executes the CBM trace to the specified Xlog position and returns the Xlog position of the actual trace end point.
Return type: text
 - `pg_enable_delay_ddl_recycle()`
Description: Enables DDL delay and returns the Xlog position of the enabling point. An administrator or O&M administrator must enable **operation_mode**.
Return type: text
 - `pg_disable_delay_ddl_recycle(barrierLSNArg text, isForce bool)`
Description: Disables DDL delay and returns the Xlog range where DDL delay takes effect. An administrator or O&M administrator must enable **operation_mode**.
Return type: record
 - `pg_enable_delay_xlog_recycle()`
Description: Enables the Xlog recycling delay function for CN recovery. An administrator or O&M administrator must enable **operation_mode**.
Return type: void
 - `pg_disable_delay_xlog_recycle()`
Description: Disables the Xlog recycling delay function for CN recovery. An administrator or O&M administrator must enable **operation_mode**.
Return type: void
 - `pg_cbm_rotate_file(rotate_lsn text)`
Description: Forcibly switches the file after the CBM parses **rotate_lsn**. This function is called during the build process.
Return type: void
 - `gs_roach_stop_backup(backupid text)`
Description: Stops a backup started by the internal backup tool GaussRoach. It is similar to the **pg_stop_backup system** function but is more lightweight.
Return type: text. The content is the insertion position of the current log.
 - `gs_roach_enable_delay_ddl_recycle(backupid name)`
Description: Enables DDL delay and returns the log location of the enabling point. It is similar to the **pg_enable_delay_ddl_recycle** system function but is more lightweight. In addition, different **backupid** values can be used to concurrently open DDL statements with delay.
Return type: text. The content is the log location of the start point.
 - `gs_roach_disable_delay_ddl_recycle(backupid text)`
Description: Disables DDL delay, returns the range of logs on which DDL delay takes effect. It is similar to the **pg_enable_delay_ddl_recycle** system function but is more lightweight. In addition, the DDL delay function can be disabled concurrently by specifying different backupid values.
Return type: record. The content is the range of logs for which DDL is delayed to take effect.
 - `gs_roach_switch_xlog(request_ckpt bool)`

Description: Switches the currently used log segment file and triggers a full checkpoint if **request_ckpt** is set to **true**.

Return type: text. The content is the location of the segment log.

- `gs_block_dw_io(timeout int, identifier text)`

Description: Blocks doublewrite page flushing.

Parameter description:

- `timeout`

Block duration.

Value range: [0,3600], in seconds. The value **0** indicates that the block duration is 0s.

- `identifier`

ID of the operation.

Value range: a string, supporting only uppercase letters, lowercase letters, digits, and underscores (_).

Return type: Boolean

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation_mode**.

- `gs_is_dw_io_blocked()`

Description: Checks whether disk flushing on the current doublewrite page is blocked. If disk flushing is blocked, **true** is returned.

Return type: Boolean

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation_mode**.

- `gs_pitr_advance_last_updated_barrier()`

Description: In PITR mode, forcibly pushes the global maximum archived recovery point uploaded to OBS/NAS last time to the current point. No input parameter is required.

Return type: text

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation_mode**. This parameter is valid only on the first normal CN in a distributed system. The return value is the latest local maximum archived recovery point.

- `gs_pitr_clean_local_barrier_files('delete_timestamp')`

Description: Clears locally cached barrier record files.

Value range: The **delete_timestamp** parameter is of the text type. It is a Linux timestamp and contains 10 characters.

Return type: text

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation_mode**. The returned result is the start timestamp of the earliest barrier file on the local host after the deletion.

- `gs_get_barrier_lsn(barrier_name text)`

Description: Obtains the LSN corresponding to the barrier created using a backup.

Return type: text

Note: Currently, only **gs_roach_full** and **gs_roach_inc** are supported. To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation_mode**.

- **gs_gbr_relation_associated_filenode**(schemaName name, tableName name)

Description: Returns the relfilenode of all indexes, sequences, partitions, toasts, and toast indexes related to the input table.

Return type: record

Note: The table columns returned by **gs_gbr_relation_associated_filenode** include the file type relkind, namespace where the file is located, relation name corresponding to the file, OID of the database where the file is located, OID of the tablespace where the file is located, and relfilenode of the file.

- **pg_create_physical_replication_slot_extern**(slotname text, dummy_standby bool, extra_content text, need_recycle_xlog bool)

Description: Creates an OBS or a NAS archive slot. **slotname** indicates the name of the archive slot or recovery slot. The primary and standby slots must use the same slot name. **dummy_standby** is a reserved parameter.

extra_content contains some information about the archive slot. For an OBS archive slot, the format is

OBS;obs_server_ip;obs_bucket_name;obs_ak;obs_sk;archive_path;is_recovery;is_vote_replicate, in which **OBS** indicates the archive media of the archive slot, **obs_server_ip** indicates the IP address of OBS, **obs_bucket_name** indicates the bucket name, **obs_ak** indicates the AK of OBS, **obs_sk** indicates the SK of OBS, **archive_path** indicates the archive path, and **is_recovery** specifies whether the slot is an archive slot or a recovery slot (**0**: archive slot; **1**: recovery slot). **is_vote_replicate** indicates whether the voting copy is archived first. The value **0** indicates that the synchronous standby server is archived first, and the value **1** indicates that the voting copy is archived first. This field is reserved in the current version and is not adapted yet. For a NAS archive slot, the format is **NAS;archive_path;is_recovery;is_vote_replicate**.

Compared with the OBS archive slot, the NAS archive slot does not have the OBS configuration information, while the meanings of other fields are the same.

If the media is not OBS or NAS, the OBS archive slot is used by default. The **extra_content** format is

obs_server_ip;obs_bucket_name;obs_ak;obs_sk;archive_path;is_recovery;is_vote_replicate.

need_recycle_xlog specifies whether to recycle old archived logs when creating an archive slot. The value **true** indicates that old archived logs are recycled, and the value **false** indicates that old archive logs are not recycled.

Return type: record contains slotname and xlog_position

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the **gs_role_replication** permission of the built-in role. Currently, multiple archive slots cannot be created.

Examples:

Create an OBS archive slot.

```
gaussdb=# SELECT * FROM pg_create_physical_replication_slot_extern('uuid', false, 'OBS;obs.cn-north-7.ulanqab.huawei.com;dyk;19D772JBCACXX3KWS51D;*****;gaussdb_uuid/dn1;0', false);
 slotname | xlog_position
-----+-----
 uuid    |
(1 row)
```

Create a NAS archive slot.

```
gaussdb=# SELECT * FROM pg_create_physical_replication_slot_extern('uuid', false, 'NAS:/data/nas/
media/gaussdb_uuid/dn1;0;0', false);
 slotname | xlog_position
-----+-----
 uuid    |
```

- `gs_set_obs_delete_location(delete_location text)`

Description: Sets the location where OBS archive logs can be deleted. The value of **delete_location** is an LSN. The logs before this location have been replayed and flushed to disks and can be deleted on OBS.

Return type: `xlog_file_name` text, indicating the file name of the logs that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

```
gaussdb=# SELECT gs_set_obs_delete_location('0/54000000');
 gs_set_obs_delete_location
-----
 0000000100000000000000054_00
(1 row)
```

- `gs_set_obs_delete_location_with_slotname(cstring, cstring)`

Description: Sets the location where OBS archive logs in a specified archive slot can be deleted. The first parameter indicates the LSN. The logs before this location have been replayed and flushed to disks and can be deleted on OBS. The second parameter indicates the name of the archive slot.

Return type: `xlog_file_name` text, indicating the file name of the logs that can be deleted. The value of this parameter is returned regardless of whether OBS is deleted successfully.

- `gs_get_global_barrier_status()`

Description: `gs_get_global_barrier_status` is used to query the latest global barrier archived in OBS.

Return type: text

global_barrier_id: globally latest barrier ID.

global_achive_barrier_id: globally latest archived barrier ID.

- `gs_get_global_barriers_status()`

Description: `gs_get_global_barriers_status` is used to query the latest global barrier archived in OBS.

Return type: text

slot_name: slot name.

global_barrier_id: globally latest barrier ID.

global_achive_barrier_id: globally latest archived barrier ID.

Restoration Control Functions

Restoration control functions provide information about the status of standby nodes. These functions may be executed both during restoration and in normal running.

- `pg_is_in_recovery()`

Description: Returns **true** if restoration is still in progress.

Return type: Boolean

- `pg_last_xlog_receive_location()`
Description: Obtains the last transaction log location received and synchronized to disk by streaming replication. While streaming replication is in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received and synchronized to disk during restoration. If streaming replication is disabled or if it has not yet started, the function returns a null value.
Return type: text
- `pg_last_xlog_replay_location()`
Description: Obtains last transaction log location replayed during restoration. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. When the server has been started normally without restoration, the function returns a null value.
Return type: text
- `pg_last_xact_replay_timestamp()`
Description: Obtains the timestamp of last transaction replayed during restoration. This is the time to commit a transaction or abort a WAL record on the primary node. If no transactions have been replayed during restoration, this function will return a null value. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. If the server normally starts without manual intervention, this function will return a null value.
Return type: timestamp with time zone

Restoration control functions control restoration threads. These functions may be executed only during restoration.

- `pg_is_xlog_replay_paused()`
Description: Returns **true** if restoration is paused.
Return type: Boolean
- `pg_xlog_replay_pause()`
Description: Pauses restoration immediately.
Return type: void
- `pg_xlog_replay_resume()`
Description: Restarts restoration if it was paused.
Return type: void
- `gs_get_active_archiving_standby()`
Description: Queries information about archive standby nodes in the same shard. The standby node name, archive location, and number of archived logs are returned.
Return type: text, int
- `gs_pitr_get_warning_for_xlog_force_recycle()`
Description: Checks whether logs are recycled because a large number of logs are stacked in the archive slot after archiving is enabled.

Return type: Boolean

- `gs_pitr_clean_history_global_barriers(stop_barrier_timestamp cstring)`
Description: Clears all barrier records generated before the specified time. The earliest barrier record is returned. The input parameter is of the cstring type and is a Linux timestamp. You need to perform this operation as an administrator or O&M administrator.

Return type: text

- `gs_pitr_archive_slot_force_advance(stop_barrier_timestamp cstring)`
Description: Forcibly pushes the archive slot and clears unnecessary barrier records. The new archive slot location is returned. The input parameter is of the cstring type and is a Linux timestamp. You need to perform this operation as an administrator or O&M administrator.

Return type: text

- `gs_recent_barrier_buffer_info(start_time text, end_time text)`
Description: Queries barrier information based on the time range entered by the user to obtain time_stamp, CSN, LSN, and standard_time.

Return type: record

Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. The input parameters **start_time** and **end_time** are in the format of year-month-day time, where the time is in the clock format. The maximum query time span is one day. If the time span exceeds the limit, the end time is automatically converted to the limit boundary based on the query start time.

Example:

```
gaussdb=# SELECT * FROM gs_recent_barrier_buffer_info('2024-01-15 23:27:50', '2024-01-15 23:28:00');
```

timestamp	lsn	csn	standard_time
1705332470	00000000/15FFBBA0	41020421	2024-01-15 23:27:50
1705332471	00000000/15FFBDF0	41020422	2024-01-15 23:27:51
1705332472	00000000/15FFC058	41020423	2024-01-15 23:27:52
1705332472	00000000/15FFC0F8	41020424	2024-01-15 23:27:52
1705332473	00000000/15FFC348	41020425	2024-01-15 23:27:53
1705332474	00000000/15FFC598	41020426	2024-01-15 23:27:54
1705332475	00000000/15FFC638	41020427	2024-01-15 23:27:55

(14 rows)

- `gs_show_obs_media_files(slot_name cstring, src cstring, offset int32, limit int32)`

Description: Queries the OBS file list based on the archive slot (**slot_name**) and OBS directory address (**src**) entered by the user.

Return type: record

Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. **offset** indicates the query result offset, and **limit** indicates the maximum number of output lines. All files in **src** are queried. Example:

```
gaussdb=# SELECT gs_show_obs_archive_files('ssh', 'cn_5001/pg_xlog', 1, 5);
```

```
gs_show_obs_archive_files
```

```
(wstdist_ssh/archive/cn_5001/pg_xlog/
```

```
000000010000000000000010_01_01_00000000_00000000_00000003)
(wstdist_ssh/archive/cn_5001/pg_xlog/
000000010000000000000010_02_01_00000000_00000000_00000003)
(wstdist_ssh/archive/cn_5001/pg_xlog/
000000010000000000000010_03_01_00000000_00000000_00000003)
(wstdist_ssh/archive/cn_5001/pg_xlog/
000000010000000000000011_00_01_00000000_00000000_00000003)
(wstdist_ssh/archive/cn_5001/pg_xlog/
000000010000000000000011_01_01_00000000_00000000_00000003)
(5 rows)
```

- `gs_upload_obs_media_file(slot_name cstring, src cstring, dest cstring, is_forced bool)`

Description: Uploads OBS files based on the archive slot (**slot_name**), source address (**src**), OBS address (**dest**), and whether to forcibly upload files (**is_forced**).

Return type: void

Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. The original file directory must be the directory specified by *\$GAUSSLOG*. Example:

```
gaussdb=# SELECT * FROM gs_upload_obs_archive_file('ssh', '/data/gauss/log/stwang/test/
000000010000000000000019_02_01_00000000_00000000_00000003', 'cn_5001/pg_xlog/
000000010000000000000019_02_01_00000000_00000000_00000003', true);
gs_upload_obs_archive_file
-----
(1 row)
```

- `gs_download_obs_media_file(slot_name cstring, src cstring, dest cstring)`

Description: Downloads OBS files based on the archive slot (**slot_name**), download source address (**src**), and local destination address (**dest**).

Return type: void

Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. The download directory must be the directory specified by *\$GAUSSLOG*. Example:

```
gaussdb=# SELECT * FROM gs_download_obs_archive_file('ssh','cn_5001/pg_xlog/
000000010000000000000019_02_01_00000000_00000000_00000003','/data/gauss/log/stwang/test');
gs_download_obs_archive_file
-----
(1 row)
```

While restoration is paused, no further database changes are applied. In hot standby mode, all new queries will see the same consistent snapshot of the database, and no further query conflicts will be generated until restoration is resumed.

If streaming replication is disabled, the paused state may continue indefinitely without problem. While streaming replication is in progress, WAL records will continue to be received, which will eventually fill available disk space. This progress depends on the duration of the pause, the rate of WAL generation, and available disk space.

7.6.26.5 Dual-Cluster DR Control Functions

- `gs_hadr_do_switchover()`

Description: Truncates services during a planned switchover in the primary cluster in the remote DR scenario.

Return type: Boolean, indicating whether the service truncation is successful and whether the switchover process can be performed normally.

- `gs_streaming_dr_in_switchover()`

Description: Truncates services during a planned switchover in the primary cluster in streaming replication-based remote DR solutions.

Return type: Boolean, indicating whether the service truncation is successful and whether the switchover process can be performed normally.

7.6.26.6 Dual-Cluster DR Query Functions

- `gs_get_local_barrier_status()`

Description: If two-city 3DC DR is enabled, the primary cluster and DR cluster synchronize logs. The barrier log is flushed to disks in the primary cluster, and replayed in the DR cluster to determine the archive log progress of the primary cluster and the log replay progress of the DR cluster.

gs_get_local_barrier_status is used to query the current log replay status of each node in the DR cluster.

Return type: text

barrier_id: latest barrier ID of a node in the DR cluster.

barrier_lsn: LSN of the latest barrier ID returned by a node in the DR cluster.

archive_lsn: location of archived logs obtained by a node in the DR cluster. This parameter does not take effect currently.

flush_lsn: location of logs that have been flushed to disks on a node in the DR cluster.

- `gs_hadr_in_recovery()`

Description: Checks whether the current node is in barrier-based log restoration if two-city 3DC DR is enabled. If yes, **true** is returned. Only after the log restoration is complete, can the DR cluster be promoted to the production cluster during the switchover process. This operation must be performed by the system administrator.

Return type: Boolean

NOTE

This function is used only when a planned switchover is performed in the DR cluster.

- `gs_streaming_dr_get_switchover_barrier()`

Description: Checks whether the CN and first standby DN in the DR cluster have received the switchover barrier logs and replayed the logs in the streaming replication-based two-city 3DC DR solution. If it has, **true** is returned. In the DR cluster, the procedure for promoting the DR database instance to the production database instance in the switchover process can be started only after the switchover barrier logs of all DNs are replayed (restricted to the system administrator).

Return type: Boolean

Note: This function is used only when a planned switchover is performed in the DR database instance in streaming DR solutions.

- `gs_streaming_dr_service_truncation_check()`

Description: Checks whether the CN and primary DN in the primary cluster has sent the switchover barrier logs in the streaming replication-based two-

city 3DC DR solution. If it has, **true** is returned. The procedure for demoting the production database instance to the DR database instance in the switchover process can be started only after the logs are sent (restricted to the system administrator).

Return type: Boolean

Note: This function is used only when a planned switchover is performed in the DR database instance.

- `gs_hadr_local_rto_and_rpo_stat()`

Description: Displays the log flow control information of the local database instance and DR database instance for streaming DR. (If this command is executed on a node that does not participate in streaming DR, for example, a standby DN or a CN, no information may be returned.)

The return value type is record. The types and meanings of the columns are as described in [Table 7-98](#).

Table 7-98 Parameters of `gs_hadr_local_rto_and_rpo_stat`

Parameter	Type	Description
<code>hadr_sender_node_name</code>	text	Node name, including the primary database instance and the first standby node of the standby database instance.
<code>hadr_receiver_node_name</code>	text	Name of the first standby node of the standby database instance.
<code>source_ip</code>	text	IP address of the primary DN of the primary database instance.
<code>source_port</code>	int	Communication port of the primary DN of the primary database instance.
<code>dest_ip</code>	text	IP address of the first standby DN of the standby database instance.
<code>dest_port</code>	int	Communication port of the first standby DN of the standby database instance.
<code>current_rto</code>	int	Flow control information, that is, log RTO time of the current primary and standby database instances (unit: second).
<code>target_rto</code>	int	Flow control information, that is, the RTO time between the target primary and standby database instances (unit: second).
<code>current_rpo</code>	int	Flow control information, that is, log RPO time of the current primary and standby database instances (unit: second).
<code>target_rpo</code>	int	Flow control information, that is, the RPO time between the target primary and standby database instances (unit: second).

Parameter	Type	Description
rto_sleep_time	int	RTO flow control information, that is, the expected sleep time (unit: μ s) required by walsender on the host to reach the specified RTO.
rpo_sleep_time	int	RPO flow control information, that is, the expected sleep time (unit: μ s) required by xlogInsert on the host to reach the specified RPO.

- gs_hadr_remote_rto_and_rpo_stat()**
 Description: Displays the log flow control information of all other shards or CN database instances and DR database instances for streaming DR. (Generally, this command is executed on CNs. If this command is executed on DNs, no information may be returned.)
 The return value type is record. The types and meanings of the columns are as described in [Table 7-99](#).

Table 7-99 gs_hadr_remote_rto_and_rpo_stat

Parameter	Type	Description
hadr_sender_node_name	text	Node name, including the primary database instance and the first standby node of the standby database instance.
hadr_receiver_node_name	text	Name of the first standby node of the standby database instance.
source_ip	text	IP address of the primary DN of the primary database instance.
source_port	int	Communication port of the primary DN of the primary database instance.
dest_ip	text	IP address of the first standby DN of the standby database instance.
dest_port	int	Communication port of the first standby DN of the standby database instance.
current_rto	int	Flow control information, that is, log RTO time of the current primary and standby database instances (unit: second).
target_rto	int	Flow control information, that is, the RTO time between the target primary and standby database instances (unit: second).
current_rpo	int	Flow control information, that is, log RPO time of the current primary and standby database instances (unit: second).

Parameter	Type	Description
target_rpo	int	Flow control information, that is, the RPO time between the target primary and standby database instances (unit: second).
rto_sleep_time	int	RTO flow control information, that is, the expected sleep time (unit: μ s) required by walsender on the host to reach the specified RTO.
rpo_sleep_time	int	RPO flow control information, that is, the expected sleep time (unit: μ s) required by xlogInsert on the host to reach the specified RPO.

7.6.26.7 Snapshot Synchronization Functions

Snapshot synchronization functions save the current snapshot and return its identifier.

- `pg_export_snapshot()`

Description: Saves the current snapshot and returns its identifier.

Return type: text

Note: **pg_export_snapshot** saves the current snapshot and returns a text string identifying the snapshot. This string must be passed to clients that want to import the snapshot. A snapshot can be imported when the **set transaction snapshot snapshot_id;** command is executed. Doing so is possible only when the transaction is set to the **SERIALIZABLE** or **REPEATABLE READ** isolation level. GaussDB does not support these two isolation levels currently. The output of the function cannot be used as the input of **set transaction snapshot**.

- `pg_export_snapshot_and_csn()`

Description: Saves the current snapshot and returns its identifier. Compared with **pg_export_snapshot()**, **pg_export_snapshot()** returns a CSN, indicating the CSN of the current snapshot.

Return type: text

7.6.26.8 Database Object Functions

Database Object Size Functions

Database object size functions calculate the actual disk space used by database objects.

- `pg_column_size(any)`

Description: Specifies the number of bytes used to store a particular value (possibly compressed).

Return type: int

Note: **pg_column_size** displays the space for storing an independent data value.

```
gaussdb=# SELECT pg_column_size(1);
pg_column_size
-----
         4
(1 row)
```

- `pg_database_size(oid)`

Description: Specifies the disk space used by the database with the specified OID.

Return type: `bigint`

- `pg_database_size(name)`

Description: Specifies the disk space used by the database with the specified name.

Return type: `bigint`

Note: **`pg_database_size`** receives the OID or name of a database and returns the disk space used by the corresponding object.

Example:

```
gaussdb=# SELECT pg_database_size('testdb');
pg_database_size
-----
    51590112
(1 row)
```

- `pg_relation_size(oid)`

Description: Specifies the disk space used by the table with a specified OID or index.

Return type: `bigint`

- `get_db_source_datasize()`

Description: Estimates the total size of non-compressed data in the current database.

Return type: `bigint`

Note: Perform an analysis before this function is called.

Example:

```
gaussdb=# analyze;
ANALYZE
gaussdb=# SELECT get_db_source_datasize();
get_db_source_datasize
-----
    35384925667
(1 row)
```

- `pg_relation_size(text)`

Description: Specifies the disk space used by the table with a specified name or index. The table name can be schema-qualified.

Return type: `bigint`

- `pg_relation_size(relation regclass, fork text)`

Description: Specifies the disk space used by the specified bifurcating tree ('main', 'fsm', or 'vm') of a certain table or index.

Return type: `bigint`

- `pg_relation_size(relation regclass)`

Description: Is an abbreviation of **`pg_relation_size(..., 'main')`**.

Return type: `bigint`

Note: **pg_relation_size** receives the OID or name of a table, an index, or a compressed table, and returns the size.

- **pg_partition_size(oid, oid)**
Description: Specifies the disk space used by the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.
Return type: bigint
- **pg_partition_size(text, text)**
Description: Specifies the disk space used by the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.
Return type: bigint
- **pg_partition_indexes_size(oid, oid)**
Description: Specifies the disk space used by the index of the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.
Return type: bigint
- **pg_partition_indexes_size(text, text)**
Description: Specifies the disk space used by the index of the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.
Return type: bigint
- **pg_indexes_size(regclass)**
Description: Specifies the total disk space used by the index appended to the specified table.
Return type: bigint
- **pg_size_pretty(bigint)**
Description: Converts a size in bytes expressed as a 64-bit integer into a human-readable format with size units.
Return type: text
- **pg_size_pretty(numeric)**
Description: Converts a size in bytes expressed as a numeric value into a human-readable format with size units.
Return type: text
Note: **pg_size_pretty** formats the results of other functions into a human-readable format. KB, MB, GB, and TB can be used.
- **pg_table_size(regclass)**
Description: Specifies the disk space used by the specified table, excluding indexes (but including TOAST, free space mapping, and visibility mapping).
Return type: bigint
- **pg_tablespace_size(oid)**
Description: Specifies the disk space used by the tablespace with a specified OID.
Return type: bigint

- pg_tablespace_size(name)**
Description: Specifies the disk space used by the tablespace with a specified name.
Return type: bigint
Note:
pg_tablespace_size receives the OID or name of a database and returns the disk space used by the corresponding object.
- pg_total_relation_size(oid)**
Description: Specifies the disk space used by the table with a specified OID, including the index and the compressed data.
Return type: bigint
- pg_total_relation_size(regclass)**
Description: Specifies the total disk space used by the specified table, including all indexes and TOAST data.
Return type: bigint
- pg_total_relation_size(text)**
Description: Specifies the disk space used by the table with a specified name, including the index and the compressed data. The table name can be schema-qualified.
Return type: bigint
Note: **pg_total_relation_size** receives the OID or name of a table or a compressed table, and returns the sizes of the data, related indexes, and the compressed table in bytes.
- datalength(any)**
Description: Specifies the number of bytes used by an expression of a specified data type (data management space, data compression, or data type conversion is not considered).
Return type: int
Note: **datalength** is used to calculate the space of an independent data value.

Example:

```
gaussdb=# SELECT datalength(1);
datalength
-----
4
(1 row)
```

The following table lists the supported data types and calculation methods.

Data Type		Storage Space	
Numeric data types	Integer types	TINYINT	1
		SMALLINT	2
		INTEGER	4
		BINARY_INTEGER	4
		BIGINT	8

Data Type		Storage Space	
	Arbitrary precision types	DECIMAL	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
		NUMERIC	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
		NUMBER	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
	Sequence integer	SMALLSERIAL	2
		SERIAL	4
		BIGSERIAL	8
	Floating point types	FLOAT4	4
		DOUBLE PRECISION	8
		FLOAT8	8
		BINARY_DOUBLE	8
		FLOAT[(p)]	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
		DEC[(p,s)]	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
		INTEGER[(p,s)]	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
Boolean data types	Boolean type	BOOLEAN	1

Data Type		Storage Space	
Character data types	Character types	CHAR	n
		CHAR(n)	n
		CHARACTER(n)	n
		NCHAR(n)	n
		VARCHAR(n)	n
		CHARACTER	Actual number of bytes of a character
		VARYING(n)	Actual number of bytes of a character
		VARCHAR2(n)	Actual number of bytes of a character
		NVARCHAR2(n)	Actual number of bytes of a character
		TEXT	Actual number of bytes of a character
		CLOB	Actual number of bytes of a character
Time data types	Time types	DATE	8
		TIME	8
		TIMEZ	12
		TIMESTAMP	8
		TIMESTAMPZ	8
		SMALLDATETIME	8
		INTERVAL DAY TO SECOND	16
		INTERVAL	16
		RELTIME	4
		ABSTIME	4
		TINTERVAL	12

Database Object Position Functions

- pg_relation_filenode(relation regclass)**
 Description: Specifies the ID of a filenode with the specified relationship.
 Return type: oid

Note: **pg_relation_filenode** receives the OID or name of a table, an index, a sequence, or a compressed table, and returns the ID of **filenode** allocated to it. **filenode** is the basic component of the file name used by the relationship. For most tables, the result is the same as that of **pg_class.relfilenode**. For the specified system directory, **relfilenode** is **0** and this function must be used to obtain the correct value. If a relationship that is not stored is transmitted, such as a view, this function returns a null value.

- **pg_relation_filepath**(relation regclass)

Description: Specifies the name of a file path with the specified relationship. It can only be used for non-segment page relationships.

Return type: text

Description: **pg_relation_filepath** is similar to **pg_relation_filenode**, except that **pg_relation_filepath** returns the whole file path name for the relationship (relative to the data directory **PGDATA** of the database cluster).

For segment-page relationships, you are advised to use functions or views. For example:

```
SELECT e.*, f.file_name
FROM gs_seg_extents e, gs_seg_datafiles f
WHERE e.tablespace_name = f.tablespace_name AND e.bucketnode = f.bucketnode AND e.file_id =
f.file_id AND e.forknum = f.forknum;
```

- **get_large_table_name**(relfile_node text, threshold_size_gb int8)

Description: Queries whether the table size (in GB) exceeds the threshold (**threshold_size_gb**) based on the table file code (**relfile_node**). If yes, the schema name and table name (in *schemaName.tableName* format) are returned, otherwise, **null** is returned.

Return type: text

- **pg_filenode_relation**(tablespacename, relname)

Description: Obtains the table names corresponding to the tablespace and relfilenode.

Return type: regclass

- **pg_partition_filenode**(partition_oid)

Description: Obtains **filenode** corresponding to the OID lock of a specified partitioned table.

Return type: oid

- **pg_partition_filepath**(partition_oid)

Description: Specifies the file path name of a specified partition. It can only be used for non-segment page relationships.

Return type: text

Note: For segment-page relationships, you are advised to use functions or views. For example:

```
SELECT e.*, f.file_name
FROM gs_seg_extents e, gs_seg_datafiles f
WHERE e.tablespace_name = f.tablespace_name AND e.bucketnode = f.bucketnode AND e.file_id =
f.file_id AND e.forknum = f.forknum;
```

Recycle Bin Object Functions

- **gs_is_recycle_object**(classid, objid, objname)

Description: Determines whether an object is in the recycle bin. This function is not supported in distributed mode.

Return type: Boolean

7.6.26.9 Advisory Lock Functions

Advisory lock functions manage advisory locks.

- `pg_advisory_lock(key bigint)`

Description: Obtains an exclusive session-level advisory lock.

Return type: void

Note: **pg_advisory_lock** locks resources defined by an application. The resources can be identified using a 64-bit or two nonoverlapped 32-bit key values. If another session locks the resources, the function blocks the resources until they can be used. The lock is exclusive. Multiple locking requests are pushed into the stack. Therefore, if the same resource is locked three times, it must be unlocked three times so that it is released to another session.

- `pg_advisory_lock(key1 int, key2 int)`

Description: Obtains an exclusive session-level advisory lock.

Return type: void

Note: Only users with the `sysadmin` permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).

- `pg_advisory_lock(lock_id int4, lock_id int4, database_name Name)`

Description: Obtains the exclusive advisory lock of a specified database.

Return type: void

- `pg_advisory_lock_shared(key bigint)`

Description: Obtains a shared session-level advisory lock.

Return type: void

- `pg_advisory_lock_shared(key1 int, key2 int)`

Description: Obtains a shared session-level advisory lock.

Return type: void

Note: **pg_advisory_lock_shared** works in the same way as **pg_advisory_lock**, except that **pg_advisory_lock_shared** obtains an advisory lock shared with other sessions requesting the lock, while **pg_advisory_lock** obtains an exclusive advisory lock.

- `pg_advisory_unlock(key bigint)`

Description: Releases an exclusive session-level advisory lock.

Return type: Boolean

- `pg_advisory_unlock(key1 int, key2 int)`

Description: Releases an exclusive session-level advisory lock.

Return type: Boolean

Note: **pg_advisory_unlock** releases the obtained exclusive advisory lock. If the release is successful, the function returns **true**. If the lock was not held, it will return **false**. In addition, a SQL warning will be reported by the server.

- `pg_advisory_unlock(lock_id int4, lock_id int4, database_name Name)`
Description: Releases the exclusive advisory lock of a specified database.
Return type: Boolean
Note: If the release is successful, **true** is returned. If no lock is held, **false** is returned.
- `pg_advisory_unlock_shared(key bigint)`
Description: Releases a shared session-level advisory lock.
Return type: Boolean
- `pg_advisory_unlock_shared(key1 int, key2 int)`
Description: Releases a shared session-level advisory lock.
Return type: Boolean
Note: **pg_advisory_unlock_shared** works in the same way as **pg_advisory_unlock**, except it releases a shared session-level advisory lock.
- `pg_advisory_unlock_all()`
Description: Releases all advisory locks owned by the current session.
Return type: void
Note: **pg_advisory_unlock_all** releases all advisory locks owned by the current session. The function is implicitly invoked when the session ends even if the client is abnormally disconnected.
- `pg_advisory_xact_lock(key bigint)`
Description: Obtains an exclusive transaction-level advisory lock.
Return type: void
- `pg_advisory_xact_lock(key1 int, key2 int)`
Description: Obtains an exclusive transaction-level advisory lock.
Return type: void
Note: **pg_advisory_xact_lock** works in the same way as **pg_advisory_lock**, except the lock is automatically released at the end of the current transaction and cannot be released explicitly. Only users with the sysadmin permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).
- `pg_advisory_xact_lock_shared(key bigint)`
Description: Obtains a shared transaction-level advisory lock.
Return type: void
- `pg_advisory_xact_lock_shared(key1 int, key2 int)`
Description: Obtains a shared transaction-level advisory lock.
Return type: void
Note: **pg_advisory_xact_lock_shared** works in the same way as **pg_advisory_lock_shared**, except the lock is automatically released at the end of the current transaction and cannot be released explicitly.
- `pg_try_advisory_lock(key bigint)`
Description: Obtains an exclusive session-level advisory lock if available.
Return type: Boolean
Note: **pg_try_advisory_lock** is similar to **pg_advisory_lock**, except **pg_try_advisory_lock** does not block the resource until the resource is

released. **pg_try_advisory_lock** either immediately obtains the lock and returns **true** or returns **false**, which indicates the lock cannot be performed currently.

- **pg_try_advisory_lock(key1 int, key2 int)**
Description: Obtains an exclusive session-level advisory lock if available.
Return type: Boolean
Note: Only users with the **sysadmin** permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).
- **pg_try_advisory_lock_shared(key bigint)**
Description: Obtains a shared session-level advisory lock if available.
Return type: Boolean
- **pg_try_advisory_lock_shared(key1 int, key2 int)**
Description: Obtains a shared session-level advisory lock if available.
Return type: Boolean
Note: **pg_try_advisory_lock_shared** works in the same way as **pg_try_advisory_lock**, except that **pg_try_advisory_lock_shared** attempts to obtain a shared lock instead of an exclusive lock.
- **pg_try_advisory_xact_lock(key bigint)**
Description: Obtains an exclusive transaction-level advisory lock if available.
Return type: Boolean
- **pg_try_advisory_xact_lock(key1 int, key2 int)**
Description: Obtains an exclusive transaction-level advisory lock if available.
Return type: Boolean
Note: **pg_try_advisory_xact_lock** works in the same way as **pg_try_advisory_lock**, except the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly. Only users with the **sysadmin** permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).
- **pg_try_advisory_xact_lock_shared(key bigint)**
Description: Obtains a shared transaction-level advisory lock if available.
Return type: Boolean
- **pg_try_advisory_xact_lock_shared(key1 int, key2 int)**
Description: Obtains a shared transaction-level advisory lock if available.
Return type: Boolean
Note: **pg_try_advisory_xact_lock_shared** works in the same way as **pg_try_advisory_lock_shared**, except the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly.
- **lock_cluster_ddl()**
Description: Attempts to obtain a session-level exclusive advisory lock for all active CNs in the cluster.
Return type: Boolean
Note: Only users with the **sysadmin** permission can call this function.

- `unlock_cluster_ddl()`
Description: Attempts to add a session-level exclusive advisory lock on the CN.
Return type: Boolean
- `pg_rel_advisory_lock(relname cstring, schema_name cstring)`
Description: Obtains a session-level advisory lock on a table.
Return type: void
Note: `pg_rel_advisory_lock` is for internal use only. You are advised not to use it.
- `pg_rel_advisory_unlock(relname cstring, schema_name cstring)`
Description: Releases a session-level advisory lock on a table.
Return type: void
Note: `pg_rel_advisory_unlock` is for internal use only. You are advised not to use it.

7.6.26.10 Logical Replication Functions

NOTE

When using the logical replication functions, set the GUC parameter `wal_level` to `logical`. For details about the configuration, see "Logical Decoding > Logical Decoding by SQL Function Interfaces" in *Feature Guide*.

- `pg_create_logical_replication_slot('slot_name', 'plugin_name', 'output_order')`
Description: Creates a logical replication slot.
Parameter:
 - `slot_name`
Indicates the name of the streaming replication slot.
Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.
 - `plugin_name`
Indicates the name of the plug-in.
Value range: a string, supporting `mppdb_decoding`
 - `output_order`
Indicates the output sequence of the replication slot decoding results. This parameter is optional.
Valid value: **0** or **1**. The default value is **0** on DN and **1** on CN.
 - **0**: The replication slot decoding results are sorted by transaction COMMIT LSN. In this case, the value of `confirmed_csn` of the replication slot is **0**. This replication slot is called an LSN-based replication slot.
 - **1**: The replication slot decoding results are sorted by transaction CSN. In this case, the value of `confirmed_csn` of the replication slot is not **0**. This replication slot is called a CSN-based replication slot. In this case, the `confirmed_flush` value is meaningless.
Return type: name, text

Example:

```
gaussdb=# SELECT * FROM pg_create_logical_replication_slot('slot_lsn','mppdb_decoding',0);
slotname | xlog_position
```

```
-----+-----
slot_lsn | 0/6D08B58
(1 row)
```

```
gaussdb=# SELECT * FROM pg_create_logical_replication_slot('slot_csn','mppdb_decoding',1);
slotname | xlog_position
```

```
-----+-----
slot_csn | 0/59AD800
(1 row)
```

Note: The first return value is the slot name, and the second one has different meanings in LSN-based replication slots and CSN-based replication slots. For an LSN-based replication slot, the value is **confirmed_flush** of the replication slot, indicating that transactions whose commit LSN is less than or equal to the value will not be decoded and output. For a CSN-based replication slot, the value is **confirmed_csn** of the replication slot, indicating that transactions whose CSN is less than or equal to the value will not be decoded and output. Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the gs_role_replication permission of the built-in role. Currently, this function can be called only on the CN or primary DNs.

 **CAUTION**

When this function is executed on a CN, if **output_order** is set to **1**, a replication slot with the same name will be created on all CNs and primary DNs. If a replication slot with the same name already exists on some DNs, a CSN-based logical replication slot will be created on other CNs and primary DNs that do not have a replication slot with the same name. In addition, an error message is displayed, indicating that the replication slot already exists. In this case, you need to delete the existing replication slot with the same name on the DN (if the replication slot is an LSN-based logical replication slot, you need to manually delete it on the corresponding node) and create a replication slot on the CN. If you set **output_order** to **0** when creating a replication slot on a CN, no replication slot will be created on DNs. Replication slots created on CNs are only used to identify whether related replication slots exist on DNs.

- `pg_create_physical_replication_slot('slot_name', 'isDummyStandby')`

Description: Creates a physical replication slot.

Parameter:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `isDummyStandby`

Reserved parameter.

Type: Boolean

Return type: name, text

 NOTE

- Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the gs_role_replication permission of the built-in role.
 - The physical replication slot created by this function does not have **restart_lsn**. Therefore, the slot is considered invalid and will be automatically deleted when the checkpoint is performed.
- `pg_drop_replication_slot('slot_name')`

Description: Deletes a streaming replication slot.

Parameter:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

Return type: void

 NOTE

- Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the gs_role_replication permission of the built-in role.
 - When a database is deleted, the logical replication slots on the database are not deleted. You need to manually delete the logical replication slots on the database. Otherwise, historical versions of Xlogs and system catalogs cannot be reclaimed.
 - When a logical replication slot is deleted from a CN, if the logical replication slot is an LSN-based logical replication slot, only the replication slot of the current node is deleted. Replication slots with the same name on other nodes are not affected. When a CSN-based logical replication slot with the same name exists on other nodes, no error is reported because some nodes do not have replication slots. In addition, replication slots with the same name on all nodes are successfully deleted. If no replication slot exists on any node, an error is reported.
 - If an LSN-based logical replication slot remains on the current CN and a CSN-based logical replication slot with the same name remains on other nodes, deleting the replication slot on the current CN will delete only the local LSN-based logical replication slot. After the deletion is complete, perform the deletion operation again to delete the CSN-based logical replication slots with the same name on other nodes.
- `pg_logical_slot_peek_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding but does not go to the next streaming replication slot. (The decoded result will be returned again during the next decoding.)

Parameter:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `upto_lsn`

For the CSN-based logical replication slot, the decoding is complete until the transaction whose CSN is less than or equal to the value is decoded (a transaction whose CSN is greater than the specified CSN may be decoded). For the LSN-based replication slot, the decoding is complete until the first transaction whose COMMIT LSN is greater than or equal to the value is decoded.

Value range: a string, for example, '1/2AAFC60', '0/A060', or '3A/0' (a hexadecimal uint64 value containing two uint32 values separated by a slash (/); if any uint32 value is 0, 0 is displayed.) **NULL** indicates that the end position of decoding is not specified.

– upto_nchanges

Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto_nchanges** is set to 4, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto_nchanges** after decoding in the first two transactions is finished.

Value range: a non-negative integer

 **NOTE**

If any of the **upto_lsn** and **upto_nchanges** values is reached, decoding ends.

– **options**: Specifies optional parameters, consisting of **options_name** and **options_value**.

▪ include-xids

Specifies whether the decoded **data** column contains XID information.

Value range: Boolean. The default value is **true**.

- **false**: The decoded **data** column does not contain XID information.
- **true**: The decoded **data** column contains XID information.

▪ skip-empty-xacts

Specifies whether to ignore empty transaction information during decoding.

Value range: Boolean. The default value is **false**.

- **false**: The empty transaction information is not ignored during decoding.
- **true**: The empty transaction information is ignored during decoding.

▪ include-timestamp

Specifies whether decoded information contains the **commit** timestamp.

Value range: Boolean. The default value is **true**.

- **false**: The decoded information does not contain the **commit** timestamp.

- **true**: The decoded information contains the **commit** timestamp.
- **only-local**
Specifies whether to decode only local logs.
Value range: Boolean. The default value is **true**.
 - **false**: Non-local logs and local logs are decoded.
 - **true**: Only local logs are decoded.
- **force-binary**
Specifies whether to output the decoding result in binary format.
Value range: Boolean. The default value is **false**.
 - **false**: The decoding result is output in text format.
 - The value cannot be set to **true** currently.
- **white-table-list**
Whitelist parameter, including the schema and table name to be decoded.
Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed. The following is an example:

```
SELECT * FROM pg_logical_slot_peek_changes('slot1', NULL, 4096, 'white-table-list', 'public.t1,public.t2');
```
- **max-txn-in-memory**
Memory control parameter. The unit is MB. If the memory occupied by a single transaction is greater than the value of this parameter, data is flushed to disks.
Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.
- **max-reorderbuffer-in-memory**
Memory control parameter. The unit is GB. If the total memory (including the cache) of transactions being concatenated in the sender thread is greater than the value of this parameter, the current decoding transaction is flushed to disks.
Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.
- **include-user**
Specifies whether the BEGIN logical log of a transaction records the username of the transaction.
Value range: Boolean. The default value is **false**.
 - **false**: The BEGIN logical log of a transaction does not record the username of the transaction.
 - **true**: The BEGIN logical log of a transaction records the username of the transaction.

- **exclude-userids**
Specifies the OID of a blacklisted user.
Value range: OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not check whether the OIDs exist.
- **exclude-users**
Specifies the name of a blacklisted user.
Value range: names of blacklisted users. Multiple names are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.
- **dynamic-resolution**
Specifies whether to dynamically parse the names of blacklisted users.
Value range: Boolean. The default value is **true**.

 - **false**: An error is reported and the logic decoding exits when the decoding detects that a user does not exist in blacklist **exclude-users**.
 - **true**: Decoding continues when it detects that a user does not exist in blacklist **exclude-users**.

 **NOTE**

For details about other configuration options, see "Logical Replication > Logical Decoding > Logical Decoding Options" in the *Feature Guide*.

Return type: text, xid, text

Example:

```
gaussdb=# SELECT * FROM pg_logical_slot_peek_changes('slot_lsn',NULL,4096,'skip-empty-xacts','on');
location | xid | data
-----+-----
0/6D0B500 | 46914 | BEGIN 46914
0/6D0B530 | 46914 | {"table_name":"public.t1","op_type":"INSERT","columns_name":
["a","b"],"columns_type":["integer","integer"],"columns_val":["3","1"],"old_keys_name":
[],"old_keys_type":["integer"],"old_keys_val":[]}
0/6D0B8B8 | 46914 | COMMIT 46914 (at 2023-02-22 17:29:31.090018+08) CSN 94034528
0/6D0BB58 | 46915 | BEGIN 46915
0/6D0BB88 | 46915 | {"table_name":"public.t1","op_type":"INSERT","columns_name":
["a","b"],"columns_type":["integer","integer"],"columns_val":["3","2"],"old_keys_name":
[],"old_keys_type":["integer"],"old_keys_val":[]}
0/6D0BF08 | 46915 | COMMIT 46915 (at 2023-02-22 17:31:30.672093+08) CSN 94034568
0/6D0BF08 | 46916 | BEGIN 46916
0/6D0BF38 | 46916 | {"table_name":"public.t1","op_type":"INSERT","columns_name":

[],"old_keys_type":[],"old_keys_val":[]}
0/59ADA8A | 46916 | COMMIT 46916 (at 2023-02-22 17:31:34.438319+08) CSN 94034570
(9 rows)
```

Note: The decoding result returned by the function contains three columns, corresponding to the preceding return value types, which are the LSN (for an LSN-based replication slot) or CSN (for a CSN-based replication slot), XID, and decoded content, respectively. If the **location** column indicates the CSN, the value of the **location** column is updated only when the commit logs are decoded. Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the `gs_role_replication` permission of the built-in role.

NOTE

On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed_csn** is not 0).

- `pg_logical_slot_get_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding and goes to the next streaming replication slot.

Parameter: This function has the same parameters as **pg_logical_slot_peek_changes**. For details, see [pg_logical_slot_peek_changes](#).

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the `gs_role_replication` permission of the built-in role.

NOTE

On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed_csn** is not 0). When this function is called on the standby DN, the corresponding logical replication slot on the primary DN is updated synchronously. If this function is executed on the standby DN, a WAL sender of the primary DN is occupied when the replication slot number on the primary DN is updated. The logical decoding function reserves a WAL sender for each logical replication slot. Therefore, if this function is executed in normal scenarios, the logical replication slot number on the primary DN is updated normally. If this function is executed continuously in a short period of time, the primary DN fails to update the slot number and no error is reported.

- `pg_logical_slot_peek_binary_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding in binary mode and does not go to the next streaming replication slot. (The decoded data can be obtained again during the next decoding.)

Parameter:

– slot_name

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

– upto_lsn

For the CSN-based logical replication slot, the decoding is complete until the transaction whose CSN is less than or equal to the value is decoded (a transaction whose CSN is greater than the specified CSN may be decoded). For the LSN-based replication slot, the decoding is complete until the first transaction whose COMMIT LSN is greater than or equal to the value is decoded.

Value range: a string, for example, '1/2AAFC60', '0/A060', or '3A/0' (a hexadecimal uint64 value containing two uint32 values separated by a slash (/); if any uint32 value is 0, 0 is displayed.) **NULL** indicates that the end position of decoding is not specified.

– upto_nchanges

Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto_nchanges** is set to 4, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto_nchanges** after decoding in the first two transactions is finished.

Value range: a non-negative integer

 **NOTE**

If any of the **upto_lsn** and **upto_nchanges** values is reached, decoding ends.

– **options**: Specifies optional parameters, consisting of **options_name** and **options_value**.

▪ include-xids

Specifies whether the decoded **data** column contains XID information.

Value range: Boolean. The default value is **true**.

- **false**: The decoded **data** column does not contain XID information.
- **true**: The decoded **data** column contains XID information.

▪ skip-empty-xacts

Specifies whether to ignore empty transaction information during decoding.

Value range: Boolean. The default value is **false**.

- **false**: The empty transaction information is not ignored during decoding.
- **true**: The empty transaction information is ignored during decoding.

- **include-timestamp**
Specifies whether decoded information contains the **commit** timestamp.
Value range: Boolean. The default value is **true**.
 - **false**: The decoded information does not contain the **commit** timestamp.
 - **true**: The decoded information contains the **commit** timestamp.
- **only-local**
Specifies whether to decode only local logs.
Value range: Boolean. The default value is **true**.
 - **false**: Non-local logs and local logs are decoded.
 - **true**: Only local logs are decoded.
- **force-binary**
This parameter is useless for the function.
Value range: Boolean. The result is output in binary format.
- **white-table-list**
Whitelist parameter, including the schema and table name to be decoded.
Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed. Example:
select * from pg_logical_slot_peek_binary_changes('slot1', NULL, 4096, 'white-table-list', 'public.t1,public.t2');
- **max-txn-in-memory**
Memory control parameter. The unit is MB. If the memory occupied by a single transaction is greater than the value of this parameter, data is flushed to disks.
Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.
- **max-reorderbuffer-in-memory**
Memory control parameter. The unit is GB. If the total memory (including the cache) of transactions being concatenated in the sender thread is greater than the value of this parameter, the current decoding transaction is flushed to disks.
Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.
- **include-user**
Specifies whether the BEGIN logical log of a transaction records the username of the transaction.
Value range: Boolean. The default value is **false**.
 - **false**: The BEGIN logical log of a transaction does not record the username of the transaction.

- **true**: The BEGIN logical log of a transaction records the username of the transaction.
- **exclude-userids**
Specifies the OID of a blacklisted user.
Value range: OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not check whether the OIDs exist.
- **exclude-users**
Specifies the name of a blacklisted user.
Value range: names of blacklisted users. Multiple names are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.
- **dynamic-resolution**
Specifies whether to dynamically parse the names of blacklisted users.
Value range: Boolean. The default value is **true**.
 - **false**: An error is reported and the logical decoding exits when the decoding detects that a user does not exist in blacklist **exclude-users**.
 - **true**: Decoding continues when it detects that a user does not exist in blacklist **exclude-users**.

 **NOTE**

Some configuration options do not take effect even if they are configured in functions. For details, see "Logical Replication > Logical Decoding > Logical Decoding Options" in the *Feature Guide*.

Return type: text, xid, bytea

Note: The function returns the decoding result. Each decoding result contains three columns, corresponding to the above return types and indicating the LSN position, XID, and decoded content in binary format, respectively. Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the gs_role_replication permission of the built-in role.

 **NOTE**

On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed_csn** is not 0).

- `pg_logical_slot_get_binary_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding in binary mode and does not go to the next streaming replication slot.

Parameter: This function has the same parameters as **pg_logical_slot_peek_binary_changes**. For details, see [pg_logical_slot_peek_bi...](#)

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the gs_role_replication permission of the built-in role.

 **NOTE**

On the CN, this function cannot be executed in a CSN-based replication slot (**confirmed_csn** is not 0). This function cannot be executed on the standby DN.

- `pg_replication_slot_advance` ('slot_name', 'upto_lsn')

Description: Directly goes to the streaming replication slot for a specified CSN (for CSN-based replication slots) or LSN (for LSN-based replication slots), without outputting any decoded result.

Parameter:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `upto_lsn`

For the CSN-based logical replication slot, it indicates the target CSN before which logs are decoded. During the next decoding, only the transaction results whose CSN is greater than this value will be output. If the input CSN is smaller than the value of **confirmed_csn** recorded in the current streaming replication slot, the function directly returns the decoded result. If the input CSN is greater than the latest CSN that can be obtained, the latest CSN will be used for decoding.

For the LSN-based logical replication slot, it indicates the target LSN before which logs are decoded. During the next decoding, only the transaction results whose LSN is greater than this value will be output. If an input LSN is smaller than the position recorded in the current streaming replication slot, an error is reported. If the input LSN is greater than the LSN of the current physical log, the latter LSN will be directly used for decoding.

Value range: a string, for example, '1/2AAFC60', '0/A060', or '3A/0' (a hexadecimal uint64 value containing two uint32 values separated by a slash (/); if any uint32 value is 0, 0 is displayed.) **NULL** indicates that the end position of decoding is not specified.

Return type: name, text

NOTICE

When a query is performed on a DN, the **confirmed_csn** query result of the LSN-based logical replication slot is empty, and the **confirmed_flush** query result of the CSN-based logical replication slot is empty. When a query is performed on the CN, **catalog_xmin**, **restart_lsn**, **confirmed_flush**, and **confirmed_csn** of the CSN-based logical replication slot are not displayed and the query result is empty.

- `pg_logical_get_area_changes('LSN_start', 'LSN_end', upto_nchanges, 'decoding_plugin', 'xlog_path', 'options_name', 'options_value')`

Description: Specifies an LSN range or an Xlog file for decoding when no DDL operation is performed.

NOTE

The constraints are as follows:

- The current network and hardware environment are normal.
- It is recommended that the size of a single tuple be less than or equal to 500 MB. If the size ranges from 500 MB to 1 GB, an error is reported.
- Data page replication is not supported for data retrieval that does not fall into Xlogs.
- When an API is called, the log level parameter **wal_level** must be set to **logical**, and only the log files generated when **wal_level** is set to **logical** can be parsed. If the used Xlog file is not at the logical level, the decoded content does not have the corresponding value or type. There is no other impact. If **wal_level** is not set to **logical**, an error is reported and decoding is not performed.
- The Xlog file can be parsed only by a copy of a completely homogeneous DN, and no DDL operation or VACUUM FULL occurs in the database to ensure that the metadata corresponding to the data can be found.
- Do not read too many Xlog files at a time. If no file is specified for decoding within a specified range, you are advised to read one Xlog file each time. Generally, the memory occupied by an Xlog file during decoding is about two to three times the size of the Xlog file.
- Data before VACUUM FULL cannot be retrieved.
- The Xlog file before scale-out cannot be decoded.
- To decode the UPDATE statement, the table must have a primary key. Otherwise, the WHERE clause in the UPDATE statement is empty.
- Fields of the TOAST, CLOB, or BLOB type cannot be decoded. If a field of the TOAST, CLOB, or BLOB type is decoded, the field is skipped or an error is reported.
- In this decoding mode, the content that can be decoded is decoded based on the Xlog text record data, and the decoding is not performed based on transactions. Therefore, data that is not in the Xlog cannot be decoded.
- If no decoding file is specified from the decoding point, the system checks whether DDL occurs between the decoding start point and the latest redo value. If DDL occurs, the system does not decode all data. If a decoding file is specified, the system checks whether DDL occurs between the start point of the decoding file and the last readable content of the file and between the start point of the Xlog in the data directory and the latest redo value. If a DDL operation is detected, the system does not decode all tables.
- The CSN-based replication slot is not supported.

Note: When separation-of-duty is enabled, only the initial database user can call the function. When separation-of-duty is disabled, the system administrator permission is required.

Parameter:

- LSN_start
Specifies the LSN at the start of decoding.
Value range: a string, in the format of *xlogid/xrecoff*, for example, '1/2AAFC60'. **NULL** indicates that the start position of decoding logs is not limited.
- LSN_end
Specifies the LSN at the end of decoding.
Value range: a string, in the format of *xlogid/xrecoff*, for example, '1/2AAFC60'. **NULL** indicates that the end position of decoding is not specified.
- upto_nchanges
Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto_nchanges** is set to 4, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto_nchanges** after decoding in the first two transactions is finished.
Value range: a non-negative integer

 **NOTE**

If any of the **LSN** and **upto_nchanges** values are reached, decoding ends.

- decoding_plugin
Decoding plug-in, which is a .so plug-in that specifies the output format of the decoded content.
Value range: **mppdb_decoding** and **sql_decoding**.
- xlog_path
Decoding plug-in, which specifies the Xlog absolute path and file level of the decoding file.
Value range: **NULL** or a character string of the absolute path of the Xlog file.
- **options**: This parameter is optional and consists of multiple pairs of **options_name** and **options_value**. You can retain the default values.
 - include-xids
Specifies whether the decoded **data** column contains XID information.
Value range: Boolean. The default value is **true**.
false: The decoded **data** column does not contain XID information.
true: The decoded **data** column contains XID information.
 - skip-empty-xacts
Specifies whether to ignore empty transaction information during decoding.
Value range: Boolean. The default value is **false**.
false: The empty transaction information is not ignored during decoding.

true: The empty transaction information is ignored during decoding.

- include-timestamp

Specifies whether decoded information contains the **commit** timestamp.

Value range: Boolean. The default value is **true**.

false: The decoded information does not contain the **commit** timestamp.

true: The decoded information contains the **commit** timestamp.

- only-local

Specifies whether to decode only local logs.

Value range: Boolean. The default value is **true**.

false: Non-local logs and local logs are decoded.

true: Only local logs are decoded.

- force-binary

Specifies whether to output the decoding result in binary format.

Value range: Boolean. The default value is **false**.

false: The decoding result is output in text format.

The value cannot be set to **true** currently.

- white-table-list

Whitelist parameter, including the schema and table name to be decoded. Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed.

Example:

```
- Perform DML operations on a CN. You can query the DML operations executed on the current DN.
gaussdb=# SELECT * FROM pg_logical_get_area_changes('0/502E418', NULL, NULL, 'sql_decoding',
NULL);
```

location	xid	data
0/502E448	17365	insert into public.t1 values (1, 1);
0/502E5A0	17365	COMMIT 17365 (at 2023-11-01 11:28:43.92526+08) 2010016
0/502E5D0	17366	delete from public.t1 where a = 1;insert into public.t1 values (1, 2);
0/502E6D8	17366	COMMIT 17366 (at 2023-11-01 11:28:45.889283+08) 2010017
0/502E7B8	17367	delete from public.t1 where a = 1;
0/502E8B0	17367	COMMIT 17367 (at 2023-11-01 11:28:48.301307+08) 2010018

(6 rows)

- gs_get_parallel_decode_status()

Description: Monitors the length of the read log queue and decoding result queue of each decoder thread to locate the concurrent decoding performance bottleneck.

Return type: text, int, text, text, text, int64, int64, TimestampTz

Example:

```
gaussdb=# SELECT * FROM gs_get_parallel_decode_status();
slot_name | parallel_decode_num | read_change_queue_length | decode_change_queue_length |
reader_lsn | working_txn_cnt | working_txn_memory | decoded_time
```

```
slot1 | 2 | queue0: 1005, queue1: 320 | queue0: 63, queue1: 748 | 0/1DCE2578
| 42 | 192927504 | 2023-01-10 11:18:22+08
(1 row)
```

Note: In the return values, **slot_name** indicates the replication slot name, **parallel_decode_num** indicates the number of parallel decoder threads in the replication slot, **read_change_queue_length** indicates the current length of the log queue read by each decoder thread, **decode_change_queue_length** indicates the current length of the decoding result queue of each decoder thread, **reader_lsn** indicates the log location read by the reader thread, **working_txn_cnt** indicates the number of transactions being concatenated in the current sender thread, **working_txn_memory** indicates the total memory (in bytes) occupied by the concatenation transactions in the sender thread, and **decoded_time** indicates the time of the latest WAL decoded by the replication slot.

NOTICE

The value of **decoded_time** comes from checkpoint logs and transaction commit logs, which has a certain error. If no log containing the time is decoded, "2000-01-01 08:00:00+08" (depending on the time zone set in the database) is displayed.

- `gs_get_slot_decoded_wal_time(slot_name)`
Description: Queries the time of the latest WAL decoded by a replication slot.
Parameter:
 - `slot_name`
Specifies the name of the replication slot to be queried.
Value range: a string, supporting only letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.).

Example:

```
gaussdb=# SELECT * FROM gs_get_slot_decoded_wal_time('replication_slot');
gs_get_slot_decoded_wal_time
-----
2023-01-10 11:25:22+08
(1 row)
```

Note: The returned values indicate the time of the latest WAL decoded by the replication slot.

NOTICE

The returned time comes from checkpoint logs and transaction commit logs, which has a certain error. If no log containing the time is decoded, "2000-01-01 08:00:00+08" (depending on the time zone set in the database) is displayed. When you query the latest decoded WAL log time of a logical replication slot that does not exist, **NULL** is returned. In `gsql`, the display of **NULL** is related to the setting, which can be set using `\pset null'null'`.

- `gs_logical_parallel_decode_status('slot_name')`
Description: Obtains the decoding statistics of a replication slot for parallel logical decoding, including 26 rows of statistical items.

The descriptions of the statistical items are listed in the following table.

Record - (stat_id int, stat_name TEXT, value TEXT)

Table 7-100 Description

Statistical Item	Description
slot_name	Name of the logical replication slot.
reader_lsn	Location of the logical logs to be decoded.
wal_read_total_time	Time required for loading the log module.
wal_wait_total_time	Time required for waiting for log decoding.
parser_total_time	Processing duration of the reader thread.
decoder_total_time	Processing duration of all decoder threads.
sender_total_time	Processing duration of the sender thread.
net_send_total_time	Time required for the network to send logical logs.
net_wait_total_time	Time required for the network to wait for sending logical logs.
net_send_total_bytes	Number of logical log bytes sent by the network.
transaction_count	Number of transactions.
big_transaction_count	Number of large transactions.
max_transaction_tuples	Maximum number of transaction operation tuples.
sent_transaction_count	Number of transactions sent (by the local database).
spill_disk_transaction_count	Number of flushed transactions.
spill_disk_bytes	Total number of bytes flushed to disks.
spill_disk_count	Number of disk flushing times.
input_queue_full_count	Total number of times that the input queues of all decoder threads are full.
output_queue_full_count	Total number of times that the output queues of all decoder threads are full.
dml_count	Total number of DML statements in WALs decoded by each decoder thread in the local database.

Statistical Item	Description
dml_filtered_count	Total number of DML statements in WALs decoded and filtered by each decoder thread in the local database.
toast_count	Number of modified TOAST table rows.
candidate_catalog_xmin	Indicates the catalog xmin candidate point of the current logical replication slot.
candidate_xmin_lsn	Updates the log confirmation receiving point required by catalog xmin .
candidate_restart_valid	Updates the log confirmation receiving point required by restart_lsn .
candidate_restart_lsn	Indicates the restart_lsn candidate point of the current logical replication slot.

Parameter:

- slot_name

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

Return type: int, text, text

Example:

```
gaussdb=# SELECT * FROM gs_logical_parallel_decode_status('replication_slot');
```

```
stat_id | stat_name | value
-----+-----+-----
 1 | slot_name | replication_slot
 2 | reader_lsn | 0/357E180
 3 | wal_read_total_time | 266694599
 4 | wal_wait_total_time | 266691307
 5 | parser_total_time | 39971
 6 | decoder_total_time | 81216
 7 | sender_total_time | 48193
 8 | net_send_total_time | 19388
 9 | net_wait_total_time | 0
10 | net_send_total_bytes | 266897
11 | transaction_count | 7
12 | big_transaction_count | 1
13 | max_transaction_tuples | 4096
14 | sent_transaction_count | 7
15 | spill_disk_transaction_count | 1
16 | spill_disk_bytes | 244653
17 | spill_disk_count | 4096
18 | input_queue_full_count | 0
19 | output_queue_full_count | 0
20 | dml_count | 4097
21 | dml_filtered_count | 0
22 | toast_count | 0
23 | candidate_catalog_xmin | 17152
24 | candidate_xmin_lsn | 0/420A598
25 | candidate_restart_valid | 0/420A598
26 | candidate_restart_lsn | 0/420A598
(26 rows)
```

Note: According to the definitions of statistical items, they must meet the following requirements:

```
wal_read_total_time >= wal_wait_total_time;
transaction_count >= big_transaction_count;
transaction_count >= sent_transaction_count;
transaction_count >= spill_disk_transaction_count;
dml_count >= dml_filtered_count;
dml_count >= toast_count;
If spill_transaction_count == 0, then spill_disk_bytes == 0;
```

However, frequent locking and unlocking are required, which greatly affects the performance. As a result, the preceding constraints may not be met in multi-thread cases.

transaction_count indicates the number of transactions in all databases.

sent_transaction_count indicates the number of transactions sent by the local database because transactions that are not in the local database will not be sent.

If the value of **slot_name** does not exist, the function does not report an error and the return value is empty.

- `gs_logical_parallel_decode_reset_status('slot_name')`

Description: Resets indicators in

`gs_logical_parallel_decode_status('slot_name')`.

Parameter:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

Return type: text

Example:

```
gaussdb=# SELECT * FROM gs_logical_parallel_decode_reset_status('replication_slot');
gs_logical_parallel_decode_reset_status
```

```
-----
OK
(1 row)
```

```
gaussdb=# SELECT * FROM gs_logical_parallel_decode_status('replication_slot');
```

stat_id	stat_name	value
1	slot_name	replication_slot
2	reader_lsn	0/357E420
3	wal_read_total_time	0
4	wal_wait_total_time	0
5	parser_total_time	0
6	decoder_total_time	0
7	sender_total_time	0
8	net_send_total_time	0
9	net_wait_total_time	0
10	net_send_total_bytes	0
11	transaction_count	0
12	big_transaction_count	0
13	max_transaction_tuples	0
14	sent_transaction_count	0
15	spill_disk_transaction_count	0

```

16 | spill_disk_bytes      | 0
17 | spill_disk_count     | 0
18 | input_queue_full_count | 0
19 | output_queue_full_count | 0
20 | dml_count            | 0
21 | dml_filtered_count    | 0
22 | toast_count          | 0
23 | candidate_catalog_xmin | 0
24 | candidate_xmin_lsn    | 0/0
25 | candidate_restart_valid | 0/420A598
26 | candidate_restart_lsn  | 0/420A598
(26 rows)

```

Note: If the value of **slot_name** does not exist, the function does not report an error and the return value is **invalid slot name**.

Do not reset a replication slot that is being observed. The error information is as follows:

- a. If **slot_name** is empty, the following error is reported: "ERROR: inputString should not be NULL".
 - b. If **slot_name** is not empty but does not exist, no error is reported but "invalid slot name" is displayed.
 - c. If **slot_name** is not empty but the replication slot corresponding to **slot_name** is being observed, no error is reported but "can't reset during observing! use gs_logical_decode_stop_observe to stop." is displayed.
- `gs_logical_decode_start_observe('slot_name', window, interval)`

Description: Enables logical replication performance sampling. Currently, the distributed system does not support this function.

Parameter:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `window`

Specifies the sampling window.

Value range: an integer ranging from 2 to 1024. Sampling data in the latest *interval* x *window* period is collected.

- `interval`

Specifies the performance monitoring interval, in seconds.

Value range: interval type. The minimum value is 1s and the maximum value is 1 minute. Sampling data in the latest *interval* x *window* period is collected.

Return type: text

- `gs_logical_decode_stop_observe('slot_name')`

Description: Stops logical replication performance sampling. Currently, the distributed system does not support this function.

Parameter:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

- Return type: text
- `gs_logical_decode_observe_data('slot_name')`
Description: Displays the original logical replication performance sampling data. Currently, the distributed system does not support this function.
Parameter:
 - `slot_name`
Indicates the name of the streaming replication slot.
Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.
 - Return type: SETOF record
- `gs_logical_decode_observe('slot_name')`
Description: Displays logical replication performance data. Currently, the distributed system does not support this function.
Parameter:
 - `slot_name`
Indicates the name of the streaming replication slot.
Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.
 - Return type: SETOF record
- `gs_logical_decode_observe_status('slot_name')`
Description: Queries the monitoring status of a specified logical decoding task. Currently, the distributed system does not support this function.
Parameter:
 - `slot_name`
Indicates the name of the streaming replication slot.
Value range: a string, supporting only lowercase letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.
 - Return type: text
- `gs_get_parallel_decode_thread_info()`
Description: Executes on the DN where parallel decoding is performed and returns the thread information of parallel decoding.
Return type: int64, text, text, int

Example:

```
gaussdb=# SELECT * FROM gs_get_parallel_decode_thread_info();
 thread_id | slot_name | thread_type | seq_number
-----+-----+-----+-----
 140335364699904 | slot1 | sender | 1
 140335214098176 | slot1 | reader | 1
 140335325312768 | slot1 | decoder | 1
 140335291750144 | slot1 | decoder | 2
 140335274968832 | slot1 | decoder | 3
```

```

140335258187520 | slot1 | decoder | 4
140335165404928 | slot2 | sender | 1
140335022864128 | slot2 | reader | 1
140335129818880 | slot2 | decoder | 1
140335113037568 | slot2 | decoder | 2
(10 rows)

```

Note: In the return values, **thread_id** indicates the thread ID, **slot_name** indicates the replication slot name, **thread_type** indicates the thread type (including the sender, reader and decoder), and **seq_number** indicates the sequence number of each thread with same type in the current replication slot. Each parallel decoding connection only has one sender and reader. Therefore, the sequence numbers of the sender and reader are both 1. The sequence numbers of the decoder are arranged from 1 to the decoding degree of parallelism (DOP) of the current replication slot.

- `pg_replication_origin_create (node_name)`

Description: Creates a replication source with a given external name and returns the internal ID assigned to it.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter:

- `node_name`

Name of the replication source to be created.

Value range: a string, supporting only letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.).

Return type: oid

- `pg_replication_origin_drop (node_name)`

Description: Deletes a previously created replication source, including any associated replay progress.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter:

- `node_name`

Name of the replication source to be deleted.

Value range: a string, supporting only letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.).

- `pg_replication_origin_oid (node_name)`

Description: Searches for a replication source by name and returns the internal ID. If no such replication source is found, an error is thrown.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter:

- `node_name`

Specifies the name of the replication source to be queried.

Value range: a string, supporting only letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.).

Return type: oid

- `pg_replication_origin_session_setup (node_name)`

Description: Marks the current session for replaying from a given origin, allowing you to track replay progress. This parameter can be used only when

no origin is selected. Run the **pg_replication_origin_session_reset** command to cancel the configuration.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter:

- node_name

Name of the replication source.

Value range: a string, supporting only letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.).

- pg_replication_origin_session_reset ()

Description: Cancels the **pg_replication_origin_session_setup()** effect.

Note: The user who calls this function must have the SYSADMIN permission.

- pg_replication_origin_session_is_setup ()

Description: Returns a true value if a replication source is selected in the current session.

Note: The user who calls this function must have the SYSADMIN permission.

Return type: Boolean

- pg_replication_origin_session_progress (flush)

Description: Returns the replay position of the replication source selected in the current session.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter:

- flush

Determines whether the corresponding local transaction has been flushed to disk.

Value range: Boolean

Return type: LSN

- pg_replication_origin_xact_setup (origin_lsn, origin_timestamp)

Description: Marks the current transaction as recommitted at a given LSN and timestamp. This function can be called only when

pg_replication_origin_session_setup is used to select a replication source.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter:

- origin_lsn

Position for replaying the replication source.

Value range: LSN

- origin_timestamp

Time point when a transaction is committed.

Value range: timestamp with time zone

- pg_replication_origin_xact_reset ()

Description: Cancels the **pg_replication_origin_xact_setup()** effect.

Note: The user who calls this function must have the SYSADMIN permission.

- pg_replication_origin_advance (node_name, lsn)

Description:

Sets the replication progress of a given node to a given position. This is primarily used to set the initial position, or to set a new position after a configuration change or similar change.

Note: Improper use of this function may cause inconsistent replication data.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter:

- **node_name**
Name of an existing replication source.
Value range: a string, supporting only letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.

- **lsn**
Position for replaying the replication source.
Value range: LSN

- **pg_replication_origin_progress (node_name, flush)**

Description: Returns the position for replaying the given replication source.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter:

- **node_name**
Name of the replication source.
Value range: a string, supporting only letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.

- **flush**
Determines whether the corresponding local transaction has been flushed to disk.
Value range: Boolean

- **pg_show_replication_origin_status()**

Description: Displays the replication status of the replication source.

Note: The user who calls this function must have the SYSADMIN permission.

Return type:

- **local_id**: OID, which specifies the ID of the replication source.
- **external_id**: text, which specifies the name of the replication source.
- **remote_lsn**: LSN of the replication source.
- **local_lsn**: local LSN.

- **gs_get_distribute_decode_status()**

Description: Obtains the distributed decoding status details (by replication slot) on the current node. This command must be executed on CNs. If it is executed on DN, null is returned.

Return type: text, int, int, int64, xid, xid, text, text, text

```
gaussdb=# SELECT * FROM gs_get_distribute_decode_status();
 slot_name | logical_receiver_num | slice_num | walsender_thread_id | last_sent_csn |
last_confirmed_csn | receiver_queue_length | connect_times |
csn_receive_array
```

```

Table 7-101 Description

Statistical Item	Type	Description
slot_name	text	Replication slot name.
logical_receiver_num	int	Number of receiver threads started for distributed decoding.
slice_num	int	Number of shards in a cluster.
walsender_thread_id	int64	WAL sender thread ID.
last_sent_csn	xid	CSN that is sent recently.
last_confirmed_csn	xid	The last CSN returned from the client that has been confirmed for reception.
receiver_queue_length	text	Length of the log queue received on each DN (displayed in the character string format after concatenation).
connect_times	text	Number of times that each DN is connected (displayed in the character string format after concatenation).
csn_receive_array	text	Latest CSN obtained by each DN (displayed in the character string format after concatenation).

- gs_get_distribute_decode_status_detail()**
 Description: Obtains the distributed decoding status details (by DN) on the current node. This command must be executed on CNs. If it is executed on DNs, null is returned.

Return type: text, int, int64, int, int, xid

```

gaussdb=# SELECT * FROM gs_get_distribute_decode_status_detail();
slot_name | slice_id | thread_id | queue_len | connect_times | received_csn
+-----+-----+-----+-----+-----+-----+
slot1 |      0 | 139959895848704 |      1 |      2 | 2012244
slot1 |      1 | 139959895848704 |      1 |      2 | 2012244
slot1 |      2 | 139959895848704 |      0 |      2 | 2012244
(3 rows)

```

Table 7-102 Description

Statistical Item	Type	Description
slot_name	text	Replication slot name.
slice_id	int	Shard ID (starting from 0).

Statistical Item	Type	Description
thread_id	int64	ID of the receiver thread started for distributed decoding.
queue_len	int	Length of the log queue received on the current DN.
connect_times	int	Number of times that each DN is connected.
received_csn	xid	Latest CSN obtained from the current DN.

7.6.26.11 Segment-Page Storage Functions

 NOTE

- To create a segment-page table on the Astore storage engine, you need to set **segment to on** when creating the table. Example:

```
CREATE TABLE t1(id int) WITH (segment=on, storage_type=astore);
```
- The values of the fields related to the segment-page storage function are described as follows:
 - a. **forknum**: data file fork.
Value range: [0: mainfork; 1: fsmfork; 2: vm fork].
 - b. **file id**: data file ID.
Value range: [1: metadata file; 2–5: data file].
 - c. **blocks**: extent size.
Value range: [1: No.1 file; 8: No.2 file; 128: No.3 file; 1024: No.4 file; 4096: No.5 file].
 - d. **file_block_id/head_block_id/block_id**: offset page number of the physical page in the data file and other fields that indicate the page number.
Value range: [0,4294967294]
 - e. **page_type**: page type.
Value range:
 Meta pages: **file head/file_header**: file header; **spc head/spc_header**: space header; **map head/map_header**: mapping header; **map page/map_pages**: mapping page; **reverse pointer page/inverse pointer page/ip pages**: reverse pointer page; **segment head page/segment head**: segment header page; **level1 page**: level-1 page; **data_pages/data extent**: data page; **fork head**: fork header.
 Data pages: **heap, uheap, btree, and ubtree**.
 Unknown pages: **unknown(data extent)**: all-zero segment page whose type cannot be determined; **unknown(fsm indexurq)**: fsm or indexurq page.
 - f. **contents**: storage content of a data file.
Value range: **permanent** (permanent), **unlogged** (no log), **temporary** (global temporary), and **temporary2** (local temporary)

- local_space_shrink**(tablespacename TEXT, databasename TEXT)

Description: Shrinks specified physical segment-page space on the current node. Only the currently connected database can be shrunk.

Return value: empty
- gs_space_shrink**(tablespace int4, database int4, extent_type int4, forknum int4)

Description: Works similar to **local_space_shrink**. That is, shrinks specified physical segment-page space. However, the parameters are different. The input parameters are the OIDs of the tablespace and database, and the value of **extent_type** is an integer ranging from 2 to 5. The value **1** of **extent_type** indicates segment-page metadata. Currently, the physical file that contains the metadata cannot be shrunk. This function is used only by tools. You are advised not to use it directly.

Return value: empty
- global_space_shrink**(tablespacename TEXT, databasename TEXT)

Description: Compresses segment-page storage space on all DN in a cluster. This is performed on a CN.

Note: If **global_space_shrink** locks the cluster. DDL operations cannot be performed. **local_space_shrink** does not lock the cluster.
- gs_stat_remain_segment_info**()

Description: Runs on the CN to query extents on DN with residual data due to faults. By default, only initial users, users with the sysadmin permission, and users with the O&M administrator permission in the O&M mode can view the information. Other users can view the information only after being granted with permissions. This function can be executed only on the primary node. Residual extents are classified into two types: segments that are allocated but not used and extents that are allocated but not used. The main difference is that a segment contains multiple extents. During reclamation, all extents in the segment need to be recycled.

Return type

Name	Description
node_name	Node name
space_id	Tablespace ID
db_id	Database ID
block_id	Extent ID
type	Extent type. The options are as follows: ALLOC_SEGMENT , DROP_SEGMENT , and SHRINK_EXTENT .

The values of **type** are described as follows:

- ALLOC_SEGMENT**: When a user creates a segment-page table and the segment is just allocated but the transaction of creating a table is not committed, the node is faulty. As a result, the segment is not used after being allocated.

- **DROP_SEGMENT:** When a user deletes a segment-page table and the transaction is successfully committed, the bit corresponding to the segment page of the table is not reset and a fault, such as power failure, occurs. As a result, the segment is not used or released.
- **SHRINK_EXTENT:** When a user shrinks a segment-page table and does not release the idle extent, a fault, such as power failure, occurs. As a result, the extent remains and cannot be reused.

Example:

```
gaussdb=# SELECT * FROM gs_stat_remain_segment_info();
```

node_name	space_id	db_id	block_id	type
dn_6001_6002_6003	16804	16803	4157	ALLOC_SEGMENT

(1 row)

- `gs_free_remain_segment()`

Description: Frees all segments queried by using the `gs_stat_remain_segment_info` function in the current database. By default, only initial users, users with the `sysadmin` permission, and users with the `O&M administrator` permission in the `O&M` mode can execute the function. Other users can use the function only after being granted with permissions. This function can be executed only on the primary node.

Return type: Boolean

- `gs_local_stat_remain_segment_info()`

Description: Runs on the primary DN to query the residual segment page information of the current node. For details about user permissions and return values, see `gs_stat_remain_segment_info`.

- `gs_local_free_remain_segment()`

Description: Runs on the primary DN to free segments queried by using the `gs_local_stat_remain_segment_info` function in the current database. For details about user permissions and return values, see `gs_free_remain_segment`.

- `gs_seg_dump_page(tablespace_name name, file_id int4, bucketnode int4, file_block_id bigint, forknum int4 default 0)`

Description: Parses a specified page in segment-page mode and returns the parsed content. Only users with the `sysadmin` attribute and users with the `O&M administrator` attribute in `O&M` mode can execute this function. This function is used to parse physical pages. The parsing result of one page is returned each time. The returned result does not contain the actual user data. This function does not require users to enter the page type. During implementation, the system attempts to determine the page type. If the page type cannot be determined, the system outputs possible parsing results.

Parameter description:

Name	Type	Description
tablespace_name	NAME	Tablespace to which a segment object belongs. Value range: a valid tablespace name.
file_id	INTEGER	Data file ID. Value range: an int4 value in the range [1,5].

Name	Type	Description
bucketnode	INTEGER	<ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. • 1025 indicates the bucket node of a segment-page global temporary table. • 1026 indicates the bucket node of a segment-page unlogged table. • 1027 indicates the bucket node of a segment-page local temporary table.
file_block_id	BIGINT	Offset page number of the physical page in the data file. Value range: [0,4294967294]
forknum	INTEGER DEFAULT 0	Fork number of a data file. The default value is 0 . Value range: <ul style="list-style-type: none"> • 0: main fork. • 1: FSM fork. • 2: VM fork.

Return type

Name	Type	Description
page_type	TEXT	Page type. Value range: <ul style="list-style-type: none"> • Service pages: heap, uheap, btree, and ubtree. • Segment-page metapages: bucket main head, file head, spc head, map head, map page, reverse pointer page, segment head page and level1 page. • Unknown pages: <ul style="list-style-type: none"> - unknown(data extent): all-zero segment page whose type cannot be determined. - unknown(fsm indexurq): fsm or indexurq page.
result	TEXT	Parsing result.

For example, perform the following operations after creating a segment-page ordinary table:

```
gaussdb=# SELECT * FROM gs_seg_dump_page('pg_default', 1, 1024, 4157);
```

```

- `gs_seg_dump_page`(relid oid, bucketnode int, block_id bigint, partition bool default false, forknum int4 default 0)

Description: Parses a specified page in segment-page mode and returns the parsed content. This function is executed on DNs. Only users with the `sysadmin` attribute and users with the `O&M administrator` attribute in `O&M` mode can execute this function. This function is used to parse logical pages. The parsing result of one page is returned each time. The returned result does not contain the actual user data. This function does not require users to enter the page type. During implementation, the system attempts to determine the page type. If the page type cannot be determined, the system outputs possible parsing results.

Parameter description:

Name	Type	Description
relid	OID	Segment object ID. Value range: a valid segment-page object ID. Otherwise, an error is reported.
bucket node	INTEGER	<ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. • 1025 indicates the bucket node of a segment-page global temporary table. • 1026 indicates the bucket node of a segment-page unlogged table. • 1027 indicates the bucket node of a segment-page local temporary table.
block_id	BIGINT	Logical page number. Value range: [0,4294967294]
partition	BOOLEAN DEFAULT FALSE	Specifies whether the segment object is a partition. The default value is false . Value range: bool, indicating whether the object corresponding to the input OID is a partition.

Name	Type	Description
forknum	INTEGER DEFAULT 0	Fork number of a data file. The default value is 0 . Value range: <ul style="list-style-type: none"> • 0: main fork. • 1: FSM fork. • 2: VM fork.

Return value description:

Name	Type	Description
page_type	TEXT	Page type. Value range: <ul style="list-style-type: none"> • Service pages: heap, uheap, btree, and ubtree. • Segment-page metapages: bucket_main_head, file head, spc head, map head, map page, reverse pointer page, segment head page, and level1 page. • Unknown pages: <ul style="list-style-type: none"> – unknown(data extent): all-zero segment page whose type cannot be determined. – unknown(fsm indexurq): fsm or indexurq page.
result	TEXT	Parsing result.

For example, perform the following operations on a DN, and ensure that **relid** must be a valid OID of the segment-page object on the DN, and the object must have data so that the page information can be queried:

```
gaussdb=# SELECT * FROM gs_seg_dump_page(16788, 1024, 0);
```

```

- `gs_seg_get_spc_location`(tablespace_name NAME, bucketnode INTEGER, head_block_id BIGINT, block_id BIGINT)

Description: Calculates the physical location given a segment and logical page number. Only an administrator can query the information.

Parameter description

Name	Type	Description
tablespace_name	NAME	Tablespace to which a segment object belongs.
bucketnode	INTEGER	<ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. • 1025 indicates the bucket node of a segment-page global temporary table. • 1026 indicates the bucket node of a segment-page unlogged table. • 1027 indicates the bucket node of a segment-page local temporary table.
head_block_id	BIGINT	Page number of a segment header.
block_id	BIGINT	Logical page number.

Return value description

Name	Type	Description
extent_id	INTEGER	Logical extent number of the logical page.
extent_size	INTEGER	Size of the logical extent where the logical page is located.

Name	Type	Description
file_id	INTEGER	ID of the data file where the physical page is located.
file_block_id	BIGINT	Offset page number of the physical page in the data file.

For example, perform the following operations on the DN after creating a segment-page ordinary table in the tablespace and inserting data:

```
gaussdb=# SELECT * FROM gs_seg_get_spc_location('pg_default', 1024, 4157, 0);
 extent_id | extent_size | file_id | file_block_id
-----+-----+-----+-----
          0 |          8 |        2 |          4157
(1 row)
```

- `gs_seg_get_spc_location(releid OID, bucketnode INTEGER, block_id BIGINT, partition BOOLEAD DEFAULT FALSE, forknum INTEGER DEFAULT 0)`

Description: Calculates the physical location given a segment and logical page number. Only an administrator can query the information.

Parameter description

Name	Type	Description
releid	OID	Segment object ID.
bucketnode	INTEGER	<ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. • 1025 indicates the bucket node of a segment-page global temporary table. • 1026 indicates the bucket node of a segment-page unlogged table. • 1027 indicates the bucket node of a segment-page local temporary table.
block_id	BIGINT	Logical page number.
partition	BOOLEAD DEFAULT FALSE	Specifies whether the segment object is a partition. The default value is FALSE .
forknum	INTEGER DEFAULT 0	Fork of a segment object. The default value is 0 . Value range: <ul style="list-style-type: none"> • 0: main fork. • 1: FSM fork. • 2: VM fork.

Return value description

Name	Type	Description
extent_id	INTEGER	Logical extent number of the logical page.
extent_size	INTEGER	Size of the logical extent where the logical page is located.
file_id	INTEGER	ID of the data file where the physical page is located.
file_block_id	BIGINT	Offset page number of the physical page in the data file.

For example, perform the following operations on a DN, and ensure that **relid** must be a valid OID of the segment-page object on the DN, and the object must have data:

```
gaussdb=# SELECT * FROM gs_seg_get_spc_location(24578,1024, 0);
 extent_id | extent_size | file_id | file_block_id
-----+-----+-----+-----
         0 |          8 |        2 |         4157
(1 row)
```

- `gs_seg_get_location(block_id BIGINT, as_extent BOOLEAN DEFAULT FALSE)`
Description: Calculates the physical location given a segment and logical page number. Only an administrator can query the information.

Parameter description

Name	Type	Description
block_id	BIGINT	Logical page number.
as_extent	BOOLEAN DEFAULT FALSE	Specifies whether the block_id parameter is an extent number. The default value is FALSE .

Return value description

Name	Type	Description
extent_id	BIGINT	Extent number.
extent_size	INTEGER	Extent size.
extent_offset	INTEGER	Extent offset block number.
level0_slots_idx	INTEGER	Index of the extent in the level-0 slot array in the segment header.
level1_slots_idx	INTEGER	Index of the extent in the level-1 slot array in the segment header.

Name	Type	Description
level1_page_offset	INTEGER	Offset of the extent on the level-1 slot page in the segment header.
segment_blocks	BIGINT	Number of pages containing this page or extended segments.
relative_fno	INTEGER	Number of the relative file that contains this page or extent.

Example:

```
gaussdb=# SELECT * FROM gs_seg_get_location(4157);
 extent_id | extent_size | extent_offset | level0_slots_idx | level1_slots_idx | level1_page_offset |
 segment_blocks | relative_fno
-----+-----+-----+-----+-----+-----+-----+-----

```

```
47 | 128 | 61 | 47 | | | 4158 | 3
(1 row)
```

- `gs_seg_get_segment_layout()`

Description: Outputs the static segment layout. Only an administrator can query the information.

Return value description

Name	Type	Description
version	TEXT	Segment-page version. The default value is 1.0 .
section_id	INTEGER	ID of the data section divided by a segment.
section_type	TEXT	Extent type of the segment data section. Value range: <ul style="list-style-type: none"> • meta: segment header. • data: data.
extent_size	INTEGER	Extent size. The unit is byte.
extent_page_count	INTEGER	Number of extent pages.
extent_count_start	BIGINT	Start extent number.
extent_count_end	BIGINT	End extent number.
total_size	BIGINT	Size of the segment data section. The unit is byte.

Example:

```
gaussdb=# SELECT * FROM gs_seg_get_segment_layout();
 version | section_id | section_type | extent_size | extent_page_count | extent_count_start |
 extent_count_end | total_size
-----+-----+-----+-----+-----+-----+-----+-----
1.0 | 1 | meta | 8192 | 1 | 0 | 0 | 8192
1.0 | 2 | data | 65536 | 8 | 1 | 16 | 1048576
1.0 | 3 | data | 1048576 | 128 | 17 | 143 | 134217728
1.0 | 4 | data | 8388608 | 1024 | 144 | 255 |
1073741824
1.0 | 5 | data | 33554432 | 4096 | 256 | 1025255 |
34394366541824
(5 rows)
```

- `gs_seg_get_datafile_layout()`

Description: Queries the static layout of data files 1 to 5. Only an administrator can query the information.

Return value description

Name	Type	Description
version	TEXT	Segment-page version. The default value is 1.0 .
seg_storage_type	TEXT	<ul style="list-style-type: none"> • segment indicates common segment-page data. • hashbucket indicates hash bucket data.
file_id	INTEGER	Data file ID.
section_id	INTEGER	Data section ID of a data file.
section_type	TEXT	Type of the data file section. Value range: <ul style="list-style-type: none"> • file_header indicates the file header. • spc_header indicates the space header. • map_header indicates the mapping header. • map_pages indicates the mapping page. • ip_pages(inverse pointer pages) indicates the reverse pointer page. • data_pages indicates the data page.
page_start	BIGINT	Start page number of the data section.
page_end	BIGINT	End page number of the data section.
page_count	BIGINT	Number of pages in the data section.
total_size	BIGINT	Size of the data section. The unit is byte.

Example:

```
gaussdb=# SELECT * FROM gs_seg_get_datafile_layout();
 version | seg_storage_type | file_id | section_id | section_type | page_start | page_end |
 page_count | total_size
-----+-----+-----+-----+-----+-----+-----+-----
```

```

+-----+
1.0 | segment | 1 | 0 | file_header | 0 | 0 | 1 | 8192
1.0 | segment | 1 | 1 | spc_header | 1 | 1 | 1 | 8192
1.0 | segment | 1 | 2 | map_header | 2 | 2 | 1 | 8192
1.0 | segment | 1 | 3 | map_pages | 3 | 66 | 64 | 524288
1.0 | segment | 1 | 4 | ip_pages | 67 | 4156 | 4090 |
33505280
1.0 | segment | 1 | 5 | data_pages | 4157 | 4147260 | 4143104 |
33940307968

```

... (There is a large amount of data. Only part of the data is displayed.)

- `gs_seg_get_slice_layout(file_id INTEGER, bucketnode INTEGER, slice_id INTEGER)`

Description: Outputs the static layout of a given data file fragment. Only an administrator can query the information.

Parameter description

Name	Type	Description
file_id	INTEGER	Data file ID.
bucketnode	INTEGER	<ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. • 1025 indicates the bucket node of a segment-page global temporary table. • 1026 indicates the bucket node of a segment-page unlogged table. • 1027 indicates the bucket node of a segment-page local temporary table.
slice_id	INTEGER	Slice file ID.

Return value description

Name	Type	Description
version	TEXT	Segment-page version. The default value is 1.0 .
section_id	INTEGER	Data section ID of a data file.

Name	Type	Description
section_type	INTEGER	Type of the data file section. Value range: <ul style="list-style-type: none"> • file_header indicates the file header. • spc_header indicates the space header. • map_header indicates the mapping header. • map_pages indicates the mapping page. • ip_pages(inverse pointer pages) indicates the reverse pointer page. • data_pages indicates the data page.
page_start	BIGINT	Start page number of the data section.
page_end	BIGINT	End page number of the data section.
page_count	BIGINT	Number of pages in the data section.
total_size	BIGINT	Size of the data section. The unit is byte.

Example:

```
gaussdb=# SELECT * FROM gs_seg_get_slice_layout(1,1024,0);
version | section_id | section_type | page_start | page_end | page_count | total_size
-----+-----+-----+-----+-----+-----+-----
1.0 | 0 | file_header | 0 | 0 | 1 | 8192
1.0 | 1 | spc_header | 1 | 1 | 1 | 8192
1.0 | 2 | map_header | 2 | 2 | 1 | 8192
1.0 | 3 | map_pages | 3 | 66 | 64 | 524288
1.0 | 4 | ip_pages | 67 | 4156 | 4090 | 33505280
1.0 | 5 | data_pages | 4157 | 131071 | 126915 | 1039687680
(6 rows)
```

- `gs_seg_get_segment(tablespace_name NAME, bucketnode INTEGER, head_block_id BIGINT)`

Description: Outputs the segment header information of the segment header page in the segment header file of the tablespace. Only an administrator can query the information.

Parameter description

Name	Type	Description
tablespace_name	NAME	Tablespace to which a segment object belongs.

Name	Type	Description
bucketnode	INTEGER	<ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. • 1025 indicates the bucket node of a segment-page global temporary table. • 1026 indicates the bucket node of a segment-page unlogged table. • 1027 indicates the bucket node of a segment-page local temporary table.
head_block_id	BIGINT	Page number of the segment header.

Return value description

Name	Type	Description
blocks	BIGINT	Number of logical pages of a segment.
total_blocks	BIGINT	Number of physical pages of a segment.
extents	INTEGER	Number of logical extents of a segment.
total_extents	INTEGER	Number of physical extents of a segment.
head_lsn	TEXT	Segment header LSN.
level0_slots	BIGINT[]	Level-0 slot array of segment extent mapping.
level1_slots	BIGINT[]	Level-1 slot array of segment extent mapping.
fork_head	BIGINT[]	Fork head array of a segment.

For example, perform the following operations after creating a segment-page ordinary table:

```
gaussdb=# SELECT * FROM gs_seg_get_segment('pg_default', 1024, 4157);
 blocks | total_blocks | extents | total_extents | head_lsn | level0_slots | level1_slots | fork_head
-----+-----+-----+-----+-----+-----+-----+-----
    9 |         16 |      2 |           2 | 62211744 | {4157,4165} | {}           | {4157,4158,-1}
(1 row)
```

- `gs_seg_get_segment(releid OID, bucketnode INTEGER, partition BOOLEAD DEFAULT FALSE, forknum INTEGER DEFAULT 0)`

Description: Outputs the corresponding segment header information based on **releid** and **bucketnode**. Only an administrator can query the information.

Parameter description

Name	Type	Description
relid	OID	Table OID.
bucketnode	INTEGER	<ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. • 1025 indicates the bucket node of a segment-page global temporary table. • 1026 indicates the bucket node of a segment-page unlogged table. • 1027 indicates the bucket node of a segment-page local temporary table.
partition	BOOLEAN DEFAULT FALSE	<p>Specifies whether the segment object is a partition. The default value is false.</p> <p>Value range: bool, indicating whether the object corresponding to the input OID is a partition.</p>
forknum	INTEGER DEFAULT 0	<p>Fork number of a data file. The default value is 0.</p> <p>Value range:</p> <ul style="list-style-type: none"> • 0: main fork. • 1: FSM fork. • 2: VM fork.

Return value description

Name	Type	Description
blocks	BIGINT	Number of logical pages of a segment.
total_blocks	BIGINT	Number of physical pages of a segment.
extents	INTEGER	Number of logical extents of a segment.
total_extents	INTEGER	Number of physical extents of a segment.
head_lsn	TEXT	Segment header LSN.
level0_slots	BIGINT[]	Level-0 slot array of segment extent mapping.
level1_slots	BIGINT[]	Level-1 slot array of segment extent mapping.
fork_head	BIGINT[]	Fork head array of a segment.

For example, perform the following operations on a DN, and ensure that **relid** must be the OID of the queried segment page object on the DN:

```
gaussdb=# SELECT * FROM gs_seg_get_segment(16768, 1024);
 blocks | total_blocks | extents | total_extents | head_lsn | level0_slots | level1_slots | fork_head
-----+-----+-----+-----+-----+-----+-----+-----
      9 |          16 |       2 |             2 | 62211744 | {4157,4165} | {}           | {4157,4158,4294967295}
(1 row)
```

- `gs_seg_get_extents(tablespace_name NAME, bucketnode INTEGER, head_block_id BIGINT)`

Description: Outputs all extents of the segment object on the segment header page in the segment header file of the tablespace, including **segment head, fork head, level1 page** in file 1, and data extents in files 2 to 5. Only an administrator can query the information.

Parameter description

Name	Type	Description
tablespace_name	NAME	Tablespace to which a segment object belongs.
bucketnode	INTEGER	<ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. • 1025 indicates the bucket node of a segment-page global temporary table. • 1026 indicates the bucket node of a segment-page unlogged table. • 1027 indicates the bucket node of a segment-page local temporary table.
head_block_id	BIGINT	Page number of the segment header.

Return value description

Name	Type	Description
extent_id	INTEGER	Logical extent number.
file_id	INTEGER	ID of the data file where the extent is located.
forknum	INTEGER	Fork of a segment object. Value range: <ul style="list-style-type: none"> • 0: main fork. • 1: FSM fork. • 2: VM fork.

Name	Type	Description
block_id	BIGINT	Start page number in the data file where the extent is located.
blocks	INTEGER	Extent size. Value range: <ul style="list-style-type: none"> • 1 indicates file 1. • 8 indicates file 2. • 128 indicates file 3. • 1024 indicates file 4. • 4096 indicates file 5.
usage_type	TEXT	Usage type of an extent. Value range: <ul style="list-style-type: none"> • segment head indicates the segment header. • fork head indicates the fork header. • level1 page indicates the level-1 page. • data extent indicates data extents.

For example, perform the following operations after creating a segment-page ordinary table:

```
gaussdb=# SELECT * FROM gs_seg_get_extents('pg_default', 1024, 4157);
 extent_id | file_id | forknum | block_id | blocks | usage_type
-----+-----+-----+-----+-----+-----
          |    1 |      0 |    4157 |      1 | segment head
          |    0 |      0 |    4157 |      8 | data extent
          |    1 |      0 |    4165 |      8 | data extent
(3 rows)
```

- `gs_seg_get_extents(releid OID, bucketnode INTEGER, partition BOOLEAD DEFAULT FALSE, forknum INTEGER DEFAULT 0)`

Description: Outputs all extents of the segment object on the segment header page in the corresponding segment header file, including **segment head, fork head, level1 page** in file 1 and, data extents in files 2 to 5. Only an administrator can query the information.

Parameter description

Name	Type	Description
releid	OID	Table OID.

Name	Type	Description
bucketnode	INTEGER	<ul style="list-style-type: none"> ● 0 to 1023 indicate the bucket nodes of a hash bucket table. ● 1024 indicates the bucket node of a segment-page ordinary table. ● 1025 indicates the bucket node of a segment-page global temporary table. ● 1026 indicates the bucket node of a segment-page unlogged table. ● 1027 indicates the bucket node of a segment-page local temporary table.
partition	BOOLEAN DEFAULT FALSE	<p>Specifies whether the segment object is a partition. The default value is false.</p> <p>Value range: Boolean, indicating whether the object corresponding to the input OID is a partition.</p>
forknum	INTEGER DEFAULT 0	<p>Fork number of a data file. The default value is 0.</p> <p>Value range:</p> <ul style="list-style-type: none"> ● 0: main fork. ● 1: FSM fork. ● 2: VM fork.

Return value description

Name	Type	Description
extent_id	INTEGER	Logical extent number.
file_id	INTEGER	ID of the data file where the extent is located.
forknum	INTEGER	<p>Fork of a segment object.</p> <p>Value range:</p> <ul style="list-style-type: none"> ● 0: main fork. ● 1: FSM fork. ● 2: VM fork.
block_id	BIGINT	Start page number in the data file where the extent is located.

Name	Type	Description
blocks	INTEGER	Extent size. Value range: <ul style="list-style-type: none"> • 1 indicates file 1. • 8 indicates file 2. • 128 indicates file 3. • 1024 indicates file 4. • 4096 indicates file 5.
usage_type	TEXT	Usage type of an extent. Value range: <ul style="list-style-type: none"> • segment head indicates the segment header. • fork head indicates the fork header. • level1 page indicates the level-1 page. • data extent indicates data extents.

In the following example, **relid** must be a valid OID of a multipart page object:

```
gaussdb=# SELECT * FROM gs_seg_get_extents(16768, 1024);
 extent_id | file_id | forknum | block_id | blocks | usage_type
-----+-----+-----+-----+-----+-----
          |    1 |      0 |    4157 |      1 | segment head
          |    0 |      0 |    4157 |      8 | data extent
          |    1 |      0 |    4165 |      8 | data extent
(3 rows)
```

- `gs_seg_free_spc_remain_segment(tablespace_name NAME, head_file_id INTEGER, bucketnode INTEGER, head_block_id BIGINT)`

Description: Releases the page occupied by the segment page-based residual segment in file 1 in a specified tablespace. You can query residual segments in the `GS_SEG_SPC_REMAIN_SEGMENTS` view. Only an administrator can query the information. This query can be executed only on the primary node.

NOTICE

- This function has a defect and is planned to be reconstructed in later versions to completely solve the residual segment-page problem. This function is an offline segment-page clearing method.
- To ensure the consistency between the queried residual segments and residual extents and the consistency of residual clearing, this function and the GS_SEG_SPC_REMAIN_SEGMENTS view must be executed in the DDL- or DML-restricted state. The current version does not provide the DML or DDL restriction capability. Therefore, when using this feature, ensure that the execution environment is in the DDL- or DML-restricted state.
- This function can be used only when **enable_segment_remain_cleanup** is set to **off**. For details about how to enable it, see "Configuring Running Parameters > GUC Parameters > Developer Options" in *Administrator Guide*.

Parameter description

Name	Type	Description
tablespace_name	NAME	Tablespace name
head_file_id	INTEGER	ID of a data file in which a segment header of a segment-page-type residual segment is located. Value range: 1
bucketnode	INTEGER	<ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. • 1025 indicates the bucket node of a segment-page global temporary table. • 1026 indicates the bucket node of a segment-page unlogged table. • 1027 indicates the bucket node of a segment-page local temporary table.
head_block_id	BIGINT	Page number of a segment header.

Return type: void

Example:

```
gaussdb=# SELECT * FROM gs_seg_free_spc_remain_segment('pg_default', 1, 1024, 4159);
gs_seg_free_spc_remain_segment
```

(1 row)

- gs_seg_free_spc_remain_extent(tablespace_name NAME, file_id INTEGER, bucketnode INTEGER, forknum INTEGER, block_id BIGINT)

Description: Releases residual segment-page-type isolated extents in a specified tablespace. Residual isolated extents can be queried in the GS_SEG_SPC_REMAIN_EXTENTS view. Only an administrator can query the information. This query can be executed only on the primary node.

NOTICE

This function can be used only when **enable_segment_remain_cleanup** is set to **off**. For details about how to enable it, see "Configuring Running Parameters > GUC Parameters > Developer Options" in *Administrator Guide*.

Parameter description

Name	Type	Description
tablespace_name	NAME	Tablespace name
file_id	INTEGER	ID of the data file where the segment-page-type residual extent is located. Value range: files 1 to 5.
bucketnode	INTEGER	<ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. • 1025 indicates the bucket node of a segment-page global temporary table. • 1026 indicates the bucket node of a segment-page unlogged table. • 1027 indicates the bucket node of a segment-page local temporary table.
forknum	INTEGER	Fork number of a data file. Value range: <ul style="list-style-type: none"> • 0: main fork. • 1: FSM fork. • 2: VM fork.
block_id	BIGINT	Page number of a segment header.

Return type: void

Example:

```
gaussdb=# SELECT * FROM gs_seg_free_spc_remain_extent('pg_default', 1, 1024, 0, 4159);
gs_seg_free_spc_remain_extent
```

(1 row)

- gs_seg_get_datafiles(database_name NAME)

Description: Displays information about all data files of an instance. Only an administrator can query the information.

Parameter description

Name	Type	Description
database_name	NAME	Database name The default value is current_database() , indicating the name of the current database.

Return value description

Name	Type	Description
file_name	TEXT	Data file name, for example, base/17467/2_fsm .
file_id	INTEGER	Data file ID. Value range: files 1 to 5.
bucketnode	INTEGER	<ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. • 1025 indicates the bucket node of a segment-page global temporary table. • 1026 indicates the bucket node of a segment-page unlogged table. • 1027 indicates the bucket node of a segment-page local temporary table.
forknum	INTEGER	Fork type of a data file.
tablespace_name	NAME	Name of the tablespace to which a data file belongs.
contents	TEXT	Storage content of a data file. Value range: <ul style="list-style-type: none"> • permanent: permanent. • unlogged: no log. • temporary: global temporary • temporary2: local temporary
extent_size	INTEGER	Extent size of a data file.
meta_blocks	BIGINT	Number of allocated metadata pages of a data file.
data_blocks	BIGINT	Number of allocated data pages of a data file.
total_blocks	BIGINT	Total number of physical pages in a data file.

Name	Type	Description
skip_unused	BOOLEAN DEFAULT TRUE	Specifies whether to output only allocated extents. The default value is TRUE , indicating that only allocated extents are output.

Return value description

Name	Type	Description
block_id	BIGIN T	Start page number of a data extent.
blocks	INTEG ER	Data extent size. Value range: <ul style="list-style-type: none"> ● 1 indicates file 1. ● 8 indicates file 2. ● 128 indicates file 3. ● 1024 indicates file 4. ● 4096 indicates file 5.
contents	TEXT	Stores content. Value range: <ul style="list-style-type: none"> ● permanent: permanent. ● unlogged: no log. ● temporary: global temporary. ● temporary2: local temporary.
in_used	TEXT	Specifies whether a resource has been allocated. Value range: <ul style="list-style-type: none"> ● Y: allocated. ● N: not allocated.
mapblock_location	TEXT	Position of the extent in the map block. Format: (page_id, offset).
head_file_id	INTEG ER	ID of the data file where the segment header is located.
head_block_id	BIGIN T	Page number of the segment header.

Parameter: void

Returned values

Name	Type	Description
bucket_id	OID	Bucket ID.
redis_state	INT1	Scale-out status of the bucket. The value 0 indicates that the scale-out has not started, and the value 1 indicates that the scale-out baseline data has been completed.
xlog_count	INT8	Number of Xlogs generated by the bucket on the original DN after the current database scale-out starts (that is, after <code>gs_redis_set_distributed_db</code> is called last time).
sndr_latest_lsn	INT8	Latest LSN generated by the bucket on the original DN after the current database scale-out starts (that is, after <code>gs_redis_set_distributed_db</code> is called last time).
parser_latest_lsn	INT8	Latest LSN where the bucket is parsed to by the scale-out thread of the original DN after the current database scale-out starts (that is, after <code>gs_redis_set_distributed_db</code> is called last time).
parser_latest_lsn_new	INT8	Latest LSN of bucketxlog where the bucket is parsed to by the scale-out thread of the original DN after the current database scale-out starts (that is, after <code>gs_redis_set_distributed_db</code> is called last time).
rcvr_redo_latest_lsn	INT8	Latest LSN where the bucket is replayed to by the scale-out thread of the new DN after the current database scale-out starts (that is, after <code>gs_redis_set_distributed_db</code> is called last time).
rcvr_redo_latest_lsn_new	INT8	Latest LSN of bucketxlog where the bucket is parsed to by the scale-out thread of the original DN after the current database scale-out starts (that is, after <code>gs_redis_set_distributed_db</code> is called last time).
rcvr_checkpoint	INT8	Checkpoint of the bucket after the current database scale-out starts (that is, after the last invoking of <code>gs_redis_set_distributed_db</code>).
rcvr_redo_start_lsn	INT8	Original LSN for starting the replay of the bucket after the scale-out of the current database starts (that is, after the last invoking of <code>gs_redis_set_distributed_db</code>).
rcvr_redo_end_lsn	INT8	Original LSN for ending the replay of the bucket after the scale-out of the current database starts (that is, after the last invoking of <code>gs_redis_set_distributed_db</code>).

Example:

```
gaussdb=# SELECT * FROM gs_redis_get_bucket_statistics();
 bucket_id | redis_state | xlog_count | sndr_latest_lsn | parser_latest_lsn | parser_latest_lsn_new |
rcvr_redo_latest_lsn | rcvr_redo_latest_lsn_new | rcvr_checkpoint | rcvr_redo_start_lsn |
rcvr_redo_end_lsn

(Only part of the data is displayed.)
```

- **gs_redis_set_distributed_db(db_name CSTRING)**

Description: Sets the database that is being redistributed using hash bucket. This can be called only on DNs during scale-out and can be queried only by administrators.

Parameter description:

- **db_name**: specifies the name of the database to be redistributed.

Return type: void

Example:

```
gaussdb=# SELECT gs_redis_set_distributed_db('gaussdb');
gs_redis_set_distributed_db
-----
0
(1 row)
```

- **gs_redis_hashbucket_update_segment_header(origin_group_id OID, target_group_id OID)**

Description: Updates the headers of all hash bucket tables in the current database. This can be called only on CNs during scale-out and can be queried only by administrators.

Parameters

Name	Type	Description
origin_group_id	OID	Source node group.
target_group_id	OID	New node group.

Return type: Boolean

Example:

```
gaussdb=# SELECT * FROM gs_redis_hashbucket_update_segment_header(16388, 16417);
gs_redis_hashbucket_update_segmen
-----
```

```
t
(1 row)
```

- `gs_redis_local_get_segment_header(table_name REGCLASS, bucketlist OIDVECTOR_EXTEND)`

Description: Obtains the header of a segment-page table. It can be called only on DNs.

Parameters

Name	Type	Description
table_name	REGCLASS	Table name.
bucketlist	OIDVECTOR_EXT END	Bucket list.

Return type: header_info

Example:

```
gaussdb=# SELECT * FROM gs_redis_local_get_segment_header('mytable', '256');
gs_redis_local_get_segment_header
```

```
-----
4294967295,4294967295,4294967295,4294967295,4294967295,4294967295,4294967295,4294967295,
4294967295,4294967295,4294967295,4294967295,4294967295, ... (Only part of the data is displayed.)
(1 row)
```

- `gs_redis_local_update_segment_header(table_name REGCLASS, header_info CSTRING)`

Description: Updates the header of a segment-page table. It can be called only on DNs.

Parameters

Name	Type	Description
table_name	REGCLASS	Table name.
header_info	CSTRING	Header of a segment-page table.

Return type: void

Example:

```
gaussdb=# SELECT * FROM gs_redis_local_update_segment_header('mytable',
'4294967295,4294967295,4294967295,4294967295, ....'); (Only part of the data is displayed.)
gs_redis_local_update_segment_header
```

```
0
(1 row)
```

- `gs_redis_hashbucket_update_inverse_pointer(buckets TEXT, origin_dn_name TEXT, new_dn_name TEXT)`

Description: Updates the inverse pointers of buckets of this batch in all hash bucket tables in the current database. This can be called only on CNs during scale-out and can be queried only by administrators.

Parameters

Name	Type	Description
buckets	TEXT	List of buckets that are brought online this time.
origin_dn_name	TEXT	Source node name.
new_dn_name	TEXT	New node name.

Return type: void

Example:

```
gaussdb=# SELECT * FROM
gs_redis_hashbucket_update_inverse_pointer('0,1,2,3,4,5,6,7,8,9,10','datanode1','datanode3');
gs_redis_hashbucket_update_inverse_pointer
-----
0
(1 row)
```

- `gs_redis_local_get_inverse_pointer(buckets TEXT, origin_dn_name TEXT, new_dn_name TEXT)`

Description: Obtains the inverse pointer. This can be called only on DNs during scale-out and can be queried only by administrators.

Parameters

Name	Type	Description
buckets	TEXT	List of buckets that are brought online this time.
origin_dn_name	TEXT	Source node name.
new_dn_name	TEXT	New node name.

Return type: void

Example:

```
gaussdb=# SELECT * FROM
gs_redis_hashbucket_update_inverse_pointer('0,1,2,3,4,5,6,7,8,9,10','datanode1','datanode3');
gs_redis_hashbucket_update_inverse_pointer
-----
0
(1 row)
```

- `gs_redis_local_update_inverse_pointer(table_name TEXT, header_info TEXT, bucketlist TEXT)`

Description: Records Xlogs for updating inverse pointers. This can be called only on DNs during scale-out and can be queried only by administrators.

Parameters

Name	Type	Description
table_name	REGCLASS	Table name.

Name	Type	Description
header_info	TEXT	Header of a segment-page table.
bucketlist	TEXT	Bucket list.

Return type: void

Example:

```
gaussdb=# SELECT * FROM gs_redis_local_update_inverse_pointer('mytable',
'4294967295,4294967295,4294967295,4294967295, ...','1 2 3'); (Only part of the data is displayed.)
gs_redis_local_update_inverse_pointer
-----
0
(1 row)
```

- **gs_redis_local_set_hashbucket_frozenxid**
Description: Changes the **relfrozenxid64** value of the hash bucket table in the system catalog. This can be called only on DNs during scale-out and can be queried only by administrators.

Parameter description: void

Return type: void

Example:

```
gaussdb=# SELECT * FROM gs_redis_local_set_hashbucket_frozenxid();
gs_redis_local_set_hashbucket_frozenxid
-----
0
(1 row)
```

- **gs_redis_set_hashbucket_frozenxid(origin_group_id OID, target_group_id OID)**
Description: Changes the **relfrozenxid64** value of the hash bucket table in the system catalog on the new DN. This can be called only on CNs during scale-out and can be queried only by administrators.

Parameters

Name	Type	Description
origin_group_id	OID	Source node group.
target_group_id	OID	New node group.

Return type: void

Example:

```
gaussdb=# SELECT * FROM gs_redis_set_hashbucket_frozenxid(16388, 16417);
gs_redis_set_hashbucket_frozenxid
-----
0
(1 row)
```

- **gs_redis_set_nextxid(xid BIGINT)**
Description: Modifies the **next_xid** value of a DN. This API can be called only during scale-out. Only administrators can query data. This API can be called only on DNs.

Parameter: **xid** indicates the expected value of **next_xid**.

Return type: void

Example:

```
gaussdb=# SELECT * FROM gs_redis_set_nextxid('15268817');
gs_redis_set_nextxid
-----
0
(1 row)
```

- **gs_redis_set_csn(csn BIGINT)**

Description: Changes the **next_csn** value of a DN. This API can be called only during scale-out. It can be queried only by administrators. It can be called only on DNs. It can be called only in GTM_FREE mode.

Parameter:

- **csn**: specifies the expected value of **next_csn**.

Return type: void

Example:

```
gaussdb=# SELECT * FROM gs_redis_set_csn('15268817');
gs_redis_set_csn
-----
0
(1 row)
```

- **gs_redis_check_bucket_flush(dn_array NAME[])**

Description: Determines whether all private buffers for RTO replay are flushed. This can be called only during scale-out and can be queried only by administrators.

Parameter:

- **dn_array**: specifies the DN name list.

Return type: Boolean

Example:

```
gaussdb=# SELECT * FROM gs_redis_check_bucket_flush('{{datanode1, datanode2}}');
gs_redis_check_bucket_flush
-----
f
(1 row)
```

- **gs_redis_get_flush_page_lsn(isclean bool)**

Description: Queries the page refreshing information of bucket scale-out replay.

Permission: It can be called only in the debug version during scale-out and queried only by system administrators.

Parameter: **isclean** indicates whether to clear page refreshing information. The value is of the Boolean type.

Returned values

Name	Type	Description
node_name	TEXT	DN where the page is located.

Name	Type	Description
space_id	OID	Tablespace ID.
db_id	OID	Database ID.
file_id	OID	Data file ID. The value ranges from 1 to 5.
bucket_id	OID	Bucket partition ID. The value ranges from 0 to 1023.
forknum	OID	Data file fork. The value ranges from 0 to 2.
blocknum	OID	Offset page number of the physical page in the data file.
latest_flush_lsn	UNITS	Latest LSN of the dirty page.

Example:

```
gaussdb=# SELECT * FROM gs_redis_get_flush_page_lsn(false);
node_name | space_id | db_id | file_id | bucket_id | forknum | blocknum | last_flush_lsn
-----
datanode2 | 1633 | 16387 | 1 | 66 | 0 | 20 | 1571838992
(1 row)
```

- `gs_redis_show_bucketxid(bucketid_list OIDVECTOR_EXTEND)`

Description: Queries the bucketxid corresponding to a specified bucket. This can be called only on DNs during scale-out and can be queried only by administrators.

Parameter:

- **bucketid_list**: specifies the bucket list.

Return type: CString

Example:

```
gaussdb=# SELECT * FROM gs_redis_show_bucketxid('1 2 3');
gs_redis_show_bucketxid
-----
88880001 88880001 88880001
(1 row)
```

- `gs_redis_drop_bucket_files(origin_group_id OID, target_group_id OID)`

Description: Deletes the files that have been physically migrated from the source node. This can be called only on CNs during scale-out and can be queried only by administrators.

Parameters

Name	Type	Description
origin_group_id	OID	Source node group.
target_group_id	OID	New node group.

Return type: Boolean

Example:

```
gaussdb=# SELECT * FROM gs_redis_drop_bucket_files(16388, 16417);
gs_redis_drop_bucket_files
-----
t
(1 row)
```

- `gs_redis_local_drop_bucket_files(bucketlist CSTRING, bucketnum SMALLINT)`
Description: Deletes the corresponding bucket list. This can be called only on DNs during scale-out and can be queried only by administrators.

Parameters

Name	Type	Description
bucketlist	CSTRING	Specified bucket list.
bucketnum	SMALLINT	Number of buckets.

Return type: Boolean

Example:

```
gaussdb=# SELECT * FROM gs_redis_local_drop_bucket_files('1 2 3', 3);
gs_redis_local_drop_bucket_files
-----
t
(1 row)
```

7.6.26.13 Undo System Functions

To check the storage mode used by the current rollback segment, query the **undostoragetype** field in the `gs_global_config` system catalog. **sepage** indicates the segment-page mode, which is a reserved parameter and is not supported currently. **page** indicates the page mode.

Example:

```
gaussdb=# SELECT * FROM gs_global_config where name like '%undostoragetype%';
name | value
-----+-----
undostoragetype | page
(1 row)
```

NOTE

- The Undo system function can be executed only on DNs.
- `gs_undo_meta(type, zoneld, location)`
Description: Specifies metadata of a module in the undo system.
Parameter description:

- **type** (metadata type)
 - **0**: indicates metadata corresponding to an undo zone (record).
 - **1**: indicates metadata corresponding to an undo zone (transaction slot).
 - **2**: indicates metadata corresponding to an undo space (record).
 - **3**: indicates metadata corresponding to an undo space (transaction slot).
- **zoneld** (undo zone ID)
 - **-1**: indicates metadata of all undo zones.
 - **0 to 1024 x 1024 - 1**: indicates the meta information of the corresponding zone ID.
- **location** (read location)
 - **0**: indicates that data is read from the current memory.
 - **1**: indicates that data is read from a physical file.

Return type: record

 **NOTE**

This system function supports only the rollback segments in page storage mode.

Table 7-103 gs_undo_meta parameters

Category	Parameter	Type	Description
Output parameter	zoneld	oid	ID of an undo zone.
Output parameter	persistType	oid	Persistence level.
Output parameter	insert	text	Position of the next undo record to be inserted
Output parameter	discard	text	Position of the undo record that is recycled in common mode
Output parameter	end	text	Position of the undo record that is forcibly recycled. Values smaller than the value of this parameter indicate that the record has been recycled.

Category	Parameter	Type	Description
Output parameter	used	text	Undo space that has been used.
Output parameter	lsn	text	Modifies the LSN of an undo zone.
Output parameter	pid	oid	ID of a thread bound to an undo zone.

- `gs_undo_translot(location, zoneld)`

Description: Specifies transaction slot information of the undo system.

Parameter description:

- **location** (read location)
 - **0**: indicates that data is read from the current memory.
 - **1**: indicates that data is read from a physical file.
- **zoneld** (undo zone ID)
 - **-1**: indicates metadata of all undo zones.
 - **0 to 1024 x 1024 - 1**: indicates the meta information of the corresponding zone ID.

Return type: record

 **NOTE**

This system function supports only the rollback segments in page storage mode.

Table 7-104 `gs_undo_translot` parameters

Category	Parameter	Type	Description
Output parameter	groupId	oid	Undo zone ID that is used.
Output parameter	xactId	text	Transaction ID.
Output parameter	startUndoPtr	text	Position where an undo record is inserted at the start of a transaction corresponding to a transaction slot.

Category	Parameter	Type	Description
Output parameter	endUndoPtr	text	Position where an undo record is inserted at the end of a transaction corresponding to a transaction slot.
Output parameter	lsn	text	Transaction slot pointer.
Output parameter	slot_states	oid	Transaction status. <ul style="list-style-type: none"> • 0 indicates that the transaction has been committed. • 1 indicates that the task is being executed. • 2 indicates that the rollback is in progress. • 3 indicates that the rollback is complete.

- `gs_stat_undo([bool init])`
Description: Collects undo statistics.
Return type: record

 **NOTE**

When rollback segments are stored in files in page storage mode, the following format is used.

Table 7-105 `gs_stat_undo` parameters

Category	Parameter	Type	Description
Input parameter	init	bool	(Optional) Specifies whether to clear statistics and restart statistics collection.
Output parameter	curr_used_zone_count	int	Number of used undo zones.
Output parameter	top_used_zones	text	Information about the first three undo zones with the maximum usage. The output format is as follows: <ul style="list-style-type: none"> • zoneId1: used size of zone 1. • zoneId2: used size of zone 2. • zoneId3: used size of zone 3.

Category	Parameter	Type	Description
Output parameter	curr_used_undo_size	int	Total size of the undo tablespace that is being used. The unit is MB.
Output parameter	undo_threshold	int	Calculation result of the value of the GUC parameter undo_space_limit_size x 80%. The unit is MB.
Output parameter	global_recycle_xid	xid	XID of the transaction recycled to the undo space. The undo records generated by the transaction whose XID is smaller than the value of XID are recycled.
Output parameter	oldest_xmin	xid	Oldest active transaction.
Output parameter	total_undo_chain_len	int8	Total length of all accessed undo chains.
Output parameter	max_undo_chain_len	int8	Maximum length of the accessed undo chain.
Output parameter	create_undo_file_count	uint32	Number of created undo files.
Output parameter	discard_undo_file_count	uint32	Number of deleted undo files.
Output parameter	info	text	<p>If the input parameter is false, suggestions on the undo_space_limit_size, undo_limit_size_per_transaction, and undo_retention_time parameters are provided.</p> <p>If the input parameter is true, init (clearing statistics) is required, and only 'The statistics have been initialized.' is displayed.</p>

Table 7-106 gs_undo_dump_parsepage_mv parameters

Category	Parameter	Type	Description
Input parameter	relpath	text	Relative path of the Ustore table data file, in the format of <i>Tablespace name/Database OID/relfilenode</i> . For example, base/16603/16384 . You can run the pg_relation_filepath('tablename') command to query the relative path.
Input parameter	blkno	int8	<ul style="list-style-type: none"> • -1: All block pages are parsed. • 0–MaxBlocNumber: A specified block page is parsed.
Input parameter	reltype	text	Table type. Currently, only the Ustore table is supported. The value is uheap .
Input parameter	rmem	Boolean	<ul style="list-style-type: none"> • false • true Currently, the value can only be false , indicating that the corresponding page is parsed from the disk file.
Output parameter	output	text	Absolute path of the parsing result file.

- **gs_undo_meta_dump_zone(zone_id int, read_memory boolean)**

Description: Parses undo zone metadata in an undo module.

Return type: record

 **NOTE**

When rollback segments are stored in files in page storage mode, the following format is used.

Table 7-107 gs_undo_meta_dump_zone parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID. <ul style="list-style-type: none"> • -1: All undo zones are queried. • 0–1048575: The undo zone metadata is queried based on the zone ID.

Category	Parameter	Type	Description
Input parameter	read_memory	Boolean	<ul style="list-style-type: none"> true: Data is read from the current memory. false: Data is read from the physical file.
Output parameter	zone_id	oid	Undo zone ID.
Output parameter	persist_type	oid	Persistence levels: <ul style="list-style-type: none"> 0: ordinary table 1: unlogged table 2: temporary table
Output parameter	insert	text	Position of the next undo record to be inserted.
Output parameter	discard	text	Position of the undo record that is recycled in common mode.
Output parameter	forcediscard	text	Position of the undo record that is forcibly recycled. Values smaller than the value of this parameter indicate that the record has been recycled.
Output parameter	lsn	text	Modifies the LSN of an undo zone.

Example:

```
gaussdb=# SELECT * FROM gs_undo_meta_dump_zone(-1,true);
zone_id | persist_type | insert | discard | forcediscard | lsn
```

```
-----+-----+-----+-----+-----+-----
0 | 0 | 244577 | 244577 | 244577 | 43967224
1 | 0 | 108 | 66 | 66 | 43967568
349525 | 1 | 24 | 24 | 24 | 0
349526 | 1 | 24 | 24 | 24 | 0
699050 | 2 | 24 | 24 | 24 | 0
699051 | 2 | 24 | 24 | 24 | 0
(6 rows)
```

- gs_undo_meta_dump_spaces(zone_id int, read_memory boolean)**
 Description: Parses metadata of an undo record space and a transaction slot space in an undo module.
 Return type: record

 NOTE

This system function supports only the rollback segments in page storage mode.

Table 7-108 gs_undo_meta_dump_spaces parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID. <ul style="list-style-type: none"> • -1: All undo zones are queried. • 0-1048575: The undo zone metadata is queried based on the zone ID.
Input parameter	read_memory	Boolean	<ul style="list-style-type: none"> • true: Data is read from the current memory. • false: Data is read from the physical file.
Output parameter	zone_id	int	Undo zone ID.
Output parameter	undorecord_space_tail	text	End position of an undo record space.
Output parameter	undorecord_space_head	text	Start position of an undo record space.
Output parameter	undorecord_space_lsn	text	Modifies the LSN of an undo record space.
Output parameter	undoslot_space_tail	text	End position of a transaction slot space.
Output parameter	undoslot_space_head	text	Start position of a transaction slot space.
Output parameter	undoslot_space_lsn	text	Modifies the LSN of a transaction slot space.

- `gs_undo_meta_dump_slot(zone_id int, read_memory boolean)`
Description: Parses transaction slot metadata in an undo module.
Return type: record

 **NOTE**

This system function supports only the rollback segments in page storage mode.

Table 7-109 `gs_undo_meta_dump_slot` parameters

Category	Parameter	Type	Description
Input parameter	<code>zone_id</code>	int	Undo zone ID. <ul style="list-style-type: none"> • -1: All undo zones are queried. • 0-1048575: The undo zone metadata is queried based on the zone ID.
Input parameter	<code>read_memory</code>	Boolean	<ul style="list-style-type: none"> • true: Data is read from the current memory. • false: Data is read from the physical file.
Output parameter	<code>zone_id</code>	int	Undo zone ID.
Output parameter	<code>allocate</code>	text	Allocation position of the undo transaction slot.
Output parameter	<code>recycle</code>	text	Recycling position of the undo transaction slot.
Output parameter	<code>frozen_xid</code>	text	Frozen XID, which is used to determine the visibility.
Output parameter	<code>global_frozen_xid</code>	text	Minimum frozen XID in the system. Transactions whose XID is smaller than the value of this parameter are visible.
Output parameter	<code>recycle_xid</code>	text	Recycled XID. Transactions whose XID is smaller than the value of this parameter are recycled.

Category	Parameter	Type	Description
Output parameter	global_recycle_xid	text	Minimum recycled XID in the system. Transactions whose XID is smaller than the value of this parameter are recycled.

- `gs_undo_translot_dump_slot(zone_id int, read_memory boolean)`

Description: Parses a transaction slot in an undo zone.

Return type: record

 **NOTE**

When rollback segments are stored in files in page storage mode, the following format is used.

Table 7-110 `gs_undo_translot_dump_slot` parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID. <ul style="list-style-type: none"> • -1: All undo zones are queried. • 0-1048575: The undo zone metadata is queried based on the zone ID.
Input parameter	read_memory	Boolean	<ul style="list-style-type: none"> • true: Data is read from the current memory. • false: Data is read from the physical file.
Output parameter	zone_id	oid	Undo zone ID.
Output parameter	slot_xid	text	Transaction ID.
Output parameter	start_undo_ptr	text	Position where the undo record is inserted at the start of the transaction corresponding to a slot.
Output parameter	end_undo_ptr	text	Position where the undo record is inserted at the end of the transaction corresponding to a slot.
Output parameter	slot_ptr	text	Position of a transaction slot.

Category	Parameter	Type	Description
Output parameter	slot_states	oid	Transaction state. <ul style="list-style-type: none"> ● 0: committed ● 1: being executed ● 2: being rolled back ● 3: rolled back

Example:

```
gaussdb=# SELECT * FROM gs_undo_translot_dump_slot(-1,true);
zone_id | slot_xid | start_undo_ptr | end_undo_ptr | slot_ptr | slot_states
-----+-----+-----+-----+-----+-----
      1 | 0000000000015758 | 0000000000000042 | 000000000000006C | 0000000000000038 |      0
(1 row)
```

- `gs_undo_translot_dump_xid(slot_xid xid, read_memory boolean)`
Description: Parses a transaction slot in an undo zone based on the XID.
Return type: record

NOTE

When rollback segments are stored in files in page storage mode, the following format is used.

Table 7-111 gs_undo_translot_dump_xid parameters

Category	Parameter	Type	Description
Input parameter	slot_xid	xid	Transaction ID to be queried.
Input parameter	read_memory	Boolean	<ul style="list-style-type: none"> ● true: Data is read from the current memory. ● false: Data is read from the physical file.
Output parameter	zone_id	oid	Undo zone ID.
Output parameter	slot_xid	text	Transaction ID.
Output parameter	start_undo_ptr	text	Position where the undo record is inserted at the start of the transaction corresponding to a slot.

Category	Parameter	Type	Description
Output parameter	end_undo_ptr	text	Position where the undo record is inserted at the end of the transaction corresponding to a slot.
Output parameter	slot_ptr	text	Position of a transaction slot.
Output parameter	slot_states	oid	Transaction state. <ul style="list-style-type: none"> • 0: committed • 1: being executed • 2: being rolled back • 3: rolled back

Example:

```
gaussdb=# SELECT * FROM gs_undo_translot_dump_xid('15758',false);
zone_id | slot_xid | start_undo_ptr | end_undo_ptr | slot_ptr | slot_states
-----+-----+-----+-----+-----+-----
      1 | 00000000000015758 | 0000000000000042 | 000000000000006C | 0000000000000038 |      0
(1 row)
```

- gs_undo_dump_record(undo_ptr bigint)

Description: Parses the undo record information of a specified URP.

Return type: record

 **NOTE**

When rollback segments are stored in files in page storage mode, the following format is used.

Table 7-112 gs_undo_dump_record parameters

Category	Parameter	Type	Description
Input parameter	undo_ptr	xid	Start position of the undo record to be parsed. The value is in decimal format.
Output parameter	undo_ptr	xid	Start position of the undo record to be parsed.
Output parameter	xactid	xid	Transaction ID.
Output parameter	cid	text	Command ID.

Category	Parameter	Type	Description
Output parameter	reloid	text	Relation OID.
Output parameter	relfilenode	text	Relfinode of the file.
Output parameter	utype	text	Undo record type.
Output parameter	blkprev	text	Position of the previous undo record in the same block.
Output parameter	blockno	text	Block number.
Output parameter	uoffset	text	Undo record offset.
Output parameter	prevurp	text	Position of the previous undo record.
Output parameter	payloadlen	text	Length of the undo record data.
Output parameter	oldxactid	text	Previous transaction ID.
Output parameter	partitionoid	text	Partition OID.
Output parameter	tablespace	text	Tablespace.
Output parameter	alreadyread_bytes	text	Length of the read undo record.
Output parameter	prev_undorec_len	text	Length of the previous undo record.

Category	Parameter	Type	Description
Output parameter	undoptr	xid	Start position of the undo record to be parsed.
Output parameter	xactid	xid	Transaction ID.
Output parameter	cid	text	Command ID.
Output parameter	reloid	text	Relation OID.
Output parameter	relfilenode	text	Relfinode of the file.
Output parameter	utype	text	Undo record type.
Output parameter	blkprev	text	Position of the previous undo record in the same block.
Output parameter	blockno	text	Block number.
Output parameter	uoffset	text	Undo record offset.
Output parameter	prevurp	text	Position of the previous undo record.
Output parameter	payloadlen	text	Length of the undo record data.
Output parameter	oldxactid	text	Previous transaction ID.
Output parameter	partitionoid	text	Partition OID.

 NOTE

When rollback segments are stored in files in page storage mode, the following format is used.

Table 7-114 gs_verify_undo_record parameters

Category	Parameter	Type	Description
Input parameter	type	text	Verification type. <ul style="list-style-type: none"> • 'urp': verifies all undo records in a specified URP range. • 'zone': verifies all undo records of all zones in a specified zone range.
Input parameter	start_idx	int8	Start position. <ul style="list-style-type: none"> • When type is set to 'urp', this parameter indicates the start position of undo records. • When type is set to 'zone', this parameter indicates the start undo zone ID.
Input parameter	end_idx	int8	End position. <ul style="list-style-type: none"> • When type is set to 'urp', this parameter indicates the end position of undo records. • When type is set to 'zone', this parameter indicates the end undo zone ID.
Input parameter	location	bool	<ul style="list-style-type: none"> • 0: memory verification • 1: disk verification Currently, this parameter can only be set to 1 .
Output parameter	zone_id	int8	Undo zone ID.
Output parameter	detail	text	Verification error information.

Example 1: Verify the undo record whose URP is 24.

```
gaussdb=# SELECT * FROM gs_verify_undo_record('urp', 24, 24, 1);
zone_id | detail
-----+-----
(0 rows)
```

Example 2: Verify all undo records from zone 0 to zone 2 on the disk.

```
gaussdb=# SELECT * FROM gs_verify_undo_record('zone', 0, 2, 1);
zone_id | detail
-----+-----
(0 rows)
```

 **NOTE**

If an error is reported when this view is called, contact Huawei technical support.

- `gs_verify_undo_slot(type, start_idx, end_idx, location)`

Description: Verifies undo transaction slots. Currently, only the disk verification mode is supported. Offline verification can be performed only when services are not running. Before the verification, you need to manually perform checkpoint flushing.

Return type: record

 **NOTE**

When rollback segments are stored in files in page storage mode, the following format is used.

Table 7-115 `gs_verify_undo_slot` parameters

Category	Parameter	Type	Description
Input parameter	<code>type</code>	text	Verification type. <ul style="list-style-type: none"> • 'zone': verifies all transaction slots of all zones in a specified zone range.
Input parameter	<code>start_idx</code>	int8	Start undo zone ID.
Input parameter	<code>end_idx</code>	int8	End undo zone ID.
Input parameter	<code>location</code>	bool	<ul style="list-style-type: none"> • 0: memory verification • 1: disk verification Currently, this parameter can only be set to 1 .
Output parameter	<code>zone_id</code>	int8	Undo zone ID.
Output parameter	<code>detail</code>	text	Verification error information.

Example: Verify all transaction slot records from zone 0 to zone 2 on the disk.

```
gaussdb=# SELECT * FROM gs_verify_undo_slot('zone', 0, 2, 1);
zone_id | detail
```

```
-----+-----
(0 rows)
```

 **NOTE**

If an error is reported when this view is called, contact Huawei technical support.

- `gs_verify_undo_meta(type, start_idx, end_idx, location)`

Description: Verifies undo metadata. Currently, only the disk verification mode is supported. Offline verification can be performed only when services are not running. Before the verification, you need to manually perform checkpoint flushing.

Return type: record

 **NOTE**

This system function supports only the rollback segments in page storage mode.

Table 7-116 `gs_verify_undo_meta` parameters

Category	Parameter	Type	Description
Input parameter	<code>type</code>	text	Verification type. The value of type can only be set to 'all'. <ul style="list-style-type: none"> • 'all': verifies all meta information of all zones in a specified zone range.
Input parameter	<code>start_idx</code>	int64	Start undo zone ID.
Input parameter	<code>end_idx</code>	int64	End undo zone ID.
Input parameter	<code>location</code>	bool	<ul style="list-style-type: none"> • 0: memory verification • 1: disk verification Currently, this parameter can only be set to 1.
Output parameter	<code>zone_id</code>	int64	Undo zone ID.
Output parameter	<code>detail</code>	text	Verification error information.

Example: Verify all meta information records from zone 0 to zone 2 on the disk.

```
gaussdb=# SELECT * FROM gs_verify_undo_meta('all', 0, 2, 1);
zone_id | detail
-----+-----
(0 rows)
```

 **NOTE**

If an error is reported when this view is called, contact Huawei technical support.

- `gs_async_rollback_worker_status()`
Description: Monitors the status of active asynchronous rollback threads.
Return type: record

Table 7-117 `gs_async_rollback_worker_status` parameters

Category	Parameter	Type	Description
Output parameter	<code>datid</code>	<code>oid</code>	Database ID.
Output parameter	<code>pid</code>	<code>int8</code>	Thread ID.
Output parameter	<code>sessionid</code>	<code>int8-</code>	Session ID.
Output parameter	<code>usesysid</code>	<code>oid</code>	ID of the user who initiates the thread.
Output parameter	<code>state</code>	<code>int=</code>	Thread status. 0: undefined 1: idle 2: running
Output parameter	<code>rollback_start_time</code>	<code>timestamptz</code>	Timestamp when a thread is started.
Output parameter	<code>idx</code>	<code>oid</code>	Index of an asynchronous rollback thread in the array.
Output parameter	<code>xid</code>	<code>xid</code>	XID of the transaction that is being rolled back.
Output parameter	<code>progress</code>	<code>text</code>	Rollback progress of the transaction (number of undo records that have been rolled back/total number of undo records, in percentage).

- `gs_async_rollback_xact_status()`
Description: Monitors the hash table of asynchronous rollback tasks.

Return type: record

Table 7-118 gs_async_rollback_xact_status parameters

Category	Parameter	Type	Description
Output parameter	xid	xid	XID of the transaction that requires asynchronous rollback.
Output parameter	start_undo_ptr	xid	Pointer to the start undo record of the transaction.
Output parameter	end_undoptr	xid	Pointer to the end undo record of the transaction.
Output parameter	dbid	uint32	ID of the database where the transaction is located.
Output parameter	slot_ptr	xid	Pointer to the transaction slot corresponding to the transaction.
Output parameter	launched	bool	Checks whether there is an active asynchronous rollback thread.

- gs_undo_recycler_status()
Description: Monitors the status of asynchronous recycling threads.
Return type: record

Table 7-119 gs_undo_recycler_status parameters

Category	Parameter	Type	Description
Output parameter	datid	oid	Database ID.
Output parameter	pid	int8	Thread ID.

Category	Parameter	Type	Description
Output parameter	sessionid	int8	Session ID.
Output parameter	usesysid	oid	ID of the user who initiates the thread.
Output parameter	state	int	Thread status. 0: undefined 1: idle 2: running
Output parameter	backend_start	timestamptz	Timestamp when a thread is started.
Output parameter	total_recycle_time	xid	Total recycling time.
Output parameter	max_recycle_time	xid	Maximum recycling time.
Output parameter	total_recycle_size	xid	Total recycled space.
Output parameter	total_recycle_count	xid	Total number of recycling times.
Output parameter	recycle_sleep_count	xid	Number of sleep times.
Output parameter	recycle_sleep_time	xid	Total sleep time.
Output parameter	max_recycle_sleep_time	xid	Maximum sleep time.
Output parameter	last_recycle_timestamp	timestamptz	Timestamp of the last successful recycling.

Category	Parameter	Type	Description
Output parameter	last_update_global_recycle_xid_timestamp	timestampz	Timestamp of the last global recycling transaction.

- gs_undo_launcher_status()**
 Description: Monitors the status of asynchronous rollback launcher threads.
 Return type: record

Table 7-120 gs_undo_launcher_status parameters

Category	Parameter	Type	Description
Output parameter	datid	oid	Database ID.
Output parameter	pid	int64	Thread ID.
Output parameter	sessionid	int64	Session ID.
Output parameter	usesysid	oid	ID of the user who initiates the thread.
Output parameter	state	int32	Thread status. 0: undefined 1: idle 2: running
Output parameter	backend_start	timestampz	Timestamp when a thread is started.
Output parameter	total_async_rollback_task_count	uint64	Total number of asynchronous rollback tasks initiated after the database on the local node is started.
Output parameter	average_async_rollback_time	uint64	Average duration of an asynchronous rollback task.
Output parameter	max_async_rollback_time	uint64	Maximum duration of an asynchronous rollback task.

Category	Parameter	Type	Description
Output parameter	min_async_rollback_time	uint64	Minimum duration of an asynchronous rollback task.

7.6.26.14 Other Functions

- pgxc_pool_check()**
Description: Checks whether the connection data buffered in the pool is consistent with pgxc_node.
Return type: Boolean
- pgxc_pool_reload()**
Description: Updates the connection information buffered in the pool.
Return type: Boolean
- reload_active_coordinator()**
Description: Updates the connection information buffered in the pool for all active CNs.
Return type: void
- pgxc_lock_for_backup()**
Description: Locks a cluster for taking backup that would be restored on the new node to be added.
Return type: Boolean

NOTE

pgxc_lock_for_backup locks a cluster before `gs_dump` or `gs_dumpall` is used to back up the cluster. After a cluster is locked, operations changing the system structure are not allowed. This function does not affect DML statements.

- pg_pool_validate(clear bool, node_name text)**
Description: Displays invalid connections in the pooler between the CN and node_name. When the value of **clear** is **true**, invalid connections are cleared.
Return type: record
- pgxc_pool_connection_status()**
Description: Checks whether the pooler connection status is **normal**.
Return type: Boolean
- pg_nodes_memory()**
Description: Queries the memory usage of all nodes.
Return type: record
- table_skewness(text)**
Description: Queries the percentage of table data among all nodes.
Parameter: Indicates that the type of the name of the to-be-queried table is text.
Return type: record

- table_skewness(text, text, text)**

Description: Queries the percentage of a specified column in the table data among all nodes.

Parameters: name of the table to be queried, specified column name, and number of records in the specified table. The default value is **0**, indicating that all records are queried. All parameters are of the text type.

Return type: record

Return value description: Node ID, number of data rows in a specified column, and percentage of the data volume of the current node to the total data volume

Example:

```
-- Return the distribution of the first five rows of data in the a column of the t table on a node.
gaussdb=# SELECT table_skewness('t', 'a',5);
table_skewness
-----
(1,3,60.000%)
(2,2,40.000%)
(2 rows)

-- Return the distribution of all data in the a column of the t table on a node.
gaussdb=# SELECT table_skewness('t', 'a');
table_skewness
-----
(1,7,70.000%)
(2,2,20.000%)
(0,1,10.000%)
(3 rows)
```
- table_skewness_with_schema(text, text)**

Description: Checks the proportion of table data on all nodes. The function is the same as that of **table_skewness(text)**.

text indicates that the types of the schema name and table name for the table to be queried are both text.

Return type: record
- table_data_skewness(colrecord, type)**

Description: Queries the node where the table data is located.

Parameter description:

colrecord: column name record of the table to be queried. The value is of the record type.

type: hash distribution type.

Return type: smallint

Example:

```
-- Return the node where the index column data of the 'test1' table is located.
gaussdb=# SELECT table_data_skewness(row(index), 'R') FROM test1;
table_data_skewness
-----
4
3
1
2
(4 rows)
```
- table_distribution(schemaname text, tablename text)**

Description: Queries the storage space occupied by a specified table on each node.

text indicates that the types of the schema name and table name for the table to be queried are both text.

Return type: record

 **NOTE**

- To query the storage distribution of a specified table by using this function, you must have the SELECT permission for the table.
- The performance of **table_distribution** is better than that of **table_skewness**. In the scenario with a large amount of data, **table_distribution** is recommended.
- When you use **table_distribution** and want to view the space usage, you can use **dnsize** or **(sum(dnsize) over ())** to view the percentage.

- **table_distribution()**

Description: Queries the storage distribution of all tables in the current database.

Return type: record

 **NOTE**

- This function involves the query for information about all tables in the database. To execute this function, you must have the administrator rights.
- Based on the **table_distribution()** function, GaussDB provides the **PGXC_GET_TABLE_SKEWNESS** view as an alternative way to query data skew. You are advised to use this view when the number of tables in the database is less than 10000.

- **plan_seed()**

Description: Obtains the seed value of the previous query statement (internal use).

Return type: int

- **pg_stat_get_env()**

Description: Obtains the environment variable information of the current node. Only users with the sysadmin or monitor admin permission can access the environment variable information.

Return type: record

Example:

```
gaussdb=# SELECT pg_stat_get_env();
```

```
pg_stat_get_env
```

```
-----  
(coordinator1,localhost,144773,49100,/data1/GaussDB_Kernel_TRUNK/install,/data1/  
GaussDB_Kernel_TRUNK/install/data/coordinator1,gs_log)  
(1 row)
```

- **pg_catalog.plancache_clean()**

Description: Clears the global plan cache that is not used on nodes.

Return type: Boolean

- **pg_stat_get_thread()**

Description: Provides thread status information on the current node. Users with the sysadmin or monitor admin permission can view information about all threads. Common users can view only their own thread information.

Return type: record

- `pgxc_get_os_threads()`
Description: Provides thread status information about all normal nodes in the entire cluster.
Return type: record
 - `pg_stat_get_sql_count()`
Description: Provides the counts of the SELECT, UPDATE, INSERT, DELETE, and MERGE INTO statements executed on the current node. Users with the `sysadmin` or `monitor admin` permission can view information about all users. Common users can view only their own statistics.
Return type: record
 - `pgxc_get_sql_count()`
Description: Provides the counts of the SELECT, UPDATE, INSERT, DELETE, and MERGE INTO statements executed on all the nodes in the entire cluster.
Return type: record
 - `pgxc_get_node_env()`
Description: Provides the environment variable information about all nodes in a cluster.
Return type: record
 - `pgxc_disaster_read_set(text)`
Description: Configures node information about the DR cluster on ETCD. Only the DR cluster is available and can be called only by initial users.
Return type: Boolean
 - `pgxc_disaster_read_init()`
Description: Initializes readable DR resources and status information. Only the DR cluster is available and can be called only by initial users.
Return type: Boolean
 - `pgxc_disaster_read_clear()`
Description: Clears readable DR resources and status information. Only the DR cluster is available and can be called only by initial users.
Return type: Boolean
 - `pgxc_disaster_read_status()`
Description: Provides node information about the DR cluster. This function is available only for the DR cluster.
Return type: record
 - `gs_switch_relfilenode()`
Description: Exchanges meta information of two tables or partitions. (This is only used for the redistribution tool. An error message is displayed when the function is directly used by users).
Return type: int
-  **NOTE**
- This function may cause clearing of statistics. You are advised to collect statistics again after this function is called.
- `pg_catalog.plancache_clean()`
Description: Clears the global plan cache that is not used on the current node.

Return type: Boolean

- DBE_PERF.global_plancache_clean()

Description: Clears the global plan cache that is not used on all nodes.

Return type: Boolean

- copy_error_log_create()

Description: Creates the error table (**public.pgxc_copy_error_log**) required for creating the COPY FROM error tolerance mechanism.

Return type: Boolean

 NOTE

- This function attempts to create the **public.pgxc_copy_error_log** table. For details about the table, see [Table 7-121](#).
- In addition, it creates a B-tree index on the **relname** column and executes **REVOKE ALL on public.pgxc_copy_error_log FROM public** to manage permissions on the error table (the permissions are the same as those of the COPY statement).
- **public.pgxc_copy_error_log** is a row-store table. Therefore, this function can be executed and COPY error tolerance is available only when row-store tables can be created in the cluster. Row-store tables cannot be created in the cluster if the GUC parameter **enable_hadoop_env** is set to **on** (by default, this parameter set to **off** for GaussDB).
- Same as the error table and the COPY statement, the function requires sysadmin or higher permissions.
- If the **public.pgxc_copy_error_log** table or the **copy_error_log_relname_idx** index exists before the function creates it, the function will report an error and roll back.

Table 7-121 Error table public.pgxc_copy_error_log

Column	Type	Description
relname	character varying	Table name, in the form of <i>Schema name.Table name</i> .
begintime	timestamp with time zone	Time when a data format error was reported.
filename	character varying	Name of the source data file where a data format error occurs.
lineno	bigint	Number of the row where a data format error occurs in a source data file.
rawrecord	text	Raw record of a data format error in the source data file.
detail	text	Error details.

- pg_stat_get_data_senders()

Description: Provides detailed information about the data-copy sender thread active at the moment.

Return type: record

- `textlen()`
Description: Provides the method of querying the logical length of text.
Return type: int
- `threadpool_status()`
Description: Displays the status of worker threads and sessions in the thread pool.
Return type: record
- `get_local_active_session()`
Description: Provides sampling records of historical active sessions stored in the memory by current node. Users with the `sysadmin` or `monitor admin` permission can view all historical active session records of the current node. Common users can view the historical active session records of the current session.
Return type: record
- `dbe_perf.get_global_active_session()`
Description: Provides sampling records of the historical active sessions stored in the memory of all nodes. The **event_start_time**, **current_xid**, and **top_xid** columns are added to GaussDB Kernel 505.0. After GaussDB Kernel is upgraded to GaussDB Kernel 505.0 or later, the columns cannot be queried during the upgrade observation period.
Return type: record
- `dbe_perf.get_global_gs_asp(timestamp,timestamp)`
Description: Provides sampling records of the historical active sessions stored in the `gs_asp` system catalog of all nodes. The **event_start_time**, **current_xid**, and **top_xid** columns are added to GaussDB Kernel 505.0. After GaussDB Kernel is upgraded to GaussDB Kernel 505.0 or later, the columns cannot be queried during the upgrade observation period.
Return type: record
- `get_wait_event_info()`
Description: Provides detailed information about the wait event.
Return type: record
- `dbe_perf.get_datanode_active_session(text)`
Description: Provides sampling records of historical active sessions stored in the memory of DN, which is queried from CN. The **event_start_time**, **current_xid**, and **top_xid** columns are added to GaussDB Kernel 505.0. After GaussDB Kernel is upgraded to GaussDB Kernel 505.0 or later, the columns cannot be queried during the upgrade observation period.
Return type: record

Note: This function queries the records in the `local_active_session` view on the target DN and matches the records with those in the `local_active_session` view on all CNs to obtain the query string. Therefore, a large amount of memory is occupied.
- `dbe_perf.get_datanode_active_session_hist(text,timestamp,timestamp)`
Description: Provides sampling records of historical active sessions stored in the `gs_asp` system catalog of DN, which is queried from CN. The **event_start_time**, **current_xid**, and **top_xid** columns are added to GaussDB

Kernel 505.0. After GaussDB Kernel is upgraded to GaussDB Kernel 505.0 or later, the columns cannot be queried during the upgrade observation period.

Return type: record

Note: This function queries the `gs_asp` records of a specified period on the target DN. If the period is specified too long, too many records will be queried, which takes a long time.

- `generate_wdr_report(bigint, bigint, cstring, cstring, cstring)`

Description: Generates a system diagnosis report based on two snapshots. By default, the initial user or monitor administrator can access the report. The result can be queried only in the system database but cannot be queried in the user database.

Return type: text

Table 7-122 generate_wdr_report parameter description

Parameter	Description	Range
<code>begin_snap_id</code>	Snapshot ID that starts the diagnosis report period.	N/A
<code>end_snap_id</code>	Snapshot ID that ends the diagnosis report period. By default, the value of end_snap_id is greater than that of begin_snap_id .	N/A
<code>report_type</code>	Specifies the type of the generated report.	<ul style="list-style-type: none"> • summary • detail • all: Both summary and detail are included.
<code>report_scope</code>	Specifies the scope for a report to be generated.	<ul style="list-style-type: none"> • cluster: database-level information • node: node-level information
<code>node_name</code>	<ul style="list-style-type: none"> • When report_scope is set to node, set this parameter to the name of the corresponding node. • If report_scope is set to cluster, this parameter can be omitted or set to NULL. 	<ul style="list-style-type: none"> • node: node name in GaussDB. • cluster: This value is omitted, left blank or set to NULL.

- `create_wdr_snapshot()`

Description: Manually generates system diagnosis snapshots. This function requires the `sysadmin` permission and can be executed only on the CCN.

Return type: text

- `kill_snapshot()`
Description: Kills the WDR snapshot backend thread. Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the `gs_role_replication` permission of the built-in role.
Return type: void
- `dbe_perf.generate_asp_report(start_time timestamp with time zone, end_time timestamp with time zone, datanode text, slot_count bigint)`
Description: Generates ASP diagnosis reports based on timestamps and node information, which can be accessed by the monadmin user. **slot_count** indicates the number of time segments for displaying metrics.
Return type: text
- `generate_asp_report(start_time timestamp with time zone, end_time timestamp with time zone, slot_count bigint)`
Description: Generates ASP diagnosis reports based on timestamps, which can be accessed by the monadmin user. **slot_count** indicates the number of time segments for displaying metrics.
Return type: text
- `dbe_perf.get_active_session_profile(start_ts timestamp with time zone, end_ts timestamp with time zone, need_final boolean)`
Description: Queries data in the ASP memory and disk based on timestamps. **need_final** specifies whether to query blocking information. The default value is **false**. The **event_start_time**, **current_xid**, and **top_xid** columns are added to GaussDB Kernel 505.0. After GaussDB Kernel is upgraded to GaussDB Kernel 505.0 or later, the columns cannot be queried during the upgrade observation period.
Return type: record
- `capture_view_to_json(text,integer)`
Description: Saves the view result to the directory specified by GUC: **perf_directory**. If **is_crossdb** is set to **1**, the view is accessed once for all databases. If the value of **is_crossdb** is **0**, the current database is accessed only once. Only users with the sysadmin or monitor admin permission can execute this function.
Return type: int
- `reset_unique_sql(text,text,bigint)`
Description: Clears the Unique SQL statements in the memory of CN/DN. (The sysadmin or monitor admin permission is required.)
Return type: Boolean

Table 7-123 reset_unique_sql parameter description

Parameter	Type	Description
scope	text	Clearance scope type. The options are as follows: 'GLOBAL' : Clears all CNs/DNs. If the value is 'GLOBAL' , this function can be executed only on the CN. 'LOCAL' : Clears the current node.
clean_type	text	'BY_USERID' : Unique SQL statements are cleared based on user IDs. 'BY_CNID' : Unique SQL statements are cleared based on CN IDs. 'ALL' : All data is cleared.
clean_value	int8	Clearance value corresponding to the clearance type. If the second parameter is set to ALL , the third parameter does not take effect and can be set to any value.

- `wdr_xdb_query(db_name_str text, query text)`
Description: Provides the capability of executing local cross-database queries. For example, when logging to the **testdb** database, access tables in the **test** database. Only the initial user has the permission to run this command.
`SELECT col1 from wdr_xdb_query('dbname=test','select col1 from t1') as dd(col1 int);`
Return type: record
- `pg_wlm_jump_queue(pid int)`
Description: Moves a task to the top of the queue of CN.
Return type: Boolean
 - **true**: success
 - **false**: failure
- `gs_wlm_switch_cgroup(pid int, cgroup text)`
Description: Moves a job to another Cgroup to change the job priority.
Return type: Boolean
 - **true**: success
 - **false**: failure
- `pv_session_memctx_detail(threadid tid, MemoryContextName text)`
Description: Records information about the memory context **MemoryContextName** of the thread **tid** into the **threadid_timestamp.log** file in the `$GAUSSLOG/gs_log/${node_name}/dumppmem` directory. **threadid** can be obtained from **sessid** in the **PV_SESSION_MEMORY_DETAIL** table. In the officially released version, only the **MemoryContextName** that is an empty string (two single quotation marks indicate that the input is an empty string) is accepted. In this case, all memory context information is recorded. Otherwise, no operation is performed. This function can be executed only by the administrator.

Return type: Boolean

- **true**: success
- **false**: failure

- `pg_shared_memctx_detail(MemoryContextName text)`

Description: Records information about the memory context

MemoryContextName into the `threadid_timestamp.log` file in the `GAUSSLOG/gs_log/{node_name}/dumppmem` directory. Calling this function in the officially released version does not involve any operation. Only the administrator can execute this function.

Return type: Boolean

- **true**: success
- **false**: failure

- `local_aio_completer_stat()`

Description: Displays statistics about the AIO Completer thread in the instance.

Return type: record

Table 7-124 Return values of `local_aio_completer_stat`

Parameter	Type	Description
<code>node_name</code>	text	Name of the current instance.
<code>tid</code>	int8	ID of the AIO Completer thread.
<code>thread_type</code>	text	AIO Completer thread type (read or write).
<code>aio_submitted_num</code>	int8	Number of committed asynchronous I/O requests of the AIO Completer thread.
<code>aio_completed_num</code>	int8	Number of completed asynchronous I/O requests of the AIO Completer thread.
<code>aio_incompleted_num</code>	int8	Number of asynchronous I/O requests that are not completed of the AIO Completer thread.
<code>slot_count_left</code>	int8	Indicates the number of idle slots.

- `local_aio_slot_usage_status()`

Description: Displays statistics about asynchronous I/O commit slots in the instance.

Return type: record

Table 7-125 Return values of `local_aio_slot_usage_status`

Parameter	Type	Description
<code>node_name</code>	text	Name of the current instance.

Parameter	Type	Description
slot_id	int4	Slot ID.
slot_type	char	Slot type. The value can be r (read) or w (write).
status	bool	Slot usage status.
buffer_id	int8	Buffer ID corresponding to the slot.
relfilenode_blocknum	text	Position of the physical page where the buffer corresponding to the slot is located.
lsn	int8	LSN corresponding to the page.
submitted_time	int8	Time when a page is committed asynchronously.
elapsed_time	int8	Waiting time of the page.

- remote_aio_completer_stat()**
 Description: Displays statistics about the AIO Completer thread in other instances (used only on CNs).
 Return type: record

Table 7-126 Return values of remote_aio_completer_stat

Parameter	Type	Description
node_name	text	Name of another instance.
tid	int8	ID of the AIO Completer thread.
thread_type	text	AIO Completer thread type (read or write).
aio_submitted_num	int8	Number of committed asynchronous I/O requests of the AIO Completer thread.
aio_completed_num	int8	Number of completed asynchronous I/O requests of the AIO Completer thread.
aio_incompleted_num	int8	Number of asynchronous I/O requests that are not completed of the AIO Completer thread.
slot_count_left	int8	Indicates the number of idle slots.

- remote_aio_slot_usage_status()**
 Description: Displays statistics about asynchronous I/O commit slots in other instances.
 Return type: record

Table 7-127 Return values of remote_aio_slot_usage_status

Parameter	Type	Description
node_name	text	Name of another instance.
slot_id	int4	Slot ID.
slot_type	char	Slot type. The value can be r (read) or w (write).
status	bool	Slot usage status.
buffer_id	int8	Buffer ID corresponding to the slot.
relfilenode_blocknum	text	Position of the physical page where the buffer corresponding to the slot is located.
lsn	int8	LSN corresponding to the page.
submitted_time	int8	Time when a page is committed asynchronously.
elapsed_time	int8	Waiting time of the page.

- `gs_get_io_type()`
Description: Displays the I/O mode of the instance.
Return type: text
 - **BIO**: The instance is running in BIO mode (ADIO is disabled).
 - **DIO**: The instance is running in DIO mode (ADIO is enabled).
 - **BIO->DIO (In progress)**: The current instance is switching from the BIO mode to the DIO mode.
- `local_bgwriter_stat()`
Description: Displays the information about pages flushed by the bgwriter thread of this instance, number of pages in the candidate buffer chain, and buffer elimination information.
Return type: record
- `local_candidate_stat()`
Description: Displays the number of pages in the candidate buffer chain of this instance and buffer elimination information, including the normal buffer pool and segment buffer pool.
Return type: record
- `local_ckpt_stat()`
Description: Displays the information about checkpoints and flushing pages of the current instance.
Return type: record
- `local_double_write_stat()`
Description: Displays the doublewrite file status of the current instance.
Return type: record

Table 7-128 local_double_write_stat parameters

Parameter	Type	Description
node_name	text	Instance name
curr_dwn	int8	Sequence number of the doublewrite file
curr_start_page	int8	Start page for restoring the doublewrite file
file_trunc_num	int8	Number of times that the doublewrite file is reused
file_reset_num	int8	Number of reset times after the doublewrite file is full
total_writes	int8	Total number of I/Os of the doublewrite file
low_threshold_writes	int8	Number of I/Os for writing doublewrite files with low efficiency (the number of I/O flushing pages at a time is less than 16)
high_threshold_writes	int8	Number of I/Os for writing doublewrite files with high efficiency (the number of I/O flushing pages at a time is more than 421)
total_pages	int8	Total number of pages that are flushed to the doublewrite file area
low_threshold_pages	int8	Number of pages that are flushed with low efficiency
high_threshold_pages	int8	Number of pages that are flushed with high efficiency
file_id	int8	ID of the current doublewrite file.

- local_single_flush_dw_stat()**
Description: Displays the elimination of dual-write files on a single page in the instance.
Return type: record
- local_pagewriter_stat()**
Description: Displays the page flushing information and checkpoint information of the current instance.
Return type: record
- local_redo_stat()**
Description: Displays the replay status of the current standby instance.
Return type: record
Note: The returned replay status includes the current replay position and the replay position of the minimum restoration point.
- local_recovery_status()**
Description: Displays log flow control information about the primary and standby nodes.

- Return type: record
- `local_rto_status()`
Description: Displays log flow control information about the primary and standby nodes.
Return type: record
- `gs_wlm_switch_cgroup(sess_id int8, cgroup name)`
Description: Switches the Cgroup of a specified session.
Return type: record
- `comm_client_info()`
Description: Queries active client connections of a single node. For details about the returned result, see [COMM_CLIENT_INFO](#).
Return type: SETOF record
- `pg_get_flush_lsn()`
Description: Returns the position of the Xlog flushed from the current node.
Return type: text
- `pg_get_sync_flush_lsn()`
Description: Returns the position of the Xlog flushed by the majority on the current node.
Return type: text
- `pgxc_wlm_rebuild_user_resource_pool()`
Description: Rebuilds user and resource pool cache information. Only the system administrator can execute this function.
Return type: Boolean
- `locktag_decode(locktag text)`
Description: Parses lock details from **locktag**.
Example:

```
gaussdb=# select locktag_decode('271b:0:0:0:6');
          locktag_decode
-----
locktype:transactionid, transactionid:10011
(1 row)
```

Return type: text
- `disable_conn(disconn_mode text, host text, port integer)`
Description: Specifies that the CM Agent processes commands delivered by the CM Server. When a DN is selected as the primary DN, it is configured to reject connections to all DNs, forcibly connect to a DN, or connect to all DNs in polling mode. Only the initial user and system administrator can call this function.
Return type: void

Table 7-129 disable_conn parameter description

Parameter	Type	Description
disconn_mode	text	DN connection mode: <ul style="list-style-type: none"> • 'prohibit_connection': rejects to connect to all DNs. • 'specify_connection': forcibly connects to a DN. • 'polling_connection': connects to all DNs in polling mode.
host	text	IP address of the DN
port	integer	Port number of the DN

- `db_perf.get_global_full_sql_by_timestamp(start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)`

Description: Obtains full SQL information about a cluster. The result can be queried only in the system database but cannot be queried in the user database.

Return type: record

Table 7-130 db_perf.get_global_full_sql_by_timestamp parameter description

Parameter	Type	Description
start_timestamp	timestamp with time zone	Start point of the SQL start time range.
end_timestamp	timestamp with time zone	End point of the SQL start time range.

- `db_perf.get_global_slow_sql_by_timestamp(start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)`

Description: Obtains cluster-level slow SQL information. The result can be queried only in the system database but cannot be queried in the user database.

Return type: record

Table 7-131 db_perf.get_global_slow_sql_by_timestamp parameter description

Parameter	Type	Description
start_timestamp	timestamp with time zone	Start point of the SQL start time range.
end_timestamp	timestamp with time zone	End point of the SQL start time range.

- `statement_detail_decode(detail text, format text, pretty boolean)`
 Description: Parses the **details** column in a full or slow SQL statement. The result can be queried only in the system database but cannot be queried in the user database.
 Return type: text

Table 7-132 `statement_detail_decode` parameter description

Parameter	Type	Description
detail	text	Set of events generated by the SQL statement (unreadable).
format	text	Parsing output format. The value is plaintext .
pretty	Boolean	Specifies whether to display the text in pretty format when format is set to plaintext . The options are as follows: <ul style="list-style-type: none"> The value true indicates that <code>\n</code> is used to separate events. The value false indicates that events are separated by commas (,).

- `pgxc_get_csn(tid)`
 Description: Returns the transaction commit sequence number (CSN) corresponding to a given transaction ID.
 Return type: int8
- `pgxc_get_csn(tid, bucketid)`
 Description: Returns the transaction commit sequence number (CSN) corresponding to the transaction ID of the specified bucket ID. The input parameter **bucketid** indicates the physical bucket ID of the hash bucket table. For an ordinary table, the value is **-1**.
 Return type: int8
- `get_global_user_transaction()`
 Description: Returns transaction information about each user on all nodes.
 Return type: node_name name, username name, commit_counter bigint, rollback_counter bigint, resp_min bigint, resp_max bigint, resp_avg bigint, resp_total bigint, bg_commit_counter bigint, bg_rollback_counter bigint, bg_resp_min bigint, bg_resp_max bigint, bg_resp_avg bigint, and bg_resp_total bigint
- `pg_collation_for()`
 Description: Returns the sorting rule corresponding to the input parameter string.
 Parameter: any (Explicit type conversion is required for constants.)
 Return type: text
- `pgxc_unlock_for_sp_database(name Name)`
 Description: Releases a specified database lock.

- Parameter: database name

Return type: Boolean

 - `pgxc_lock_for_sp_database(name Name)`

Description: Locks a specified database.

Parameter: database name

Return type: Boolean
 - `pgxc_unlock_for_transfer(name Name)`

Description: Releases the lock used for data transmission (data redistribution).

Parameter: database name

Return type: Boolean
 - `pgxc_lock_for_transfer(name Name)`

Description: Locks the database for data transmission (data redistribution).

Parameter: database name

Return type: Boolean
 - `gs_comm_proxy_thread_status()`

Description: Collects statistics on data packets sent and received by the proxy communications library **comm_proxy** when a user-mode network is configured for the cluster. This function is not supported in the current version.

Parameter: nan

Return type: record
 - `gs_catalog_attribute_records()`

Description: Returns the definition of each field in a specified system catalog. Only ordinary system catalogs whose OIDs are less than 10000 are supported. Indexes and TOAST tables are not supported.

Parameter: OID of the system catalog

Return type: record
 - `dynamic_func_control(scope text, function_name text, action text, "{params}" text[])`

Description: Dynamically enables built-in functions. Currently, only full SQL statements can be dynamically enabled.

Return type: record

Table 7-133 Parameter description of `dynamic_func_control`

Parameter	Type	Description
scope	text	Scope where the function is to be dynamically enabled. Currently, only GLOBAL and LOCAL are supported.
function_name	text	Function name. Currently, only STMT is supported.

Parameter	Type	Description
action	text	<p>When function_name is set to STMT, the value of action can only be TRACK, UNTRACK, LIST, or CLEAN.</p> <ul style="list-style-type: none"> • TRACK: records the full SQL information of normalized SQL statements. • UNTRACK: cancels the recording of full SQL information of normalized SQL statements. • LIST: lists normalized SQL information that is recorded in the current track. • CLEAN: cleans normalized SQL information that is recorded in the current track.
params	text[]	<p>When function_name is set to STMT, the parameters corresponding to different actions are set as follows:</p> <ul style="list-style-type: none"> • TRACK: '{"Normalized SQLID", "L0/L1/L2"}' • UNTRACK: '{"Normalized SQLID"}' • LIST: '{}' • CLEAN: '{}'

- `gs_parse_page_bypath(path text, blocknum bigint, relation_type text, read_memory boolean)`

Description: Parses a specified table page and returns the path for storing the parsed content.

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.

Table 7-134 gs_parse_page_bypath parameters

Parameter	Type	Description
path	text	<ul style="list-style-type: none"> For an ordinary table or a segment-page ordinary table, the relative path is <i>Tablespace name/Database OID/Relfilenode of the table (physical file name)</i>, for example, base/16603/16394. For the visibility map of an ordinary table, the relative path is <i>Tablespace name/Database OID/Visibility map of the ordinary table</i>. For example, base/16603/16394_vm. For clog files, the parsed content is stored in the pg_clog directory. For example: 000000000000. For csnlog files, the parsed content is stored in the pg_csnlog directory. For example: 000000000000. For undo record files, the relative path is undo/UNDOPERSISTENCE/zonidid.segno in the undo directory. Example: undo/permanent/00000.0000009. For undo meta files, the relative path is undo/UNDOPERSISTENCE/zonidid.meta.segno in the undo directory. Example: undo/permanent/00000.meta.0000004. You can run the pg_relation_filepath(table_name text) command to query the relative path of the table file. To obtain the path of the partitioned table, view the pg_partition system catalog and call pg_partition_filepath(partition_oid). Valid path formats are as follows: <ul style="list-style-type: none"> global/relNode base/dbNode/relNode pg_tblspc/spcNode/version_dir/dbNode/relNode

Parameter	Type	Description
blocknum	bigint	<ul style="list-style-type: none"> • -1: Information about all blocks (forcibly parsed from disks) • 0-MaxBlockNumber: Information about the corresponding block • For B-tree/UB-tree indexes, 0 indicates the index meta-page. • For undo record files, the logical block number is used. The block number of the corresponding file is greater than or equal to segno x 128 and less than (segno + 1) x 128. • For undo meta files, the logical block number is used. The block number of the corresponding file is greater than or equal to segno x 4 and less than (segno + 1) x 4.
relation_type	text	<ul style="list-style-type: none"> • heap: Astore table • uheap: Ustore table • btree: B-tree index • ubtree: UB-tree index • vm: visibility map of the Astore ordinary table • clog (commit log): transaction status log • csnlog (commit sequence number log): snapshot timestamp log • undo_slot: transaction slot information • undo_record: undo record information • indexurq: indexurq page
read_memory	Boolean	<ul style="list-style-type: none"> • false: The system parses the page from the disk file. • true: The system attempts to parse the page from the shared buffer. If the page does not exist in the shared buffer, the system parses the page from the disk file.

Example:

```
# Parse the information of all pages in the B-tree index file.
# Before calling the function, ensure that the file path exists based on the parameter description.
gaussdb=# SELECT gs_parse_page_bypath('base/16603/16394', -1, 'btree', false);
gs_parse_page_bypath
-----
/gs_log_dir/dump/1663_16603_16394_-1.page
(1 row)

# Parse the visibility result of all blocks in the visibility map file.
gaussdb=# SELECT gs_parse_page_bypath('base/12828/16771_vm', -1, 'vm', false);
gs_parse_page_bypath
```

```
-----  
/gs_log_dir/dump/1663_12828_16771_-1_vm.page  
(1 row)  
  
# Parse the commit log of block 0 in the Clog file.  
gaussdb=# SELECT gs_parse_page_bypath('000000000000', 0, 'clog', false);  
           gs_parse_page_bypath  
-----  
/gs_log_dir/dump/000000000000.clog  
(1 row)
```

The following is an example of an exception error:

```
# An error is reported when the value of the block number exceeds the value range.  
gaussdb=# SELECT gs_parse_page_bypath('base/12828/16777', -10, 'heap', false);  
ERROR:  Blocknum should be between -1 and 4294967294.  
CONTEXT:  referenced column: gs_parse_page_bypath
```

- `gs_xlogdump_lsn(start_lsn text, end_lsn text)`
Description: Parses Xlogs within the specified LSN range and returns the path for storing the parsed content. You can use `pg_current_xlog_location()` to obtain the current Xlog position.
Parameters: LSN start position and LSN end position
Return type: text
Note: Only the system administrator or O&M administrator can execute this function.
- `gs_xlogdump_xid(c_xid xid)`
Description: Parses Xlogs of a specified XID and returns the path for storing the parsed content. You can use `txid_current()` to obtain the current XID.
Parameter: XID
Return type: text
Note: Only the system administrator or O&M administrator can execute this function.
- `gs_xlogdump_tablepath(path text, blocknum bigint, relation_type text)`
Description: Parses logs corresponding to a specified table page and returns the path for storing the parsed content.
Return type: text
Note: Only the system administrator or O&M administrator can execute this function.

Table 7-135 gs_xlogdump_tablepath parameters

Parameter	Type	Description
path	text	<ul style="list-style-type: none"> For an ordinary table or a segment-page ordinary table, the relative path is <i>Tablespace name/Database OID/Relfilenode of the table (physical file name)</i>. for example, base/16603/16394. For a segment-page hash bucket table, the relative path is <i>Tablespace name/Database OID/Logical page number of the segment head_b(bucketid)</i>, for example, base/16603/16394_b1437. You can run the pg_relation_filepath(table_name text) command to query the relative path of the table file. To obtain the path of the partitioned table, view the pg_partition system catalog and call pg_partition_filepath(partition_oid). Valid path formats are as follows: <ul style="list-style-type: none"> global/relNode base/dbNode/relNode pg_tblspc/spcNode/version_dir/dbNode/relNode For hash bucket tables, add _b(bucketid) to the end of the path.
blocknum	bigint	<ul style="list-style-type: none"> -1: Information about all blocks (forcibly parsed from disks) 0–MaxBlockNumber: Information about the corresponding block
relation_type	text	<ul style="list-style-type: none"> heap: Astore table btree: B-tree index segment: segment-page table

- gs_xlogdump_parsepage_tablepath(path text, blocknum bigint, relation_type text, read_memory boolean)

Description: Parses the specified table page and logs corresponding to the table page and returns the path for storing the parsed content. It can be regarded as one execution of **gs_parse_page_bypath** and **gs_xlogdump_tablepath**. The prerequisite for executing this function is that the table file exists. To view logs of deleted tables, call **gs_xlogdump_tablepath**.

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.

Table 7-136 gs_xlogdump_parsepage_tablepath parameters

Parameter	Type	Description
path	text	<ul style="list-style-type: none"> For an ordinary table or a segment-page ordinary table, the relative path is <i>Tablespace name/Database OID/Relfilenode of the table (physical file name)</i>, for example, base/16603/16394. You can run the pg_relation_filepath(table_name text) command to query the relative path of the table file. To obtain the path of the partitioned table, view the pg_partition system catalog and call pg_partition_filepath(partition_oid). Valid path formats are as follows: <ul style="list-style-type: none"> global/relNode base/dbNode/relNode pg_tblspc/spcNode/version_dir/dbNode/relNode For hash bucket tables, add _b(bucketid) to the end of the path.
blocknum	bigint	<ul style="list-style-type: none"> -1: information about all blocks (forcibly parsed from disks) 0–MaxBlockNumber: information about the corresponding block
relation_type	text	<ul style="list-style-type: none"> heap: Astore table btree: B-tree index indexurq: indexurq page
read_memory	Boolean	<ul style="list-style-type: none"> false: The system parses the page from the disk file. true: The system attempts to parse the page from the shared buffer. If the page does not exist in the shared buffer, the system parses the page from the disk file.

- gs_index_recycle_queue(Oid oid, int type, uint32 blkno)**
 Description: Parses the UB-tree index recycling queue information.
 Return type: record

Table 7-137 gs_index_recycle_queue parameters

Parameter	Type	Description
oid	oid	<ul style="list-style-type: none"> Index file relfilenode, which can be queried using select relfilenode from pg_class where relname='Index file name'.
type	int	<ul style="list-style-type: none"> 0: The entire queue to be recycled is parsed. 1: The entire empty page queue is parsed. 2: A single page is parsed.
blkno	uint32	ID of the recycling queue page. This parameter is valid only when type is set to 2 . The value of blkno ranges from 1 to 4294967294.

 **NOTE**

This function is not supported in the distributed version. An error message will be displayed if it is used in the distributed version.

- gs_stat_wal_entrytable(int64 idx)

Description: Exports the content of the write-ahead log insertion status table in the Xlog.

Return type: record

Table 7-138 gs_stat_wal_entrytable parameters

Category	Parameter	Type	Description
Input parameter	idx	int64	<ul style="list-style-type: none"> -1: queries all elements in an array. 0–Maximum value: content of a specific array element.
Output parameter	idx	uint64	Records the subscripts in the corresponding array.
Output parameter	endsln	uint64	Records the LSN label.

Category	Parameter	Type	Description
Output parameter	lrc	int32	Records the corresponding LRC.
Output parameter	status	uint32	Specifies whether the Xlog corresponding to the current entry has been completely copied to the WAL buffer. <ul style="list-style-type: none"> • 0: Not copied. • 1: copied

- `gs_walwriter_flush_position()`
Description: Outputs the refresh position of write-ahead logs.
Return type: record

Table 7-139 `gs_walwriter_flush_position` parameters

Category	Parameter	Type	Description
Output parameter	last_flush_status_entry	int32	Index obtained after the Xlog flushes the tblEntry of the last flushed disk.
Output parameter	last_scanned_lrc	int32	LRC obtained after the Xlog flushes the last tblEntry scanned last time.
Output parameter	curr_lrc	int32	Latest LRC usage in the WALInsertStatusEntry status table. The LRC indicates the LRC value corresponding to the WALInsertStatusEntry when the next Xlog record is written.
Output parameter	curr_byte_pos	uint64	The latest Xlog position after the Xlog is written to the WAL file, which is also the next Xlog insertion point.
Output parameter	prev_byte_size	uint32	Length of the previous Xlog record.

Category	Parameter	Type	Description
Output parameter	flush_result	uint64	Position of the current global Xlog flush.
Output parameter	send_result	uint64	Xlog sending position on the current host.
Output parameter	shm_rqst_write_pos	uint64	The write position of the LogwrtRqst request in the XLogCtl recorded in the shared memory.
Output parameter	shm_rqst_flush_pos	uint64	The flush position of the LogwrtRqst request in the XLogCtl recorded in the shared memory.
Output parameter	shm_result_write_pos	uint64	The write position of the LogwrtResult request in the XLogCtl recorded in the shared memory.
Output parameter	shm_result_flush_pos	uint64	The flush position of the LogwrtResult request in the XLogCtl recorded in the shared memory.
Output parameter	curr_time	text	Current time.

- gs_walwriter_flush_stat(int operation)**
 Description: Collects statistics on the frequency of writing and synchronizing write-ahead logs, data volume, and Xlog file information.
 Return type: record

Table 7-140 gs_walwriter_flush_stat parameters

Category	Parameter	Type	Description
Input parameter	operation	int	<ul style="list-style-type: none"> • -1 (default): disables the statistics function. • 0: enables the statistics function. • 1: queries statistics. • 2: resets statistics.
Output parameter	write_times	uint 64	Number of times that the Xlog calls the write API.
Output parameter	sync_times	uint 64	Number of times that the Xlog calls the sync API.
Output parameter	total_xlog_sync_bytes	uint 64	Total number of backend thread requests for writing data to Xlogs.
Output parameter	total_actual_xlog_sync_bytes	uint 64	Total number of Xlogs that call the sync API for disk flushing.
Output parameter	avg_write_bytes	uint 32	Number of Xlogs written each time the XLogWrite API is called.
Output parameter	avg_actual_write_bytes	uint 32	Number of Xlogs written each time the write API is called.
Output parameter	avg_sync_bytes	uint 32	Average number of Xlogs for each synchronization request.
Output parameter	avg_actual_sync_bytes	uint 32	Actual Xlog amount of disk flushing by calling sync each time.
Output parameter	total_write_time	uint 64	Total time of calling the write operation (unit: μ s).

Category	Parameter	Type	Description
Output parameter	total_sync_time	uint64	Total time for calling the sync API (unit: μ s).
Output parameter	avg_write_time	uint32	Average time for calling the write API each time (unit: μ s).
Output parameter	avg_sync_time	uint32	Average time for calling the sync API each time (unit: μ s).
Output parameter	curr_init_xlog_segno	uint64	ID of the latest Xlog segment file.
Output parameter	curr_open_xlog_segno	uint64	ID of the Xlog segment file that is being written.
Output parameter	last_reset_time	text	Time when statistics were last collected.
Output parameter	curr_time	text	Current time.

- pg_ls_tmpdir()

Description: Returns the name, size, and last modification time of each file in the temporary directory (**pgsql_tmp**) of the default tablespace.

Parameter: nan

Return type: record

Note: Only the system administrator or monitor administrator can execute this function.

Category	Parameter	Type	Description
Output parameter	name	text	File name.
Output parameter	size	int8	File size (unit: byte).

Category	Parameter	Type	Description
Output parameter	modification	timestampz	Last file modification time.

- pg_ls_tmpdir(oid)

Description: Returns the name, size, and last modification time of each file in the temporary directory (**pgsql_tmp**) of the specified tablespace.

Parameter: oid

Return type: record

Note: Only the system administrator or monitor administrator can execute this function.

Category	Parameter	Type	Description
Input parameter	oid	oid	Tablespace ID.
Output parameter	name	text	File name.
Output parameter	size	int8	File size (unit: byte).
Output parameter	modification	timestampz	Last file modification time.

- pg_ls_waldir()

Description: Returns the name, size, and last modification time of each file in the WAL directory.

Parameter: nan

Return type: record

Note: Only the system administrator or monitor administrator can execute this function.

Category	Parameter	Type	Description
Output parameter	name	text	File name.
Output parameter	size	int8	File size (unit: byte).
Output parameter	modification	timestampz	Last file modification time.

- gs_stat_anti_cache()

Description: Returns AntiCache statistics.

Parameter: nan

Return type: record

Category	Parameter	Type	Description
Output parameter	table_nums	int8	Number of partitions.
Output parameter	table_init_size	int8	Initial size of a partition.
Output parameter	table_max_size	int8	Upper limit of the partition size.
Output parameter	anti_cache_upper_limit_size	int8	Upper limit of the AntiCache size.
Output parameter	anti_cache_size	int8	Real-time AntiCache size.
Output parameter	anti_cache_max_table_size	int8	Real-time maximum partition size.
Output parameter	anti_cache_min_table_size	int8	Real-time minimum partition size.

- `gs_stat_vlog_buffer()`

Description: Returns verifyLog buffer statistics.

Parameter: nan

Return type: record

Category	Parameter	Type	Description
Output parameter	vbuffer_write_offset	int8	Vlog write location.
Output parameter	vbuffer_flushed_offset	int8	Vlog disk flushing location.
Output parameter	max_vbuffer_flushed_value	int8	Maximum number of bytes for vlog flushing.
Output parameter	min_vbuffer_flushed_value	int8	Minimum number of bytes for vlog flushing.
Output parameter	ave_vbuffer_flushed_value	int8	Average number of bytes for vlog flushing.

Category	Parameter	Type	Description
Output parameter	vbuffer_flush_latency	int8	Vlog refresh delay.

- `gs_stat_vlog_related_io()`

Description: Returns I/O statistics about read and write operations on the verifylog file.

Parameter: nan

Return type: record

Category	Parameter	Type	Description
Output parameter	read_data_iops	float8	Number of pages read from files per second.
Output parameter	vlog_read_iops	float8	Number of pages read from vlogs per second.
Output parameter	vlog_write_iops	float8	Number of pages written to vlogs per second.

- `gs_write_term_log(void)`

Description: Writes a log to record the current **term** value of a DN. The standby DN returns **false**. After the data is successfully written to the primary DN, **true** is returned.

Return type: Boolean

- `gs_stat_space(bool init)`

Description: Queries the status of extended pages when the INSERT operation is performed on a Ustore table.

Return type: record

Category	Parameter	Type	Description
Input parameter	init	bool	Specifies whether to reset the statistics.
Output parameter	access_func	int8	Total number of access times of the <code>relation_get_buffer_for_utuple</code> API.
Output parameter	cache_blk	int8	Number of times that the <code>relation_get_buffer_for_utuple</code> API obtains buffers.

Category	Parameter	Type	Description
Output parameter	cache_succ	int8	Number of times that the relation_get_buffer_for_utuple API successfully obtains buffers.
Output parameter	nblk_first	int8	Number of times that relation_get_buffer_for_utuple obtains nblocks-1 for the first time.
Output parameter	nblk_first_succ	int8	Number of times that relation_get_buffer_for_utuple obtains nblocks-1 successfully for the first time.
Output parameter	nblk_second	int8	Number of times that relation_get_buffer_for_utuple obtains nblocks-1 for the second time.
Output parameter	nblk_second_succ	int8	Number of times that relation_get_buffer_for_utuple obtains nblocks-1 successfully for the second time.
Output parameter	fsm_first	int8	Number of times that FSM is accessed for the first time.
Output parameter	fsm_first_success	int8	Number of times that FSM is accessed successfully for the first time.
Output parameter	fsm_rewrite	int8	Number of FSM writeback times.
Output parameter	fsm_second	int8	Number of times that FSM is accessed for the second time.
Output parameter	fsm_second_success	int8	Number of times that FSM is accessed successfully for the second time.
Output parameter	prune_count	int8	Number of prune times in relation_get_buffer_for_utuple.
Output parameter	prune_space	int8	Total prune space in relation_get_buffer_for_utuple.
Output parameter	coprune_count	int8	Number of times that joint prune is performed.

Category	Parameter	Type	Description
Output parameter	coprunescan_blocks	int8	Total number of pages scanned for joint prune.
Output parameter	copruneprunecount	int8	Number of joint prune times.
Output parameter	copruneprunespace	int8	Total space for joint prune.
Output parameter	con_extend_count	int8	Number of concurrent extended pages.
Output parameter	con_extend_time	int8	Total time for concurrent page extension.
Output parameter	single_extend_time	int8	Number of single-page extension times.

Example:

```
gaussdb=# SELECT * FROM gs_stat_space(false);
 access_func | cache_blk | cache_succ | nblk_first | nblk_first_succ | nblk_sencond | nblk_sencond_succ | fsm_first | fsm_first_success | fsm_rewrite | fsm_second | fsm_second_success | prune_count | prune_space | coprunecount | coprunescan_blocks | copruneprunecount | copruneprunespace | con_extend_count | con_extend_time | single_extend_count
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
 10082397 | 10082397 | 10082235 |      88 |           78 |         47021 |         47021 |          162
 |           74 |    360996 |
 360996 |      270948 |      6711 |          0 |        45497 |        222619 |           0
 |           0 |         3675
 |    25542884 |         26791
(1 row)
```

Note: Pay special attention to the value of **cache_succ**. If it is small, the system cache is invalid. If the value of **prune_space** is small, the Ustore data page cleaning mechanism may be faulty. If the value of **con_extend_time** is too large, the Ustore concurrent page extension takes a long time.

- gs_redo_upage(directory_path text, backup_path text, blocknum bigint, relation_type text, xlog_path text, lsn text)**
 Description: Redoes a specific Ustore data page that is backed up to a specified LSN and verifies the page in this process. If a damaged page is detected, the page is flushed to the disk and the disk flushing path, page LSN, and damage information is returned; otherwise, the page is redone to the specified LSN and flushed to the disk, and the result is returned. Only system administrators and O&M administrators can execute this function.

Return type: record

Category	Parameter	Type	Description
Input parameter	directory_path	text	Specifies the directory for storing the backup file.
Input parameter	backup_path	text	Relative path of the backup table file, which is combined with the directory where the backup file is located to form the complete path of the table file, for example, base/15635/12488 . If the backup file does not exist, set this parameter to null.
Input parameter	blocknum	bigint	0 to <i>MaxBlockNumber</i> : block number of the corresponding page.
Input parameter	relation_type	text	<ul style="list-style-type: none"> • uheap: Ustore data page • ubtree: Ustore index page • indexurq: URQ page • undo_record: undo record page • undo_slot: transaction slot page
Input parameter	xlog_path	text	Absolute path of the archive log directory.
Input parameter	lsn	text	The LSN consists of two hexadecimal numbers (32 bits each), which are separated by a slash (/), for example, 2/962D1DF8. If the value is 0 , the latest version is used.
Output parameter	output_filename	text	Path and name of the file to be flushed to the disk.
Output parameter	output_lsn	text	LSN of the last page redo.
Output parameter	corruption_desc	text	Page damage description.

- `gs_xlogdump_bylastlsn(last_lsn text, blocknum bigint, relation_type text)`
Description: Inputs a page LSN and block number, parses the WAL corresponding to the LSN, obtains the last LSN of the corresponding block number, continues parsing until the last LSN is 0 or the WAL of an earlier version has been reused and recycled, and flushes the parsed log to a specified path. Only system administrators or O&M administrators can execute this function. This system function cannot be called by the standby node.

Return type: text

Category	Parameter	Type	Description
Input parameter	last_lsn	text	Parses the LSN of a specified page in hexadecimal notation, for example, 12BA/32CEDEDD. The LSN can be obtained using a page parsing tool (such as gs_parse_page_bypath).
Input parameter	blocknum	bigint	Specifies the logical block number of a page. Value range: -1 to <i>MaxBlockNumber</i> . If the block number is set to -1 , the default block number is obtained from the WAL.
Input parameter	relation_type	text	Specifies the type of the page to be parsed. Valid value: uheap , ubtree , heap , btree , undo_record , and undo_slot .
Output parameter	output_filepath	text	Specifies the path for flushing WAL parsing results to disks.

Example:

```
# Obtain the page LSN.
# Before calling the function, ensure that the file path exists based on the parameter description.
gaussdb=# SELECT * FROM gs_parse_page_bypath('base/15833/16768', 0, 'uheap', false);
          output_filepath
-----
/data1/database/cluster/primary/data/1663_15833_16768_0.page
(1 row)
gaussdb=# SELECT * FROM gs_xlogdump_bylastlsn('0/4593570', -1, 'uheap');
          output_filepath
-----
/data1/database/cluster/primary/data/gs_log/dump/4593570_-1.xlog
(1 row)
gaussdb=# SELECT * FROM gs_xlogdump_bylastlsn('0/4593570', 0, 'ubtree');
ERROR: The input lsn 0/4593570 related xlog is not ubtree.
```

- `dbperf.get_full_sql_by_parent_id_and_timestamp`(parent_id bigint, start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)

Description: Obtains the records of database-level full SQL statements and their substatements that execute a stored procedure in a specified period based on **parent_id**. The result can be queried only in the system database but cannot be queried in the user database.

Return type: record

Parameter	Type	Description
parent_id	bigint	Specifies the unique_sql_id of the statement calling a stored procedure.

Parameter	Type	Description
start_timestamp	timestamp with time zone	Start point of the SQL start time range.
end_timestamp	timestamp with time zone	End point of the SQL start time range.

Example:

```

gaussdb=# CREATE TABLE test(a int,b int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# INSERT INTO test values(1,1);
INSERT 0 1
gaussdb=# CREATE PROCEDURE mypro1() as num int;
gaussdb$# begin
gaussdb$# INSERT INTO test values(2,2);
gaussdb$# DELETE FROM test where a = 2;
gaussdb$# end;
gaussdb$# /
CREATE PROCEDURE

-- Enable the parameter to trace the substatements of the stored procedure.
gaussdb=# SET instr_unique_sql_track_type = 'all';
SET

-- Enable the parameter. Full statement records are generated in the db_perf.statement_history
table.
gaussdb=# SET track_stmt_stat_level = 'L0,L0';
SET

gaussdb=# CALL mypro1();

```

- `gs_index_dump_read(int8 reset, text out_type)`

Description: Queries the buffer read information generated in the cyclic queue when an index is used to obtain a new page. The buffer read information traverses leaf pages from left to right using the same key as the index page.

Return type: record

Category	Parameter	Type	Description
Input parameter	reset	int8	<ul style="list-style-type: none"> • 0: The statistics are reset to the initial value 0 and the statistics are collected again. • 1: The current statistics are displayed.
Input parameter	out_type	text	<ul style="list-style-type: none"> • urq: outputs statistics about cyclic queues. • ubtree: outputs statistics on index pages. • all: outputs all statistics about cyclic queues and index pages.
Output parameter	relfilenode	oid	Index relfilenode corresponding to the maximum buffer read value.
Output parameter	max_count	int8	Maximum buffer read value.
Output parameter	ave_count	int8	Average buffer read value.

 **NOTE**

- Currently, this API supports only Ustore index tables.
- When this API is executed, the reset operation is performed to clear all records and set all records to 0. If you query the information again, the query result is always 0 until the information is collected next time. The following are query examples:

```
gaussdb=# SELECT * FROM gs_index_dump_read(0, 'all');
relfilenode | max_count | ave_count
-----+-----+-----
|          |          |
(1 row)
gaussdb=# SELECT * FROM gs_index_dump_read(1, 'all');
relfilenode | max_count | ave_count
-----+-----+-----
0 |          |          0
0 |          |          0
(2 rows)
```

- `pg_get_ilmdef(pidx integer)`
Description: Specifies a row-store compression system function, which returns the corresponding policy information based on the input ILM policy index.

Return type: text

Category	Parameter	Type	Description
Input parameter	pidx	integer	Specifies an index of an ILM policy.
Output parameter	ilm_policy_info	text	Specifies the policy information of an ILM policy.

- `gs_shared_storage_flush_stat(int operation)`
Description: Collects statistics on the amount of written data, write speed, write time, amount of read data, read speed, and read time of shared disks.

Return type: record

Category	Parameter	Type	Description
Input parameter	operation	int	<ul style="list-style-type: none"> • -1: disables the statistics function. • 0 (default): enables the statistics function. • 1: queries statistics. • 2: resets statistics. After the statistics function is disabled and then enabled again, the previous statistics are cleared.

Category	Parameter	Type	Description
Output parameter	stat_switch	bool	Specifies whether the statistics function is enabled.
Output parameter	write_times	uint64	Number of times that the shared_storage_xlog_copy thread calls the dorado_write_xlog API.
Output parameter	avg_write_bytes	uint32	Amount of Xlogs to be written each time the dorado_write_xlog API is called, in byte.
Output parameter	avg_actual_write_bytes	uint32	Actual amount of Xlogs to be written each time the dorado_write_xlog API is called, in byte.
Output parameter	total_write_time	uint64	Total time for calling the dorado_write_xlog API, in μ s.
Output parameter	avg_write_time	uint32	Average time for calling the dorado_write_xlog API each time, in μ s.
Output parameter	avg_write_speed	uint32	Average speed of invoking the dorado_write_xlog API to write Xlogs, in KB/s.
Output parameter	avg_actual_write_speed	uint32	Actual average speed of invoking the dorado_write_xlog API to write Xlogs, in KB/s.
Output parameter	total_write_sleep_time	uint64	Total sleep time of the shared_storage_xlog_copy thread.
Output parameter	read_times	uint64	Number of times that the walreceiver thread calls the dorado_read_xlog API.
Output parameter	avg_read_bytes	uint32	Amount of Xlogs to be written each time the dorado_read_xlog API is called, in byte.
Output parameter	avg_actual_read_bytes	uint32	Actual amount of Xlogs to be written each time the dorado_read_xlog API is called, in byte.
Output parameter	total_read_time	uint64	Total time for calling the dorado_read_xlog API, in μ s.

7.6.27 SPM Functions

⚠ CAUTION

Currently, the SPM feature is not supported in the distributed system. Therefore, when the following functions are called in the distributed system, an error message is displayed, indicating that the SPM feature is not supported in the distributed system.

- `GS_SPM_EVOLUTE_PLAN(sql_hash, plan_hash)`

Description: `GS_SPM_EVOLUTE_PLAN` belongs to the `DBE_SQL_UTIL` schema and is an API function used by the SPM feature to plan evolution.

Parameters: For details, see [Table 7-141](#).

Table 7-141 `GS_SPM_EVOLUTE_PLAN` input parameters and return values

Parameter	Type	Description	Value Range
<code>sql_hash</code>	IN bigint	Specifies a hash value of SQL text.	-
<code>plan_hash</code>	IN bigint	Specifies a hash value of the outline text of the SQL plan.	-
<code>evolute_status</code>	OUT boolean	Determines whether the evolution is complete. t indicates normal. If an exception occurs, an error is reported.	t/f

Return type: Boolean

- `GS_SPM_SET_PLAN_STATUS(sql_hash, plan_hash, plan_status)`

Description: `GS_SPM_SET_PLAN_STATUS` belongs to the `DBE_SQL_UTIL` schema and is an API function used by the SPM feature to change the baseline status.

Parameters: For details, see [Table 7-142](#).

Table 7-142 `GS_SPM_SET_PLAN_STATUS` input parameters and return values

Parameter	Type	Description	Value Range
<code>sql_hash</code>	IN bigint	Specifies a hash value of SQL text.	-
<code>plan_hash</code>	IN bigint	Specifies a hash value of the outline text of the SQL plan.	-

Parameter	Type	Description	Value Range
plan_status	IN text	Specifies the status of a plan.	<ul style="list-style-type: none"> ● ACC: indicates that the plan has been accepted. ● UNACC: indicates that the plan is not accepted. ● FIXED: indicates a special ACC plan. The matching priority of this plan is higher than that of other ACC plans.
execute_status	OUT boolean	Determines whether the plan status change is complete. t indicates normal. If an exception occurs, an error is reported.	t/f

Return type: Boolean

- GS_SPM_DISPLAY_PLANS(sql_hash)

Description: GS_SPM_DISPLAY_PLANS belongs to the DBE_SQL_UTIL schema and is an API function used by the SPM feature to view all baselines of a single SQL statement.

Parameters: For details, see [Table 7-143](#).

Table 7-143 GS_SPM_DISPLAY_PLANS input parameters and return values

Parameter	Type	Description	Value Range
sql_hash	IN bigint	Unique ID of an SQL statement.	-
sql_hash	OUT bigint	Specifies a hash value of SQL text.	-
plan_hash	OUT bigint	Specifies a hash value of the outline text of the SQL plan.	-

Parameter	Type	Description	Value Range
outline	OUT text	Specifies the combination character string of all hints of the outline corresponding to the current plan.	-
cost	OUT double	Specifies the cost of the current plan.	-
status	OUT text	Specifies the status of the current plan.	<ul style="list-style-type: none"> ● ACC: indicates that the plan has been accepted. ● UNACC: indicates that the plan is not accepted. ● FIXED: indicates a special ACC plan. The matching priority of this plan is higher than that of other ACC plans.
gplan	OUT boolean	Determines whether the current plan is a gplan. t indicates gplan. If an exception occurs, an error is reported.	t/f

Return type: bigint, text, double, text, boolean

- GS_SPM_RELOAD_PLAN(sql_hash, plan_hash)

Description: GS_SPM_RELOAD_PLAN belongs to the DBE_SQL_UTIL schema and is an API function used by the SPM feature to load a baseline in the baseline system catalog to the SPM global cache.

Parameters: For details, see [Table 7-144](#).

Table 7-144 GS_SPM_RELOAD_PLAN input parameters and return values

Parameter	Type	Description	Value Range
sql_hash	IN bigint	Specifies a hash value of SQL text.	-
plan_hash	IN bigint	Specifies a hash value of the outline text of the SQL plan.	-

Parameter	Type	Description	Value Range
execute_status	OUT boolean	Determines whether the baseline loading is complete. t indicates normal. If an exception occurs, an error is reported.	t/f

Return type: Boolean

- GS_SPM_VALIDATE_PLAN(sql_hash, plan_hash)

Description: GS_SPM_VALIDATE_PLAN belongs to the DBE_SQL_UTIL schema and is an API function used by the SPM feature to verify plan availability.

Parameters: For details, see [Table 7-145](#).

Table 7-145 GS_SPM_VALIDATE_PLAN input parameters and return values

Parameter	Type	Description	Value Range
sql_hash	IN bigint	Specifies a hash value of SQL text.	-
plan_hash	IN bigint	Specifies a hash value of the outline text of the SQL plan.	-
execute_status	OUT boolean	Determines whether the verified plan is available: t : The verified plan is available. f : The verified plan is unavailable.	t/f

Return type: Boolean

- GS_SPM_DELETE_PLAN(sql_hash, plan_hash)

Description: GS_SPM_DELETE_PLAN belongs to DBE_SQL_UTIL schema and is an API function used by the SPM feature to delete the plan baseline.

Parameters: For details, see [Table 7-146](#).

Table 7-146 GS_SPM_DELETE_PLAN input parameters and return values

Parameter	Type	Description	Value Range
sql_hash	IN bigint	Specifies a hash value of SQL text.	-
plan_hash	IN bigint	Specifies a hash value of the outline text of the SQL plan.	-

Parameter	Type	Description	Value Range
execute_status	OUT boolean	Determines whether the plan deletion is complete. t indicates normal. If an exception occurs, an error is reported.	t/f

Return type: Boolean

7.6.28 Statistics Information Functions

Statistics information functions are divided into the following two categories: functions that access databases, using the OID of each table or index in a database to mark the database for which statistics are generated; functions that access servers, identified by the server thread ID, whose value ranges from 1 to the number of currently active servers.

- pg_stat_get_db_conflict_tablespace(oid)**
 Description: Specifies the number of queries canceled due to a conflict between the restored tablespace and the deleted tablespace in the database.
 Return type: bigint
- pg_control_group_config()**
 Description: Prints Cgroup configurations on the current node. Only users with the SYSADMIN permission can execute this function.
 Return type: record
- pg_stat_get_db_stat_reset_time(oid)**
 Description: Specifies the most recent time when database statistics were reset. It is initialized to the system time during the first connection to each database. The reset time is updated when you call **pg_stat_reset** on the database and execute **pg_stat_reset_single_table_counters** against any table or index in it.
 Return type: timestamptz
- pg_stat_get_function_total_time(oid)**
 Description: Specifies the total wall clock time spent in the function, in microseconds. The time spent on this function calling other functions is included.
 Return type: bigint
- pg_stat_get_xact_tuples_returned(oid)**
 Description: Specifies the number of rows read through sequential scans when the parameter is a table in the current transaction or the number of index entries returned when the parameter is an index.
 Return type: bigint
- pg_stat_get_xact_numscans(oid)**
 Description: Specifies the number of sequential scans performed when the parameter is a table in the current transaction or the number of index scans performed when the parameter is an index.

- Return type: bigint
- `pg_stat_get_xact_blocks_fetched(oid)`
Description: Specifies the number of disk block fetch requests for a table or an index in the current transaction.
Return type: bigint
 - `pg_stat_get_xact_blocks_hit(oid)`
Description: Specifies the number of disk block fetch requests for tables or indexes found in cache in the current transaction.
Return type: bigint
 - `pg_stat_get_xact_function_calls(oid)`
Description: Specifies the number of times the function is called in the current transaction.
Return type: bigint
 - `pg_stat_get_xact_function_self_time(oid)`
Description: Specifies the time spent only on this function in the current transaction. The time spent on other function call inside this function is not included.
Return type: bigint
 - `pg_stat_get_xact_function_total_time(oid)`
Description: Specifies the total wall clock time spent on this function in the current transaction, in microseconds. The time spent on other function call inside this function is included.
Return type: bigint
 - `pg_lock_status()`
Description: Queries information about locks held by open transactions. All users can execute this function.
Return type: For details, see the return result of [PG_LOCKS](#), which is obtained by querying this function.
 - `bucket_lock_status()`
Description: Queries information about bucket locks held by open transactions. All users can execute this function.
Return value type: For details about the returned columns, see the columns except **node_name** in the [GS_BUCKET_LOCKS](#) view.
 - `gs_bucket_lock_status()`
Description: Queries information about bucket locks held by open transactions on all nodes. All users can execute this function.
Return type: For details, see the return result of [GS_BUCKET_LOCKS](#), which is obtained by querying this function.
 - `gs_lwlock_status()`
Description: Queries information about all lightweight locks in the database system, including lock waiting and lock holding information. All users can execute this function.
Return type: setofrecord
 - `pg_stat_get_wal_senders()`

Description: Queries WAL sender information on the primary node.

Return type: setofrecord

The following table describes return columns.

Table 7-147 Return column description

Column	Type	Description
pid	bigint	Thread ID of the WAL sender
sender_pid	integer	Lightweight thread ID of the WAL sender
local_role	text	Type of the primary node
peer_role	text	Type of the standby node
peer_state	text	Status of the standby node
state	text	Status of the WAL sender
catchup_start	timestamp with time zone	Startup time of a catchup task
catchup_end	timestamp with time zone	End time of a catchup task
sender_sent_location	text	Sending position of the primary node
sender_write_location	text	Writing position of the primary node
sender_flush_location	text	Flushing position of the primary node
sender_replay_location	text	Redo position of the primary node
receiver_received_location	text	Receiving position of the standby node
receiver_write_location	text	Writing position of the standby node
receiver_flush_location	text	Flushing position of the standby node
receiver_replay_location	text	Redo position of the standby node

Column	Type	Description
sync_percent	text	Synchronization percentage
sync_state	text	Synchronization status
sync_group	text	Group to which the synchronous replication belongs
sync_priority	text	Priority of synchronous replication
sync_most_available	text	Maximum availability mode
channel	text	Channel information of the WAL sender

- pgxc_get_senders_catchup_time()**
 Description: Queries whether a standby DN in the log catchup state exists in the CN instance query cluster and details about the log catchup state.
 Return type: setofrecord
- pg_stat_get_stream_replications()**
 Description: Queries the primary/standby replication status.
 Return type: setofrecord
 The following table describes return values.

Table 7-148 Return value description

Return Parameter	Type	Description
local_role	text	Local role
static_connections	integer	Connection statistics
db_state	text	Database status
detail_information	text	Detailed information

- pg_stat_get_db_numbackends(oid)**
 Description: Specifies the number of active server threads for a database.
 Return type: integer.
- pg_stat_get_db_xact_commit(oid)**
 Description: Specifies the number of transactions committed in a database.
 Return type: bigint
- pg_stat_get_db_xact_rollback(oid)**
 Description: Specifies the number of transactions rolled back in a database.
 Return type: bigint

- `pg_stat_get_db_blocks_fetched(oid)`
Description: Specifies the number of disk blocks fetch requests for a database.
Return type: `bigint`
- `pg_stat_get_db_blocks_hit(oid)`
Description: Specifies the number of disk block fetch requests found in cache for a database.
Return type: `bigint`
- `pg_stat_get_db_tuples_returned(oid)`
Description: Specifies the number of tuples returned for a database.
Return type: `bigint`
- `pg_stat_get_db_tuples_fetched(oid)`
Description: Specifies the number of tuples fetched for a database.
Return type: `bigint`
- `pg_stat_get_db_tuples_inserted(oid)`
Description: Specifies the number of tuples inserted in a database.
Return type: `bigint`
- `pg_stat_get_db_tuples_updated(oid)`
Description: Specifies the number of tuples updated in a database.
Return type: `bigint`
- `pg_stat_get_db_tuples_deleted(oid)`
Description: Specifies the number of tuples deleted in a database.
Return type: `bigint`
- `pg_stat_get_db_conflict_lock(oid)`
Description: Specifies the number of lock conflicts in a database.
Return type: `bigint`
- `pg_stat_get_db_deadlocks(oid)`
Description: Specifies the number of deadlocks in a database.
Return type: `bigint`
- `pg_stat_get_numscans(oid)`
Description: Number of sequential row scans done if parameters are in a table, or the number of index rows if parameters are in an index.
Return type: `bigint`
- `pg_stat_get_role_name(oid)`
Description: Obtains the username based on the user OID. Only users with the SYSADMIN and MONADMIN permissions can access the information.
Return type: `text`.
Example:

```
gaussdb=# SELECT pg_stat_get_role_name(10);
pg_stat_get_role_name
-----
aabbcc
(1 row)
```
- `pg_stat_get_tuples_returned(oid)`

Description: Specifies the number of sequential rows read by sequential scans if parameters are in a table, or the number of index rows if parameters are in an index.

Return type: bigint

- `pg_stat_get_tuples_fetched(oid)`

Description: Specifies the number of table rows fetched by bitmap scans if parameters are in a table, or the number of table rows fetched by simple index scans in the original table if parameters are in an index.

Return type: bigint

- `pg_stat_get_tuples_inserted(oid)`

Description: Specifies the number of rows inserted into a table.

Return type: bigint

- `pg_stat_get_tuples_updated(oid)`

Description: Specifies the number of rows updated in a table.

Return type: bigint

- `pg_stat_get_tuples_deleted(oid)`

Description: Specifies the number of rows deleted from a table.

Return type: bigint

- `pg_stat_get_tuples_changed(oid)`

Description: Specifies the total number of inserted, updated, and deleted rows after a table was last analyzed or autoanalyzed.

Return type: bigint

- `pg_stat_get_tuples_hot_updated(oid)`

Description: Specifies the number of rows hot updated in a table.

Return type: bigint

- `pg_stat_get_live_tuples(oid)`

Description: Specifies the number of live rows in a table.

Return type: bigint

- `pg_stat_get_dead_tuples(oid)`

Description: Specifies the number of dead rows in a table.

Return type: bigint

- `pg_stat_get_blocks_fetched(oid)`

Description: Specifies the number of disk block fetch requests for a table or an index.

Return type: bigint

- `pg_stat_get_blocks_hit(oid)`

Description: Specifies the number of disk block requests found in cache for a table or an index.

Return type: bigint

- `pg_stat_get_xact_tuples_fetched(oid)`

Description: Specifies the number of tuple rows scanned in a transaction.

Return type: bigint

- `pg_stat_get_xact_tuples_inserted(oid)`
Description: Specifies the number of tuple inserted into the active subtransactions related to a table.
Return type: `bigint`
- `pg_stat_get_xact_tuples_deleted(oid)`
Description: Specifies the number of deleted tuples in the active subtransactions related to a table.
Return type: `bigint`
- `pg_stat_get_xact_tuples_hot_updated(oid)`
Description: Specifies the number of hot updated tuples in the active subtransactions related to a table.
Return type: `bigint`
- `pg_stat_get_xact_tuples_updated(oid)`
Description: Specifies the number of updated tuples in the active subtransactions related to a table.
Return type: `bigint`
- `pg_stat_get_last_vacuum_time(oid)`
Description: Specifies the most recent time when the autovacuum thread is manually started to clear a table.
Return type: `timestampz`
- `pg_stat_get_last_autovacuum_time(oid)`
Description: Specifies the time of the last vacuum initiated by the autovacuum daemon thread on a table.
Return type: `timestampz`
- `pg_stat_get_vacuum_count(oid)`
Description: Specifies the number of times a table is manually cleared.
Return type: `bigint`
- `pg_stat_get_autovacuum_count(oid)`
Description: Specifies the number of times the autovacuum daemon thread is started to clear a table.
Return type: `bigint`
- `pg_stat_get_last_analyze_time(oid)`
Description: Specifies the last time when a table starts to be analyzed manually or by the autovacuum thread.
Return type: `timestampz`
- `pg_stat_get_last_autoanalyze_time(oid)`
Description: Specifies the time when the last analysis initiated by the autovacuum daemon thread on a table.
Return type: `timestampz`
- `pg_stat_get_analyze_count(oid)`
Description: Specifies the number of times a table is manually analyzed.
Return type: `bigint`

- pg_stat_get_autoanalyze_count(oid)**
 Description: Specifies the number of times the autovacuum daemon thread analyzes a table.
 Return type: bigint
- pg_total_autovac_tuples(bool)**
 Description: Returns tuple records related to the total autovac, such as **nodename**, **nspname**, **relname**, and tuple IUDs. The input parameter specifies whether to query the **relation** information.
 Return type: setofrecord
 The following table describes return parameters.

Table 7-149 Return parameter description

Return Parameter	Type	Description
nodename	name	Node name.
nspname	name	Name of a namespace
relname	name	Name of an object, such as a table, an index, or a view
partname	name	Partition name
n_dead_tuples	bigint	Number of dead rows in a table partition
n_live_tuples	bigint	Number of live rows in a table partition
changes_since_analyze	bigint	Number of changes generated by ANALYZE

- pg_total_gsi_autovac_tuples(bool)**
 Description: Returns tuple records related to **total autovac**, such as **nodename**, **nspname**, **relname**, and number of GSI records that have changed since the last ANALYZE. The input parameter specifies whether to query relation information. This function assists AUTOVACUUM on GSIs. You are advised not to use this function.
 Return type: setofrecord
- pg_autovac_status(oid)**
 Description: Returns autovac information, such as **nodename**, **nspname**, **relname**, **analyze**, **vacuum**, thresholds for the ANALYZE and VACUUM operations, and the number of analyzed or vacuumed tuples. Only users with the SYSADMIN permission can use this function.
 Return type: setofrecord
 The following table describes return parameters.

Table 7-150 Return parameter description

Return Parameter	Type	Description
nspname	text	Name of a namespace.
relname	text	Name of an object, such as a table, an index, or a view.
nodename	text	Node name.
doanalyze	Boolean	Specifies whether to execute ANALYZE .
anltuples	bigint	Number of ANALYZE tuples.
anlthresh	bigint	ANALYZE threshold.
dovacuum	Boolean	Specifies whether to execute VACUUM .
vactuples	bigint	Number of VACUUM tuples.
vacthresh	bigint	VACUUM threshold.

- `pg_autovac_timeout(oid)`
Description: Returns the number of consecutive timeouts during the autovac operation on a table. If the table information is invalid or the node information is abnormal, **NULL** will be returned.
Return type: bigint
- `pg_autovac_coordinator(oid)`
Description: Returns the name of the CN performing the autovac operation on a table. If the table information is invalid or the node information is abnormal, **NULL** is returned.
Return type: text.
- `pg_stat_get_last_data_changed_time(oid)`
Description: Returns the time when INSERT, UPDATE, DELETE, or TRUNCATE was last performed on a table, or the time when EXCHANGE, TRUNCATE, or DROP was last performed on a partition or subpartition. The data in the **last_data_changed** column of the **PG_STAT_ALL_TABLES** view is calculated by using this function. The performance of obtaining the last modification time by using the view is poor when the table has a large amount of data. In this case, you are advised to use functions. The input parameter is a table OID.
Return type: timestampz
- `pg_stat_set_last_data_changed_time(oid)`
Description: Manually changes the time when **INSERT, UPDATE, DELETE, or EXCHANGE/TRUNCATE/DROP PARTITION** was last performed.
Return type: void

Return Parameter	Type	Description
application_name	text	Name of the application connected to the backend
state	text	Overall status of the backend
query	text	Latest query at the backend. If state is active , this column shows the ongoing query. In all other states, it shows the last query that was executed.
waiting	Boolean	Specifies whether the backend is currently waiting on a lock. If yes, the value is true .
xact_start	timestamp with time zone	Time when current transaction was started (null if no transaction is active). If the current query is the first of its transaction, the value of this column is the same as that of the query_start column.
query_start	timestamp with time zone	Time when the currently active query was started, or time when the last query was started if state is not active . For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.
backend_start	timestamp with time zone	Time when this process was started, that is, when the client connected to the server

Return Parameter	Type	Description
state_change	timestamp with time zone	Time when state was last modified
client_addr	inet	IP address of the client connected to the backend. If this column is NULL , it indicates either the client is connected via a Unix socket on the server or this is an internal thread, such as AUTOVACUUM .
client_hostname	text	Host name of the connected client, as reported by a reverse DNS lookup of client_addr . This column will be non-null only for IP connections and only when log_hostname is enabled.
client_port	integer	TCP port number that the client uses for communication with this backend (-1 if a Unix socket is used)
enqueue	text	Unsupported currently
query_id	bigint	ID of a query
srespool	name	Name of the resource pool
global_sessionid	text	Global session ID
unique_sql_id	bigint	Unique SQL statement ID
trace_id	text	Driver-specific trace ID, which is associated with an application request

- `pg_stat_get_activity_with_conninfo(integer)`

Description: Returns a record about the backend thread with the specified PID. A record for each active backend in the system is returned if **NULL** is specified. The initial user, system administrators and users with the

MONADMIN permission can view all data. Common users can only query their own results.

Return type: setofrecord

The following table describes return values.

Return Parameter	Return Type	Return value description
datid	oid	OID of the database that the user session connects to in the backend
pid	bigint	Backend thread ID.
sessionid	bigint	Session ID
usesysid	oid	OID of the user logged in to the backend.
application_name	text	Name of the application connected to the backend
state	text	Overall status of the backend
query	text	Latest query at the backend. If state is active , this column shows the ongoing query. In all other states, it shows the last query that was executed.
waiting	Boolean	Specifies whether the backend is currently waiting on a lock. If yes, the value is true .
xact_start	timestamp with time zone	Time when current transaction was started (null if no transaction is active). If the current query is the first of its transaction, the value of this column is the same as that of the query_start column.

Return Parameter	Return Type	Return value description
query_start	timestamp with time zone	Time when the currently active query was started, or time when the last query was started if state is not active . For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.
backend_start	timestamp with time zone	Time when this process was started, that is, when the client connected to the server.
state_change	timestamp with time zone	Time when state was last modified.
client_addr	inet	IP address of the client connected to the backend. If this column is NULL , it indicates either the client is connected via a Unix socket on the server or this is an internal thread, such as AUTOVACUUM .
client_hostname	text	Host name of the connected client, as reported by a reverse DNS lookup of client_addr . This column will be non-null only for IP connections and only when log_hostname is enabled.
client_port	integer	TCP port number that the client uses for communication with this backend (-1 if a Unix socket is used).

Return Parameter	Return Type	Return value description
enqueue	text	This field is not currently supported.
query_id	bigint	ID of a query
connection_info	text	A string in JSON format recording the driver type, driver version, driver deployment path, and thread owner of the connected database.
srespool	name	Name of the resource pool
global_sessionid	text	Global session ID
unique_sql_id	bigint	Unique SQL statement ID
trace_id	text	Driver-specific trace ID, which is associated with an application request
top_xid	xid	Top-level transaction ID of a transaction.
current_xid	xid	Current transaction ID of a transaction.
xlog_quantity	bigint	Amount of Xlogs currently used by a transaction, in bytes.

- `gs_get_explain(integer)`

Description: Returns a running plan for the background thread with the specified PID. The PID cannot be empty. This function takes effect only when the GUC parameter **track_activities** is set to **on**. Only explainable SQL statements whose plans do not contain stream operators are supported. Details are as follows:

- If the GUC parameter **plan_collect_thresh** is set to **-1**, the return result of the function is always empty.
- If **plan_collect_thresh** is set to **0**, the current SQL execution time is greater than or equal to the value of **log_min_duration_statement**, and the total number of tuples processed by all operators in the plan is greater than or equal to 10000, the system starts to collect plans in running state. Each time the total number of tuples processed by all operators exceeds 10000, a collection is performed.

- If **plan_collect_thresh** is set to a value greater than 0, running plans are collected incrementally based on the threshold specified by this parameter.
- In addition, this function can view only the plans generated on CNs. To view the plans generated on DN, see the `gs_get_dn_explain` function.

The return value type is text. The types and meanings of the fields are as follows:

Return Value	Return Type	Return value description
Character string of the plans in the running state	text	A-rows in the plan string indicates the number of rows returned by the operator in real time.

- `gs_get_dn_explain(text, bigint)`

Description: Returns a running plan for the background thread of the DN with the specified node name (from the **node_name** field in the **pgxc_node** system catalog) and global session ID. The global session ID cannot be empty. This function takes effect only when the GUC parameter **track_activities** is set to **on**. Only explainable SQL statements whose plans do not contain stream operators are supported. Details are as follows:

- Same as the `gs_get_explain` function. The global session ID is calculated based on the **global_sessionid** field in **pg_stat_activity**. The format of **global_sessionid** is $\{number1\}:\{number2\}\#\{number3\}$, for example, **1938253334:1#0**. Therefore, the parameter value of the `gs_get_dn_explain` function is $\{number2\} \times 10000000000 + \{number1\}$.
- In addition, this function can be executed only with the ADMIN or MONADMIN permission.

The return value type is text. The types and meanings of the fields are as follows:

Return Value	Return Type	Return value description
Character string of the plans in the running state	text	A-rows in the plan string indicates the number of rows returned by the operator in real time.

- `pg_stat_get_activity_ng(integer)`

Description: Returns a record about the active background thread with the specified PID. A record for each active background thread is returned if **NULL** is specified. System administrators and users with the MONADMIN permission can view all data. Common users can query only their own data.

Return type: setofrecord

The following table describes return fields.

Name	Type	Description
datid	oid	Database OID

Name	Type	Description
pid	bigint	Backend thread ID
sessionid	bigint	Session ID

- `pg_stat_get_function_calls(oid)`
Description: Specifies the number of times the function has been called.
Return type: bigint
- `pg_stat_get_function_self_time(oid)`
Description: Specifies the time spent on only this function. The time spent on nested functions to call other functions is excluded.
Return type: bigint
- `pg_stat_get_backend_idset()`
Description: Sets the number of currently active server threads (from 1 to the number of active server threads).
Return type: setofinteger
- `pg_stat_get_backend_pid(integer)`
Description: Specifies the ID of the given server thread.
Return type: bigint
- `pg_stat_get_backend_dbid(integer)`
Description: Specifies the ID of the database connected to the given server thread.
Return type: oid
- `pg_stat_get_backend_userid(integer)`
Description: Specifies the user ID of the given server process. This function can be called only by the system administrator.
Return type: oid
- `pg_stat_get_backend_activity(integer)`
Description: Active command of the given server thread, but only if the current user is a system administrator or the same user as that of the session being queried and **track_activities** is enabled.
Return type: text.
- `pg_stat_get_backend_waiting(integer)`
Description: Returns true if the given server thread is waiting for a lock, but only if the current user is a system administrator or the same user as that of the session being queried and **track_activities** is enabled.
Return type: Boolean.
- `pg_stat_get_backend_activity_start(integer)`
Description: Specifies the time when the given server thread's currently executing query is started only if the current user is the system administrator or the user of the session being queried and **track_activities** is enabled.
Return type: timestamp with time zone

- `pg_stat_get_backend_xact_start(integer)`
Description: Specifies the time when the given server thread's currently executing transaction is started only if the current user is the system administrator or the user of the session being queried and **track_activities** is enabled.
Return type: timestamp with time zone
- `pg_stat_get_backend_start(integer)`
Description: Specifies the time when the given server thread is started. If the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** is returned.
Return type: timestamp with time zone
- `pg_stat_get_backend_client_addr(integer)`
Description: Specifies the IP address of the client connected to the given server process. If the connection is over a Unix domain socket, or if the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** will be returned.
Return type: inet
- `pg_stat_get_backend_client_port(integer)`
Description: Specifies the TCP port number of the client connected to the given server process. If the connection is over a Unix domain socket, **-1** will be returned. If the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** will be returned.
Return type: integer.
- `pg_stat_get_bgwriter_timed_checkpoints()`
Description: Specifies the time when the background writer thread starts scheduled checkpoints (because **checkpoint_timeout** has expired).
Return type: bigint
- `pg_stat_get_bgwriter_requested_checkpoints()`
Description: Specifies the time when the background writer thread starts checkpoints based on requests from the backend because **checkpoint_segments** has been exceeded or the **CHECKPOINT** command has been executed.
Return type: bigint
- `pg_stat_get_bgwriter_buf_written_checkpoints()`
Description: Specifies the number of buffers written by the background writer thread during checkpoints.
Return type: bigint
- `pg_stat_get_bgwriter_buf_written_clean()`
Description: Specifies the number of buffers written by the background writer thread for routine cleaning of dirty pages.
Return type: bigint
- `pg_stat_get_bgwriter_maxwritten_clean()`
Description: Specifies the time when the background writer thread stops its cleaning scan because it has written more buffers than specified in the **bgwriter_lru_maxpages** parameter.

- Return type: bigint
- `pg_stat_get_buf_written_backend()`
Description: Specifies the number of buffers written by the backend thread because they need to allocate a new buffer.
Return type: bigint
 - `pg_stat_get_buf_alloc()`
Description: Specifies the total number of the allocated buffers.
Return type: bigint
 - `pg_stat_clear_snapshot()`
Description: Discards the current statistics snapshot. Only users with the SYSADMIN or MONADMIN permission can execute this function.
Return type: void
 - `pg_stat_reset()`
Description: Resets all statistics counters for the current database to zero (requires system administrator permissions).
Return type: void
 - `gs_stat_reset()`
Description: Resets all statistics counters for the current database on each node to zero (requiring system administrator permissions).
Return type: void
 - `pg_stat_reset_shared(text)`
Description: Resets all statistics counters for the current database in each node in a shared cluster to zero (requires system administrator permissions).
Return type: void
 - `pg_stat_reset_single_table_counters(oid)`
Description: Resets statistics for a single table or index in the current database to zero (requires system administrator permissions).
Return type: void
 - `pg_stat_reset_single_function_counters(oid)`
Description: Resets statistics for a single function in the current database to zero (requires system administrator permissions).
Return type: void
 - `pgxc_fenced_udf_process(integer)`
Description: Displays the number of UDF master and worker threads. Only users with the SYSADMIN or MONADMIN permission can execute this function. If the input parameter is set to **1**, the number of Master threads is queried. If the input parameter is set to **2**, the number of Worker threads is queried. If the input parameter is set to **3**, all Worker threads are terminated.
Return type: text.
 - `fenced_udf_process(integer)`
Description: Shows the number of local UDF Master and Work threads. If the input parameter is set to **1**, the number of Master threads is queried. If the input parameter is set to **2**, the number of Worker threads is queried. If the input parameter is set to **3**, all Worker threads are terminated.

- Return type: text.
- `total_cpu()`
Description: Obtains the CPU time used by the current node, in jiffies.
Return type: bigint
 - `total_memory()`
Description: Obtains the size of the virtual memory used by the current node, in KB.
Return type: bigint
 - `pgxc_terminate_all_fenced_udf_process()`
Description: Kills all UDF worker threads. Only users with the SYSADMIN or MONADMIN permission can execute this function.
Return type: Boolean
 - `gs_get_nodegroup_tablecount(name)`
Description: Obtains the total number of user tables in all databases in a node group.
Return type: integer.
 - `gs_check_tables_distribution()`
Description: Checks whether the user table distribution in the system is consistent. If no record is returned, table distribution is consistent. This function cannot be called during redistribution in scale-in or scale-out.
Return type: record
 - `pg_stat_bad_block(text, int, int, int, int, int, timestamp with time zone, timestamp with time zone)`
Description: Obtains damage information about pages after the current node is started.
Return type: record
 - `pgxc_stat_bad_block(text, int, int, int, int, int, timestamp with time zone, timestamp with time zone)`
Description: Obtains damage information about pages after all nodes in the cluster are started.
Return type: record
 - `pg_stat_bad_block_clear()`
Description: Deletes the page damage information that is read and recorded on the node (requires system administrator permissions).
Return type: void
 - `pgxc_stat_bad_block_clear`
Description: Deletes the page damage information that is read and recorded on all nodes in the cluster (requiring system administrator permissions).
Return type: void
 - `pgxc_log_comm_status(void)`
Description: When the SCTP communication mode is used, the PGXC system view exports the communication layer status of DNs to each log file. (Due to specification changes, the current version no longer supports this feature. Do not use it.)

Return type: void

- `gs_respool_exception_info(pool text)`

Description: Queries the query rule of a specified resource pool.

Return type: record

- `gs_control_group_info(pool text)`

Description: Queries information about Cgroups associated with a resource pool. Only users with the SYSADMIN permission can execute this function.

Return type: record

The command output is as follows:

Attribute	Value	Description
name	class_a:workload_a1	Class name and workload name
class	class_a	Class Cgroup name
workload	workload_a1	Workload Cgroup name
type	DEFWD	Cgroup type (Top , CLASS , BAKWD , DEFWD , or TSWD)
gid	87	Cgroup ID
shares	30	Percentage of CPU resources to those on the parent node
limits	0	Percentage of CPU cores to those on the parent node
rate	0	Allocation ratio in Timeshare
cpucore	0-3	Number of CPU cores

- `gs_all_control_group_info()`

Description: Collects information about all Cgroups in the database. For details about the columns returned by the function, see [16.3.48 GS_ALL_CONTROL_GROUP_INFO](#).

Return type: record

- `gs_get_control_group_info()`

Description: Collects information about all Cgroups. For details about the columns returned by the function, see [16.3.53 GS_GET_CONTROL_GROUP_INFO](#). Only users with the SYSADMIN permission can execute this function.

Return type: record

- `get_instr_workload_info(integer)`

Description: Obtains the transaction volume and time information on the current CN.

Return type: record

Attribute	Value	Description
user_oid	10	User ID
commit_counter	4	Number of frontend transactions that were committed
rollback_counter	1	Number of frontend transactions that were rolled back
resp_min	949	Minimum response time of frontend transactions (unit: μ s)
resp_max	201891	Maximum response time of frontend transactions (unit: μ s)
resp_avg	43564	Average response time of frontend transactions (unit: μ s)
resp_total	217822	Total response time of frontend transactions (unit: μ s)
bg_commit_counter	910	Number of background transactions that were committed
bg_rollback_counter	0	Number of background transactions that were rolled back
bg_resp_min	97	Minimum response time of background transactions (unit: μ s)
bg_resp_max	678080687	Maximum response time of background transactions (unit: μ s)
bg_resp_avg	327847884	Average response time of background transactions (unit: μ s)
bg_resp_total	298341575300	Total response time of background transactions (unit: μ s)

- `pv_instance_time()`
 Description: Obtains the time consumed in each execution phase on the current node.
 Return type: record

Stat_name Attribute	Value	Description
DB_TIME	1062385	Total end-to-end wall time consumed by all threads (unit: μ s)
CPU_TIME	311777	Total CPU time consumed by all threads (unit: μ s)
EXECUTION_TIME	380037	Total time consumed on the executor (unit: μ s)
PARSE_TIME	6033	Total time consumed for parsing SQL statements (unit: μ s)
PLAN_TIME	173356	Total time consumed for generating an execution plan (unit: μ s)
REWRITE_TIME	2274	Total time consumed for rewriting queries (unit: μ s)
PL_EXECUTION_TIME	0	Total time consumed for executing PL/pgSQL statements (unit: μ s)
PL_COMPILATION_TIME	557	Total time consumed for compiling SQL statements (unit: μ s)
NET_SEND_TIME	1673	Total time consumed for sending data over the network (unit: μ s)
DATA_IO_TIME	426622	Total time consumed for reading and writing data (unit: μ s)

- DBE_PERF.get_global_instance_time()**

Description: Provides the time consumed in each key phase in the entire cluster. The time consumed can be queried only on the CN. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record
- get_instr_unique_sql()**

Description: Obtains information about execution statements (normalized SQL statements) on the current node. Only users with the SYSADMIN or MONADMIN permission can query this function.

Return type: record
- get_instr_wait_event(integer)**

Description: Obtains the statistics on wait events of the current node.

Return type: record
- get_instr_user_login()**

Description: Obtains the number of user login and logout times on the current node. Only users with the SYSADMIN or MONADMIN permission can execute this function.

Return type: record

- `get_instr_rt_percentile(integer)`

Description: Obtains the response time distribution for 80% and 95% SQL statements in the CCN. The unified cluster information is stored on the CCN. The query result from other nodes is **0**.

Return type: record

- `get_node_stat_reset_time()`

Description: Obtains statistics about reset (restart, primary/standby switchover, and database deletion) time of the current node.

Return type: record

- `gs_paxos_stat_replication()`

Description: Queries the standby node information on the primary node.

Return type: setofrecord

The following table describes return columns.

Column	Type	Description
<code>local_role</code>	text	Role of the node that sends logs
<code>peer_role</code>	text	Role of the receiver node
<code>local_dcf_role</code>	text	DCF role of the node that sends logs
<code>peer_dcf_role</code>	text	DCF role of the receiver node
<code>peer_state</code>	text	Status of the receiver node
<code>sender_write_location</code>	text	Location in the Xlog buffer where the node that sends logs is written
<code>sender_commit_location</code>	text	Consistency point reached for the DCF logs of the node that sends logs
<code>sender_flush_location</code>	text	Location in the Xlog disk where the node that sends logs is written
<code>sender_replay_location</code>	text	Location where the sender node replays logs
<code>receiver_write_location</code>	text	Location in the Xlog buffer where the receiver node is written
<code>receiver_commit_location</code>	text	Consistency point reached for the DCF logs of the receiver node
<code>receiver_flush_location</code>	text	Location in the Xlog disk where the receiver node is written
<code>receiver_replay_location</code>	text	Location where the receiver node replays Xlogs
<code>sync_percent</code>	text	Synchronization percentage
<code>dcf_run_mode</code>	int4	DCF synchronization mode

Column	Type	Description
channel	text	Channel information

- get_paxos_replication_info()**
 Description: Queries the primary/standby replication status in Paxos mode.
 Return type: setofrecord
 The following table describes return columns.

Column	Type	Description
paxos_write_location	text	Location of the Xlog that has been written to the Distribute Consensus Framework (DCF)
paxos_commit_location	text	Location of the Xlog agreed in the DCF
local_write_location	text	Writing position of a node
local_flush_location	text	Flushing position of a node
local_replay_location	text	Redo position of a node
dcf_replication_info	text	DCF module information of a node

- gs_wlm_get_user_info(int)**
 Description: Obtains information about all users. The input parameter is of the int type and can be any int value or **NULL**. Only users with the SYSADMIN permission can execute this function.
 Return type: record
- gs_wlm_readjust_user_space(oid)**
 Description: Corrects the storage space usage of all users. Only the administrator can execute this function.
 Return type: record
- gs_wlm_readjust_user_space_through_username(text name)**
 Description: Corrects the storage space usage of a specified user. Common users can use this function to modify only their own usage. Only the administrator can modify the usage of all users. If the value of **name** is **0000**, the usage of all users needs to be modified.
 Return type: record
- gs_wlm_readjust_user_space_with_reset_flag(text name, boolean isfirst)**
 Description: Corrects the storage space usage of a specified user. If the input parameter **isfirst** is set to **true**, statistics are collected from 0. Otherwise, statistics are collected from the previous result. Common users can use this

function to modify only their own usage. Only the administrator can modify the usage of all users. If the value of **name** is **0000**, the usage of all users needs to be modified.

Return type: record

- `gs_io_wait_status()`

Description: Returns the real-time statistics on I/O control on the current node.

Return type: setof record

Name	Type	Description
node_name	text	Node name
device_name	text	Name of the data disk mounted to the node.
read_per_second	float	Number of read completions per second.
write_per_second	float	Number of write completions per second.
write_ratio	float	Ratio of the disk write I/Os to the total I/Os.
io_util	float	Percentage of the I/O time to the total CPU time per second.
total_io_util	integer	Level of the CPU time occupied by the last three I/Os. The value ranges from 0 to 6.
tick_count	integer	Interval for updating disk I/O information. The value is fixed to 1 second. The value is cleared each time before data is read.
io_wait_list_length	integer	Size of the I/O request thread wait queue. If the value is 0 , no I/O is under control.

- `gs_get_shared_memctx_detail(text)`

Description: Returns the memory application details of the specified memory context, including the file, line number, and size of each memory application (the size of the same line in the same file is accumulated). Only the memory context queried through the `pg_shared_memory_detail` view can be queried. The input parameter is the memory context name (that is, the **contextname** column in the result returned by the `pg_shared_memory_detail` view). To query this function, you must have the `SYSADMIN` or `MONADMIN` permission.

Return type: setof record

Name	Type	Description
file	text	Name of the file where the memory is applied for.
line	int8	Line number of the code in the file where the requested memory is located.

Name	Type	Description
size	int8	Size of the allocated memory. The value is accumulated if the memory is allocated for multiple times to the same line in the same file.

 **NOTE**

This view is not supported in the Lite release version.

- `gs_get_session_memctx_detail(text)`

Description: Returns the memory application details of the specified memory context, including the file, line number, and size of each memory application (the size of the same line in the same file is accumulated). This parameter is valid only in thread pool mode. Only the memory context queried through the `pv_session_memory_context` view can be queried. The input parameter is the memory context name (that is, the **contextname** column in the result returned by the `pv_session_memory_context` view). To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: setof record

Name	Type	Description
file	text	Name of the file where the memory is applied for.
line	int8	Line number of the code in the file where the requested memory is located.
size	int8	Size of the allocated memory, in bytes. The value is accumulated if the memory is allocated for multiple times to the same line of the same file.

 **NOTE**

This view takes effect only in thread pool mode and is not supported in the Lite release version.

- `gs_get_thread_memctx_detail(tid,text)`

Description: Returns the memory application details of the specified memory context, including the file, line number, and size of each memory application (the size of the same line in the same file is accumulated). Only the memory context queried through the `pv_thread_memory_context` view can be queried. The first input parameter is the thread ID (the **tid** column of the data returned by `pv_thread_memory_context`), and the second parameter is the memory context name (the **contextname** column of the data returned by `pv_thread_memory_context`). To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: setof record

Name	Type	Description
file	text	Name of the file where the memory is applied for.
line	int8	Line number of the code in the file where the requested memory is located.
size	int8	Size of the allocated memory, in bytes. The value is accumulated if the memory is allocated for multiple times to the same line of the same file.

 **NOTE**

This view is not supported in the Lite release version.

- `gs_get_history_memory_detail(cstring)`
Description: Queries historical memory snapshot information. The input parameter type is `cstring`. The value can be **NULL** or the name of the memory snapshot log file.
 - a. If the value of the input parameter is **NULL**, the list of all memory snapshot log files on the current node is displayed.
 - b. If the value of the input parameter is the name of the memory snapshot log file in the list queried in [a](#), the detailed information about the memory snapshot recorded in the log file is displayed.
 - c. If you enter any other input parameter, the system displays a message indicating that the input parameter is incorrect or the file fails to be opened.

To query this function, you must have the `SYSADMIN` or `MONADMIN` permission.

Return type: `text`.

Name	Type	Description
memory_info	text	Memory information. If the input parameter of the function is set to NULL , the memory snapshot file list is displayed. If the input parameter is set to the name of the memory snapshot file, the content of the file is displayed.

- `gs_stat_get_hotkeys_info()`

 **NOTE**

If the GUC parameter `enable_hotkeys_collection` is set to **off**, the `gs_stat_get_hotkeys_info` and `global_stat_get_hotkeys_info` functions as well as the `global_stat_hotkeys_info` view cannot be queried. The use of the `gs_stat_clean_hotkeys` and `global_stat_clean_hotkeys` APIs is not affected.

Description: Obtains the hotspot key statistics on the current node.

Return type: `record`

```
gaussdb=# SELECT * FROM gs_stat_get_hotkeys_info() order by count, hash_value;
database_name | schema_name | table_name | key_value | hash_value | count
-----+-----+-----+-----+-----+-----
regression   | public     | hotkey_single_col | {22}     | 1858004829 | 2
regression   | public     | hotkey_single_col | {11}     | 2011968649 | 2
(2 rows)
```

Name	Type	Description
database_name	text	Name of the database where the hotspot key is located
schema_name	text	Name of the schema where the hotspot key is located
table_name	text	Name of the table where the hotspot key is located
key_value	text	Value of the hotspot key
hash_value	bigint	Hash value of the hotspot key in the database. If the table is a list or range distribution table, the value of this field is 0 .
count	bigint	Frequency of accessing the hotspot key

- `gs_stat_clean_hotkeys()`

 **NOTE**

- Hot key detection is designed for high-concurrency and heavy-traffic scenarios. In the scenario where the access is performed for several times, the query result may be inaccurate.
- The clearing API is designed to clear only the statistics in the LRU queue but not the historical data in the FIFO. Therefore, if the historical key value in the FIFO is accessed again after the clearing, the historical key value is still processed as a hotspot key. This rule also applies to **global_stat_clean_hotkeys**.

Description: Clears statistics on hotspot keys on the current node.

Return type: Boolean

```
gaussdb=# SELECT * FROM gs_stat_clean_hotkeys();
gs_stat_clean_hotkeys
-----
t
(1 row)
```

- `global_stat_get_hotkeys_info()`

 **NOTE**

Run the **select * from global_stat_hotkeys_info minus select * from global_stat_get_hotkeys_info()** command during service execution. The value may not be **0** due to time difference.

Description: Obtains statistics on hotspot keys in the entire cluster.

Return type: record

```
gaussdb=# SELECT * FROM global_stat_get_hotkeys_info() order by count, hash_value;
database_name | schema_name | table_name | key_value | hash_value | count
-----+-----+-----+-----+-----+-----
regression   | public     | hotkey_single_col | {22}     | 1858004829 | 2
regression   | public     | hotkey_single_col | {11}     | 2011968649 | 2
(2 rows)
```

- `global_stat_clean_hotkeys()`

Description: Clears statistics on hotspot keys in the entire cluster.

Return type: Boolean.

```
gaussdb=# SELECT * FROM global_stat_clean_hotkeys();
global_stat_clean_hotkeys
-----
t
(1 row)
```
- `global_comm_get_rcv_stream()`

Description: Obtains the status of the stream received by all communications libraries on all DNs. For details about the columns returned by the function, see [PG_COMM_RECV_STREAM](#).

Return type: record.
- `global_comm_get_send_stream()`

Description: Obtains the status of the stream sent by all communications libraries on all DNs. For details about the columns returned by the function, see [PG_COMM_SEND_STREAM](#).

Return type: record.
- `global_comm_get_status()`

Description: Obtains the communications library status on all DNs. For details about the columns returned by the function, see [PG_COMM_STATUS](#).

Return type: record.
- `global_comm_client_info()`

Description: Obtains information about active client connections of global nodes. For details about the columns returned by the function, see [COMM_CLIENT_INFO](#).

Return type: record.
- `global_comm_get_client_info()`

Description: Obtains information about client connections of global nodes. For details about the columns returned by the function, see [COMM_CLIENT_INFO](#).

Return type: record.
- `pgxc_stat_activity()`

Description: Displays information about all CNs in the current cluster queried by the current user. Only users with the SYSADMIN or MONADMIN permission can execute this function, and common users can view only their own information. Three columns are added to version 505.0.0. During the gray upgrade observation period, an error is reported. You need to use PG_STAT_ACTIVITY to directly connect to the target node for query.

Return type: record.

Name	Type	Description
coorname	text	Name of a CN in the current cluster
datid	oid	OID of the database that the user session connects to in the backend

Name	Type	Description
datname	text	Name of the database that the user session connects to in the backend
pid	bigint	Backend thread ID.
sessionid	bigint	Session ID
usesysid	oid	OID of the user logged in to the backend.
username	text	Name of the user logged in to the backend.
application_name	text	Name of the application connected to the backend
client_addr	inet	IP address of the client connected to the backend. If this column is NULL , it indicates either the client is connected via a Unix socket on the server or this is an internal thread, such as AUTOVACUUM .
client_hostname	text	Host name of the connected client, as reported by a reverse DNS lookup of client_addr . This column will be non-null only for IP connections and only when log_hostname is enabled.
client_port	integer	TCP port number that the client uses for communication with this backend (-1 if a Unix socket is used)
backend_start	timestamp with time zone	Time when this process was started, that is, when the client connected to the server
xact_start	timestamp with time zone	Time when current transaction was started (null if no transaction is active). If the current query is the first of its transaction, the value of this column is the same as that of the query_start column.
query_start	timestamp with time zone	Time when the currently active query was started, or time when the last query was started if state is not active . For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.

Name	Type	Description
state_change	timestamp with time zone	Time when state was last modified
waiting	Boolean	Specifies whether the backend is currently waiting on a lock. If yes, the value is true .
enqueue	text	Queuing status of a statement. The value can be: <ul style="list-style-type: none">• waiting in queue: The statement is in the queue.• Empty: The statement is running.

Name	Type	Description
state	text	<p>Overall status of the backend The value can be:</p> <ul style="list-style-type: none"> • active: The backend is executing a query. • idle: The backend is waiting for a new client command. • idle in transaction: The backend is in a transaction, but there is no statement being executed in the transaction. • idle in transaction (aborted): The backend is in a transaction, but there are statements failed in the transaction. • fastpath function call: The backend is executing a fast-path function. • disabled: This state is reported if track_activities is disabled in this backend. <p>NOTE Only system administrators can view the session status of their accounts. The state information of other accounts is empty. For example, after user judy is connected to the database, the state information of user joe and the initial user omm in pgxc_stat_activity is empty.</p> <pre>SELECT datname, username, usesysid, state,pid FROM pgxc_stat_activity; datname username usesysid state pid -----+-----+-----+-----+----- +-----+-----+-----+-----+----- testdb omm 10 139968752121616 testdb omm 10 139968903116560 db_tpcds judy 16398 active 139968391403280 testdb omm 10 139968643069712 testdb omm 10 139968680818448 testdb joe 16390 139968563377936 (6 rows)</pre>
resource_pool	name	Resource pool used by the user.
query_id	bigint	ID of a query

Name	Type	Description
query	text	Latest query at the backend. If state is active , this column shows the ongoing query. In all other states, it shows the last query that was executed.
global_sessionid	text	Global session ID
unique_sql_id	bigint	Unique SQL statement ID
trace_id	text	Driver-specific trace ID, which is associated with an application request
top_xid	xid	Top-level transaction ID of a transaction.
current_xid	xid	Current transaction ID of a transaction.
xlog_quantity	bigint	Amount of Xlogs currently used by a transaction, in bytes.

- pgxc_stat_activity_with_conninfo()**

Description: Displays query information about the current user on all CNs in the current cluster. For details, see the **pgxc_stat_activity** view. Only users with the SYSADMIN or MONADMIN permission can execute this function, and common users can view only their own information.

Return type: record.
- pgxc_stat_all_tables()**

Description: Displays statistics on a row in each table (including TOAST tables) on each node. Only users with the SYSADMIN or MONADMIN permission can execute this function.

Return type: record.
- pgxc_get_thread_wait_status()**

Description: Queries the call hierarchy between threads generated by all SQL statements on each node in a cluster and the block waiting status of each thread.

Return type: record.
- pv_session_memory**

Description: Collects statistics on memory usage at the session level, including all the memory allocated to GaussDB and stream threads on DN for jobs currently executed by users.

 **NOTE**

If the GUC parameter **enable_memory_limit** is set to **off**, this function cannot be used.

Return type: record.

Table 7-152 Return value description

Name	Type	Description
sessid	text	Thread start time and ID
init_mem	integer	Memory allocated to the currently executed jobs before they enter the executor, in MB
used_mem	integer	Memory allocated to the currently executed jobs, in MB
peak_mem	integer	Peak memory allocated to the currently executed jobs, in MB

- DBE_PERF.gs_stat_activity_timeout(int)

Description: Obtains information about query jobs whose execution time exceeds the timeout threshold on the current node. The correct result can be returned only when the GUC parameter **track_activities** is set to **on**. The timeout threshold ranges from 0 to 2147483. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: SETOF record.

Name	Type	Description
database	name	Name of the database to which a user session is connected
pid	bigint	Backend thread ID.
sessionid	bigint	Session ID
usesysid	oid	OID of the user logged in to the backend.
application_name	text	Name of the application connected to the backend.
query	text	Query that is being executed on the backend
xact_start	timestampz	Time when the current transaction is started
query_start	timestampz	Time when the current query starts
query_id	bigint	Query statement ID

- DBE_PERF.global_stat_activity_timeout(int)

Description: Obtains information about query jobs whose execution time exceeds the timeout threshold in the current system (all CNs). The correct result can be returned only when the GUC parameter **track_activities** is set to **on**. The timeout threshold ranges from 0 to 2147483. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: SETOF record.

Name	Type	Description
nodename	text	Name of the CN connected to the user session
database	name	Name of the database to which a user session is connected
pid	bigint	Backend thread ID.
sessionid	bigint	Session ID
usesysid	oid	OID of the user logged in to the backend.
application_name	text	Name of the application connected to the backend.
query	text	Query that is being executed on the backend
xact_start	timestampz	Time when the current transaction is started
query_start	timestampz	Time when the current query starts
query_id	bigint	Query statement ID.

- DBE_PERF.get_global_active_session()

Description: Displays a summary of samples in the ACTIVE SESSION PROFILE memory on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function. The **event_start_time**, **current_xid**, and **top_xid** columns are added to GaussDB Kernel 505.0. After GaussDB Kernel is upgraded to GaussDB Kernel 505.0 or later, the columns cannot be queried during the upgrade observation period.

Return type: record.

- DBE_PERF.get_global_os_runtime()

Description: Displays the running status of the current OS. This function can be queried only on CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record

- DBE_PERF.get_global_os_threads()

Description: Provides thread status information on all normal nodes in the entire cluster. The information can be queried only on CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- DBE_PERF.get_global_os_threads()

Description: Provides thread status information on all normal nodes in the entire cluster. The information can be queried only on CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_summary_workload_sql_count()`
Description: Provides the count information of SELECT, UPDATE, INSERT, DELETE, DDL, DML, and DCL in different loads in the entire cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_summary_workload_sql_elapse_time()`
Description: Provides SELECT, UPDATE, INSERT, DELETE, and response time information (TOTAL, AVG, MIN, and MAX) in different loads in the entire cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_workload_transaction()`
Description: Obtains the transaction volume and time information on all nodes in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_session_stat()`
Description: Obtains the session status information on all nodes in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.

 **NOTE**

The status information contains the following 14 items: ommit, rollback, sql, table_scan, blocks_fetched, physical_read_operation, shared_blocks_dirtied, local_blocks_dirtied, shared_blocks_read, local_blocks_read, blocks_read_time, blocks_write_time, sort_imemory, and sort_idisk.

- `DBE_PERF.get_global_session_time()`
Description: Provides the time consumed in each key phase on each node in the entire cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_session_memory()`
Description: Aggregates statistics on memory usage at the session level on each node in the unit of MB, including all the memory allocated to GaussDB and stream threads on DNs for jobs currently executed by users. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_session_memory_detail()`
Description: Aggregates statistics on thread memory usage on each node by the MemoryContext node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_session_stat_activity()`

Description: Aggregates information about running threads on each node in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- DBE_PERF.get_global_thread_wait_status()

Description: Aggregates the blocking waiting status of the backend thread and auxiliary thread on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- DBE_PERF.get_global_operator_ec_history()

Description: Aggregates the historical status information about the current user's EC operators on each CN. After a cluster is created, by default, you must have the MONADMIN or SYSADMIN permission to query this function.

Return type: record.

- DBE_PERF.get_global_operator_ec_history_table()

Description: Aggregates the historical status information (persistent) of the current user's EC operators on each CN. After a cluster is created, by default, you must have the MONADMIN or SYSADMIN permission to query this function.

Return type: record.

- DBE_PERF.get_global_operator_ec_runtime()

Description: Aggregates the real-time status information about the current user's EC operators on each CN. After a cluster is created, by default, you must have the MONADMIN or SYSADMIN permission to query this function.

Return type: record.

- DBE_PERF.get_global_operator_history_table()

Description: Aggregates the operator records (persistent) after jobs are executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- DBE_PERF.get_global_operator_history()

Description: Aggregates the operator records after jobs are executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN or SYSADMIN permission to query this function.

Return type: record.

- DBE_PERF.get_global_operator_runtime()

Description: Aggregates real-time operator records of jobs executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN or SYSADMIN permission to query this function.

Return type: record.

- DBE_PERF.get_global_statement_complex_history()

Description: Aggregates the historical records of complex queries executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_global_statement_complex_history_table()`
Description: Aggregates the historical records of complex queries (persistent) executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_statement_complex_runtime()`
Description: Aggregates real-time information about complex queries executed by the current user on all CNs. After a cluster is created, by default, you must have the MONADMIN or SYSADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_memory_node_detail()`
Description: Aggregates the memory usage of a database on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_shared_memory_detail()`
Description: Aggregates the usage information about the shared memory contexts on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_comm_delay()`
Description: Aggregates the communications library delay status on all DNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_comm_recv_stream()`
Description: Aggregates the status of the stream received by the communications library on all DNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_comm_send_stream()`
Description: Aggregates the status of the stream sent by the communications library on all DNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_comm_status()`
Description: Aggregates the status of the communications library on all DNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_statio_all_indexes()`
Description: Aggregates index information and I/O statistics in the current database on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_local_toastname_and_toastindexname()`

Description: Provides the mapping between the name and index of the local TOAST table and its associated tables. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_summary_statio_all_indexes()`

Description: Collects I/O statistics on specific indexes, covering all index lines in the current database on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_global_statio_all_sequences()`

Description: Provides I/O status information about all sequences in the namespace. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_global_statio_all_tables()`

Description: Aggregates I/O statistics on each table in the database on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_summary_statio_all_tables()`

Description: Collects statistics on I/Os of each table in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_local_toast_relation()`

Description: Provides the mapping between the name of the local TOAST table and its associated tables. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_global_statio_sys_indexes()`

Description: Aggregates I/O status information about all system catalog indexes in namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_summary_statio_sys_indexes()`

Description: Collects statistics on I/O status information about all system catalog indexes in namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_global_statio_sys_sequences()`

Description: Provides I/O status information about all system catalog sequences in namespaces. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_global_statio_sys_tables()`
Description: Provides I/O status information about all system catalogs in the namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_summary_statio_sys_tables()`
Description: Aggregates I/O status information about all system catalogs in the namespaces of the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_statio_user_indexes()`
Description: Provides I/O status information about all user relationship table indexes in the namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_summary_statio_user_indexes()`
Description: Aggregates I/O status information about all user relationship table indexes in the namespaces of the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_statio_user_sequences()`
Description: Provides I/O status information about all user sequences in the namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_statio_user_tables()`
Description: Provides I/O status information about all user relationship tables in the namespaces on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_summary_statio_user_tables()`
Description: Aggregates I/O status information about all user relationship tables in the namespaces of the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_dn_stat_all_tables()`
Description: Aggregates statistics on all tables in the database on each DN. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_cn_stat_all_tables()`
Description: Aggregates statistics on all tables in the database on each CN. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_summary_dn_stat_all_tables()`

Description: Collects statistics on all tables in the database on each DN. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_summary_cn_stat_all_tables()`

Description: Collects statistics on all tables in the database on each CN. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_global_stat_all_indexes()`

Description: Aggregates statistics on all indexes in the database on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_summary_stat_all_indexes()`

Description: Collects statistics on all indexes in the database on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_global_stat_sys_tables()`

Description: Aggregates statistics on the system catalogs of all the namespaces in the `pg_catalog` or `information_schema` schema on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_summary_stat_sys_tables()`

Description: Collects statistics on the system catalogs of all the namespaces in the `pg_catalog` or `information_schema` schema on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_global_stat_sys_indexes()`

Description: Aggregates index status information about all system catalogs in the `pg_catalog` or `information_schema` schema on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_summary_stat_sys_indexes()`

Description: Collects index status information about all system catalogs in the `pg_catalog` or `information_schema` schema on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.get_global_stat_user_tables()`
Description: Aggregates status information about user-defined ordinary tables in all namespaces. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_summary_stat_user_tables()`
Description: Collects status information about user-defined ordinary tables in all namespaces. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_stat_user_indexes()`
Description: Aggregates status information about the indexes of user-defined ordinary tables in all databases. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_summary_stat_user_indexes()`
Description: Collects status information about the indexes of user-defined ordinary tables in all databases. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_stat_database()`
Description: Aggregates statistics on databases on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_stat_database_conflicts()`
Description: Collects statistics on databases on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_stat_xact_all_tables()`
Description: Aggregates transaction status information about all ordinary tables and TOAST tables in namespaces. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_summary_stat_xact_all_tables()`
Description: Collects transaction status information about all ordinary tables and TOAST tables in the namespace. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_stat_xact_sys_tables()`
Description: Aggregates transaction status information about system catalogs in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.

- `DBE_PERF.get_summary_stat_xact_sys_tables()`
Description: Collects transaction status information about system catalogs in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_stat_xact_user_tables()`
Description: Aggregates transaction status information about user tables in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_summary_stat_xact_user_tables()`
Description: Collects transaction status information about user tables in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_stat_user_functions()`
Description: Aggregates transaction status information about user-defined functions in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_stat_xact_user_functions()`
Description: Collects transaction status information about user-defined functions in namespaces on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_stat_bad_block()`
Description: Aggregates information about the failure to read files such as tables and indexes on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_file_redo_iostat()`
Description: Collects information about the failure to read files such as tables and indexes on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_file_iostat()`
Description: Collects I/O statistics of data files on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_locks()`
Description: Aggregates lock information on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.

- `DBE_PERF.get_global_replication_slots()`
Description: Aggregates logical replication information on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.GET_GLOBAL_PARALLEL_DECODE_STATUS()`
Description: Displays the parallel decoding information of replication slots on all primary DNs in a cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function. This function can be executed only on CNs. An error is reported when it is executed on DNs. The returned value is the same as that of the view [GLOBAL_PARALLEL_DECODE_STATUS](#).
Return type: record.
- `DBE_PERF.GET_GLOBAL_PARALLEL_DECODE_THREAD_INFO()`
Description: Displays the parallel decoding thread information of replication slots on all primary DNs in a cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function. This function can be executed only on CNs. An error is reported when it is executed on DNs. The returned value is the same as that of the view [GLOBAL_PARALLEL_DECODE_THREAD_INFO](#).
Return type: record.
- `DBE_PERF.get_global_bgwriter_stat()`
Description: Aggregates statistics on the backend write thread activities on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_replication_stat()`
Description: Aggregates status information about log synchronization on all nodes, such as the location where the sender sends logs and the location where the receiver receives logs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_pooler_status()`
Description: Aggregates cache connection status in the pooler on all CNs. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_global_transactions_running_xacts()`
Description: Aggregates information about running transactions on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.get_summary_transactions_running_xacts()`
Description: Collects information about running transactions on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

- Return type: record.
- `DBE_PERF.get_global_transactions_prepared_xacts()`
Description: Aggregates information about transactions that are currently prepared for two-phase commit on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
 - `DBE_PERF.get_summary_transactions_prepared_xacts()`
Description: Collects information about transactions that are currently prepared for two-phase commit on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
 - `DBE_PERF.get_summary_statement()`
Description: Aggregates the status of historical statements executed on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
 - `DBE_PERF.get_global_statement_count()`
Description: Aggregates SELECT, UPDATE, INSERT, DELETE, and response time information (TOTAL, AVG, MIN, and MAX) on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
 - `DBE_PERF.get_global_config_settings()`
Description: Aggregates GUC parameter settings on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
 - `DBE_PERF.get_global_wait_events()`
Description: Aggregates status information about the wait events on each node. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
 - `DBE_PERF.get_statement_responsetime_percentile()`
Description: Obtains the response time distribution for 80% and 95% SQL statements in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
 - `DBE_PERF.get_summary_user_login()`
Description: Collects statistics on the number of user login and logout times on each node in the cluster. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
 - `DBE_PERF.get_global_record_reset_time()`
Description: Aggregates statistics on reset (restart, primary-standby switchover, and database deletion) time in the cluster. After a cluster is

created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- DBE_PERF.standby_statement_history(only_slow[, time1, time2])

Description: Queries full SQL statements on the standby node. The primary node queries full SQL statements using the statement_history table, while the standby node queries using this function. To query this function, you must have the MONADMIN permission.

For details, see [Table 7-153](#).

Return type: record, which is the same as that in the statement_history table.

Table 7-153 standby_statement_history parameters

Parameter	Type	Description
only_slow	Boolean	Specifies whether to query only slow SQL statements. <ul style="list-style-type: none"> • true: yes, which is equivalent to select .. where is_slow_sql = true. • false or NULL indicates that all SQL statements are queried, that is, is_slow_sql is not used as a filtering condition.
time1	timestamp	Minimum time specified by finish_time for querying SQL statements. This parameter is optional.
time2	timestamp	Maximum time specified by finish_time for querying SQL statements. This parameter is optional.

 **NOTE**

- The two time parameters **time1** and **time2** indicate the time segment to which **finish_time** of the queried SQL statement belongs. They indicate the start time and end time respectively. If **NULL** or no value is entered, there is no limit. The function of **time1** and **time2** is the same as that of **select .. where finish_time between time1 and time2**.
- The data generated from this function on the standby node is not stored in a table, and there is no index on the **start_time** column. You are advised to use the parameter to search for **finish_time**.
- Full/Slow SQL statements on the standby node are written to disks asynchronously. Therefore, the storage of user SQL information may be delayed. You are advised to query this API to expand the query time range.
- DBE_PERF.track_memory_context(context_list text)

Description: Sets the memory context whose memory application details need to be collected. The input parameter is the memory context names, which are separated by commas (,), for example, **ThreadTopMemoryContext**, **SessionCacheMemoryContext**. Note that the memory context names are context-sensitive. In addition, the length of a single memory context is 63, and the excess part is truncated. The maximum number of memory contexts

that can be collected at a time is 16. If the number of memory contexts exceeds 16, the setting fails. Each time this function is called, the previous statistics result is cleared. When the input parameter is set to "", the statistics function is disabled. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: Boolean.

- `DBE_PERF.track_memory_context_detail()`
Description: Obtains the memory application details of the memory context specified by the `DBE_PERF.track_memory_context` function. For details, see the `DBE_PERF.track_memory_context_detail` view. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `DBE_PERF.global_io_wait_info()`
Description: Queries real-time I/O control statistics on all CNs and DN. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `pg_stat_get_mem_mbytes_reserved(tid)`
Description: Collects statistics on variables related to resource management, which is used only for fault locating.
Parameter: thread ID
Return type: text.
- `pg_stat_get_file_stat()`
Description: Collects statistics on data file I/Os to indicate I/O performance and detect performance problems such as abnormal I/O operations.
Return type: record.
- `pg_stat_get_redo_stat()`
Description: Displays statistics on the replay of session thread logs.
Return type: record.
- `pg_stat_get_status(int8)`
Description: Tests the block waiting status about the backend thread and auxiliary thread of the current instance.
Return type: record.
- `get_local_rel_iostat()`
Description: Queries the accumulated I/O status of data files on the current node.
Return type: record.
- `DBE_PERF.get_global_rel_iostat()`
Description: Aggregates I/O statistics on data files on all nodes. After a cluster is created, by default, you must have the MONADMIN permission to query this function.
Return type: record.
- `pg_catalog.plancache_status()`

Description: Displays status information about the global plan cache on the current node. The information returned by the function is the same as that in [GLOBAL_PLANCACHE_STATUS](#).

Return type: record.

- `DBE_PERF.global_plancache_status()`

Description: Displays status information about the global plan cache on all nodes. For details about the information returned by the function, see [GLOBAL_PLANCACHE_STATUS](#). After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `pg_catalog.prepare_statement_status()` (Discarded)

Description: Displays the PREPARE statement status information on the current node. The information returned by the function is the same as that in [GLOBAL_PLANCACHE_STATUS](#).

Return type: record.

- `DBE_PERF.global_prepare_statement_status()` (Discarded)

Description: Displays status information about the PREPARE statement on all nodes. For details about the information returned by the function, see [GLOBAL_PREPARE_STATEMENT_STATUS](#). After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `DBE_PERF.global_threadpool_status()`

Description: Displays the status of worker threads and sessions in thread pools on all nodes. For details about the information returned by the function, see [18.7.14-Table GLOBAL_THREADPOOL_STATUS](#). After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Return type: record.

- `comm_check_connection_status()`

Description: Returns the connection status between the CN and all active nodes (CNs and primary DN). This function can be queried only on CNs and can be used by common users.

Parameter: nan

Return type: node_name text, remote_name text, remote_host text, remote_port integer, is_connected boolean, and no_error_occur boolean

- `DBE_PERF.global_comm_check_connection_status()`

Description: Returns the connection status between all CNs and all active nodes (CNs and primary DN). This function can be queried only on CNs. Permission control is inherited from the **DBE_PERF** schema. After a cluster is created, by default, you must have the MONADMIN permission to query this function.

Parameter: nan

Return type: node_name text, remote_name text, remote_host text, remote_port integer, is_connected boolean, and no_error_occur boolean

- `remote_candidate_stat()`

Description: Displays the number of pages in the candidate buffer chain of this instance and buffer elimination information, including the normal buffer pool and segment buffer pool.

Return type: record.

Table 7-154 remote_candidate_stat parameter description

Name	Type	Description
node_name	text	Node name
candidate_slots	integer	Number of pages in the candidate buffer chain of the current normal buffer pool
get_buf_from_list	bigint	Number of times that pages are obtained from the candidate buffer chain during buffer eviction in the current normal buffer pool
get_buf_clock_sweep	bigint	Number of times that pages are obtained from the original eviction solution during buffer eviction in the current normal buffer pool
seg_candidate_slots	integer	Number of pages in the candidate buffer chain of the current segment buffer pool
seg_get_buf_from_list	bigint	Number of times that pages are obtained from the candidate buffer chain during buffer eviction in the current segment buffer pool
seg_get_buf_clock_sweep	bigint	Number of times that pages are obtained from the original eviction solution during buffer eviction in the current segment buffer pool

- remote_ckpt_stat()

Description: Displays the checkpoint information and log flushing information about all instances in the cluster (unavailable on DNs, except for the current node).

Return type: record.

Table 7-155 remote_ckpt_stat parameter description

Parameter	Type	Description
node_name	text	Instance name
ckpt_redo_point	text	Checkpoint of the current instance
ckpt_clog_flush_num	int8	Number of Clog flushing pages from the startup time to the current time

Parameter	Type	Description
ckpt_csnlog_flush_num	int8	Number of CSN log flushing pages from the startup time to the current time
ckpt_multixact_flush_num	int8	Number of MultiXact flushing pages from the startup time to the current time
ckpt_predicate_flush_num	int8	Number of predicate flushing pages from the startup time to the current time
ckpt_twophase_flush_num	int8	Number of two-phase flushing pages from the startup time to the current time

- remote_double_write_stat()

Description: Displays doublewrite file status of all instances in the cluster (unavailable on DNs, except for the current node).

Return type: record.

Table 7-156 remote_double_write_stat parameter description

Parameter	Type	Description
node_name	text	Instance name
curr_dwn	int8	Sequence number of the doublewrite file.
curr_start_page	int8	Start page for restoring the doublewrite file
file_trunc_num	int8	Number of times that the doublewrite file is reused.
file_reset_num	int8	Number of reset times after the doublewrite file is full.
total_writes	int8	Total number of I/Os of the doublewrite file
low_threshold_writes	int8	Number of I/Os for writing the doublewrite files with low efficiency (the number of I/O flushing pages at a time is less than 16.)
high_threshold_writes	int8	Number of I/Os for writing the doublewrite files with high efficiency (the number of I/O flushing pages at a time is more than 421.)
total_pages	int8	Total number of pages that are flushed to the doublewrite file area

Parameter	Type	Description
low_threshold_pages	int8	Number of pages that are flushed with low efficiency
high_threshold_pages	int8	Number of pages that are flushed with high efficiency
file_id	int8	ID of the current doublewrite file

- remote_single_flush_dw_stat()

Description: Displays the single-page doublewrite file eviction status of all instances in the cluster (unavailable on DNs, except for the current node).

Return type: record.

Table 7-157 remote_single_flush_dw_stat parameter description

Parameter	Type	Description
node_name	text	Instance name
curr_dwn	integer	Sequence number of the doublewrite file.
curr_start_page	integer	Start position of the current doublewrite file.
total_writes	bigint	Total number of data write pages in the current doublewrite file.
file_trunc_num	bigint	Number of times that the doublewrite file is reused.
file_reset_num	bigint	Number of reset times after the doublewrite file is full.

- remote_pagewriter_stat()

Description: Displays the page flushing information and checkpoint information about all instances in the cluster (unavailable on DNs, except for the current node).

Return type: record.

Table 7-158 remote_pagewriter_stat parameter description

Parameter	Type	Description
node_name	text	Instance name
pgwr_actual_flush_total_num	int8	Total number of dirty pages flushed from the startup time to the current time

Parameter	Type	Description
pgwr_last_flush_num	int4	Number of dirty pages flushed in the previous batch
remain_dirty_page_num	int8	Estimated number of dirty pages that are not flushed
queue_head_page_rec_lsn	text	recovery_lsn of the first dirty page in the dirty page queue of the current instance
queue_rec_lsn	text	recovery_lsn of the dirty page queue of the current instance
current_xlog_insert_lsn	text	Write position of Xlogs in the current instance
ckpt_redo_point	text	Checkpoint of the current instance

- remote_recovery_status()

Description: Displays log flow control information about the primary and standby nodes (except the current node and DNs).

Return type: record.

Table 7-159 remote_recovery_status parameter description

Parameter	Type	Description
node_name	text	Node name (including the primary and standby nodes)
standby_node_name	text	Name of the standby node
source_ip	text	IP address of the primary node
source_port	int4	Port number of the primary node
dest_ip	text	IP address of the standby node
dest_port	int4	Port number of the standby node
current_rto	int8	Current log flow control time of the standby node (unit: s)
target_rto	int8	Expected flow control time of the standby node specified by the corresponding GUC parameter (unit: s)

Parameter	Type	Description
current_sleep_time	int8	Sleep time required to achieve the expected flow control time (unit: μ s)

- remote_rto_stat()

Description: Displays log flow control information about the primary and standby nodes (unavailable on DNs, except for the current node).

Return type: record.

Table 7-160 remote_rto_stat parameters

Parameter	Type	Description
node_name	text	Node name (including the primary and standby nodes)
rto_info	text	Flow control information, including the current log flow control time (unit: second) of the standby server, the expected flow control time (unit: second) specified by the GUC parameter, and the primary server sleep time (unit: μ s) required to reach the expectation

- remote_redo_stat()

Description: Displays the log replay status of all instances in the cluster (unavailable on DNs, except for the current node).

Return type: record.

Table 7-161 remote_redo_stat parameter description

Parameter	Type	Description
node_name	text	Instance name
redo_start_ptr	int8	Start point for replaying the instance logs
redo_start_time	int8	Start time (UTC) when the instance logs are replayed
redo_done_time	int8	End time (UTC) when the instance logs are replayed
curr_time	int8	Current time (UTC) of the instance
min_recovery_point	int8	Position of the minimum consistency point for the instance logs

Parameter	Type	Description
read_ptr	int8	Position for reading the instance logs
last_replayed_read_ptr	int8	Position for replaying the instance logs
recovery_done_ptr	int8	Replay position after the instance is started
read_xlog_io_counter	int8	Number of I/Os when the instance reads and replays logs
read_xlog_io_total_dur	int8	Total I/O latency when the instance reads and replays logs
read_data_io_counter	int8	Number of data page I/O reads during replay in the instance
read_data_io_total_dur	int8	Total I/O latency of data page reads during replay in the instance
write_data_io_counter	int8	Number of data page I/O writes during replay in the instance
write_data_io_total_dur	int8	Total I/O latency of data page writes during replay in the instance
process_pending_counter	int8	Number of synchronization times of log distribution threads during replay in the instance
process_pending_total_dur	int8	Total synchronization latency of log distribution threads during replay in the instance
apply_counter	int8	Number of synchronization times of replay threads during replay in the instance
apply_total_dur	int8	Total synchronization latency of replay threads during replay in the instance
speed	int8	Log replay rate of the current instance
local_max_ptr	int8	Maximum number of replay logs received by the local host after the instance is started

Parameter	Type	Description
primary_flush_ptr	int8	Log point where the host flushes logs to a disk
worker_info	text	Replay thread information of the instance. If concurrent replay is not enabled, the value is NULL .

- pgxc_gtm_snapshot_status()**

Description: Queries for transaction information on the current GTM. This function is supported only in GTM mode, and is not supported in GTM-LITE or GTM-FREE mode.

Return type: record.

The following table describes return parameters.

Table 7-162 PGXC_GTM_SNAPSHOT_STATUS return parameters

Name	Type	Description
xmin	xid	Minimum XID of the running transactions
xmax	xid	XID of the transaction next to the executed transaction with the maximum XID
csn	integer	Specifies the sequence number of the transaction to be committed.
oldestxmin	xid	Minimum XID of the executed transactions
xcnt	integer	Number of the running transactions
running_xids	text	XID of the running transaction

- pv_os_run_info()**

Description: Displays the running status of the current OS. For details about the columns, see [PV_OS_RUN_INFO](#).

Parameter: nan

Return type: SETOF record.
- pv_session_stat()**

Description: Collects session status information by session thread or AutoVacuum thread. For details about the columns, see [PV_SESSION_STAT](#).

Parameter: **nan**

Return type: SETOF record.
- pv_session_time()**

Description: Collects statistics on the running time of session threads and the time consumed in each execution phase. For details about the columns, see [PV_SESSION_TIME](#).

Parameter: **nan**

Return type: SETOF record.

- `pg_stat_get_db_temp_bytes()`

Description: Collects statistics on the total amount of data written to temporary files through database query. All temporary files are counted, regardless of why the temporary file was created, and regardless of the **log_temp_files** setting.

Parameter: **oid**

Return type: bigint.

- `pg_stat_get_db_temp_files()`

Description: Queries the number of temporary files created in the database. All temporary files are counted, regardless of why the temporary file was created (for example, sorting or hashing), and regardless of the **log_temp_files** setting.

Parameter: **oid**

Return type: bigint.

- `gs_prepared_statements()`

Description: Displays prepared statements that are available in all sessions. Only users with the SYSADMIN permission can execute this function. The fields in the information returned by the function are the same as those in [GS_ALL_PREPARED_STATEMENTS](#).

Return type: record.

- `local_redo_time_count()`

Description: Returns the time consumption statistics on each process of each replayer thread on the current node (valid data exists only on the standby node).

The return values are as follows:

Table 7-163 local_redo_time_count return parameters

Column	Description
thread_name	Thread name.

Column	Description
step1_total	<p>Total duration of step 1. The process of each thread is as follows:</p> <ul style="list-style-type: none"> • Ultimate RTO: <ul style="list-style-type: none"> redo batch: obtains a log from a queue. redo manager: obtains a log from a queue. redo worker: obtains a log from a queue. trxn manager: reads a log from a queue. trxn worker: reads a log from a queue. read worker: reads an Xlog page (overall) from a file. read page worker: obtains a log from a queue. startup: obtains a log from a queue. • Parallel replay: <ul style="list-style-type: none"> page redo: obtains a log from a queue. startup: reads a log.
step1_count	<p>Number of accumulated execution times of step 1.</p>
step2_total	<p>Total duration of step 2. The process of each thread is as follows:</p> <ul style="list-style-type: none"> • Ultimate RTO: <ul style="list-style-type: none"> redo batch: processes logs (overall). redo manager: processes logs (overall). redo worker: processes logs (overall). trxn manager: processes logs (overall). trxn worker: processes logs (overall). read worker: specifies the time required for reading the Xlog page. read page worker: generates and sends LSN forwarders. startup: checks whether to replay to the specified position. • Parallel replay: <ul style="list-style-type: none"> startup: checks whether to replay to the specified position.
step2_count	<p>Number of accumulated execution times of step 2.</p>

Column	Description
step3_total	<p>Total duration of step 3. The process of each thread is as follows:</p> <ul style="list-style-type: none"> • Ultimate RTO: <ul style="list-style-type: none"> redo batch: updates the standby state. redo manager: processes data logs. redo worker: replays page logs (overall). txn manager: updates the flushing LSN. txn worker: replays logs. read worker: pushes the Xlog segment. read page worker: obtains a new item. • Parallel replay: <ul style="list-style-type: none"> page redo: updates the standby state. startup: collects statistics on the wait time of delayed replay feature.
step3_count	Number of accumulated execution times of step 3.
step4_total	<p>Total duration of step 4. The process of each thread is as follows:</p> <ul style="list-style-type: none"> • Ultimate RTO: <ul style="list-style-type: none"> redo batch: parses Xlogs. redo manager: processes DDL operations. redo worker: reads data pages. txn manager: synchronizes the wait time. txn worker: updates the LSN of the current thread. read page worker: stores logs in the distribution thread. • Parallel replay: <ul style="list-style-type: none"> page redo: replays undo logs. startup: distributes logs (overall).
step4_count	Number of accumulated execution times of step 4.

Column	Description
step5_total	<p>Total duration of step 5. The process of each thread is as follows:</p> <ul style="list-style-type: none"> Ultimate RTO: <ul style="list-style-type: none"> redo batch: distributes to the redo manager. redo manager: distributes logs to redo workers. redo worker: replays data page logs. trxn manager: distributes data to the trxn worker. trxn worker: forcibly synchronizes the wait time. read page worker: updates the LSN of the current thread. startup: decodes logs. Parallel replay: <ul style="list-style-type: none"> page redo: replays sharetrxn logs. startup: replays logs.
step5_count	Number of accumulated execution times of step 5.
step6_total	<p>Total duration of step 6. The process of each thread is as follows:</p> <ul style="list-style-type: none"> Ultimate RTO: <ul style="list-style-type: none"> redo worker: replays non-data page logs. trxn manager: updates global LSNs. redo manager: stores data page logs to the hash table. Parallel replay: <ul style="list-style-type: none"> page redo: replays synctrxn logs. startup: forcibly synchronizes the wait time.
step6_count	Number of accumulated execution times of step 6.
step7_total	<p>Total duration of step 7. The process of each thread is as follows:</p> <ul style="list-style-type: none"> Ultimate RTO: <ul style="list-style-type: none"> redo manager: creates tablespaces. redo worker: updates FSM. Parallel replay: <ul style="list-style-type: none"> page redo: replays a single log.
step7_count	Number of accumulated execution times of step 7.

Column	Description
step8_total	Total duration of step 8. The process of each thread is as follows: <ul style="list-style-type: none"> • Ultimate RTO: redo worker: forcibly synchronizes the wait time. • Parallel replay: page redo: replays all workers do logs.
step8_count	Number of accumulated execution times of step 8.
step9_total	Total duration of step 9. The process of each thread is as follows: <ul style="list-style-type: none"> • Ultimate RTO: redo manager: distributes logs to the page redo thread. • Parallel replay: page redo: replays multi-worker do logs.
step9_count	Number of accumulated execution times of step 9.

- local_xlog_redo_statics()

Description: Returns the statistics on each type of logs that have been replayed on the current node (valid data exists only on the standby node).

The return values are as follows:

Table 7-164 local_xlog_redo_statics parameters

Column	Description
xlog_type	Log types.
rmid	Resource manager ID.
info	Xlog operation.
num	Number of logs.
extra	Valid values are available for page replay logs and xact logs. <ul style="list-style-type: none"> • Number of pages read from the disk if the log is of the page type. • Number of deleted files if the log is of the xact type.

- remote_bgwriter_stat()

Description: Displays information about pages flushed by the bgwriter threads of all instances in the cluster, number of pages in the candidate buffer chain,

and buffer eviction information (not available on the DN, except for the current node).

Return type: record.

Table 7-165 remote_bgwriter_stat parameter description

Parameter	Type	Description
node_name	text	Instance name
bgwr_actual_flush_total_num	bigint	Total number of dirty pages flushed by the bgwriter thread from the startup time to the current time
bgwr_last_flush_num	integer	Number of dirty pages flushed by the bgwriter thread in the previous batch
candidate_slots	integer	Number of pages in the current candidate buffer chain
get_buffer_from_list	bigint	Number of times that pages are obtained from the candidate buffer chain during buffer eviction
get_buf_clock_sweep	bigint	Number of times that pages are obtained from the original eviction solution during buffer eviction

Example:

The remote_bgwriter_stat function is used to query the page refreshing information of the bgwriter thread.

```
gaussdb=# SELECT * FROM remote_bgwriter_stat();
 node_name | bgwr_actual_flush_total_num | bgwr_last_flush_num | candidate_slots |
get_buffer_from_list | get_buf_clock_sweep
-----+-----+-----+-----+-----+-----
datanode3 |          0 |          0 |      266232 |          404 |          0
datanode2 |          0 |          0 |      266232 |          424 |          0
datanode1 |          0 |          0 |      266232 |          393 |          0
(3 rows)
```

- gs_stack()**

Description: Displays the call stack of a thread. To query this function, you must have the SYSADMIN or MONADMIN permission.

Parameter: tid, which indicates the thread ID. **tid** is an optional parameter. If it is specified, the function returns the call stack of the thread corresponding to **tid**. If it is not specified, the function returns the call stacks of all threads.

Return value: If **tid** is specified, the return value is of the TEXT type. If **tid** is not specified, the return value is a SETOF record.

Example:

Obtain the call stack of a specified thread.

```
gaussdb=# SELECT * FROM gs_stack(139663481165568);
gs_stack
-----
__poll + 0x2d
WaitLatchOrSocket(Latch volatile*, int, int, long) + 0x29f
WaitLatch(Latch volatile*, int, long) + 0x2e
JobScheduleMain() + 0x90f

- gs_perf_start()

Description: Calls perf_event_open to collect the call stack of each thread and the running time of each function. To query this function, you must have the SYSADMIN or MONADMIN permission.

The parameters are described as follows.

Parameter	Description	Type	Range
duration	Stack collection duration, in seconds. If a floating-point number is entered, the first digit after the decimal point is rounded off.	integer	1~60
freq	Stack collection frequency. This parameter is optional. The unit is Hz. The default value is 100 .	integer	10~1000

Return type: text

Example:

Set the frequency to 100 Hz and collect stack information for 10s.

```
gaussdb=# SELECT * FROM gs_perf_start(10, 100);
 gs_perf_start
-----
Perf start succeed.
(1 row)
```

 **CAUTION**

During data collection, `gs_perf_start` needs to apply for a ring buffer. The buffer size is controlled by `/proc/sys/kernel/perf_event_mlock_kb` in the OS. If the error message "perf mmap failed" is displayed during the collection, adjust the size of `/proc/sys/kernel/perf_event_mlock_kb` and start the collection again.

- `gs_perf_query()`

Description: Collects the function call stacks of each thread, sums up the function running time, and displays the collection result. To query this function, you must have the SYSADMIN or MONADMIN permission.

Parameter: nan

Return type: SETOF record.

The following table describes the fields returned by the function.

Name	Type	Description
backtrace	text	Stack name (in a tree structure).
period	bigint	Execution time of a stack.
level	integer	Level of the stack call tree where a stack is located.
sequence	integer	Sequence in the stack call tree after sorting.
thread_name	text	Name of the thread where a stack is located.
overhead	float	Percentage of the stack execution time.

Example:

Query the collected stack information.

```
gaussdb=# SELECT * FROM gs_perf_query() WHERE overhead > 2 AND level < 10;
 thread_name | overhead | backtrace | period | level | sequence |
-----+-----+-----+-----+-----+-----+
root
100
worker

- `gs_perf_report()`

Description: Generates a graphical flame graph file based on the stack data collected by executing the `gs_perf_start` function and saves the file in the `$GAUSSLOG/gs_flamegraph/{datanode}` directory. To query this function, you must have the SYSADMIN or MONADMIN permission.

Parameter: nan

Return type: text

Example:

Generate a flame graph file.

```
gaussdb=# SELECT * FROM gs_perf_report();
          gs_perf_report
```

```
-----
Perf report succeed, flamegraph file: flamegraph-2023-11-26_164802.html
(1 row)
```

- `gs_perf_clean()`

Description: Clears data generated by **perf**. To query this function, you must have the SYSADMIN or MONADMIN permission.

Parameter: nan

Return type: text.

Example:

Clear the collected stack information.

```
gaussdb=# SELECT * FROM gs_perf_clean();
          gs_perf_clean
```

```
-----
Perf clean succeed.
(1 row)
```

- `gs_tpworker_execstmt_stat()`

Description: Displays the runtime information of a statement. If the SYSADMIN or MONADMIN user runs the statement, the information about all the statements that are being executed is displayed. Common users can query only the information about the SQL statements executed by themselves.

Return type: SETOF record.

Name	Type	Description
db_oid	oid	OID of the database that the user session connects to in the backend
db_name	name	Name of the database that the user session connects to in the backend
threadpool_worker	varchar	NUMA group to which a thread belongs and thread ID. The format is <i>numagroup_threadid</i> .
thread_id	bigint	Thread ID.
session_id	bigint	Session ID.
query_id	bigint	ID of the SQL statement that is being executed

Name	Type	Description
query_text	text	Content of the SQL statement that is being executed
unique_sql_id	bigint	Unique ID generated by the SQL statement
client_hostname	text	Host name of the connected client, as reported by a reverse DNS lookup of client_addr . This column will be non-null only for IP connections and only when log_hostname is enabled.
client_app_name	text	Name of the client app
stmt_slow_time_threshold	int	Preset timeout interval for marking an SQL statement as a slow SQL statement, in milliseconds
stmt_start_time	timestamp with time zone	Time when the statement starts to be executed
stmt_elapsed_time	int	Time elapsed since the query starts
stmt_control_status	varchar	Current statement state <ul style="list-style-type: none"> • Waiting: The session access is successful but it is not executed by the thread. • Running: The current statement is executed properly. • Control: The current statement enters the resource control phase.
stmt_control_rule	text	Slow SQL control rule corresponding to the current language
stmt_control_iostat	text	IOPS value and maximum IOPS of the current statement. The format is <i>curVal maxVal</i> .
stmt_control_memstat	text	This field is reserved and is not supported currently.
stmt_control_cpustat	text	This field is reserved and is not supported currently.
stmt_control_netstat	text	This field is reserved and is not supported currently.

- `gs_tpwoker_execslot_stat()`

Description: Displays the thread running information. If the SYSADMIN or MONADMIN user runs the command, information about all threads is displayed. Common users can query only information about the threads where the SQL statements executed by themselves are located.

Return type: SETOF record.

Name	Type	Description
numagroup	int	NUMA group to which the current thread belongs
worker_id	int	Thread ID of the current thread
worker_bind_type	text	Thread binding mode. The value can be numabind , cpubind , allbind , or nobind .
worker_cpu_affinity	text	Affinity between threads and CPU cores, that is, the range of CPU cores that can be scheduled by threads.
worker_status	varchar	Current thread status: <ul style="list-style-type: none"> • Waiting: The session access is successful but it is not executed by the thread. • Running: The current statement is executed properly. • Control: The current statement enters the resource control phase.
served_query_id	bigint	ID of the SQL statement that is being executed
served_query_text	text	Content of the SQL statement that is being executed

- `gs_session_all_settings(sessionid bigint)`

Description: Queries the full GUC parameter settings of the session corresponding to the session ID on the local node. To execute this function, you must have the SYSADMIN or MONADMIN permission.

Input parameter description: **sessionid** indicates the session ID.

Return type: SETOF record.

The following table describes return fields.

Name	Type	Description
name	text	Parameter name
setting	text	Current parameter value
unit	text	Implicit unit of a parameter

Example:

```
gaussdb=# SELECT sessionid FROM pg_stat_activity WHERE username = 'testuser';
 sessionid
-----
 788861
(1 row)

gaussdb=# SELECT * FROM gs_session_all_settings(788861) WHERE name = 'work_mem';
 name | setting | unit
-----+-----+-----
work_mem | 131072 | kB
(1 row)
```

- **gs_session_all_settings()**

Description: Queries full GUC parameter settings of all sessions on the local node. To execute this function, you must have the SYSADMIN or MONADMIN permission.

Return type: SETOF record.

Name	Type	Description
sessionid	bigint	Session ID
pid	bigint	Backend thread ID
name	text	Parameter name
setting	text	Current parameter value
unit	text	Implicit unit of a parameter

Example:

```
gaussdb=# SELECT * FROM gs_session_all_settings() WHERE name = 'work_mem';
 sessionid | pid | name | setting | unit
-----+-----+-----+-----+-----
140550214145792 | 96974 | work_mem | 65536 | kB
140550214145792 | 96971 | work_mem | 65536 | kB
140549731735296 | 140549731735296 | work_mem | 65536 | kB
140549764413184 | 140549764413184 | work_mem | 65536 | kB
(4 rows)
```

- **gs_local_wal_preparse_statistics()**

Description: Queries the latest startup of the log pre-parsing thread on the local node as well as the pre-parsing logs. Only the user with the SYSADMIN permission can execute this function.

Return type: SETOF record.

Name	Type	Description
preparser_term	text	Maximum term value obtained from the latest pre-parsing log.
preparser_start_time	timestampz	Time when the latest pre-parsing is started.
preparser_end_time	timestampz	End time of the latest pre-parsing.

Name	Type	Description
preparser_start_location	text	Start position of the latest pre-parsing log.
preparser_end_location	text	End position of the latest pre-parsing log.
preparser_total_bytes	int8	Number of latest pre-parsed logs, in bytes.
preparser_speed	int8	Latest pre-parsing speed, in bytes/ms.
is_valid	bool	Specifies whether the latest pre-parsing result can be used for leader selection.

Example:

```
gaussdb=# SELECT * FROM gs_local_wal_preparse_statistics();
preparser_term | preparser_start_time | preparser_end_time | preparser_start_location |
preparser_end_location | preparser_total_bytes | preparser_speed | is_valid
-----+-----+-----+-----+-----+-----+-----+-----
3107          | 2023-02-01 17:04:23.367946+08 | 2023-02-01 17:04:25.354434+08 | 00000003/
C3EEA660     | 00000004/OBE60738 | 1207394520 | 1207394520 | f
(1 row)
```

- **gs_hot_standby_space_info()**
Description: Queries the total number and total size of files in the **standby_read/base_page**, **standby_read/block_info_meta** and **standby_read/lsn_info_meta** folders.

Return type: SETOF record.

Name	Type	Description
base_page_file_num	xid	Total number of base_page_files.
base_page_total_size	xid	Total size of base_page_files.
lsn_info_meta_file_num	xid	Total number of lsn_info_meta_files.
lsn_info_meta_total_size	xid	Total size of the lsn_info_meta_files.
block_info_meta_file_num	xid	Total number of block_info_meta_files.
block_info_meta_total_size	xid	Total size of the block_info_meta_files.

Example:

```
gaussdb=# SELECT * FROM gs_hot_standby_space_info();
 base_page_file_num | base_page_total_size | lsn_info_meta_file_num | lsn_info_meta_total_size |
 block_info_meta_file_num | block_info_meta_total_size
-----+-----+-----+-----+-----+-----
          6 |      163840 |          6 |          3136 |          16
|
|          147456
(1 row)
```

- `exrto_file_read_stat()`

Description: Queries the number of disk access times and total access latency of new **base page files**, **lsn info meta files**, and **block info meta files** read by the standby node. Connect to the standby DN for query. In other cases, the query result is 0.

Return type: SETOF record.

Name	Type	Description
lsn_info_page_disk_read_counter	int8	Number of disk access times of lsn info meta files
lsn_info_page_disk_read_dur	int8	Total latency of lsn info meta file access to disks.
blk_info_meta_disk_read_counter	int8	Number of disk access times of block info meta files
blk_info_meta_disk_read_dur	int8	Total latency of block info meta file access to disks.
base_page_read_disk_counter	int8	Number of disk access times of base page files
base_page_read_disk_dur	int8	Total latency of base page file access to disks.

Example:

```
gaussdb=# SELECT * FROM exrto_file_read_stat();
 lsn_info_page_disk_read_counter | lsn_info_page_disk_read_dur | blk_info_meta_disk_read_counter |
 blk_info_meta_disk_read_dur | base_page_read_disk_counter | base_page_read_disk_dur
-----+-----+-----+-----+-----+-----
          14987 |          0 |          92313 |          23879 |          129811
|
|          0 |          0
(1 row)
```

- `gs_exrto_recycle_info()`

Description: Queries the resource recycling location, including the recycling LSN of each thread, global recycling LSN, and the earliest snapshot LSN of a query thread. Connect to the standby DN for query. In other cases, the query result is 0.

Return type: SETOF record.

Name	Type	Description
page_redo_worker_thread_id	text	Reclamation LSN location of redo thread. thread_id indicates the redo thread ID.
global_recycle_lsn	text	LSN of global reclamation location
exrto_snapshot_oldest_lsn	text	Earliest snapshot LSN of a query thread.

Example:

```
gaussdb=# SELECT * FROM gs_exrto_recycle_info();
          thread_id          | recycle_lsn
-----+-----
page_redo_worker_140148895381248 | 0/7B4552E0
page_redo_worker_140148872312576 | 0/7B4535B8
global_recycle_lsn          | 0/7B4535B8
exrto_snapshot_oldest_lsn   | 0/8488E6D0
(4 rows)
```

- `gs_stat_get_db_conflict_all(oid)`

Input parameter: **dbid(oid)** indicates the database OID.

Description: Queries the number of sent replay conflict signals of different types.

Return type: SETOF record.

Name	Type	Description
conflict_all	int8	Number of sent replay conflict signals
conflict_tablespace	int8	Number of sent replay conflict signals of the tablespace type
conflict_lock	int8	Number of sent replay conflict signals of the lock type
conflict_snapshot	int8	Number of sent replay conflict signals of the snapshot type
conflict_bufferpin	int8	Number of sent replay conflict signals of the bufferpin type
conflict_startup_deadlock	int8	Number of sent replay conflict signals of the startup_deadlock type
conflict_truncate	int8	Number of sent replay conflict signals of the truncate type
conflict_standby_query_timeout	int8	Number of sent replay conflict signals of the standby_query_timeout type
conflict_force_recycle	int8	Number of sent replay conflict signals of the force_recycle type

Example:

```
gaussdb=# SELECT * FROM gs_stat_get_db_conflict_all(12738);
 conflict_all | conflict_tablespace | conflict_lock | conflict_snapshot | conflict_bufferpin |
 conflict_startup_deadlock | conflict_truncate | conflict_standby_query_timeout | conflict_force_recycle
-----+-----+-----+-----+-----+-----+-----+-----+-----
          0 |          0 |          0 |          0 |          0 |          0 |          0 |          0
|
(1 row)
```

- `gs_redo_stat_info()`

Description: Queries redo information, including the buffer hit ratio of the redo thread, number of unlink_rels files executed, wait event information of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario, and wait event information of **wal_read_from_write_buffer**. The query must be executed by connecting to the standby DN.

Return type: SETOF record.

Name	Type	Description
buffer_hit_rate	float8	Buffer hit ratio of the redo thread.
ddl_unlink_nrels_count	int8	Number of unlink rel files executed during the redo process of DDL statements.
read_buffer_io_counter	int8	Number of wait events of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario.
read_buffer_io_total_dur	int8	Total wait event duration of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario.
read_buffer_io_avg_dur	int8	Average wait event duration of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario.
read_buffer_io_min_dur	int8	Minimum wait event duration of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario.
read_buffer_io_max_dur	int8	Maximum wait event duration of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario.
read_wal_buf_counter	int8	Number of wait events triggered by wal_read_from_write_buffer in the ultimate RTO scenario.
read_wal_buf_total_dur	int8	Total wait event duration of wal_read_from_write_buffer in the ultimate RTO scenario.

Name	Type	Description
read_wal_buf_avg_dur	int8	Average wait event duration of wal_read_from_write_buffer in the ultimate RTO scenario.
read_wal_buf_min_dur	int8	Minimum wait event duration of wal_read_from_write_buffer in the ultimate RTO scenario.
read_wal_buf_max_dur	int8	Maximum wait event duration of wal_read_from_write_buffer in the ultimate RTO scenario.

Example:

```
gaussdb=# SELECT * FROM gs_redo_stat_info();
-[ RECORD 1 ]-----+-----
buffer_hit_rate      | 70.5707
ddl_unlink_nrels_count | 3
read_buffer_io_counter | 1732
read_buffer_io_total_dur | 2850806
read_buffer_io_avg_dur | 1645
read_buffer_io_min_dur | 3
read_buffer_io_max_dur | 981639
read_wal_buf_counter | 9779
read_wal_buf_total_dur | 193612470
read_wal_buf_avg_dur | 19798
read_wal_buf_min_dur | 3
read_wal_buf_max_dur | 1914777
```

- `gs_recovery_conflict_waitevent_info()`

Description: Queries wait event information about the function that processes redo conflicts. The query must be executed by connecting to the standby DN.

Return type: SETOF record.

Name	Type	Description
conflict_lock_counter	int8	Number of times that lock redo conflicts are triggered.
conflict_lock_total_dur	int8	Total duration for processing lock redo conflicts.
conflict_lock_avg_dur	int8	Average duration for processing lock redo conflicts.
conflict_lock_min_dur	int8	Minimum duration for processing lock redo conflicts.
conflict_lock_max_dur	int8	Maximum duration for processing lock redo conflicts.
conflict_snapshot_counter	int8	Number of times that snapshot redo conflicts are triggered.

Name	Type	Description
conflict_snapshot_total_dur	int 8	Total duration for processing snapshot redo conflicts.
conflict_snapshot_avg_dur	int 8	Average duration for processing snapshot redo conflicts.
conflict_snapshot_min_dur	int 8	Minimum duration for processing snapshot redo conflicts.
conflict_snapshot_max_dur	int 8	Maximum duration for processing snapshot redo conflicts.
conflict_tablespace_counter	int 8	Number of times that tablespace redo conflicts are triggered.
conflict_tablespace_total_dur	int 8	Total duration for processing tablespace redo conflicts.
conflict_tablespace_avg_dur	int 8	Average duration for processing tablespace redo conflicts.
conflict_tablespace_min_dur	int 8	Minimum duration for processing tablespace redo conflicts.
conflict_tablespace_max_dur	int 8	Maximum duration for processing tablespace redo conflicts.
conflict_database_counter	int 8	Number of times that database redo conflicts are triggered.
conflict_database_total_dur	int 8	Total duration for processing database redo conflicts.
conflict_database_avg_dur	int 8	Average duration for processing database redo conflicts.
conflict_database_min_dur	int 8	Minimum duration for processing database redo conflicts.
conflict_database_max_dur	int 8	Maximum duration for processing database redo conflicts.
conflict_truncate_counter	int 8	Number of times that TRUNCATE redo conflicts are triggered.
conflict_truncate_total_dur	int 8	Total duration for processing TRUNCATE redo conflicts.
conflict_truncate_avg_dur	int 8	Average duration for processing TRUNCATE redo conflicts.
conflict_truncate_min_dur	int 8	Minimum duration for processing TRUNCATE redo conflicts.

Name	Type	Description
conflict_truncate_max_dur	int8	Maximum duration for processing TRUNCATE redo conflicts.
conflict_standby_query_timeout_counter	int8	Number of times that standby_query_timeout redo conflicts are triggered.
conflict_standby_query_timeout_total_dur	int8	Total duration for processing standby_query_timeout redo conflicts.
conflict_standby_query_timeout_avg_dur	int8	Average duration for processing standby_query_timeout redo conflicts.
conflict_standby_query_timeout_min_dur	int8	Minimum duration for processing standby_query_timeout redo conflicts.
conflict_standby_query_timeout_max_dur	int8	Maximum duration for processing standby_query_timeout redo conflicts.
conflict_force_recycle_counter	int8	Number of times that force_recycle redo conflicts are triggered.
conflict_force_recycle_total_dur	int8	Total duration for processing force_recycle redo conflicts.
conflict_force_recycle_avg_dur	int8	Average duration for processing force_recycle redo conflicts.
conflict_force_recycle_min_dur	int8	Minimum duration for processing force_recycle redo conflicts.
conflict_force_recycle_max_dur	int8	Maximum duration for processing force_recycle redo conflicts.

Example:

```
gaussdb=# SELECT * FROM gs_recovery_conflict_waitevent_info();
-[ RECORD 1 ]-----+-----
conflict_lock_counter          | 0
conflict_lock_total_dur       | 0
conflict_lock_avg_dur         | 0
conflict_lock_min_dur         | 0
conflict_lock_max_dur         | 0
conflict_snapshot_counter     | 0
conflict_snapshot_total_dur   | 0
conflict_snapshot_avg_dur     | 0
conflict_snapshot_min_dur     | 0
conflict_snapshot_max_dur     | 0
conflict_tablespace_counter   | 0
conflict_tablespace_total_dur | 0
conflict_tablespace_avg_dur   | 0
conflict_tablespace_min_dur   | 0
conflict_tablespace_max_dur   | 0
conflict_database_counter     | 0
conflict_database_total_dur   | 0
conflict_database_avg_dur     | 0
conflict_database_min_dur     | 0
```

```

conflict_database_max_dur      | 0
conflict_truncate_counter     | 6
conflict_truncate_total_dur   | 35872
conflict_truncate_avg_dur     | 5978
conflict_truncate_min_dur     | 5130
conflict_truncate_max_dur     | 7459
conflict_standby_query_timeout_counter | 0
conflict_standby_query_timeout_total_dur | 0
conflict_standby_query_timeout_avg_dur | 0
conflict_standby_query_timeout_min_dur | 0
conflict_standby_query_timeoutmax_dur | 0

```

- `gs_display_delay_ddl_info()`

Description: Views information about files that are delayed for deletion on the standby node.

Return type: SETOF record.

Name	Type	Description
type	INT4	Indicates that the deleted object is a table or database.
lsn	TEXT	Marks the location of a particular log file.
tablespace	INT4	Indicates the physical space for storing tables and indexes in a database.
database	INT4	Indicates the physical storage location of a database.
relation	INT4	Indicates the object in a database, which can be the physical location of a table, view, or index.
bucketid	INT4	Specifies the bucket to which the relationship object belongs.
opt	INT4	Indicates the attribute of a compressed table.
forknum	INT4	Specifies a suffix name for a subject name. You can find a unique physical file based on the subject name and suffix name.

Example:

```

gaussdb=# SELECT * FROM gs_display_delay_ddl_info();
 type | lsn | tablespace | database | relation | bucketid | opt | forknum
-----+-----+-----+-----+-----+-----+-----+-----
(0 rows)
    
```

Functions for Collecting Statistics in Partitioned Tables

- `gs_stat_get_partition_stats(oid)`
Description: Obtains the statistics of a specific partition.
Return type: record.
 - `gs_stat_get_xact_partition_stats(oid)`
Description: Obtains transaction statistics of a specific partition.
Return type: record.
 - `gs_stat_get_all_partitions_stats()`
Description: Obtains the statistics of all partitions.
Return type: SETOF record.
 - `gs_stat_get_xact_all_partitions_stats()`
Description: Obtains transaction statistics of all partitions.
Return type: SETOF record.
 - `gs_statio_get_all_partitions_stats()`
Description: Obtains the I/O statistics of all partitions.
Return type: SETOF record.
- Examples of the preceding five functions

CAUTION

Statistics are reported asynchronously during execution. Based on UDP, delay and packet loss may occur during background thread processing. The following example is for reference only.

Querying out-of-transaction statistics:

```
gaussdb=# CREATE TABLE part_tab1
gaussdb=# (
gaussdb(#   a int, b int
gaussdb(# )
gaussdb=# PARTITION BY RANGE(b)

```

- `gs_stat_get_partition_analyze_count(oid)`
Description: Specifies the number of times that a user starts analysis on a partition.
Return type: `bigint`.
- `gs_stat_get_partition_autoanalyze_count(oid)`
Description: Specifies the number of times that the autovacuum daemon thread starts analysis in a partition.
Return type: `bigint`.
- `gs_stat_get_partition_autovacuum_count(oid)`
Description: Specifies the number of times that the autovacuum daemon thread starts vacuum in a partition.
Return type: `bigint`.
- `gs_stat_get_partition_last_analyze_time(oid)`
Description: Specifies the last time when a partition starts to be analyzed manually or by the autovacuum thread.
Return type: `timestampz`.
- `gs_stat_get_partition_last_autoanalyze_time(oid)`
Description: Specifies the time when the last analysis initiated by the autovacuum daemon thread in a partition.
Return type: `timestampz`.
- `gs_stat_get_partition_last_autovacuum_time(oid)`
Description: Specifies the time of the last vacuum initiated by the autovacuum daemon thread in a partition.
Return type: `timestampz`.
- `gs_stat_get_partition_last_data_changed_time(oid)`
Description: Specifies the last time of a modification in a partition, such as insert, update, delete, and truncate. Currently, this parameter is not supported.
Return type: `timestampz`.
- `gs_stat_get_partition_last_vacuum_time(oid)`
Description: Specifies the most recent time when the user manually cleared a table or when the autovacuum thread was started to clear a partition.
Return type: `timestampz`.
- `gs_stat_get_partition_numscans(oid)`
Description: Specifies the number of rows scanned and read in partition order.
Return type: `bigint`.
- `gs_stat_get_partition_tuples_returned(oid)`
Description: Specifies the number of rows scanned and read in partition order.
Return type: `bigint`.
- `gs_stat_get_partition_tuples_fetched(oid)`
Description: Specifies the number of rows fetched by bitmap scans in a partition.
Return type: `bigint`.

- `gs_stat_get_partition_vacuum_count(oid)`
Description: Specifies the number of times that a user starts vacuum in a partition.
Return type: `bigint`.
- `gs_stat_get_xact_partition_tuples_fetched(oid)`
Description: Specifies the number of tuple rows scanned in a transaction.
Return type: `bigint`.
- `gs_stat_get_xact_partition_numscans(oid)`
Description: Specifies the number of sequential scans performed on a partition in the current transaction.
Return type: `bigint`.
- `gs_stat_get_xact_partition_tuples_returned(oid)`
Description: Specifies the number of rows read through sequential scans in a partition in the current transaction.
Return type: `bigint`.
- `gs_stat_get_partition_blocks_fetched(oid)`
Description: Specifies the number of disk block fetch requests for a partition.
Return type: `bigint`.
- `gs_stat_get_partition_blocks_hit(oid)`
Description: Specifies the number of disk block requests found in cache for a partition.
Return type: `bigint`.
- `pg_stat_get_partition_tuples_inserted(oid)`
Description: Specifies the number of rows in the corresponding table partition.
Return type: `bigint`.
- `pg_stat_get_partition_tuples_updated(oid)`
Description: Specifies the number of rows that have been updated in the corresponding table partition.
Return type: `bigint`.
- `pg_stat_get_partition_tuples_deleted(oid)`
Description: Specifies the number of rows deleted from the corresponding table partition.
Return type: `bigint`.
- `pg_stat_get_partition_tuples_changed(oid)`
Description: Specifies the total number of inserted, updated, and deleted rows after a table partition was last analyzed or autoanalyzed.
Return type: `bigint`.
- `pg_stat_get_partition_live_tuples(oid)`
Description: Specifies the number of live rows in a partitioned table.
Return type: `bigint`.
- `pg_stat_get_partition_dead_tuples(oid)`
Description: Specifies the number of dead rows in a partitioned table.

- Return type: bigint.
- `pg_stat_get_xact_partition_tuples_inserted(oid)`
Description: Specifies the number of inserted tuples in the active sub-transactions related to a table partition.
Return type: bigint.
 - `pg_stat_get_xact_partition_tuples_deleted(oid)`
Description: Specifies the number of deleted tuples in the active sub-transactions related to a table partition.
Return type: bigint.
 - `pg_stat_get_xact_partition_tuples_hot_updated(oid)`
Description: Specifies the number of hot updated tuples in the active sub-transactions related to a table partition.
Return type: bigint.
 - `pg_stat_get_xact_partition_tuples_updated(oid)`
Description: Specifies the number of updated tuples in the active sub-transactions related to a table partition.
Return type: bigint.
 - `pg_stat_get_partition_tuples_hot_updated(oid)`
Description: Returns statistics on the number of hot updated tuples in a partition with a specified partition ID.
Parameter: **oid**
Return type: bigint.
 - `gs_wlm_respool_cpu_info()`
Description: Displays the limit and usage of CPU resources in a resource pool.
Return type: SETOF record.

Name	Type	Description
respool_name	name	Name of the resource pool.
control_group	name	Cgroup name.
cpu_affinity	name	Value of cores bound to the CPU.
cpu_usage	integer	CPU usage of a resource pool.

 **NOTE**

If the CN and DN are deployed together, the CN and DN share the same CPU resources. Therefore, the **cpu_usage** values of the CN and DN are the same. If the CN and DN are independently deployed, the **cpu_usage** values of the CN and DN are displayed separately.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_RESPOOL_CPU_INFO();
respool_name | control_group | cpu_affinity | cpu_usage
-----+-----+-----+-----
respool_cpu_2 | respool_cpu_2:Medium | 0-95 | 78
```

```
default_pool | DefaultClass:Medium | 0-32 | 65
(2 rows)
```

- `gs_wlm_respool_connection_info()`

Description: Displays the limit and usage of the number of connections in a resource pool.

Return type: SETOF record.

Name	Type	Description
respool_name	name	Name of the resource pool.
max_connections	integer	Maximum number of connections to a resource pool.
curr_connections	integer	Number of existing connections in the current resource pool.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_RESPPOOL_CONNECTION_INFO();
respool_name | max_connections | curr_connections
-----+-----+-----
respool1    |          -1    |                0
default_pool |          -1    |                1
(2 rows)
```

- `gs_wlm_respool_memory_info()`

Description: Displays the limit and usage of memory resources in a resource pool.

Return type: SETOF record

Name	Type	Description
respool_name	name	Name of the resource pool.
max_dynamic_memory	integer	Maximum dynamic memory that can be used.
current_dynamic_memory	integer	Used dynamic memory.
max_shared_memory	integer	Maximum shared memory that can be used.
current_shared_memory	integer	Shared memory that has been used.
shared_memory_hits_percent	integer	Cache hit ratio of the current resource pool.

 **NOTE**

When the dynamic memory usage of the resource pool exceeds the maximum value, the returned value of the GUC parameter **current_dynamic_memory** may be greater than the value of **max_dynamic_memory**. This is normal because no memory is allocated.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_RESPOOL_MEMORY_INFO();
 respool_name | max_dynamic_memory | current_dynamic_memory | max_shared_memory |
current_shared_memory | shared_memory_hits_percent
-----+-----+-----+-----+-----
 default_pool | -1 | 3383kB | -1 | 3848kB |
90
 resource_pool_a | 30720kB | 0kB | -1 | 0kB |
|
0
(2 rows)
```

- `gs_wlm_respool_concurrency_info()`

Description: Displays the limit and usage of concurrent resources in a resource pool.

Return type: SETOF record

Name	Type	Description
respool_name	name	Name of the resource pool.
max_concurrency	integer	Maximum number of concurrent queries allowed by the resource pool.
running_concurrency	integer	Number of concurrent tasks that are being executed in the current resource pool.
waiting_concurrency	integer	Number of concurrent tasks that are waiting in the current resource pool.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_RESPOOL_CONCURRENCY_INFO();
 respool_name | max_concurrency | running_concurrency | waiting_concurrency
-----+-----+-----+-----
 default_pool | -1 | 1 | 0
 resource_pool_a | -1 | 0 | 0
(2 rows)
```

- `gs_wlm_respool_io_info()`

Description: Displays the limit and usage of I/O resources in a resource pool.

Return type: SETOF record

Name	Type	Description
respool_name	name	Name of the resource pool.

Name	Type	Description
io_limits	integer	Upper limit of IOPS. The value 0 indicates there is no limit. <ul style="list-style-type: none"> Unit: The unit is determined by GUC parameter io_control_unit, which is used to count the number of I/Os during I/O control. The value of io_control_unit is one IOPS.
io_priority	text	I/O priority set for jobs that consume I/O resources. It takes effect when the I/O usage reaches 90%. None indicates there is no control.
current_iops	integer	Number of times that the current I/O has been triggered. The current I/O statistics occasionally exceed the upper limit, which is related to the I/O statistics algorithm and is normal.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_RESPOOL_IO_INFO();
respool_name | io_limits | io_priority | current_iops
-----+-----+-----+-----
default_pool | 0 | None | 0
resource_pool_a | 0 | Low | 0
(2 rows)
```

- `gs_wlm_user_space_info()`

Description: Displays the storage space usage of a user.

Return type: SETOF record

Name	Type	Description
user_name	name	Username.
max_permanent_space	bigint	Maximum permanent storage space that can be used by a user, in bytes.
current_permanent_space	bigint	Permanent storage space used by the current user, in bytes.
max_temp_space	bigint	Maximum temporary storage space that can be used by a user, in bytes.
current_temp_space	bigint	Temporary storage space used by the current user, in bytes.
max_spill_space	bigint	Maximum operator flushing storage space that can be used by a user, in bytes.
current_spill_space	bigint	Operator flushing storage space used by the current user, in bytes.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_USER_SPACE_INFO();
 user_name      | max_permanent_space | current_permanent_space | max_temp_space |
current_temp_space | max_spill_space | current_spill_space
-----+-----+-----+-----+-----+-----+-----
xy              |          -1         |          2464           |          -1     |
0              |                    |                        |                |
(1 rows)
```

- `gs_wlm_session_io_info()`

Description: Displays the I/O usage of a session.

Return type: SETOF record

Name	Type	Description
session_id	integer	Session ID.
io_limits	integer	Upper limit of IOPS. The value 0 indicates there is no limit. <ul style="list-style-type: none"> • Unit: The unit is determined by GUC parameter io_control_unit, which is used to count the number of I/Os during I/O control. The value of io_control_unit is one IOPS.
io_priority	text	I/O priority set for jobs that consume I/O resources. It takes effect when the I/O usage reaches 90%. None indicates there is no control.
current_iops	integer	Number of times that the current I/O has been triggered. The current I/O statistics occasionally exceed the upper limit, which is related to the I/O statistics algorithm and is normal.
wait_time	integer	Total waiting time after the current I/O exceeds the upper limit.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_SESSION_IO_INFO();
 session_id | io_limits | io_priority | current_iops | wait_time
-----+-----+-----+-----+-----
139976325986048 | 10 | None | 0 | 2709
(1 row)
```

- `gs_wlm_session_memory_info()`

Description: Displays the memory usage of a session.

Return type: SETOF record

Name	Type	Description
session_id	integer	Session ID

Name	Type	Description
sess_used_dynamic_memory	bigint	Used dynamic memory, in bytes.
sess_max_dynamic_memory	bigint	Maximum dynamic memory that can be used, in bytes.

Example:

```
gaussdb=# SELECT * FROM GS_WLM_SESSION_MEMORY_INFO();
  sessid | sess_used_dynamic_memory | sess_max_dynamic_memory
-----+-----+-----
139976325986048 | 4326056 | -1
139976402532096 | 4452664 | -1
(2 rows)
```

7.6.29 Trigger Functions

- `pg_get_triggerdef(oid)`

Description: Obtains the definition information of a trigger.

Parameter: OID of the trigger to be queried

Return type: text

Example:

```
-- Create the tri_insert table.
gaussdb=# CREATE TABLE tri_insert (a int, b int) distribute by hash(a);
CREATE TABLE
-- Create the trigger_func function.
gaussdb=# CREATE FUNCTION trigger_func() RETURNS trigger LANGUAGE plpgsql AS '
BEGIN
RAISE NOTICE "trigger_func(%) called: action = %, when = %, level = %", TG_ARGV[0], TG_OP,
TG_WHEN, TG_LEVEL;
RETURN NULL;
END;';
CREATE FUNCTION
-- Create the before_ins_stmt_trig trigger.
gaussdb=# CREATE TRIGGER before_ins_stmt_trig BEFORE INSERT ON tri_insert FOR EACH
STATEMENT EXECUTE PROCEDURE trigger_func('before_ins_stmt');
CREATE TRIGGER
-- Create the after_ins_when_trig trigger.
gaussdb=# CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert FOR EACH ROW WHEN
(new.a IS NOT NULL) EXECUTE PROCEDURE trigger_func('after_ins_when');
CREATE TRIGGER
-- View the trigger definition information of the tri_insert table.
gaussdb=# SELECT pg_get_triggerdef(oid) FROM pg_trigger WHERE tgrelid = 'tri_insert'::regclass;

pg_get_triggerdef
-----
CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert FOR EACH ROW WHEN ((new.a IS
NOT NULL)) EXECUTE PROCEDURE trigger_func('after_ins_when')
CREATE TRIGGER before_ins_stmt_trig BEFORE INSERT ON tri_insert FOR EACH STATEMENT
EXECUTE PROCEDURE trigger_func('before_ins_stmt')
(2 rows)
```

- `pg_get_triggerdef(oid, boolean)`

Description: Obtains the definition information of a trigger.

Parameter: OID of the trigger to be queried and whether it is displayed in pretty mode

 NOTE

Boolean parameters take effect only when the WHEN condition is specified during trigger creation.

Return type: text

Example:

```
-- View the trigger definition information of the tri_insert table in non-pretty mode.
gaussdb=# SELECT pg_get_triggerdef(oid, false) FROM pg_trigger WHERE tgrelid = 'tri_insert'::regclass;

pg_get_triggerdef
-----
CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert FOR EACH ROW WHEN ((new.a IS
NOT NULL)) EXECUTE PROCEDURE trigger_func('after_ins_when')
CREATE TRIGGER before_ins_stmt_trig BEFORE INSERT ON tri_insert FOR EACH STATEMENT
EXECUTE PROCEDURE trigger_func('before_ins_stmt')
(2 rows)

-- View the trigger definition information of the tri_insert table in pretty mode.
gaussdb=# SELECT pg_get_triggerdef(oid, true) FROM pg_trigger WHERE tgrelid = 'tri_insert'::regclass;

pg_get_triggerdef
-----
CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert FOR EACH ROW WHEN (new.a IS

7.6.30 Hash Functions

- bucketabstime (value, flag)

Description: Hashes the value in the abstime format and finds the corresponding hash bucket.

Parameter: **value** indicates the value to be converted, which is of the abstime type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

Return type: int32

Example:

```
gaussdb=# SELECT bucketabstime('2011-10-01 10:10:10.112',1);
bucketabstime
-----
13954
(1 row)
```

- bucketbool (value, flag)

Description: Hashes the value in the bool format and finds the corresponding hash bucket.

Parameter: **value** indicates the value to be converted, which is of the bool type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

Return type: int32

Example:

```
gaussdb=# SELECT bucketbool(true,1);
bucketbool
-----
         1
(1 row)
gaussdb=# SELECT bucketbool(false,1);
bucketbool
-----
         0
(1 row)
```

- bucketbpchar(value, flag)

Description: Hashes the value in the bpchar format and finds the corresponding hash bucket.

Parameter: **value** indicates the value to be converted, which is of the bpchar type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

Return type: int32

Example:

```
gaussdb=# SELECT bucketbpchar('test',1);
bucketbpchar
-----
         9761
(1 row)
```

- bucketbytea (value, flag)

Description: Hashes the value in the bytea format and finds the corresponding hash bucket.

Parameter: **value** indicates the value to be converted, which is of the bytea type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

Return type: int32

Example:

```
gaussdb=# SELECT bucketbytea('test',1);
bucketbytea
-----
         9761
(1 row)
```

- bucketcash (value, flag)

Description: Hashes the value in the money format and finds the corresponding hash bucket.

Parameter: **value** indicates the value to be converted, which is of the money type. **flag** is of the int type, indicating the data distribution mode. The value **0** indicates hash distribution.

Return type: int32

Example:

```
gaussdb=# SELECT bucketcash(10::money,1);
bucketcash
-----
         8468
(1 row)
```

- getbucket (value, flag)

Description: Obtains the hash bucket from the distribution key.

value indicates the value to be entered, which can be of the following types:

"char", abstime, bigint, boolean,bytea, character varying, character, date, double precision, int2vector, integer, interval, money, name, numeric, nvarchar2, oid, oidvector, raw, real, record, reltime, smalldatetime, smallint,text, time with time zone, time without time zone, timestamp with time zone, timestamp without time zone, tinyint, uuid

flag is of the int type, indicating the data distribution mode.

Return type: integer

Example:

```
gaussdb=# SELECT getbucket(10,'H');
getbucket
-----
      14535
(1 row)

gaussdb=# SELECT getbucket(11,'H');
getbucket
-----
      13449
(1 row)

gaussdb=# SELECT getbucket(11,'R');
getbucket
-----
      13449
(1 row)

gaussdb=# SELECT getbucket(12,'R');
getbucket
-----
       9412
(1 row)
```

- ora_hash(expression,[seed])

Description: Calculates the hash value of a given expression. **expression**: The value can be a character string, time, or number. The hash value is calculated based on the expression. **seed**: an int8 value that can return different results for the same input value. This parameter is optional and is used to calculate the hash value with a random number.

Return type: hash value of the int8 type.

Example:

```
gaussdb=# SELECT ora_hash(123);
ora_hash
-----
4089882933
(1 row)
gaussdb=# SELECT ora_hash('123');
ora_hash
-----
2034089965
(1 row)
gaussdb=# SELECT ora_hash('sample');
ora_hash
-----
1573005290
(1 row)
gaussdb=# SELECT ora_hash(to_date('2012-1-2','yyyy-mm-dd'));
ora_hash
-----
1171473495
```

```
(1 row)
gaussdb=# SELECT ora_hash(123,234);
ora_hash
-----
-9089505052966355682
(1 row)
gaussdb=# SELECT ora_hash('123',234);
ora_hash
-----
5742589019960764616
(1 row)
gaussdb=# SELECT ora_hash('sample',234);
ora_hash
-----
-1747984408055821656
(1 row)
gaussdb=# SELECT ora_hash(to_date('2012-1-2','yyyy-mm-dd'),234);
ora_hash
-----
-3306025179710572679
(1 row)
```

NOTE

This function is valid only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**.

- **hash_array(anyarray)**

Description: Hashes an array, obtains the result of an array element using the hash function, and returns the combination result.

Parameter: data of the anyrange type.

Return type: integer

Example:

```
gaussdb=# SELECT hash_array(ARRAY[[1,2,3],[1,2,3]]);
hash_array
-----
-382888479
(1 row)
```

- **hash_numeric(numeric)**

Description: Calculates the hash value of numeric data.

Parameter: data of the numeric type.

Return type: integer

Example:

```
gaussdb=# SELECT hash_numeric(30);
hash_numeric
-----
-282860963
(1 row)
```

- **hash_range(anyrange)**

Description: Calculates the hash value of a range.

Parameter: data of the anyrange type.

Return type: integer

Example:

```
gaussdb=# SELECT hash_range(numrange(1.1,2.2));
hash_range
-----
683508754
(1 row)
```

- **hashbpchar(character)**
Description: Calculates the hash value of bpchar.
Parameter: data of the character type.
Return type: integer
Example:

```
gaussdb=# SELECT hashbpchar('hello');
hashbpchar
-----
-1870292951
(1 row)
```
- **hashchar(char)**
Description: Converts char and Boolean data into hash values.
Parameter: data of the char or bool type.
Return type: integer
Example:

```
gaussdb=# SELECT hashbpchar('hello');
hashbpchar
-----
-1870292951
(1 row)

gaussdb=# SELECT hashchar('true');
hashchar
-----
1686226652
(1 row)
```
- **hashenum(anyenum)**
Description: Converts enumerated values to hash values.
Parameter: data of the anyenum type.
Return type: integer
Example:

```
gaussdb=# CREATE TYPE b1 AS ENUM('good', 'bad', 'ugly');
CREATE TYPE
gaussdb=# call hashenum('good'::b1);
hashenum
-----
1821213359
(1 row)
```
- **hashfloat4(real)**
Description: Converts float4 values to hash values.
Parameter: data of the real type.
Return type: integer
Example:

```
gaussdb=# SELECT hashfloat4(12.1234);
hashfloat4
-----
1398514061
(1 row)
```
- **hashfloat8(double precision)**
Description: Converts float8 values to hash values.
Parameter: data of the double precision type.
Return type: integer

Example:

```
gaussdb=# SELECT hashfloat8(123456.1234);
hashfloat8
-----
1673665593
(1 row)
```

- **hashinet(inet)**

Description: Converts inet or cidr values to hash values.

Parameter: data of the inet type.

Return type: integer

Example:

```
gaussdb=# SELECT hashinet('127.0.0.1'::inet);
hashinet
-----
-1435793109
(1 row)
```

- **hashint1(tinyint)**

Description: Converts INT1 values to hash values.

Parameter: data of the tinyint type.

Return type: uint32

Example:

```
gaussdb=# SELECT hashint1(20);
hashint1
-----
-2014641093
(1 row)
```

- **hashint2(smallint)**

Description: Converts INT2 values to hash values.

Parameter: data of the smallint type.

Return type: uint32

Example:

```
gaussdb=# SELECT hashint2(20000);
hashint2
-----
-863179081
(1 row)
```

- **bucketchar()**

Description: Calculates the hash value of the input parameter.

Parameter: char, integer

Return type: integer

- **bucketdate()**

Description: Calculates the hash value of the input parameter.

Parameter: date, integer

Return type: integer

- **bucketfloat4()**

Description: Calculates the hash value of the input parameter.

Parameter: real, integer

Return type: integer

- `bucketfloat8()`
Description: Calculates the hash value of the input parameter.
Parameters: double precision, integer
Return type: integer
- `bucketint1()`
Description: Calculates the hash value of the input parameter.
Parameter: tinyint, integer
Return type: integer
- `bucketint2()`
Description: Calculates the hash value of the input parameter.
Parameter: smallint, integer
Return type: integer
- `bucketint2vector()`
Description: Calculates the hash value of the input parameter.
Parameter: int2vector, integer
Return type: integer
- `bucketint4()`
Description: Calculates the hash value of the input parameter.
Parameter: integer, integer
Return type: integer
- `bucketint8()`
Description: Calculates the hash value of the input parameter.
Parameter: bigint, integer
Return type: integer
- `bucketinterval()`
Description: Calculates the hash value of the input parameter.
Parameter: interval, integer
Return type: integer
- `bucketname()`
Description: Calculates the hash value of the input parameter.
Parameter: name, integer
Return type: integer
- `bucketnumeric()`
Description: Calculates the hash value of the input parameter.
Parameter: numeric, integer
Return type: integer
- `bucketnvarchar2()`
Description: Calculates the hash value of the input parameter.
Parameter: nvarchar2, integer
Return type: integer

- bucketoid()
Description: Calculates the hash value of the input parameter.
Parameters: oid, integer
Return type: integer
- bucketoidvector()
Description: Calculates the hash value of the input parameter.
Parameter: oidvector, integer
Return type: integer
- bucketraw()
Description: Calculates the hash value of the input parameter.
Parameter: raw, integer
Return type: integer
- bucketreltime()
Description: Calculates the hash value of the input parameter.
Parameter: reltime, integer
Return type: integer
- bucketsmalldatetime()
Description: Calculates the hash value of the input parameter.
Parameter: smalldatetime, integer
Return type: integer
- buckettext()
Description: Calculates the hash value of the input parameter.
Parameter: text, integer
Return type: integer
- buckettime()
Description: Calculates the hash value of the input parameter.
Parameter: time without time zone, integer
Return type: integer
- buckettimestamp()
Description: Calculates the hash value of the input parameter.
Parameter: timestamp without time zone, integer
Return type: integer
- buckettimestampptz()
Description: Calculates the hash value of the input parameter.
Parameter: timestamp with time zone, integer
Return type: integer
- buckettimetz()
Description: Calculates the hash value of the input parameter.
Parameter: time with time zone, integer
Return type: integer

- bucketuuid()
Description: Calculates the hash value of the input parameter.
Parameter: uuid, integer
Return type: integer
- bucketvarchar()
Description: Calculates the hash value of the input parameter.
Parameter: character varying, integer
Return type: integer

7.6.31 Prompt Message Function

- report_application_error
Description: This function can be used to throw errors during PL execution.
Return type: void

Table 7-166 report_application_error parameter description

Parameter	Type	Description	Mandatory or Not
log	text	Content of an error message.	Yes
code	int4	Error code corresponding to an error message. The value ranges from -20999 to -20000.	No

7.6.32 Fault Injection System Function

gs_fault_inject(int64, text, text, text, text, text)

Description: This function cannot be called. WARNING information "unsupported fault injection" is reported when this function is called, which does not affect or change the database.

Parameter: fault injection of the int64 type (**0**: CLOG extended page; **1**: CLOG page reading; **2**: forcible deadlock)

- If the first input parameter of text is set to **2** and the second input parameter of text is set to **1**, the second input parameter deadlock occurs. Other input parameters are not deadlocked. When the first input parameter is **0** or **1**, the second input parameter indicates the number of the start page from which the CLOG starts to be extended or read.
- The third input parameter of text indicates the number of extended or read pages when the first input parameter is **0** or **1**.
- The fourth to sixth input parameters of text are reserved.

Return type: int64

7.6.33 Redistribution Functions

The following functions are system functions used by `gs_redis` during redistribution (Do not call them unless absolutely necessary.):

- `pg_get_redis_rel_end_ctid(text, name, int, int)`
- `pg_get_redis_rel_start_ctid(text, name, int, int)`
- `pg_enable_redis_proc_cancelable()`
- `pg_disable_redis_proc_cancelable()`
- `pg_tupleid_get_blocknum(tid)`
- `pg_tupleid_get_offset(tid)`
- `pg_tupleid_get_ctid_to_bigint(ctid)`

7.6.34 Distribution Key Recommendation Functions

Distribution key recommendation is used to recommend distribution keys and distribution modes in a distributed database. The purpose is to reduce the labor cost of selecting distribution keys during service migration or rollout.

- `sqladvisor.init(char, boolean, boolean, boolean, int, int)`

Description: Initializes parameters.

Return type: Boolean

Table 7-167 Parameter description of `init`

Parameter	Type	Description	Required
<code>kind</code>	<code>char</code>	Recommendation type. Currently, this parameter can only be set to 'D'.	Yes
<code>isUseCost</code>	<code>boolean</code>	Indicates whether optimizers are used. If data is available, optimizers are used.	Yes
<code>isUseCollect</code>	<code>boolean</code>	Indicates whether the analysis is started from the collected load. The default value is false .	No
<code>isConstraint PrimaryKey</code>	<code>boolean</code>	Indicates whether primary key constraints are retained. The default value is true .	No
<code>sqlCount</code>	<code>int</code>	Number of collected SQL statements. The default value is 10000 . The value ranges from 1 to 100000.	No
<code>maxMemory</code>	<code>int</code>	Maximum memory occupied by distribution key recommendation. The default value is 1024 . The value ranges from 1 to 10240, in MB.	No

- `sqladvisor.set_weight_params(real, real, real)`

Description: Sets the weight of different components in heuristic rules. A default parameter is set when the init function is called. This function does not need to be called during analysis.

Return type: Boolean

Table 7-168 Parameter description of `set_weight_params`

Parameter	Type	Description	Required
<code>joinWeight</code>	real	Weight of JOIN. The value ranges from 0 to 1000.	Yes
<code>goupbyWeight</code>	real	Weight of GROUP BY. The value ranges from 0 to 1000.	Yes
<code>qualWeight</code>	real	Weight of predicate. The value ranges from 0 to 1000.	Yes

 **NOTE**

This function is optional. When the init function is executed, the default weights of JOIN, GROUP BY, and predicate are preset to 1.0, 0.1, and 0.05, respectively.

- `sqladvisor.set_cost_params(bigint, boolean, text)`

Description: Parameter that can be set in the Whtif cost model.

Return type: Boolean

Table 7-169 Parameter description of `set_cost_params`

Parameter	Type	Description	Required
<code>maxTime</code>	bigint	Maximum recommendation duration, in minutes. If the value is less than or equal to 0 , the duration is not limited by default.	Yes
<code>isTotalSQL</code>	boolean	Indicates whether all SQL statements are used for calculation. The value true indicates that all SQL statements are used for calculation. The value false indicates that SQL statements whose cost is too high or too low are filtered out based on the percentile.	Yes
<code>compressLevel</code>	text	Search space size of the recommendation algorithm. The options are low , med , and high .	Yes

 NOTE

- This function is optional. When the init function is executed, **maxTime** is preset to **-1**, **isTotalSQL** is preset to **true**, and **compressLevel** is preset to **high**.
- A lower compression level indicates longer time, and it is more likely that a better result can be achieved.
- `sqladvisor.assign_table_type(text)`

Description: Specifies a table as a replication table.

Parameter: table name

Return type: Boolean

 NOTE

The specified replication table must be used before **analyze_query** and **analyze_workload** are called.

- `sqladvisor.analyze_query(text, int)`

Description: Imports SQL statements to be recommended and analyzes the components of the statements.

Return type: Boolean

Table 7-170 Parameter description of `analyze_query`

Parameter	Type	Description	Required
query	text	SQL statement	Yes
frequency	int	Frequency of a statement in the load. The default value is 1 . The value ranges from 1 to 2147483647.	No

 NOTE

- If the value of the **query** parameter contains special characters, such as single quotation marks ('), you can use single quotation marks (') to escape the special characters.
- This function is not supported in semi-online mode.
- `sqladvisor.analyze_workload()`

Description: Analyzes the load information collected online.

Return type: Boolean

- `sqladvisor.get_analyzed_result(text)`

Description: Obtains beneficial components extracted from the current table.

Parameter: text

Return type: record

The following table describes return columns.

Name	Type	Description
schema_name	text	Schema name
table_name	text	Table name
col_name	text	Column name
operator	text	Operator type
count	int	Number of times that an operator is used

- `sqladvisor.run()`

Description: Performs calculation and analysis based on the specified schema and input SQL statements.

Return type: Boolean

- `sqladvisor.get_distribution_key()`

Description: Obtains the recommendation result.

 **NOTE**

The analysis result is saved in a session. If the session disconnects, the result will be lost.

Return type: record

The following table describes return columns.

Name	Type	Description
db_name	text	Database name
schema_name	text	Schema name
table_name	text	Table name
distribution_type	text	Recommended distribution type
distribution_key	text	Recommended distribution key
start_time	timestamp	Recommended start time

Name	Type	Description
end_time	timestamp	Recommended end time
cost_improve	text	Cost increase brought by the recommendation result
comment	text	Comment

- `sqladvisor.clean()`

Description: Clears all the memory in the recommendation process of a session.

Return type: Boolean

- `sqladvisor.start_collect_workload(int, int)`

Description: Starts online load collection.

Return type: Boolean

Table 7-171 Parameter description of `start_collect_workload`

Parameter	Type	Description	Required
sqlCount	int	Maximum number of SQL statements for online load collection. The value ranges from 1 to 100000 and the default value is 10000 .	Yes
maxMemory	int	Maximum memory occupied by online load collection. The default value is 1024 . The value ranges from 1 to 10240, in MB.	Yes

NOTICE

- The online collection function can be called only by the system administrator.
- The load of only one database can be collected at a time.
- Currently, only common SQL statements as well as DML and DQL statements in stored procedures are supported.

- `sqladvisor.end_collect_workload()`

Description: Disables online load collection.

Return type: Boolean

NOTICE

- The online collection function can be disabled only by the system administrator.

- `sqladvisor.clean_workload()`

Description: Clears the memory in the load.

Return type: Boolean

NOTICE

- The function of clearing memory in the load can be called only by a system administrator.
- You must manually execute the cleanup function.

Suggestions

- Call state machines in the heuristic or WhatIf cost recommendation mode.

- Call state machines in semi-online recommendation mode.

7.6.35 Other System Functions

- Built-in functions and operators of GaussDB are compatible with PostgreSQL.

 **NOTE**

In upgrade mode, system functions, for example, concat, with variable-length parameters cannot be called.

The following table lists the functions used by GaussDB to implement internal system functions. You are advised not to use these functions. If you need to use them, contact Huawei technical support.

- spread_collect()**

Description: Calculates the difference between the maximum and minimum values in a certain period of time. This function is used for data collection of aggregate functions.

Parameters: s real[], v real[]

Return type: real[]
- spread_final()**

Description: Calculates the difference between the maximum and minimum values in a certain period of time. This function is used for the final data processing of the aggregate function.

Parameter: s real[]

Return type: real
- spread_internal()**

Description: Calculates the difference between the maximum and minimum values in a certain period of time. This function is used for the process of aggregate functions.

- Parameters: s real[], v real
Return type: real[]
- xidin4()
Description: Inputs a 4-byte xid.
Parameter:cstring
Return type: xid32
 - set_hashbucket_info()
Description: Sets hash bucket information.
Parameter: text
Return type: Boolean
 - gap_fill_internal()
Description: Returns the first non-NULL value in the parameter list.
Parameter: s anyelement, v anyelement
Return type: anyelement
 - int1send()
Description: Packs unsigned 1-byte integers into the internal data buffer stream.
Parameter: tinyint
Return type: bytea
 - is_contain_namespace()
Description: Searches for the table name and namespace split location. If no namespace exists, 0 is returned.
Parameter: relationname name
Return type: integer
 - is_oid_in_group_members()
Description: Not supported
Parameter: node_oid oid, group_members oidvector_extend
Return type: Boolean
 - isubmit_on_nodes_internal()
Description: Not supported
Parameter: job bigint, node_name name, database name, what text, next_date timestamp without time zone, job_interval text
Return type: integer
 - listagg()
Description: Specifies aggregate functions of the list type.
Parameters: smallint, text
Return type: text
 - log_fdw_validator()
Description: Specifies validation functions.
Parameters: text[], oid
Return type: void

- `nvarchar2typmodin()`
Description: Obtains the typmod information of the varchar type.
Parameter: `cstring[]`
Return type: integer
- `nvarchar2typmodout()`
Description: Obtains the typmod information of the varchar type, constructs a character string, and returns the character string.
Parameter: integer
Return type: `cstring`
- `pg_nodes_memmon()`
Description: Not supported.
Parameter: `nan`
Return type: `innernname text, innerusedmem bigint, innertopctxt bigint, nname text, usedmem text, sharedbuffercache text, topcontext text`
- `read_disable_conn_file()`
Description: Reads forbidden connection files.
Parameter: `nan`
Return type: `disconn_mode text, disconn_host text, disconn_port text, local_host text, local_port text, redo_finished text`
- `regex_like_m()`
Description: Specifies the regular expression match, which is used to determine whether a character string complies with a specified regular expression.
Parameters: `text, text`
Return type: Boolean
- `update_pgjob()`
Description: Updates a job.
Parameters: `bigint, "char", bigint, timestamp without time zone, timestamp without time zone, timestamp without time zone, timestamp without time zone, timestamp without time zone, smallint, text`
Return type: void
- `enum_cmp()`
Description: Specifies the enumeration comparison function, which is used to determine whether two enumeration classes are equal and determine their relative sizes.
Parameters: `anyenum, anyenum`
Return type: integer
- `enum_eq()`
Description: Specifies the enumeration comparison function, which is used to implement the equal sign (=).
Parameters: `anyenum, anyenum`
Return type: Boolean
- `enum_first()`

Description: Returns the first element in the enumeration class.

Parameter: anyenum

Return type: anyenum

- `enum_ge()`

Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>) and equal sign (=).

Parameters: anyenum, anyenum

Return type: Boolean

- `enum_gt()`

Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>).

Parameters: anyenum, anyenum

Return type: Boolean

- `enum_in()`

Description: Specifies the enumeration comparison function, which is used to determine whether an element is in an enumeration class.

Parameters: cstring, OID

Return type: anyenum

- `enum_larger()`

Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>).

Parameters: anyenum, anyenum

Return type: anyenum

- `enum_last()`

Description: Returns the last element in the enumeration class.

Parameter: anyenum

Return type: anyenum

- `enum_le()`

Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<) and equal sign (=).

Parameters: anyenum, anyenum

Return type: Boolean

- `enum_lt()`

Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<).

Parameters: anyenum, anyenum

Return type: Boolean

- `enum_smaller()`

Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<).

Parameters: anyenum, anyenum

Return type: Boolean

- `node_oid_name()`
Description: Not supported
Parameter: oid
Return type: cstring
- `pg_buffercache_pages()`
Description: Reads data from the shared buffer.
Parameter: nan
Return type: bufferid integer, relfilenode oid, bucketid smallint, storage_type oid, reltablespace oid, reldatabase oid, relforknumber smallint, relblocknumber bigint, isdirty boolean, usage_count smallint
- `pg_check_xidlimit()`
Description: Checks whether nextxid is greater than or equal to xidwarnlimit.
Parameter: nan
Return type: Boolean
- `pg_comm_delay()`
Description: Displays the delay status of the communications library of a single DN.
Parameter: nan
Return type: text, text, integer, integer, integer, integer
- `pg_comm_rcv_stream()`
Description: Displays the receiving stream status of all communication libraries on a single DN.
Parameter: nan
Return type: text, bigint, text, bigint, integer, integer, integer, text, bigint, integer, integer, integer, bigint, bigint, bigint, bigint, bigint
- `pg_comm_send_stream()`
Description: Displays the sending stream status of all communication libraries on a single DN.
Parameter: nan
Return type: text, bigint, text, bigint, integer, integer, integer, text, bigint, integer, integer, integer, bigint, bigint, bigint, bigint, bigint
- `pg_comm_status()`
Description: Displays the communication status of a single DN.
Parameter: nan
Return type: text, integer, integer, bigint, bigint, bigint, bigint, bigint, integer, integer, integer, integer, integer
- `pg_log_comm_status()`
Description: Prints some logs on the DN.
Parameter: nan
Return type: Boolean
- `pg_parse_clog()`
Description: Parses Clog to obtain the XID status of an ordinary table.
Parameter: nan

- Return type: xid xid, status text
- pg_parse_clog(bucketid)**
 Description: Parses Clog to obtain the XID status of a specified bucket ID.
 Parameter: **bucketid** indicates the physical bucket ID of the hash bucket table. The value **-1** indicates an ordinary table.
 Return type: xid xid, status text
 - pg_pool_ping()**
 Description: Sets PoolerPing.
 Parameter: Boolean
 Return type: SETOF boolean
 - pg_pool_validate()**
 Description: Compares fields in the **pgxc_node** system catalog to check whether a connection is available.
 Parameter: clear boolean, co_node_name cstring
 Return type: pid bigint, node_name text
 - pg_resume_bkp_flag()**
 Description: Obtains the delay xlong flag for backup and restoration.
 Parameter: slot_name name
 Return type: start_backup_flag boolean, to_delay boolean, ddl_delay_recycle_ptr text, rewind_time text
 - gs_static_threadpool_ctrl_status()**
 Description: Queries statistics about the static pool threads in the thread pool. When the CN thread pool is enabled, the distributed CN supports the query of related static pool information, and the DN returns a blank line.
 Parameter: nan
 Return value: text node_name, int group_id, text worker_info

Table 7-172 GS_STATIC_THREADPOOL_CTRL_STATUS columns

Name	Type	Description
node_name	OUT text	Instance name.
group_id	OUT int	Group ID of the thread pool.

Name	Type	Description
worker_info	OUT text	<p>Dynamic statistics about the running thread pool of the current group. The information includes:</p> <p>default and default_s: number of threads, including default value of the dynamic thread pool and that of the static thread pool.</p> <p>expect and expect_s: number of threads, including the expected value of the dynamic thread pool and that of the static thread pool.</p> <p>actual: actual number of running threads, including dynamic pool threads and static pool threads.</p> <p>static threads limit: indicates the number of static pool threads configured for the current group.</p> <p>has static threads: specifies whether a static pool is created for the current group. The default value is 0, indicating no creation.</p> <p>idle static threads: number of idle static pool threads.</p> <p>wait session num: number of waiting sessions.</p>

- `pg_stat_get_pooler_status()`
 Description: Queries the cache connection status in the pooler.
 Parameter: nan
 Return value type: See the following table.

Table 7-173 Return values of `pg_stat_get_pooler_status`

Name	Type	Description
database_name	OUT text	Database name.
user_name	OUT text	Username.
tid	OUT bigint	In non-thread pool logic, this parameter indicates the ID of the thread connected to the CN. In thread pool logic, this parameter indicates the ID of the session connected to the CN.
pgoptions	OUT text	Database connection option. For details, see the options column in Connection Parameters .

Name	Type	Description
node_oid	OUT bigint	OID of the node connected.
in_use	OUT boolean	Specifies whether the connection is currently used. <ul style="list-style-type: none"> • t (true): The connection is in use. • f (false): The connection is not in use.
session_params	OUT text	GUC session parameter delivered by the connection.
fdsock	OUT bigint	Local socket.
local_host	OUT text	Local IP address.
local_port	OUT bigint	Local port number.
remote_host	OUT text	Peer IP address.
remote_port	OUT bigint	Peer port number.
remote_pid	OUT bigint	If the peer site is not in the thread pool logic, the value is the thread ID of the peer site. If the peer site is in the thread pool logic, the value is the session ID of the peer site.
used_count	OUT bigint	Number of reuse times of a connection.
idx	OUT bigint	Peer DN ID in the local CN.
streamid	OUT bigint	Stream ID in the physical connection.

- `get_node_modulo()`
Description: Computes subscripts of a node in a group.
Parameters: For details, see the following table.

Table 7-174 `get_node_modulo` input parameters

Parameter	Type	Description	Value Range
node_oid	IN oid	Node OID.	[0, 2 ³² -1]
group_oid	IN oid	OID of a node group.	[0, 2 ³² -1]

Return type: uint4

- `check_murmurhash_route_node()`

Description: Checks whether the node where the key is distributed is correct.

Parameters: For details, see the following table.

Table 7-175 `check_murmurhash_route_node` input parameters

Parameter	Type	Description	Value Range
key	IN text	Character string of the hash key.	-
node_modulo	IN uint4	Index of a node in a node group.	[0, 2 ³² -1]
node_num	IN uint4	Number of nodes in a node group.	[0, 2 ³² -1]

Return type: uint4

- `gs_libcomm_fd_info()`

Description: Queries the socket persistent connection information of the libcomm communications library.

Parameter: nan

Return value: For details, see the following table.

Table 7-176 Return values of `gs_libcomm_fd_info`

Name	Type	Description
node_name	OUT text	DN name.
ip	OUT text	IP address of the DN.
ctrl_port	OUT bigint	Control channel port.
data_port	OUT bigint	Data channel port.
remote_name	OUT text	Name of the peer DN.
remote_ip	OUT text	Peer IP address.
remote_port	OUT bigint	Peer port number.
local_ip	OUT text	Local IP address.
local_port	OUT bigint	Local port number.

Name	Type	Description
fd	OUT bigint	Socket connection.
type	OUT text	Type of the TCP connection channel. The options are as follows: <ul style="list-style-type: none"> • DATA_SEND_FD: socket of the sender of the data channel • DATA_RECV_FD: socket of the receiver of the data channel. • CTL_SEND_FD: socket of the sender of the control channel. • CTL_RECV_FD: socket of the receiver of the control channel.

 **NOTE**

This function can be used only on the DN. If no information is returned, the libcomm persistent connection is not established for the current DN instance.

- `gs_libcomm_memory_info()`
Description: Queries the basic configuration information used by the internal memory of the current libcomm communications library.

Parameter: nan

Return value: For details, see the following table.

Table 7-177 Return values of `gs_libcomm_memory_info`

Name	Type	Description
node_name	OUT text	Instance name of the DN.
current_used_memory	OUT bigint	Memory used by the libcomm communications library, in bytes.
current_data_item_num	OUT bigint	Number of data blocks in the libcomm lockless queue.
init_mailbox_memory	OUT bigint	Memory used by libcomm to initialize the mailbox, in bytes.
max_datanode	OUT bigint	Maximum number of DNs supported by the libcomm communications library.
max_stream	OUT bigint	Maximum number of data streams supported by a single TCP connection of the libcomm.
max_quota_size	OUT bigint	Total buffer size of the libcomm logical connection, in bytes.

Name	Type	Description
max_usable_memory	OUT bigint	Maximum memory that can be used by the libcomm communications library cache, in bytes.
max_memory_pool	OUT bigint	Total size of the memory resource pool that can be used by the libcomm communications library on each DN. The unit is byte.

- gs_validate_ext_listen_ip()

Description: Connects to DNs, queries invalid service threads on DNs connected to the original extended IP address, and clears the threads.

Parameters: For details, see [Table 7-178](#).

Return value: bigint pid, text node_name

Note: This function is used only when old connections still exist on the original extended IP address after the extended IP address is reloaded. This function clears the threads where the original IP connections are located. Executing this function will clear communication listening on the extended IP address. Exercise caution when performing O&M operations. Currently, this command can be executed only by connecting to DNs and delivered by the administrator.

Table 7-178 GS_VALIDATE_EXT_LISTEN_IP columns

Name	Type	Description
clear	IN cstring	Specifies whether to clear data. The options are as follows: on : clear; off : not clear.
validate_node_name	IN cstring	Name of the DN where the extended IP address connections to be cleared are located.
validate_ip	IN cstring	Extended IP address whose connections are to be cleared.
pid	OUT bigint	ID of the service thread where the extended IP address connections to be cleared are located.
node_name	OUT text	Name of the instance to which the extended IP address connections to be cleared belong.

- gs_comm_listen_address_ext_info()

Description: Displays the DFX information about the extended IP address configured for **listen_address_ext** connected to the current instance.

Parameter: nan

Return type: text node_name, text app, bigint tid, integer lwtid, bigint query_id, integer socket, text remote_ip, text remote_port, text local_ip, text local_port

Table 7-179 GS_COMM_LISTEN_ADDRESS_EXT_INFO columns

Name	Type	Description
node_name	OUT text	Name of the current instance.
app	OUT text	Client connected to the DN.
tid	OUT bigint	Thread ID of the current thread.
lwtid	OUT integer	Lightweight thread ID of the current thread.
query_id	OUT bigint	Query ID of the current thread.
socket	OUT integer	Socket FD of the current physical connection.
remote_ip	OUT text	Peer IP address of the current connection.
remote_port	OUT text	Peer port of the current connection.
local_ip	OUT text	Local IP address of the current connection.
local_port	OUT text	Local port of the current connection.

- `gs_get_global_listen_address_ext_info`
Description: Queries the global extended IP address configuration on the CN.
Parameter: For details, see [Table 7-180](#).
Return type: text node_name, text host, text port, text ext_listen_ip
Note: If the input parameter of the function is **all**, the function depends on the **ext_ip_info** static configuration file. If the file is abnormal, use the CM/OM tool to rectify the fault. In this case, the configuration cannot be updated in real time. You can set the input parameter to **primary** to obtain the configuration information about all primary DNs.

Table 7-180 GS_GET_GLOBAL_LISTEN_ADDRESS_EXT_INFO columns

Name	Type	Description
dn_mode	IN cstring	Specifies the range of DNs to be displayed. If this parameter is set to null , all DNs are queried by default.
node_name	OUT text	DN name.
host	OUT text	Listening IP address of the DN.
port	OUT text	Listening port of the DN.

Name	Type	Description
ext_listen_ip	OUT text	Extended listening IP address of the DN.

- gs_get_listen_address_ext_info()**
 Description: Queries the extended IP address configuration of the current instance.
 Parameter: nan
 Return type: text node_name, text host, bigint port, text ext_listen_ip

Table 7-181 GS_GET_LISTEN_ADDRESS_EXT_INFO

Name	Type	Description
node_name	OUT text	DN name.
host	OUT text	Listening IP address of the DN.
port	OUT bigint	Listening port of the DN.
ext_listen_ip	OUT text	Extended listening IP address of the DN.

- psortoptions()**
 Description: Returns the psort attribute.
 Parameters: text[], Boolean
 Return type: bytea
- remove_job_class_depend()**
 Description: Removes the job dependency.
 Parameter: oid
 Return type: void
- xideq4()**
 Description: Compares two xids to check whether they are the same.
 Parameters: xid32, xid32
 Return type: Boolean
- xideqint8()**
 Description: Compares two xids to check whether they are the same.
 Parameters: xid, bigint
 Return type: Boolean
- xidlt()**
 Description: Returns whether xid1 < xid2 is true.
 Parameters: xid, xid
 Return type: Boolean
- xidlt4()**

Description: Returns whether $xid1 < xid2$ is true.

Parameters: $xid32$, $xid32$

Return type: Boolean

- `get_local_cont_query_stat()`

Description: Obtains the statistics of a specified continuous computing view on the local node.

Parameter: cq_id oid

Return value type: cq oid, w_in_rows int8, w_in_bytes int8, w_out_rows int8, w_out_bytes int8, $w_pendings$ int8, w_errors int8, r_in_rows int8, r_in_bytes int8, r_out_rows int8, r_out_bytes int8, r_errors int8, c_in_rows int8, c_in_bytes int8, c_out_rows int8, c_out_bytes int8, $c_pendings$ int8, c_errors int8

- `get_local_cont_query_stats()`

Description: Obtains all continuous computing view statistics of the local node.

Parameter: nan

Return value type: cq oid, w_in_rows int8, w_in_bytes int8, w_out_rows int8, w_out_bytes int8, $w_pendings$ int8, w_errors int8, r_in_rows int8, r_in_bytes int8, r_out_rows int8, r_out_bytes int8, r_errors int8, c_in_rows int8, c_in_bytes int8, c_out_rows int8, c_out_bytes int8, $c_pendings$ int8, c_errors int8

- `get_cont_query_stats()`

Description: Obtains statistics about all continuous computing views on each DN.

Parameter: nan

Return value type: node name, cq oid, w_in_rows int8, w_in_bytes int8, w_out_rows int8, w_out_bytes int8, $w_pendings$ int8, w_errors int8, r_in_rows int8, r_in_bytes int8, r_out_rows int8, r_out_bytes int8, r_errors int8, c_in_rows int8, c_in_bytes int8, c_out_rows int8, c_out_bytes int8, $c_pendings$ int8, c_errors int8

- `reset_local_cont_query_stat()`

Description: Resets the statistics of a specified continuous computation view on the local node.

Parameter: cq_id oid

Return type: Boolean

- `reset_local_cont_query_stats()`

Description: Resets association statistics on the specified continuous computation view of the local node.

Parameter: cq_id oid

Return type: Boolean

- `reset_cont_query_stats()`

Description: Resets the continuous computation view statistics corresponding to the STREAM object on each DN.

Parameter: $stream_id$ oid

Return type: Boolean

- `check_cont_query_schema_changed()`

Description: Determines the schema change status of a specified continuous computation view.

Parameter: cq_id oid

Return type: Boolean

- gs_get_standby_cluster_barrier_status()

Description: Queries the barrier log replay information of the standby CN or DN, including the latest received barrier, LSN of the latest received barrier, barrier played back last time, and target barrier to be played back.

Parameter: nan

Return type: barrier_id text, barrier_lsn text, recovery_id text, target_id text

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission, and **operate_mode** must be enabled for the O&M administrator role.

- gs_set_standby_cluster_target_barrier_id()

Description: Sets the target barrier to be played back.

Parameter: barrier_id

Return type: target_id text

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission, and **operate_mode** must be enabled for the O&M administrator role.

- gs_query_standby_cluster_barrier_id_exist()

Description: Queries whether the specified barrier is received by the standby node.

Parameter: barrier_id

Return type: Boolean

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission, and **operate_mode** must be enabled for the O&M administrator role.

- standby_read_status()

Description: Obtains the CSN snapshot information of all DNs in a cluster, the difference between the primary and standby DNs, and the CSN snapshot information used for the last read query on the standby node.

Parameter: nan

Return type: text, text, text, integer, bigint, bigint, bigint

Table 7-182 standby_read_status columns

Name	Type	Description
name	text	DN name
type	text	DN type (primary for the primary node and standby for the standby node)
host	text	IP address used by the DN
port	integer	Port used by the DN

Name	Type	Description
collected_csn	bigint	CSN snapshot information of the DN (For the primary node, the value is 0 . For the standby node, the value is the collected CSN.)
delay	bigint	Difference between the primary and standby DNs. The unit is ms.
visited_csn	bigint	CSN information used for the last read query on the standby node. (This parameter is valid only for the standby node where the last query is executed.)

- gs_shutdown_cross_region_walsenders()**
 Description: Interrupts cross-cluster streaming replication.
 Parameter: nan
 Return type: void
 Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission, and **operate_mode** must be enabled for the O&M administrator role.
 The following stream functions exist but are not supported. You are advised not to use them.
 streaming_int8_avg_gather, streaming_numeric_avg_gather,
 streaming_float8_avg_gather, streaming_interval_avg_gather,
 streaming_int8_sum_gather, streaming_int2_int4_sum_gather
- is_dblink_in_transaction()**
 Description: Checks whether a database link corresponding to an OID is used in the current transaction.
 Parameter: oid
 Return type: Boolean
- dblink_has_updatasent()**
 Description: Checks whether DML statements are sent using a database link corresponding to an OID in the current transaction and are not committed.
 Parameter: oid
 Return type: Boolean
- get_last_xmin_by_oid()**
 Description: Obtains the maximum **xmin** value of all columns in a table based on the table OID.
 Parameter: oid
 Return type: xid
- get_relid_by_relname()**
 Description: Obtains the OID of a table based on the table name and renamespace.
 Parameters: cstring, OID

- Return type: oid
- `btint12cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: `int1`, `int2`
Return type: integer
 - `btint14cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: `int1`, `int4`
Return type: integer
 - `btint18cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: `int1`, `int8`
Return type: integer
 - `btint116cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: `int1`, `int16`
Return type: integer
 - `btint1numericcmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: `int1`, `numeric`
Return type: integer
 - `btint21cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: `int2`, `int1`
Return type: integer
 - `btint216cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to

another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: int2, int16

Return type: integer

- btint2numericcmp()

Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: int2, numeric

Return type: integer

- btint41cmp()

Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: int4, int1

Return type: integer

- btint416cmp()

Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: int4, int16

Return type: integer

- btint4numericcmp()

Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: int4, numeric

Return type: integer

- btint81cmp()

Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: int8, int1

Return type: integer

- btint816cmp()

Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: int8, int16

- Return type: integer
- `btint8numericcmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: int8, numeric
Return type: integer
 - `btint161cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: int16, int1
Return type: integer
 - `btint162cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: int16, int2
Return type: integer
 - `btint164cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: int16, int4
Return type: integer
 - `btint168cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: int16, int8
Return type: integer
 - `btnumericint1cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.
Parameters: numeric, int1
Return type: integer
 - `btnumericint2cmp()`
Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to

another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: numeric, int2

Return type: integer

- `btnumericint4cmp()`

Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: numeric, int4

Return type: integer

- `btnumericint8cmp()`

Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: numeric, int8

Return type: integer

- `btint16cmp()`

Description: Compares the values of two parameters. If the value is greater than another one, a positive number is returned. If the value is equal to another one, **0** is returned. If the value is less than another one, a negative number is returned.

Parameters: int16, int16

Return type: integer

- `hashint16()`

Description: Calculates the hash value of an input parameter.

Parameter: int16

Return type: integer

- `hashint1_numeric()`

Description: Calculates the hash value of an input parameter.

Parameter: int1

Return type: integer

- `hashint2_numeric()`

Description: Calculates the hash value of an input parameter.

Parameter: int2

Return type: integer

- `hashint4_numeric()`

Description: Calculates the hash value of an input parameter.

Parameter: int4

Return type: integer

- `hashint8_numeric()`

Description: Calculates the hash value of an input parameter.

Parameter: int8

Return type: integer

- int12eq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int2

Return type: Boolean

- int14eq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int4

Return type: Boolean

- int18eq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int8

Return type: Boolean

- int116eq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int16

Return type: Boolean

- int1numericq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, numeric

Return type: Boolean

- int21eq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int2, int1

Return type: Boolean

- int216eq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int2, int16

Return type: Boolean

- int2numericq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int2, numeric

Return type: Boolean

- `int41eq()`
Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int4`, `int1`
Return type: Boolean
- `int416eq()`
Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int4`, `int16`
Return type: Boolean
- `int4numriceq()`
Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int4`, `numeric`
Return type: Boolean
- `int81eq()`
Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int8`, `int1`
Return type: Boolean
- `int816eq()`
Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int8`, `int16`
Return type: Boolean
- `int8numriceq()`
Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int8`, `numeric`
Return type: Boolean
- `int161eq()`
Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int16`, `int1`
Return type: Boolean
- `int162eq()`
Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int16`, `int2`
Return type: Boolean
- `int164eq()`
Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int16, int4

Return type: Boolean

- int168eq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int16, int8

Return type: Boolean

- numericint1eq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int1

Return type: Boolean

- numericint2eq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int2

Return type: Boolean

- numericint4eq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int4

Return type: Boolean

- numericint8eq()

Description: Compares whether two parameter values are equal. If they are equal, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int8

Return type: Boolean

- int12ne()

Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int2

Return type: Boolean

- int14ne()

Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int4

Return type: Boolean

- int18ne()

Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int8

Return type: Boolean

- `int16ne()`
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int1`, `int16`
Return type: Boolean
- `int1numericne()`
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int1`, `numeric`
Return type: Boolean
- `int21ne()`
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int2`, `int1`
Return type: Boolean
- `int216ne()`
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int2`, `int16`
Return type: Boolean
- `int2numericne()`
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int2`, `numeric`
Return type: Boolean
- `int41ne()`
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int4`, `int1`
Return type: Boolean
- `int416ne()`
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int4`, `int16`
Return type: Boolean
- `int4numericne()`
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: `int4`, `numeric`
Return type: Boolean
- `int81ne()`
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.

- Parameters: int8, int1
Return type: Boolean
- int816ne()
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: int8, int16
Return type: Boolean
 - int8numericne()
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: int8, numeric
Return type: Boolean
 - int161ne()
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: int16, int1
Return type: Boolean
 - int162ne()
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: int16, int2
Return type: Boolean
 - int164ne()
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: int16, int4
Return type: Boolean
 - int168ne()
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: int16, int8
Return type: Boolean
 - numericint1ne()
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: numeric, int1
Return type: Boolean
 - numericint2ne()
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: numeric, int2
Return type: Boolean

- `numericint4ne()`
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: numeric, int4
Return type: Boolean
- `numericint8ne()`
Description: Compares whether two parameter values are equal. If they are not equal, **true** is returned. Otherwise, **false** is returned.
Parameters: numeric, int8
Return type: Boolean
- `int12lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int1, int2
Return type: Boolean
- `int14lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int1, int4
Return type: Boolean
- `int18lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int1, int8
Return type: Boolean
- `int116lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int1, int16
Return type: Boolean
- `int1numericlt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int1, numeric
Return type: Boolean
- `int21lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int2, int1
Return type: Boolean
- `int216lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.

- Parameters: int2, int16
Return type: Boolean
- int2numericlt()
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int2, numeric
Return type: Boolean
 - int41lt()
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int4, int1
Return type: Boolean
 - int416lt()
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int4, int16
Return type: Boolean
 - int4numericlt()
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int4, numeric
Return type: Boolean
 - int81lt()
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int8, int1
Return type: Boolean
 - int816lt()
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int8, int16
Return type: Boolean
 - int8numericlt()
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int8, numeric
Return type: Boolean
 - int161lt()
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int16, int1
Return type: Boolean

- `int162lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int16`, `int2`
Return type: Boolean
- `int164lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int16`, `int4`
Return type: Boolean
- `int168lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int16`, `int8`
Return type: Boolean
- `numericint1lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `numeric`, `int1`
Return type: Boolean
- `numericint2lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `numeric`, `int2`
Return type: Boolean
- `numericint4lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `numeric`, `int4`
Return type: Boolean
- `numericint8lt()`
Description: Compares whether a parameter is less than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `numeric`, `int8`
Return type: Boolean
- `int12gt()`
Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int1`, `int2`
Return type: Boolean
- `int14gt()`
Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int4

Return type: Boolean

- int18gt()

Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int8

Return type: Boolean

- int116gt()

Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int16

Return type: Boolean

- int1numericgt()

Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, numeric

Return type: Boolean

- int21gt()

Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int2, int1

Return type: Boolean

- int216gt()

Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int2, int16

Return type: Boolean

- int2numericgt()

Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int2, numeric

Return type: Boolean

- int41gt()

Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int4, int1

Return type: Boolean

- int416gt()

Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int4, int16

Return type: Boolean

- `int4numericgt()`
Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int4`, `numeric`
Return type: Boolean
- `int81gt()`
Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int8`, `int1`
Return type: Boolean
- `int816gt()`
Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int8`, `int16`
Return type: Boolean
- `int8numericgt()`
Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int8`, `numeric`
Return type: Boolean
- `int161gt()`
Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int16`, `int1`
Return type: Boolean
- `int162gt()`
Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int16`, `int2`
Return type: Boolean
- `int164gt()`
Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int16`, `int4`
Return type: Boolean
- `int168gt()`
Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int16`, `int8`
Return type: Boolean
- `numericint1gt()`
Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int1

Return type: Boolean

- numericint2gt()

Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int2

Return type: Boolean

- numericint4gt()

Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int4

Return type: Boolean

- numericint8gt()

Description: Compares whether a parameter is greater than another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int8

Return type: Boolean

- int12le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int2

Return type: Boolean

- int14le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int4

Return type: Boolean

- int18le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int8

Return type: Boolean

- int116le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, int16

Return type: Boolean

- int1numericle()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int1, numeric

Return type: Boolean

- `int21le()`
Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int2`, `int1`
Return type: Boolean
- `int216le()`
Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int2`, `int16`
Return type: Boolean
- `int2numericle()`
Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int2`, `numeric`
Return type: Boolean
- `int41le()`
Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int4`, `int1`
Return type: Boolean
- `int416le()`
Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int4`, `int16`
Return type: Boolean
- `int4numericle()`
Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int4`, `numeric`
Return type: Boolean
- `int81le()`
Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int8`, `int1`
Return type: Boolean
- `int816le()`
Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int8`, `int16`
Return type: Boolean
- `int8numericle()`
Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int8, numeric

Return type: Boolean

- int161le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int16, int1

Return type: Boolean

- int162le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int16, int2

Return type: Boolean

- int164le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int16, int4

Return type: Boolean

- int168le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: int16, int8

Return type: Boolean

- numericint1le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int1

Return type: Boolean

- numericint2le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int2

Return type: Boolean

- numericint4le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int4

Return type: Boolean

- numericint8le()

Description: Compares whether a parameter is less than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

Parameters: numeric, int8

Return type: Boolean

- `int12ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int1`, `int2`
Return type: Boolean
- `int14ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int1`, `int4`
Return type: Boolean
- `int18ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int1`, `int8`
Return type: Boolean
- `int116ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int1`, `int16`
Return type: Boolean
- `int1numericge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int1`, `numeric`
Return type: Boolean
- `int21ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int2`, `int1`
Return type: Boolean
- `int216ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int2`, `int16`
Return type: Boolean
- `int2numericge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int2`, `numeric`
Return type: Boolean
- `int41ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.

- Parameters: int4, int1
Return type: Boolean
- int416ge()
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int4, int16
Return type: Boolean
 - int4numericge()
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int4, numeric
Return type: Boolean
 - int81ge()
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int8, int1
Return type: Boolean
 - int816ge()
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int8, int16
Return type: Boolean
 - int8numericge()
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int8, numeric
Return type: Boolean
 - int161ge()
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int16, int1
Return type: Boolean
 - int162ge()
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int16, int2
Return type: Boolean
 - int164ge()
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: int16, int4
Return type: Boolean

- `int168ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `int16`, `int8`
Return type: Boolean
- `numericint1ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `numeric`, `int1`
Return type: Boolean
- `numericint2ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `numeric`, `int2`
Return type: Boolean
- `numericint4ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `numeric`, `int4`
Return type: Boolean
- `numericint8ge()`
Description: Compares whether a parameter is greater than or equal to another one. If yes, **true** is returned. Otherwise, **false** is returned.
Parameters: `numeric`, `int8`
Return type: Boolean
- `gs_relation_is_updatable()`
Description: Returns whether a relationship can be inserted, updated, or deleted. If the value can be updated, **4** is returned. If the value can be inserted, **8** is returned. If the value can be deleted, **16** is returned. If the value meets the requirements, the value obtained by adding the corresponding values is returned.
Parameters: `OID`, Boolean
Return type: `int32`
- `gs_column_is_updatable()`
Description: Returns whether a column can be updated. If yes, **t** is returned. Otherwise, **f** is returned.
Parameters: `OID`, `int16`, Boolean
Return type: Boolean

7.6.36 Internal Functions

The following functions of GaussDB use internal data types, which cannot be directly called by users.

- Selection rate calculation functions

areajoin el	areasel	arraycon tjoin sel	arraycon tsel	contjoin el	contsel	eqjoin sel

- Functions for reading data remotely

gs_read_block_from_remote is used to read the pages of a non-segment-page table file. By default, only the initial user can view the data. Other users can use the data only after being granted with permissions.

gs_read_segment_block_from_remote is used to read the pages of a segment-page table file. By default, only the initial user can view the data. Other users can use the data only after being granted with permissions.

- Functions for reading files remotely

gs_read_file_size_from_remote is used to read the size of a specified file. Before using the gs_repair_file function to repair a file, you need to obtain the size of the file from the remote end to verify the missing file information and repair the missing files one by one. By default, only the initial user can view the data. Other users can use the data only after being granted with permissions.

gs_read_file_from_remote is used to read a specified file. After obtaining the file size by using the gs_read_file_size_from_remote function, gs_repair_file reads the remote file segment by segment using this function. By default, only the initial user can view the data. Other users can use the data only after being granted with permissions.

- Auxiliary functions for incrementally rebuilding other standby or cascaded standby DNs using the standby DN.

gs_standby_incremental_filemap_create is used to create a temporary filemap file for incremental rebuilding on the standby DN. The filemap file is used to store the path and size of the data to be transferred during the incremental rebuilding. This API can be called only when the initial user is used and **application** is **gs_rewind**.

gs_standby_incremental_filemap_insert is used to insert file information into a specified temporary filemap file. The file information includes the file path,

transfer start point, length of data to be transferred at a time, and rebuild flag bit. This API can be called only when the initial user is used and **application** is **gs_rewind**.

`gs_standby_incremental_filemap_execute` is used to obtain file information stored in a specified temporary filemap file and delete the specified filemap file for data transmission during incremental standby DN rebuilding. This API can be called only when the initial user is used and **application** is **gs_rewind**.

- Ledger database function
`get_dn_hist_relhash`
- View-related reference functions
`adm_hist_sqlstat_func`
`adm_hist_sqlstat_idlog_func`
`adm_hist_sqltext_func`
- `gs_txn_snapshot` system catalog maintenance function
`gs_insert_delete_txn_snapshot` is used to maintain the `gs_txn_snapshot` system catalog of each node in distributed GTM-Lite mode. Only the system administrator can call `gs_insert_delete_txn_snapshot`.
- XMLType function
`isschemavalid` (unavailable)

7.6.37 AI Feature Functions

- `gs_index_advise(text)`
Description: Recommends an index for a single query statement.
Parameter: SQL statement string
Return type: record
For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Single-Query Index Recommendation" in *Feature Guide*.
- `hypopg_create_index(text, [text])`
Description: Creates a virtual index.
Parameter: (optional) character string of the statement for creating an index, level of the created virtual index
Return type: record
For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Virtual Index" in *Feature Guide*.
- `hypopg_display_index([text])`
Description: Displays information about all created virtual indexes.
Parameter: (optional) level of the virtual index to be displayed
Return type: record
For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Virtual Index" in *Feature Guide*.
- `hypopg_drop_index(oid)`

Description: Deletes a specified virtual index.

Parameter: OID of the index

Return type: Boolean

For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Virtual Index" in *Feature Guide*.

- `hypopg_reset_index([text])`

Description: Clears all virtual indexes.

Parameter: (optional) level of the virtual index to be cleared

Return type: none

For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Virtual Index" in *Feature Guide*.

- `hypopg_estimate_size(oid)`

Description: Estimates the space required for creating a specified index.

Parameter: OID of the index

Return type: int8

For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Virtual Index" in *Feature Guide*.

- `db4ai_predict_by_bool (text, VARIADIC "any")`

Description: Obtains a model whose return value is of the Boolean type for model inference. This function is an internal function. You are advised to use the PREDICT BY syntax for inference.

Parameter: model name and input column name of the inference task

Return type: Boolean

- `db4ai_predict_by_float4(text, VARIADIC "any")`

Description: Obtains a model whose return value is of the float4 type for model inference. This function is an internal function. You are advised to use the PREDICT BY syntax for inference.

Parameter: model name and input column name of the inference task

Return type: float

- `db4ai_predict_by_float8(text, VARIADIC "any")`

Description: Obtains a model whose return value is of the float8 type for model inference. This function is an internal function. You are advised to use the PREDICT BY syntax for inference.

Parameter: model name and input column name of the inference task

Return type: float

- `db4ai_predict_by_int32(text, VARIADIC "any")`

Description: Obtains a model whose return value is of the int32 type for model inference. This function is an internal function. You are advised to use the PREDICT BY syntax for inference.

Parameter: model name and input column name of the inference task

Return type: int

- `db4ai_predict_by_int64(text, VARIADIC "any")`
Description: Obtains a model whose return value is of the int64 type for model inference. This function is an internal function. You are advised to use the PREDICT BY syntax for inference.
Parameter: model name and input column name of the inference task
Return type: int
- `db4ai_predict_by_numeric(text, VARIADIC "any")`
Description: Obtains a model whose return value is of the numeric type for model inference. This function is an internal function. You are advised to use the PREDICT BY syntax for inference.
Parameter: model name and input column name of the inference task
Return type: numeric
- `db4ai_predict_by_text(text, VARIADIC "any")`
Description: Obtains a model whose return value is of the character type for model inference. This function is an internal function. You are advised to use the PREDICT BY syntax for inference.
Parameter: model name and input column name of the inference task
Return type: text
- `db4ai_predict_by_float8_array(text, VARIADIC "any")`
Description: Obtains a model whose return value is of the character type for model inference. This function is an internal function. You are advised to use the PREDICT BY syntax for inference.
Parameter: model name and input column name of the inference task
Return type: text
- `gs_explain_model(text)`
Description: Obtains the model whose return value is of the character type for text-based model parsing.
Parameter: model name
Return type: text
- `gs_ai_stats_explain(text, text[])`
Description: Prints the intelligent statistics of multiple columns in the corresponding table and columns on the current node.
Parameters: table name and column name collection.
Return type: text
- `gs_acm_analyze_workload_manual()`
Description: Manually trains the cardinality estimation model based on the operator feedback data in the current database.
Parameter: none
Return type: text
Description: This function is unavailable in the current version.
- `gs_stat_get_acm_feedback_operator_info()`
Description: Displays all operator feedback data collected in the global memory.
Parameter: none

Return type: record

Description: This function is unavailable in the current version.

- `gs_stat_get_sql_feedback_info()`

Description: Displays the number of times that SQL statements are used and the execution time when SQL statements are used and not used within the effective range of the feedback cardinality function in the global memory.

Parameter: none

Return type: record

Description: This function is unavailable in the current version.

- `gs_costmodel_calibration_manual()`

Description: Manually triggers operator time collection and corrects cost model parameters.

Parameter: none

Return type: text

Description: This function is unavailable in the current version.

- `gs_show_aplan(cstring)`

Description: Views the multi-plan cache of queries cached in the current session.

Parameter: prepare name is used to search for the corresponding cache plan.

Return type: text

Description: This function is unavailable in the current version.

- `ai_watchdog_detection_warnings()`

Description: Obtains the risk alarm information of the AI watchdog. The `sysadmin` or `monadmin` access permission is required.

Parameter: none

Return type: record

- `ai_watchdog_monitor_status(int)`

Description: Obtains the monitoring information of the AI watchdog. The `sysadmin` or `monadmin` access permission is required.

Parameter: Returns the upper limit of the length of the monitored sequence.

Return type: record

- `ai_watchdog_parameters()`

Description: Obtains the internal parameters or status information of the AI watchdog. The `sysadmin` or `monadmin` access permission is required.

Parameter: none

Return type: record

7.6.38 Sensitive Data Discovery Function

- `gs_sensitive_data_discovery(scan_target text, scan_classifier text)`

Description: Scans target data and returns statistical scanning results.

Parameters:

scan_target: specifies the object to be scanned. The value must be the name of a schema, table, or column, and the upper-level names of the object to be

scanned must be specified. For example, if a column is scanned, the object to be scanned is *schema_name.table_name.column_name*.

scan_classifier: specifies the classifier to be used. Five classifiers can be specified: email, creditcard, phonenumber, chinesename, and encryptedcontent. Multiple classifiers are separated by commas (,). The value **all** indicates all classifiers are selected.

Return type: record

For details, see section "Sensitive Data Discovery" in *Feature Guide*.

- `gs_sensitive_data_discovery_detail(scan_target text, scan_classifier text)`

Description: Scans the target data and returns the detailed scanning result.

scan_target: specifies the object to be scanned. The value must be the name of a schema, table, or column, and the upper-level names of the object to be scanned must be specified. For example, if a column is scanned, the object to be scanned is *schema_name.table_name.column_name*.

scan_classifier: specifies the classifier to be used. Five classifiers can be specified: email, creditcard, phonenumber, chinesename, and encryptedcontent. Multiple classifiers are separated by commas (,). The value **all** indicates all classifiers are selected.

Return type: record

For details, see section "Sensitive Data Discovery" in *Feature Guide*.

7.6.39 Dynamic Data Masking Functions

NOTE

This function is an internal function.

- `creditcardmasking(col text, letter char default 'x')`

Description: Replaces the digits before the last four bits following the col string with letters.

Parameter: Character string to be replaced or character string used for replacement

Return type: text

- `basicmailmasking(col text, letter char default 'x')`

Description: Replaces the characters before the first at sign (@) in the col string with letters.

Parameter: Character string to be replaced or character string used for replacement

Return type: text

- `fullmailmasking(col text, letter char default 'x')`

Description: Replaces the characters (except @) before the last period (.) in the col string with letters.

Parameter: Character string to be replaced or character string used for replacement

Return type: text

- `alldigitsmasking(col text, letter char default '0')`

Description: Replaces the digits in the col string with letters.

Parameter: Character string to be replaced or character string used for replacement

Return type: text

- `shufflemasking(col text)`

Description: Sorts the characters in the col string out of order.

Parameter: Character string to be replaced or character string used for replacement

Return type: text

- `randommasking(col text)`

Description: Randomizes the characters in the col string.

Parameter: Character string to be replaced or character string used for replacement

Return type: text

- `regexprmasking(col text, reg text, replace_text text, pos INTEGER default 0, reg_len INTEGER default -1)`

Description: Replaces the col string with a regular expression.

Parameters: Character string to be replaced, regular expression, replacement start position, and replacement length.

Return type: text

7.6.40 Hotkey Feature Functions

- `gs_stat_get_hotkeys_info()`

Description: Obtains hotkey information queried on the local node.

Return type: Tuple

Example:

```
gaussdb=# SELECT * FROM gs_stat_get_hotkeys_info() order by count, hash_value;
database_name | schema_name | table_name | key_value | hash_value | count
-----+-----+-----+-----+-----+-----
regression   | public     | hotkey_single_col | {22}      | 1858004829 | 2
regression   | public     | hotkey_single_col | {11}      | 2011968649 | 2
(2 rows)
```

- `gs_stat_clean_hotkeys()`

Description: Clears hotkey cache and resets hotkey status information.

Return type: bool, and the return value is always **true**.

Example:

```
gaussdb=# SELECT * FROM gs_stat_clean_hotkeys();
gs_stat_clean_hotkeys
-----
t
(1 row)
```

7.6.41 Global SysCache Functions

- `gs_gsc_table_detail(database_id default NULL, rel_id default NULL)`

Description: Queries the table metadata in the global system cache in a database. The user who calls this function must have the SYSADMIN permission.

7.6.42 Data Damage Detection and Repair Functions

- The restrictions for repairing file or page of the primary and standby nodes are as follows:

File Type	File/ Page	Prim ary/ Stan dby	Detection and Repair
Ordinary row-store tables (including Astore and Ustore) and segment-page tables (excluding indexes and compressed tables)	File and page	Prima ry	Manual detection and repair.
Undo files (excluding undo meta)	Page	Prima ry	Manual detection and repair (excluding analyse verify).
init fork file for unlogged tables	File	Prima ry	Manual detection and repair.
Ordinary row-store tables (including Astore and Ustore), indexes (including B-tree and UB-tree), and undo files (excluding undo meta. Undo files support only CRC errors verification.)	Page	Stand by	Automatic detection and repair during replay.

CAUTION

The first standby node and cascaded standby node of the standby cluster can be repaired.

A critical section is used in the database to ensure the consistency of access to key resources. Errors cannot be thrown in the critical section. If a damaged page is accessed in the critical area, PANIC is triggered. Repair detection and automatic repair are not supported. Typical operations that access the critical area during execution include database write operations such as INSERT, DELETE, UPDATE, and DROP.

- `gs_verify_data_file(verify_segment bool)`
Description: Checks whether files in the current database of the current instance are lost. The verification only checks whether intermediate segments are lost in the main file of the data table. The default value is **false**, indicating that the segment-page table data file is not verified. If this parameter is set to **true**, only segment-page table files are verified. By default, only initial users, users with the sysadmin permission, and users with the O&M administrator permission in the O&M mode can view the information. Other users can view the information only after being granted with permissions.

The returned result is as follows:

- Non-segment-page table: **rel_oid** and **rel_name** indicate the table OID and table name of the corresponding file, and **miss_file_path** indicates the relative path of the lost file.
- Segment-page table: All tables are stored in the same file. Therefore, **rel_oid** and **rel_name** cannot display information about a specific table. For a segment-page table, if the first file is damaged, the subsequent files such as .1 and .2 are not checked. For example, if 3, 3.1, and 3.2 are damaged, only 3 damage can be detected. When the number of segment-page files is less than 5, the files that are not generated are also detected during function detection. For example, if there are only files 1 and 2, files 3, 4, and 5 are detected during segment-page file detection. In the following examples, the first is an example of checking a non-segment-page table, and the second is an example of checking a segment-page table.

Parameter description:

- **verify_segment**
Specifies the range of files to be checked. **false** indicates that non-segment-page tables are verified. **true** indicates that segment-page tables are verified.

The value can be **true** or **false** (default value).

Return type: record

Example (The abnormal line is displayed only when an exception is detected. Otherwise, no line is displayed.):

Verify a non-segment-page table:

```
gaussdb=# SELECT * FROM gs_verify_data_file();
node_name | rel_oid | rel_name | miss_file_path
-----+-----+-----+-----
dn_6001_6002_6003 | 16554 | test | base/16552/24745
```

Verify a segment-page table:

```
gaussdb=# SELECT * FROM gs_verify_data_file(true);
node_name | rel_oid | rel_name | miss_file_path
-----+-----+-----+-----
dn_6001_6002_6003 | 0 | none | base/16573/2
```

- **gs_repair_file(tableoid Oid, path text, timeout int)**
Description: Repairs the file based on the input parameters. Only the primary DN with normal primary/standby connection is supported. Only the main file of the data table can be repaired. The parameters are set based on the OID and path returned by the `gs_verify_data_file` function. The value of table OID for a segment-page table ranges from 0 to 4294967295. (The internal verification determines whether a file is a segment-page table file based on the file path. The table OID is not used for a segment-page table file.) If the repair is successful, **true** is returned. If the repair fails, the failure cause is displayed. By default, only initial users, users with the sysadmin permission, and users with the O&M administrator permission in the O&M mode on the primary DN can view the information. Other users can view the information only after being granted with permissions.

 **CAUTION**

1. If a file on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be promoted to primary, which is normal.
2. If a file exists but its size is 0, the file will not be repaired. To repair the file, you need to delete the file whose size is 0 and then repair it.
3. You can delete a file only after the file descriptor is automatically closed. You can manually restart the process or perform a primary/standby switchover.
4. The restoration function requires that the paths of the files to be restored on the primary and standby nodes be the same. If the paths are different, the restoration fails. That is, if the RELATIVE LOCATION tablespace is used, the path is different because tblspcversiondir is different. As a result, the restoration fails.

Parameter description:

– **tableoid**

OID of the table corresponding to the file to be repaired. Set this parameter based on the **rel_oid** column in the list returned by the `gs_verify_data_file` function.

Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.

– **path**

Path of the file to be repaired. Set this parameter based on the **miss_file_path** column in the list returned by the `gs_verify_data_file` function.

Value range: a string

– **timeout**

Specifies the duration for waiting for the standby DN to replay. The repair file needs to wait for the standby DN to be put back to the corresponding location on the current primary DN. Set this parameter based on the replay duration of the standby DN.

Value range: 60s to 3600s.

Return type: Boolean

Example (Set **tableoid** and **path** based on the output of `gs_verify_data_file`):

Page-based storage:

```
gaussdb=# SELECT * FROM gs_repair_file(16554,'base/16552/24745',360);
gs_repair_file
-----
t
```

Segment-page storage:

```
gaussdb=# SELECT * FROM gs_repair_file(16554,'base/16552/2',360);
gs_repair_file
-----
t
```

- **local_bad_block_info()**

Description: Displays the page damage of the instance. You can read the page from the disk and record the page CRC failure. By default, only initial users,

users with the sysadmin permission, users with the monitor administrator permission, users with the O&M administrator permission in the O&M mode, and monitor users can view the information. Other users can view the information only after being granted with permissions. **file_path** indicates the relative path of the damaged file. **block_num** indicates the number of the page where the file is damaged. The page number starts from 0. **check_time** indicates the time when the page damage is detected. **repair_time** indicates the time when the page is repaired.

Return type: record

Example (Related entries are displayed only when there are damaged records. Otherwise, no log is displayed.):

```
gaussdb=# SELECT * FROM local_bad_block_info();
node_name | spc_node | db_node | reL_node| bucket_node | fork_num | block_num | file_path |
check_time | repair_time
-----+-----+-----+-----+-----+-----+-----+-----
dn_6001_6002_6003| 1663 | 16552 | 24745 | -1 | 0 | 0 | base/16552/24745 |
2022-01-13 20:19:08.385004+08 | 2022-01-13 20:19:08.407314+08
```

- `remote_bad_block_info()`

Description: Queries the page damage of other instances except the current instance when a query is performed on the CN. The recorded data is the same as that of the `local_bad_block_info` function executed on other instances. The execution result on the DN is empty. By default, only initial users, users with the sysadmin permission, users with the monitor administrator permission, users with the O&M administrator permission in the O&M mode, and monitor users can view the information. Other users can view the information only after being granted with permissions.

Return type: record

- `local_clear_bad_block_info()`

Description: Deletes data of repaired pages from `local_bad_block_info`, that is, information whose **repair_time** is not empty. By default, only initial users, users with the sysadmin permission, users with the O&M administrator permission in the O&M mode, and monitor users can view the information. Other users can view the information only after being granted with permissions.

Return type: Boolean

Example:

```
gaussdb=# SELECT * FROM local_clear_bad_block_info();
result
-----
t
```

- `remote_clear_bad_block_info()`

Description: Clears the data of the repaired pages of other instances except the current instance when this function is executed on the CN, that is, information whose **repair_time** is not empty. The execution result on the DN is empty. By default, only initial users, users with the sysadmin permission, users with the O&M administrator permission in the O&M mode, and monitor users can view the information. Other users can view the information only after being granted with permissions.

Return type: record

- `gs_verify_and_tryrepair_page` (path text, blocknum Oid, verify_mem bool, is_segment bool)

Description: Verifies the page specified by the instance. By default, only initial users, users with the sysadmin permission, and users with the O&M administrator permission in the O&M mode on the primary DN can view the information. Other users can view the information only after being granted with permissions. In the command output, **disk_page_res** indicates the verification result of the page on the disk, **mem_page_res** indicates the verification result of the page in the memory, and **is_repair** indicates whether the repair function is triggered during the verification. **t** indicates that the page is repaired, and **f** indicates that the page is not repaired.

 **NOTE**

- If a page on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be promoted to primary, which is normal. Damaged pages of hash bucket tables cannot be repaired.
- The repair triggered by this function can only repair pages in the memory. The repair takes effect only after the memory pages are flushed to disks and the physical pages are repaired.

Parameter description:

– path

Path of the damaged file. Set this parameter based on the **file_path** column in `local_bad_block_info`. To verify the undo pages of the Ustore table, enter the path of the undo pages to be verified.

Value range: a string

– blocknum

Page number of the damaged file. Set this parameter based on the **block_num** column in `local_bad_block_info`. If you want to verify the undo pages of the Ustore table, enter the block number of the undo pages to be verified.

Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.

– verify_mem

Specifies whether to verify a specified page in the memory. If this parameter is set to **false**, only pages on the disk are verified. If this parameter is set to **true**, pages in the memory and on the disk are verified. If a page on the disk is damaged, the system verifies the basic information of the page in the memory and flushes the page to the disk to restore the page. If a page is not found in the memory during memory page verification, the page on the disk is read through the memory API. During this process, if the disk page is faulty, the remote read automatic repair function is triggered.

Value range: The value is of a Boolean type and can be **true** or **false**.

– is_segment

Determines whether the table is a segment-page table. Set this parameter based on the value of **bucket_node** in `local_bad_block_info`. If the value of **bucket_node** is **-1**, the table is not a segment-page table. In this case, set **is_segment** to **false**. If the value of **bucket_node** is not **-1**, set **is_segment** to **true**. Segment-page storages are supported.

Value range: The value is of a Boolean type and can be **true** or **false**.

Return type: record

Examples (Transfer parameters based on the output of `local_bad_block_info`. Otherwise, an error is reported.):

Page-based storage:

```
gaussdb=# SELECT * FROM gs_verify_and_tryrepair_page('base/16552/24745',0,false,false);
node_name | path | blocknum | disk_page_res | mem_page_res | is_repair
-----+-----+-----+-----+-----+-----
dn_6001_6002_6003 | base/16552/24745 | 0 | page verification succeeded. | | f
```

Segment-page storage:

```
gaussdb=# SELECT * FROM gs_verify_and_tryrepair_page('base/14365/1',4494,false,true);
node_name | path | blocknum | disk_page_res | mem_page_res | is_repair
-----+-----+-----+-----+-----+-----
dn_6001_6002_6003 | base/14365/1 | 4494 | page verification succeeded. | | f
```

- `gs_repair_page(path text, blocknum oid, is_segment bool, timeout int)`

Description: Restores the specified page of the instance. This function can be used only by the primary DN that is properly connected to the primary and standby DNs. By default, only initial users, users with the `sysadmin` permission, and users with the O&M administrator permission in the O&M mode on the primary DN can view the information. Other users can view the information only after being granted with permissions.

Note: If a page on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be promoted to primary, which is normal. Damaged pages of hash bucket tables cannot be repaired.

Parameters

- `path`

Path of the damaged page. Set this parameter based on the `file_path` column in `local_bad_block_info` or the `path` column in the `gs_verify_and_tryrepair_page` function.

Value range: a string

- `blocknum`

Number of the damaged page. Set this parameter based on the `block_num` column in `local_bad_block_info` or the `blocknum` column in the `gs_verify_and_tryrepair_page` function.

Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.

- `is_segment`

Determines whether the table is a segment-page table. The value of this parameter is determined by the value of `bucket_node` in `local_bad_block_info`. If the value of `bucket_node` is `-1`, the table is not a segment-page table and `is_segment` is set to `false`. If the value of `bucket_node` is not `-1`, `is_segment` is set to `true`. Segment-page storages are supported.

Value range: The value is of a Boolean type and can be `true` or `false`.

- `timeout`

Duration of waiting for standby DN replay. The page to be repaired needs to wait for the standby DN to be played back to the location of the current primary DN. Set this parameter based on the replay duration of the standby DN.

Value range: 60s to 3600s.

Return type: Boolean

Examples (Transfer parameters based on the output of local_bad_block_info. Otherwise, an error is reported.):

Page-based storage:

```
gaussdb=# SELECT * FROM gs_repair_page('base/16552/24745',0,false,60);
result
-----
t
```

Segment-page storage:

```
gaussdb=# SELECT * FROM gs_repair_page('base/16552/1',4494,true,60);
result
-----
t
```

- gs_seg_verify_datafile(IN tablespace_name name, IN database_name name, IN file_id integer, IN bucketnode integer, IN start_block_id bigint default 0, IN end_block_id bigint default UINT32MAX)

a. Description

Description: Verifies segment-page files 1 to 5, checks whether the main fork has page damage, and records the verification result in the local_bad_block_info() function.

Permission: Only users with the sysadmin attribute and users with the O&M administrator attribute in O&M mode can execute this function.

b. Parameters

Name	Type	Description
tablespace_name	name	Tablespace name.
database_name	name	Database name.
file_id	integer	File name. The value ranges from 1 to 5.
bucketnode	integer	Bucket node of the table. <ul style="list-style-type: none"> • 0 to 1023 indicate the bucket nodes of a hash bucket table. • 1024 indicates the bucket node of a segment-page ordinary table. Currently, only hash bucket tables and segment-page ordinary tables are supported.
start_block_id	bigint	Start value of the verification page range. The default value is 0 .
end_block_id	bigint	End value of the verification page range. The default value is 4294967295 .

c. Return value: None

Example:

```
gaussdb=# SELECT * FROM gs_seg_verify_datafile('seg_tblspc', 'postgres', 2, 1024);
WARNING: page verification failed, calculated checksum 60994 but expected 11565, the block num is
```

```
4157
gs_seg_verify_datafile
-----
```

(1 row)

- `gs_edit_page_bypath`(path text, blocknum int64, offset int, data text, data_size int, read_backup bool, storage_type text)

Description: Transfers the path, block number, offset, target data to be modified, and length of the target table file, modifies the target data to the corresponding fields on the page, and returns the path of the modified file to be flushed to the disk. The **read_backup** column determines the file reading mode, and the **storage_type** column indicates the file storage mode (for example, segment-page storage). To prevent incorrect modification, this function does not directly modify the original page but modifies the copied page and flushes the modified page to the specified path. Only the system administrator or O&M administrator in O&M mode can execute this function. In a distributed environment, this function must be executed on DNs.

Return type: text.

Table 7-183 `gs_edit_page_bypath` parameters

Category	Parameter	Type	Description
Input parameter	path	text	Physical file path of the file to be modified, which is related to the read_backup field. The value can be the relative path of the file in the database directory or the absolute path of files such as the backup file. If the target file does not exist or fails to be read, an error message is displayed. <ul style="list-style-type: none"> • If read_backup is false, the path format is <i>tablespace name/database oid/table relfilenode (physical file name)</i>. For example, base/16603/16394. • If read_backup is true, path is a valid path. In this case, because other information about the input file cannot be obtained, you need to ensure that the input data is correct. <p>In a page-based file, only U-page and UB-tree data pages can be edited and modified. In a segment-page file, Astore data pages can be edited and modified. Tables with tablespaces are not supported. Other information about the input file cannot be obtained. Therefore, you need to ensure that the input data type is correct.</p>
Input parameter	blocknum	bigint	Block number of the page to be repaired. Value range: 0 to <i>MaxBlockNumber</i> . Reads the page corresponding to the specified physical or logical block number based on the read_backup field. If the specified block number is out of range, an error message is returned.

Category	Parameter	Type	Description
Input parameter	offset	int	In-page offset of the field to be modified. Value range: 0 to <i>BLCKSZ</i> (<i>BLCKSZ</i> is excluded.) If the specified value is less than 0 or greater than or equal to that of BLCKSZ , the system view is used to return the corresponding error information.
Input parameter	data	text	Type of the target value to be modified. Type: <ul style="list-style-type: none"> • '0x': hexadecimal. • '0b': binary. • '0s': character string. Others: If the value of the data parameter is not one of the preceding types, the value can only be a decimal numeric string.
Input parameter	data_size	int	Length of the written data, in bytes. Value range: 1 to 8. If the specified write length is less than 1 byte or greater than 8 bytes, or the sum of offset and data_size is greater than the value of BLCKSZ , the system view is used to return the corresponding error information.
Input parameter	read_backup	bool	Specifies whether to read pages from the backup directory. If this parameter is set to false , the target page is read based on the logical block number. Otherwise, the page is read based on the physical block number.
Input parameter	storage_type	text	Specifies the file storage mode. This parameter is optional. <ul style="list-style-type: none"> • 'page': page mode. • 'segment': segment-page mode.
Output parameter	output_msg	text	If the modification is successful, the absolute path of the modified file is returned. The modified file is stored in the gs_log/dump directory. If the modification fails, a failure message is returned.

In the example, transfer parameters based on the parameter description and use the actual physical path.

Example 1: Overwrite the data whose value is **0X1FFF** at the offset of 16 bytes on page 0 in the **base/15808/25075** table.

```
gaussdb=# SELECT gs_edit_page_bypath('base/15808/25075',0,16,'0x1FFF', 2, false, 'page');
gs_edit_page_bypath
```

```
-----  
/gs_log_dir/dump/1663_15808_25075_0.editpage  
(1 rows)
```

Example 2: If the input parameter does not comply with the specifications, an error message is returned.

```
gaussdb=# SELECT gs_edit_page_bypath('base/15808/25075', 0,16,'@1231!', 8, false, 'page');  
gs_edit_page_bypath
```

```
-----  
Error: the parameter 'data' decode failed.  
(1 row)
```

Example 3: When the data to be written is the same as the original value, an alarm is returned.

```
gaussdb=# SELECT gs_edit_page_bypath('/gs_log_dir/dump/1663_15808_25075_0.editpage',  
0,16,'0x1FFF', 2, true, 'page');  
gs_edit_page_bypath
```

```
-----  
Warning: source buffer is consistent with target buffer.  
(1 row)
```

- `gs_repair_page_bypath(src_path text, src_blkno int64, dest_path text, dest_blkno int64, storage_type text)`

Description: Transfers the path and page number of the source file, and writes the page to the specified page number of the target file. You can repair pages of the standby node through the primary node or repair the pages of the primary node through the standby node. In addition, you can initialize bad blocks in this view. In a distributed environment, this function must be executed on DNs.

- a. The target page is overwritten and synchronized to the standby node. The page-based modification object supports the U-heap and UB-tree pages. The Undo Record page, Undo Slot page, compressed table, and Astore page will be supported later. The segment-page modification object supports the Astore pages. System catalog files and data sections cannot be modified.
- b. With this function, you can overwrite target pages during the write operation. Before overwriting, the target page is backed up and flushed to a specified directory. The backup page can be rewritten back to the target page. If an ordinary table is modified on the primary node, a new WAL is generated and synchronized to the standby node. If an ordinary table is modified on the standby node, no WAL is recorded.
- c. The repair view applies only to the primary node in a centralized or distributed system or the standby node when the read function is enabled on the standby node. Only the system administrator or O&M administrator in O&M mode can use this function. All modifications will be recorded in database logs. In addition, you are advised to enable the audit logging function of system functions before using this function to record audit information.
- d. When the repair view is called on the standby node, the standby node can be repaired only by reading pages from the primary node.
- e. The LSNs of the source and target pages must be the same. Otherwise, the repair fails.

Return type: text

 **CAUTION**

Invoking this system function is a high-risk operation. Exercise caution when performing this operation.

Category	Parameter	Type	Description
Input parameter	src_path	text	Path of the source file. The following types of paths are supported: <ul style="list-style-type: none">• Data files and index files: gs_log/dump/1663_15808_25075_0.editpage.• src_path is set to 'standby' on the primary node. That is, pages are read from the standby node to repair the primary node.• src_path is set to 'primary' on the standby node. That is, pages are read from the primary node to repair the standby node. On the standby node, src_path can only be set to 'primary' and the read function must be enabled on the standby node before the repair.• src_path is set to init_block on the primary node to allow skipping bad blocks in extreme scenarios.
Input parameter	src_blkno	bigint	Physical block number of the source page. Value range: 0 to <i>MaxBlockNumber</i> .
Input parameter	dest_path	text	Relative path of the target file. For example, base/15808/25075 .
Input parameter	dest_blkno	bigint	Logical block number of the target page. Value range: 0 to <i>MaxBlockNumber</i> .
Input parameter	storage_type	text	Specifies the target file storage mode. This parameter is optional. <ul style="list-style-type: none">• 'page': page mode.• 'segment': segment-page mode.

Category	Parameter	Type	Description
Output parameter	output_msg	text	If the write overwrite operation is successful, the backup path of the target page is returned. If the write overwrite operation fails, an error message is returned. The format of the flushed file name is <i>relfilepath_blocknum_timestamp.repairpage</i> .

Transfer parameters based on the preceding table and ensure that the physical file exists. If the input parameter is abnormal or the restoration fails, an error is reported.

Example 1: Enter a file in a specified path to overwrite the target file.

```
gaussdb=# SELECT * FROM gs_repair_page_bypath('gs_log/dump/1663_15991_16767_0.editpage', 0,
'base/15991/16767', 0, 'page');
          output_msg
-----
/gs_log_dir/dump/1663_15991_16767_0_738039702421788.repairpage
(1 row)
```

Example 2: Read pages from the standby node to repair the primary node.

```
gaussdb=# SELECT * FROM gs_repair_page_bypath('standby', 0, 'base/15990/16768', 0, 'page');
          output_msg
-----
/gs_log_dir/dump/1663_15990_16768_0_738040397197907.repairpage
(1 row)
```

Example 3: Read pages from the primary node to repair the standby node.

```
gaussdb=# SELECT * FROM gs_repair_page_bypath('primary', 0, 'base/15990/16768', 0, 'page');
          output_msg
-----
/gs_log_dir/dump/1663_15990_16768_0_738040506157799.repairpage
(1 row)
```

Example 4:

```
gaussdb=# SELECT * FROM gs_repair_page_bypath('init_block', 0, 'base/15990/16768', 0, 'page');
          output_msg
-----
/gs_log_dir/dump/1663_15990_16768_0_738040768010281.repairpage
(1 row)
```

- `gs_repair_undo_byzone(zone_id int)`

Description: Transfers the ID of the undo zone to be repaired, repairs the metadata of the target undo zone, and returns the repair result details. If the undo zone is not repaired, no information is output.

Return type: record

Note: Currently, the function can be called only on the primary node. After the repair is successful, the repair will be synchronized to the standby node by recording Xlogs. The caller must be a system administrator or an O&M administrator in O&M mode. You are advised to enable the audit logging function before using the function to record audit information.

 **CAUTION**

Invoking this system function is a high-risk operation. Exercise caution when performing this operation.

Table 7-184 gs_repair_undo_byzone parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID: <ul style="list-style-type: none"> • -1: repairs the metadata of all undo zones. • 0 to 1048575: repairs the metadata of the undo zone corresponding to the zone ID.
Output parameter	zone_id	int	Undo zone ID.
Output parameter	repair_detail	text	Repair result of the undo zone metadata corresponding to the zone ID. If the repair is successful, "rebuild undo meta succeed." is displayed. If the repair fails, "rebuild undo meta failed." as well as the failure cause is displayed.

Example 1: If the undo zone meta information corresponding to the entered **zone_id** is not damaged, no output is expected.

```
gaussdb=# SELECT * FROM gs_repair_undo_byzone(4);
zone_id | repair_detail
-----+-----
(0 rows)
```

Example 2: If the undo zone metadata corresponding to the entered **zone_id** is successfully restored, the system displays a message indicating that the restoration is successful.

```
gaussdb=# SELECT * FROM gs_repair_undo_byzone(78);
zone_id | repair_detail
-----+-----
    78 | rebuild undo meta succeed.
(1 row)
```

Example 3: If the undo zone metadata corresponding to the entered zone ID fails to be repaired, the detailed information about the repair failure is displayed.

```
gaussdb=# SELECT * FROM gs_repair_undo_byzone(0);
zone_id | repair_detail
-----+-----
    0 | rebuild undo meta failed. try lock undo zone_id failed.
(1 row)
```

 NOTE

If the undo zone to be repaired is damaged and the zone ID is occupied by another active thread, calling this repair function will end the thread that occupies the zone ID and forcibly repair the damaged undo zone metadata.

- `gs_verify_urq(index_oid oid, partindex_oid oid, blocknum bigint, queue_type text)`

Description: Verifies the correctness of the index recycling queue (potential queue/available queue/single page).

Parameters: See [Table 7-185](#).

Return type: record

Table 7-185 `gs_verify_urq` parameters

Category	Parameter	Type	Description
Input parameter	<code>index_oid</code>	oid	UB-tree index OID. <ul style="list-style-type: none"> • Common index: index OID. • Global index: GPI OID. • Local index: OID of the primary index.
Input parameter	<code>partindex_oid</code>	oid	UB-Tree partitioned index OID: <ul style="list-style-type: none"> • Common index: 0. • Global index: 0. • Local index: OID of the partitioned index (primary or secondary).
Input parameter	<code>blocknum</code>	bigint	Specifies the page number: <ul style="list-style-type: none"> • If the queue type is single page, the correctness of all tuples of blocknum on a single page is verified. The value range is $[0, Queue\ file\ size/8192)$. • If the queue is empty or free, blocknum is an invalid value.
Input parameter	<code>queue_type</code>	text	Specifies the queue type: <ul style="list-style-type: none"> • empty queue: potential queue • free queue: available queue • single page: single-page queue
Output parameter	<code>error_code</code>	text	Error code
Output parameter	<code>detail</code>	text	Detailed error information and other key information.

When using the example, transfer parameters based on the parameter description and use the actual OID and **blocknum**. Otherwise, an error is reported.

Example 1:

```
gaussdb=# SELECT * FROM gs_verify_urq(16387, 0, 1, 'free queue');
error_code | detail
-----+-----
(0 rows)
```

Example 2:

```
gaussdb=# SELECT * FROM gs_verify_urq(16387, 0, 1, 'empty queue');
error_code |
detail
-----+-----
VERIFY_URQ_PAGE_ERROR | invalid urq meta: oid 16387, blkno 1, head_blkno = 1, tail_blkno = 3,
nblocks_upper = 4294967295, nblocks_lower = 1; urq_blocks = 6, index_blocks = 12
(1 row)
```

 **NOTE**

Currently, this API supports only Ustore index tables. If the verification of the index recycling queue is normal, the view does not display the error code and error details. Otherwise, the view displays the error code and error details. The error codes include "VERIFY_URQ_PAGE_ERROR", "VERIFY_URQ_LINK_ERROR", "VERIFY_URQ_HEAD_MISSED_ERROR", and "VERIFY_URQ_TAIL_MISSED_ERROR". If any of the preceding error codes is displayed, contact Huawei engineers to locate the fault.

- `gs_urq_dump_stat(index_oid oid, partindex_oid oid)`

Description: Queries information about a specified index recycling queue.

In the return result, **recentGlobalDataXmin** and **globalFrozenXid** are two oldestxmins used by the recycling queue to determine whether the index page can be recycled, **next_xid** is the XID of the next latest transaction, **urq_blocks** indicates the total number of pages in the recycling queue and information about valid pages in the free queue (available queue) and empty queue (potential queue). For PCR indexes, the output recentGlobalDataXmin is replaced by globalRecycleXid that affects the recycling of the PCR index pages.

Parameters: See [Table 7-186](#).

Table 7-186 gs_urq_dump_stat parameters

Category	Parameter	Type	Description
Input parameter	index_oid	oid	UB-tree index OID. <ul style="list-style-type: none"> • Common index: index OID. • Global index: GPI OID. • Local index: OID of the primary index.

Category	Parameter	Type	Description
Input parameter	partindex_oid	oid	UB-Tree partitioned index OID: <ul style="list-style-type: none"> • Common index: 0. • Global index: 0. • Local index: OID of the partitioned index (primary or secondary).
Output parameter	result	text	Detailed statistics about the index recycling queue.

When using the example, transfer parameters based on the parameter description and use the actual OID. Otherwise, an error is reported.

Example (RCR):

```
gaussdb=# SELECT * FROM gs_urq_dump_stat(16387, 0);
          result
-----
urq stat info: recentGlobalDataXmin = 213156, globalFrozenXid = 213156, next_xid = 214157,
urq_blocks = 6,
  free queue: head page blkno = 0 min_xid = 211187 max_xid = 214157, tail page blkno = 0
min_xid = 211187 max_xid = 214157,+
             middle page min_xid = 1152921504606846975 max_xid = 0, valid_pages = 1, valid_items =
6, can_use_item = 3
  empty queue: head page blkno = 1 min_xid = 212160 max_xid = 213160, tail page blkno = 3
min_xid = 213162 max_xid = 214156,+
             middle page min_xid = 1152921504606846975 max_xid = 0, valid_pages = 2, valid_items =
999, can_use_item = 498
(1 row)
```

Example (PCR):

```
gaussdb=# SELECT gs_urq_dump_stat(17260,0);
          gs_urq_dump_stat
-----
urq stat info: globalRecycleXid = 22113, globalFrozenXid = 22107, next_xid = 22116, urq_blocks =
6,
  free queue: head page blkno = 0 min_xid = 1152921504606846975 max_xid = 0, tail page blkno
= 0 min_xid = 1152921504606846975 max_xid = 0,+
             middle page min_xid = 1152921504606846975 max_xid = 0, valid_pages = 1, valid_items =
0, can_use_item = 0
  empty queue: head page blkno = 1 min_xid = 1152921504606846975 max_xid = 0, tail page blkno
= 1 min_xid = 1152921504606846975 max_xid = 0,+
             middle page min_xid = 1152921504606846975 max_xid = 0, valid_pages = 1, valid_items =
0, can_use_item = 0
(1 row)
```

 **NOTE**

Currently, this API supports only Ustore index tables.

- `gs_repair_urq(index_oid oid, partindex_oid oid)`

Description: Repairs (with loss) index recycling queues (potential and available queues). The recycling queue file of the current index is deleted and an empty recycling queue file is created. If the repair is successful, "reinitial the recycle queue of index relation successfully" is displayed.

Parameters: See [Table 7-187](#).

Note: The current function can be called only on the primary node.

Table 7-187 gs_repair_urq parameters

Category	Parameter	Type	Description
Input parameter	index_oid	oid	UB-tree index OID. <ul style="list-style-type: none"> Common index: index OID. Global index: GPI OID. Local index: OID of the primary index.
Input parameter	partindex_oid	oid	UB-Tree partitioned index OID: <ul style="list-style-type: none"> Common index: 0. Global index: 0. Local index: OID of the partitioned index (primary or secondary).
Output parameter	result	text	When the rebuilding is successful, "reinitial the recycle queue of index relation successfully" is displayed. Otherwise, the rebuilding fails.

When using the example, transfer parameters based on the parameter description and use the actual OID. Otherwise, an error is reported.

Example:

```
gaussdb=# SELECT * FROM gs_repair_urq(16387, 0);
          result
-----
reinitial the recycle queue of index relation successfully.
(1 row)
```

 **NOTE**

Currently, this API supports only Ustore index tables.

- gs_get_standby_bad_block_info()**
 Description: Displays the pages that have been detected on the standby node but have not been repaired. By default, only initial users, users with the sysadmin permission, users with the O&M administrator permission in the O&M mode, and users with the monitor administrator permission on the standby DN can view the information. Other users can view the information only after being granted with permissions. There are four return values in the **invalid_type** column: **NOT_PRESENT** (the page does not exist), **NOT_INITIALIZED** (the page initialization fails), **LSN_CHECK_ERROR** (the LSN check fails), and **CRC_CHECK_ERROR** (the CRC check fails).

Return type: record

Example (If no page is detected but not repaired, no line is displayed.)

```
gaussdb=# SELECT * FROM gs_get_standby_bad_block_info();
 spc_node | db_node | rel_node | bucket_node | fork_num | block_num | invalid_type |
 master_page_lsn
-----+-----+-----+-----+-----+-----+-----+-----
 1663 | 16552 | 24745 | -1 | 0 | 0 | CRC_CHECK_ERROR | 0/B2009E8
(1 rows)
```

7.6.43 Functions of the XML Type

NOTE

In all the following XML functions, when the GUC parameter **xmloption** is set to **content**, the value of **encoding** in the XML declaration can be **ZHS16GBK**. When the GUC parameter **xmloption** is set to **document**, the value of **encoding** in the XML declaration cannot be **ZHS16GBK**. If **encoding** is set to **ZHS16GBK**, an error is reported.

- `xmlparse ({ DOCUMENT | CONTENT } value [wellformed])`

Description: Generates XML values from character data.

Parameter: data of the TEXT type

Return type: XML

Example:

```
gaussdb=# SELECT XMLPARSE (DOCUMENT '<?xml version="1.0"?><book><title>Manual</title><chapter>...</chapter></book>');
xmlparse
```

```
-----
<book><title>Manual</title><chapter>...</chapter></book>
(1 row)
```

```
gaussdb=# SELECT XMLPARSE (CONTENT 'abc<foo>bar</foo><bar>foo</bar>');
xmlparse
```

```
-----
abc<foo>bar</foo><bar>foo</bar>
(1 row)
```

```
gaussdb=# SELECT XMLPARSE (CONTENT 'abc<foo>bar</foo>' wellformed);
xmlparse
```

```
-----
abc<foo>bar</foo>
(1 row)
```

- `xmlserialize({ DOCUMENT | CONTENT } value AS type)`

Description: Generates a string from an XML file.

Parameter: The data type can be character, character varying, text, or any variant of them.

Return type: XML

Example:

```
gaussdb=# SELECT xmlserialize(CONTENT 'good' AS CHAR(10));
xmlserialize
```

```
-----
good
(1 row)
```

```
gaussdb=# SELECT xmlserialize(DOCUMENT '<head>bad</head>' as text);
xmlserialize
```

```
-----
<head>bad</head>
(1 row)
```

 **NOTE**

If a string value is converted to XML without using the `xmlparse` or `xmlserialize` function, the **XML OPTION** session parameter determines the value, **DOCUMENT** or **CONTENT**. The **XML OPTION** session parameter can be set by the standard command.

```
SET XML OPTION { DOCUMENT | CONTENT };
```

Or use similar syntax to set this parameter.

```
SET xmloption TO { DOCUMENT | CONTENT };
```

- `xmlcomment(text)`

Description: Creates an XML value that contains an XML comment with the specified text as the content. The text does not contain the "--" character and does not end with a "-" character. Besides, the text should meet the format requirements of XML comments. If the parameter is empty, the result is also empty.

Parameter: data of the TEXT type

Return type: XML

Example:

```
gaussdb=# SELECT xmlcomment('hello');
xmlcomment
-----
<!--hello-->
```

- `xmlconcat(xml[, ...])`

Description: Concatenates a list of single XML values into a single value that contains an XML content fragment. Null values are ignored, and the result is null only when all parameters are null. In ORA-compatible mode, you can set **a_format_version** to **10c** and **a_format_dev_version** to **s2** to check whether the input segment is well-formed XML text.

Parameter: data of the XML type.

Return type: XML

Example 1:

```
gaussdb=# SET xmloption=content;
SET
gaussdb=# SELECT XMLCONCAT(('<?xml version="1.0" encoding="GB2312" standalone="no"?
><bar>foo</bar>'),('<?xml version="1.0" encoding="GB2312" standalone="no" ?><bar>foo</bar>'));
xmlconcat
-----
<?xml version="1.0" standalone="no"?><bar>foo</bar><bar>foo</bar>
(1 row)
gaussdb=# SELECT XMLCONCAT('abc');
xmlconcat
-----
abc>
(1 row)
```

Example 2: Syntax of the ORA-compatible database

```
gaussdb=# CREATE DATABASE gaussdb_ora DBCOMPATIBILITY='ORA';
CREATE DATABASE
gaussdb=# \c gaussdb_ora
gaussdb_ora=# SET a_format_version='10c';
SET
gaussdb_ora=# SET a_format_dev_version=s2;
SET
gaussdb_ora=# SET xmloption=content;
SET
gaussdb_ora=# SELECT XMLCONCAT(('<?xml version="1.0" encoding="GB2312" standalone="no"?
><bar>foo</bar>'),('<?xml version="1.0" encoding="GB2312" standalone="no" ?><bar>foo</bar>')); ;
```

```

xmlconcat
-----
<?xml version="1.0" standalone="no"?><bar>foo</bar><bar>foo</bar>
(1 row)

gaussdb_ora=# SELECT XMLCONCAT('abc');
ERROR:  invalid XML document
DETAIL:  line 1: Start tag expected, '<' not found
abc>
^
CONTEXT:  referenced column: xmlconcat
gaussdb_ora=# \c postgres
gaussdb=# DROP DATABASE gaussdb_ora;
DROP DATABASE

```

 **NOTE**

In ORA-compatible database, if **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**, and the **encoding** attribute in the XML declaration is set to **ZHS16GBK**, the XMLCONCAT function reports an error.

- xmlagg(xml [order_by_clause])**

Description: Concatenates the input values called by the aggregate function. Cross-line concatenation is supported. For details about **order_by_clause**, see [SELECT](#). In ORA-compatible database mode, you can set **a_format_version** to **10c** and **a_format_dev_version** to **s2**. The **xmloption** parameter of the database is set to **content** by default. When **xmloption** is set to **document**, newline characters are used to concatenate multiple XML lines. If the encoding attribute value in the XML declaration is not the default UTF-8, the aggregation result contains the XML declaration.

Parameter: XML

Return type: XML

Example 1:

```

gaussdb=# CREATE TABLE xmltest (
      id int,
      data xml
    );
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'id' as the distribution column by default.
HINT:   Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
gaussdb=# INSERT INTO xmltest VALUES (1, '<value>one</value>');
INSERT 0 1
gaussdb=# INSERT INTO xmltest VALUES (2, '<value>two</value>');
INSERT 0 1
gaussdb=# SELECT xmlagg(data) FROM xmltest;
          xmlagg
-----
<value>one</value><value>two</value>
(1 row)

```

Example 2: Syntax of the ORA-compatible database

```

gaussdb=# SET xmloption=document;
SET
gaussdb=# SELECT xmlagg(data) FROM xmltest;
          xmlagg
-----
<value>one</value>+
<value>two</value>
(1 row)
gaussdb=# DELETE FROM XMLTEST;
DELETE 2
gaussdb=# INSERT INTO xmltest VALUES (1, '<?xml version="1.0" encoding="GBK"?><value>one</value>');
INSERT 0 1
gaussdb=# INSERT INTO xmltest VALUES (2, '<?xml version="1.0" encoding="GBK"?><value>two</value>');
INSERT 0 1

```

```
value>');
INSERT 0 1
gaussdb=# SELECT xmlagg(data) FROM xmltest;
          xmlagg
-----
<?xml version="1.0" encoding="GBK"?><value>one</value>+
<value>two</value>
(1 row)
gaussdb=# SELECT xmlagg(data order by id desc) FROM xmltest;
          xmlagg
-----
<?xml version="1.0" encoding="GBK"?><value>two</value>+
<value>one</value>
(1 row)

gaussdb=# DROP TABLE xmltest;
```

- xmlelement**([ENTITYESCAPING | NOENTITYESCAPING] { [NAME] element_name | EVALNAME element_name } [, xmlattributes([ENTITYESCAPING | NOENTITYESCAPING] value [[AS] attname | AS EVALNAME attname] [, ...])] [, content [[AS] alias] [, ...]])

Description: Generates an XML element with the given name, attribute, and content.

Return type: XML

Example:

```
gaussdb=# SELECT xmlelement(name foo);
 xmlelement
-----
<foo/>

-- In ORA-compatible mode:
gaussdb=# CREATE DATABASE gaussdb_ora DBCOMPATIBILITY='ORA';
CREATE DATABASE
gaussdb=# \c gaussdb_ora
gaussdb_ora=# SET a_format_version='10c';
SET
gaussdb_ora=# SET a_format_dev_version=s2;
SET
-- If the keyword ENTITYESCAPING is not set in XMLElement by default or is set, the reserved
characters in the content of XMLElement are escaped.
gaussdb_ora=# SELECT xmlelement("entityescaping<>", 'a$<&"b');
          xmlelement
-----
<entityescaping<>>a$&gt;&lt;&lt;&amp;quot;b</entityescaping<>>
(1 row)

gaussdb_ora=# SELECT xmlelement(entityescaping "entityescaping<>", 'a$<&"b');
          xmlelement
-----
<entityescaping<>>a$&gt;&lt;&lt;&amp;quot;b</entityescaping<>>
(1 row)

-- When the keyword NOENTITYESCAPING is set in XMLElement, the reserved characters in the
content of XMLElement will not be escaped.
gaussdb_ora=# SELECT xmlelement(noentityescaping "entityescaping<>", 'a$<&"b');
          xmlelement
-----
<entityescaping<>>a$<&"b</entityescaping<>>
(1 row)

-- When [AS] alias is used to declare an alias for the content in XMLElement, the content value type
must be XML.
gaussdb_ora=# SELECT xmlelement("entityescaping<>", '<abc/>' b);
ERROR:  argument of XMLELEMENT must be type xml, not type unknown
LINE 1: SELECT xmlelement("entityescaping<>", '<abc/>' b);
```

```

      ^
CONTEXT:  referenced column: xmlelement

gaussdb_ora=# SELECT xmlelement("entityescaping<>", '<abc/>' as b);
ERROR:  argument of XMLELEMENT must be type xml, not type unknown
LINE 1: SELECT xmlelement("entityescaping<>", '<abc/>' as b);
      ^
CONTEXT:  referenced column: xmlelement

gaussdb_ora=# SELECT xmlelement("entityescaping<>", xml('<abc/>') b);
xmlelement
-----
<entityescaping<>><abc/></entityescaping<>>
(1 row)

gaussdb_ora=# SELECT xmlelement("entityescaping<>", xml('<abc/>') as b);
xmlelement
-----
<entityescaping<>><abc/></entityescaping<>>
(1 row)

-- If the keyword ENTITYESCAPING is not set in XMLAttributes by default or is set, the reserved
characters in XMLAttributes are escaped.
gaussdb_ora=# SELECT xmlelement("entityescaping<>", xmlattributes('entityescaping<>'
"entityescaping<>"));
xmlelement
-----
<entityescaping<> entityescaping<>="entityescaping&lt;&gt;"/>
(1 row)

gaussdb_ora=# SELECT xmlelement(name "entityescaping<>", xmlattributes(entityescaping
'entityescaping<>' "entityescaping<>"));
xmlelement
-----
<entityescaping<> entityescaping<>="entityescaping&lt;&gt;"/>
(1 row)

-- When the NOENTITYESCAPING keyword is set in XMLAttributes, the reserved characters in
XMLAttributes will not be escaped.
gaussdb_ora=# SELECT xmlelement("entityescaping<>", xmlattributes(noentityescaping
'entityescaping<>' "entityescaping<>"));
xmlelement
-----
<entityescaping<> entityescaping<>="entityescaping<>"/>
(1 row)

gaussdb_ora=# \c postgres
gaussdb=# DROP DATABASE gaussdb_ora;
DROP DATABASE

```

NOTE

- For **xmlelement** and **xmlattributes**, when the value of **name** is **NULL**, the database behavior is different from that of the O database. When the **name** field of **xmlelement** is set to **NULL**, the name information is empty and the attribute information is not displayed. When the **name** field of **xmlattributes** is set to **NULL**, the attribute information is not displayed.
- After the following two parameters are set, the content escape rule of **xmlelement** is ORA compatible. If the two parameters are not set, the content escape rule of **xmlelement** is PG compatible.

```

SET a_format_version='10c';
SET a_format_dev_version=52;

```
- **xmlforest**(content [AS name] [, ...])
Description: Generates an XML sequence of elements using the given name and content.
Return type: XML

Example:

```
gaussdb=# SELECT xmlforest('abc' AS foo, 123 AS bar);
xmlforest
-----
<foo>abc</foo><bar>123</bar>
```

- `xmlpi(name target [, content])`

Description: Creates an XML processing instruction. If the content is not empty, the content cannot contain character collations.

Return type: XML

Example:

```
gaussdb=# SELECT xmlpi(name php, 'echo "hello world";');
xmlpi
-----
<?php echo "hello world";?>
```

- `xmlroot(xml, version text | no value [, standalone yes|no|no value])`

Description: Modifies the attributes of the root node of an XML value. If a version is specified, it replaces the value in the version declaration of the root node. If a standalone property is specified, it replaces the value of standalone declaration in the root node.

Example:

```
gaussdb=# SELECT xmlroot('<?xml version="1.1"?><content>abc</content>',version '1.0', standalone yes);
xmlroot
-----
<?xml version="1.0" standalone="yes"?><content>abc</content>
(1 row)
```

- `xmlexists(text passing [BY REF] xml [BY REF])`

Description: Evaluates an XPath 1.0 expression (the first parameter) with the passed XML value as its context item. If the evaluation result generates an empty set of nodes, the function returns **false**. If any other value is generated, the function returns **true**. If the value of any parameter is null, the function returns **Null**. The non-null value passed as a context item must be an XML document, not a content fragment or any non-XML value.

Parameter: XML

Return type: Boolean

Example:

```
gaussdb=# SELECT xmlexists('//*[town[text() = "Toronto"]]' PASSING BY REF '<towns><town>Toronto</town><town>Ottawa</town></towns>');
xmlexists
-----
t
(1 row)
```

- `xml_is_well_formed(text)`

Description: Checks whether the text is in the correct XML format and returns a Boolean value.

Parameter: text

Return type: Boolean

Example:

```
gaussdb=# SELECT xml_is_well_formed('<>');
xml_is_well_formed
-----
f
(1 row)
```

- `xml_is_well_formed_document(text)`

Description: Checks whether the text is in the correct XML format and returns a Boolean value.

Parameter: text

Return type: Boolean

Example:

```
gaussdb=# SELECT xml_is_well_formed_document('<pg:foo xmlns:pg="http://postgresql.org/stuff">bar</pg:foo>');
xml_is_well_formed_document
-----
t
(1 row)
```
- `xml_is_well_formed_content(text)`

Description: Checks whether the text is in the correct XML format and returns a Boolean value.

Parameter: text

Return type: Boolean

Example:

```
gaussdb=# SELECT xml_is_well_formed_content('k');
xml_is_well_formed_content
-----
t
(1 row)
```
- `xpath(xpath, xml [, nsarray])`

Description: Calculates an XPath 1.0 expression, for example, `xpath` (a text value), on XML data. It returns an array of XML values corresponding to the node set generated by the XPath expression. If the XPath expression returns a scalar value rather than a node set, a single-element array is returned.

The second parameter must be a well formed XML document. It must have a single root node element.

The optional third parameter of the function is an array of namespace mappings. This array should be a two-dimensional text array with the length of the second axis being equal to 2 (that is, it should be an array of arrays, each of which consists of exactly 2 elements). The first element of each array entry is the namespace name (alias), and the second element is the namespace URI. It is not required that aliases provided in this array be the same as those being used in the XML document itself (that is, both in the XML document and in the XPath function context, aliases are local).

Return type: XML

Example:

```
gaussdb=# SELECT xpath('/my:a/text()', '<my:a xmlns:my="http://example.com">test</my:a>', ARRAY[ARRAY['my', 'http://example.com']]);
xpath
-----
{test}
(1 row)
```
- `xpath_exists(xpath, xml [, nsarray])`

Description: This function is a special form of the `xpath` function. It returns a Boolean indicating whether the query is satisfied or not (that is, whether it produces any value other than an empty node set), instead of returning the individual XML values that satisfy the XPath 1.0 expression. This function is

equivalent to the standard XMLEXISTS predicate, but it also provides support for a namespace mapping parameter.

Return type: Boolean

Example:

```
gaussdb=# SELECT xpath_exists('/my:a/text()', '<my:a xmlns:my="http://example.com">test</my:a>',ARRAY[ARRAY['my', 'http://example.com']]);
xpath_exists
-----
t
(1 row)
```

 **NOTE**

The following XML function examples show the data you need to prepare:

```
gaussdb=# CREATE SCHEMA testxmlschema;
CREATE SCHEMA
gaussdb=# CREATE TABLE testxmlschema.test1 (a int, b text);
CREATE TABLE
gaussdb=# INSERT INTO testxmlschema.test1 VALUES (1, 'one'), (2, 'two'), (-1, null);
INSERT 0 3
gaussdb=# CREATE DATABASE test;
CREATE DATABASE
```

-- After the example is executed, run the following commands to delete the preceding data:

```
gaussdb=# DROP DATABASE test;
DROP DATABASE
gaussdb=# DROP TABLE testxmlschema.test1;
DROP TABLE
gaussdb=# DROP SCHEMA testxmlschema;
DROP SCHEMA
```

- `query_to_xml(query text, nulls boolean, tableforest boolean, targetns text)`

Description: This function maps the contents of a query to an XML schema document.

Return type: XML

Example:

```
gaussdb=# SELECT query_to_xml('SELECT * FROM testxmlschema.test1', false, false, '');
query_to_xml
-----
<table xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">+
+
<row>+
<a>1</a>+
<b>one</b>+
</row>+
+
<row>+
<a>2</a>+
<b>two</b>+
</row>+
+
<row>+
<a>-1</a>+
</row>+
+
</table>+
(1 row)
```

- `query_to_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)`

Description: This function maps the contents of a query to an XML document and an XML schema document, and joins the two documents together.

Return type: XML

Example:

```
gaussdb=# SELECT query_to_xmlschema('SELECT * FROM testxmlschema.test1', false, false, '');
               query_to_xmlschema
```

```
-----
<xsd:schema                                     +
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  +
  <xsd:simpleType name="INTEGER">               +
    <xsd:restriction base="xsd:int">           +
      <xsd:maxInclusive value="2147483647"/>   +
      <xsd:minInclusive value="-2147483648"/>  +
    </xsd:restriction>                         +
  </xsd:simpleType>                             +
  +
  <xsd:simpleType name="UDT.regression.pg_catalog.text"> +
    <xsd:restriction base="xsd:string">       +
      </xsd:restriction>                       +
  </xsd:simpleType>                             +
  +
  <xsd:complexType name="RowType">             +
    <xsd:sequence>                             +
      <xsd:element name="a" type="INTEGER" minOccurs="0"></xsd:element> +
      <xsd:element name="b" type="UDT.regression.pg_catalog.text" minOccurs="0"></xsd:element>+
    </xsd:sequence>                             +
  </xsd:complexType>                           +
  +
  <xsd:complexType name="TableType">           +
    <xsd:sequence>                             +
      <xsd:element name="row" type="RowType" minOccurs="0" maxOccurs="unbounded"/> +
    </xsd:sequence>                             +
  </xsd:complexType>                           +
  +
  <xsd:element name="table" type="TableType"/> +
  +
</xsd:schema>
(1 row)
```

- query_to_xml_and_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)

Description: This function maps the contents of a query to an XML document and an XML schema document, and joins the two documents together.

Return type: XML

Example:

```
gaussdb=# SELECT query_to_xml_and_xmlschema('SELECT * FROM testxmlschema.test1', true, true, '');
               query_to_xml_and_xmlschema
```

```
-----
<xsd:schema                                     +
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  +
  <xsd:simpleType name="INTEGER">               +
    <xsd:restriction base="xsd:int">           +
      <xsd:maxInclusive value="2147483647"/>   +

(1 row)

```

- `cursor_to_xml(cursor refcursor, count int, nulls boolean, tableforest boolean, targetns text)`

Description: This function maps the contents of a cursor to an XML document.

Return type: XML

Example:

```

gaussdb=# CURSOR xc WITH HOLD FOR SELECT * FROM testxmlschema.test1 ORDER BY 1, 2;
DECLARE CURSOR
gaussdb=# SELECT cursor_to_xml('xc':refcursor, 5, false, true, '');
           cursor_to_xml

```

```

-----
<row xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">+
  <a>-1</a>          +
</row>             +
  <row xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">+
  <a>1</a>          +
  <b>one</b>        +
</row>             +
  <row xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">+
  <a>2</a>          +
  <b>two</b>        +
</row>             +
(1 row)

```

- `cursor_to_xmlschema(cursor refcursor, nulls boolean, tableforest boolean, targetns text)`

Description: This function maps the contents of a cursor to an XML schema document.

Return type: XML

Example:

```

gaussdb=# SELECT cursor_to_xmlschema('xc':refcursor, true, false, '');
           cursor_to_xmlschema

```

```

<xsd:schema                                +

  <a>2</a>                                             +
  <b>two</b>                                           +
</row>                                               +
                                                    +
<row>                                                 +
  <a>-1</a>                                            +
</row>                                               +
                                                    +
</test1>                                             +
(1 row)

```

 **NOTE**

- For XPath-related functions, only XPath() and XPath_exists() are supported. These functions use the XPath language to query XML files and depend on the Libxml2 library, which is provided only in XPath1.0. Therefore, only XPath 1.0 is supported.
- The XQuery, XML extension, and XSLT functions are not supported.
- getclobval(xml)

Description: Converts an XML type to a CLOB type. This function is valid only when parameters **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s4**.

Parameter: The input parameter is of the XML type.

Return type: CLOB

Example:

```

gaussdb=# CREATE DATABASE gaussdb_ora DBCOMPATIBILITY='ORA';
CREATE DATABASE
gaussdb=# \c gaussdb_ora
gaussdb_ora=# SET a_format_version='10c';
SET
gaussdb_ora=# SET a_format_dev_version='s4';
SET
gaussdb_ora=# declare
xmldata xml;
result clob;
begin
xmldata := '<a>123</a>';
result := getclobval(xmldata);
RAISE NOTICE 'result is : %',result;
END;
/
NOTICE: result is : <a>123</a>
gaussdb_ora=# SELECT getclobval(xmlparse(document '<a>123</a>'));
getclobval
-----
<a>123</a>

```

```
(1 row)

gaussdb_ora=# \c postgres
gaussdb=# DROP DATABASE gaussdb_ora;
DROP DATABASE
```

- **getstringval(xml)**

Description: Converts an XML type to a string. This function is valid only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s4**.

Parameter: The input parameter is of the XML type.

Return type: VARCHAR2

Example:

```
gaussdb=# CREATE DATABASE gaussdb_ora DBCOMPATIBILITY='ORA';
CREATE DATABASE
gaussdb=# \c gaussdb_ora
gaussdb_ora=# SET a_format_version='10c';
SET
gaussdb_ora=# SET a_format_dev_version='s4';
SET
gaussdb_ora=# declare
xmldata xml;
result varchar2;
begin
xmldata := '<a>123<b>456</b></a>';
result := getstringval(xmldata);
RAISE NOTICE 'result is : %',result;
END;
/
NOTICE: result is : <a>123<b>456</b></a>
gaussdb_ora=# select getstringval(xmlparse(document '<a>123<b>456</b></a>'));
getstringval
-----
<a>123<b>456</b></a>
(1 row)

gaussdb_ora=# \c postgres
gaussdb=# DROP DATABASE gaussdb_ora;
DROP DATABASE
```

- **xmlsequence(xml)**

Description: Converts an XML parameter into an array of the XMLTYPE type. Each array element is an XMLTYPE object. The input parameter of this function cannot be null and must be a valid XML document. If the input parameter does not meet the requirements, the function returns a null value or throws an exception. This function can be used to process multiple child nodes in an XML document or split an XML document into multiple fragments.

Parameter: XML

Return type: Array of the XMLType type.

Example: If you want to convert this document into an array containing three elements, each of which is a book node, use the following statement:

```
gaussdb=# SELECT xmlsequence(xml('<books><book><title>The Catcher in the Rye</title><author>J.D. Salinger</author><year>1951</year></book><book><title>1984</title><author>George Orwell</author><year>1949</year></book><book><title>The Hitchhiker's Guide to the Galaxy</title><author>Douglas Adams</author><year>1979</year></book></books>'));
xmlsequence
-----
{"<books>                                +
  <book>                                  +
    <title>The Catcher in the Rye</title>  +
    <author>J.D. Salinger</author>        +
    <year>1951</year>                     +
```

```

</book>                +
<book>                  +
  <title>1984</title>    +
  <author>George Orwell</author>  +
  <year>1949</year>      +
</book>                +
<book>                  +
  <title>The Hitchhiker's Guide to the Galaxy</title>+
  <author>Douglas Adams</author>  +
  <year>1979</year>      +
</book>                +
</books>"}
(1 row)

```

 **NOTE**

If an XML file contains double quotation marks, the result of the `xmlsequence` function contains escape characters of double quotation marks when you query the result of the `xmlsequence` function independently. The use of the `xmlsequence` function is not affected.

7.6.44 Functions of the XMLType Type

- `createxml(varchar2[,varchar2,numeric,numeric])`

Description: Statically creates the XMLType type. The input parameters are of the `varchar2` type.

Parameters: The first parameter is the character string to be converted to XMLType (mandatory column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

Example:

```

gaussdb=# SELECT createxml('<a>123</a>');
createxml
-----
<a>123</a>
(1 row)

```

 NOTE

- Different from that in database A, in PL/SQL, createxml allows input parameters to be empty strings and returns **NULL**.
- For character encoding, only UTF-8, GBK, ZHS16GBK, and LATIN1 to LATIN10 are supported, and the **version** column can only be set to **1.x**.
- The createxml function can be invoked using the xmltype.createxml() syntax.

Example:

```
gaussdb=# SELECT xmltype.createxml('<a>123</a>');
createxml
-----
<a>123</a>
(1 row)
```

- In this chapter, the function whose input parameter is xmltype() can be invoked in xmltype().func() mode. The XMLType type returned by a function is transferred to the next function as the input parameter. This syntax supports multi-layer nesting. (If the input parameter is defined as XMLType by a user, this syntax is not supported.)

Example:

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').extract('/a/b').getstringval();
xmltypefunc
-----
<b>456</b>
(1 row)
```

The actual effect of the preceding example is the same as that of the following function nesting:

```
gaussdb=# SELECT getstringval(extractxml(xmltype('<a>123<b>456</b></a>'),'a/b'));
getstringval
-----
<b>456</b>
(1 row)
```

- In a stored procedure, variables of the XMLType type can invoke functions in a.func() mode. This syntax supports one-layer nesting.

Example:

```
gaussdb=# declare
a xmltype;
b varchar2;
begin
a:=xmltype('<a>123<b>456</b></a>');
b:=a.getstringval();
RAISE NOTICE 'xmltype_str is : %',b;
end;
/
NOTICE: xmltype_str is : <a>123<b>456</b></a>
```

- createxml(clob [,varchar2,numeric ,numeric])

Description: Statically creates the XMLType type. The input parameters are of the CLOB type.

Parameters: The first parameter is the CLOB to be converted to XMLType (mandatory column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

Example:

```
gaussdb=# declare
xmltype_clob clob;
xmltype_obj xmltype;
xmltype_str varchar2(1000);
begin
xmltype_clob := '<a>123</a>';
xmltype_obj := createxml(xmltype_clob);
xmltype_str := xmltype_obj.getstringval();
RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE: xmltype_str is : <a>123</a>
```

 **NOTE**

The maximum size of the input parameter of the CLOB type is 1 GB minus 1 byte.

- `createxml(blob,numeric[,varchar2,numeric,numeric])`

Description: Statically creates the XMLType type. The input parameters are of the BLOB type.

Parameters: The first parameter is the BLOB to be converted to XMLType (mandatory column). The second parameter is the character set ID of the input XML data (mandatory column). The third parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fifth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

Example:

```
gaussdb=# declare
xmltype_blob blob;
xmltype_obj xmltype;
xmltype_str varchar2(1000);
begin
xmltype_blob := xmltype('<a>123</a>').getblobval(7);
xmltype_obj := createxml(xmltype_blob,7);
xmltype_str := xmltype_obj.getstringval();
RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE: xmltype_str is : <?xml version="1.0" encoding="UTF8"?>
<a>123</a>
```

 **NOTE**

- The maximum size of input parameters of the BLOB type is 256 MB minus 1 byte.
- The character set ID ranges from 1 to 43.
- `getblobval(xmltype,numeric)`

Description: Converts the XMLType type to the BLOB type. The `xmltype().func()` method can be invoked.

Parameters: The first parameter is of the XMLType type, and the second parameter is the ID of the target character set to be converted.

Return type: BLOB

Example:

```
gaussdb=# SELECT getblobval(xmltype('<asd/>'),7);
          getblobval
-----
3C3F786D6C2076657273696F6E3D22312E302220656E636F64696E673D2255544638223F3E0A3C6173
642F3E
(1 row)
```

xmltype ().func ():

```
gaussdb=# SELECT xmltype('<asd/>').getblobVal(7);
          xmltypefunc
-----
3C3F786D6C2076657273696F6E3D22312E302220656E636F64696E673D2255544638223F3E0A3C6173
642F3E
(1 row)
```

 **NOTE**

The maximum length of the input parameter of the XMLType type is 256 MB minus 1 byte.

- **getclobval(xmltype)**

Description: Converts the XMLType type to the CLOB type. The xmltype().func() method can be invoked.

Parameter: The input parameter is of the XMLType type.

Return type: CLOB

Example:

```
gaussdb=# SELECT getclobval(xmltype('<a>123</a>'));
          getclobval
-----
<a>123</a>
(1 row)
```

xmltype ().func ():

```
gaussdb=# SELECT xmltype('<a>123</a>').getclobval();
          xmltypefunc
-----
<a>123</a>
(1 row)
```

- **getnumberval(xmltype)**

Description: Converts the XMLType type to the numeric type. The xmltype().func() method can be invoked.

Parameter: The input parameter is of the XMLType type.

Return type: numeric

Example:

```
gaussdb=# SELECT getnumberval(xmltype('<a>123</a>').extract('/a/text()'));
          getnumberval
-----
123
(1 row)
```

xmltype ().func ():

```
gaussdb=# SELECT xmltype('<a>123</a>').extract('/a/text()').getnumberval();
          xmltypefunc
-----
123
(1 row)
```

- **isfragment(xmltype)**

Description: Returns a result indicating whether the XMLType type is fragment (1) or document (0). The xmltype().func() method can be invoked.

Parameter: The input parameter is of the XMLType type.

Return type: numeric

Example:

```
gaussdb=# SELECT isfragment(xmltype('<a>123</a>'));
isfragment
-----
         0
(1 row)
```

xmltype ().func ():

```
gaussdb=# SELECT xmltype('<a>123</a>').isfragment();
xmltypefunc
-----
         0
(1 row)
```

- xmltype(varchar2[,varchar2,numeric,numeric])

Description: Creates the XMLType type from the varchar2 type.

Parameters: The first parameter is the character string to be converted to XMLType (mandatory column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

Example:

```
gaussdb=# SELECT xmltype('<a>123</a>');
xmltype
-----
<a>123</a>
(1 row)
```

NOTE

- Different from that in database A, in PL/SQL, XMLType allows input parameters to be empty strings and returns **NULL**.
- For character encoding, only UTF-8, GBK, ZHS16GBK, and LATIN1 to LATIN10 are supported, and the **version** column can only be set to **1.x**.
- xmltype(clob[,varchar2,numeric,numeric])

Description: Creates the XMLType type from the CLOB type.

Parameters: The first parameter is the CLOB to be converted to XMLType (mandatory column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

Example:

```
gaussdb=# declare
xmltype_clob clob;
```

```
xmltype_obj xmltype;
xmltype_str varchar2(1000);
begin
xmltype_clob := '<a>123</a>';
xmltype_obj := xmltype(xmltype_clob);
xmltype_str := xmltype_obj.getstringval();
RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE: xmltype_str is : <a>123</a>
```

NOTE

The maximum size of the input parameter of the CLOB type is 1 GB minus 1 byte.

- `xmltype(blob, numeric [,varchar2,numeric ,numeric])`

Description: Creates the XMLType type from the BLOB type.

Parameters: The first parameter is the BLOB to be converted to XMLType (mandatory column). The second parameter is the character set ID of the input XML data. The third parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fifth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

Example:

```
gaussdb=# declare
xmltype_blob blob;
xmltype_obj xmltype;
xmltype_str varchar2(1000);
begin
xmltype_blob := getblobval(createxml('<a>123</a>'),7);
xmltype_obj := xmltype(xmltype_blob,7);
xmltype_str := xmltype_obj.getstringval();
RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE: xmltype_str is : <?xml version="1.0" encoding="UTF8"?>
<a>123</a>
```

NOTE

- The maximum size of input parameters of the BLOB type is 256 MB minus 1 byte.
- The character set ID ranges from 1 to 42.
- `getstringval(xmltype)`

Description: Converts the XMLType to a string.

Parameter: XMLType to be converted.

Return type: varchar2

The `getstringval` function can be invoked in either of the following ways:

Example 1:

```
gaussdb=# SELECT getstringval('<a>123<b>456</b></a>');
getstringval
-----
<a>123<b>456</b></a>
(1 row)
```

Example 2: The invoking mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').getstringval();
xmltypefunc
-----
<a>123<b>456</b></a>
(1 row)
```

- **getrootelement(xmltype)**

Description: Gets the root element of the XMLType type.

Parameter: XMLType whose root element is to be obtained.

Return type: varchar2

The getrootelement function can be invoked in either of the following ways:

Example 1:

```
gaussdb=# SELECT getrootelement('<a>123<b>456</b></a>');
getrootelement
-----
a
(1 row)
```

Example 2: The invoking mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').getrootelement();
xmltypefunc
-----
a
(1 row)
```

- **getnamespace(xmltype)**

Description: Gets the namespace of the XMLType top-level element.

Parameter: XMLType whose namespace is to be obtained.

Return type: varchar2

The getnamespace function can be invoked in either of the following ways:

Example 1:

```
gaussdb=# SELECT getnamespace('<c:a xmlns:c="asd">123<d:b xmlns:d="qwe">456</d:b></c:a>');
getnamespace
-----
asd
(1 row)
```

Example 2: The invoking mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<c:a xmlns:c="asd">123<d:b xmlns:d="qwe">456</d:b></c:a>').getnamespace();
xmltypefunc
-----
asd
(1 row)
```

- **existsnode(xmltype, varchar2[, varchar2])**

Description: Determines whether the XML node exists in XMLType based on the XPath expression. If the XML node exists, **1** is returned. Otherwise, **0** is returned.

Parameters: XMLType to be queried, path of the XPath node to be queried, and namespace of the XPath path (If the input parameter has a namespace, aliases must be defined for both the XPath and namespace, as shown in example 3.)

Return type: numeric

The existsnode function can be invoked in either of the following ways:

Example 1:

```
gaussdb=# SELECT existsnode('<a>123<b>456</b></a>', '/a/b');
existsnode
-----
          1
(1 row)
```

Example 2: The invoking mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').existsnode('/a/b');
xmltypefunc
-----
          1
(1 row)
```

Example 3:

```
gaussdb=# SELECT existsnode('<a:b xmlns:a="asd">123<c>456</c></a:b>', '/a:b/c', 'xmlns:a="asd"');
existsnode
-----
          1
(1 row)
```

Example 4: The invoking mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a:b xmlns:a="asd">123<c>456</c></a:b>').existsnode('/a:b/c', 'xmlns:a="asd"');
xmltypefunc
-----
          1
(1 row)
```

- `extractxml(xmltype, varchar2[, varchar2])`

Description: Checks whether an XML node exists in the given XMLType based on the XPath expression. If yes, the XMLType containing the node is returned. If no, **NULL** is returned. The return value can be inserted into a table of the XMLType type.

Parameters: XMLType to be queried, path of the XPath node to be queried, and namespace of the XPath path (If the input parameter has a namespace, aliases must be defined for both the XPath and namespace, as shown in example 3.)

Return type: XMLType

The `extractxml` function can be invoked in either of the following ways:

Example 1:

```
gaussdb=# SELECT extractxml('<a>123<b>456</b></a>', '/a/b');
extractxml
-----
<b>456</b>
(1 row)
```

Example 2: The invoking mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').extract('/a/b');
xmltypefunc
-----
<b>456</b>
(1 row)
```

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').extractxml('/a/b');
xmltypefunc
-----
<b>456</b>
(1 row)
```

Example 3:

```
gaussdb=# SELECT extractxml('<a:b xmlns:a="asd">123<c>456</c></a:b>', '/a:b', 'xmlns:a="asd"');
extractxml
-----
```

```
<a:b xmlns:a="asd">123<c>456</c></a:b>
(1 row)
```

Example 4: The invoking mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a:b xmlns:a="asd">123<c>456</c></a:b>').extract('/a:b','xmlns:a="asd"');
xmltypefunc
```

```
-----
<a:b xmlns:a="asd">123<c>456</c></a:b>
(1 row)
```

```
gaussdb=# SELECT xmltype('<a:b xmlns:a="asd">123<c>456</c></a:b>').extractxml('/
a:b','xmlns:a="asd"');
xmltypefunc
```

```
-----
<a:b xmlns:a="asd">123<c>456</c></a:b>
(1 row)
```

- `extractvalue(xmltype | xml, varchar2[, varchar2])`

Description: Extracts the value of an XPath expression from an XML file based on the XPath expression (only XPath 1.0 is supported). The result of the XPath expression must be a single node and must be a text node, attribute, or element. If the XPath expression contains an element expression, the element must have a text node as a child node. The function returns the text. If the result is an attribute, the function returns the value of the attribute.

Parameters: **xmltype | xml**: XML text to be queried; **varchar2**: XPath expression to be queried (XPath node path); **[, varchar2]** (optional): Namespace of the XPath node path. (If the input parameter contains a namespace with an alias, you need to define an alias for both the XPath expression and namespace. If the default namespace is used, you do not need to define an alias, as shown in example 3.)

Return type: `varchar2`

The `extractvalue` function can be invoked in two ways: input without namespace and input with namespace.

Example 1: The input does not contain a namespace.

```
gaussdb=# SELECT EXTRACTVALUE(xmltype('<book><title>Harry Potter</title><author>J.K. Rowling</
author></book>'), '/book/title') AS book_title;
book_title
```

```
-----
Harry Potter
(1 row)
```

Example 2: The input contains a namespace.

```
gaussdb=# SELECT EXTRACTVALUE(xmltype('<ns:book xmlns:ns="http://
www.example.com"><ns:title>Harry Potter</ns:title><ns:author>J.K. Rowling</ns:author></ns:book>'),
'/ns:book/ns:title', 'xmlns:ns="http://www.example.com"') AS book_title;
book_title
```

```
-----
Harry Potter
(1 row)
```

Example 3: The input contains multiple namespaces.

```
gaussdb=# SELECT EXTRACTVALUE(xmltype('<ns:book xmlns:ns="http://www.example.com"
xmlns:ff="http://www.ff.com"><ff:title>Harry Potter</ff:title><ns:author>J.K. Rowling</ns:author></
ns:book>'), '/ns:book/ff:title', 'xmlns:ns="http://www.example.com" xmlns:ff="http://www.ff.com"') AS
book_title;
book_title
```

```
-----
Harry Potter
(1 row)
```

```
gaussdb=# SELECT EXTRACTVALUE(xmltype('<store><book xmlns="abc"><root xmlns="abcd">mike</
root><root>mikeab</root></book><root xmlns="abcd">mikedwsa</root></store>'),
'//root', 'xmlns="abc" xmlns:ns2="abc1" xmlns="abcd"') FROM dual;
```

```
extractvalue
-----
mikeab
(1 row)
```

 **NOTE**

- If the input contains multiple namespaces, they can be separated by one or more spaces (or newline characters). However, the namespace expression is in the `xmlns:Name="Namespace"` format and the default namespace rule is in the `xmlns='URL'` format.
- This function is compatible with the `xmltype` expression function, but the node value returned by the `xmltype` text must be unique.
- The XPath expression supports only XPath 1.0.
- Currently, the namespace URL in the XML text cannot be a space, and the namespace URL in the namespace expression cannot be a space.
- In the default namespace scenario, the default namespace declared first in the namespace expression is the default namespace of the current XML text.

• `xmlsequence(xmltype)`

Description: Converts an XMLTYPE parameter into an array of the XMLTYPE type. Each array element is an XMLTYPE object. The input parameter of this function cannot be null and must be a valid XML document. If the input parameter does not meet the requirements, the function returns a null value or throws an exception. This function can be used to process multiple child nodes in an XML document or split an XML document into multiple fragments.

Parameter: The input parameter is of the XMLType type.

Return value type: array of the XMLType type

Example 1: If you want to convert this document into an array containing three elements, each of which is a book node, use the following statement:

```
gaussdb=# SELECT xmlsequence(xmltype('<books><book><title>The Catcher in the Rye</title><author>J.D. Salinger</author><year>1951</year></book><book><title>1984</title><author>George Orwell</author><year>1949</year></book><book><title>The Hitchhiker's Guide to the Galaxy</title><author>Douglas Adams</author><year>1979</year></book></books>'));
xmlsequence
```

```
{"<books>
  <book>
    <title>The Catcher in the Rye</title>
    <author>J.D. Salinger</author>
    <year>1951</year>
  </book>
  <book>
    <title>1984</title>
    <author>George Orwell</author>
    <year>1949</year>
  </book>
  <book>
    <title>The Hitchhiker's Guide to the Galaxy</title>
    <author>Douglas Adams</author>
    <year>1979</year>
  </book>
</books>"}
(1 row)
```

Example 2: If you want to extract the title and author of each book from this array, use the following statement:

```
gaussdb=# SELECT unnest(xmlsequence(xmltype('<books><book><title>The Catcher in the Rye</title><author>J.D. Salinger</author><year>1951</year></book><book><title>1984</title><author>George Orwell</author><year>1949</year></book><book><title>The Hitchhiker's Guide to the Galaxy</title><author>Douglas Adams</author><year>1979</year></book></books>'))
```

```
books>').extract('//title/text()')) AS title
, unnest(xmlsequence(xmltype('<books><book><title>The Catcher in the Rye</title><author>J.D.
Salinger</author><year>1951</year></book><book><title>1984</title><author>George Orwell</
author><year>1949</year></book><book><title>The Hitchhiker's Guide to the Galaxy</
title><author>Douglas Adams</author><year>1979</year></book></books>').extract('//author/
text()')) AS author;
-----+-----
title | author
-----+-----
The Catcher in the Rye1984The Hitchhiker's Guide to the Galaxy | J.D. SalingerGeorge OrwellDouglas
Adams
(1 row)
```

Example 3: If you want to convert the array into a JSON string, use the following statement:

```
gaussdb=# SELECT array_to_json(array_agg(row_to_json(t)))
FROM (
SELECT unnest(xmlsequence(xmltype('<books><book><title>The Catcher in the Rye</
title><author>J.D. Salinger</author><year>1951</year></book><book><title>1984</
title><author>George Orwell</author><year>1949</year></book><book><title>The Hitchhiker's
Guide to the Galaxy</title><author>Douglas Adams</author><year>1979</year></book></
books>').extract('//title/text()')) AS title
, unnest(xmlsequence(xmltype('<books><book><title>The Catcher in the Rye</title><author>J.D.
Salinger</author><year>1951</year></book><book><title>1984</title><author>George Orwell</
author><year>1949</year></book><book><title>The Hitchhiker's Guide to the Galaxy</
title><author>Douglas Adams</author><year>1979</year></book></books>').extract('//author/
text()')) AS author
) t;
-----+-----
array_to_json
-----+-----
[{"title":"The Catcher in the Rye1984The Hitchhiker's Guide to the Galaxy","author":"J.D.
SalingerGeorge OrwellDouglas Adams"}]
(1 row)
```

NOTE

If an XML file contains double quotation marks, the result of the `xmlsequence` function contains escape characters of double quotation marks when you query the `xmlsequence` function independently. The use of the `xmlsequence` function is not affected.

7.6.45 Pivot Table Functions

- `tablefunc()`

Description: Extended API for processing table data, including pivot table functions. Only the system administrator can install extensions.

NOTE

By default, the extension is installed in the public schema. You are advised to install the extension in the user schema by running `create extension tablefunc [schema {user_schema}]`. The extended function is for internal use only. You are advised not to use it.

- `crosstab(source_sql text [, N int])`

Description: Uses the result of `source_sql` as the source data to generate a pivot table.

Return type: setof record

Example:

```
gaussdb=# CREATE extension tablefunc;
CREATE EXTENSION
gaussdb=# CREATE TABLE cross_test(group_id text, id int, var text);
CREATE TABLE
gaussdb=# SELECT * FROM cross_test;
group_id | id | var
```

```

-----+-----+-----
(0 rows)

gaussdb=# SELECT * FROM crosstab('SELECT group_id, var FROM cross_test order by 1, 2;') AS
c(group_ text, cat1 text, cat2 text, cat3 text);
 group_ | cat1 | cat2 | cat3
-----+-----+-----+-----
(0 rows)

```

 **NOTE**

N is a deprecated parameter and does not affect the function result.

- **crosstabN(source_sql text)**

Description: Uses the result of **source_sql** as the source data to generate a pivot table with "**N**+1" columns. **crosstabN** is a group of functions, including **crosstab2**, **crosstab3**, and **crosstab4**.

Return type: setof tablefunc_crosstab_N. tablefunc_crosstab_N includes tablefunc_crosstab_2, tablefunc_crosstab_3, and tablefunc_crosstab_4.

Example:

```

-- If N in crosstabN(source_sql text) is set to 2, a pivot table with three columns is generated.
gaussdb=# CREATE extension tablefunc;
CREATE EXTENSION
gaussdb=# CREATE TABLE cross_test(group_id text, id int, var text);
CREATE TABLE
gaussdb=# SELECT * FROM crosstab2('SELECT group_id, var FROM cross_test ORDER BY 1, 2;')
 row_name | category_1 | category_2
-----+-----+-----
(0 rows)

```

- **crosstab(source_sql text, category_sql text)**

Description: Uses the result of **source_sql** as the source data to generate a pivot table based on the result category of **category_sql**.

Return type: setof record

Example:

```

gaussdb=# CREATE extension tablefunc;
CREATE EXTENSION
gaussdb=# CREATE TABLE cross_test(group_id text, id int, var text);
CREATE TABLE
gaussdb=# SELECT * FROM crosstab('SELECT group_id, var FROM cross_test order by 1, 2;', 'SELECT
generate_series(1, 4)') AS c(group_ text, cat1 text, cat2 text, cat3 text, cat4 text);
 group_ | cat1 | cat2 | cat3 | cat4
-----+-----+-----+-----+-----
(0 rows)

```

7.6.46 UUID Functions

- **sys_guid()**

Description: Generates and returns a 16-byte **universally unique identifier (UUID)**. The generated UUID contains the IP address of the current node, generation timestamp, and random number.

Parameter: none

Return type: raw

Example:

```

gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s5';
SET
gaussdb=# SELECT sys_guid();

```

```
sys_guid
-----
9010675E560CB33C1BDFAFA163E378F87
(1 row)
```

- `uuid()`

Description: Returns a UUID defined in RFC 4122, ISO/IEF 9834-8:2005, and related standards. The identifier is a string of lowercase hexadecimal digits, which are divided into several groups: a group of 8 digits, three groups of 4 digits, and a group of 12 digits. A total of 32 digits represent 128 bits.

Parameter: none

Return type: varchar

Example:

```
gaussdb=# SELECT uuid();
         uuid
-----
dd8cbe92-1a25-013c-a514-e435c87e9182
(1 row)
```

- `uuid_short()`

Description: Returns a short UUID under certain conditions. This identifier is a 64-bit unsigned integer.

The returned value is unique when the following conditions are met:

- The number of service nodes in the current cluster cannot exceed 256.
- You cannot set the system time of the server host between node restarts.
- The average number of `uuid_short()` calls per second between node restarts is less than 16 million.

Parameter: none

Return type: uint64

Example:

```
gaussdb=# SELECT uuid_short();
         uuid_short
-----
100440026956955649
(1 row)
```

 **NOTE**

For upgrade from a version to GaussDB Kernel 505.0.0, the `uuid_short()` function cannot be used if the upgrade is not committed.

7.6.47 SQL Statement Concurrency Control Function

- `gs_add_workload_rule(rule_type, rule_name, databases, start_time, end_time, max_workload, option_val)`

Description: Creates an SQL statement concurrency control rule. Users must have the `sysadmin` permission. This function can be executed only on the CN.

Parameters: For details, see [Table 7-188](#).

Return type: int8

Table 7-188 gs_add_workload_rule parameters

Parameter	Type	Description	Value Range
rule_type	text	Type of the concurrency control rule, which is case insensitive.	"sqlid": Concurrency control is based on the unique SQL ID. "select", "insert", "update", "delete", and "merge": Concurrency control is based on the query type and keyword. "resource": Instance-level concurrency control is based on the system resource usage.
rule_name	name	Name of a concurrency control rule, which is used to search for the concurrency control rule.	Any character string or NULL .
databases	name[]	Array of database names for which the concurrency control rule takes effect. The value is case-sensitive.	List of names of created databases. The value can be NULL , indicating that the configuration takes effect in all databases. Currently, the database list takes effect only when rule_type is set to a query type because a unique SQL ID is bound to a database and belongs to only one database. The concurrency control rules based on resource usage take effect for instances, that is, all databases.
start_time	timestampz	Start time of a concurrency control rule.	The value can be NULL , indicating that it takes effect from now on.
end_time	timestampz	End time of a concurrency control rule.	The value can be NULL , indicating that the rule is always effective.
max_workload	int8	Maximum number of concurrent requests set in a concurrency control rule.	-

Parameter	Type	Description	Value Range
option_val	text[]	Supplementary information about the concurrency control rule.	<p>It matches rule_type. The matching relationship is as follows:</p> <ul style="list-style-type: none"> • "sqlid": specifies the unique ID of the SQL statement whose concurrency is to be controlled and slow SQL control rule. The format is '{id=1234, time_limit=100, max_execute_time=500, max_iops=1}', in which id indicates the unique SQL ID and is mandatory. You can obtain it from the <code>dbe_perf.statement</code> or <code>pg_stat_activity</code> view. Others are optional. For details about their meanings, see section "Hint for Setting Slow SQL Control Rules." • "select", "insert", "update", "delete", and "merge": keyword sequence for concurrency control, which is case insensitive and can be NULL. • "resource": resource threshold for traffic limiting. The format is '{cpu-80, memory-70}'. No matter what the CPU and memory thresholds are set, the value 0 is used.

Example:

```

gaussdb=# SELECT gs_add_workload_rule('sqlid', 'rule for one query', '{}', now(), NULL, 20,
'{id=32413214}');
gs_add_workload_rule
-----
1
(1 row)
gaussdb=# CREATE database db1;
gaussdb=# CREATE database db2;
gaussdb=# SELECT gs_add_workload_rule('select', 'rule for select', '{db1, db2}', NULL, NULL, 100,
'{tb1, tb2}');
gs_add_workload_rule
-----
2
(1 row)
gaussdb=# SELECT gs_add_workload_rule('resource', 'rule for resource', '{}', NULL, NULL, 20,
'{cpu-80}');

```

```
gs_add_workload_rule
```

```
-----  
3  
(1 row)
```

- `gs_update_workload_rule(rule_id, rule_name, databases, start_time, end_time, max_workload, option_val)`

Description: To update an SQL statement concurrency control rule, users need to reset all parameters instead of only some parameters. Users must have the `sysadmin` permission. This function can be executed only on the CN.

Parameters: For details, see [Table 7-189](#).

Return type: Boolean

Table 7-189 `gs_update_workload_rule` parameters

Parameter	Type	Description	Value Range
<code>rule_id</code>	<code>int8</code>	ID of the concurrency control rule to be updated.	-
<code>rule_name</code>	<code>name</code>	Name of a concurrency control rule, which is used to search for the concurrency control rule.	Any character string or NULL .
<code>databases</code>	<code>name[]</code>	Array of database names for which the concurrency control rule takes effect. The value is case sensitive.	List of names of created databases. The value can be NULL , indicating that the configuration takes effect in all databases. Currently, the database list takes effect only when rule_type is set to a query type because a unique SQL ID is bound to a database and belongs to only one database. The concurrency control rules based on resource usage take effect for instances, that is, all databases.
<code>start_time</code>	<code>timestamptz</code>	Start time of a concurrency control rule.	The value can be NULL , indicating that it takes effect from now on.
<code>end_time</code>	<code>timestamptz</code>	End time of a concurrency control rule.	The value can be NULL , indicating that the rule is always effective.

Parameter	Type	Description	Value Range
max_workload	int8	Maximum number of concurrent requests set in a concurrency control rule.	-
option_val	text[]	Supplementary information about the concurrency control rule.	<p>It matches rule_type. The matching relationship is as follows:</p> <ul style="list-style-type: none"> • "sqlid": specifies the unique ID of the SQL statement whose concurrency is to be controlled and slow SQL control rule. The format is '{id=1234, time_limit=100, max_execute_time=500, max_iops=1}', in which id indicates the unique SQL ID and is mandatory. You can obtain it from the <code>dbe_perf.statement</code> or <code>pg_stat_activity</code> view. Others are optional. For details about their meanings, see section "Hint for Setting Slow SQL Control Rules." • "select", "insert", "update", "delete", and "merge": keyword sequence for concurrency control, which is case insensitive and can be NULL. • "resource": resource threshold for triggering instance-level concurrency control. The value is in the format of '{cpu-80, memory-70}', indicating the OS resource threshold for triggering instance-level concurrency control. The value can be NULL, indicating that concurrency control is performed regardless of the resource usage.

Example:

```
gaussdb=# CREATE database db1;
gaussdb=# SELECT gs_update_workload_rule(2, 'rule for select 2', '{db1}', now(), NULL, 50, '{tb1}');
gs_update_workload_rule
-----
t
(1 row)
```

- `gs_delete_workload_rule(rule_id)`

Description: Deletes an SQL statement concurrency control rule. Users must have the sysadmin permission. This function can be executed only on the CN.

Parameter: **rule_id** indicates the ID of the concurrency control rule to be updated. The type is int8.

Return type: Boolean

Example:

```
gaussdb=# SELECT gs_delete_workload_rule(3);
gs_delete_workload_rule
-----
t
(1 row)
```

- `gs_get_workload_rule_stat(rule_id)`

Description: Queries the number of times that SQL statements are blocked by SQL statement concurrency control rules. Users must have the sysadmin permission. This function can be executed only on the CN.

Parameter: **rule_id** indicates the ID of the concurrency control rule to be queried. The type is int8. You can set **rule_id** to **-1**, indicating that all SQL statement concurrency control rules are queried.

Table 3 Return value types

Name	Type	Description
rule_id	int8	ID of the SQL statement concurrency control rule.
validate_count	int8	Number of SQL statements intercepted by the SQL statement concurrency control rule.

Example:

```
gaussdb=# SELECT * FROM gs_get_workload_rule_stat(1);
rule_id | validate_count
-----+-----
1 | 0
(1 row)
gaussdb=# SELECT * FROM gs_get_workload_rule_stat(-1);
rule_id | validate_count
-----+-----
1 | 0
2 | 0
(2 rows)
```

7.6.48 Obsolete Functions

The following functions in GaussDB have been discarded in the latest version:

- `gs_wlm_get_session_info`
- `gs_wlm_get_user_session_info`
- `check_engine_status`
- `encode_plan_node`
- `model_train_opt`
- `gs_stat_get_wlm_plan_operator_info`
- `track_model_train_opt`
- `array_extend`
- `dbe_perf.global_slow_query_info`
- `dbe_perf.global_slow_query_info_bytime`
- `dbe_perf.global_slow_query_history`
- `pg_reload_conf`
- `pg_rotate_logfile`
- `gs_stat_ustore`
- `local_segment_space_info`
- `global_segment_space_info`
- `remote_segment_space_info`
- `pg_stat_segment_extent_usage`
- `pgxc_get_wlm_current_instance_info(text, int default null)`
- `pgxc_get_wlm_history_instance_info(text, TIMESTAMP, TIMESTAMP, int default null)`
- `GS_ALL_NODEGROUP_CONTROL_GROUP_INFO(text)`
- `create_wlm_operator_info(int flag)`
- `create_wlm_session_info(int flag)`
- `pg_stat_get_wlm_session_info(int flag)`
- `gs_wlm_get_resource_pool_info(int)`
- `gs_wlm_get_all_user_resource_info()`
- `gs_wlm_get_workload_records()`
- `gs_wlm_persistent_user_resource_info()`
- `gs_wlm_session_respools(bigint)`
- `gs_total_nodegroup_memory_detail()`
- `pgxc_get_wlm_ec_operator_history()`
- `pgxc_get_wlm_ec_operator_info()`
- `pgxc_get_wlm_ec_operator_statistics()`
- `pgxc_get_wlm_operator_history()`
- `pgxc_get_wlm_operator_info()`
- `pgxc_get_wlm_operator_statistics()`
- `pgxc_get_wlm_session_history()`
- `pgxc_get_wlm_session_info()`
- `pgxc_get_wlm_session_info_bytime(tag text, begin timestamp, end timestamp, limit int)`

- `pgxc_get_wlm_session_statistics()`
- `pgxc_wlm_get_workload_records()`
- `DBE_PERF.get_wlm_controlgroup_ng_config()`
- `DBE_PERF.get_global_wlm_workload_runtime()`
- `gs_wlm_user_resource_info(name text)`
- `create_wlm_instance_statistics_info()`
- `pg_stat_get_session_wlmstat()`
- `pg_stat_get_wlm_ec_operator_info()`
- `pg_stat_get_wlm_instance_info()`
- `pg_stat_get_wlm_instance_info_with_cleanup()`
- `pg_stat_get_wlm_node_resource_info()`
- `pg_stat_get_wlm_operator_info()`
- `pg_stat_get_wlm_realtime_ec_operator_info()`
- `pg_stat_get_wlm_realtime_operator_info()`
- `pg_stat_get_wlm_realtime_session_info()`
- `pg_stat_get_wlm_session_info_internal()`
- `pg_stat_get_wlm_statistics()`
- `gs_redis_set_bucketxid(bigint)`
- `gs_check_logic_cluster_consistency()`

7.7 Expressions

7.7.1 Simple Expressions

Logical Expressions

[Logical Operators](#) lists the operators and calculation rules of logical expressions.

Comparative Expressions

[Comparison Operators](#) lists the common comparative operators.

In addition to comparative operators, you can also use the following sentence structure:

- BETWEEN operators:
 - a BETWEEN x AND y** is equivalent to **a >= x AND a <= y**.
 - a NOT BETWEEN x AND y** is equivalent to **a < x OR a > y**.
- To check whether a value is null, use:
 - `expression IS NULL`
 - `expression IS NOT NULL`
 - or an equivalent (non-standard) sentence structure:
 - `expression ISNULL`
 - `expression NOTNULL`

NOTICE

- Do not write **expression=NULL** or **expression<>(!=)NULL**, because **NULL** represents an unknown value, and these expressions cannot determine whether two unknown values are equal.
 - Only the comparative expressions **IS NULL** and **IS NOT NULL** support data of XML type.
-
- is distinct from/is not distinct from
 - is distinct from
If the data types and values of A and B are different, the value is **true**.
If the data types and values of A and B are the same, the value is **false**.
Empty values are considered the same.
 - is not distinct from
If the data types and values of A and B are different, the value is **false**.
If the data types and values of A and B are the same, the value is **true**.
Empty values are considered the same.
 - <=> NULL-safe equal operator
The comparison of NULL values is added on the basis of the comparison of '='. If neither the left nor right value of the operator is NULL, the result is the same as that of '='.
If the data types and values of A and B are different, the value is **false**.
If the data types and values of A and B are the same, the value is **true**.
Empty values are considered the same.

 **NOTE**

- The usage of the <=> operator is the same as that of IS NOT DISTINCT FROM.
- This operator is valid only when the database is compatible with the MySQL type (that is, **sql_compatibility** is set to 'MYSQL'). Other types do not support this operator.

Examples

```
gaussdb=# SELECT 2 BETWEEN 1 AND 3 AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT 2 >= 1 AND 2 <= 3 AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT 2 NOT BETWEEN 1 AND 3 AS RESULT;
result
-----
f
(1 row)

gaussdb=# SELECT 2 < 1 OR 2 > 3 AS RESULT;
result
```

```

-----
f
(1 row)

gaussdb=# SELECT 2+2 IS NULL AS RESULT;
result
-----
f
(1 row)

gaussdb=# SELECT 2+2 IS NOT NULL AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT 2+2 ISNULL AS RESULT;
result
-----
f
(1 row)

gaussdb=# SELECT 2+2 NOTNULL AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT 2+2 IS DISTINCT FROM NULL AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT 2+2 IS NOT DISTINCT FROM NULL AS RESULT;
result
-----
f
(1 row)

gaussdb=# SELECT 1 <=> 1 AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT NULL <=> 1 AS RESULT;
result
-----
f
(1 row)

gaussdb=# SELECT NULL <=> NULL AS RESULT;
result
-----
t
(1 row)

```

7.7.2 Condition Expressions

Data that meets the requirements specified by conditional expressions are filtered during SQL statement execution.

Conditional expressions include the following types:

- **CASE**
CASE expressions are similar to the **CASE** statements in other coding languages.

Figure 7-1 shows the syntax of a CASE expression.

Figure 7-1 case::=

A CASE clause can be used in a valid expression. The condition is an expression that returns a value of Boolean type.

- If the result is **true**, the result of the CASE expression is the required result.
- If the result is false, the following WHEN or ELSE clauses are processed in the same way.
- If every WHEN condition is not true, the result of the expression is the result of the ELSE clause. If the ELSE clause is omitted and has no match condition, the result is NULL.
- Operations on XML data are supported.
- When the GUC parameter **enable_case_intervaltonumeric** is set to **true**, INTERVAL can be converted to NUMERIC without reporting an error.

Example:

```

gaussdb=# CREATE TABLE case_when_t1(CW_COL1 INT) DISTRIBUTE BY HASH (CW_COL1);
gaussdb=# INSERT INTO case_when_t1 VALUES (1), (2), (3);

gaussdb=# SELECT * FROM case_when_t1;
 cw_col1
---
 1
 2
 3
(3 rows)

gaussdb=# SELECT CW_COL1, CASE WHEN CW_COL1=1 THEN 'one' WHEN CW_COL1=2 THEN 'two'
ELSE 'other' END FROM case_when_t1 ORDER BY 1;
 cw_col1 | case
-----+-----
 1 | one
 2 | two
 3 | other
(3 rows)

gaussdb=# DROP TABLE case_when_t1;

-- The default value of the GUC parameter is false. In this case, an error is reported.
gaussdb=# SHOW enable_case_intervaltonumeric;
enable_case_intervaltonumeric
-----
off
(1 row)

gaussdb=# SELECT case
gaussdb-#   WHEN 1=1 THEN
gaussdb-#     to_date('20240118','yyyymmdd')-to_date('20240116','yyyymmdd')
gaussdb-#   ELSE
gaussdb-#     1
gaussdb-# end;
ERROR: CASE types integer and interval cannot be matched
LINE 3:   to_date('20240118','yyyymmdd')-to_date('20240116','y...
      ^
CONTEXT: referenced column: case
  
```

```
-- Enable the GUC parameter. The result can be correctly returned.
gaussdb=# SET enable_case_intervaltonumeric=true;
SET
gaussdb=# SELECT case
gaussdb-#   WHEN 1=1 THEN
gaussdb-#     to_date('20240118','yyyymmdd')-to_date('20240116','yyyymmdd')
gaussdb-#   ELSE
gaussdb-#     1::int1
gaussdb-# END;
case
-----
 2
(1 row)
```

- DECODE

Figure 7-2 shows the syntax of DECODE.

Figure 7-2 decode::=

Compare each following compare(n) with base_expr, **value(n)** is returned if a compare(n) matches the base_expr expression. If base_expr does not match each compare(n), the default value is returned.

Operations on XML data are supported.

Conditional Expression Functions describes the examples.

```
gaussdb=# SELECT DECODE('A','A',1,'B',2,0);
case
-----
 1
(1 row)
```

- COALESCE

Figure 7-3 shows the syntax of COALESCE.

Figure 7-3 coalesce::=

COALESCE returns its first not-NULL value. If all the parameters are **NULL**, **NULL** is returned. This value is replaced by the default value when data is displayed. Like a CASE expression, COALESCE only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first not-NULL parameter are not evaluated.

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE c_tabl(description varchar(10), short_description varchar(10), last_value
varchar(10))
DISTRIBUTE BY HASH (last_value);
```

```

gaussdb=# INSERT INTO c_tabl VALUES('abc', 'efg', '123');
gaussdb=# INSERT INTO c_tabl VALUES(NULL, 'efg', '123');

gaussdb=# INSERT INTO c_tabl VALUES(NULL, NULL, '123');

gaussdb=# SELECT description, short_description, last_value, COALESCE(description, short_description,
last_value) FROM c_tabl ORDER BY 1, 2, 3, 4;
description | short_description | last_value | coalesce
-----+-----+-----+-----
abc         | efg              | 123       | abc
           | efg              | 123       | efg
           |                  | 123       | 123
(3 rows)

gaussdb=# DROP TABLE c_tabl;
    
```

If **description** is not **NULL**, the value of **description** is returned. Otherwise, **short_description** is calculated. If **short_description** is not **NULL**, the value of **short_description** is returned. Otherwise, **last_value** is calculated. If **last_value** is not **NULL**, the value of **last_value** is returned. Otherwise, **none** is returned.

```

gaussdb=# SELECT COALESCE(NULL,'Hello World');
 coalesce
-----
Hello World
(1 row)
    
```

- NULLIF

Figure 7-4 shows the syntax of NULLIF.

Figure 7-4 nullif::=

Only if **value1** is equal to **value2** can **NULLIF** return the **NULL** value. Otherwise, **value1** is returned. Operations on XML data are supported.

Example:

```

gaussdb=# CREATE TABLE null_if_t1 (
NI_VALUE1 VARCHAR(10),
NI_VALUE2 VARCHAR(10)
)DISTRIBUTE BY HASH (NI_VALUE1);

gaussdb=# INSERT INTO null_if_t1 VALUES('abc', 'abc');
gaussdb=# INSERT INTO null_if_t1 VALUES('abc', 'efg');

gaussdb=# SELECT NI_VALUE1, NI_VALUE2, NULLIF(NI_VALUE1, NI_VALUE2) FROM null_if_t1 ORDER
BY 1, 2, 3;

ni_value1 | ni_value2 | nullif
-----+-----+-----
abc       | abc       |
abc       | efg       | abc
(2 rows)

gaussdb=# DROP TABLE null_if_t1;
    
```

If **value1** is equal to **value2**, **NULL** is returned. Otherwise, **value1** is returned.

```

gaussdb=# SELECT NULLIF('Hello','Hello World');
 nullif
-----
Hello
(1 row)
    
```

- GREATEST (maximum value) and LEAST (minimum value)
Figure 7-5 shows the syntax of GREATEST.

Figure 7-5 greatest::=

You can select the maximum value from any numerical expression list.
Operations on XML data are supported.

```

gaussdb=# SELECT greatest(9000,15555,2.01);
greatest
-----
15555
(1 row)
  
```

Figure 7-6 shows the syntax of LEAST.

Figure 7-6 least::=

You can select the minimum value from any numerical expression list.
Each of the preceding numeric expressions can be converted into a common data type, which will be the data type of the result.

The NULL values in the list will be ignored. The result is **NULL** only if the results of all expressions are **NULL**.

Operations on XML data are supported.

```

gaussdb=# SELECT least(9000,2);
least
-----
2
(1 row)
  
```

Conditional Expression Functions describes the examples.

- NVL
Figure 7-7 shows the syntax of NVL.

Figure 7-7 nvl::=

If the value of **value1** is **NULL**, **value2** is returned. Otherwise, **value1** is returned. Operations on XML data are supported.

Example:

```

gaussdb=# SELECT nvl(null,1);
nvl
-----
1
(1 row)
gaussdb=# SELECT nvl('Hello World',1);
nvl
-----
Hello World
(1 row)

```

7.7.3 Subquery Expressions

Subquery expressions include the following types:

- EXISTS/NOT EXISTS

Figure 7-8 shows the syntax of EXISTS/NOT EXISTS.

Figure 7-8 EXISTS/NOT EXISTS::=

The parameter of an EXISTS expression is an arbitrary SELECT statement, that is, subquery. The subquery is evaluated to determine whether it returns any rows. If it returns at least one row, the result of EXISTS is true. If the subquery returns no rows, the result of EXISTS is false.

The subquery will generally only be executed long enough to determine whether at least one row is returned, not all the way to completion.

Operations on XML data are not supported.

Example:

```

gaussdb=# CREATE TABLE exists_t1(a int, b int);
gaussdb=# INSERT INTO exists_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

gaussdb=# CREATE TABLE exists_t2(a int, c int);
gaussdb=# INSERT INTO exists_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

gaussdb=# SELECT * FROM exists_t1 t1 WHERE EXISTS (SELECT * FROM exists_t2 t2 WHERE t2.a =
t1.a);
a | b
---+---
3 | 4
4 | 5
(2 rows)

gaussdb=# DROP TABLE exists_t1, exists_t2;

```

- IN/NOT IN

Figure 7-9 shows the syntax of IN/NOT IN.

Figure 7-9 IN/NOT IN::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result. The result of IN is true if any equal subquery row is found. The result is false if no equal row is found (including the case where the subquery returns no rows).

This is in accordance with SQL normal rules for Boolean combinations of null values. If the columns corresponding to two rows equal and are not empty, the two rows are equal to each other. If any columns corresponding to the two rows do not equal and are not empty, the two rows are not equal to each other. Otherwise, the result is **NULL**. If the results in each row are either unequal or NULL, with at least one NULL, the result of IN is null.

Operations on XML data are not supported.

Example:

```
gaussdb=# CREATE TABLE in_t1(a int, b int);
gaussdb=# INSERT INTO in_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

gaussdb=# CREATE TABLE in_t2(a int, c int);
gaussdb=# INSERT INTO in_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

gaussdb=# SELECT * FROM in_t1 t1 WHERE t1.a IN (SELECT t2.a FROM in_t2 t2);
 a | b
---+---
 3 | 4
 4 | 5
(2 rows)

gaussdb=# DROP TABLE in_t1, in_t2;
```

- ANY/SOME

Figure 7-10 shows the syntax of ANY/SOME.

Figure 7-10 any/some::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given operator, which must yield a Boolean result. The result of ANY is true if any true result is obtained. The result is false if no true result is found (including the case where the subquery returns no rows). SOME is a synonym of ANY. IN can be equivalently replaced with ANY.

Operations on XML data are not supported.

Example:

```
gaussdb=# CREATE TABLE any_t1(a int, b int);
gaussdb=# INSERT INTO any_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

gaussdb=# CREATE TABLE any_t2(a int, c int);
gaussdb=# INSERT INTO any_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

gaussdb=# SELECT * FROM any_t1 t1 WHERE t1.a < ANY(SELECT t2.a FROM any_t2 t2 where t2.a = 3
or t2.a = 4);
 a | b
```

```

----+----
1 | 2
2 | 3
3 | 4
(3 rows)

gaussdb=# DROP TABLE any_t1, any_t2;

```

- ALL
Figure 7-11 shows the syntax of ALL.

Figure 7-11 all::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given operator, which must yield a Boolean result. The result of ALL is true if all values are true (including the case where the subquery returns no rows). The result is false if any false result is found.

Operations on XML data are not supported.

Example:

```

gaussdb=# CREATE TABLE all_t1(a int, b int);
gaussdb=# INSERT INTO all_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

gaussdb=# CREATE TABLE all_t2(a int, c int);
gaussdb=# INSERT INTO all_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

gaussdb=# SELECT * FROM all_t1 t1 WHERE t1.a < ALL(SELECT t2.a FROM all_t2 t2 where t2.a = 3 or
t2.a = 4);
 a | b
----+----
1 | 2
2 | 3
(2 rows)

gaussdb=# DROP TABLE all_t1, all_t2;

```

7.7.4 Array Expressions

IN

expression **IN** (*value* [, ...])

The parentheses on the right contain an expression list. The expression result on the left is compared with the content in the expression list. If the content in the list meets the expression result on the left, the result of IN is true. If no result meets the requirements, the result of IN is false.

Example:

```

gaussdb=# SELECT 8000+500 IN (10000, 9000) AS RESULT;
 result
-----
f
(1 row)

```

 **NOTE**

- If the expression result is null or the expression list does not meet the expression conditions and at least one empty value is returned for the expression list on the right, the result of IN is null rather than false. This method is consistent with the Boolean rules used when SQL statements return empty values.
- Operations on XML data are not supported.

NOT IN

expression **NOT IN** (*value* [, ...])

The parentheses on the right contain an expression list. The expression result on the left is compared with the content in the expression list. If the content in the list does not meet the expression result on the left, the result of NOT IN is true. If any content meets the expression result, the result of NOT IN is false.

Example:

```
gaussdb=# SELECT 8000+500 NOT IN (10000, 9000) AS RESULT;
result
-----
t
(1 row)
```

 **NOTE**

- If the query statement result is null or the expression list does not meet the expression conditions and at least one empty value is returned for the expression list on the right, the result of NOT IN is null rather than false. This method is consistent with the Boolean rules used when SQL statements return empty values.
- In all situations, X NOT IN Y equals to NOT(X IN Y).
- Operations on XML data are not supported.

ANY/SOME (array)

expression operator **ANY** (*array expression*)

expression operator **SOME** (*array expression*)

The right side is a parenthesized expression, which must yield an array value. The result of the expression on the left uses operators to compute and compare the results in each row of the array expression. The comparison result must be a Boolean value.

Example:

```
gaussdb=# SELECT 8000+500 < SOME (array[10000,9000]) AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 8000+500 < ANY (array[10000,9000]) AS RESULT;
result
-----
t
(1 row)
```

 **NOTE**

- If at least one comparison result is true, the result of ANY is true.
- If no comparison result is true, the result of ANY is false.
- If no comparison result is true and the array expression generates at least one null value, the value of **ANY** is **NULL** rather than **false**. This method is consistent with the Boolean rules used when SQL statements return empty values.
- SOME is a synonym of ANY.
- Operations on XML data are not supported.

ALL (array)

expression operator ALL (array expression)

The right-hand side is a parenthesized expression, which must yield an array value. The result of the expression on the left uses operators to compute and compare the results in each row of the array expression. The comparison result must be a Boolean value.

- The result of ALL is true if all comparisons yield true (including the case where the array has zero elements).
- If one or more comparison results are false, the result of ALL is false.

If the array expression yields a null array, the result of ALL will be NULL. If the expression on the left yields NULL, the result of ALL is generally NULL (though a non-strict comparison operator could possibly yield a different result). If the array on the right contains any null elements and no false comparison result is found, the result of ALL is NULL, not true (again, assuming a strict comparison operator). This method is consistent with the Boolean rules used when SQL statements return empty values.

Operations on XML data are not supported.

```
gaussdb=# SELECT 8000+500 < ALL (array[10000,9000]) AS RESULT;  
result  
-----  
t  
(1 row)
```

7.7.5 Row Expressions

Syntax:

row_constructor operator row_constructor

Both sides of the row expression are row constructors. The values of both rows must have the same number of fields and they are compared with each other. The row comparison allows operators including =, <>, <, <=, and >= or a similar operator.

For operators <, <=, >, and >=, the columns in rows are compared from left to right until a pair of columns that are not equal or are empty are detected. If the pair of columns contains at least one null value, the comparison result is null. Otherwise, the comparison result of this pair of columns is the final result. If no unequal or empty column is found, the values in the two rows are equal. The final result is determined based on the operator meaning.

Operations on XML data are not supported.

Example:

```
gaussdb=# SELECT ROW(1,2,NULL) < ROW(1,3,0) AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT (4,5,6) > (3,2,1) AS result;
result
-----
t
(1 row)

gaussdb=# SELECT (4,1,1) > (3,2,1) AS result;
result
-----
t
(1 row)

gaussdb=# SELECT ('test','data') > ('data','data') AS result;
result
-----
t
(1 row)

gaussdb=# SELECT (4,1,1) > (3,2,null) AS result;
result
-----
t
(1 row)

gaussdb=# SELECT (null,1,1) > (3,2,1) AS result;
result
-----

(1 row)

gaussdb=# SELECT (null,5,6) > (null,5,6) AS result;
result
-----

(1 row)

gaussdb=# SELECT (4,5,6) > (4,5,6) AS result;
result
-----
f
(1 row)

gaussdb=# SELECT (2,2,5) >= (2,2,3) AS result;
result
-----
t
(1 row)

gaussdb=# SELECT (2,2,1) <= (2,2,3) AS result;
result
-----
t
(1 row)
```

The use of operators = and <> is slightly different from other operators. If all columns in the two rows are not empty and meet the operator condition, the two rows meet the operator condition. If any column in the two rows is not empty and

does not meet the operator condition, the two rows do not meet the operator condition. If any column in the two rows is empty, the comparison result is null.

Example:

```
gaussdb=# SELECT (1,2,3) = (1,2,3) AS result;
result
-----
t
(1 row)

gaussdb=# SELECT (1,2,3) <> (2,2,3) AS result;
result
-----
t
(1 row)

gaussdb=# SELECT (2,2,3) <> (2,2,null) AS result;
result
-----

(1 row)

gaussdb=# SELECT (null,5,6) <> (null,5,6) AS result;
result
-----

(1 row)
```

7.7.6 Time Interval Expressions

Syntax: INTERVAL EXPR UNIT

Description: **EXPR** indicates a value, and the **UNIT** specifier indicates a unit of the value, such as HOUR, DAY, and WEEK. The keyword INTERVAL and specifier are case insensitive.

Table 7-190 describes the value range of **UNIT** in a time interval expression. Any punctuation-separated EXPR format is allowed. The recommended separators are displayed in **Table 7-190**.

NOTE

The INTERVAL expression supports the preceding functions only when **sql_compatibility** is set to 'MYSQL', **b_format_version** is set to 5.7, and **b_format_dev_version** is set to s1.

Table 7-190 Value range of UNIT in a time interval expression

UNIT Value Range	Expected EXPR Format
MICROSECOND	MICROSECONDS
SECOND	SECONDS
MINUTE	MINUTES
HOUR	HOURS
DAY	DAYS
WEEK	WEEKS

UNIT Value Range	Expected EXPR Format
MONTH	MONTHS
QUARTER	QUARTERS
YEAR	YEARS
SECOND_MICROSECOND	'SECOND_MICROSECOND'
MINUTE_MICROSECOND	'MINUTES:SECONDS.MICROSECONDS'
MINUTE_SECOND	'MINUTES:SECONDS'
HOUR_MICROSECOND	'HOURS:MINUTES:SECONDS.MICROSECONDS'
HOUR_SECOND	'HOURS:MINUTES:SECONDS'
HOUR_MINUTE	'HOURS:MINUTES'
DAY_MICROSECOND	'DAYS HOURS:MINUTES:SECONDS.MICROSECONDS'
DAY_SECOND	'DAYS HOURS:MINUTES:SECONDS'
DAY_MINUTE	'DAYS HOURS:MINUTES'
DAY_HOUR	'DAYS HOURS'
YEAR_MONTH	'YEAR_MONTH'

Example:

```

gaussdb=# SELECT DATE_ADD('2018-05-01', INTERVAL 1 DAY);
date_add
-----
2018-05-02
(1 row)

gaussdb=# SELECT DATE_SUB('2018-05-01', INTERVAL 1 YEAR);
date_sub
-----
2017-05-01
(1 row)

gaussdb=# SELECT DATE'2023-01-10' - INTERVAL 1 DAY;
?column?
-----
2023-01-09 00:00:00
(1 row)

gaussdb=# SELECT DATE'2023-01-10' + INTERVAL 1 MONTH;
?column?
-----
2023-02-10 00:00:00
(1 row)

```

7.8 Pseudocolumn

ROWNUM is a pseudocolumn that returns a number indicating the row number of the obtained query result. The value of **ROWNUM** in the first row is **1**, the value of **ROWNUM** in the second row is **2**, and so on. **ROWNUM** can be used to limit the number of rows returned by a query, as shown in the following example:

```
gaussdb=# CREATE TABLE Students (name varchar(20), id int) with (STORAGE_TYPE = USTORE);
gaussdb=# INSERT INTO Students VALUES ('Jack', 35);
gaussdb=# INSERT INTO Students VALUES ('Leon', 15);
gaussdb=# INSERT INTO Students VALUES ('James', 24);
gaussdb=# INSERT INTO Students VALUES ('Taker', 81);
gaussdb=# INSERT INTO Students VALUES ('Mary', 25);
gaussdb=# INSERT INTO Students VALUES ('Rose', 64);
gaussdb=# INSERT INTO Students VALUES ('Perl', 18);
gaussdb=# INSERT INTO Students VALUES ('Under', 57);
gaussdb=# INSERT INTO Students VALUES ('Angel', 101);
gaussdb=# INSERT INTO Students VALUES ('Frank', 20);
gaussdb=# INSERT INTO Students VALUES ('Charlie', 40);
```

```
-- Output the first 10 rows in the Students table.
gaussdb=# SELECT * FROM Students WHERE rownum <= 10;
name | id
-----+-----
Jack | 35
Leon | 15
James | 24
Taker | 81
Mary | 25
Rose | 64
Perl | 18
Under | 57
Angel | 101
Frank | 20
(10 rows)
```

If the statement has a clause, the output rows are reordered according to the clause.

```
gaussdb=# SELECT * FROM Students WHERE rownum < 5 order by 1;
name | id
-----+-----
Jack | 35
James | 24
Leon | 15
Taker | 81
(4 rows)
```

If a subquery has a clause but the condition is placed in the outermost query, you can use the **ROWNUM** condition after sorting.

```
gaussdb=# SELECT rownum, * FROM (SELECT * FROM Students order by 1) WHERE rownum <= 2;
rownum | name | id
-----+-----+-----
1 | Angel | 101
2 | Charlie | 40
(2 rows)
```

As long as **ROWNUM** is greater than a specific positive integer, the condition is always false. As shown in the following example, the statement does not return any result in the table:

```
gaussdb=# SELECT * FROM Students WHERE rownum > 1;
name | id
-----+-----
(0 rows)
```

Use **ROWNUM** to assign a value to each row within a certain range of the table.

```
gaussdb=# SELECT * FROM Students;
 name | id
-----+-----
 Jack | 35
 Leon | 15
 James | 24
 Taker | 81
 Mary | 25
 Rose | 64
 Perl | 18
 Under | 57
 Angel | 101
 Frank | 20
 Charlie | 40
(11 rows)

gaussdb=# UPDATE Students set id = id + 5 WHERE rownum < 4;
UPDATE 3
gaussdb=# SELECT * FROM Students;
 name | id
-----+-----
 Jack | 40
 Leon | 20
 James | 29
 Taker | 81
 Mary | 25
 Rose | 64
 Perl | 18
 Under | 57
 Angel | 101
 Frank | 20
 Charlie | 40
(11 rows)

gaussdb=# DROP TABLE Students;
DROP TABLE
```

The restrictions on using **ROWNUM** are as follows:

- Do not use ROWNUM as an alias to avoid ambiguity in SQL statements.
- Do not use ROWNUM when creating an index.
- Do not use ROWNUM as the default value when creating a table.
- Do not use ROWNUM as an alias in the WHERE clause.
- Do not use ROWNUM when inserting data.
- Do not use ROWNUM in a tableless query.
- Do not use ROWNUM in the LIMIT clause.
- Do not use ROWNUM as a parameter of the EXECUTE statement.
- Do not use ROWNUM to update a clause in the UPSERT statement.
- Do not use ROWNUM as a projection column or WHERE condition in the SELECT ... FOR UPDATE statement.
- If the HAVING clause contains ROWNUM (not in an aggregate function), the GROUP BY clause must also contain ROWNUM (not in an aggregate function), unless the GROUP BY clause contains an expression, for example, **SELECT a + a FROM t group by a + a having rownum < 5**.
- If the ROWNUM condition exists in the HAVING clause, the HAVING clause cannot be pushed down to any scan node.

```
gaussdb=# CREATE TABLE test (a int, b int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# INSERT INTO test SELECT generate_series, generate_series FROM generate_series(1, 10);
```

```

INSERT 0 10

-- The rownum condition cannot be pushed down to seqscan.
gaussdb=# EXPLAIN SELECT a,rownum FROM test group by a,rownum having rownum < 5;
QUERY PLAN
-----
HashAggregate (cost=3.45..3.49 rows=3 width=4)
  Group By Key: a, ROWNUM
  Filter: ((ROWNUM) < 5::numeric)
    -> Rownum (cost=0.19..3.40 rows=10 width=4)
      -> Streaming (type: GATHER) (cost=0.19..3.40 rows=10 width=4)
          Node/s: All datanodes
          -> Seq Scan on test (cost=0.00..3.03 rows=10 width=4)
(7 rows)

```

- If a subquery contains the ROWNUM condition, the predicate cannot be pushed down to any scan node.

```

gaussdb=# EXPLAIN SELECT * FROM (SELECT * FROM test WHERE rownum < 5) WHERE b < 5; -- The
b<5 WHERE clause cannot be pushed down to Seq Scan.
QUERY PLAN
-----
Streaming (type: GATHER) (cost=0.06..0.63 rows=2 width=8)
  Node/s: All datanodes
    -> Subquery Scan on __unnamed_subquery__ (cost=0.00..0.50 rows=2 width=8)
      Filter: (__unnamed_subquery__.b < 5)
        -> Rownum (cost=0.00..0.45 rows=4 width=8)
          StopKey: (ROWNUM < 5::numeric)
            -> Streaming(type: BROADCAST) (cost=0.00..1.36 rows=12 width=8)
              Spawn on: All datanodes
                -> Rownum (cost=0.00..1.35 rows=4 width=8)
                  StopKey: (ROWNUM < 5::numeric)
                    -> Seq Scan on test (cost=0.00..3.03 rows=10 width=8)
(11 rows)

gaussdb=# DROP TABLE test;
DROP TABLE

```

 CAUTION

- The query result of **ROWNUM** may be unstable due to the sequence in which the CN receives DN data.

```
gaussdb=# CREATE TABLE test(a int, b int);
gaussdb=# INSERT INTO test VALUES(generate_series(1,10),generate_series(1,10));
```

-- The CN receives data from DN1 and then from DN2.

```
gaussdb=# SELECT rownum,* FROM test;
```

```
rownum | a | b
```

```
-----+-----+-----
```

```
1 | 1 | 1
```

```
2 | 2 | 2
```

```
3 | 5 | 5
```

```
4 | 6 | 6
```

```
5 | 8 | 8
```

```
6 | 9 | 9
```

```
7 | 3 | 3
```

```
8 | 4 | 4
```

```
9 | 7 | 7
```

```
10 | 10 | 10
```

(10 rows)

-- The CN receives data from DN2 and then from DN1.

```
gaussdb=# SELECT rownum,* FROM test;
```

```
rownum | a | b
```

```
-----+-----+-----
```

```
1 | 3 | 3
```

```
2 | 4 | 4
```

```
3 | 7 | 7
```

```
4 | 10 | 10
```

```
5 | 1 | 1
```

```
6 | 2 | 2
```

```
7 | 5 | 5
```

```
8 | 6 | 6
```

```
9 | 8 | 8
```

```
10 | 9 | 9
```

(10 rows)

- It is not recommended that the **ROWNUM** condition be used in the **JOIN ON** clause. In GaussDB, when the **ROWNUM** condition is used in the **JOIN ON** clause, the behavior in the **LEFT JOIN**, **RIGHT JOIN**, **FULL JOIN**, and **MERGE INTO** scenarios is different from that in other databases, causing risks in service migration.

If the parent query contains the **rownum** restriction and the projection column of the subquery contains **rownum**, the restriction is pushed down to the subquery.

The constraints are as follows:

- The parent query can be pushed down only when the **rownum** restriction condition is **<**, **<=**, or **=** and the subquery directly uses **rownum** as the pseudocolumn.
- If the parent query has multiple filter criteria for **rownum** in the subquery and the pushdown requirements are met, only the first filter criterion is pushed down.
- If a subquery contains volatile functions and stored procedures, the pushdown is not supported.

7.9 Type Conversion

7.9.1 Overview

Background

SQL is a typed language. That is, every data item has an associated data type which determines its behavior and allowed usage. GaussDB has an extensible type system that is more general and flexible than other SQL implementations. Hence, most type conversion behaviors in GaussDB are governed by general rules. This allows the use of mixed-type expressions.

The GaussDB scanner/parser divides lexical elements into five fundamental categories: integers, floating-point numbers, strings, identifiers, and keywords. Constants of most non-numeric types are first classified as strings. The SQL language definition allows specifying type names with constant strings. For example:

```
gaussdb=# SELECT text 'Origin' AS "label", point '(0,0)' AS "value";
label | value
-----+-----
Origin | (0,0)
(1 row)
```

In the example, there are two literal constants of the text and point types. If a type is not specified for a string literal, then the placeholder type **unknown** is assigned initially.

There are four fundamental SQL constructs requiring distinct type conversion rules in GaussDB parser:

- **Function calls**
Much of the SQL type system is built around a rich set of functions. Functions can have one or more arguments. Since SQL permits function overloading, the function name alone does not uniquely identify the function to be called. The parser must select the right function based on the data types of the supplied arguments.
- **Operators**
SQL allows expressions with prefix and postfix unary (one-argument) operators, as well as binary (two-argument) operators. Like functions, operators can be overloaded, so the same problem of selecting the right operator exists.
- **Value storage**
SQL **INSERT** and **UPDATE** statements place the results of expressions into a table. The expressions in the statement must be matched up with, and perhaps converted to, the types of the target columns.
- **UNION, CASE, and Related Constructs**
Since all query results from a unionized **SELECT** statement must appear in a single set of columns, the types of the results of each **SELECT** clause must be matched up and converted to a uniform set. Similarly, the result expressions of a **CASE** construct must be converted to a common type so that the **CASE** expression as a whole has a known output type. The same holds for **ARRAY** constructs, and for the **GREATEST** and **LEAST** functions.

The system catalog `pg_cast` stores information about which conversions, or casts, exist between which data types, and how to perform those conversions. For details, see [PG_CAST](#).

The return type and conversion behavior of an expression are determined during semantic analysis. Data types are divided into several basic type categories, including **Boolean**, **numeric**, **string**, **bitstring**, **datetime**, **timespan**, **geometric**, and **network**. Within each category there can be one or more preferred types, which are preferred when there is a choice of possible types. With careful selection of preferred types and available implicit casts, it is possible to ensure that ambiguous expressions (those with multiple candidate parsing solutions) can be resolved in a useful way.

All type conversion rules are designed based on the following principles:

- Implicit conversions should never have surprising or unpredictable outcomes.
- There should be no extra overhead in the parser or executor if a query does not need implicit type conversion. That is, if a query is well-formed and the types already match, then the query should execute without spending extra time in the parser and without introducing unnecessary implicit conversion calls in the query.
- Additionally, if a query usually requires an implicit conversion for a function, and if then the user defines a new function with the correct argument types, the parser should use this new function.
- XML data does not support implicit type conversion, including implicit conversion between strings and XML types.

7.9.2 Operators

Operator Type Resolution

1. Select the operators to be considered from the `pg_operator` system catalog. Considered operators are those with the matching name and argument count. If the search path finds multiple available operators, only the most suitable one is considered.
2. Look for the best match.
 - a. Discard candidate operators for which the input types do not match and cannot be converted (using an implicit conversion) to match. Unknown text can be converted to anything for this purpose. If only one candidate remains, use it; otherwise, go to the next step.
 - b. Run through all candidates and keep those with the most exact matches on input types. In this case, the domain types are considered the same as their basic types. Keep all candidates if none survives these tests. If only one candidate remains, use it; otherwise, go to the next step.
 - c. Run through all candidates and keep those that accept preferred types (of the input data type's type category) at the most positions where type conversion will be required. Keep all candidates if none accepts preferred types. If only one candidate remains, use it; otherwise, go to the next step.
 - d. If any input arguments are of unknown types, check the type categories accepted at those argument positions by the remaining candidates. At

each position, select the string category if any candidate accepts that category. (This bias towards string is appropriate since an unknown-type literal looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument. Keep all candidates if none survives these tests. If only one candidate remains, use it; otherwise, go to the next step.

- e. If there are both unknown and known-type arguments, and all the known-type arguments have the same type, assume that the unknown arguments are also of that type, and check which candidates can accept that type at the unknown-argument positions. If exactly one candidate passes this test, use it. Otherwise, an error occurs.

CAUTION

After an operator is found, if the type of the input parameter is different from that of the operator, implicit type conversion may occur. After the conversion, unpredictable behavior may occur. If the behavior is incorrect after implicit conversion, you can use explicit type conversion to avoid this problem. For example, after the fixed-length `bpchar` type is converted to the variable-length text type, spaces at the end of the character string are deleted. If the character string is compared with other character strings, errors may occur.

Examples

Example 1: Use factorial operator type resolution. There is only one factorial operator (postfix `!`) defined in the system catalog, and it takes an argument of `bigint` type. The scanner assigns `bigint` as an initial type to the argument in this query expression:

```
gaussdb=# SELECT 40 ! AS "40 factorial";
          40 factorial
-----
815915283247897734345611269596115894272000000000
(1 row)
```

So the parser does a type conversion on the operand and the query is equivalent to:

```
gaussdb=# SELECT CAST(40 AS bigint) ! AS "40 factorial";
```

Example 2: String concatenation operator type resolution. A string-like syntax is used for working with string types and for working with complex extension types. Strings with unspecified type are matched with likely operator candidates. An example with one unspecified argument:

```
gaussdb=# SELECT text 'abc' || 'def' AS "text and unknown";
text and unknown
-----
abcdef
(1 row)
```

In this example, the parser looks for an operator whose parameters are of the text type. Such an operator is found.

Here is a concatenation of two values of unspecified types:

```
gaussdb=# SELECT 'abc' || 'def' AS "unspecified";
unspecified
-----
abcdef
(1 row)
```

NOTE

In this case there is no initial hint for which type to use, since no types are specified in the query. So, the parser looks for all candidate operators and finds that there are candidates accepting both string-category and bit-string-category inputs. Since string category is preferred when available, that category is selected, and then the preferred type for strings, text, is used as the specific type to resolve the unknown-type literals as.

Example 3: Absolute-value and negation operator type resolution. The GaussDB operator catalog has several entries for the prefix operator @. All the entries implement absolute-value operations for various numeric data types. One of these entries is for the float8 type, which is the preferred type in the numeric category. Therefore, GaussDB will use that entry when faced with an unknown input:

```
gaussdb=# SELECT @ '-4.5' AS "abs";
abs
----
4.5
(1 row)
```

Here the system has implicitly resolved the unknown-type literal as type **float8** before applying the chosen operator.

Example 4: Use the array inclusion operator type resolution as an example. Here is another example of resolving an operator with one known and one unknown input:

```
gaussdb=# SELECT array[1,2] <@ '{1,2,3}' as "is subset";
is subset
-----
t
(1 row)
```

NOTE

The GaussDB operator catalog has several entries for the infix operator <@, but the only two that could possibly accept an integer array on the left side are array inclusion (anyarray <@ anyarray) and range inclusion (anyelement <@ anyrange). Since none of these polymorphic pseudo-types (see [Pseudo-Types](#)) is considered preferred, the parser cannot resolve the ambiguity on that basis. However, the last resolution rule tells it to assume that the unknown-type literal is of the same type as the other input, that is, integer array. Now only one of the two operators can match, so array inclusion is selected. (Had range inclusion been selected, we would have gotten an error, because the string does not have the right format to be a range literal.)

7.9.3 Functions

Function Type Resolution

1. Select the functions to be considered from the pg_proc system catalog. If a non-schema-qualified function name was used, the functions in the current

search path are considered. If a qualified function name was given, only functions in the specified schema are considered.

If the search path finds multiple functions of different argument types, a proper function in the path is considered.

2. Check for a function accepting exactly the input argument types. If the function exists, use it. Cases involving unknown types will never find a match at this step.
3. If no exact match is found, see if the function call appears to be a special type conversion request.
4. Look for the best match.
 - a. Discard candidate functions for which the input types do not match and cannot be converted (using an implicit conversion) to match. Unknown text can be converted to anything for this purpose. If only one candidate remains, use it; otherwise, go to the next step.
 - b. Run through all candidates and keep those with the most exact matches on input types. Domains are considered the same as their base type for this purpose. Keep all candidates if none has exact matches. If only one candidate remains, use it; otherwise, go to the next step.
 - c. Run through all candidates and keep those that accept preferred types at the most positions where type conversion will be required. Keep all candidates if none accepts preferred types. If only one candidate remains, use it; otherwise, go to the next step.
 - d. If any input arguments are of unknown types, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the string category if any candidate accepts that category. (This bias towards string is appropriate since an unknown-type literal looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument. Keep all candidates if none survives these tests. If only one candidate remains, use it; otherwise, go to the next step.
 - e. If there are both unknown and known arguments, and all the known arguments have the same type, assume that the unknown arguments are also of that type, and check which candidates can accept that type at the unknown-argument positions. If exactly one candidate passes this test, use it. Otherwise, fail.

Examples

Example 1: Use the rounding function argument type resolution as the first example. There is only one round function that takes two arguments; it takes a first argument of type numeric and a second argument of type integer. In this case, the following query automatically converts the first argument of type integer to numeric:

```
gaussdb=# SELECT round(4, 4);
round
-----
```

```
4.0000
(1 row)
```

That query is actually transformed by the parser to:

```
gaussdb=# SELECT round(CAST (4 AS numeric), 4);
```

Since numeric constants with decimal points are initially assigned the type numeric, the following query will require no type conversion and therefore might be slightly more efficient:

```
gaussdb=# SELECT round(4.0, 4);
```

Example 2: Use the substring function type resolution as the second example. There are several substr functions, one of which takes types text and integer. If the function is called with a string constant of unspecified type, the system chooses the candidate function that accepts an argument of the preferred category string (namely of type text).

```
gaussdb=# SELECT substr('1234', 3);
substr
-----
    34
(1 row)
```

If the string is declared to be of type varchar, as might be the case if it comes from a table, then the parser will try to convert it to text:

```
gaussdb=# SELECT substr(varchar '1234', 3);
substr
-----
    34
(1 row)
```

This is transformed by the parser to effectively become:

```
gaussdb=# SELECT substr(CAST (varchar '1234' AS text), 3);
```

NOTE

The parser learns from the pg_cast catalog that text and varchar are binary-compatible, meaning that one can be passed to a function that accepts the other without doing any physical conversion. Therefore, no type conversion is really inserted in this case.

And, if the function is called with an argument of type integer, the parser will try to convert that to text:

```
gaussdb=# SELECT substr(1234, 3);
substr
-----
    34
(1 row)
```

This is transformed by the parser to effectively become:

```
gaussdb=# SELECT substr(CAST (1234 AS text), 3);
substr
-----
    34
(1 row)
```

7.9.4 Value Storage

Value Storage Type Resolution

1. Search for an exact match with the target column.
2. Try to convert the expression to the target type. This will succeed if there is a registered cast between the two types. If the expression is an unknown-type literal, the content of the literal string will be fed to the input conversion routine for the target type.
3. Check to see if there is a sizing cast for the target type. A sizing cast is a cast from that type to itself. If one is found in the **pg_cast** catalog, apply it to the expression before storing into the destination column. The implementation function for such a cast always takes an extra parameter of type **integer**. The parameter receives the destination column's **atttypmod** value (typically its declared length, although the interpretation of **atttypmod** varies for different data types), and may take a third Boolean parameter that says whether the cast is explicit or implicit. The cast function is responsible for applying any length-dependent semantics such as size checking or truncation.

Examples

Use the **character** storage type conversion as an example. For a target column declared as **character(20)**, the following statement shows that the stored value is sized correctly:

```
gaussdb=# CREATE TABLE tpcds.value_storage_t1 (
VS_COL1 CHARACTER(20)
)DISTRIBUTE BY HASH (VS_COL1);
gaussdb=# INSERT INTO tpcds.value_storage_t1 VALUES('abcdef');
gaussdb=# SELECT VS_COL1, octet_length(VS_COL1) FROM tpcds.value_storage_t1;
 vs_col1      | octet_length
-----+-----
abcdef       |          20
(1 row)
)
```

```
gaussdb=# DROP TABLE tpcds.value_storage_t1;
```

NOTE

What has happened here is that the two unknown literals are resolved to **text** by default, allowing the **||** operator to be resolved as **text** concatenation. Then the **text** result of the operator is converted to **bpchar** ("blank-padded char", the internal name of the **character** data type) to match the target column type. Since the conversion from **text** to **bpchar** is binary-coercible, this conversion does not insert any real function call. Finally, the sizing function **bpchar(bpchar, integer, Boolean)** is found in the system catalog and used for the operator's result and the stored column length. This type-specific function performs the required length check and addition of padding spaces.

7.9.5 UNION, CASE, and Related Constructs

SQL UNION constructs must match up possibly dissimilar types to become a single result set. The resolution algorithm is applied separately to each output column of a union query. The INTERSECT and EXCEPT constructs resolve dissimilar types in the same way as UNION. The CASE, ARRAY, VALUES, GREATEST and LEAST constructs use the identical algorithm to match up their component expressions and select a result data type.

Type Resolution for UNION, CASE, and Related Constructs

- If all inputs are of the same type and are not unknown, resolve them as the unknown type.
- If all inputs are of the unknown type, resolve them as the text type (the preferred type of the string category). Otherwise, unknown inputs are ignored.
- If the inputs are not all of the same type category, a failure will be resulted. (The unknown type is not included in this case.)
- If the inputs are all of the same type category, choose the top preferred type in that category. (Exception: The UNION operation regards the type of the first branch as the selected type.)

NOTE

typcategory in the `pg_type` system catalog indicates the data type category. **typispreferred** indicates whether a type is preferred in **typcategory**.

- Convert all inputs to the selected type. (Retain the original lengths of strings). Fail if there is not an implicit conversion from a given input to the selected type.
- If the input contains the `json`, `txid_snapshot`, `sys_refcursor`, or `geometry` type, UNION cannot be performed.

Type Resolution for CASE and COALESCE in TD Compatibility Type

- If all inputs are of the same type and are not unknown, resolve them as the unknown type.
- If all inputs are of the unknown type, resolve them as the text type.
- If inputs are of the string type (including unknown which is resolved as text) and digit type, resolve them as the string type. If the inputs are not of the two types, an error will be reported.
- If the inputs are all of the same type category, choose the top preferred type in that category.
- Convert all inputs to the selected type. Fail if there is not an implicit conversion from a given input to the selected type.

Type Resolution for CASE in ORA Compatibility Mode

decode(expr, search1, result1, search2, result2, ..., defresult): When the `sql_beta_feature` is set to `a_style_coerce`, the final return value type of the expression is set to the data type of `result1` or a higher-precision data type in the same type as `result1`, as that in ORA-compatible mode. (For example, `numeric` and `int` are both numeric data types, but `numeric` has higher precision and priority than `int`.) For CASE WHEN, the behavior is the same as the default behavior in ORA-compatible mode.

- If all inputs are of the same type and are not unknown, resolve them as the unknown type. Otherwise, proceed to the next step.
- Set the data type of `result1` to the final return value type `preferType`, which belongs to `preferCategory`.
- Consider the data types of `result2`, `result3`, and `defresult` in sequence. If the type category is also `preferCategory`, which is the same as that of `result1`,

check whether the precision (priority) is higher than that of preferType. If it is, update preferType to a data type with higher precision. If the precision is higher than that of preferCategory, check whether the category can be implicitly converted to preferType. If it cannot, an error is reported.

- Uses the data type recorded by preferType as the return value type of the expression. The expression result is implicitly converted to this data type.

Note 1:

There is a special case where the character type of a super-large number is converted to the numeric type, for example, **select decode(1, 2, 2, '53465465676465454657567678676')**, in which the large number exceeds the range of the bigint and double types. If result1 is of the numeric type and does not meet the condition that all inputs are of the same type, the type of the return value is set to numeric to be compatible with this special case.

Note 2:

Priority of the numeric types: numeric > float8 > float4 > int8 > int4 > int2 > int1

Priority of the character types: text > varchar (nvarchar2) > bpchar > char

Priority of date types: timestamptz > timestamp > smalldatetime > date > abstime > timetz > time

Priority of date span types: interval > tinterval > reltime

Note 3:

The following figure shows the supported implicit type conversion when **set sql_beta_feature** is set to **'a_style_coerce'** in ORA-compatible mode. \ indicates that conversion is not required, **yes** indicates that conversion is supported, and the null value indicates that conversion is not supported.

	bool	int1	int2	int4	int8	float4	float8	numeric	money	char	bpchar	varchar2	nvarchar2	text/clob	raw	blob	date	time	timetz	timestamp	timestamptz	smalldatetime	interval	reltime	abstime
bool	\																								
int1		\	yes	yes	yes	yes	yes	yes		yes	yes	yes	yes	yes											
int2		yes	\	yes	yes	yes	yes	yes		yes	yes	yes	yes	yes											
int4		yes	yes	\	yes	yes	yes	yes		yes	yes	yes	yes	yes											
int8		yes	yes	yes	\	yes	yes	yes		yes	yes	yes	yes	yes											
float4		yes	yes	yes	yes	\	yes	yes		yes	yes	yes	yes	yes											
float8		yes	yes	yes	yes	yes	\	yes		yes	yes	yes	yes	yes											
numeric		yes	yes	yes	yes	yes	yes	\		yes	yes	yes	yes	yes											
money									\																
char		yes	yes	yes	yes	yes	yes	yes		\	yes	yes	yes	yes											
bpchar		yes	yes	yes	yes	yes	yes	yes		yes	\	yes	yes	yes											
varchar2		yes	yes	yes	yes	yes	yes	yes		yes	yes	\	yes	yes	yes										
nvarchar2		yes	yes	yes	yes	yes	yes	yes		yes	yes	yes	\	yes											
text/clob		yes	yes	yes	yes	yes	yes	yes		yes	yes	yes	yes	\											
raw												yes	yes	\	yes										
blob														yes	\										
date												yes	yes	yes			\		yes	yes	yes				yes
time														yes				\	yes						
timetz														yes				yes	\						
timestamp												yes	yes	yes			yes		\	yes	yes				yes
timestamptz														yes			yes		\	yes	\	yes			yes
smalldatetime												yes		yes			yes		yes	yes	\				yes
interval												yes	yes	yes									\	yes	
reltime														yes									yes	\	
abstime														yes		yes			yes	yes	yes				\

Examples

Example 1: Use type resolution with underspecified types in a union as the first example. The unknown-type literal 'b' will be resolved to the text type.

```
gaussdb=# SELECT text 'a' AS "text" UNION SELECT 'b';
text
-----
a
b
(2 rows)
```

Example 2: Use type resolution in a simple union as the second example. The literal 1.2 is of type **numeric**, and the **integer** value 1 can be cast implicitly to **numeric**, so that type is used.

```
gaussdb=# SELECT 1.2 AS "numeric" UNION SELECT 1;
numeric
-----
1
1.2
(2 rows)
```

Example 3: Use type resolution in a transposed union as the third example. The type real cannot be implicitly cast to integer, but integer can be implicitly cast to real, the union result type is resolved as real.

```
gaussdb=# SELECT 1 AS "real" UNION SELECT CAST('2.2' AS REAL);
real
-----
1
2.2
(2 rows)
```

Example 4: In TD mode, if input parameters for **COALESCE** are of int and varchar types, resolve them as the varchar type. In ORA mode, an error is reported.

```
-- In Oracle mode, create the oracle_1 database compatible with Oracle.
gaussdb=# CREATE DATABASE oracle_1 dbcompatibility = 'ORA';

-- Switch to the oracle_1 database.
gaussdb=# \c oracle_1

-- Create the t1 table.
oracle_1=# CREATE TABLE t1(a int, b varchar(10));

-- Show the execution plan of a statement for querying the types int and varchar of input parameters for COALESCE.
a_1=# EXPLAIN SELECT coalesce(a, b) FROM t1;
ERROR: COALESCE types integer and character varying cannot be matched
LINE 1: EXPLAIN SELECT coalesce(a, b) FROM t1;
                        ^
CONTEXT: referenced column: coalesce
```

```
-- Delete the table.
oracle_1=# DROP TABLE t1;

-- Switch to the testdb database.
oracle_1=# \c testdb

-- In TD mode, create the td_1 database compatible with Teradata.
gaussdb=# CREATE DATABASE td_1 dbcompatibility = 'TD';

-- Switch to the td_1 database.
gaussdb=# \c td_1
```

```
-- Create the t2 table.
td_1=# CREATE TABLE t2(a int, b varchar(10));

-- Show the execution plan of a statement for querying the types int and varchar of input parameters for COALESCE.
td_1=# EXPLAIN VERBOSE select coalesce(a, b) from t2;
          QUERY PLAN
-----
Data Node Scan (cost=0.00..0.00 rows=0 width=0)
  Output: (COALESCE((t2.a)::character varying, t2.b))
  Node/s: All DNs
  Remote query: SELECT COALESCE(a::character varying, b) AS "coalesce" FROM public.t2
(4 rows)

-- Delete the table.
td_1=# DROP TABLE t2;

-- Switch to the testdb database.
td_1=# \c testdb

-- Delete Oracle- and TD-compatible databases.
gaussdb=# DROP DATABASE oracle_1;
gaussdb=# DROP DATABASE td_1;
```

Example 5: In ORA mode, set the final return value type of the expression to the data type of result1 or a higher-precision data type whose category is the same as that of the data type of result1.

```
-- In ORA mode, create the ora_1 database compatible with ORA.
gaussdb=# CREATE DATABASE ora_1 dbcompatibility = 'A';

-- Switch to the ora_1 database.
gaussdb=# \c ora_1

-- Enable the decode compatibility parameters.
set sql_beta_feature='a_style_coerce';

-- Create the t1 table.
ora_1=# CREATE TABLE t1(c_int int, c_float8 float8, c_char char(10), c_text text, c_date date);

-- Insert data.
ora_1=# INSERT INTO t1 VALUES(1, 2, '3', '4', date '12-10-2010');

-- The data type of result1 is char and that of defresult is text. The precision of text is higher, and the type of the return value is changed to text from char.
ora_1=# SELECT decode(1, 2, c_char, c_text) AS result, pg_typeof(result) FROM t1;
 result | pg_typeof
-----+-----
      4 | text
(1 row)

-- The data type of result1 is int, which is a numeric type. The type of the return value is set to numeric.
ora_1=# SELECT decode(1, 2, c_int, c_float8) AS result, pg_typeof(result) FROM t1;
 result | pg_typeof
-----+-----
       2 | numeric
(1 row)

-- The implicit conversion from the data type of defresult to that of result1 does not exist. If it is performed, an error is reported.
ora_1=# SELECT decode(1, 2, c_int, c_date) FROM t1;
ERROR:  CASE types integer and timestamp without time zone cannot be matched
LINE 1: SELECT decode(1, 2, c_int, c_date) FROM t1;
                ^
CONTEXT:  referenced column: c_date

-- Disable the decode compatibility parameters.
set sql_beta_feature='none';
```

```
-- Delete the table.
ora_1=# DROP TABLE t1;
DROP TABLE

-- Switch to the testdb database.
ora_1=# \c testdb

-- Delete the ORA-compatible database.
gaussdb=# DROP DATABASE ora_1;
DROP DATABASE
```

7.10 System Operation

GaussDB text runs SQL statements to perform different system operations, such as setting variables, displaying the execution plan, and collecting garbage data.

Setting Variables

For details about how to set various parameters for a session or transaction, see [SET](#).

Displaying the Execution Plan

For details about how to display the execution plan that GaussDB makes for SQL statements, see [EXPLAIN](#).

Specifying a Checkpoint in Transaction Logs

By default, WALs periodically specify checkpoints in a transaction log. **CHECKPOINT** forces an immediate checkpoint when the related command is issued, without waiting for a regular checkpoint scheduled by the system. For details, see [CHECKPOINT](#).

Collecting Unnecessary Data

For details about how to collect garbage data and analyze a database as required, For details, see [VACUUM](#).

Collecting Statistics

For details about how to collect statistics on tables in databases, see [ANALYZE | ANALYZE](#).

Setting the Constraint Check Mode for the Current Transaction

For details about how to set the constraint check mode for the current transaction, see [SET CONSTRAINTS](#).

7.11 Controlling Transactions

A transaction is a user-defined sequence of database operations, which form an integral unit of work.

Starting a Transaction

GaussDB starts a transaction using **START TRANSACTION** and **BEGIN**. For details, see [START TRANSACTION](#) and [BEGIN](#).

Setting a Transaction

GaussDB sets a transaction using **SET TRANSACTION** or **SET LOCAL TRANSACTION**. For details, see [SET TRANSACTION](#).

Committing a Transaction

GaussDB commits all operations of a transaction using **COMMIT** or **END**. For details, see [COMMIT | END](#).

Rolling Back a Transaction

If a fault occurs during a transaction and the transaction cannot proceed, the system performs rollback to cancel all the completed database operations related to the transaction. For details, see [ROLLBACK](#).

NOTE

If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. If one of the statements fails, the entire request will be rolled back.

7.12 SQL Syntax

7.12.1 SQL Syntax

Table 7-191 SQL syntax

Format	Description
[]	The part enclosed in brackets ([]) is optional.
...	Preceding elements can appear repeatedly.
[x y ...]	One item is selected from two or more options or no item is selected.
{ x y ... }	One item is selected from two or more options.
[x y ...] [...]	Multiple parameters or no parameter can be selected. If multiple parameters are selected, separate them with spaces.
[x y ...] [, ...]	Multiple parameters or no parameter can be selected. If multiple parameters are selected, separate them with commas (,).
{ x y ... } [...]	At least one parameter can be selected. If multiple parameters are selected, separate them with spaces.

Format	Description
{ x y ... } [,...]	At least one parameter can be selected. If multiple parameters are selected, separate them with commas (,).

7.12.2 DCL Syntax Overview

Data control language (DCL) is used to set or change the permissions of database users or roles.

Granting Rights

GaussDB provides a statement for granting rights to data objects and roles. For details, see [GRANT](#).

Revoking Rights

GaussDB provides a statement for revoking rights. For details, see [REVOKE](#).

Setting Default Rights

GaussDB allows users to set rights for objects that will be created in the future. For details, see [ALTER DEFAULT PRIVILEGES](#).

Changing Owners

GaussDB provides statements for changing owners of database objects. For details, see [REASSIGN OWNED](#).

7.12.3 DDL Syntax Overview

Data definition language (DDL) is used to define or modify an object in a database, such as a table, an index, or a view.

NOTE

GaussDB does not support DDL operations when the CN is incomplete. For example, if a CN in cluster is faulty, creating a database or a table will fail.

Defining a Role

A role is used to manage permissions. For database security, management and operation permissions can be granted to different roles. For details about related SQL statements, see [Table 7-192](#).

Table 7-192 SQL statements for defining a role

Function	SQL Statement
Creating a role	CREATE ROLE

Function	SQL Statement
Altering role attributes	ALTER ROLE
Dropping a role	DROP ROLE
Dropping the database objects owned by a database role	DROP OWNED

Defining a User

A user is used to log in to a database. Different permissions can be granted to users for managing data accesses and operations of the users. For details about related SQL statements, see [Table 7-193](#).

Table 7-193 SQL statements for defining a user

Function	SQL Statement
Creating a user	CREATE USER
Altering user attributes	ALTER USER
Dropping a user	DROP USER

Defining a CMK

Client master keys (CMKs) are used to encrypt column encryption keys (CEKs) for the encrypted database feature. CMK definition includes creating and deleting a CMK. For details about related SQL statements, see [Table 7-194](#).

Table 7-194 SQL statements for defining a CMK

Function	SQL Statement
Creating a CMK	CREATE CLIENT MASTER KEY
Deleting a CMK	DROP CLIENT MASTER KEY

Defining a CEK

CEKs are used to encrypt data for the encrypted database feature. You can create a CEK, change the client master key specified by a CEK, and delete a CEK. For details about related SQL statements, see [Table 7-194](#).

Table 7-195 SQL statements for defining a CEK

Function	SQL Statement
Creating a CEK	CREATE COLUMN ENCRYPTION KEY
Changing the client master key specified by a CEK	7.14.173-ALTER COLUMN ENCRYPTION KEY
Deleting a CEK	DROP COLUMN ENCRYPTION KEY

Defining a Database

A database is the warehouse for organizing, storing, and managing data. Defining a database includes: creating a database, altering the database attributes, and dropping the database. For details about related SQL statements, see [Table 7-196](#).

Table 7-196 SQL statements for defining a database

Function	SQL Statement
Creating a database	CREATE DATABASE
Altering database attributes	ALTER DATABASE
Dropping a Database	DROP DATABASE

Defining a Schema

A schema is the set of a group of database objects and is used to control the access to the database objects. For details about related SQL statements, see [Table 7-197](#).

Table 7-197 SQL statements for defining a schema

Function	SQL Statement
Creating a schema	CREATE SCHEMA
Altering schema attributes	ALTER SCHEMA
Dropping a schema	DROP SCHEMA

Defining a Tablespace

A tablespace is used to manage data objects and corresponds to a catalog on a disk. For details about related SQL statements, see [Table 7-198](#).

Table 7-198 SQL statements for defining a tablespace

Function	SQL Statement
Creating a tablespace	CREATE TABLESPACE
Altering tablespace attributes	ALTER TABLESPACE
Dropping a tablespace	DROP TABLESPACE

Defining a Table

A table is a special data structure in a database and is used to store data objects and relationship between data objects. For details about related SQL statements, see [Table 7-199](#).

Table 7-199 SQL statements for defining a table

Function	SQL Statement
Creating a table	CREATE TABLE
Altering table attributes	ALTER TABLE
Renaming one or more tables	RENAME TABLE
Dropping a table	DROP TABLE
Creating a table from the results of a query	CREATE TABLE AS

Defining a Partitioned Table

A partitioned table is a logical table used to improve query performance and does not store data (data is stored in common tables). For details about related SQL statements, see [Table 7-200](#).

Table 7-200 SQL statements for defining a partitioned table

Function	SQL Statement
Creating a partitioned table	CREATE TABLE PARTITION
Create a partition	ALTER TABLE PARTITION
Altering partitioned table attributes	ALTER TABLE PARTITION
Deleting a partition	ALTER TABLE PARTITION
Dropping a partitioned table	DROP TABLE

Defining an Index

An index indicates the sequence of values in one or more columns in a database table. It is a data structure that improves the speed of data access to specific information in a database table. For details about related SQL statements, see [Table 7-201](#).

Table 7-201 SQL statements for defining an index

Function	SQL Statement
Creating an index	CREATE INDEX
Altering index attributes	ALTER INDEX
Dropping an index	DROP INDEX
Rebuilding an index	REINDEX
Creating a global secondary index in a specified table	CREATE GLOBAL INDEX

Defining a Stored Procedure

A stored procedure is a set of SQL statements for achieving specific functions and is stored in the database after compiling. Users can specify a name and provide parameters (if necessary) to execute the stored procedure. For details about related SQL statements, see [Table 7-202](#).

Table 7-202 SQL statements for defining a stored procedure

Function	SQL Statement
Creating a stored procedure	CREATE PROCEDURE
Dropping a stored procedure	DROP PROCEDURE

Defining a Function

In GaussDB, a function is similar to a stored procedure, which is a set of SQL statements. The function and stored procedure are used the same. For details about related SQL statements, see [Table 7-203](#).

Table 7-203 SQL statements for defining a function

Function	SQL Statement
Creating a function	CREATE FUNCTION
Modifying attributes of a function or recompiling the function	ALTER FUNCTION

Function	SQL Statement
Dropping a function	DROP FUNCTION

Defining a Cursor

To process SQL statements, the stored procedure thread assigns a memory segment to store context association. Cursors are handles or pointers to context regions. With a cursor, the stored procedure can control alterations in context areas. For details, see [Table 7-204](#).

Table 7-204 SQL statements for defining a cursor

Function	SQL Statement
Creating a cursor	CURSOR
	DECLARE
Moving a cursor	MOVE
Closing a cursor	CLOSE

Defining a Resource Pool

A resource pool is a system catalog used by the resource load management module to specify attributes related to resource management, such as Cgroups. For details about related SQL statements, see [Table 7-205](#).

Table 7-205 SQL statements for defining a resource pool

Function	SQL Statement
Creating a resource pool	CREATE RESOURCE POOL
Altering resource attributes	ALTER RESOURCE POOL
Dropping a resource pool	DROP RESOURCE POOL

Defining an Aggregate Function

Table 7-206 SQL statements for defining an aggregate function

Function	SQL Statement
Creating an aggregate function	CREATE AGGREGATE
Modifying an aggregate function	ALTER AGGREGATE

Function	SQL Statement
Deleting an aggregate function	DROP AGGREGATE

Defining a Plug-in Extension

Table 7-207 SQL statements for defining a plug-in extension

Function	SQL Statement
Creating an extension	CREATE EXTENSION

NOTICE

The extended function is for internal use only. You are advised not to use it.

Defining a Data Type

Table 7-208 SQL statements for defining a data type

Function	SQL Statement
Creating a data type	CREATE TYPE
Modifying a data type	ALTER TYPE
Deleting a data type	DROP TYPE

Defining a Database Link

A database link can be used to remotely operate a database object. For details about corresponding SQL statements, see [Table 7-209](#).

Table 7-209 DATABASE LINK-related SQL statements

Function	SQL Statement
Creating a database link	CREATE DATABASE LINK
Modifying a database link	ALTER DATABASE LINK
Deleting a database link	DROP DATABASE LINK

Defining an Audit Policy

Table 7-210 SQL statements for defining an audit policy

Function	SQL Statement
Creating a unified audit policy	CREATE AUDIT POLICY
Modifying a unified audit policy	ALTER AUDIT POLICY
Deleting an audit policy	DROP AUDIT POLICY

Setting the `nodeis_active` Column of a Specified Node

ALTER COORDINATOR describes how to change the value of the `nodeis_active` column of a specified node in the `pgxc_node` system catalog.

Defining a Directory

Table 7-211 SQL statements for defining a directory

Function	SQL Statement
Creating a directory	CREATE DIRECTORY
Modifying attributes of a directory	ALTER DIRECTORY
Deleting a specified directory	DROP DIRECTORY

Defining a Foreign Data Wrapper

Table 7-212 SQL statements related to the foreign data wrapper

Function	SQL Statement
Creating a foreign data wrapper	CREATE FOREIGN DATA WRAPPER
Modifying a foreign data wrapper	ALTER FOREIGN DATA WRAPPER
Deleting a foreign data wrapper	DROP FOREIGN DATA WRAPPER

SQL Statements Related to the gs_global_config System Catalog

Table 7-213 SQL statements related to the gs_global_config system catalog

Function	SQL Statement
Adding and modifying parameter values in the gs_global_config system catalog	ALTER GLOBAL CONFIGURATION
Deleting parameter values from the gs_global_config system catalog	DROP GLOBAL CONFIGURATION
Inserting one or more weak passwords into the gs_global_config system catalog	CREATE WEAK PASSWORD DICTIONARY
Clearing all weak passwords in the gs_global_config system catalog	DROP WEAK PASSWORD DICTIONARY

Defining a User Group

Table 7-214 SQL statements for defining a user group

Function	SQL Statement
Creating a user group	CREATE GROUP
Modifying attributes of a user group	ALTER GROUP
Deleting a user group	DROP GROUP

Defining a Procedural Language

Table 7-215 SQL statements for defining a procedural language

Function	SQL Statement
Defining a new procedural language	CREATE LANGUAGE
Modifying the definition of a procedural language	ALTER LANGUAGE
Deleting a procedural language	DROP LANGUAGE

Defining a Masking Policy

Table 7-216 SQL statements for defining a masking policy

Function	SQL Statement
Creating a masking policy	CREATE MASKING POLICY
Modifying a masking policy	ALTER MASKING POLICY
Deleting a masking policy	DROP MASKING POLICY

Defining a Materialized View

Table 7-217 SQL statements for defining a materialized view

Function	SQL Statement
Creating a complete-refresh materialized view	CREATE MATERIALIZED VIEW
Creating a fast-refresh materialized view	CREATE INCREMENTAL MATERIALIZED VIEW
Modifying multiple auxiliary attributes of an existing materialized view	ALTER MATERIALIZED VIEW
Forcibly deleting an existing materialized view from the database	DROP MATERIALIZED VIEW
Refreshing a materialized view in complete refresh mode	REFRESH MATERIALIZED VIEW
Refreshing a materialized view in fast refresh mode	REFRESH INCREMENTAL MATERIALIZED VIEW

Defining a Node

Table 7-218 SQL statements for defining a node

Function	SQL Statement
Creating a cluster node	CREATE NODE
Modifying the definition of an existing node	ALTER NODE
Deleting a node	DROP NODE

Defining a Node Group

Table 7-219 SQL statements for defining a node group

Function	SQL Statement
Creating a cluster node group	CREATE NODE GROUP
Modifying information about an existing node group	ALTER NODE GROUP
Deleting a node group	DROP NODE GROUP

Defining a Resource Label

Table 7-220 SQL statements for defining a resource label

Function	SQL Statement
Creating a resource label	CREATE RESOURCE LABEL
Modifying a resource label	ALTER RESOURCE LABEL
Deleting a resource label	DROP RESOURCE LABEL

Defining a Row-Level Security Policy

Table 7-221 SQL statements for defining a row-level security policy

Function	SQL Statement
Creating a row-level security policy for a table	CREATE ROW LEVEL SECURITY POLICY
Modifying an existing row-level security policy	ALTER ROW LEVEL SECURITY POLICY
Deleting a row-level security policy from a table	DROP ROW LEVEL SECURITY POLICY

Defining a Sequence

Table 7-222 SQL statements for defining a sequence

Function	SQL Statement
Adding a sequence to the current database	CREATE SEQUENCE

Function	SQL Statement
Modifying parameters of an existing sequence	ALTER SEQUENCE
Deleting a sequence from the current database	DROP SEQUENCE

Defining a Foreign Server

Table 7-223 SQL statements for defining a foreign server

Function	SQL Statement
Defining a new foreign server	CREATE SERVER
Adding, modifying, and deleting parameters of an existing server	ALTER SERVER
Deleting a data server	DROP SERVER

Defining a Synonym Object

Table 7-224 SQL statements for defining a synonym object

Function	SQL Statement
Creating a synonym object	CREATE SYNONYM
Modifying the owner of a synonym object	ALTER SYNONYM
Deleting a specified synonym object	DROP SYNONYM

Defining a Trigger

Table 7-225 SQL statements for defining a trigger

Function	SQL Statement
Creating a trigger	CREATE TRIGGER
Renaming a trigger	ALTER TRIGGER
Deleting a trigger	DROP TRIGGER

Defining a View

Table 7-226 SQL statements for defining a view

Function	SQL Statement
Creating a view	CREATE VIEW
Modifying the auxiliary attributes of a view	ALTER VIEW
Forcibly deleting a view from the database	DROP VIEW

Collecting Statistics

For details about how to collect statistics related to the contents of ordinary tables in the database, see [ANALYZE | ANALYSE](#).

Creating a Synchronization Point

For details about how to create a synchronization point between nodes in a new cluster, see [CREATE BARRIER](#).

Creating an Encoding Conversion Task

For details about how to define a new conversion between two character set encodings, see [CREATE CONVERSION](#).

Defining a Model

Table 7-227 SQL statements for defining a model

Function	SQL Statement
Training a machine learning model and saving the model	CREATE MODEL
Deleting a model that has been trained and saved	DROP MODEL

Defining a Security Label

Table 7-228 SQL statements for defining a security label

Function	SQL Statement
Creating a security label	CREATE SECURITY LABEL

Function	SQL Statement
Applying, updating, or canceling a security label	SECURITY LABEL ON
Deleting a security label	DROP SECURITY LABEL

Importing a Database/Table

Table 7-229 SQL statements for data import

Function	SQL Statement
Preparation phase for importing a database	IMPDP DATABASE CREATE
Execution phase of importing a database	IMPDP RECOVER
Preparation phase for importing a table	IMPDP TABLE PREPARE
Execution phase of importing a table	IMPDP TABLE

Clearing a Recycle Bin

GaussDB provides statements for clearing a recycle bin. For details, see [PURGE](#).

Clustering a Table

GaussDB supports statements for clustering a table based on an index. For details, see [CLUSTER](#).

Defining an Object Comment

GaussDB supports statements for defining or modifying an object comment. For details, see [COMMENT](#).

Creating a Table Based on Query Results

GaussDB supports statements for creating a table based on query results and inserting queried data into the new table. For details, see [SELECT INTO](#).

Restoring a Table to an Earlier State

GaussDB allows you to restore a table to an earlier state in the event of a manual operation or application error. For details, see [TIMECAPSULE TABLE](#).

Clearing Table Data

GaussDB supports statements for quickly deleting all rows from a table. For details, see [TRUNCATE](#).

Recycling Storage Space

GaussDB supports statements for recycling storage space occupied by deleted rows in a table or B-Tree index. For details, see [VACUUM](#).

7.12.4 DML Syntax Overview

Data manipulation language (DML) is used to perform operations on data in database tables, such as inserting, updating, querying, or deleting data.

Inserting Data

Inserting data refers to adding one or multiple records to a database table. For details, see [INSERT](#).

Updating Data

Updating data refers to modifying one or multiple records in a database table. For details, see [UPDATE](#).

Modifying or Inserting Data

GaussDB provides statements for matching data in a target table with that in a source table based on join conditions. If data matches, UPDATE is executed on the target table; if data does not match, INSERT is executed. For details, see [MERGE INTO](#).

Querying Data

The database query statement SELECT is used to search required information in a database. For details, see [SELECT](#).

Deleting Data

GaussDB provides statements for deleting data that meets specified conditions from a table. For details, see [DELETE](#).

Copying Data

GaussDB provides a statement for copying data between tables and files. For details, see [COPY](#).

Locks

GaussDB provides multiple lock modes to control concurrent accesses to table data. For details, see [LOCK](#).

GaussDB provides bucket-level locks. For details, see [LOCK BUCKETS](#).

Calling a Function

GaussDB provides three statements for calling functions. These statements are the same in the syntax structure. For details, see [CALL](#).

Prepared Statements

Table 7-230 SQL statements related to prepared statements

Function	SQL Statement
Executing a prepared statement	EXECUTE
Deallocating a prepared statement	DEALLOCATE

Session Management

A session is a connection established between the user and the database. [Table 7-231](#) lists the related SQL statements.

Table 7-231 SQL statements related to sessions

Function	SQL Statement
Altering a session	ALTER SESSION
Killing a session	ALTER SYSTEM KILL SESSION

Executing an Anonymous Code Block

GaussDB provides statements for executing an anonymous code block. For details, see [DO](#).

Executing an SQL Statement on a Specified Node

GaussDB provides statements for executing an SQL statement on a specified node. For details, see [EXECUTE DIRECT](#).

Exporting Files

Table 7-232 SQL statements for exporting files

Function	SQL Statement
Exporting all physical files in a database	EXPDP DATABASE
Exporting all files related to the table	EXPDP TABLE

Retrieving Data Using a Cursor

GaussDB provides statements for retrieving data using a created cursor. For details, see [FETCH](#).

Inserting or Replacing Data

GaussDB provides statements for inserting or replacing data in a table. For details, see [REPLACE](#).

Calculating a Value based on an Expression

GaussDB provides statements for calculating a value of a row or a group of rows based on a given value expression. For details, see [VALUES](#).

Importing Data

GaussDB provides a statement for importing data from a file to a specified table in the database. For details, see [LOAD DATA](#).

7.12.5 Other Syntax List

In addition to DCL, DDL, and DML syntax, GaussDB also provides syntax for other functions.

Shutting Down The Current Node

GaussDB allows users to run the **shutdown** command to shut down the current database node. For details, see [SHUTDOWN](#).

SQL Statements Related to Bucket Scale-out

GaussDB supports statements used by the scale-out tool to notify the kernel of the buckets that have been migrated. For details, see [MARK BUCKETS](#).

Clearing Database Connections

GaussDB supports statements for clearing database connections. For details, see [CLEAN CONNECTION](#).

Showing an Execution Plan of an SQL Statement

GaussDB provides statements for showing an execution plan of an SQL statement. For details, see [EXPLAIN](#).

Storage Execution Plan

GaussDB provides statements for storing query execution plan information in the **PLAN_TABLE** table. For details, see [EXPLAIN PLAN](#).

Prediction:

GaussDB provides statements for using a trained model to perform inference tasks. For details, see [PREDICT BY](#).

Creating a Prepared Statement

GaussDB provides statements for creating a prepared statement. For details, see [PREPARE](#).

SQL Statements Related to Transactions

Table 7-233 SQL statements related to transactions

Function	SQL Statement
Rolling back the current transaction and canceling the changes in the transaction	ABORT
	ROLLBACK
Starting a transaction	BEGIN
	SET TRANSACTION
	START TRANSACTION
Setting transaction log checkpoints	CHECKPOINT
Committing the current transaction	COMMIT END
Committing a prepared two-phase transaction	COMMIT PREPARED
Preparing the current transaction for two-phase commit	PREPARE TRANSACTION
Deleting a savepoint previously defined for the current transaction	RELEASE SAVEPOINT
Canceling a transaction ready for two-phase commit	ROLLBACK PREPARED
Rolling back to a savepoint	ROLLBACK TO SAVEPOINT
Creating a savepoint in the current transaction	SAVEPOINT
Setting constraint check timing for the current transaction	SET CONSTRAINTS

Modifying, Displaying, and Restoring a Runtime Parameter

Table 7-234 SQL statements for modifying, displaying, and restoring a runtime parameter

Function	SQL Statement
Modifying a runtime parameter	SET
Showing the current value of a runtime parameter	SHOW
Restoring a runtime parameter to the default value	RESET

Setting a User Identifier

Table 7-235 SQL statements for setting a user identifier

Function	SQL Statement
Setting the current user identifier of the current session	SET ROLE
Setting the session user identifier and the current user identifier of the current session to a specified user	SET SESSION AUTHORIZATION

7.12.6 A

7.12.6.1 ABORT

Description

Rolls back the current transaction and cancels the changes in the transaction.

This command is equivalent to **ROLLBACK**, and is present only for historical reasons. Now ROLLBACK is recommended.

Precautions

ABORT has no impact outside a transaction, but will return a NOTICE message.

Syntax

```
ABORT [ WORK | TRANSACTION ] ;
```

permission on the new schema. To change the owner, you must be a direct or indirect member of the new role, and the role must have the CREATE permission on the aggregate function's schema. (These constraints restrict the owner from performing illegal operations by deleting and rebuilding aggregate functions.) However, a user with the SYSADMIN permission can change the ownership of an aggregate function in any way.

Syntax

```
ALTER AGGREGATE name ( argtype [ , ... ] ) RENAME TO new_name;  
ALTER AGGREGATE name ( argtype [ , ... ] ) OWNER TO new_owner;  
ALTER AGGREGATE name ( argtype [ , ... ] ) SET SCHEMA new_schema;
```

Parameters

- **name**
Name (optionally schema-qualified) of an existing aggregate function.
- **argtype**
Input data type of the aggregate function. To reference a zero-parameter aggregate function, you can write an asterisk (*) instead of a list of input data types.
- **new_name**
New name of the aggregate function.
- **new_owner**
New owner of the aggregate function.
- **new_schema**
New schema of the aggregate function.

Examples

- Change the name of the aggregate function.
-- Create a user-defined function.
gaussdb=# CREATE OR REPLACE FUNCTION int_add(int,int)
returns int as \$BODY\$
declare
begin
return \$1 + \$2;
end;
\$BODY\$ language plpgsql;

-- Create an aggregate function.
gaussdb=# CREATE AGGREGATE myavg (int)
(
sfunc = int_add,
stype = int,
initcond = '0'
);

-- Rename the aggregate function **myavg** that accepts int-type parameters to **my_average**.
gaussdb=# ALTER AGGREGATE myavg(int) RENAME TO my_average;
- Change the owner of the aggregate function.
-- Create a user **joe**.
gaussdb=# CREATE USER joe PASSWORD '*****';

-- Change the owner of the aggregate function **my_average** that accepts int-type parameters to **joe**.
gaussdb=# ALTER AGGREGATE my_average(int) OWNER TO joe;

- Change the schema of the aggregate function.

```
-- Create a schema myschema:
gaussdb=# CREATE SCHEMA myschema;

-- Move the aggregate function my_average that accepts int-type parameters to myschema.
gaussdb=# ALTER AGGREGATE my_average(int) SET SCHEMA myschema;

-- Delete the schema, user, and related function.
gaussdb=# DROP SCHEMA myschema CASCADE;
gaussdb=# DROP USER joe;
gaussdb=# DROP FUNCTION int_add(int,int);
```

Helpful Links

[CREATE AGGREGATE](#) and [DROP AGGREGATE](#)

Compatibility

The SQL standard does not contain the ALTER AGGREGATE statement.

7.12.6.3 ALTER AUDIT POLICY

Description

Modifies the unified audit policy.

Precautions

- Only the **poladmin**, **sysadmin**, or initial user has the permission to maintain audit policies.
- The unified audit policy takes effect only after **enable_security_policy** is set to **on**.

Syntax

Add or delete an operation type in the audit policy.

```
ALTER AUDIT POLICY [ IF EXISTS ] policy_name { ADD | REMOVE } { privilege_audit_clause | access_audit_clause };
```

Modify the filter criteria in the audit policy.

```
ALTER AUDIT POLICY [ IF EXISTS ] policy_name MODIFY ( filter_group_clause );
```

Delete the filter criteria from the audit policy.

```
ALTER AUDIT POLICY [ IF EXISTS ] policy_name DROP FILTER;
```

Modify the description of the audit policy.

```
ALTER AUDIT POLICY [ IF EXISTS ] policy_name COMMENTS policy_comments;
```

Enable or disable the audit policy.

```
ALTER AUDIT POLICY [ IF EXISTS ] policy_name { ENABLE | DISABLE };
```

- `privilege_audit_clause`

DDL operation type and target resource label in the audit policy.

```
PRIVILEGES ( { DDL | ALL } [ ON LABEL ( resource_label_name [, ... ] ) ] )
```

- `access_audit_clause`

DML operation type and target resource label in the audit policy.

```
ACCESS ( { DML | ALL } [ ON LABEL ( resource_label_name [, ... ] ) ] )
```

- `filter_group_clause`

Filter criteria in the audit policy.

```
FILTER ON { filter_type ( filter_value [, ... ] ) } [, ... ]
```

Parameters

- **policy_name**
Specifies the audit policy name, which must be unique.
Value range: a string. It must comply with the [naming convention](#).
- **resource_label_name**
Specifies the resource label name.
- **DDL**
Specifies the operations that will be audited within the database: ALTER, ANALYZE, COMMENT, CREATE, DROP, GRANT, REVOKE, SET, and SHOW.
- **DML**
Specifies the operations that are audited within the database: COPY, DEALLOCATE, DELETE_P, EXECUTE, REINDEX, INSERT, PREPARE, SELECT, TRUNCATE, and UPDATE.
- **ALL**
Specifies all operations supported by the specified DDL or DML statements in the database. When the form is { DDL | ALL }, **ALL** indicates all DDL operations. When the form is { DML | ALL }, **ALL** indicates all DML operations.

- **filter_type**
Specifies the types of information to be filtered by the policy: **IP**, **ROLES**, and **APP**.
- **filter_value**
Indicates the detailed information to be filtered.
- **policy_comments**
Records description information of audit policies.
- **ENABLE|DISABLE**
Enables or disables the unified audit policy.

Examples

- Add or delete an operation type in the audit policy.
-- Create audit policy adt1 for executing CREATE on the database.
gaussdb=# CREATE AUDIT POLICY adt1 PRIVILEGES CREATE;

-- Add DROP to the adt1 audit policy.
gaussdb=# ALTER AUDIT POLICY adt1 ADD PRIVILEGES (DROP);

-- Delete DROP from the adt1 audit policy.
gaussdb=# ALTER AUDIT POLICY adt1 REMOVE PRIVILEGES (DROP);
- Modify the comments of the audit policy.
-- Change the comment of the adt1 audit policy to adt1_comments.
gaussdb=# ALTER AUDIT POLICY adt1 COMMENTS 'adt1_comments';
- Modify the filter information of the audit policy.
-- Create a user **bob_audit**.
gaussdb=# CREATE USER bob_audit PASSWORD '*****';

-- Change the filtering user of the adt1 audit policy to **bob_audit**.
gaussdb=# ALTER AUDIT POLICY adt1 MODIFY (FILTER ON (ROLES(bob_audit)));

-- Delete user **bob_audit**.
gaussdb=# DROP USER bob_audit;
- Delete the filter criteria from the audit policy.
-- Delete the filter criteria in the adt1 audit policy.
gaussdb=# ALTER AUDIT POLICY adt1 DROP FILTER;
- Disable the audit policy.
-- Disable the adt1 audit policy.
gaussdb=# ALTER AUDIT POLICY adt1 DISABLE;

-- Delete the adt1 audit policy.
gaussdb=# DROP AUDIT POLICY adt1;

Helpful Links

[CREATE AUDIT POLICY](#) and [DROP AUDIT POLICY](#)

7.12.6.4 ALTER COLUMN ENCRYPTION KEY

Description

Encrypts the CMKs of CEKs in round robin (RR) mode and encrypts the plaintext of CEKs.

Precautions

- This syntax is specific to the fully-encrypted database. When connecting to the database server, enable the fully-encrypted database before using this syntax.
- This syntax takes effect on CMKs only. Encrypting the plaintext of CEKs does not change the ciphertext of the encrypted columns.

Syntax

```
ALTER COLUMN ENCRYPTION KEY column_encryption_key_name WITH VALUES ( CLIENT_MASTER_KEY = client_master_key_name );
```

Parameters

- **column_encryption_key_name**
Specifies the key name. In the same namespace, the value of this parameter must be unique.
Value range: a string. It must comply with the [naming convention](#).
- **client_master_key_name**
Specifies the CMK used to encrypt the CEK. The value is the CMK name, which is created using the CREATE CLIENT MASTER KEY syntax. The encrypted CMKs are different from those specified before RR encryption.

NOTICE

The constraints of using Chinese cryptographic algorithms are as follows: SM2, SM3, and SM4 are Chinese cryptographic algorithms. To avoid legal risks, these algorithms must be used together. The Chinese cryptographic algorithms used for the RR encryption must be the same as those used before RR encryption.

Helpful Links

[CREATE COLUMN ENCRYPTION KEY](#) and [DROP COLUMN ENCRYPTION KEY](#)

7.12.6.5 ALTER COORDINATOR

Description

Modifies the CN status. You can run the SQL statement on any normal CN in the cluster to change the value of the **nodeis_active** field of a specified node in the pgxc_node system catalog. You can also specify the nodes on which the system catalog is modified.

Precautions

- ALTER COORDINATOR is a statement used to modify the system catalog. Only the administrator and users in internal maintenance mode (for example, CM administrator) can execute this statement. This statement is dedicated for the

CN removal feature and must be used together with other operations. You are advised not to run it by yourself.

- After this statement is executed, **SELECT reload_active_coordinator()** needs to be called to update the connection pool information of the node on which the system catalog is modified.

Syntax

```
ALTER COORDINATOR nodename SET status  
WITH (nodename1[, nodename2, nodename3 ...]);
```

Parameters

- **nodename**
Specifies the CN name corresponding to a row of records in the `pgxc_node` system catalog. After the node name is specified, the value of **nodeis_active** in the record is changed.
Value range: a string. Only CNs are supported. Ensure that the node name has a corresponding record in the `pgxc_node` system catalog.
- **status**
Specifies the CN status, that is the updated value of **nodeis_active** in the `pgxc_node` system catalog.
Value range:
 - FALSE
 - TRUE
- **nodename1[, nodename2, nodename3 ...]**
Specifies the range of nodes on which the SQL statement is executed. When **ALTER COORDINATOR** is executed, the SQL statement is automatically delivered to all nodes in the range. The current execution node must be included.
Value range: a string. Only CNs are supported. Ensure that the node name has a corresponding record in the `pgxc_node` system catalog and the node is normal. Otherwise, the SQL statement fails to be executed.

Examples

- Remove a faulty CN.
-- The cluster has three CNs: **cn_5001**, **cn_5002**, and **cn_5003**, which are working properly. If **cn_5001** is faulty and the removal time meets the requirement, **cn_5001** needs to be removed from the cluster.
`gaussdb=# ALTER COORDINATOR cn_5001 SET False WITH (cn_5002,cn_5003);`

-- Refresh the `pgxc_node` system catalog. On the **cn_5002** and **cn_5003** nodes, run the following SQL statement to update the value of **nodeis_active** corresponding to the **cn_5001** record in the `pgxc_node` system catalog to **false**:
`gaussdb=# SELECT reload_active_coordinator();`

-- Check the CN status. The value of **nodeis_active** changes to **f** (false).
`gaussdb=# SELECT nodeis_active,node_name FROM pgxc_node where node_name='cn_5001';`

nodeis_active	node_name
f	cn_5001

(1 row)
- Restore the CN whose fault has been rectified.
-- After the **cn_5001** fault is rectified, add **cn_5001** back to the cluster.
`gaussdb=# ALTER COORDINATOR cn_5001 SET True WITH (cn_5002,cn_5003);`

```
-- Refresh the pgxc_node system catalog. On the cn_5002 and cn_5003 nodes, run the following SQL
statement to update the value of nodeis_active corresponding to the cn_5001 record in the
pgxc_node system catalog to true:
gaussdb=# SELECT reload_active_coordinator();

-- Check the CN status. The value of nodeis_active changes to t (true).
gaussdb=# SELECT nodeis_active,node_name FROM pgxc_node where node_name='cn_5001';
nodeis_active | node_name
-----+-----
t             | cn_5001
(1 row)
```

7.12.6.6 ALTER DATABASE

Description

Modifies a database, including its name, owner, object isolation, and connection limitation.

Precautions

- Only the database owner or a user granted with the ALTER permission can run the ALTER DATABASE command. The system administrator has this permission by default. The following are permission constraints depending on the attributes to be modified:
 - To modify the database name, you must have the CREATEDB permission.
 - To modify a database owner, you must be a database owner or system administrator and a member of the new owner role, with the CREATEDB permission.
 - To modify the default tablespace of the database, the user must have the CREATE permission on the tablespace. This statement physically migrates tables and indexes in a default tablespace to a new tablespace. Note that tables and indexes outside the default tablespace are not affected.
- You are not allowed to rename a database in use. To rename it, connect to another database.

Syntax

- Modify the maximum number of connections to the database.

```
ALTER DATABASE database_name
[ WITH ] CONNECTION LIMIT connlimit;
```
- Rename the database.

```
ALTER DATABASE database_name
RENAME TO new_name;
```
- Change the database owner.

```
ALTER DATABASE database_name
OWNER TO new_owner;
```
- Change the default tablespace of the database.

```
ALTER DATABASE database_name
SET TABLESPACE new_tablespace;
```

NOTE

If some tables or objects in the database have been created in `new_tablespace`, the default tablespace of the database cannot be changed to **new_tablespace**. An error will be reported during the execution.

- Modify the object isolation attribute of the database.
`ALTER DATABASE database_name [WITH] { ENABLE | DISABLE } PRIVATE OBJECT;`

NOTE

- To modify the object isolation attribute of a database, the database must be connected. Otherwise, the modification will fail.
- For a new database, the object isolation attribute is disabled by default. After the database object isolation attribute is enabled, the database automatically adds row-level security policies to the system catalogs PG_CLASS, PG_ATTRIBUTE, PG_PROC, PG_NAMESPACE, PGXC_SLICE, and PG_PARTITION. Common users can only view the objects (tables, functions, views, and columns) that they have the permission to access. This attribute does not take effect for administrators. After this attribute is enabled, administrators can still view all database objects.
- Change the database time zone.
`ALTER DATABASE database_name SET DBTIMEZONE = time_zone;`
- Bind a node group to the hash bucket table to determine the bucket mapping.
`ALTER DATABASE database_name
TO GROUP group_name ;`
- Migrate a specified bucket from one DN to another.
`ALTER DATABASE database_name
MOVE BUCKETS(bucketlist) FROM datanode_name TO datanode_name;`

NOTE

This statement can be called only during hash bucket scale-out. It is a hash bucket database-level redistribution command.

Example:

```
ALTER DATABASE testdb MOVE BUCKETS (0, 1, 2, 3) FROM datanode1 TO datanode3;
```

- Enable or disable the ILM feature of the database.
`ALTER DATABASE set ilm = { on | off } ;`

Parameters

- **database_name**
Specifies the name of the database whose attributes are to be modified.
Value range: a string. It must comply with the [naming convention](#).
- **connlimit**
Specifies the maximum number of concurrent connections that can be made to this database (excluding administrators' connections).
Value range: an integer ranging from -1 to $2^{31} - 1$. You are advised to set this parameter to an integer ranging from 1 to 50. The default value -1 indicates that there is no restriction on the number of concurrent connections.
- **new_name**
Specifies the new name of a database.
Value range: a string. It must comply with the [naming convention](#).
- **new_owner**
Specifies the new owner of a database.
Value range: a string. It must be a valid username.
- **new_tablespace**
Specifies the new default tablespace of a database. The tablespace exists in the database. The default tablespace is **pg_default**.

Value range: a string. It must be a valid tablespace name.

- **configuration_parameter**

Sets a specified database session parameter to a specified value. If the value is **DEFAULT** or **RESET**, the default setting is used in the new session. **OFF** disables the setting.

NOTICE

The current version does not support setting database-level parameters.

- **value**

Sets a specified database session parameter to a specified value. If the value is **DEFAULT** or **RESET**, the default setting is used in the new session. **OFF** disables the setting.

Value range: a string.

- **DEFAULT**

- **OFF**

- **RESET**

- User-specified value: The value must meet the restriction of the modified parameter.

- **FROM CURRENT**

Uses the value of **configuration_parameter** of the current session.

- **time_zone**

Sets the time zone of the database specified by **database_name**. You must have the permission on the corresponding database.

Value range: a string.

- Time zones supported by the system and their abbreviations.

- -15:59~+15:00

- **RESET configuration_parameter**

Resets the specified database session parameter.

NOTICE

The current version does not support resetting database-level parameters.

- **RESET ALL**

Resets all database session parameters.

NOTICE

The current version does not support resetting database-level parameters.

- **group_name**
Specifies the name of the node group bound to the hash bucket table.
Common users can only bind the table to the installation node group but cannot modify it.

NOTE

- If you modify the default tablespace of a database, the tables and indexes in the old tablespace are moved into the new tablespace. This operation does not affect the tables or indexes in other non-default tablespaces.
 - The modified database session parameter values will take effect in the next session.
 - After setting the parameters, you need to manually run the **CLEAN CONNECTION** command to clear the old connections. Otherwise, the parameter values between cluster nodes may be inconsistent.
- **bucketlist**
Specifies the bucketlist involved in redistribution
Value range: a string. The value range of each bucket is [0,1023].
 - **datanode_name**
Specifies the name of the node involved in bucket migration.
Value range: a string. It must comply with the [naming convention](#).

Examples

- Rename the database.
-- Create the database testdb.
gaussdb=# CREATE DATABASE testdb;

-- Rename **testdb** to **test_db1**.
gaussdb=# ALTER DATABASE testdb RENAME TO test_db1;
- Change the maximum number of database connections.
-- Change the maximum number of connections to **test_db1** to **100**.
gaussdb=# ALTER DATABASE test_db1 WITH CONNECTION LIMIT 100;

-- View the **test_db1** information.
gaussdb=# SELECT datname,datconlimit FROM pg_database WHERE datname = 'test_db1';
datname | datconlimit
-----+-----
test_db1 | 100
(1 row)
- Change the database owner.
-- Create user **scott**.
gaussdb=# CREATE USER scott PASSWORD '*****';

-- Change the owner of **test_db1** to **scott**.
gaussdb=# ALTER DATABASE test_db1 OWNER TO scott;

-- View the **test_db1** information.
gaussdb=# SELECT t1.datname, t2.username
FROM pg_database t1, pg_user t2
WHERE t1.datname='test_db1' AND t1.datdba=t2.usesysid;
datname | username
-----+-----
test_db1 | scott
(1 row)
- Change the default tablespace of the database.
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Modify the default tablespace of **test_db1**.

```
gaussdb=# ALTER DATABASE test_db1 SET TABLESPACE tbs_data1;

-- View the test_db1 information.
gaussdb=# SELECT t1.datname AS database, t2.spcname AS tablespace
          FROM pg_database t1, pg_tablespace t2
          WHERE t1.dattablespace = t2.oid AND
                t1.datname = 'test_db1';
 database | tablespace
-----+-----
 test_db1 | tbs_data1
(1 row)
```

- **Modify the object isolation attribute of the database.**

```
-- Create user jack.
gaussdb=# CREATE USER jack PASSWORD '*****';

-- Create the test_tbl1 table in test_db1.
gaussdb=# \c test_db1
test_db1=# CREATE TABLE test_tbl1(c1 int,c2 int);

-- Switch to user jack and view pg_tables.
test_db1=# SET ROLE jack PASSWORD '*****';
test_db1=> SELECT tablename FROM pg_tables WHERE tablename = 'test_tbl1';
 tablename
-----
 test_tbl1
(1 row)

-- Modify the object isolation attribute.
test_db1=> SET ROLE scott PASSWORD '*****';
test_db1=> ALTER DATABASE test_db1 ENABLE PRIVATE OBJECT;

-- Switch to user jack and view pg_tables.
test_db1=> SET ROLE jack PASSWORD '*****';

-- Due to the isolation attribute, 0 data records can be queried.
test_db1=> SELECT tablename FROM pg_tables WHERE tablename = 'test_tbl1';
 tablename
-----
(0 rows)

-- Switch to the default user and perform the deletion.
test_db1=> RESET ROLE;
test_db1=# DROP TABLE public.test_tbl1;

-- Switch to the default database. Change the database name based on the actual situation.
test_db1=# \c postgres
gaussdb=# DROP DATABASE test_db1;
gaussdb=# DROP TABLESPACE tbs_data1;
gaussdb=# DROP USER jack;
gaussdb=# DROP USER scott;
```

Helpful Links

[CREATE DATABASE](#) and [DROP DATABASE](#)

7.12.6.7 ALTER DATABASE LINK

Description

Modifies database link objects. For details about database links, see [DATABASE LINK](#).

Precautions

Currently, only the username and password can be modified for database links.

Syntax

```
ALTER [PUBLIC] DATABASE LINK dblink_name  
[CONNECT TO 'user_name' IDENTIFIED BY 'password'];
```

Parameters

- **dblink_name**
Name of a connection.
- **user_name**
Username for connecting to a remote database.
- **password**
Password for connecting to a remote database.
- **PUBLIC**
Connection type. If **PUBLIC** is not specified, the database link is private by default.

Examples

```
-- Create an ORA-compatible data record.  
gaussdb=# CREATE DATABASE ora_test_db DBCOMPATIBILITY 'ORA';  
  
-- Switch to another database.  
gaussdb=# \c ora_test_db  
  
-- Create a user with the system administrator permission.  
ora_test_db=# CREATE USER user01 WITH SYSADMIN PASSWORD '*****';  
ora_test_db=# SET ROLE user01 PASSWORD '*****';  
  
-- Create a public database link.  
ora_test_db=# CREATE PUBLIC DATABASE LINK public_dblink CONNECT TO 'user01' IDENTIFIED BY '*****'  
USING (host '192.168.11.11',port '54399',dbname 'db01');  
  
-- Create a common user.  
ora_test_db=# CREATE USER user2 PASSWORD '*****';  
  
-- Modify database link object information.  
ora_test_db=# ALTER PUBLIC DATABASE LINK public_dblink CONNECT TO 'user2' IDENTIFIED BY '*****';  
  
-- Delete a public database link.  
ora_test_db=# DROP PUBLIC DATABASE LINK public_dblink;  
  
-- Delete the user.  
ora_test_db=# RESET ROLE;  
ora_test_db=# DROP USER user01;  
ora_test_db=# DROP USER user2;  
  
-- Switch back to the initial database and delete the test database. Replace postgres with the actual  
database name.  
ora_test_db=# \c postgres  
gaussdb=# DROP DATABASE ora_test_db;
```

Helpful Links

[CREATE DATABASE LINK](#) and [DROP DATABASE LINK](#)

7.12.6.8 ALTER DEFAULT PRIVILEGES

Description

ALTER DEFAULT PRIVILEGES is used to modify the default permissions of a user on a specific object in the database. It does not affect the permissions assigned to existing objects.

Precautions

Currently, you can change only the permissions for tables (including views), sequences, functions, types, client master keys of encrypted databases, and column encryption keys.

Syntax

```
ALTER DEFAULT PRIVILEGES
  [ FOR { ROLE | USER } target_role [, ...] ]
  [ IN SCHEMA schema_name [, ...] ]
  abbreviated_grant_or_revoke;
```

- **abbreviated_grant_or_revoke** grants or revokes permissions on some objects.

```
grant_on_tables_clause
| grant_on_sequences_clause
| grant_on_functions_clause
| grant_on_types_clause
| grant_on_client_master_keys_clause
| grant_on_column_encryption_keys_clause
| revoke_on_tables_clause
| revoke_on_sequences_clause
| revoke_on_functions_clause
| revoke_on_types_clause
| revoke_on_client_master_keys_clause
| revoke_on_column_encryption_keys_clause
```

- **grant_on_tables_clause** grants permissions on tables.

```
GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | ALTER | DROP |
COMMENT | INDEX | VACUUM }
[, ...] | ALL [ PRIVILEGES ] }
ON TABLES
TO { [ GROUP ] role_name | PUBLIC } [, ...]
[ WITH GRANT OPTION ]
```

- **grant_on_sequences_clause** grants permissions on sequences.

```
GRANT { { SELECT | UPDATE | USAGE | ALTER | DROP | COMMENT }
[, ...] | ALL [ PRIVILEGES ] }
ON SEQUENCES
TO { [ GROUP ] role_name | PUBLIC } [, ...]
[ WITH GRANT OPTION ]
```

- **grant_on_functions_clause** grants permissions on functions.

```
GRANT { { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
ON FUNCTIONS
TO { [ GROUP ] role_name | PUBLIC } [, ...]
[ WITH GRANT OPTION ]
```

- **grant_on_types_clause** grants permissions on types.

```
GRANT { { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }
ON TYPES
TO { [ GROUP ] role_name | PUBLIC } [, ...]
[ WITH GRANT OPTION ]
```

- **grant_on_client_master_keys_clause** grants permissions on CMKs.

```
GRANT { { USAGE | DROP } [, ...] | ALL [ PRIVILEGES ] }
ON CLIENT_MASTER_KEYS
TO { [ GROUP ] role_name | PUBLIC } [, ...]
[ WITH GRANT OPTION ]
```

- **grant_on_column_encryption_keys_clause** grants permissions on column encryption keys.

```
GRANT { { USAGE | DROP } [, ...] | ALL [ PRIVILEGES ] }  
ON COLUMN_ENCRYPTION_KEYS  
TO { [ GROUP ] role_name | PUBLIC } [, ...]  
[ WITH GRANT OPTION ]
```

- **revoke_on_tables_clause** revokes permissions on tables.

```
REVOKE [ GRANT OPTION FOR ]  
{ { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | ALTER | DROP | COMMENT |  
INDEX | VACUUM }  
[, ...] | ALL [ PRIVILEGES ] }  
ON TABLES  
FROM { [ GROUP ] role_name | PUBLIC } [, ...]  
[ CASCADE | RESTRICT | CASCADE CONSTRAINTS ]
```

- **revoke_on_sequences_clause** revokes permissions on sequences.

```
REVOKE [ GRANT OPTION FOR ]  
{ { SELECT | UPDATE | USAGE | ALTER | DROP | COMMENT }  
[, ...] | ALL [ PRIVILEGES ] }  
ON SEQUENCES  
FROM { [ GROUP ] role_name | PUBLIC } [, ...]  
[ CASCADE | RESTRICT | CASCADE CONSTRAINTS ]
```

- **revoke_on_functions_clause** revokes permissions on functions.

```
REVOKE [ GRANT OPTION FOR ]  
{ { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }  
ON FUNCTIONS  
FROM { [ GROUP ] role_name | PUBLIC } [, ...]  
[ CASCADE | RESTRICT | CASCADE CONSTRAINTS ]
```

- **revoke_on_types_clause** revokes permissions on types.

```
REVOKE [ GRANT OPTION FOR ]  
{ { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [ PRIVILEGES ] }  
ON TYPES  
FROM { [ GROUP ] role_name | PUBLIC } [, ...]  
[ CASCADE | RESTRICT | CASCADE CONSTRAINTS ]
```

- **revoke_on_client_master_keys_clause** revokes permissions on CMKs.

```
REVOKE [ GRANT OPTION FOR ]  
{ { USAGE | DROP } [, ...] | ALL [ PRIVILEGES ] }  
ON CLIENT_MASTER_KEYS  
FROM { [ GROUP ] role_name | PUBLIC } [, ...]  
[ CASCADE | RESTRICT | CASCADE CONSTRAINTS ]
```

- **revoke_on_column_encryption_keys_clause** revokes permissions on CEKs.

```
REVOKE [ GRANT OPTION FOR ]  
{ { USAGE | DROP } [, ...] | ALL [ PRIVILEGES ] }  
ON COLUMN_ENCRYPTION_KEYS  
FROM { [ GROUP ] role_name | PUBLIC } [, ...]  
[ CASCADE | RESTRICT | CASCADE CONSTRAINTS ]
```

Parameters

- **target_role**
Specifies the name of an existing role. If **FOR ROLE/USER** is omitted, the current role is assumed.
Value range: an existing role name
- **schema_name**
Specifies the name of an existing schema.
target_role must have the **CREATE** permission for **schema_name**.
Value range: an existing schema name
- **role_name**
Specifies the name of an existing role to grant or revoke permissions for.

Value range: an existing role name

NOTICE

To drop a role for which the default permissions have been granted, reverse the changes in its default permissions or use **DROP OWNED BY** to get rid of the default permission entry for the role.

Examples

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Grant the SELECT permission on all the tables (and views) in tpcds to every user.
gaussdb=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds GRANT SELECT ON TABLES TO PUBLIC;

-- Create a common user jack.
gaussdb=# CREATE USER jack PASSWORD '*****';

-- Grant the INSERT permission on all the tables in tpcds to the user jack.
gaussdb=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds GRANT INSERT ON TABLES TO jack;

-- Grant the INSERT permission on all the tables created by jack in tpcds to the user jack.
gaussdb=# GRANT USAGE,CREATE ON SCHEMA tpcds TO jack;
gaussdb=# ALTER DEFAULT PRIVILEGES FOR ROLE jack IN SCHEMA tpcds GRANT INSERT ON TABLES TO jack;

-- Revoke the preceding permissions.
gaussdb=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds REVOKE SELECT ON TABLES FROM PUBLIC;
gaussdb=# ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds REVOKE INSERT ON TABLES FROM jack;

-- Delete user jack.
gaussdb=# DROP USER jack CASCADE;

-- Delete the schema.
gaussdb=# DROP SCHEMA tpcds;
```

[GRANT](#) and [REVOKE](#)

7.12.6.9 ALTER DIRECTORY

Description

Modifies directory attributes.

Precautions

- Currently, only the directory owner can be changed.
- When **enable_access_server_directory** is set to **off**, only the initial user is allowed to change the directory owner. When **enable_access_server_directory** is set to **on**, users with the **SYSADMIN** permission and the directory object owner can change the directory object owner, and the user who changes the owner is required to be a member of the new owner.

Syntax

```
ALTER DIRECTORY directory_name  
OWNER TO new_owner;
```

Parameters

- **directory_name**
Specifies the name of a directory to be modified. The value must be an existing directory name.
- **new_owner**
Specifies the new owner of the directory.

Examples

```
-- Create a directory.  
gaussdb=# CREATE OR REPLACE DIRECTORY dir as '/tmp/';  
  
-- Create a user.  
gaussdb=# CREATE USER jim PASSWORD '*****';  
  
-- Change the owner of the directory.  
gaussdb=# ALTER DIRECTORY dir OWNER TO jim;  
  
-- Delete the directory object.  
gaussdb=# DROP DIRECTORY dir;  
  
-- Delete the user.  
gaussdb=# DROP USER jim;
```

[CREATE DIRECTORY](#) and [DROP DIRECTORY](#)

7.12.6.10 ALTER FOREIGN DATA WRAPPER

Description

Modifies the definition of a foreign data wrapper.

Precautions

- Only initial users and system administrators can modify foreign data wrappers.
- The ALTER statement can be successfully executed only when **support_extended_features** is set to **on**.

Syntax

- Set attributes of a foreign data wrapper.

```
ALTER FOREIGN DATA WRAPPER name  
[ HANDLER handler_function | NO HANDLER ]  
[ VALIDATOR validator_function | NO VALIDATOR ]  
[ OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] ) ];
```

- Set a new owner.
`ALTER FOREIGN DATA WRAPPER name OWNER TO new_owner;`
- Set a new name.
`ALTER FOREIGN DATA WRAPPER name RENAME TO new_name;`

Parameters

- **name**
Specifies a name of an existing foreign data wrapper.
- **HANDLER handler_function**
Specifies a new handler function for a foreign data wrapper.
- **NO HANDLER**
Specifies that a foreign data wrapper no longer has the handler function.

NOTICE

Foreign tables that use foreign data wrappers but do not have handlers cannot be accessed.

-
- **VALIDATOR validator_function**
Specifies a new validator function for a foreign data wrapper.

NOTICE

Depending on the new validator, existing options for the foreign data wrappers, dependent servers, user mapping, and foreign tables may be invalid. Before using foreign data wrapper, ensure that these options are correct. However, any options specified in the **ALTER FOREIGN DATA WRAPPER** command will be checked using the new validator function.

-
- **NO VALIDATOR**
Specifies that a foreign data wrapper no longer has the validator function.
 - **OPTIONS ([ADD | SET | DROP] option ['value'] [, ...])**
Modifies the options of a foreign data wrapper. **ADD**, **SET**, and **DROP** specify the actions to be performed. The default operation is **ADD**. The option name must be unique. When foreign data is used to wrap validator functions, names and values are also validated.
 - **new_owner**
Specifies the username of the new owner for a foreign data wrapper.
 - **new_name**
Specifies the new name of a foreign data wrapper.

Examples

```
-- Modify a foreign data wrapper dbi, add the foo option, and delete bar.
gaussdb=# ALTER FOREIGN DATA WRAPPER dbi OPTIONS (ADD foo '1', DROP 'bar');

-- Change the validator of the foreign data wrapper dbi to bob.myvalidator.
gaussdb=# ALTER FOREIGN DATA WRAPPER dbi VALIDATOR bob.myvalidator;
```

Helpful Links

[CREATE FOREIGN DATA WRAPPER](#) and [DROP FOREIGN DATA WRAPPER](#)

7.12.6.11 ALTER FUNCTION

Description

Modifies the attributes of a user-defined function or recompiles a function.

Precautions

- Only the function owner or a user granted with the ALTER permission can run the **ALTER FUNCTION** command. System administrators have this permission by default. The following is permission constraints depending on attributes to be modified:
 - If a function involves operations on temporary tables, ALTER FUNCTION cannot be used.
 - To modify the owner or schema of a function, you must be a function owner or system administrator and a member of the new owner role.
 - Only the system administrator and initial user can change the schema of a function to public.
- When separation of duties is enabled, no role is allowed to modify the owner of a function with the definer permission.
- When separation of duties is disabled, only the initial user and system administrator can change the owner of a function with the definer permission. However, the function owner cannot be changed to an O&M administrator.
- Only the initial user can change the owner of a function to the initial user.

Syntax

- Modify additional parameters of a user-defined function.

```
ALTER FUNCTION function_name ( [ { [ argname ] [ argmode ] argtype } [, ...] ] )  
    action [ ... ] [ RESTRICT ];
```

The syntax of the action clause is as follows:

```
{ CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }  
| { IMMUTABLE | STABLE | VOLATILE }  
| { SHIPPABLE | NOT SHIPPABLE }  
| { NOT FENCED | FENCED }  
| [ NOT ] LEAKPROOF  
| { [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER }  
| AUTHID { DEFINER | CURRENT_USER }  
| COST execution_cost  
| ROWS result_rows  
| SET configuration_parameter { { TO | = } { value | DEFAULT } } FROM CURRENT }  
| RESET { configuration_parameter | ALL }
```

- Rename the user-defined function.

```
ALTER FUNCTION function_name ( [ { [ argname ] [ argmode ] argtype } [, ...] ] )  
    RENAME TO new_name;
```
- Change the owner of the user-defined function.

```
ALTER FUNCTION function_name ( [ { [ argname ] [ argmode ] argtype } [, ...] ] )  
    OWNER TO new_owner;
```

- Modify the schema of the user-defined function.

```
ALTER FUNCTION function_name ( ( [ argname ] [ argmode ] argtype) [, ...] )  
SET SCHEMA new_schema;
```
- Recompile the function (not supported in this version).

```
ALTER FUNCTION function_name COMPILE;
```

Parameters

- **function_name**
Specifies the name of a function to be modified.
Value range: an existing function name.
- **argmode**
Specifies whether a parameter is an input or output parameter.
Value range:
 - **IN**: declares input parameters.
 - **OUT**: declares output parameters.
 - **INOUT**: declares input and output parameters.
 - **VARIADIC**: declares parameters of the array type.
- **argname**
Specifies a parameter name.
Value range: a string. It must comply with the [naming convention](#).
- **argtype**
Specifies a parameter type.
Value range: a valid type. For details, see [Data Types](#).
- **CALLED ON NULL INPUT**
Declares that a function can be called normally even if some parameter values are **NULL**. Omitting this parameter is the same as specifying it.
- **RETURNS NULL ON NULL INPUT**
STRICT
Specifies that a function always returns **NULL** whenever any of its parameters is **NULL**. If this parameter is specified, the function is not executed when there is **NULL** parameter; instead a **NULL** result is assumed automatically.
RETURNS NULL ON NULL INPUT and **STRICT** have the same functions.
- **IMMUTABLE**
Specifies that a function always returns the same result if the parameter values are the same.
- **STABLE**
Specifies that a function cannot modify databases. For the same parameter values, the return value of the function remains unchanged in the same table scan, but the return value may vary between different SQL statements.
- **VOLATILE**
Specifies that a function value can change in a single table scan and no optimization is performed.
- **SHIPPABLE**

- **NOT SHIPPABLE**
Specifies whether a function can be pushed down to DN for execution.
Functions of the IMMUTABLE type can always be pushed down to DN.
Functions of the STABLE or VOLATILE type can be pushed down to DN only if their attribute is **SHIPPABLE**.
- **LEAKPROOF**
Specifies that a function has no side effect and the parameter contains only the return value. LEAKPROOF can be set only by system administrators.
- **EXTERNAL**
(Optional) The purpose is to be compatible with SQL. This feature applies to all functions, not only external functions.
- **SECURITY INVOKER**
AUTHID CURRENT_USER
Specifies that a function will be executed with the permissions of a user who calls it. Omitting this parameter is the same as specifying it.
SECURITY INVOKER and **AUTHID CURRENT_USER** have the same functions.
- **SECURITY DEFINER**
AUTHID DEFINER
Specifies that a function will be executed with the permissions of a user who created it.
AUTHID DEFINER and **SECURITY DEFINER** have the same functions.
- **COST execution_cost**
Estimates the execution cost of a function.
The unit of **execution_cost** is **cpu_operator_cost**.
Value range: a positive number.
- **ROWS result_rows**
Estimates the number of rows returned by a function. This is only allowed when the function is declared to return a set.
Value range: a positive number. The default value is **1000**.
- **configuration_parameter**
 - **value**
Sets a specified database session parameter to a specified value. If the value is **DEFAULT** or **RESET**, the default setting is used in the new session. **OFF** disables the setting.
Value range: a string.
 - **DEFAULT**
 - **OFF**
 - **RESET**
 - User-specified value: The value must meet the restriction of the modified parameter.
 - **FROM CURRENT**

Uses the value of **configuration_parameter** of the current session.

- **new_name**
Specifies the new name of a function. To change the schema of a function, you must have the CREATE permission on the new schema.
Value range: a string. It must comply with the [naming convention](#).
- **new_owner**
Specifies the new owner of a function. To change the owner of a function, the new owner must have the CREATE permission on the schema to which the function belongs. Note that only the initial user can set the function owner to another initial user.
Value range: an existing user role.
- **new_schema**
Specifies the new schema of a function.
Value range: an existing schema.

Examples

The following is an example of modifying a function:

```
-- Create a function.
gaussdb=# CREATE OR REPLACE FUNCTION test_func(a int) RETURN int
IS
    proc_var int;
BEGIN
    proc_var := a;
    return 1;
END;
/

-- Change the name of the function test_func(a int) to test_func_tk(a int).
gaussdb=# ALTER FUNCTION test_func(a int) RENAME TO test_func_tk;

-- Create a user jim.
gaussdb=# CREATE USER jim PASSWORD '*****';

-- Create a test schema.
gaussdb=# CREATE SCHEMA test;

-- Change the owner of the function to jim.
gaussdb=# ALTER FUNCTION test_func_tk(a int) OWNER TO jim;

-- Change the function schema to test.
gaussdb=# ALTER FUNCTION test_func_tk(a int) SET SCHEMA test;

-- Delete the function.
gaussdb=# DROP FUNCTION test.test_func_tk(a int);

-- Delete user jim.
gaussdb=# DROP USER jim;

-- Delete a schema.
gaussdb=# DROP SCHEMA test;
```

Helpful Links

[CREATE FUNCTION](#) and [DROP FUNCTION](#)

7.12.6.12 ALTER GLOBAL CONFIGURATION

Description

Adds or modifies **key-value** of the `gs_global_config` system catalog. You can modify an existing parameter or add a new one.

Precautions

- Only the initial database user can run this command.
- The parameter name cannot be **weak_password** or **undostorage**.

Syntax

```
ALTER GLOBAL CONFIGURATION with(name=value, name=value...);
```

Parameters

- **name**
Parameter name, which is of the text type. The value cannot be **weak_password** or **undostorage**.
- **value**
Parameter value, which is of the text type.

Examples

```
-- Insert.
gaussdb=# ALTER GLOBAL CONFIGURATION with(redis_is_ok = true);

-- Query.
gaussdb=# SELECT * FROM gs_global_config;
   name   | value
-----+-----
 buckets_len | 16384
 undostorage | page
 redis_is_ok | true
(3 rows)

-- Modify.
gaussdb=# ALTER GLOBAL CONFIGURATION with(redis_is_ok = false);

-- Query.
gaussdb=# SELECT * FROM gs_global_config;
   name   | value
-----+-----
 buckets_len | 16384
 undostorage | page
 redis_is_ok | false
(3 rows)

-- Delete.
gaussdb=# DROP GLOBAL CONFIGURATION redis_is_ok;

-- Query.
gaussdb=# SELECT * FROM gs_global_config;
   name   | value
-----+-----
```

```
buckets_len | 16384  
undostoragetype | page  
(2 rows)
```

Helpful Links

[DROP GLOBAL CONFIGURATION](#)

7.12.6.13 ALTER GROUP

Description

Modifies the attributes of a user group.

Precautions

- ALTER GROUP is not a standard SQL statement and is not recommended.
- Two clauses (ADD USER and DROP USER) are used to add users to or delete users from a user group. Any user can be a user or a user group. These two clauses are equivalent to granting or revoking the permissions of a user or role to other users or roles. Therefore, you are advised to replace them with GRANT or REVOKE.
- The RENAME TO clause changes the user group name, which is equivalent to renaming roles using ALTER ROLE.

Syntax

- Add users to a group.

```
ALTER GROUP group_name  
ADD USER user_name [, ... ];
```

- Remove users from a group.

```
ALTER GROUP group_name  
DROP USER user_name [, ... ];
```

- Change the name of the group.

```
ALTER GROUP group_name  
RENAME TO new_name;
```

Parameters

- **user_name**

Role name.

Value range: an existing role name. If a role name contains uppercase letters, enclose the name with double quotation marks ("").

- **group_name**
Name of an existing user group.
Value range: an existing role name. If a role name contains uppercase letters, enclose the name with double quotation marks ("").
- **new_name**
Name of a new role.
Value range: a string. It must comply with the identifier naming convention and can contain a maximum of 63 characters. If the value contains more than 63 characters, the database truncates it and retains the first 63 characters as the role name. If a role name contains uppercase letters, the database automatically converts the uppercase letters into lowercase letters. To create a role name that contains uppercase letters, enclose the role name with double quotation marks ("").

Examples

- Rename a user group.
-- Create a user **test**.
gaussdb=# CREATE ROLE test PASSWORD '*****';

-- Change the username, which is equivalent to the role of ALTER ROLE RENAME.
gaussdb=# ALTER GROUP test RENAME TO tu_a1;
- Add users to or delete users from a user group.
-- Create users **tu_a2** and **tu_a3**.
gaussdb=# CREATE ROLE tu_a2 PASSWORD '*****';
gaussdb=# CREATE ROLE tu_a3 PASSWORD '*****';

-- Add user **tu_a2** to user group **tu_a1**.
gaussdb=# ALTER GROUP tu_a1 ADD USER tu_a2;

-- The preceding SQL statement is equivalent to the GRANT statement.
gaussdb=# GRANT tu_a1 TO tu_a3;

-- Query.
gaussdb=# SELECT groname, grolist FROM pg_group WHERE groname = 'tu_a1';
groname | grolist
-----+-----
tu_a1 | {25590,25593}
(1 row)
gaussdb=# SELECT rolname, oid FROM pg_roles WHERE oid IN (25590,25593);
rolname | oid
-----+-----
tu_a2 | 25590
tu_a3 | 25593
(2 rows)

-- Delete.
gaussdb=# DROP ROLE tu_a1,tu_a2,tu_a3;

Helpful Links

[CREATE GROUP](#), [DROP GROUP](#), and [ALTER ROLE](#)

7.12.6.14 ALTER INDEX

Description

ALTER INDEX modifies the definition of an existing index.

Precautions

Only the index owner, a user who has the INDEX permission on the table where the index resides, or a user who has the ALTER ANY INDEX permission can run the ALTER INDEX command. When separation of duties is disabled, the system administrator has this permission by default.

Do not keep a large number of invisible indexes on the same base table. Otherwise, the performance of DML operations such as INSERT, UPDATE, and DELETE may be affected.

Syntax

- Rename a table index.

```
ALTER INDEX [ IF EXISTS ] index_name  
  RENAME TO new_name;
```
- Change the tablespace to which a table index belongs.

```
ALTER INDEX [ IF EXISTS ] index_name  
  SET TABLESPACE tablespace_name;
```
- Modify the storage parameter of a table index.

```
ALTER INDEX [ IF EXISTS ] index_name  
  SET ( {storage_parameter = value} [, ... ] );
```
- Reset the storage parameter of a table index.

```
ALTER INDEX [ IF EXISTS ] index_name  
  RESET ( storage_parameter [, ... ] );
```
- Set a table index or an index partition to be unavailable.

```
ALTER INDEX [ IF EXISTS ] index_name  
  [ MODIFY PARTITION index_partition_name ] UNUSABLE;
```
- Rebuild a table index or index partition.

```
ALTER INDEX index_name  
  REBUILD [ PARTITION index_partition_name ];
```
- Rename an index partition.

```
ALTER INDEX [ IF EXISTS ] index_name  
  RENAME PARTITION index_partition_name TO new_index_partition_name;
```
- Modify the tablespace to which an index partition belongs.

```
ALTER INDEX [ IF EXISTS ] index_name  
  MOVE PARTITION index_partition_name TABLESPACE new_tablespace;
```
- Set the distributed global secondary index to be ready.

```
ALTER INDEX [ IF EXISTS ] index_name GSIVALID;
```

NOTE

This syntax is internally called by the CREATE GLOBAL INDEX CONCURRENTLY function to change the status of a global secondary index. You are advised not to use this syntax. Otherwise, the index data may be inconsistent with the table data. To enable a GSI in the UNVALID state, you are advised to use the REINDEX INDEX syntax to rebuild the GSI.

- Set the distributed global secondary index to be available.

```
ALTER INDEX [ IF EXISTS ] index_name GSIUSABLE;
```

NOTE

This syntax is internally called by the VACUUM FULL function to change the status of a global secondary index. You are advised not to use this syntax. Otherwise, the index data may be inconsistent with the table data. To enable a GSI in the UNUSABLE state, you are advised to use the REINDEX INDEX syntax to rebuild the GSI.

- Set the index to be visible.

```
ALTER INDEX [ IF EXISTS ] index_name VISIBLE;
```

 NOTE

- This syntax can be set only in the ORA-compatible database (that is, **sql_compatibility = 'ORA'**).
- When **disable_keyword_options** is set to "**visible**", the **VISIBLE** keyword cannot be used.
- This syntax is not supported in the upgrade uncommitted phase.
- Set the index to be invisible.

```
ALTER INDEX [ IF EXISTS ] index_name INVISIBLE;
```

 NOTE

- This syntax can be set only in the ORA-compatible database (that is, **sql_compatibility = 'ORA'**).
- When **disable_keyword_options** is set to "**invisible**", the **INVISIBLE** keyword cannot be used.
- This syntax is not supported in the upgrade uncommitted phase.
- In the standby node read scenario, after the index is set to invisible, the execution plan of the query statement may change, and the query performance of the standby node may be affected.

Parameters

- **index_name**
Specifies the index name to be modified.
- **IF EXISTS**
Sends a notice instead of an error if the specified index does not exist.
- **RENAME TO new_name**
Changes only the name of the index. The stored data is not affected.
 - **new_name**
Specifies the new name of the index.
Value range: a string. It must comply with the [naming convention](#).
- **SET TABLESPACE tablespace_name**
This option changes the index tablespace to the specified tablespace and moves index-related data files to the new tablespace.
 - **tablespace_name**
Specifies the tablespace name.
Value range: an existing tablespace name
- **SET ({storage_parameter = value} [, ...])**
Changes one or more index-method-specific storage parameters of an index. Note that the index content will not be modified immediately by this statement. You may need to use **REINDEX** to rebuild the index based on different parameters to achieve the expected effect.
 - **storage_parameter**
Specifies the name of an index-method-specific parameter.
ACTIVE_PAGES indicates the number of index pages, which may be less than the actual number of physical file pages and can be used for optimization. Currently, this parameter is valid only for the local index of the Ustore partitioned table and will be updated by **VACUUM** and

ANALYZE (including AUTOVACUUM). You are advised not to manually set this parameter because it is invalid in distributed mode. When ALTER is executed on GSI, the **INTERNAL_MASK**, **APPEND_MODE_INTERNAL**, **WAIT_CLEAN_GPI**, **PARTITION_DDL_FLAG**, **COLLATE**, **CROSSBUCKET**, and **DEDUPLICATION** parameters are not supported. The behavior is the same as that of UB-tree. The **FILLFACTOR**, and **INDEXSPLIT** parameters are supported. **ACTIVE_PAGES** and **WAIT_CLEAN_CBI** are not applicable to GSI.

– **value**

Specifies the new value for an index-method-specific storage parameter. This might be a number or a word depending on the parameter.

- **RESET ({ storage_parameter } [, ...])**
Resets one or more index-method-specific storage parameters of an index to the default value. Similar to the SET statement, REINDEX may be used to completely update the index.
- **[MODIFY PARTITION index_partition_name] UNUSABLE**
Sets the indexes on a table or index partition to be unavailable.
- **REBUILD [PARTITION index_partition_name]**
Rebuilds indexes on a table or an index partition. If the index contains the **lpi_parallel_method** option and the value is **PARTITION** when the index is rebuilt, and the **parallel_workers** value of the index's table is greater than 0, the index cannot be rebuilt in parallel. If the index does not contain the **lpi_parallel_method** option or the value of the option is set to **AUTO**, page-level parallel index is rebuilt by default. For details, see [LPI_PARALLEL_METHOD](#).
- **RENAME PARTITION index_partition_name TO new_index_partition_name**
Renames an index partition.
- **MOVE PARTITION index_partition_name TABLESPACE new_tablespace**
Modifies the tablespace to which an index partition belongs.
- **new_index_partition_name**
Specifies the new name of the index partition.
- **index_partition_name**
Specifies the name of an index partition.
- **new_tablespace**
Specifies a new tablespace.
- **GSIVALID**
Internally called by the CREATE GLOBAL INDEX CONCURRENTLY function to modify the status of distributed global secondary indexes.
- **GSIOUSABLE**
This syntax is internally called by the VACUUM FULL function to modify the status of distributed global secondary indexes.
- **VISIBLE**
Sets the index to be visible.
- **INVISIBLE**
Sets the index to be invisible.

Examples

- Rename an index.**

```
-- Create the test1 table and create an index for it.
gaussdb=# CREATE TABLE test1(col1 int, col2 int);
gaussdb=# CREATE INDEX aa ON test1(col1);

-- Rename index aa to idx_test1_col1.
gaussdb=# ALTER INDEX aa RENAME TO idx_test1_col1;

-- Query the index information in the test1 table.
gaussdb=# SELECT tablename,indexname,tablespace FROM pg_indexes WHERE tablename = 'test1';
tablename | indexname | tablespace
-----+-----+-----
test1 | idx_test1_col1 |
(1 row)
```
- Change the tablespace to which the index belongs.**

```
-- Create the tbs_index1 tablespace.
gaussdb=# CREATE TABLESPACE tbs_index1 RELATIVE LOCATION 'tablespace1/tbs_index1';

-- Change the tablespace to which the idx_test1_col1 index belongs to tbs_index1.
gaussdb=# ALTER INDEX IF EXISTS idx_test1_col1 SET TABLESPACE tbs_index1;

-- Query the index information in the test1 table.
gaussdb=# SELECT tablename,indexname,tablespace FROM pg_indexes WHERE tablename = 'test1';
tablename | indexname | tablespace
-----+-----+-----
test1 | idx_test1_col1 | tbs_index1
(1 row)
```
- Modify and reset index storage parameters.**

```
-- View details about the idx_test1_col1 index.
gaussdb=# \di idx_test1_col1 List of relations
Schema | Name | Type | Owner | Table | Storage
-----+-----+-----+-----+-----+-----
public | idx_test1_col1 | index | omm | test1 |
(1 row)

-- Modify the fill factor of the idx_test1_col1 index.
gaussdb=# ALTER INDEX IF EXISTS idx_test1_col1 SET (FILLFACTOR = 70);
-- View details about the idx_test1_col1 index.
gaussdb=# \di idx_test1_col1 List of relations
Schema | Name | Type | Owner | Table | Storage
-----+-----+-----+-----+-----+-----
public | idx_test1_col1 | index | omm | test1 | {fillfactor=70}
(1 row)
-- Reset the storage parameter of the idx_test1_col1 index.
gaussdb=# ALTER INDEX IF EXISTS idx_test1_col1 RESET (FILLFACTOR);
-- View details about the idx_test1_col1 index.
gaussdb=# \di idx_test1_col1 List of relations
Schema | Name | Type | Owner | Table | Storage
-----+-----+-----+-----+-----+-----
public | idx_test1_col1 | index | omm | test1 |
(1 row)
```
- Modify the index availability.**

```
-- Set the idx_test1_col1 index to be unavailable.
gaussdb=# ALTER INDEX IF EXISTS idx_test1_col1 UNUSABLE;
-- Check the availability of the idx_test1_col1 index.
gaussdb=# SELECT indisusable FROM pg_index WHERE indexrelid = 'idx_test1_col1'::regclass;
indisusable
-----
f
(1 row)

-- Rebuild the idx_test1_col1 index.
gaussdb=# ALTER INDEX idx_test1_col1 REBUILD;
```

```
-- Check the availability of the idx_test1_col1 index.
gaussdb=# SELECT indisusable FROM pg_index WHERE indexrelid = 'idx_test1_col1'::regclass;
indisusable
-----
t
(1 row)

-- Delete.
gaussdb=# DROP INDEX idx_test1_col1;
gaussdb=# DROP TABLE test1;
gaussdb=# DROP TABLESPACE tbs_index1;
```

- **Rename an index partition.**

```
-- Create the partitioned table test2.
gaussdb=# CREATE TABLE test2(col1 int, col2 int) PARTITION BY RANGE (col1)(
    PARTITION p1 VALUES LESS THAN (100),
    PARTITION p2 VALUES LESS THAN (200)
);
-- Create a partitioned index.
gaussdb=# CREATE INDEX idx_test2_col1 ON test2(col1) LOCAL(
    PARTITION p1,
    PARTITION p2
);
-- Rename the index partition.
gaussdb=# ALTER INDEX idx_test2_col1 RENAME PARTITION p1 TO p1_test2_idx;
gaussdb=# ALTER INDEX idx_test2_col1 RENAME PARTITION p2 TO p2_test2_idx;

-- Query the partition name of the idx_test2_col1 index.
gaussdb=# SELECT relname FROM pg_partition WHERE parentid = 'idx_test2_col1'::regclass;
relname
-----
p1_test2_idx
p2_test2_idx
(2 rows)
```

- **Modify the tablespace to which an index partition belongs.**

```
-- Create tablespaces tbs_index2 and tbs_index3.
gaussdb=# CREATE TABLESPACE tbs_index2 RELATIVE LOCATION 'tablespace1/tbs_index2';
gaussdb=# CREATE TABLESPACE tbs_index3 RELATIVE LOCATION 'tablespace1/tbs_index3';

-- Change the tablespace to which the idx_test2_col1 index partition belongs.
gaussdb=# ALTER INDEX idx_test2_col1 MOVE PARTITION p1_test2_idx TABLESPACE tbs_index2;
gaussdb=# ALTER INDEX idx_test2_col1 MOVE PARTITION p2_test2_idx TABLESPACE tbs_index3;

-- Query the tablespace to which the idx_test2_col1 index partition belongs.
gaussdb=# SELECT t1.relname index_name,
    t2.spcname tablespace_name
FROM pg_partition t1, pg_tablespace t2
WHERE t1.parentid = 'idx_test2_col1'::regclass AND
    t1.reltablespace = t2.oid;
index_name | tablespace_name
-----+-----
p1_test2_idx | tbs_index2
p2_test2_idx | tbs_index3
(2 rows)

-- Delete.
gaussdb=# DROP INDEX idx_test2_col1;
gaussdb=# DROP TABLE test2;
gaussdb=# DROP TABLESPACE tbs_index2;
gaussdb=# DROP TABLESPACE tbs_index3;
```

7.12.6.15 ALTER LANGUAGE

This version does not support this syntax.

7.12.6.16 ALTER MASKING POLICY

Description

Modifies a masking policy.

Precautions

- Only users with the poladmin or sysadmin permission, or the initial user can perform this operation.
- The masking policy takes effect only after the security policy is enabled, that is, **enable_security_policy** is set to **on**.

Syntax

- Modify the policy description.

```
ALTER MASKING POLICY policy_name COMMENTS policy_comments;
```

- Modify the masking method.

```
ALTER MASKING POLICY policy_name {ADD | REMOVE | MODIFY} masking_actions[, ...];
```

- The syntax of **masking_actions**

```
masking_function ON LABEL(label_name[, ...])
```

- The syntax of **masking_function**

```
{ maskall | randommasking | creditcardmasking | basicemailmasking | fullemailmasking | shufflemasking | alldigitsmasking | regexprmasking }
```

- Modify the scenarios where the masking policies take effect.

```
ALTER MASKING POLICY policy_name MODIFY (filter_group_clause);
```

- The syntax of **filter_group_clause**

```
FILTER ON { ( FILTER_TYPE ( filter_value [, ... ] ) ) [, ... ] }
```

- Remove the filters of the masking policies.

```
ALTER MASKING POLICY policy_name DROP FILTER;
```

- Enable or disable the masking policies.

```
ALTER MASKING POLICY policy_name {ENABLE | DISABLE};
```

Parameters

- **policy_name**
Specifies the masking policy name, which must be unique.
Value range: a string. It must comply with the **naming convention**.
- **policy_comments**
Adds or modifies description of masking policies.
- **masking_function**
Specifies eight preset masking methods or user-defined functions. Schema is supported.
maskall is not a preset function and cannot be displayed by running **\df**.
The masking methods during presetting are as follows:

```
{ maskall | randommasking | creditcardmasking | basicemailmasking | fullemailmasking | shufflemasking | alldigitsmasking | regexpmasking }
```
- **label_name**
Specifies the resource label name.
- **FILTER_TYPE**
Specifies the types of information to be filtered by the policies: **IP**, **ROLES**, and **APP**.
- **filter_value**
Indicates the detailed information to be filtered, such as the IP address, app name, and username.
- **ENABLE|DISABLE**
Enables or disables the masking policy. If **ENABLE|DISABLE** is not specified, **ENABLE** is used by default.

Examples

- Modify the policy description.
-- Create table **tb_for_masking**.
gaussdb=# CREATE TABLE tb_for_masking(idx int, col1 text, col2 text, col3 text, col4 text, col5 text, col6 text, col7 text,col8 text);

```
-- Insert data into the tb_for_masking table.
gaussdb=# INSERT INTO tb_for_masking VALUES(1, '9876543210', 'usr321usr', 'abc@huawei.com',
'abc@huawei.com', '1234-4567-7890-0123', 'abcdef 123456 ui 323 jsfd321 j3k2l3',
'4880-9898-4545-2525', 'this is a llt case');

-- View data.
gaussdb=# SELECT * FROM tb_for_masking;
idx | col1 | col2 | col3 | col4 | col5 | col6
    | col7 | col8
-----+-----+-----+-----+-----+-----+-----
1 | 9876543210 | usr321usr | abc@huawei.com | abc@huawei.com | 1234-4567-7890-0123 | abcdef
123456 ui 323 jsfd321 j
3k2l3 | 4880-9898-4545-2525 | this is a llt case
(1 row)

-- Create a resource label for sensitive column col1.
gaussdb=# CREATE RESOURCE LABEL mask_lb1 ADD COLUMN(tb_for_masking.col1);

-- Create a data masking policy named maskpol1.
gaussdb=# CREATE MASKING POLICY maskpol1 maskall ON LABEL(mask_lb1);

-- Add description for masking policy maskpol1.
gaussdb=# ALTER MASKING POLICY maskpol1 COMMENTS 'masking policy for tb_for_masking.col1';

-- View the description of data masking policy maskpol1.
gaussdb=# SELECT * FROM GS_MASKING_POLICY;
polname | polcomments | modifydate | polenabed
-----+-----+-----+-----
maskpol1 | masking policy for tb_for_masking.col1 | 2023-11-07 16:38:31.607374 | t
(1 row)
```

- **Modify a masking policy:**

```
-- Create a resource label for sensitive column col2.
gaussdb=# CREATE RESOURCE LABEL mask_lb2 ADD COLUMN(tb_for_masking.col2);

-- Add the randommasking masking mode to the masking policy maskpol1.
gaussdb=# ALTER MASKING POLICY maskpol1 ADD randommasking ON LABEL(mask_lb2);

-- Access the tb_for_masking table. The masking policy is triggered for the col2 column.
gaussdb=# SELECT col2 FROM tb_for_masking;
col2
-----
27e8da66cc
(1 row)

-- Remove the randommasking masking mode from the masking policy maskpol1.
gaussdb=# ALTER MASKING POLICY maskpol1 REMOVE randommasking ON LABEL(mask_lb2);

-- Access the tb_for_masking table. The data in the col2 column is not masked, indicating that the
masking mode randommasking is invalid.
gaussdb=# SELECT col2 FROM tb_for_masking;
col2
-----
usr321usr
(1 row)

-- Change the masking mode of the masking policy maskpol1 to randommasking.
gaussdb=# ALTER MASKING POLICY maskpol1 MODIFY randommasking ON LABEL(mask_lb1);

-- Access the tb_for_masking table. The masking policy is triggered for the col1 column.
gaussdb=# SELECT col1 FROM tb_for_masking;
col1
-----
5a03debac1
(1 row)
```

- **Modify the scenarios where the masking policies take effect.**

```
-- Create users dev_mask and bob_mask.
gaussdb=# CREATE USER dev_mask PASSWORD '*****';
gaussdb=# CREATE USER bob_mask PASSWORD '*****';

-- Create a resource label for sensitive column col8.
gaussdb=# CREATE RESOURCE LABEL mask_lb8 ADD COLUMN(tb_for_masking.col8);

-- Create a data masking policy named maskpol8.
gaussdb=# CREATE MASKING POLICY maskpol8 randommasking ON LABEL(mask_lb8) FILTER ON
ROLES(dev_mask, bob_mask), APP(gsql), IP('172.31.17.160', '127.0.0.0/24');

-- Modify the filtering information ROLES of data masking policy maskpol8.
gaussdb=# ALTER MASKING POLICY maskpol1 MODIFY (FILTER ON ROLES(dev_mask));

-- Check tb_for_masking as the dev_mask user.
gaussdb=# GRANT ALL PRIVILEGES TO dev_mask;

-- Access the tb_for_masking table. The masking policy is triggered for the col8 column.
gaussdb=# SELECT col8 FROM tb_for_masking;
      col8
-----
f134e06ef528013b46
(1 row)
```

- Remove the filters of the masking policies for the policies to take effect.

```
gaussdb=# ALTER MASKING POLICY maskpol1 DROP FILTER;
```

- Disable a masking policy:

```
-- Disable masking policy maskpol1.
gaussdb=# ALTER MASKING POLICY maskpol1 DISABLE;
```

```
-- Check the status of data masking policy maskpol1. If the value of polenabled is f, the data
masking policy is disabled successfully.
```

```
gaussdb=# SELECT * FROM GS_MASKING_POLICY;
 polname | polcomments |      modifydate      | polenabled
-----+-----+-----+-----
 maskpol1 |              | 2023-11-07 17:22:54.594111 | f
```

- Delete data:

```
-- Delete a masking policy.
gaussdb=# DROP MASKING POLICY maskpol1, maskpol8;
```

```
-- Delete a resource label.
gaussdb=# DROP RESOURCE LABEL mask_lb1, mask_lb2, mask_lb8;
```

```
-- Delete the tb_for_masking table.
gaussdb=# DROP TABLE tb_for_masking;
```

```
-- Delete the dev_mask and bob_mask users.
gaussdb=# DROP USER dev_mask, bob_mask;
```

7.12.6.17 ALTER MATERIALIZED VIEW

Description

Modifies multiple auxiliary attributes of an existing materialized view.

Statements and actions that can be used for ALTER MATERIALIZED VIEW are a subset of ALTER TABLE and have the same meaning when used for materialized views. For details, see [ALTER TABLE](#).

Precautions

- Only the owner of a materialized view or a system administrator has the ALTER MATERIALIZED VIEW permission.
- The materialized view structure cannot be modified.

Syntax

- Change the owner of a materialized view.

```
ALTER MATERIALIZED VIEW [ IF EXISTS ] mv_name  
OWNER TO new_owner;
```

→ALTER→MATERIALIZED→VIEW→IF→EXISTS→mv_name→OWNER→TO→new_owner→;

- Rename a column of a materialized view.

```
ALTER MATERIALIZED VIEW [ IF EXISTS ] mv_name  
RENAME [ COLUMN ] column_name TO new_column_name;
```

→ALTER→MATERIALIZED→VIEW→IF→EXISTS→mv_name→RENAME→COLUMN→column_name→TO→new_column_name→;

- Rename a materialized view.

```
ALTER MATERIALIZED VIEW [ IF EXISTS ] mv_name  
RENAME TO new_name;
```

→ALTER→MATERIALIZED→VIEW→IF→EXISTS→mv_name→RENAME→TO→new_name→;

Parameters

- **mv_name**
Specifies the name of an existing materialized view, which can be schema-qualified.
Value range: a string. It must comply with the [naming convention](#).
- **column_name**
Specifies the name of a new or existing column.
Value range: a string. It must comply with the [naming convention](#).
- **new_column_name**
Specifies the new name of an existing column.
- **new_owner**
Specifies the username of the new owner of a materialized view.
- **new_name**
Specifies the new name of a materialized view.

Examples

- Change the owner of a materialized view.

```
-- Create a table.  
gaussdb=# CREATE TABLE my_table (c1 int, c2 int) WITH(STORAGE_TYPE=ASTORE);  
  
-- Create a complete-refresh materialized view.  
gaussdb=# CREATE MATERIALIZED VIEW foo AS SELECT * FROM my_table;  
  
-- Create a user.  
gaussdb=# CREATE USER test PASSWORD '*****';  
  
-- Change the owner of the complete-refresh materialized view.  
gaussdb=# ALTER MATERIALIZED VIEW foo OWNER TO test;
```

```
-- View the information about the materialized view.
gaussdb=# \dm foo
                List of relations
 Schema | Name | Type      | Owner | Storage
-----+-----+-----+-----+-----
 public | foo | materialized view | test | {orientation=row,compression=no}
(1 row)
```

- **Rename a column of a materialized view.**

```
-- Query the columns of the materialized view.
gaussdb=# \d foo;
Materialized view "public.foo"
 Column | Type | Modifiers
-----+-----+-----
 c1     | integer |
 c2     | integer |
Rules:
 "_RETURN" AS
  ON SELECT TO foo DO INSTEAD SELECT my_table.c1, my_table.c2
  FROM my_table
Replica Identity: NOTHING

-- Change column c1 of materialized view foo to col1 and column c2 to col2.
gaussdb=# ALTER MATERIALIZED VIEW foo RENAME c1 to col1;
gaussdb=# ALTER MATERIALIZED VIEW foo RENAME c2 to col2;

-- Use the SELECT statement to view the columns of the MV.
gaussdb=# SELECT * FROM foo WHERE 1=2;
 col1 | col2
-----+-----
(0 rows)
```

- **Rename a materialized view.**

```
-- Rename the materialized view foo to my_mview.
gaussdb=# ALTER MATERIALIZED VIEW foo RENAME TO my_mview;

-- Query information.
gaussdb=# \dm my_mview
                List of relations
 Schema | Name | Type      | Owner | Storage
-----+-----+-----+-----+-----
 public | my_mview | materialized view | test | {orientation=row,compression=no}
(1 row)

-- Delete.
gaussdb=# DROP MATERIALIZED VIEW my_mview;
gaussdb=# DROP TABLE my_table ;
gaussdb=# DROP USER test;
```

7.12.6.18 ALTER NODE

Function

Modifies the definition of an existing node.

Precautions

ALTER NODE is an API of the cluster management tool and is used to manage clusters. Only administrators have the permission to use this API. You are advised not to use this API, because doing so affects the cluster.

Syntax

```
ALTER NODE nodename WITH
(
  [ TYPE = nodetype,]
  [ HOST = hostname,]
  [ PORT = portnum,]
  [ HOST1 = 'hostname',]
  [ PORT1 = portnum,]
  [ HOSTPRIMARY [ = boolean ],]
  [ PRIMARY [ = boolean ],]
  [ PREFERRED [ = boolean ],]
  [ SCTP_PORT = portnum,]
  [ CONTROL_PORT = portnum,]
  [ SCTP_PORT1 = portnum,]
  [ CONTROL_PORT1 = portnum, ]
  [ NODEIS_CENTRAL [ = boolean ]]
);
```

NOTE

The port whose number is specified by **PORT** is used for internal communications between nodes. Unlike the port connecting to an external client, it can be queried in the `pgxc_node` table.

Parameters

See [Parameters](#) in "CREATE NODE."

Examples

See [Examples](#) in "CREATE NODE."

Helpful Links

[CREATE NODE](#) and [DROP NODE](#)

7.12.6.19 ALTER NODE GROUP

Description

Modifies information about a node group.

Precautions

- Only a system administrator or a user who has the ALTER permission of a node group can modify the information about the node group.
- Node group modification is an internal operation of the system. Except SET DEFAULT, other operations must be performed in maintenance mode (by calling `set xc_maintenance_mode=on;`).
- ALTER NODE GROUP can be used only within a database. To avoid data inconsistency in DBMS, do not manually run this SQL statement.

Syntax

```
ALTER NODE GROUP groupname
{ SET DEFAULT
  | RENAME TO new_group_name
  | SET TABLE GROUP new_group_name
  | COPY BUCKETS FROM src_group_name
  | ADD NODE ( nodename [, ... ] )
  | DELETE NODE ( nodename [, ... ] )
  | RESIZE TO dest_group_name
};
```

Parameters

- **groupname**
Specifies the name of the node group to be modified.
Value range: a string. It must comply with the [naming convention](#).
- **SET DEFAULT**
Sets **in_redistribution** to 'y' for all node groups excluding the one specified by **groupname**. To be compatible with earlier versions, this syntax is retained and does not need to be executed in maintenance mode.
- **RENAME TO new_group_name**
Renames the node group specified by **groupname** to **new_group_name**.
- **SET TABLE GROUP new_group_name**
Changes all the **group_names** in the **pgroup** columns of the **pgxc_class** tables on all CNs to **new_group_name**.
- **COPY BUCKETS FROM src_group_name**
Copies values in the **group_members** and **group_buckets** columns from the node group specified by **src_group_name** to the node group specified by **groupname**.
- **ADD NODE (nodename [, ...])**
Adds nodes from the node group specified by **groupname**. After the statement execution, the new nodes are registered with the **PGXC_NODE** system catalog. This statement only modifies the system catalog and does not add nodes or redistribute data. Do not call this statement. You can observe the impact of the statement in the **PGXC_GROUP** system catalog.
- **DELETE NODE (nodename [, ...])**
Deletes nodes from the node group specified by **groupname**. The deleted nodes still exist in the **PGXC_NODE** system catalog. This statement only modifies the system catalog and does not delete nodes or redistribute data. Do not call this statement. You can observe the impact of the statement in the **PGXC_GROUP** system catalog.
- **RESIZE TO dest_group_name**
Specifies a resize flag for the cluster. Set **groupname** to the source node group before data redistribution and cancel the **is_installation** flag. Set **dest_group_name** to the destination node group and set the **is_installation** flag.

Examples

For details, see [Examples](#) in section "CREATE NODE GROUP."

Helpful Links

[CREATE NODE GROUP](#) and [DROP NODE GROUP](#)

7.12.6.20 ALTER RESOURCE LABEL

Description

ALTER RESOURCE LABEL is used to modify a resource label.

Precautions

Only users with the poladmin or sysadmin permission, or the initial user can perform this operation.

Syntax

```
ALTER RESOURCE LABEL label_name {ADD|REMOVE}
label_item_list[, ...];
```

- **label_item_list**

```
resource_type(resource_path[, ...])
```

- **resource_type**

```
TABLE | COLUMN | SCHEMA | VIEW | FUNCTION
```

Parameters

- **label_name**
Specifies the resource label name.
Value range: a string. It must comply with the [naming convention](#).
- **resource_type**
Specifies the type of database resources to be labeled.
- **resource_path**
Specifies the path of database resources.

Examples

```
-- Create basic table table_for_label.
gaussdb=# CREATE TABLE table_for_label(col1 int, col2 text);

-- Create resource label table_label.
gaussdb=# CREATE RESOURCE LABEL table_label ADD COLUMN(table_for_label.col1);

-- Attach resource label table_label to col2.
gaussdb=# ALTER RESOURCE LABEL table_label ADD COLUMN(table_for_label.col2);

-- Remove table_label from an item.
gaussdb=# ALTER RESOURCE LABEL table_label REMOVE COLUMN(table_for_label.col1);

-- Delete the resource label table_label.
gaussdb=# DROP RESOURCE LABEL table_label;

-- Delete the base table table_for_label.
gaussdb=# DROP TABLE table_for_label;
```

Helpful Links

[CREATE RESOURCE LABEL](#) and [DROP RESOURCE LABEL](#)

7.12.6.21 ALTER RESOURCE POOL

Description

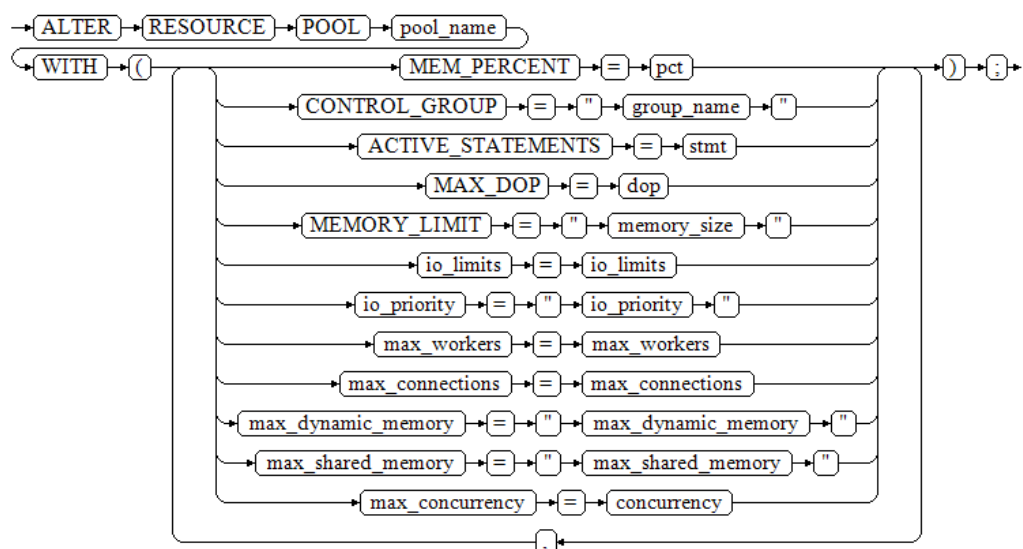

Modifies the Cgroup of a resource pool.

Precautions

Only users with the sysadmin permission, or the initial user can perform this operation.

Syntax

```
ALTER RESOURCE POOL pool_name
WITH ({MEM_PERCENT= pct | CONTROL_GROUP="group_name" | ACTIVE_STATEMENTS=stmt |
MAX_DOP = dop | MEMORY_LIMIT="memory_size" | io_limits=io_limits | io_priority="io_priority" |
max_workers=max_workers | max_connections=max_connections |
max_dynamic_memory="max_dynamic_memory" | max_shared_memory="max_shared_memory" |
max_concurrency=concurrency}[, ... ]);
```

Parameters

- **pool_name**
Specifies the name of a resource pool.
The resource pool must already exist.
Value range: a string. It must comply with the [naming convention](#).

- **group_name**
Specifies the name of a Cgroup.

NOTE

- You can use either double quotation marks ("") or single quotation marks (') in the syntax when setting the name of a Cgroup.
- The value of **group_name** is case-sensitive.
- If **group_name** is not specified, the string "Medium" will be used by default in the syntax, indicating the **Medium** Timeshare Cgroup under **DefaultClass**.
- If an administrator specifies a Workload Cgroup under Class, for example, **control_group** set to **class1:workload1**, the resource pool will be associated with the **workload1** Cgroup under **class1**. The level of **Workload** can also be specified. For example, **control_group** is set to **class1:workload1:1**.
- If a database user specifies the Timeshare string (**Rush**, **High**, **Medium**, or **Low**) in the syntax, for example, **control_group** is set to **High**, the resource pool will be associated with the **High** Timeshare Cgroup under **DefaultClass**.
- In multi-tenant scenarios, the Cgroup associated with a group resource pool is a Class Cgroup, and that associated with a service resource pool is a Workload Cgroup. Additionally, switching Cgroups between different resource pools is not allowed.

Value range: an existing Cgroup.

- **dop**
Specifies the maximum statement concurrency degree for a resource pool, equivalent to the number of threads that can be created for executing a statement.

Value range: numeric data ranging from 1 to 2147483647

- **memory_size**
Specifies the maximum memory size of a resource pool.
Value range: a string of 1 KB to 2047 GB case-sensitive characters.

- **mem_percent**
Specifies the proportion of available resource pool memory to the total memory or group user memory.

In multi-tenant scenarios, **mem_percent** of group users or service users ranges from 1 to 100. The default value is **20**.

In common scenarios, **mem_percent** of common users is an integer ranging from 0 to 100. The default value is **0**.

NOTE

When both of **mem_percent** and **memory_limit** are specified, only **mem_percent** takes effect.

- **io_limits**
Specifies the upper limit of IOPS in a resource pool. The value **0** indicates no limit.

It is counted by 10 thousands per second.

Value range: numeric data ranging from 0 to 2147483647

- **io_priority**

Specifies the I/O priority for jobs that consume many I/O resources. It takes effect when the I/O usage reaches 90%.

There are three priorities: **Low**, **Medium**, and **High**. If you do not want to control I/O resources, set this parameter to **None**, which is the default value.

Value range: enumerated type. The options are **None**, **Low**, **Medium**, and **High**.

 **NOTE**

The settings of **io_limits** and **io_priority** are valid only for complex jobs, such as batch import (using INSERT INTO SELECT, COPY FROM, or CREATE TABLE AS), complex queries involving over 500 MB data on each DN, and VACUUM FULL.

- **max_workers**

Concurrency in a table during data redistribution. This is used only for scaling.

- **max_connections**

Limits the maximum number of connections that can be used by a resource pool.

 **NOTE**

The total maximum number of connections in all resource pools cannot exceed the maximum number of connections specified by **max_connections** of the entire GaussDB process.

- **max_dynamic_memory**

Specifies the maximum dynamic memory that can be used by a resource pool.

- **max_shared_memory**

Specifies the maximum shared memory that can be used by a resource pool.

- **max_concurrency**

Specifies the maximum concurrent requests that can be used by a resource pool.

Examples

The following example assumes that the user has created the **class1** Cgroup and three Workload Cgroups under **class1**: **Low**, **wg1**, and **wg2**. Contact the administrator to create a Cgroup.

```
-- Create a resource pool.
gaussdb=# CREATE RESOURCE POOL pool1;

-- Specify the High Timeshare Workload Cgroup under the DefaultClass Cgroup.
gaussdb=# ALTER RESOURCE POOL pool1 WITH (CONTROL_GROUP="High");

-- Specify the Low Timeshare Workload Cgroup under the class1 Cgroup.
gaussdb=# ALTER RESOURCE POOL pool1 WITH (CONTROL_GROUP="class1:Low");

-- Specify the wg1 Workload Cgroup under the class1 Cgroup.
gaussdb=# ALTER RESOURCE POOL pool1 WITH (CONTROL_GROUP="class1:wg1");

-- Specify the wg2 Workload Cgroup under the class1 Cgroup.
gaussdb=# ALTER RESOURCE POOL pool1 WITH (CONTROL_GROUP="class1:wg2:3");
```

```
-- Delete the resource pool pool1.
gaussdb=# DROP RESOURCE POOL pool1;
```

7.12.6.22 ALTER ROLE

Description

Modifies role attributes.

Precautions

None

Syntax

- Modify the permissions of a role.

```
ALTER ROLE role_name [ [ WITH ] option [ ... ] ];
```

- The **option** clause for granting permissions is as follows.

```
{CREATEDB | NOCREATEDB}
| {CREATEROLE | NOCREATEROLE}
| {INHERIT | NOINHERIT}
| {AUDITADMIN | NOAUDITADMIN}
| {SYSADMIN | NOSYSADMIN}
| {MONADMIN | NOMONADMIN}
| {OPRADMIN | NOOPRADMIN}
| {POLADMIN | NOPOLADMIN}
| {USEFT | NOUSEFT}
| {LOGIN | NOLOGIN}
| {REPLICATION | NOREPLICATION}

| {PERSISTENCE | NOPERSISTENCE}
| CONNECTION LIMIT connlimit
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD { 'password' [ EXPIRED ] | DISABLE | EXPIRED }
| [ ENCRYPTED | UNENCRYPTED ] IDENTIFIED BY { 'password' [ REPLACE 'old_password' |
EXPIRED ] | DISABLE }
| VALID BEGIN 'timestamp'
| VALID UNTIL 'timestamp'
| RESOURCE POOL 'respool'
| USER GROUP 'groupuser'
| PERM SPACE 'spacelimit'
| TEMP SPACE 'tmpspacelimit'
| SPILL SPACE 'spillspacelimit'
| NODE GROUP logic_cluster_name
| ACCOUNT { LOCK | UNLOCK }
| PGUSER
```

- Rename a role.

```
ALTER ROLE role_name
  RENAME TO new_name;
```

- Lock or unlock.

```
ALTER ROLE role_name
ACCOUNT { LOCK | UNLOCK };
```

- Set parameters for a role.

```
ALTER ROLE role_name [ IN DATABASE database_name ]
SET configuration_parameter {{ TO | = } { value | DEFAULT } | FROM CURRENT};
```

- Reset parameters for a role.

```
ALTER ROLE role_name
[ IN DATABASE database_name ] RESET {configuration_parameter|ALL};
```

Parameters

- **role_name**

Specifies a role name.

Value range: an existing role name. If a role name contains uppercase letters, enclose the name with double quotation marks ("").

- **IN DATABASE database_name**

Modifies the parameters of a role in a specified database.

- **SET configuration_parameter {{ TO | = } { value | DEFAULT } | FROM CURRENT}**

Sets parameters for a role. The session parameters modified using ALTER ROLE is only for a specific role and is valid in the next session triggered by the role.

NOTICE

The current version does not support setting user-level parameters.

Value range:

For details about the values of **configuration_parameter** and **value**, see [SET](#).

DEFAULT: clears the value of **configuration_parameter**.

configuration_parameter will inherit the default value of the new session generated for the role.

FROM CURRENT: uses the value of **configuration_parameter** of the current session.

- **RESET {configuration_parameter|ALL}**
Clears the value of **configuration_parameter**. The statement has the same effect as that of **SET configuration_parameter TO DEFAULT**.

NOTICE

The current version does not support the resetting of user-level parameters.

Value range: **ALL** indicates that the values of all parameters are cleared.

- **ACCOUNT LOCK | ACCOUNT UNLOCK**
 - **ACCOUNT LOCK**: locks an account to forbid login to databases.
 - **ACCOUNT UNLOCK**: unlocks an account to allow login to databases.
- **PGUSER**
In the current version, the PGUSER permission of a role cannot be modified.
- **{PASSWORD|IDENTIFIED BY} 'password'**
Resets or changes the user password. Except the initial user, other administrators and common users need to enter the correct old password when changing their own passwords. Only the initial user, the system administrators (sysadmin) when separation of duties is disabled, or users who have the permission (CREATEROLE) to create users can reset the password of a common user without entering the old password. The initial user can reset passwords of system administrators. A system administrator cannot reset passwords of other system administrators.
- **EXPIRED**
Invalidates the password. Only the initial user, the system administrators (sysadmin), or users who have the permission to create a user (CREATEROLE) can invalidate the user password. A system administrator can invalidate the password of itself or other system administrators only when the separation of duties is disabled. The password of the initial user cannot be invalidated.
The user whose password is invalid can log in to the database but cannot perform the query operation. The query operation can be performed only after the password is changed or the administrator resets the password.

For details about other parameters, see [Parameters](#) in "CREATE ROLE."

Examples

```
-- Create role test_role.
gaussdb=# CREATE ROLE test_role PASSWORD '*****';

-- Set role test_role to log in to the database.
gaussdb=# ALTER ROLE test_role WITH LOGIN;

-- Lock role test_role.
gaussdb=# ALTER ROLE test_role ACCOUNT LOCK;

-- Unlock a locked role.
gaussdb=# ALTER ROLE test_role ACCOUNT UNLOCK;

-- Change the password of role test_role.
gaussdb=# ALTER ROLE test_role PASSWORD '*****';

-- Rename role test_role to test_role2.
```

```
gaussdb=# ALTER ROLE test_role RENAME TO test_role2;
-- Change role test_role2 to the system administrator.
gaussdb=# ALTER ROLE test_role2 SYSADMIN;
-- Delete.
gaussdb=# DROP ROLE test_role2;
```

7.12.6.23 ALTER ROW LEVEL SECURITY POLICY

Description

Modifies an existing row-level security policy, including the policy name and the users and expressions affected by the policy.

Precautions

Only the table owner or a system administrator can perform this operation.

Syntax

- Change the name of an existing row-level security policy.
ALTER [ROW LEVEL SECURITY] POLICY policy_name ON table_name RENAME TO new_policy_name;

- Change the specified user and policy expression of an existing row-level security policy.

```
ALTER [ ROW LEVEL SECURITY ] POLICY policy_name ON table_name
[ TO { role_name | PUBLIC } [, ...] ]
[ USING ( using_expression ) ];
```

Parameters

- policy_name**
Specifies the name of a row-level security policy.
- table_name**
Specifies the name of a table to which a row-level security policy is applied.
- new_policy_name**
Specifies the new name of a row-level security policy.
- role_name**
Specifies names of users affected by a row-level security policy. PUBLIC indicates that the row-level security policy will affect all users.

- **using_expression**

Specifies a row-level security policy, which is similar to a Boolean expression in the WHERE clause.

Examples

```
-- Create the data table all_data.
gaussdb=# CREATE TABLE all_data(id int, role varchar(100), data varchar(100));

-- Create a row-level security policy to specify that the current user can view only their own data.
gaussdb=# CREATE ROW LEVEL SECURITY POLICY all_data_ri ON all_data USING(role = CURRENT_USER);
gaussdb=# \d+ all_data
          Table "public.all_data"
Column |      Type      | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
id     | integer        |           |         |              |
role   | character varying(100) |           | extended |              |

Row Level Security Policies:
  POLICY "all_data_ri" FOR ALL
    TO public
    USING (((role)::name = "current_user"()))
Has OIDs: no
Distribute By: HASH(id)
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no

-- Change the name of the all_data_ri policy.
gaussdb=# ALTER ROW LEVEL SECURITY POLICY all_data_ri ON all_data RENAME TO all_data_new_ri;

-- Create users alice and bob.
gaussdb=# CREATE ROLE alice WITH PASSWORD "*****";
gaussdb=# CREATE ROLE bob WITH PASSWORD "*****";

-- Change the users affected by the row-level security policy.
gaussdb=# ALTER ROW LEVEL SECURITY POLICY all_data_new_ri ON all_data TO alice, bob;
gaussdb=# \d+ all_data
          Table "public.all_data"
Column |      Type      | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
id     | integer        |           |         |              |
role   | character varying(100) |           | extended |              |
data   | character varying(100) |           | extended |              |
Row Level Security Policies:
  POLICY "all_data_new_ri" FOR ALL
    TO alice,bob
    USING (((role)::name = "current_user"()))
Has OIDs: no
Distribute By: HASH(id)
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no, enable_rowsecurity=true

-- Modify the expression defined for the row-level security policy.
gaussdb=# ALTER ROW LEVEL SECURITY POLICY all_data_new_ri ON all_data USING (id > 100 AND role =
current_user);
gaussdb=# \d+ all_data
          Table "public.all_data"
Column |      Type      | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
id     | integer        |           |         |              |
role   | character varying(100) |           | extended |              |
data   | character varying(100) |           | extended |              |
Row Level Security Policies:
  POLICY "all_data_new_ri" FOR ALL
    TO alice,bob
    USING (((id > 100) AND ((role)::name = "current_user"()))))
Has OIDs: no
Distribute By: HASH(id)
```

```

Location Nodes: ALL DATANODES
Options: orientation=row, compression=no, enable_rowsecurity=true

-- Delete the policy.
gaussdb=# DROP ROW LEVEL SECURITY POLICY all_data_new_rls ON all_data;

-- Delete users alice and bob.
gaussdb=# DROP ROLE alice, bob;

-- Delete the all_data table.
gaussdb=# DROP TABLE all_data;
    
```

Helpful Links

[CREATE ROW LEVEL SECURITY POLICY](#) and [DROP ROW LEVEL SECURITY POLICY](#)

7.12.6.24 ALTER SCHEMA

Description

Modifies schema attributes.

Precautions

- Only the owner of a schema or users granted with the ALTER permission on the schema can run the **ALTER SCHEMA** command. When separation of duties is disabled, system administrators have this permission by default. To change the owner of a schema, you must be the owner of the schema or system administrator and a member of the new owner role.
- For system schemas other than public, such as pg_catalog and sys, only the initial user is allowed to change the owner of a schema. Changing the names of the built-in system schemas may make some functions unavailable or even affect the normal running of the database. By default, the names of the built-in system schemas cannot be changed. To ensure forward compatibility, you can change the names of the built-in system schemas only when the system is being started or upgraded or when **allow_system_table_mods** is set to **on**.
- Except the initial user, other users cannot change the owner of a schema to an O&M administrator.

Syntax

- Alter the tamper-proof attribute of a schema.
ALTER SCHEMA schema_name { WITH | WITHOUT } BLOCKCHAIN;

- Rename a schema.
ALTER SCHEMA schema_name
RENAME TO new_name;

- Change the owner of a schema.
ALTER SCHEMA schema_name
OWNER TO new_owner;

- Modify the default character set and collation of the schema.

```
ALTER SCHEMA schema_name
  [ [DEFAULT] CHARACTER SET | CHARSET [=] default_charset ] [ [DEFAULT] COLLATE [=]
default_collation ];
```

Parameters

- **schema_name**
Specifies the name of an existing schema.
Value range: an existing schema name.
- **RENAME TO new_name**
Renames a schema.
new_name: new name of the schema.

NOTICE

- The schema name must be unique in the current database.
- The schema name cannot be the same as the initial username of the current database.
- The schema name cannot start with **pg_**.
- The schema name cannot start with **gs_role_**.

Value range: a string. It must comply with the [naming convention](#).

- **OWNER TO new_owner**
Changes the owner of a schema. To do this as a non-administrator, you must be a direct or indirect member of the new owner role, and that role must have the CREATE permission on the database.
new_owner: new owner of the schema.
Value range: an existing username or role name.
- **{ WITH | WITHOUT } BLOCKCHAIN**
Alters the tamper-proof attribute of a schema by using WITH. Common row-store tables with the tamper-proof attribute are tamper-proof history tables, excluding foreign tables, temporary tables, and system catalogs. The tamper-proof attribute can be altered only when no table is contained in the schema. The tamper-proof attribute of the temporary table schema, the TOAST table schema, db_perf schema, and blockchain schema cannot be modified. This syntax can be used to convert between normal and tamper-proof modes only if the schema does not contain any tables.

 **NOTE**

To change a common schema to a tamper-proof schema, set the GUC parameter **enable_ledger** to **on**. The default value is **off**, and the level is **SIGHUP**.

- **default_charset**

Changes the default character set of the schema. If this parameter is specified separately, the default collation of the schema is set to the default collation of the specified character set.

This syntax is supported only when **sql_compatibility** is set to **'MYSQL'**. For details about the supported character sets, see [Table 7-240](#).

- **default_collate**

Changes the default collation of the schema. If this parameter is specified separately, the default character set of the schema is set to the character set corresponding to the specified collation.

This syntax is supported only when **sql_compatibility** is set to **'MYSQL'**. For details about the supported collation, see [Table 7-240](#).

Examples

- Alter the tamper-proof attribute of a schema.

To alter the common mode to the tamper-proof mode, you need to set the GUC parameter **enable_ledger** to determine whether to enable the ledger database function. Contact the administrator for information about how to use the parameters.

```
-- Create a schema test_schema1.
gaussdb=# CREATE SCHEMA test_schema1;

-- Change the schema test_schema1 to the tamper-proof mode.
gaussdb=# ALTER SCHEMA test_schema1 WITH BLOCKCHAIN;

-- Query mode information. The tamper-proof attribute is true.
gaussdb=# \dn+ test_schema1
List of schemas
Name | Owner | Access privileges | Description | WithBlockChain
-----+-----+-----+-----+-----
test_schema1 | omm | | | t
(1 row)
```

- Rename a schema.

```
-- Rename the schema test_schema1 to test_sch1.
gaussdb=# ALTER SCHEMA test_schema1 RENAME TO test_sch1;

-- Query schema information
gaussdb=# \dn+ test*
List of schemas
Name | Owner | Access privileges | Description | WithBlockChain
-----+-----+-----+-----+-----
test_sch1 | omm | | | t
(1 row)
```

- Change the owner of a schema.

```
-- Create user test_user.
gaussdb=# CREATE ROLE test_user PASSWORD '*****';

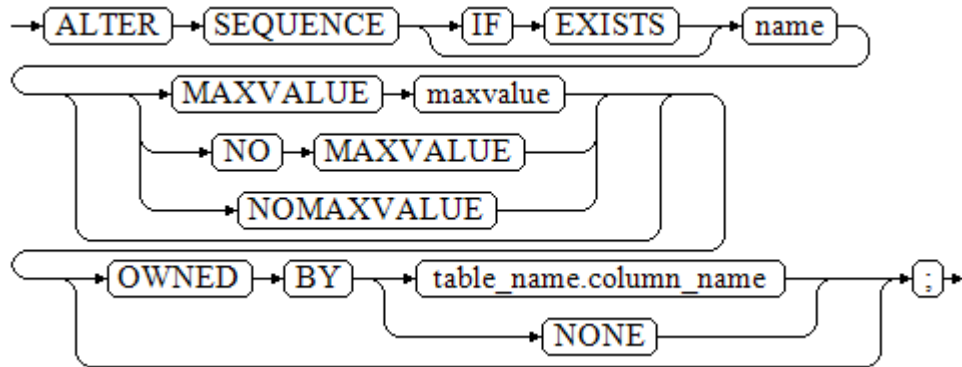

-- Change the owner of schema test_sch1 to test_user.
gaussdb=# ALTER SCHEMA test_sch1 OWNER TO test_user;

-- Query schema information
gaussdb=# \dn+ test_sch1;
List of schemas
Name | Owner | Access privileges | Description | WithBlockChain
```

Syntax

- Change the owning column and maximum value of a sequence.

```
ALTER SEQUENCE [ IF EXISTS ] name
[ MAXVALUE maxvalue | NO MAXVALUE | NOMAXVALUE ]
[ OWNED BY { table_name.column_name | NONE } ] ;
```

- Change the owner of a sequence.

```
ALTER SEQUENCE [ IF EXISTS ] name OWNER TO new_owner;
```

Parameters

- name**
Specifies the name of the sequence to be modified.
- IF EXISTS**
This option is used when the sequence does not exist. ERROR is not displayed. Instead, a NOTICE message is returned.
- MAXVALUE maxvalue | NO MAXVALUE | NOMAXVALUE**
Specifies the maximum value of the sequence. The new maximum value must be greater than the current maximum value stored by GTM. If this parameter is not specified, the original maximum value is retained.
Value range: (gtm_last_value, 2⁶³ - 1].
- OWNED BY**
Associates a sequence with a specified column included in a table. In this way, the sequence will be deleted when you delete its associated column or the table where the column belongs to.
If the sequence has been associated with another table before you use this option, the new association will overwrite the old one.
The associated table and sequence must be owned by the same user and in the same schema.
If OWNED BY NONE is used, all existing associations will be deleted.
- new_owner**
Specifies the username of the new owner of the sequence. To change the owner, you must also be a direct or indirect member of the new role, and this role must have the CREATE permission on the sequence's schema.

Examples

```
-- Create an ascending sequence named serial, which starts from 101.
gaussdb=# CREATE SEQUENCE serial START 101;

-- Create a table and specify default values for the sequence.
gaussdb=# CREATE TABLE t1(c1 bigint default nextval('serial'));

-- Change the owning column of serial to t1.c1.
gaussdb=# ALTER SEQUENCE serial OWNED BY t1.c1;

-- Delete a sequence and a table.
gaussdb=# DROP SEQUENCE serial CASCADE;
gaussdb=# DROP TABLE t1;
```

Helpful Links

[CREATE SEQUENCE](#) and [DROP SEQUENCE](#)

7.12.6.26 ALTER SERVER

Description

Adds, modifies, or deletes the parameters of an existing server. You can query existing servers from the `pg_foreign_server` system catalog.

Precautions

- Only the server owner or a user granted with the ALTER permission can run the **ALTER SERVER** command. The system administrator has this permission by default. To change the owner of a server, the current user must be the owner of the server or the system administrator, and the user must be a member of the new owner role.
- When multi-layer quotation marks are used for sensitive columns (such as **password** and **secret_access_key**) in **OPTIONS**, the semantics is different from that in the scenario where quotation marks are not used. Therefore, sensitive columns are not identified for anonymization.

Syntax

- Change the parameters for a foreign server.

```
ALTER SERVER server_name [ VERSION 'new_version' ]
[ OPTIONS ( {[ ADD | SET | DROP ] option ['value']} [, ... ] ) ] ;
```

In **OPTIONS**, **ADD**, **SET**, and **DROP** are operations to be performed. If these operations are not specified, **ADD** operations will be performed by default. **option** and **value** are the parameters of the corresponding operation.

- Change the owner of a foreign server.

```
ALTER SERVER server_name  
OWNER TO new_owner;
```

→ ALTER → SERVER → server_name → OWNER → TO → new_owner → ; →

- Change the name of a foreign server.

```
ALTER SERVER server_name  
RENAME TO new_name;
```

→ ALTER → SERVER → server_name → RENAME → TO → new_name → ; →

Parameters

- **server_name**
Specifies the name of the server to be modified.
- **new_version**
Specifies the new version of the server.
- **OPTIONS**
Change options of the server. **ADD**, **SET**, and **DROP** are operations to be performed. If the operation is not set explicitly, **ADD** is used. The option name must be unique, and the name and value are also validated with the foreign data wrapper library of the server.
Options for modifying a server are as follows:
 - **encrypt**
Specifies whether to encrypt data. This parameter can be set only when **type** is set to **OBS**. The default value is **off**.
Value range:
 - **on** indicates that data is encrypted.
 - **off** indicates that data is not encrypted.
 - **access_key**
Specifies the access key (AK) (obtained by users from the OBS console) used for the OBS access protocol. This parameter is available only when **type** is set to **OBS**.
 - **secret_access_key**
Specifies the secret key (SK) value (obtained by users from the OBS console) used for the OBS access protocol. This parameter is available only when **type** is set to **OBS**.
- **new_owner**
Specifies the new owner of the server. To change the owner, you must be the owner of the foreign server and a direct or indirect member of the new owner role, and must have the **USAGE** permission on the encapsulator of the foreign server.
- **new_name**
Specifies the new name of the server.

Examples

```
-- Create my_server.  
gaussdb=# CREATE SERVER my_server FOREIGN DATA WRAPPER log_fdw;  
  
-- Change the name of an external service.  
gaussdb=# ALTER SERVER my_server RENAME TO my_server_1;  
  
-- Delete my_server_1.  
gaussdb=# DROP SERVER my_server_1;
```

Helpful Links

[CREATE SERVER](#) and [DROP SERVER](#)

7.12.6.27 ALTER SESSION

Description

ALTER SESSION defines or modifies the conditions or parameters that affect the current session. Modified session parameters are kept until the current session is disconnected.

Precautions

- If the START TRANSACTION statement is not executed before the SET TRANSACTION statement, the transaction is ended instantly and the statement does not take effect.
- You can use the transaction_mode(s) method declared in the START TRANSACTION statement to avoid using the SET TRANSACTION statement. For details, see [START TRANSACTION](#).

Syntax

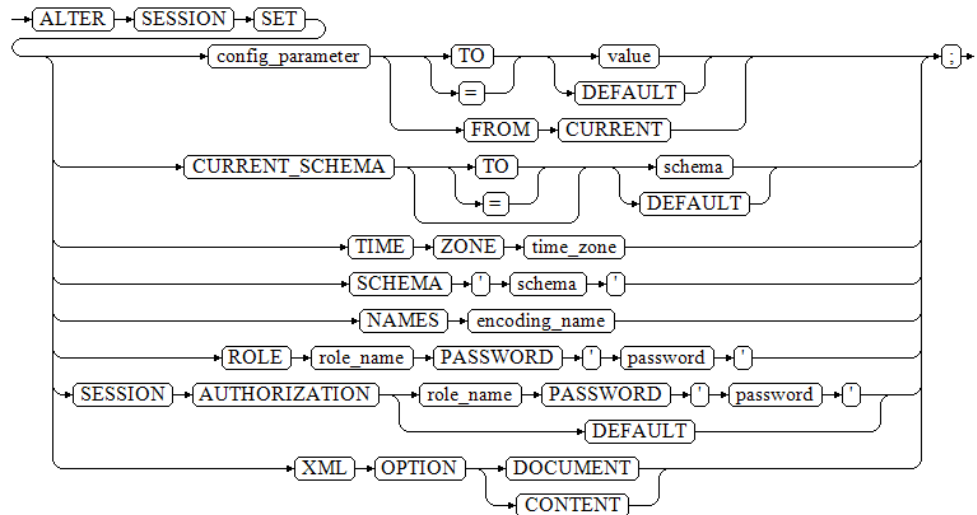

- Set transaction parameters of a session.

```
ALTER SESSION SET [ SESSION CHARACTERISTICS AS ] TRANSACTION  
{ ISOLATION LEVEL { READ COMMITTED } | { READ ONLY | READ WRITE } } [, ...] ;
```

- Set other GUC parameters of a session.

```
ALTER SESSION SET  
{{config_parameter { { TO | = } { value | DEFAULT } FROM CURRENT } }  
| CURRENT_SCHEMA [ TO | = ] { schema | DEFAULT }  
| TIME_ZONE time_zone  
| SCHEMA 'schema'  
| NAMES encoding_name  
| ROLE role_name PASSWORD 'password'  
| SESSION AUTHORIZATION { role_name PASSWORD 'password' | DEFAULT }  
| XML OPTION { DOCUMENT | CONTENT }  
};
```

Parameters

- **config_parameter**

Specifies the name of a configurable GUC parameter. You can use SHOW ALL to view available GUC parameters.

- **value**

Specifies the new value of **config_parameter**. This parameter can be specified as string constants, identifiers, numbers, or comma-separated lists of these. **DEFAULT** is used to set default values for parameters.

- **DEFAULT**

- **OFF**

- **RESET**

- User-specified value: The value must meet the restriction of the modified parameter.

- **FROM CURRENT**

Uses the value of **configuration_parameter** of the current session.

- **CURRENT_SCHEMA**

- **schema**

Specifies the current schema.

Value range: an existing schema name. If the schema name does not exist, the value of **CURRENT_SCHEMA** will be empty.

- **TIME ZONE timezone**

Specifies the local time zone for the current session.

Value range: a valid local time zone. The corresponding GUC parameter is **TimeZone**. The default value is **PRC**.

- **SCHEMA schema**

Specifies the current schema. The schema here is a string.

- **NAMES encoding_name**

Specifies the client character encoding. This statement is equivalent to **set client_encoding to encoding_name**.

Value range: a valid character encoding name. The GUC parameter corresponding to this option is **client_encoding**. The default encoding is **UTF8**.

- **role_name**

Value range: a string. It must comply with the **naming convention**.

- **password**

Specifies the password of a role. It must comply with the password convention. Encrypted passwords are not supported.

- **SESSION AUTHORIZATION**

Sets the session user identifier of the current session.

- **XML OPTION { DOCUMENT | CONTENT }**

Specifies the XML parsing mode.

Value range: **CONTENT** (default) and **DOCUMENT**

Examples

- Set transaction parameters of a session.

The keyword **ALTER SESSION** can be omitted in the example.

```
-- Start a transaction and set the transaction level.
gaussdb=# START TRANSACTION;
gaussdb=# ALTER SESSION SET TRANSACTION READ ONLY;
gaussdb=# END;
```

- Set other GUC parameters of a session.

The keyword **ALTER SESSION** can be omitted in the example.

```
-- Create the ds schema.
gaussdb=# CREATE SCHEMA ds;

-- Set the search path of a schema.
gaussdb=# SET SEARCH_PATH TO ds, public;

-- Set the time/date type to the traditional postgres format (date before month).
gaussdb=# SET DATESTYLE TO postgres, dmy;

-- Set the character code of the current session to UTF8.
gaussdb=# ALTER SESSION SET NAMES 'UTF8';

-- Set the time zone to Berkeley of California.
gaussdb=# SET TIME_ZONE 'PST8PDT';

-- Set the time zone to Italy.
gaussdb=# SET TIME_ZONE 'Europe/Rome';

-- Set the current schema.
gaussdb=# ALTER SESSION SET CURRENT_SCHEMA TO tpcds;

-- Set XML OPTION to DOCUMENT.
gaussdb=# ALTER SESSION SET XML OPTION DOCUMENT;

-- Create the role joe, and set the session role to joe.
gaussdb=# CREATE ROLE joe WITH PASSWORD '*****';
gaussdb=# ALTER SESSION SET SESSION AUTHORIZATION joe PASSWORD '*****';

-- Switch to the default user.
gaussdb=> ALTER SESSION SET SESSION AUTHORIZATION default;

-- Delete the ds schema.
```

```
gaussdb=# DROP SCHEMA ds;  
-- Delete the role joe.  
gaussdb=# DROP ROLE joe;
```

Helpful Links

[SET](#)

7.12.6.28 ALTER SYNONYM

Description

Modifies the attributes of the SYNONYM object.

Precautions

- Currently, only the owner of the SYNONYM object can be changed.
- Only a system administrator has the permission to modify the owner of the SYNONYM object. When separation of duties is enabled, system administrators do not have the permission to change the owner of the SYNONYM object by default.
- The new owner must have the CREATE permission on the schema where the SYNONYM object resides.
- PUBLIC synonyms cannot be modified.

Syntax

```
ALTER SYNONYM synonym_name  
OWNER TO new_owner;
```

→ ALTER → SYNONYM → synonym_name → OWNER → TO → new_owner → ; →

Parameters

- **synonym_name**
Specifies the name of the synonym to be modified, which can contain the schema name.
Value range: a string. It must comply with the [naming convention](#).
- **new_owner**
Specifies the new owner of the SYNONYM object.
Value range: a string. It must be a valid username.

Examples

```
-- Create a system administrator.  
gaussdb=# CREATE USER sysadmin WITH SYSADMIN PASSWORD '*****';  
  
-- Switch the system administrator.  
gaussdb=# \c - sysadmin  
  
-- Create synonym t1.  
gaussdb=# CREATE OR REPLACE SYNONYM t1 FOR ot.t1;
```

```
-- Create user u1.
gaussdb=# CREATE USER u1 PASSWORD '*****';

-- Assign permissions to the new user.
gaussdb=# GRANT ALL ON SCHEMA sysadmin TO u1;

-- Change the owner of synonym t1 to u1.
gaussdb=# ALTER SYNONYM t1 OWNER TO u1;

-- Delete synonym t1.
gaussdb=# DROP SYNONYM t1;

-- Revoke permissions from user u1.
gaussdb=# REVOKE ALL ON SCHEMA sysadmin FROM u1;

-- Delete user u1.
gaussdb=# DROP USER u1;

-- Switch to the initial user init_user. Replace init_user with the actual initial username.
gaussdb=# \c - init_user

-- Delete user sysadmin.
gaussdb=# DROP USER sysadmin;
```

Helpful Links

[CREATE SYNONYM](#) and [DROP SYNONYM](#)

7.12.6.29 ALTER SYSTEM KILL SESSION

Description

ALTER SYSTEM KILL SESSION ends a session.

Syntax

```
ALTER SYSTEM KILL SESSION 'session_sid, serial' [ IMMEDIATE ] ;
```

Parameters

- **session_sid, serial**
Specifies **SID** and **SERIAL** of a session (see examples for format). You can use the `pg_stat_activity` system catalog to query the current active threads (see the examples). However, when you run the **ALTER SYSTEM KILL SESSION** command, the threads may have ended.
Value range: SIDs and SERIALs of all sessions that can be queried from the system catalog `dv_sessions`.
- **IMMEDIATE**
Specifies that a session will be ended instantly after the statement is executed.

Examples

```
-- Start two sessions, and create a table and start a transaction to insert data in the first session.
gaussdb=# CREATE TABLE tbl_test(id int);
gaussdb=# BEGIN;
```

```
gaussdb=# INSERT INTO tbl_test VALUES (1);

-- Query the session information in the second session. If the value of state is idle in transaction, the
transaction is waiting to be committed.
gaussdb=# SELECT t1.datname,
           t1.username,
           t1.pid,
           t2.serial#,
           t1.state
FROM pg_stat_activity t1,
     dv_sessions t2
WHERE t1.query LIKE 'INSERT INTO tbl_test%'
      AND t1.sessionid = t2.sid;
 datname | username | pid | serial# | state
-----+-----+-----+-----+-----
 postgres | omm      | 139802072635136 | 0 | idle in transaction
(1 row)

-- End a session. If the IMMEDIATE parameter is not specified, the session and transactions in the session
are forcibly ended.
gaussdb=# ALTER SYSTEM KILL SESSION '139802072635136,0';
pg_terminate_backend
-----
 t
(1 row)

-- Perform the reconnection and query the tbl_test table. The transaction is forcibly ended and the data is
rolled back.
gaussdb=# SELECT * FROM tbl_test;
 id
----
(0 rows)

-- Drop the table.
gaussdb=# DROP TABLE tbl_test;
```

7.12.6.30 ALTER TABLE

Description

Modifies tables, including modifying table definitions, renaming tables, renaming specified columns in tables, renaming table constraints, setting table schemas, enabling or disabling row-level security policies, and adding or updating multiple columns.

Precautions

- If the base table is a hash-distributed table, to create a primary key or unique index that does not contain the distribution key of the base table, use a GSI (by specifying the **BY GLOBAL INDEX** field); to create a primary key or unique index that contains the distribution key of the base table, use a common index (without specifying the **BY GLOBAL INDEX** field). In single-DN deployment mode, both the GSI and common index can be successfully created. If the base table is a non-hash-distributed table, you can only create the primary key or unique index as a common index. That is, the index key must contain the distribution key of the base table.
- The owner of a table, users granted with the ALTER permission on the table, or users granted with the ALTER ANY TABLE permission can run the **ALTER TABLE** command. The system administrator has the permission to run the command by default. To modify the owner or schema of a table, you must be the table owner or system administrator and a member of the new owner role.

- The tablespace of a partitioned table cannot be modified, but the tablespace of the partition can be modified.
- The storage parameter **ORIENTATION** cannot be modified.
- Currently, SET SCHEMA can only set schemas to user schemas. It cannot set a schema to a system internal schema.
- The distribution key (or column) of a table cannot be modified.
- The partition key column of a partitioned table cannot be changed or the character set cannot be converted.
- Auto-increment columns cannot be added, or a column whose **DEFAULT** value contains the NEXTVAL() expression cannot be added.
- Row-level security cannot be enabled for foreign tables and temporary tables.
- When you delete a PRIMARY KEY constraint by constraint name, the NOT NULL constraint is not deleted. If necessary, manually delete the NOT NULL constraint.
- When JDBC is used, the **DEFAULT** value can be set through PreparedStatement.
- If you add a column using ADD COLUMN, all existing rows in the table are initialized to the column's default value (**NULL** if no **DEFAULT** value is specified).

If no **DEFAULT** value is specified for the new column, **NULL** is used, and no full table update is triggered.

If the new column has the **DEFAULT** value, the column must meet all the following requirements. Otherwise, the entire table is updated, leading to additional overheads and affecting online services.

1. The data type is BOOL, BYTEA, SMALLINT, BIGINT, SMALLINT, INTEGER, NUMERIC, FLOAT, DOUBLE PRECISION, CHAR, VARCHAR, TEXT, TIMESTAMPTZ, TIMESTAMP, DATE, TIME, TIMETZ, or INTERVAL.
2. The length of the **DEFAULT** value of the added column cannot exceed 128 bytes.
3. The **DEFAULT** value of the added column does not contain the volatile function.
4. The **DEFAULT** value is required and cannot be **NULL**.

If you are not sure whether condition 3 is met, check whether the **provolatile** attribute of the function in the PG_RPOC system catalog is **v**.

- If you add a row-level expression when adding or changing an ILM policy for a data object, note that the row-level expression supports only the functions listed in the whitelist. For details about the whitelist function list, see [Row Expression Function Whitelist](#).
- The number of table constraints cannot exceed 32,767.

Syntax

- Modify the definition of a table.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }
    action [, ... ];
ALTER TABLE [ IF EXISTS ] table_name
    ADD ( { column_name data_type [ compress_mode ] [ COLLATE collation ] [ column_constraint
[ ... ] } } [, ... ] );
ALTER TABLE [ IF EXISTS ] table_name
    MODIFY ( { column_name data_type | column_name [ CONSTRAINT constraint_name ] NOT NULL
```

```
[ ENABLE ] | column_name [ CONSTRAINT constraint_name ] NULL } [, ... ] );
ALTER TABLE [ IF EXISTS ] table_name
    RENAME [ TO | AS | = ] new_table_name;
RENAME { TABLE | TABLES } { table_name TO new_table_name } [, ... ];
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }
    RENAME [ COLUMN ] column_name TO new_column_name;
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }
    RENAME CONSTRAINT constraint_name TO new_constraint_name;
ALTER TABLE [ IF EXISTS ] table_name
    SET SCHEMA new_schema;
ALTER TABLE [ IF EXISTS ] table_name GSIWAITALL;
```

The table operation **ACTION** can be one of the following clauses:

```
column_clause
| ADD table_constraint [ NOT VALID ]
| ADD table_constraint_using_index
| VALIDATE CONSTRAINT constraint_name
| DROP CONSTRAINT [ IF EXISTS ] constraint_name [ RESTRICT | CASCADE ]
| DROP PRIMARY KEY
| CLUSTER ON index_name
| SET WITHOUT CLUSTER
| SET ( { storage_parameter = value } [, ... ] )
| RESET ( storage_parameter [, ... ] )
| OWNER TO new_owner
| SET TABLESPACE new_tablespace
| SET { COMPRESS | NOCOMPRESS }
| TO { GROUP groupname | NODE ( nodename [, ... ] ) }
| ADD NODE ( nodename [, ... ] )
| DELETE NODE ( nodename [, ... ] )
| UPDATE SLICE LIKE table_name
| DISABLE TRIGGER [ trigger_name | ALL | USER ]
| ENABLE TRIGGER [ trigger_name | ALL | USER ]
| ENABLE REPLICA TRIGGER trigger_name
| ENABLE ALWAYS TRIGGER trigger_name
| ENABLE ROW LEVEL SECURITY
| DISABLE ROW LEVEL SECURITY
| FORCE ROW LEVEL SECURITY
| NO FORCE ROW LEVEL SECURITY
| ENCRYPTION KEY ROTATION
| REPLICA IDENTITY { DEFAULT | USING INDEX index_name | FULL | NOTHING }
| AUTO_INCREMENT [ = ] value
| COMMENT [ = ] 'string'
| [ [ DEFAULT ] CHARACTER SET | CHARSET [ = ] default_charset ] [ [ DEFAULT ] COLLATE [ = ]
default_collation ]
| CONVERT TO CHARACTER SET | CHARSET charset [ COLLATE collation ]
| ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year }
OF { NO MODIFICATION } [ ON ( EXPR ) ]
| [ MODIFY { PARTITION | SUBPARTITION } ] ILM { ENABLE | DISABLE | DELETE } POLICY
policy_name
| [ MODIFY { PARTITION | SUBPARTITION } ] ILM { ENABLE_ALL | DISABLE_ALL | DELETE_ALL }
```

 NOTE

- **ADD table_constraint [NOT VALID]**
Adds a table constraint.
- **ADD table_constraint_using_index**
Adds a primary key constraint or unique constraint to a table based on the existing unique index. If the specified index is a GSI, an error is reported. In this case, you need to use the BY GLOBAL INDEX syntax to add a GSI index constraint.
- **VALIDATE CONSTRAINT constraint_name**
Validates a check-class constraint created with the **NOT VALID** option, and scans the entire table to ensure that all rows meet the constraint. Nothing happens if the constraint is already marked valid.
- **DROP CONSTRAINT [IF EXISTS] constraint_name [RESTRICT | CASCADE]**
Deletes a table constraint.
- **DROP PRIMARY KEY**
Deletes a primary key constraint from a table. This syntax is valid only when **sql_compatibility** is set to 'MYSQL'.
- **CLUSTER ON index_name**
Selects the default index for future CLUSTER operations. Actually, the table is not re-clustered.
- **SET WITHOUT CLUSTER**
Deletes the most recently used CLUSTER index from the table. Deletes the most recently used CLUSTER index from the table.
- **SET ({storage_parameter = value} [, ...])**
Changes one or more storage parameters for the table. If the value of **table_name** is an index name, **ACTIVE_PAGES** specifies the number of index pages, which may be less than the actual number of physical file pages and can be used for optimizer optimization. Currently, this parameter is valid only for the local index of the Ustore partitioned table and will be updated by VACUUM (including AUTOVACUUM) and ANALYZE. You are advised not to manually set this parameter because it is invalid in distributed mode.
- **RESET (storage_parameter [, ...])**
Resets one or more storage parameters to their defaults. As with SET, a table rewrite might be needed to update the table entirely.
- **OWNER TO new_owner**
Changes the owner of a table, sequence, or view to the specified user.
- **SET TABLESPACE new_tablespace**
Changes the table's tablespace to the specified tablespace and moves the data files associated with the table to the new tablespace. Indexes on the table, if any, are not moved; but they can be moved separately with additional **SET TABLESPACE** option in ALTER INDEX.
- **SET { COMPRESS | NOCOMPRESS }**
Sets the compression feature of a table. The table compression feature affects only the storage mode of data inserted in a batch subsequently and does not affect storage of existing data. Setting the table compression feature will result in the fact that there are both compressed and uncompressed data in the table. Row-store tables do not support compression.
- **TO { GROUP groupname | NODE (nodename [, ...]) }**
The syntax is only available in extended mode (when GUC parameter **support_extended_features** is on). Exercise caution when enabling the mode. It is mainly used for tools like internal dilatation tools. Common users should not use the mode. This command only modifies the logical mapping relationship of the

table distribution nodes and does not migrate the table's metadata and data on the DN.

- **ADD NODE (nodename [, ...])**

It is only available for internal scale-out tools. Common users should not use the syntax.

- **DELETE NODE (nodename [, ...])**

It is only available for internal scale-in tools. Common users should not use the syntax.

- **UPDATE SLICE LIKE table_name**

This syntax is used by internal scaling tools and cannot be used by common users.

- **DISABLE TRIGGER [trigger_name | ALL | USER]**

Disables a single trigger specified by **trigger_name**, disables all triggers, or disables only user triggers (excluding internally generated constraint triggers, for example, deferrable unique constraint triggers and exclusion constraints triggers).

Exercise caution when using this function because data integrity cannot be ensured as expected if the triggers are not executed.

- **| ENABLE TRIGGER [trigger_name | ALL | USER]**

Enables a single trigger specified by **trigger_name**, enables all triggers, or enables only user triggers.

- **| ENABLE REPLICA TRIGGER trigger_name**

Determines that the trigger firing mechanism is affected by the configuration variable *session_replication_role*. When the replication role is **origin** (default value) or **local**, a simple trigger is fired.

When **ENABLE REPLICA** is configured for a trigger, it is triggered only when the session is in replica mode.

- **| ENABLE ALWAYS TRIGGER trigger_name**

Determines that all triggers are fired regardless of the current replica mode.

- **| { DISABLE | ENABLE } [REPLICA | ALWAYS] RULE**

Enables or disables a rule for tables. Disabled rules are still visible in the system, but are not applied during query rewriting. The ON SELECT rule cannot be disabled because it is related to the view implementation. Rules configured as **ENABLE REPLICA** are enabled only when the session is in replica mode, while those configured as **ENABLE ALWAYS** can be enabled regardless of the replica mode. Rule triggering is also affected by configuration variable *session_replication_role*, which is similar to the preceding trigger setting.

- **| { DISABLE | ENABLE } ROW LEVEL SECURITY**

Enables or disables row-level security for a table.

If row-level security is enabled for a data table but no row-level security policy is defined, the row-level access to the data table is not affected. If row-level security for a table is disabled, the row-level access to the table is not affected even if a row-level security policy has been defined. For details, see [CREATE ROW LEVEL SECURITY POLICY](#).

- **| {NO FORCE|FORCE} ROW LEVEL SECURITY**

Forcibly enables or disables row-level security for a table.

By default, the table owner is not affected by the row-level security feature. However, if row-level security is forcibly enabled, the table owner (excluding system administrators) will be affected. System administrators are not affected by any row-level security policies.

- **| ENCRYPTION KEY ROTATION**

Rotation of the transparent data encryption key.

The data encryption key rotation of a table can be performed only when the TDE function is enabled for the database and **enable_tde** of the table is set to **on**. After

the key rotation operation is performed, the system automatically applies for a new KMS key. After the key rotation, the data encrypted using the old key is decrypted using the old key, and the newly written data is encrypted using the new key. To ensure the security of encrypted data, you can periodically update the key based on the amount of new data in the encrypted table. It is recommended that the key be updated every two to three years.

- **REPLICA IDENTITY { DEFAULT | USING INDEX index_name | FULL | NOTHING }**

Specifies the record level of old tuples in UPDATE and DELETE statements on a table in logical replication scenarios.

- **DEFAULT** records the old value of the primary key column. If there is no primary key, **DEFAULT** does not record the old value.
- **USING INDEX** records the old values of columns covered by the named indexes. These values must be unique, non-local, and non-deferrable, and contain the values of columns marked **NOT NULL**.
- **FULL** records the old values of all columns in the row.
- **NOTHING** does not record information in old rows.

In logical replication scenarios, when the UPDATE and DELETE statements of a table are parsed, the parsed old tuples consist of the information recorded in this method. For tables with primary keys, this option can be set to **DEFAULT** or **FULL**. For a table without a primary key, set this parameter to **FULL**. Otherwise, the old tuple will be parsed as empty during decoding. You are advised not to set this parameter to **NOTHING** in common scenarios because old tuples are always parsed as empty.

For Ustore tables, the **NOTHING** option is invalid, and the actual effect is the same as that of **FULL**. If **DEFAULT** does not have a primary key, all columns in the row are recorded.

- **AUTO_INCREMENT [=] value**

Sets the next auto-increment value of the auto-increment column. The configured value takes effect only when it is greater than the current auto-increment counter.

The value must be a non-negative integer and cannot be greater than $2^{127} - 1$.

This clause takes effect only when **sql_compatibility** is set to 'MYSQL'.

- **[[DEFAULT] CHARACTER SET | CHARSET [=] default_charset] [[DEFAULT] COLLATE [=] default_collation]**

Modifies the default character set and default collation of a table to the specified values. The modification does not affect the existing columns in the table.

- **CONVERT TO CHARACTER SET | CHARSET charset [COLLATE collation]**

Modifies the default character set and default collation of a table to the specified values, sets the character set and collation of all columns with character type to the specified value and converts the data in the column to new character set encoding.

- **ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year } OF { NO MODIFICATION } [ON (EXPR)]**

Adds an ILM policy to a table. A complete ILM policy consists of two parts: ILM action and ILM condition. The ILM action is used to define a specific data compression or movement behavior. The ILM condition is used to define a condition for triggering the ILM action. The ILM condition is a row-level condition, that is, when the ILM condition applies to each row in the heap table and the current row is not modified within a period of time, the ILM condition is met, and the ILM action is triggered. EXPR supports only basic operation functions (such as `to_date` and `substr`) of table columns and types.

- **[MODIFY { PARTITION | SUBPARTITION }] ILM { ENABLE | DISABLE | DELETE } POLICY policy_name**

Modifies a single ILM policy of a table. **policy_name** is the value of **POLICY_NAME** queried from the system view `GS_ADM_ILMOBJECTS` or `GS_MY_ILMOBJECTS`.

- **[MODIFY { PARTITION | SUBPARTITION } ILM { ENABLE_ALL | DISABLE_ALL | DELETE_ALL }**
Modifies all ILM policies of a table.
- **The column_clause can be one of the following clauses:**
ADD [COLUMN] [IF NOT EXISTS] column_name data_type [CHARACTER SET | CHARSET charset] [compress_mode] [COLLATE collation] [column_constraint [...]]
| MODIFY column_name data_type
| MODIFY column_name [CONSTRAINT constraint_name] NOT NULL [ENABLE]
| MODIFY column_name [CONSTRAINT constraint_name] NULL
| MODIFY column_name data_type { { [COMMENT 'string'] [...] } | AUTO_INCREMENT }
| MODIFY [COLUMN] column_name data_type [CHARACTER SET | CHARSET charset]
[[[COLLATE collation] | [column_constraint]] [...]]
| CHANGE [COLUMN] column_name new_column_name data_type [CHARACTER SET | CHARSET charset] [[[COLLATE collation] | [column_constraint]] [...]]
| DROP [COLUMN] [IF EXISTS] column_name [RESTRICT | CASCADE]
| ALTER [COLUMN] column_name [SET DATA] TYPE data_type [COLLATE collation] [USING expression]
| ALTER [COLUMN] column_name { SET DEFAULT expression | DROP DEFAULT }
| ALTER [COLUMN] column_name { SET | DROP } NOT NULL
| ALTER [COLUMN] column_name SET STATISTICS [PERCENT] integer
| ADD STATISTICS ((column_1_name, column_2_name [, ...]))
| DELETE STATISTICS ((column_1_name, column_2_name [, ...]))
| ALTER [COLUMN] column_name SET ({attribute_option = value} [, ...])
| ALTER [COLUMN] column_name RESET (attribute_option [, ...])
| ALTER [COLUMN] column_name SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }

 NOTE

- **ADD [COLUMN] [IF NOT EXISTS] column_name data_type [CHARACTER SET | CHARSET [=] charset] [compress_mode] [COLLATE collation] [column_constraint [...]]**

Adds a column to a table. If a column is added using ADD COLUMN, all existing rows in the table are initialized with the column's default value (NULL if no DEFAULT clause is specified). When IF NOT EXISTS is specified and columns with the same name exist, a notice is returned, indicating that the column already exists. When IF NOT EXISTS is not specified and columns with the same name exist, an error is returned.

- **ADD ({ column_name data_type [compress_mode] } [, ...])**

Adds columns in the table.

- **MODIFY ({ column_name data_type | column_name [CONSTRAINT constraint_name] NOT NULL [ENABLE] | column_name [CONSTRAINT constraint_name] NULL } [, ...])**

Modifies the data type of an existing column in the table. Running this command will clear the statistics of this column. You are advised to collect the statistics of this column again after the modification.

- **MODIFY column_name data_type { { [COMMENT 'string'] [...] } | AUTO_INCREMENT }**

- Replaces the definition of existing column in a table with a new definition. The indexes and independent object constraints, such as primary keys, unique key and CHECK constraints in the previous column are not deleted.
- This syntax can be used only in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL').
- This syntax cannot be used for foreign tables, or modifying encrypted columns.
- The data type and collation rule of partition key columns cannot be modified. The data type and collation rule of columns referenced by rules and materialized views cannot be modified.
- If a column whose data type or collation rule is modified is referenced by a generated column, the data in the generated column is regenerated.
- If some objects (such as indexes, independent object constraints, views, triggers, and row-level security policies) depend on a modified column, these objects are rebuilt during column modification. If the definition of the modified column violates the constraints of this type of object, the modification fails. For example, the data type of the column that is used as the view result column cannot be modified. Pay attention on the failure impact before modification.
- In HASH, LIST, and RANGE distribution scenarios, the data type and comments of distribution keys cannot be modified.
- If a modified column is called by some objects (such as user-defined functions and stored procedures), the modified column does not process these objects. After the column names are modified, these objects may be unavailable. Please evaluate the impact before modification.
- The syntax of this clause is the same as that of **MODIFY column_name data_type** in the previous clause, but the semantic function is different. When the GUC parameter **b_format_behavior_compat_options** contains the **enable_modify_column** option, the function of this clause is used.
- Running this command will clear the statistics of this column. You are advised to collect the statistics of this column again after the modification.

- **MODIFY [COLUMN] column_name data_type [CHARACTER SET | CHARSET charset] [[COLLATE collation] | [column_constraint]] [...]]**

Replaces the definition of existing field in a table with a new definition. The indexes and independent object constraints, such as primary keys, unique key and CHECK constraints in the previous field are not deleted.

This syntax can be used only when **sql_compatibility** is set to 'MYSQL'. Foreign tables are not supported. Encrypted columns cannot be modified. The data type and collation rule of partition key columns cannot be modified. The data type and collation rule of columns referenced by rules and materialized views cannot be modified.

If a column whose data type or collation rule is modified is referenced by a generated column, the data in the generated column is regenerated.

If some objects (such as indexes, independent object constraints, views, triggers, and row-level security policies) depend on a modified column, these objects are rebuilt during column modification. If the definition of the modified column violates the constraints of this type of object, the modification fails. For example, the data type of the column that is used as the view result column cannot be modified. Pay attention on the failure impact before modification.

If a modified column is called by some objects (such as user-defined functions and stored procedures), the modified column does not process these objects. After the columns are modified, these objects may be unavailable. Please evaluate the impact before modification.

Changing the character set or collation of a column converts the data in the column to the new character set for encoding.

The syntax of this clause is the same as that of **MODIFY column_name data_type** in the previous clause, but the semantic function is different. When the GUC parameter **b_format_behavior_compat_options** contains the **enable_modify_column** option, the function of this clause is used.

Running this command will clear the statistics of this column. You are advised to collect the statistics of this column again after the modification.

- **CHANGE [COLUMN] column_name new_column_name data_type [CHARACTER SET | CHARSET charset] [[COLLATE collation] | [column_constraint]] [...]]**

Replaces the definition and name of existing column in a table with a new definition and name. The new column name must be different from the previous. The indexes and independent object constraints, such as primary keys, unique key and CHECK constraints in the previous column are not deleted.

This syntax can be used only when **sql_compatibility** is set to 'MYSQL'. Foreign tables are not supported. Encrypted columns cannot be modified. The data type and collation rule of partition key columns cannot be modified. The data type and collation rule of columns referenced by rules and materialized views cannot be modified.

If a column whose data type or collation rule is modified is referenced by a generated column, the data in the generated column is regenerated.

If some objects (such as indexes, independent object constraints, views, triggers, and row-level security policies) depend on a modified column, these objects are rebuilt during column modification. If the definition of the modified column violates the constraints of this type of object, the modification fails. For example, the data type of the column that is used as the view result column cannot be modified. Pay attention on the failure impact before modification.

If a modified column is called by some objects (such as user-defined functions and stored procedures), the modified column does not process these objects. After the column names are modified, these objects may be unavailable. Please evaluate the impact before modification.

Modifying the character set or collation of a column converts the data in the column to the new character set for encoding.

- **DROP [COLUMN] [IF EXISTS] column_name [RESTRICT | CASCADE]**

Drops a column from a table. Indexes and constraints related to the column are automatically dropped. If an object not belonging to the table depends on the column (for example, view), CASCADE must be specified.

The DROP COLUMN statement does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent INSERT and UPDATE operations in the table will store a **NULL** value for the column. Therefore, column deletion takes a short period of time but does not immediately release the tablespace on the disks, because the space occupied by the deleted column is not recycled. The space will be recycled when VACUUM is executed.

- **ALTER [COLUMN] column_name [SET DATA] TYPE data_type [COLLATE collation] [USING expression]**

Modifies the type of a column in a table. Indexes and simple table constraints on the column will automatically use the new data type by reparsing the originally supplied expression.

If the original data type of a column and the modified data type are binary compatible, you do not need to rewrite the entire table when running this statement. In other scenarios, the entire table is rewritten. You can check whether the original type and target type are binary compatible in the PG_CAST system catalog. If **castmethod** is **b**, they are binary compatible. For example, if the data type of the source table is text and is converted to int, table rewriting is triggered. If it is converted to clob, table rewriting is not triggered. If table rewriting is triggered, the deleted space on the table is recycled immediately.

Running this command will clear the statistics of this column. You are advised to collect the statistics of this column again after the modification.

- **ALTER [COLUMN] column_name { SET DEFAULT expression | DROP DEFAULT }**

Sets or removes the default value for a column. The default values only apply to subsequent INSERT operations; they do not cause rows already in the table to change. Defaults can also be created for views, in which case they are inserted into INSERT statements on the view before the view's ON INSERT rule is applied.

- **ALTER [COLUMN] column_name { SET | DROP } NOT NULL**

Changes whether a column is marked to allow null values or to reject null values. You can only use SET NOT NULL when the column contains no null values.

- **ALTER [COLUMN] column_name SET STATISTICS [PERCENT] integer**

Specifies the per-column statistics-gathering target for subsequent ANALYZE operations. The target can be set in the range from 0 to 10000. Set it to -1 to revert to using the default system statistics target.

- **{ADD | DELETE} STATISTICS ((column_1_name, column_2_name [, ...]))**

Adds or deletes the declaration of collecting multi-column statistics to collect multi-column statistics as needed when ANALYZE is performed for a table or a database. The statistics about a maximum of 32 columns can be collected at a time. You are not allowed to add or delete such declaration for system catalogs or foreign tables.

- **ALTER [COLUMN] column_name SET ({attribute_option = value} [, ...])**
ALTER [COLUMN] column_name RESET (attribute_option [, ...])

Sets or resets per-attribute options.

Currently, the only defined per-attribute options are **n_distinct** and **n_distinct_inherited**. **n_distinct** affects statistics of a table, while

n_distinct_inherited affects the statistics of the table and its subtables. Currently, only **SET/RESET n_distinct** is supported, and **SET/RESET n_distinct_inherited** is forbidden.

- **ALTER [COLUMN] column_name SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }**

Sets the storage mode for a column. It specifies whether this column is held inline or in an attached table, and whether the data should be compressed. **SET STORAGE** does not change a table. It only specifies the recommended strategy for future table updates.

- **column_constraint** is as follows:

```
[ CONSTRAINT constraint_name ]
{ NOT NULL |
  NULL |
  CHECK ( expression ) |
  DEFAULT default_expr |
  ON UPDATE update_expr |
  GENERATED ALWAYS AS ( generation_expr ) [STORED] |
  AUTO_INCREMENT |
  COMMENT 'string' |
  UNIQUE [KEY] index_parameters |
  PRIMARY KEY index_parameters |
  ENCRYPTED WITH ( COLUMN_ENCRYPTION_KEY = column_encryption_key,
  ENCRYPTION_TYPE = encryption_type_value ) |
  REFERENCES reftable [ ( refcolumn ) ] [ MATCH FULL | MATCH PARTIAL | MATCH
SIMPLE ]
  [ ON DELETE action ] [ ON UPDATE action ] }
[ DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

- **index_parameters** is as follows:

```
[ WITH ( {storage_parameter = value} [, ... ] ) ]
[ USING INDEX TABLESPACE tablespace_name ]
```

- **update_expr** is as follows:

```
{ CURRENT_TIMESTAMP | LOCALTIMESTAMP | NOW() }
```

- **compress_mode** of a column is as follows:

```
{ DELTA | PREFIX | DICTIONARY | NUMSTR | NOCOMPRESS }
```

- **table_constraint_using_index** used to add the primary key constraint or unique constraint based on the unique index is as follows:

```
[ CONSTRAINT constraint_name ]
{ UNIQUE | PRIMARY KEY } USING INDEX index_name
[ DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

- **table_constraint** is as follows:

```
[ CONSTRAINT [ constraint_name ] ]
{ CHECK ( expression ) |
  UNIQUE [ idx_name ] [ USING method ] ( { {column_name [ ( length ) ] | ( expression ) }
[ ASC | DESC ] } [, ... ] ) index_parameters |
  PRIMARY KEY [ USING method ] ( {column_name [ ASC | DESC ] } [, ... ] ) index_parameters
}
[ DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
{ [ COMMENT 'string' ] [ ... ] }
```

index_parameters is as follows:

```
[ WITH ( {storage_parameter = value} [, ... ] ) ]
[ USING INDEX TABLESPACE tablespace_name ][BY GLOBAL INDEX]
```

NOTE

If **index_parameters** is set to **BY GLOBAL INDEX**, the global secondary index is used to create constraints.

- Rename a table. The renaming does not affect stored data.

```
ALTER TABLE [ IF EXISTS ] table_name
RENAME [ TO | AS | = ] new_table_name;
```

 NOTE

If you specify this parameter in a version 5.7 MySQL-compatible database (**sql_compatibility** set to 'MYSQL', **b_format_version** set to '5.7', and **b_format_dev_version** set to 's2'), the following situations may occur:

- If the character string corresponding to the new table name starts with "#mysql50#" and is followed by other characters, "#mysql50#" will be ignored.
- If the old and new table names are the same, no error is reported.

- Rename the specified column in the table.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
  RENAME [ COLUMN ] column_name TO new_column_name;
```

- Rename the constraint of the table.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
  RENAME CONSTRAINT constraint_name TO new_constraint_name;
```

- Set the schema of the table.

```
ALTER TABLE [ IF EXISTS ] table_name  
  SET SCHEMA new_schema;
```

 NOTE

- The schema setting moves the table into another schema. Associated indexes and constraints owned by table columns are migrated as well. Currently, the schema for sequences cannot be changed. If the table has sequences, delete the sequences, and create them again or delete the ownership between the table and sequences. In this way, the table schema can be changed.
 - To change the schema of a table, you must also have the CREATE permission on the new schema. To add the table as a new child of a parent table, you must own the parent table as well. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have the CREATE permission on the table's schema. These restrictions enforce that the user can only rebuild and delete the table. A system administrator can alter the ownership of any table anyway.
 - All the actions except for RENAME and SET SCHEMA can be combined into a list of multiple alterations to apply in parallel. For example, it is possible to add several columns or alter the type of several columns in a single statement. This is useful with large tables, since only one pass over the tables need be made.
 - Adding a CHECK or NOT NULL constraint will scan the table to validate that existing rows meet the constraint.
 - Adding a column with a non-NULL default or changing the type of an existing column will rewrite the entire table. Rewriting a large table may take much time and temporarily needs doubled disk space.
- Add columns.
ALTER TABLE [IF EXISTS] table_name
 ADD ({ column_name data_type [compress_mode] [COLLATE collation] [column_constraint [...] } [, ...]);
 - Update columns.
ALTER TABLE [IF EXISTS] table_name
 MODIFY ({ column_name data_type | column_name [CONSTRAINT constraint_name] NOT NULL [ENABLE] | column_name [CONSTRAINT constraint_name] NULL } [, ...]);
 - Commit all DML transactions in the table when the SQL statement is executed.
ALTER TABLE [IF EXISTS] table_name GSIWAITALL;

 NOTE

This syntax is internally called by the CREATE GLOBAL INDEX CONCURRENTLY function to synchronize lock wait during online creation of global secondary indexes. You are advised not to use this syntax.

Parameters

- **IF EXISTS**
Sends a notice instead of an error if no tables have identical names. The notice prompts that the table you are querying does not exist.
- **table_name [*] | ONLY table_name | ONLY (table_name)**
table_name is the name of the table that you need to modify.
If **ONLY** is specified, only the table is modified. If **ONLY** is not specified, the table and all subtables are modified. You can add the asterisk (*) option following the table name to specify that all subtables are scanned, which is the default operation.
- **constraint_name**
 - Specifies the name of an existing constraint to drop in the DROP CONSTRAINT operation.
 - Specifies the name of a new constraint in the ADD CONSTRAINT operation.

NOTICE

For a new constraint, **constraint_name** is optional in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL'). In other databases, **constraint_name** must be added.

- **index_name**
Specifies the index name.

NOTICE

In the ADD CONSTRAINT operation:

- The **index_name** parameter is supported only in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL').
 - For foreign key constraints, if **constraint_name** and **index_name** are specified at the same time, **constraint_name** is used as the index name.
 - For a unique key constraint, if both **constraint_name** and **index_name** are specified, the value of **index_name** is used as the index name.
-
- **USING method**
Specifies the name of the index method to be used.
For details about the value range, see USING method in [Parameters](#).

NOTICE

In the ADD CONSTRAINT operation:

- The USING method is supported only in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL').
- In MySQL-compatible mode, if USING method is not specified, the default index method is B-tree for Astore or UB-tree for Ustore.
- If the storage mode of a table is Ustore and the constraint in the SQL statement is specified as USING BTREE, the underlying layer automatically creates the constraint as USING UBTREE.

- **ASC | DESC**

ASC specifies an ascending (default) sort order. **DESC** specifies a descending sort order.

NOTICE

In ADD CONSTRAINT, ASC|DESC is supported only in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL').

- **expression**

Specifies an expression index constraint based on one or more columns of the table. It must be written in parentheses.

NOTICE

Expression indexes in the UNIQUE constraint are supported only in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL').

- **storage_parameter**

Specifies the name of a storage parameter.

The following options are added for online scale-out:

- **append_mode** (enumerated type)

Scales out a table online or offline, or stops scaling it. You can modify certain content in the table during online scaling but cannot do so during offline scaling.

To modify a table that is being scaled, append new data so that they can be recorded as incremental data.

- **on**: scales out a table online. New data will be appended.
- **off**: stops scaling. New data will be written in normal mode, and options for online scaling will not be displayed in **pg_class.reloptions**.
- **read_only**: scales a table offline, during which no other operations can be performed on the table.

- **end_catchup**: reports errors for the write service in the last round of data increment. The read service is executed normally.
- **rel_cn_oid** (OID type)
Records the OID of tables on the current CN to generate **delete_delta** on the DNs.
If **append_mode** is set to **on**, **rel_cn_oid** must be specified.
The **append_mode** and **rel_cn_oid** options are used only for online scale-out tools.
- **exec_step** (integer)
Records resumable transmission steps in **relOptions** of the temporary table.
Value range: [1,4]
It can be used only for data redistribution.
- **create_time** (long integer)
Records the time when the temporary table is created during resumable transmission in **relOptions** of the temporary table.
Only the data redistribution tool is supported.
- **wait_clean_cbi** (string type)
Specifies whether the current global index contains the residual tuple generated during bucket migration for scale-out. After scale-out, **wait_clean_cbi** is set to **y**. After the residual tuple is cleared in the vacuum process, **wait_clean_cbi** is set to **n**.
This option is used only in scaling tools.
- **enable_update_distkey**
Determines whether the table supports the UPDATE operation on distribution keys. The distribution keys can be updated only when this attribute of the table is set to **on** and constraints are met. Otherwise, distribution keys do not support the UPDATE operation.
Value range: **on** and **off**
Default value: **off**

 NOTE

The constraints on updating distribution keys are as follows:

- Distribution columns can be updated only when **enable_update_distkey** is set to **on**.
- The UPDATE statement cannot be pushed down to DNs for execution. The PGXC plan is directly generated and is not changed based on the values before and after the distribution key is updated.
- Tables with row-level UPDATE TRIGGER are not supported. Otherwise, the execution fails and an error message is displayed. The row-level INSERT/DELETE TRIGGER does not take effect, and the update-statement-level TRIGGER is executed normally.
- Concurrent update of the same row is not supported. You need to obtain a lock first. The result (returning 0 or reporting an error) of obtaining a lock on DNs depends on the setting of the GUC parameter **concurrent_dml_mode**. If an error is reported, the possible causes are as follows: (1) The error message "update distribute column conflict" is reported. (2) When the lock obtaining time exceeds the threshold, an error is reported, indicating that the lock times out.
- Tables with global secondary indexes (GSIs) are not supported. Otherwise, an error is reported.
- Only Hash distribution is supported. LIST/RANGE distribution tables are not supported. Otherwise, an error is reported.
- MERGE INTO and UPSERT cannot be used to update distribution keys. Otherwise, an error is reported.
- GTM_FREE is not supported. Otherwise, an error is reported.
- UPDATE RETURNING is not supported. Otherwise, an error is reported.
- Statements with joined tables are not supported. Otherwise, an error is reported.
- UPDATE+LIMIT is not supported. Otherwise, an error is reported.

The following option is added for creating an index:

- **parallel_workers** (int type)

Number of bgworker threads started when an index is created. For example, value 2 indicates that two bgworker threads are started to create indexes concurrently.

Value range: [0,32]. The value 0 indicates that concurrent index creation is disabled.

Default value: If this parameter is not set, the concurrent index creation function is disabled.

The following option is added to the replication table:

- **primarynode** (Boolean type)

Default value: **off**

When primarynode is set to **on**, the primary node is selected for the replication table. Generally, the primary node is the first node recorded in the **nodeoids** column in the **pgxc_class** table. When the IUD operation is performed on the replication table, the operation is delivered to the primary node first. After the result is received, the operation is delivered to other DNs.

- **logical_repl_node** (string type)

Name of the DN that returns logical logs to the CN during logical decoding of a distributed replication table. For the replication table, if this

parameter is not specified, the first node in the node group where the current table is located is used by default. When the RESET operation is performed on this option, **logical_repl_node** is reset to the first node of current table.

Value range: a string

Default value: For the non-replication table, this parameter is empty by default. For the replication table, this parameter is set to the name of the first node by default.

TDE options:

- **enable_tde** (Boolean type)

Specifies whether to set a table as an encrypted table. This parameter applies only to row-store tables, segment-page tables, hash bucket tables, temporary tables, and unlogged tables. When setting **enable_tde** to **on**, ensure that the TDE function has been enabled using the GUC parameter **enable_tde** and the information for accessing the key service has been set using the GUC parameter **tde_key_info**. For details about how to use this parameter, see section "Transparent Data Encryption" in *Feature Guide*.

Value range: **on** and **off**.

on: Transparent data encryption is enabled.

off: Transparent data encryption is disabled.

NOTE

- After the value is changed from **on** to **off**, the inserted or updated data is still encrypted when being written to the old page, and is not encrypted when being written to the new page generated after the switchover.
- After the value is changed from **off** to **on**, the inserted or updated data is not encrypted when being written to the old page, and is automatically encrypted when being written to the new page generated after the switchover.

That is, the encryption status on the new data page is the same as that after the encryption switchover, and the encryption status on the old data page is the same as that before the switchover. You are advised to manually perform VACUUM FULL on the table after the encryption switchover to ensure that the encryption status of all data pages is consistent.

Default value: **off**

- **encrypt_algo** (string type)

Specifies the encryption algorithm of the encryption table.

Value range: a string. The value can be **AES_128_CTR** or **SM4_CTR**.

Default value: **AES_128_CTR** if **enable_tde** is set to **on**; otherwise, null.

- **hasuids** (Boolean type)

Default value: **off**

If this parameter is set to **on**, a unique table-level ID is allocated to a tuple when the tuple is updated.

- **statistic_granularity**

Records the default **partition_mode** when the table analyzes statistics. For details about **partition_mode**, see [ANALYZE | ANALYSE](#). This parameter is invalid for non-partitioned tables.

Value range: See the value range of **partition_mode**.

Default value: **AUTO**

- **new_owner**
Specifies the name of the new table owner.
- **new_tablespace**
Specifies the new name of the tablespace to which the table belongs.
- **column_name, column_1_name, column_2_name**
Specifies the name of a new or existing column.
- **data_type**
Specifies the type of a new column or a new type of an existing column.
- **compress_mode**
Specifies whether to compress a table column. The clause specifies the compression algorithm preferentially used by the column. Row-store tables do not support compression.
- **charset**
Specifies the character set of a table column. If this parameter is specified separately, the collation of the table column is set to the default collation of the specified character set.

This syntax is supported only in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL').
- **collation**
Specifies the collation rule name of a column. The optional COLLATE clause specifies a collation for the new column; if omitted, the collation is the default for the new column. You can run the **select * from pg_collation** command to query collation rules from the **pg_collation** system catalog. The default collation rule is the row starting with **default** in the query result.

In a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL'), **utf8mb4_bin**, **utf8mb4_general_ci**, **utf8mb4_unicode_ci**, **binary**, **gbk_chinese_ci**, **gbk_bin**, **gb18030_chinese_ci**, and **gb18030_bin** are also supported. For details, see [Table 7-240](#).

 **NOTE**

- Only the character type supports the specified character set. If the binary character set or collation is specified, the character type is converted to the corresponding binary type. If the type mapping does not exist, an error is reported. Currently, only the mapping from the TEXT type to the BLOB type is available.
- Except the binary character set and collation, only the character set that is the same as the database encoding can be specified.
- If the character set or collation of a column is not explicitly specified and the default character set or collation of the table is specified, the character set or collation of the column is inherited from the table. If the default character set or collation of a table does not exist, the character set and collation of table columns inherit the character set and collation of the current database when **b_format_behavior_compat_options** contains 'default_collation'.
- If the character set corresponding to the modified character set or collation is different from the character set of current column, the data in the column is converted to the specified character set for encoding.
- **USING expression**
Specifies how to compute the new column value from the old; if omitted, the default conversion is an assignment cast from old data type to new. A USING

clause must be provided if there is no implicit or assignment cast from the old to new type.

 **NOTE**

USING in ALTER TYPE can specify any expression involving the old values of the row; that is, it can refer to any columns other than the one being cast. This allows general casting to be done with the ALTER TYPE syntax. Because of this flexibility, the USING expression is not applied to the column's default value (if any); the result might not be a constant expression as required for a default. This means that when there is no implicit or assignment cast from old to new type, ALTER TYPE might fail to convert the default even though a USING clause is supplied. In such cases, drop the default with DROP DEFAULT, perform ALTER TYPE, and then use SET DEFAULT to add a suitable new default. Similar considerations apply to indexes and constraints involving the column.

- **NOT NULL | NULL**
Sets whether the column allows null values.
- **ENABLE**
Specifies that the constraint is enabled. By default, the constraint is enabled.
- **integer**
Specifies the constant value of a signed integer. When using **PERCENT**, the range of **integer** is from 0 to 100.
- **attribute_option**
Specifies an attribute option.
- **PLAIN | EXTERNAL | EXTENDED | MAIN**
Specifies a column-store mode.
 - **PLAIN** must be used for fixed-length values (such as integers). It must be inline and uncompressed.
 - **MAIN** is for inline, compressible data.
 - **EXTERNAL** is for external, uncompressed data. Use of **EXTERNAL** will make substring operations on **text** and **bytea** values run faster, at the penalty of increased storage space.
 - **EXTENDED** is for external, compressed data. **EXTENDED** is the default for most data types that support non-**PLAIN** storage.
- **CHECK (expression)**
New rows or rows to be updated must satisfy for an expression to be true. If any row produces a false result, an error is raised and the database is not modified.

A check constraint specified as a column constraint should reference only the column's values, while an expression in a table constraint can reference multiple columns.

Currently, **CHECK (expression)** does not include subqueries and cannot use variables apart from the current column.
- **DEFAULT default_expr**
Assigns a default data value to a column.

The data type of the default expression must match the data type of the column.

The default expression will be used in any insert operation that does not specify a value for the column. If there is no default value for a column, then the default value is **NULL**.

- **ON UPDATE update_expr**

The ON UPDATE clause is an attribute constraint of a column.

When an UPDATE operation is performed on a tuple in a table, if new values of updated columns are different from old values in the table, column values with this attribute but not in updated columns are automatically updated to the current timestamp. If new values of updated columns are the same as old values in the table, column values with this attribute but not in updated columns remain unchanged. If columns with this attribute are in updated columns, column values are updated according to the specified update value.

 **NOTE**

- This attribute can be specified only in MySQL 5.7 (that is, **sql_compatibility** is set to 'MYSQL', **b_format_version** is set to '5.7', and **b_format_dev_version** is set to 's1').
 - In terms of syntax, **update_expr** supports three keywords: CURRENT_TIMESTAMP, LOCALTIMESTAMP, and NOW(). You can also specify or not specify the precision of a keyword with parentheses. For example, ON UPDATE CURRENT_TIMESTAMP(), ON UPDATE CURRENT_TIMESTAMP(5), ON UPDATE LOCALTIMESTAMP(), and ON UPDATE LOCALTIMESTAMP(6). If the keyword does not contain parentheses or contains empty parentheses, the precision is 0. The NOW keyword cannot contain parentheses. The three types of keywords are synonyms of each other and have the same attribute effect.
 - This attribute can be specified only for columns of the following types: timestamp, datetime, date, time without time zone, smalldatetime, and abstime.
 - The CREATE TABLE AS syntax does not inherit the column attributes.
 - The CREATE TABLE LIKE syntax can use INCLUDING UPDATE or EXCLUDING UPDATE to inherit or exclude a constraint. The LIKE syntax is inherited from the LIKE syntax of PostgreSQL. Currently, the ILM policy information of the old table cannot be copied.
 - The precision specified by this attribute can be different from the precision specified by the type in the corresponding column. After the column value is updated through this attribute, the minimum precision is displayed. For example, ALTER TABLE t1 ADD col1 timestamp(6) ON UPDATE CURRENT_TIMESTAMP(3);. If the UPDATE syntax triggers the attribute to take effect, three decimal places in the value of **col1** are displayed after the update.
 - The same column cannot be specified for this attribute and the generated column constraint at the same time.
 - This attribute cannot be specified for the partition key in a partitioned table.
 - In distributed scenarios, this attribute cannot be specified for distribution keys and primary keys.
- **AUTO_INCREMENT**
Specifies an auto-increment column.
For details, see [AUTO_INCREMENT](#).
 - **COLUMN_ENCRYPTION_KEY = column_encryption_key**
Specifies the name of the column encryption key in the ENCRYPTED WITH constraint.
Value range: a string. It must comply with the [naming convention](#).
 - **ENCRYPTION_TYPE = encryption_type_value**

For the encryption type in the ENCRYPTED WITH constraint, the value of **encryption_type_value** is **DETERMINISTIC** or **RANDOMIZED**.

- **COMMENT [=] 'string'**

- The COMMENT [=] 'string' clause is used to add comments to a table.
- The **COMMENT 'string'** in **column_constraint** indicates that comments are added to a column.
- The **COMMENT 'string'** in **table_constraint** indicates that comments are added to the indexes corresponding to the primary key and unique key.

For details, see [COMMENT \[= \] 'string'](#).

- **UNIQUE [KEY] index_parameters**

UNIQUE specifies that a group of one or more columns of a table can contain only unique values.

For the purpose of a unique constraint, null is not considered equal.

UNIQUE KEY can be used only when **sql_compatibility** is set to 'MYSQL', which has the same semantics as UNIQUE.

- **UNIQUE [index_name][USING method] ({ {column_name [(length)] | (expression) } [ASC | DESC] }, ...) index_parameters**

UNIQUE specifies that a group of one or more columns of a table can contain only unique values.

column_name (length) is the prefix key. For details, see [column_name \(length \)](#).

For the purpose of a unique constraint, null is not considered equal.

NOTICE

- The **index_name** parameter is supported only in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL').
- For a unique key constraint, if both **constraint_name** and **index_name** are specified, the value of **index_name** is used as the index name.

- **PRIMARY KEY index_parameters**

PRIMARY KEY [USING method] ({ column_name [ASC | DESC] } [, ...]) index_parameters

Specifies that a column or columns of a table can contain only unique (non-duplicate) and non-null values.

- **USING method**

Specifies the name of the index method to be used.

For details about the value range, see the USING method in [Parameters](#).

NOTICE

- The USING method is supported only in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL').
- In MySQL-compatible mode, if USING method is not specified, the default index method is B-tree for Astore or UB-tree for Ustore.
- For the constraint of building a global secondary index by default, the bottom layer of the global secondary index uses UB-tree storage, even if the storage mode specified by the user is B-tree.
- If the storage mode of a table is Ustore and the constraint in the SQL statement is specified as USING BTREE, the underlying layer automatically creates the constraint as USING UBTREE.

- **ASC | DESC**

ASC specifies an ascending (default) sort order. **DESC** specifies a descending sort order.

NOTICE

ASC|DESC is supported only in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL').

- **expression**

Specifies an expression index constraint based on one or more columns of the table. It must be written in parentheses.

NOTICE

Expression indexes in the UNIQUE constraint are supported only in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL').

- **DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE**

Sets whether the constraint can be deferrable.

- **DEFERRABLE**: deferrable to the end of the transaction and checked using **SET CONSTRAINTS**.
- **NOT DEFERRABLE**: checks immediately after the execution of each command.
- **INITIALLY IMMEDIATE**: checks immediately after the execution of each statement.
- **INITIALLY DEFERRED**: checks when the transaction ends.

- **WITH ({storage_parameter = value} [, ...])**

Specifies an optional storage parameter for a table or an index.

- **tablespace_name**

Specifies the name of the tablespace where the index locates.

- **COMPRESS|NOCOMPRESS**
 - **NOCOMPRESS**: If the **NOCOMPRESS** keyword is specified, the existing compression feature of the table will not be changed.
 - **COMPRESS**: If the **COMPRESS** keyword is specified, the table compression feature will be triggered by batch tuple insertion. Row-store tables do not support compression.
- **new_table_name**

Specifies the new table name.
- **new_column_name**

Specifies the new name of a specific column in a table.
- **new_constraint_name**

Specifies the new name of a table constraint.
- **new_schema**

Specifies the new schema name.
- **CASCADE**

Automatically drops objects that depend on the dropped column or constraint (for example, views referencing the column).
- **RESTRICT**

Refuses to drop the column if the column is referenced by other columns or constraints. **RESTRICT** is the default option. If **CASCADE** is not specified, the value is **RESTRICT**. An example of the statement is as follows:

```
ALTER TABLE table_name [DROP [column] col_name [CASCADE | RESTRICT]];
```

table_name indicates the table name, and **col_name** indicates the column name.
- **schema_name**

Specifies the schema name of a table.
- **IF NOT EXISTS**

When IF NOT EXISTS is specified and columns with the same name exist, a notice is returned, indicating that the column already exists. When IF NOT EXISTS is not specified and columns with the same name exist, an error is returned.
- **[DEFAULT] CHARACTER SET | CHARSET [=] default_charset**

Changes the default character set of the table. If you specify a character set separately, the default collation of the table is set to the default collation of the specified character set.

This syntax is supported only when **sql_compatibility** is set to 'MYSQL'.
- **[DEFAULT] COLLATE [=] default_collation**

Changes the default collation of the table. If you specify a collation separately, the default character set of the table is set to the character set corresponding to the specified collation.

This syntax is supported only when **sql_compatibility** is set to 'MYSQL'. For details about the collation, see [Table 7-240](#).

 NOTE

If the character set or collation of a table is not explicitly specified and the default character set or collation of the schema is specified, the character set or collation of the table is inherited from the schema. If the default character set or collation of a schema does not exist, the character set and collation of the table inherit the character set and collation of the current database when **b_format_behavior_compat_options** contains 'default_collation'.

Examples of Modifying a Table

- Rename a table.

```
gaussdb=# CREATE TABLE aa(c1 int, c2 int);
gaussdb=# ALTER TABLE IF EXISTS aa RENAME TO test_alt1;
```
- Modify the schema of a table.

```
-- Create the test_schema schema.
gaussdb=# CREATE SCHEMA test_schema;

-- Change the schema of the test_alt1 table to test_schema.
gaussdb=# ALTER TABLE test_alt1 SET SCHEMA test_schema;

-- Query table information.
gaussdb=# SELECT schemaname,tablename FROM pg_tables WHERE tablename = 'test_alt1';
schemaname | tablename
-----+-----
test_schema | test_alt1
(1 row)
```
- Change the owner of a table.

```
-- Create user test_user.
gaussdb=# CREATE USER test_user PASSWORD '*****';

-- Change the owner of the test_alt1 table to test_user.
gaussdb=# ALTER TABLE IF EXISTS test_schema.test_alt1 OWNER TO test_user;

-- Query.
gaussdb=# SELECT tablename, schemaname, tableowner FROM pg_tables WHERE tablename = 'test_alt1';
tablename | schemaname | tableowner
-----+-----+-----
test_alt1 | test_schema | test_user
(1 row)
```
- Modify the tablespace of a table.

```
-- Create the tbs_data1 tablespace.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Change the tablespace of the test_alt1 table to tbs_data1.
gaussdb=# ALTER TABLE test_schema.test_alt1 SET TABLESPACE tbs_data1;

-- Query.
gaussdb=# SELECT tablename, tablespace FROM pg_tables WHERE tablename = 'test_alt1';
tablename | tablespace
-----+-----
test_alt1 | tbs_data1
(1 row)

-- Delete.
gaussdb=# DROP TABLE test_schema.test_alt1;
gaussdb=# DROP TABLESPACE tbs_data1;
gaussdb=# DROP SCHEMA test_schema;
gaussdb=# DROP USER test_user;
```

Examples of Modifying a Column

- Change column names.

```
-- Create a table.
gaussdb=# CREATE TABLE test_alt2(c1 INT,c2 INT);

-- Change column names.
gaussdb=# ALTER TABLE test_alt2 RENAME c1 TO id;
gaussdb=# ALTER TABLE test_alt2 RENAME COLUMN c2 to areaid;

-- Query.
gaussdb=# \d test_alt2
Table "public.test_alt2"
Column | Type | Modifiers
-----+-----+-----
id | integer |
areaid | integer |
```

- **Add columns.**

```
-- Add a column to the test_alt2 table.
gaussdb=# ALTER TABLE IF EXISTS test_alt2 ADD COLUMN name VARCHAR(20);

-- Query.
gaussdb=# \d test_alt2
Table "public.test_alt2"
Column | Type | Modifiers
-----+-----+-----
id | integer |
areaid | integer |
name | character varying(20) |
```

- **Add auto-increment columns.**

```
-- Add the AUTO_INCREMENT column to the local_autoinc table. (Change the DN name by running SELECT node_name FROM pgxc_node WHERE node_type = 'D' based on the actual situation.)
```

```
gaussdb=# CREATE TABLE local_autoinc(col1 int)
DISTRIBUTE BY LIST(col1)(
  SLICE s1 VALUES (1) DATANODE datanode1,
  SLICE s2 VALUES (2) DATANODE datanode2
);
```

```
-- Distribute data to DN1.
```

```
gaussdb=# INSERT INTO local_autoinc(col1) VALUES(1);
```

```
-- Add a local auto-increment column. The value starts from 1 for each DN.
```

```
gaussdb=# ALTER TABLE local_autoinc ADD COLUMN col int AUTO_INCREMENT;
```

```
gaussdb=# SELECT col,col1 FROM local_autoinc ORDER BY 2,1;
```

```
col | col1
-----+-----
1 | 1
(1 row)
```

```
-- Set the next auto-increment value of all DNs to 10.
```

```
gaussdb=# ALTER TABLE local_autoinc AUTO_INCREMENT = 10;
```

```
-- Distribute data to DN1. The value NULL triggers auto-increment, and the auto-increment value is 10.
```

```
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(NULL,1);
```

```
-- Distribute data to DN2. The value 0 triggers auto-increment, and the auto-increment value is 10.
```

```
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(0,2);
```

```
gaussdb=# SELECT col,col1 FROM local_autoinc ORDER BY 2,1;
```

```
col | col1
-----+-----
1 | 1
10 | 1
10 | 2
(3 rows)
```

- **Modify the data type of a column.**

```
-- Change the type of the name column in the test_alt2 table.
```

```
gaussdb=# ALTER TABLE test_alt2 MODIFY name VARCHAR(50);
```

```
-- Query.
```

```
gaussdb=# \d test_alt2
Table "public.test_alt2"
```

```

Column |      Type      | Modifiers
-----+-----+-----
id     | integer        |
areaid | integer        |
name   | character varying(50) |
-- Change the type of the name column in the test_alt2 table.
gaussdb=# ALTER TABLE test_alt2 ALTER COLUMN name TYPE VARCHAR(25);

-- Query.
gaussdb=# \d test_alt2
          Table "public.test_alt2"
Column |      Type      | Modifiers

-- Delete.
gaussdb=# DROP TABLE test_alt2;

```

Examples of Modifying a Constraint

- **Add a not-null constraint to a column.**

```

-- Create a table.
gaussdb=# CREATE TABLE test_alt3(pid INT, areaid CHAR(5), name VARCHAR(20));

Add a not-null constraint to pid.
gaussdb=# ALTER TABLE test_alt3 MODIFY pid NOT NULL;

-- Query.

```

```
gaussdb=# \d test_alt3
      Table "public.test_alt3"
  Column |      Type      | Modifiers
-----+-----+-----
 pid    | integer        | not null
 areaid | character(5)   |
 name   | character varying(20) |
```

- **Cancel the not-null constraint on a column.**

```
gaussdb=# ALTER TABLE test_alt3 MODIFY pid NULL;
-- Query.
```

```
gaussdb=# \d test_alt3
      Table "public.test_alt3"
  Column |      Type      | Modifiers
-----+-----+-----
 pid    | integer        |
 areaid | character(5)   |
 name   | character varying(20) |
```

- **Modify the default value of a column.**

```
-- Modify the default value of id in the test_alt3 table.
gaussdb=# ALTER TABLE test_alt3 ALTER COLUMN areaid SET DEFAULT '00000';
```

```
-- Query.
gaussdb=# \d test_alt3
      Table "public.test_alt3"
  Column |      Type      | Modifiers
-----+-----+-----
 pid    | integer        |
 areaid | character(5)   | default '00000'::bpchar
 name   | character varying(20) |
-- Delete the default value of id.
```

```
gaussdb=# ALTER TABLE test_alt3 ALTER COLUMN areaid DROP DEFAULT;
```

```
-- Query.
gaussdb=# \d test_alt3
      Table "public.test_alt3"
  Column |      Type      | Modifiers
-----+-----+-----
 pid    | integer        |
 areaid | character(5)   |
 name   | character varying(20) |
```

- **Add a table-level constraint.**

- **Directly add a constraint.**

```
-- Add a primary key constraint to the table.
gaussdb=# ALTER TABLE test_alt3 ADD CONSTRAINT pk_test3_pid PRIMARY KEY (pid);
```

```
-- Query.
gaussdb=# \d test_alt3
      Table "public.test_alt3"
  Column |      Type      | Modifiers
-----+-----+-----
 pid    | integer        | not null
 areaid | character(5)   |
 name   | character varying(20) |
Indexes:
 "pk_test3_pid" PRIMARY KEY, btree (pid) TABLESPACE pg_default
```

- **Create an index and then add constraints.**

```
-- Create a table.
gaussdb=# CREATE TABLE test_alt4(c1 INT, c2 INT);

-- Create an index.
gaussdb=# CREATE UNIQUE INDEX pk_test4_c1 ON test_alt4(c1);

-- Associate the created index when adding a constraint.
gaussdb=# ALTER TABLE test_alt4 ADD CONSTRAINT pk_test4_c1 PRIMARY KEY USING INDEX
pk_test4_c1;
```

```
-- Query.
gaussdb=# \d test_alt4
Table "public.test_alt4"
Column | Type | Modifiers
-----+-----+-----
c1 | integer | not null
c2 | integer |
Indexes:
"pk_test4_c1" PRIMARY KEY, btree (c1) TABLESPACE pg_default

-- Delete.
gaussdb=# DROP TABLE test_alt4;
```

- Delete a table-level constraint.

```
-- Delete a constraint.
gaussdb=# ALTER TABLE test_alt3 DROP CONSTRAINT IF EXISTS pk_test3_pid;

-- Query.
gaussdb=# \d test_alt3
Table "public.test_alt3"
Column | Type | Modifiers
-----+-----+-----
pid | integer | not null
areaid | character(5) |
name | character varying(20) |

-- Delete.
gaussdb=# DROP TABLE test_alt3;

-- Delete a primary key constraint. (This syntax is supported only in MySQL-compatible mode.)
gaussdb=# CREATE TABLE test_drop_primary_key(c1 INT PRIMARY KEY);
gaussdb=# \d test_drop_primary_key
Table "public.test_drop_primary_key"
Column | Type | Modifiers
-----+-----+-----
c1 | integer | not null
Indexes:
"test_drop_primary_key_pkey" PRIMARY KEY, btree (c1) TABLESPACE pg_default

gaussdb=# ALTER TABLE test_drop_primary_key DROP PRIMARY KEY;
gaussdb=# \d test_drop_primary_key
Table "public.test_drop_primary_key"
Column | Type | Modifiers
-----+-----+-----
c1 | integer | not null
```

[CREATE TABLE](#) and [DROP TABLE](#)

7.12.6.31 ALTER TABLE PARTITION

Description

Modifies table partitions, including adding, deleting, splitting, merging, clearing, exchanging, and renaming partitions, moving partition tablespaces, and modifying partition attributes.

Precautions

- Only the partitioned table owner or a user granted with the ALTER permission can run the **ALTER TABLE PARTITION** command. When separation of duties is disabled, system administrators have this permission by default.

- The tablespace of the added partition cannot be PG_GLOBAL.
- The name of the added partition must be different from names of existing partitions in the partitioned table.
- The key value of the added partition must be consistent with the type of partition keys in the partitioned table.
- If a range partition is added, the key value of the added partition must be greater than the upper limit of the last range partition in the partitioned table.
- If a list partition is added, the key value of the added partition cannot be the same as that of an existing partition.
- Hash partitions cannot be added.
- If the number of partitions in the target partitioned table has reached the maximum (**1048575**), partitions cannot be added.
- If a partitioned table has only one partition, the partition cannot be deleted.
- Use PARTITION FOR() to choose partitions. The number of specified values in the brackets should be the same as the number of columns specified when you define a partition, and they must be consistent.
- The **Value** partitioned table does not support the ALTER PARTITION operation.
- Hash partitioned tables do not support splitting, combination, addition, or deletion of partitions.
- Deleting, splitting, merging, clearing, and exchanging partitions will invalidate global indexes. The UPDATE GLOBAL INDEX clause can be used to update the indexes synchronously.
- If the UPDATE GLOBAL INDEX clause is not used when you delete, split, merge, clear, or exchange partitions, concurrent DML services may report errors due to invalidated indexes.
- Deleting, splitting, merging, clearing, or exchanging partitions invalidates GSIs on partitioned tables. For exchanging partitions, all GSIs on ordinary tables become invalid. You can declare the UPDATE DISTRIBUTED GLOBAL INDEX clause to update indexes synchronously.
- If the UPDATE DISTRIBUTED GLOBAL INDEX clause is not used when you delete, split, merge, clear, or exchange partitions, concurrent DML services may report errors due to invalidated indexes.
- If **enable_gpi_auto_update** is set to **on**, the global index is automatically updated even if the UPDATE GLOBAL INDEX clause is not declared.
- If you add a row-level expression when adding or changing an ILM policy for a data object, note that the row-level expression supports only the functions listed in the whitelist. For details about the whitelist function list, see [Row Expression Function Whitelist](#).

Syntax

Modifying a partition in a partitioned table includes modifying the table partition itself and the table partition name, and resetting the partition ID.

- Modify the syntax of the table partition.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
action [, ... ];
```

action indicates the following clauses for maintaining partitions. For the partition continuity when multiple clauses are used for partition maintenance, GaussDB executes DROP PARTITION and ADD PARTITION first, and then the rest clauses in sequence.

```
move_clause |
exchange_clause |
row_clause |
merge_clause |
modify_clause |
split_clause |
add_clause |
drop_clause |
truncate_clause |
ilm_clause
```

- The `move_clause` syntax is used to move the partition to a new tablespace.

```
MOVE PARTITION { partition_name | FOR ( partition_value [, ...] ) } TABLESPACE tablespacename
```

- The `exchange_clause` syntax is used to move the data from a general table to a specified partition.

```
EXCHANGE PARTITION { ( partition_name ) | partition_name | FOR ( partition_value [, ...] ) }
WITH TABLE {[ ONLY ] ordinary_table_name | ordinary_table_name * | ONLY
( ordinary_table_name )}
[ { WITH | WITHOUT } VALIDATION ] [ VERBOSE ] [ UPDATE GLOBAL INDEX ] [ UPDATE
DISTRIBUTED GLOBAL INDEX | NO UPDATE DISTRIBUTED GLOBAL INDEX ]
```

The ordinary table and partition whose data is to be exchanged must meet the following requirements:

- The number of columns in the ordinary table is the same as that of the partition, and their information should be consistent, including: column name, data type, constraint, collation information, storage parameter, and compression information.
- The compression information of the ordinary table and partition should be consistent.
- The distribution key information of the ordinary table and partition should be consistent.
- The number of ordinary table indexes is the same as that of local indexes of the partition, and the index information is the same.
- The number and information of constraints of the ordinary table and partition should be consistent.
- An ordinary table cannot be a temporary table. A partitioned table can only be a range partitioned table, list partitioned table, hash partitioned table, or interval partitioned table.
- When the built-in security policy is enabled, common and partitioned tables cannot have dynamic data masking or row-level security constraints.

NOTICE

- When the exchange is done, the data and tablespace of the ordinary table and partition are exchanged. The statistics about ordinary tables and partitions become unreliable, and they should be analyzed again.
- A non-partition key cannot be used to create a local unique index. Therefore, if an ordinary table contains a unique index, data cannot be exchanged.

To exchange data, you can create an intermediate table, insert partition data into the intermediate table, truncate partitions, insert ordinary table data into the partitioned table, drop the ordinary table, and rename the intermediate table.

- In a scenario where both an ordinary table and a partitioned table are Ustore tables, if the UB-tree index type (RCR or PCR, RCR by default) of the ordinary table is different from the local UB-tree index type (RCR or PCR, RCR by default) of the partitioned table, data cannot be exchanged.
- If the DROP COLUMN operation is performed on an ordinary or partitioned table, the deleted column still exists physically. Therefore, you need to ensure that the deleted column of the ordinary table is strictly aligned with that of the partition. Otherwise, the exchange will fail.
- The EXCHANGE PARTITION { (partition_name) | partition_name | FOR (partition_value [, ...]) } operation is available in B-compatible database (that is, **sql_compatibility** set to 'MYSQL'). In other modes, only the EXCHANGE PARTITION { (partition_name) | FOR (partition_value [, ...]) } operation is available. If **partition_name** is the name of a level-1 partition, the level-1 partition and ordinary table are exchanged.

- The row_clause syntax is used to set row movement of a partitioned table.

```
{ ENABLE | DISABLE } ROW MOVEMENT
```

- The merge_clause syntax is used to merge partitions into one. The maximum number of source partitions that can be merged in a command is 300.

```
MERGE PARTITIONS { partition_name } [, ...] INTO PARTITION partition_name  
[ ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month |  
year } OF { NO MODIFICATION } [ ON ( EXPR ) ] [ TABLESPACE tablespacename ] [ UPDATE  
GLOBAL INDEX ] [ UPDATE DISTRIBUTED GLOBAL INDEX | NO UPDATE DISTRIBUTED GLOBAL  
INDEX ]
```

NOTICE

- For range partitioning and interval partitioning, the ranges of the source partitions must increase continuously, and the partition name after MERGE can be the same as the name of the last source partition. For list partitioning, there is no such range requirement on the source partitions, and the partition name after MERGE can be the same as that of any source partition. If the partition name after MERGE is the same as that of a source partition, they are considered as the same partition.
 - If the GUC parameter **enable_ilm** is not enabled and the merge_clause syntax is used to merge multiple partitions with the ILM policy into one partition, the new partition does not inherit the ILM policy.
-

CAUTION

Ustore tables do not support ALTER TABLE MERGE PARTITIONS in transaction blocks and stored procedures.

- The modify_clause syntax is used to set whether a partitioned index is usable.
`MODIFY PARTITION partition_name { UNUSABLE LOCAL INDEXES | REBUILD UNUSABLE LOCAL INDEXES }`
 - The split_clause syntax is used to split one partition into multiple ones.
`SPLIT PARTITION { partition_name | FOR (partition_value [, ...]) } { split_point_clause | no_split_point_clause } [UPDATE GLOBAL INDEX] [UPDATE DISTRIBUTED GLOBAL INDEX | NO UPDATE DISTRIBUTED GLOBAL INDEX]`
-

NOTICE

- The partition name after SPLIT can be the same as the source partition name, but they are regarded as different partitions.
 - If the GUC parameter **enable_ilm** is not enabled and the split_clause syntax is used to split a partition with the ILM policy into multiple partitions, the new partitions do not inherit the ILM policy.
-
- The split_point_clause syntax for specifying the split point for a range partitioned table is as follows:
`AT (partition_value) INTO (PARTITION partition_name [ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year } OF { NO MODIFICATION } [ON (EXPR)] [TABLESPACE tablespacename] , PARTITION partition_name [ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year } OF { NO MODIFICATION } [ON (EXPR)] [TABLESPACE tablespacename])`
-

NOTICE

The size of the split point should be in the range of partition keys of the partition to be split. The split point can only split one partition into two new partitions.

- The `no_split_point_clause` syntax without specifying a split point for a range partitioned table is as follows:
`INTO { (partition_less_than_item [, ...]) | (partition_start_end_item [, ...]) }`

NOTICE

- The first new partition key specified by **partition_less_than_item** should be greater than that of the previously split partition (if any), and the last partition key specified by **partition_less_than_item** should equal that of the partition being split.
- The first new partition key specified by **partition_start_end_item** should equal that of the former partition (if any), and the last partition key specified by **partition_start_end_item** should equal that of the partition being split.
- **partition_less_than_item** supports a partition key with up to 16 columns, while **partition_start_end_item** supports a one-column partition key. For details about the supported data types, see [PARTITION BY RANGE\(partition_key\)](#).
- **partition_less_than_item** and **partition_start_end_item** cannot be used in the same statement. There is no restriction on different SPLIT statements.

- The `partition_less_than_item` syntax is as follows (the range of the last partition is not defined, that is, the VALUES LESS THAN (partition_value) part is not defined; by default, the last partition inherits the upper boundary value of the range defined for the source partition):

```
PARTITION partition_name VALUES LESS THAN (( { partition_value | MAXVALUE } [, ...] ) |
MAXVALUE }
[ ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day |
month | year } OF { NO MODIFICATION } [ ON ( EXPR ) ] [ TABLESPACE
tablespacename ]
```

NOTICE

During range partitioning, the MAXVALUE keyword can be used without parentheses. It can be used only in MySQL-compatible mode. It cannot be used in subpartitions of level-2 partitions or in scenarios where multi-column partition keys are used.

- The `partition_start_end_item` syntax is as follows. For details about the constraints, see [START END](#).

```
PARTITION partition_name {
{START(partition_value) END (partition_value) EVERY (interval_value)} |
```

```
{START(partition_value) END ({partition_value | MAXVALUE})} |
{START(partition_value)} |
{END({partition_value | MAXVALUE})}
} [ ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day |
month | year } OF { NO MODIFICATION } [ ON ( EXPR ) ] ] [TABLESPACE
tablespace_name]
```

- The `split_point_clause` syntax for specifying the split point for a list partitioned table is as follows:

```
VALUES ( partition_value_list ) INTO ( PARTITION partition_name [ ILM ADD POLICY
ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year } OF { NO
MODIFICATION } [ ON ( EXPR ) ] ] [ TABLESPACE tablespace_name ] , PARTITION
partition_name [ ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW }
AFTER n { day | month | year } OF { NO MODIFICATION } [ ON ( EXPR ) ] ] [ TABLESPACE
tablespace_name ] )
```

NOTICE

The split point must be a non-empty true subset of the source partition. Specifying a split point can only split one partition into two partitions.

- The `no_split_point_clause` syntax for not specifying the split point for a list partitioned table is as follows:

```
INTO ( PARTITION partition_name VALUES (partition_value_list) [ ILM ADD POLICY ROW
STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year } OF { NO
MODIFICATION } [ ON ( EXPR ) ] ] [ TABLESPACE tablespace_name ] [, ... ] )
```

NOTICE

- The range of the last partition is not defined, that is, the `VALUES (partition_value_list)` part is not defined; the partition range is equal to the remaining set of the source partition excluding other level-2 partitions.
- If no split point is specified, each new partition must be a non-empty true subset of the source partition and does not overlap with each other.

- The `add_clause` syntax is used to add one or more partitions to a specified partitioned table.

```
ADD {{partition_less_than_item | partition_start_end_item} |
PARTITION({partition_less_than_item | partition_start_end_item | partition_list_item})}
```

NOTICE

- The `PARTITION({partition_less_than_item | partition_start_end_item | partition_list_item})` syntax can be used only in MySQL-compatible mode.
- The `ALTER TABLE table_name ADD PARTITION (partition_definition1, partition_definition2,...);` syntax cannot be used to add multiple partitions. Only the original syntax for adding multiple partitions is supported: `ALTER TABLE table_name ADD PARTITION (partition_definition1), ADD PARTITION (partition_definition2), ...`

The `partition_list_item` syntax is as follows:

```
PARTITION partition_name VALUES [IN] (list_values_clause)
  [ ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month |
year } OF { NO MODIFICATION } [ ON ( EXPR ) ] [ TABLESPACE tablespacename ]
```

NOTICE

- **partition_list_item** supports a maximum of 16 partition keys. For details about the supported data types, see [PARTITION BY LIST \[COLUMNS\] \(partition_key\)](#).
- Partitions cannot be added to a hash partitioned table.
- IN needs to be used in MySQL-compatible mode and cannot be used in subpartitions of level-2 partitions.

- The `drop_clause` syntax is used to remove a partition from a specified partitioned table.

```
DROP PARTITION { partition_name | FOR ( partition_value [, ...] ) } [ UPDATE GLOBAL
INDEX ] [ UPDATE DISTRIBUTED GLOBAL INDEX | NO UPDATE DISTRIBUTED GLOBAL INDEX ]
```

NOTICE

- Hash partitioned table does not support partition deletion.
- If a partitioned table has only one partition, the partition cannot be deleted.

- The `truncate_clause` syntax is used to remove a specified partition from a partitioned table.

```
TRUNCATE PARTITION { partition_name | FOR ( partition_value [, ...] ) } [ UPDATE GLOBAL
INDEX ] [ UPDATE DISTRIBUTED GLOBAL INDEX | NO UPDATE DISTRIBUTED GLOBAL INDEX ]
```

- The `ilm_clause` syntax adds an ILM policy to a partition. It supports the syntax for the OLTP table compression feature of data lifecycle management.

```
MODIFY PARTITION partition_name ILM ADD POLICY ROW STORE { COMPRESS ADVANCED }
{ ROW } AFTER n { day | month | year } OF { NO MODIFICATION } [ ON ( EXPR ) ]
```

- The syntax for modifying the name of a partition is as follows:

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }
  RENAME PARTITION { partition_name | FOR ( partition_value [, ...] ) } TO partition_new_name;
```
- Reset a partition ID.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) } RESET
PARTITION;
```

Parameters

- **table_name**
Specifies the name of a partitioned table.
Value range: an existing table name
- **partition_name**
Specifies the name of a partition.
Value range: an existing partition name
- **tablespacename**
Specifies which tablespace the partition moves to.

Value range: an existing tablespace name

- **partition_value**

Specifies the key value of a partition.

The value specified by `PARTITION FOR (partition_value [, ...])` can uniquely identify a partition.

Value range: partition keys for the partition to be operated.

- **UNUSABLE LOCAL INDEXES**

Sets all the indexes unusable in the partition.

- **REBUILD UNUSABLE LOCAL INDEXES**

Rebuilds all the indexes in the partition.

- **{ ENABLE | DISABLE } ROW MOVEMENT**

Sets row movement.

If the tuple value is updated on the partition key during the `UPDATE` operation, the partition where the tuple is located is altered. Setting this parameter enables error messages to be reported or movement of the tuple between partitions.

Value range:

- **ENABLE**: Row movement is enabled.
- **DISABLE**: Row movement is disabled.

By default, this parameter is disabled.

- **ordinary_table_name**

Specifies the name of the ordinary table whose data is to be migrated.

Value range: an existing ordinary table name.

- **{ WITH | WITHOUT } VALIDATION**

Checks whether the ordinary table data meets the specified partition key range of the partition to be migrated.

Value range:

- **WITH**: checks whether the ordinary table data meets the partition key range of the partition to be migrated. If any data does not meet the required range, an error is reported.
- **WITHOUT**: does not check whether the ordinary table data meets the partition key range of the partition to be migrated.

The default value is **WITH**.

The check is time consuming, especially when the data volume is large.

Therefore, use **WITHOUT** when you are sure that the current ordinary table data meets the partition key range of the partition to be migrated.

- **VERBOSE**

When **VALIDATION** is **WITH**, if the ordinary table contains data that is out of the partition key range, insert the data to the correct partition. If there is no correct partition where the data can be inserted to, an error is reported.

NOTICE

Only when **VALIDATION** is **WITH**, **VERBOSE** can be specified.

- partition_new_name**
 Specifies the new name of a partition.
 Value range: a string. It must comply with the [naming convention](#).
- UPDATE GLOBAL INDEX**
 Updates all global indexes in the partitioned table to ensure that correct data can be queried using global indexes.
 If this parameter is not used, all global indexes in the partitioned table become invalid.
- UPDATE DISTRIBUTED GLOBAL INDEX**
 Updates all available global secondary indexes in the partitioned table to ensure that the data in the global secondary indexes is consistent with that in the base table. EXCHANGE PARTITION also updates all available global secondary indexes in the ordinary table.
 If this parameter is not used, all global secondary indexes in the partitioned table become invalid. EXCHANGE PARTITION also invalidates all global secondary indexes in the ordinary table.
- NO UPDATE DISTRIBUTED GLOBAL INDEX**
 If this parameter is used, all GSIs in the partitioned table become invalid. EXCHANGE PARTITION also invalidates all global secondary indexes in the ordinary table.

Examples

- Change the name of a table partition.

```

-- Create a pre-partitioned table.
gaussdb=# CREATE TABLE test_p1 (col1 INT, col2 INT) PARTITION BY RANGE (col1)
(
    PARTITION p1 VALUES LESS THAN (10),
    PARTITION p2 VALUES LESS THAN (20),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

-- Change the partition name.
gaussdb=# ALTER TABLE test_p1 RENAME PARTITION p3 TO pmax;

-- Query partition information.
gaussdb=# SELECT relname, boundaries, oid FROM pg_partition WHERE parentid='test_p1'::regclass
AND parttype <> 'r';
 relname | boundaries | oid
-----+-----+-----
 p1     | {10}      | 17066
 p2     | {20}      | 17067
 pmax   | {NULL}    | 17068
(3 rows)
            
```
- Move partition tablespaces.

```

-- Create a partition.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Move partition tablespaces.
gaussdb=# ALTER TABLE test_p1 MOVE PARTITION P1 TABLESPACE tbs_data1;

-- Check the partition tablespace.
gaussdb=# SELECT relname, spcname FROM pg_partition t1, pg_tablespace t2 WHERE
T1.reltablespace=t2.oid and t1.parentid='test_p1'::regclass;
 relname | spcname
-----+-----
 p1     | tbs_data1
(1 row)
            
```

- Exchange partitions.

```
-- Create an ordinary table and insert data into the table.
gaussdb=# CREATE TABLE test_ep1(col1 INT,col2 INT);
gaussdb=# INSERT INTO test_ep1 VALUES (GENERATE_SERIES(1,30), 1000);

-- Migrate ordinary table data to a specified partition.
gaussdb=# ALTER TABLE test_p1 EXCHANGE PARTITION (p1) WITH TABLE test_ep1 VERBOSE;

-- Query.
gaussdb=# SELECT COUNT(*) FROM test_p1 PARTITION (p1);
count
-----
      9
(1 row)

-- Delete the test_ep1 table.
gaussdb=# DROP TABLE test_ep1;
```

- Merge partitions.

```
-- Merge the p2 and pmax partitions in the test_p1 table into pmax.
gaussdb=# ALTER TABLE test_p1 MERGE PARTITIONS p2,pmax INTO PARTITION pmax;

-- View a partition.
gaussdb=# SELECT relname, boundaries, oid FROM pg_partition WHERE parentid='test_p1'::regclass
AND parttype <> 'r' order by 1;
 relname | boundaries | oid
-----+-----+-----
p1      | {10}      | 17066
pmax    | {NULL}    | 17070
(2 rows)

-- Delete tables and tablespaces.
gaussdb=# DROP TABLE test_p1;
gaussdb=# DROP TABLESPACE tbs_data1;
```

- Split partitions.

```
-- Create a table.
gaussdb=# CREATE TABLE test_r1 (col1 INT,col2 INT) PARTITION BY RANGE (col1)(
PARTITION p1 VALUES LESS THAN (10),
PARTITION pmax VALUES LESS THAN (MAXVALUE)
);

-- Split partitions.
gaussdb=# ALTER TABLE test_r1 SPLIT PARTITION pmax AT (20) INTO (PARTITION p2, PARTITION
pmax);

gaussdb=# SELECT * FROM test_p5 PARTITION (p2);
col1 | col2
-----+-----
(0 rows)
```

```
ALTER TABLESPACE tablespace_name
RESIZE MAXSIZE { UNLIMITED | 'space_size'};
```

Parameters

- tablespace_name**
 Specifies the tablespace to be modified.
 Value range: an existing table name.
- new_tablespace_name**
 Specifies the new name of the tablespace. The new name cannot start with **PG_**.
 Value range: a string. It must comply with the [naming convention](#).
- new_owner**
 Specifies the new owner of the tablespace.
 Value range: an existing username
- tablespace_option**
 Sets or resets the parameters of a tablespace.
 Value range:
 - **seq_page_cost**: sets the optimizer to calculate the cost of obtaining disk pages in sequence. The default value is **1.0**.
 - **random_page_cost**: sets the optimizer to calculate the cost of obtaining disk pages in a non-sequential manner. The default value is **4.0**.

NOTE

- The value of **random_page_cost** is relative to that of **seq_page_cost**. It is meaningless when the value is equal to or less than the value of **seq_page_cost**.
- The prerequisite for the default value **4.0** is that the optimizer uses indexes to scan table data and the hit ratio of table data in the cache is about 90%.
- If the size of the table data space is smaller than that of the physical memory, decrease the value to a proper level. On the contrary, if the hit ratio of table data in the cache is lower than 90%, increase the value.
- If random-access memory like SSD is adopted, the value can be decreased to a certain degree to reflect the cost of true random scan.

Value range: Positive number of the floating-point type.

- RESIZE MAXSIZE**
 Resets the maximum size of tablespace.
 Value range:
 - **UNLIMITED**: No limit is set for the tablespace.
 - Determined by **space_size**. For details about the format, see [CREATE TABLESPACE](#).

NOTE

- If the adjusted quota is smaller than the current tablespace usage, the adjustment is successful. You need to decrease the tablespace usage to a value less than the new quota before writing data to the tablespace.

Examples

- Rename a tablespace.

```
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Rename a tablespace.
gaussdb=# ALTER TABLESPACE tbs_data1 RENAME TO tbs_data2;

-- Query.
gaussdb=# \db tbs_data2
      List of tablespaces
  Name | Owner |   Location
-----+-----+-----
 tbs_data2 | omm | tablespace1/tbs_data1
```

- Set the tablespace owner.

Example:

```
-- Create a user.
gaussdb=# CREATE USER test PASSWORD '*****';

-- Change the owner of the tablespace.
gaussdb=# ALTER TABLESPACE tbs_data2 OWNER TO test;

-- Query.
gaussdb=# \db tbs_data2
      List of tablespaces
  Name | Owner |   Location
-----+-----+-----
 tbs_data2 | test | tablespace1/tbs_data1
(1 row)
```

- Set tablespace attributes.

Example:

```
-- Change the value of seq_page_cost.
gaussdb=# ALTER TABLESPACE tbs_data2 SET (seq_page_cost = 10);

-- Query.
gaussdb=# SELECT * FROM pg_tablespace WHERE spcname = 'tbs_data2';
 spcname | spcowner | spcacl | spcoptions | spcmaxsize | relative
-----+-----+-----+-----+-----+-----
 tbs_data2 | 16778 | | {seq_page_cost=10} | | t
(1 row)
```

- Reset tablespace attributes.

```
-- Reset the value of seq_page_cost to the default value.
gaussdb=# ALTER TABLESPACE tbs_data2 RESET (seq_page_cost);

-- Query.
gaussdb=# SELECT * FROM pg_tablespace WHERE spcname = 'tbs_data2';
 spcname | spcowner | spcacl | spcoptions | spcmaxsize | relative
-----+-----+-----+-----+-----+-----
 tbs_data2 | 16778 | | | | t
(1 row)
```

- Set the tablespace limit.

Example:

```
-- Set the maximum size of a tablespace.
gaussdb=# ALTER TABLESPACE tbs_data2 RESIZE MAXSIZE '10G';

-- Query.
gaussdb=# SELECT * FROM pg_tablespace WHERE spcname = 'tbs_data2';
 spcname | spcowner | spcacl | spcoptions | spcmaxsize | relative
-----+-----+-----+-----+-----+-----
 tbs_data2 | 16778 | | | 10485760 K | t
(1 row)

-- Delete the tablespace.
```

```
gaussdb=# DROP TABLESPACE tbs_data2;
-- Delete the user.
gaussdb=# DROP USER test;
```

7.12.6.33 ALTER TRIGGER

Description

ALTER TRIGGER is used to change the name of a trigger.

NOTE

Currently, only the trigger name can be modified.

Precautions

The owner of the table where a trigger resides or a user granted the ALTER ANY TRIGGER permission can perform the ALTER TRIGGER operation. A system administrator has this permission by default.

Syntax

```
ALTER TRIGGER trigger_name ON table_name RENAME TO new_name;
```

→ ALTER → TRIGGER → trigger_name → ON → table_name → RENAME → TO → new_name → ; →

Parameters

- **trigger_name**
Specifies the name of the trigger to be modified.
Value range: an existing trigger
- **table_name**
Specifies the name of the table where the trigger to be modified is located.
Value range: an existing table having a trigger
- **new_name**
Specifies the new name after modification.
Value range: a string, which complies with the [naming convention](#). A value contains a maximum of 63 characters and cannot be the same as other triggers on the same table.

Examples

```
-- Create a source table and a destination table.
gaussdb=# CREATE TABLE test_trigger_src_tbl(id1 INT, id2 INT, id3 INT);
gaussdb=# CREATE TABLE test_trigger_des_tbl(id1 INT, id2 INT, id3 INT);

-- Create a DELETE trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION TRI_DELETE_FUNC() RETURNS TRIGGER AS
$$
```

```
DECLARE
BEGIN
    DELETE FROM test_trigger_des_tbl WHERE id1=OLD.id1;
    RETURN OLD;
END
$$ LANGUAGE plpgsql;

-- Create a DELETE trigger.
gaussdb=# CREATE TRIGGER delete_trigger BEFORE DELETE ON test_trigger_src_tbl FOR EACH ROW
EXECUTE PROCEDURE tri_delete_func();

-- Rename a trigger.
gaussdb=# ALTER TRIGGER delete_trigger ON test_trigger_src_tbl RENAME TO delete_trigger_renamed;

-- Delete the trigger.
gaussdb=# DROP TRIGGER delete_trigger_renamed ON test_trigger_src_tbl;

-- Delete the function.
gaussdb=# DROP FUNCTION tri_delete_func;

-- Delete the source table and destination table.
gaussdb=# DROP TABLE test_trigger_src_tbl;
gaussdb=# DROP TABLE test_trigger_des_tbl;
```

[CREATE TRIGGER](#), [DROP TRIGGER](#), and [ALTER TABLE](#)

7.12.6.34 ALTER TYPE

Description

Modifies the definition of a type.

Precautions

Only the owner of a type, a user granted the ALTER permission on a type, or a user granted the ALTER ANY TYPE permission on a sequence can run the **ALTER TYPE** command. When separation of duties is disabled, system administrators have this permission by default. To modify the owner or schema of a type, you must be a type owner or system administrator and a member of the new owner role.

Syntax

- Modify a type.
ALTER TYPE name action [, ...];

The clauses corresponding to **action** are as follows:

- Add a new attribute to a composite type.
ADD ATTRIBUTE attribute_name data_type [COLLATE collation] [CASCADE | RESTRICT]

- Delete an attribute from a composite type.

DROP ATTRIBUTE [IF EXISTS] attribute_name [CASCADE | RESTRICT]

- Change the type of an attribute in a composite type.

ALTER ATTRIBUTE attribute_name [SET DATA] TYPE data_type [COLLATE collation] [CASCADE | RESTRICT]

- Change the owner of a type.

ALTER TYPE name OWNER TO { new_owner | CURRENT_USER | SESSION_USER };

- Change the name of a type.

ALTER TYPE name RENAME TO new_name;

- Change the name of an attribute in a composite type.

ALTER TYPE name RENAME ATTRIBUTE attribute_name TO new_attribute_name [CASCADE | RESTRICT];

- Move a type to a new schema.

ALTER TYPE name SET SCHEMA new_schema;

- Add a new value to an enumerated type.

ALTER TYPE name ADD VALUE [IF NOT EXISTS] new_enum_value [{ BEFORE | AFTER } neighbor_enum_value];

- Change an enumerated value in the value list.

ALTER TYPE name RENAME VALUE existing_enum_value TO new_enum_value;

Parameters

- **name**
Specifies the name of an existing type that needs to be modified (optionally schema-qualified).
- **new_name**
Specifies the new name of the type.
- **new_owner**
Specifies the new owner of the type.
- **new_schema**
Specifies the new schema of the type.

- **attribute_name**
Specifies the name of the attribute to be added, modified, or deleted.
- **new_attribute_name**
Specifies the new name of the attribute to be renamed.
- **data_type**
Specifies the data type of the attribute to be added, or the new type of the attribute to be modified.
- **new_enum_value**
Specifies a new enumerated value. It is a non-null string with a maximum length of 63 bytes.
- **neighbor_enum_value**
Specifies an existing enumerated value before or after which a new enumerated value will be added.
- **existing_enum_value**
Specifies an enumerated value to be changed. It is a non-null string with a maximum length of 63 bytes.
- **CASCADE**
Determines that the type to be modified, its associated records, and subtables that inherit the type will all be updated.
- **RESTRICT**
(Default) Refuses to update the associated records of the modified type.

NOTICE

- **ADD ATTRIBUTE, DROP ATTRIBUTE, and ALTER ATTRIBUTE** can be combined for modifying multiple attributes. For example, it is possible to add several attributes or change the types of several attributes at the same time in one command.
 - To modify a schema of a type, you must have the CREATE permission on the new schema. To alter the owner, you must be a direct or indirect member of the new owner role, and that member must have CREATE permission on the schema of this type (these restrictions enforce that the operation of altering the owner cannot be done by other means other than deleting and rebuilding the type). However, the system administrators can change ownership of any type in any way when separation of duties is disabled.) To add an attribute or modify the type of an attribute, you must also have the USAGE permission of this type.
-
- **CURRENT_USER**
Specifies the current user.
 - **SESSION_USER**
Specifies the current system user.
 - **COLLATE collation**
Assigns a collation to the column, which must be a sortable data type. If the collation is not specified, the default collation for the column's data type is used.

Examples

- Modify a composite type:

```
-- Create a composite type.
gaussdb=# CREATE TYPE typ_stu AS (name varchar(10),age int);

-- Create a table and insert data into the table. The data type of the info column is typ_stu.
gaussdb=# CREATE TABLE tbl_test (id int PRIMARY KEY,info typ_stu);
gaussdb=# INSERT INTO tbl_test VALUES (1,('Jim',16));

-- View data in the tbl_test table.
gaussdb=# SELECT * FROM tbl_test;
 id | info
-----+-----
  1 | (Jim,16)
(1 row)

-- Add an attribute to a composite type.
gaussdb=# ALTER TYPE typ_stu ADD ATTRIBUTE year int CASCADE;

-- Check data in the tbl_test table again. The info column contains an extra attribute.
gaussdb=# SELECT * FROM tbl_test;
 id | info
-----+-----
  1 | (Jim,16,)
(1 row)

-- Delete an attribute from a composite type.
gaussdb=# ALTER TYPE typ_stu DROP ATTRIBUTE year;
```

- Change the type owner:

```
-- Create a user test.
gaussdb=# CREATE ROLE test PASSWORD '*****';

-- Change the owner of typ_stu to test.
gaussdb=# ALTER TYPE typ_stu OWNER TO test;

-- Query the owner of typ_stu.
gaussdb=# SELECT t1.typname, t2.rolname AS owner
FROM pg_type t1, pg_roles t2
WHERE t1.typname = 'typ_stu' AND
      t1.typowner = t2.oid;
 typname | owner
-----+-----
 typ_stu | test
(1 row)
```

- Change a type or the name of an attribute in a composite type.

```
-- Rename one of the attributes age of typ_stu to age1.
gaussdb=# ALTER TYPE typ_stu RENAME ATTRIBUTE age to age1;

-- Run the following SQL statement to query the data whose age is 16 in the tbl_test table:
gaussdb=# SELECT id,(info).name,(info).age1 FROM tbl_test WHERE (info).age1 = 16;
 id | name | age1
-----+-----+-----
  1 | Jim  | 16
(1 row)
```

- Move a type to a new schema.

```
-- Create a schema sctest.
gaussdb=# CREATE SCHEMA sctest;

-- Move typ_stu to the sc_test schema.
gaussdb=# ALTER TYPE typ_stu SET SCHEMA sctest;

-- Query the schema of typ_stu.
gaussdb=# \dT sctest.*
      List of data types
 Schema | Name      | Description
-----+-----+-----
```

```
sctest | sctest.typ_stu |
(1 row)
```

```
-- Drop the table.
gaussdb=# DROP TABLE tbl_test;
gaussdb=# DROP TYPE sctest.typ_stu;
gaussdb=# DROP ROLE test;
gaussdb=# DROP SCHEMA sctest;
```

- Add a new value to an enumerated type.

```
-- Create an enumerated type typ_bugstatus.
gaussdb=# CREATE TYPE typ_bugstatus AS ENUM ('create', 'modify', 'closed');

-- Create a table tbl_test1.
gaussdb=# CREATE TABLE tbl_test1 (id serial, bugstat typ_bugstatus);

-- Insert data and ensure that the value of the bugstat column must be of the enumerated type.
Otherwise, an error is reported.
gaussdb=# INSERT INTO tbl_test1 (bugstat) VALUES ('closed');
gaussdb=# INSERT INTO tbl_test1 (bugstat) VALUES ('deleted');
ERROR: invalid input value for enum typ_bugstatus: "deleted"
LINE 1: INSERT INTO tbl_test1 (bugstat) VALUES ('deleted');
          ^
CONTEXT: referenced column: bugstat

-- View data in the tbl_test1 table.
gaussdb=# SELECT * FROM tbl_test1;
 id | bugstat
-----+-----
  1 | closed
(1 row)
```

```
-- Add a tag value to an enumerated type.
gaussdb=# ALTER TYPE typ_bugstatus ADD VALUE IF NOT EXISTS 'regress' BEFORE 'closed';
```

```
-- Query.
gaussdb=# \dT+ typ_bugstatus
                List of data types
 Schema | Name | Internal name | Size | Elements | Access privileges | Description
-----+-----+-----+-----+-----+-----+-----
 public | typ_bugstatus | typ_bugstatus | 4 | create + | |
        | | | | modify + | |
        | | | | regress + | |
        | | | | closed | |
(1 row)
```

- Change an enumerated value in the value list.

```
-- Change closed in typ_bugstatus to close.
gaussdb=# ALTER TYPE typ_bugstatus RENAME VALUE 'closed' TO 'close';
```

```
-- Check the data in the tbl_test1 table. closed is changed to close.
gaussdb=# SELECT * FROM tbl_test1;
```

```
 id | bugstat
-----+-----
  1 | close
(1 row)
```

```
-- Query.
gaussdb=# \dT+ typ_bugstatus;

[CREATE TYPE](#) and [DROP TYPE](#)

7.12.6.35 ALTER USER

Description

ALTER USER modifies the attributes of a database user.

Precautions

Session parameters modified by ALTER USER apply to a specified user and take effect in the next session.

Syntax

- Modify user permissions or other information.

```
ALTER USER user_name [ [ WITH ] option [ ... ] ];  
ALTER USER user_name  
    RENAME TO new_name;  
ALTER USER user_name [ IN DATABASE database_name ]  
    SET configuration_parameter {{ TO | = } { value | DEFAULT }}FROM CURRENT};  
ALTER USER user_name  
    [ IN DATABASE database_name ] RESET {configuration_parameter|ALL};
```

The **option** clause is as follows:

```
{ CREATEDB | NOCREATEDB }  
| { CREATEROLE | NOCREATEROLE }  
| { INHERIT | NOINHERIT }  
| { AUDITADMIN | NOAUDITADMIN }  
| { SYSADMIN | NOSYSADMIN }  
| { MONADMIN | NOMONADMIN }  
| { OPRADMIN | NOOPRADMIN }  
| { POLADMIN | NOPOLADMIN }  
| { USEFT | NOUSEFT }  
| { LOGIN | NOLOGIN }  
| { REPLICATION | NOREPLICATION }  
| { PERSISTENCE | NOPERSISTENCE }  
| CONNECTION LIMIT connlimit  
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD { 'password' [ EXPIRED ] | DISABLE | EXPIRED }  
| [ ENCRYPTED | UNENCRYPTED ] IDENTIFIED BY { 'password' [ REPLACE 'old_password' |  
EXPIRED ] | DISABLE }  
| VALID BEGIN 'timestamp'  
| VALID UNTIL 'timestamp'  
| RESOURCE POOL 'respool'  
| USER GROUP 'groupuser'  
| PERM SPACE 'spacelimit'  
| TEMP SPACE 'tmpspacelimit'  
| SPILL SPACE 'spillspacelimit'  
| NODE GROUP logic_cluster_name  
| ACCOUNT { LOCK | UNLOCK }  
| PGUSER
```

- Change the username.

```
ALTER USER user_name  
    RENAME TO new_name;
```

- Change the value of a specified parameter associated with the user.

```
ALTER USER user_name [ IN DATABASE database_name ]  
    SET configuration_parameter {{ TO | = } { value | DEFAULT }}FROM CURRENT};
```

- Reset the value of a specified parameter associated with the user.

```
ALTER USER user_name  
[ IN DATABASE database_name ] RESET {configuration_parameter|ALL};
```

Parameters

- **user_name**

Specifies the current username.

Value range: an existing username. If a username contains uppercase letters, enclose the name with double quotation marks ("").

- **new_password**

Specifies a new password.

The new password must:

- Differ from the old password.
- Contain at least eight characters. This is the default length.
- Differ from the username or the username spelled backward.
- Contain at least three types of the following four types of characters: uppercase characters (A to Z), lowercase characters (a to z), digits (0 to 9), and special characters, including: ~!@#%&^*()-_+=\|{ } ; , < . > / ? If the password contains characters other than the preceding characters, an error will be reported during statement execution.
- Be enclosed by single quotation marks.

Value range: a string.

- **old_password**

Specifies the old password.

- **ACCOUNT { LOCK | UNLOCK }**

- **ACCOUNT LOCK:** locks an account to forbid login to databases.
- **ACCOUNT UNLOCK:** unlocks an account to allow login to databases.

- **PGUSER**

In the current version, the **PGUSER** attribute of a user cannot be modified.

For details about other parameters, see "Parameters" in [CREATE ROLE](#) and [ALTER ROLE](#).

NOTICE

The current version does not support the setting of user-level parameters.

Examples

```
-- Create user jim whose login password is *****  
gaussdb=# CREATE USER jim PASSWORD '*****';  
  
-- Change the login password of user jim.  
gaussdb=# ALTER USER jim IDENTIFIED BY '*****' REPLACE '*****';  
  
-- Lock jim.  
gaussdb=# ALTER USER jim ACCOUNT LOCK;
```

```
-- Unlock jim.  
gaussdb=# ALTER USER jim ACCOUNT UNLOCK;  
  
-- Change the username.  
gaussdb=# ALTER USER jim RENAME TO lisa;  
  
-- Delete the user.  
gaussdb=# DROP USER lisa CASCADE;
```

Helpful Links

[CREATE ROLE](#), [CREATE USER](#), and [DROP USER](#)

7.12.6.36 ALTER VIEW

Description

ALTER VIEW changes the auxiliary attributes of a view. If you want to change the query definition of a view, use CREATE OR REPLACE VIEW.

Precautions

Only the view owner or a user granted the ALTER permission on a view can run the **ALTER VIEW** command. When separation of duties is disabled, a system administrator has this permission by default. The following are permission constraints depending on the attributes to be modified:

- To modify the schema of a view, you must be the owner of the view or system administrator and have the CREATE permission on the new schema. When separation of duties is enabled, a system administrator cannot change the view mode.
- To modify the owner of a view, you must be the owner of the view or system administrator and a member of the new owner role, with the CREATE permission on the schema of the view. When separation of duties is enabled, a system administrator cannot change the owner of a view.
- Do not change the type of a column in a view.

Syntax

- Set the default value of a view column.

```
ALTER VIEW [ IF EXISTS ] view_name  
ALTER [ COLUMN ] column_name SET DEFAULT expression;
```

- Remove the default value of a view column.

```
ALTER VIEW [ IF EXISTS ] view_name  
ALTER [ COLUMN ] column_name DROP DEFAULT;
```

- Change the owner of a view.

```
ALTER VIEW [ IF EXISTS ] view_name  
OWNER TO new_owner;
```

- **Rename a view.**
ALTER VIEW [IF EXISTS] view_name
RENAME TO new_name;

- **Set the schema of a view.**
ALTER VIEW [IF EXISTS] view_name
SET SCHEMA new_schema;

- **Set the options of a view.**
ALTER VIEW [IF EXISTS] view_name
SET ({ view_option_name [= view_option_value] } [, ...]);

- **Reset the options of a view.**
ALTER VIEW [IF EXISTS] view_name
RESET (view_option_name [, ...]);

Parameters

- **IF EXISTS**
If this option is used, no error is generated when the view does not exist, and only a message is displayed.
- **view_name**
Specifies the view name, which can be schema-qualified.
Value range: a string. It must comply with the naming convention.
- **column_name**
Specifies the column name.
Value range: a string, which indicates the name of a column in an existing view.
- **SET/DROP DEFAULT**
Sets or deletes the default value of a column. This parameter does not take effect.
- **new_owner**
Specifies the new owner of a view.
- **new_name**
Specifies the new view name.
- **new_schema**
Specifies the new schema of the view.
- **view_option_name [= view_option_value]**
Specifies an optional parameter for a view.
 - **security_barrier**: specifies whether the view provides row-level security. The value is of the Boolean type. The default value is **true**.

- **check_option**: Controls the behavior of updating a view. This parameter can be set to **CASCADDED** or **LOCAL**. This parameter cannot be left blank.
- **expression**
Specifies constants, functions, or SQL expressions.

Examples

- **Rename a view.**

```
-- Create the test_tbl table.
gaussdb=# CREATE TABLE test_tbl(col1 INT,col2 INT);

-- Create a view.
gaussdb=# CREATE VIEW abc AS SELECT * FROM test_tbl1;

-- Rename the view.
gaussdb=# ALTER VIEW IF EXISTS abc RENAME TO test_v1;

-- Query the view.
gaussdb=# \dv
          List of relations
 Schema | Name  | Type | Owner | Storage
-----+-----+-----+-----+-----
 public | test_v1 | view | omm   |
(1 row)
```
- **Change the owner of the view.**

```
-- Create a user.
gaussdb=# CREATE ROLE role_test PASSWORD '*****';

-- Change the owner of the view.
gaussdb=# ALTER VIEW IF EXISTS test_v1 OWNER TO role_test;

-- Query the view information.
gaussdb=# \dv
          List of relations
 Schema | Name  | Type | Owner  | Storage
-----+-----+-----+-----+-----
 public | test_v1 | view | role_test |
(1 row)
```
- **Set the schema of the view.**

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tcpds;

-- Change the schema of the view.
gaussdb=# ALTER VIEW test_v1 SET SCHEMA tcpds;

-- Query the view information.
gaussdb=# \dv tcpds.test_v1;
          List of relations
 Schema | Name  | Type | Owner  | Storage
-----+-----+-----+-----+-----
 tcpds  | test_v1 | view | role_test |
(1 row)
```
- **Set and reset view options.**

```
-- Modify view options.
gaussdb=# ALTER VIEW tcpds.test_v1 SET (security_barrier = TRUE);
ALTER VIEW

-- Query.
gaussdb=# \dv tcpds.test_v1;
          List of relations
 Schema | Name  | Type | Owner  | Storage
-----+-----+-----+-----+-----
 tcpds  | test_v1 | view | chenxi | {security_barrier=true}
(1 row)
```

```
-- Modify the check_option option.
gaussdb=# ALTER VIEW tcpds.test_v1 SET (check_option = 'LOCAL');
ALTER VIEW

-- Query.
gaussdb=# \dv tcpds.test_v1;
                List of relations
 Schema | Name  | Type | Owner | Storage
-----+-----+-----+-----+-----
 tcpds  | test_v1 | view | chenxi | {security_barrier=true,check_option=LOCAL}
(1 row)

-- Reset view options.
gaussdb=# ALTER VIEW tcpds.test_v1 RESET (security_barrier);
ALTER VIEW
gaussdb=# ALTER VIEW tcpds.test_v1 RESET (check_option);
ALTER VIEW

-- Query.
gaussdb=# \dv tcpds.test_v1;
                List of relations
 Schema | Name  | Type | Owner | Storage
-----+-----+-----+-----+-----
 tcpds  | test_v1 | view | chenxi |
(1 row)

-- Delete the test_v1 view.
gaussdb=# DROP VIEW tcpds.test_v1;
DROP VIEW

-- Delete the test_tb1 table.
gaussdb=# DROP TABLE test_tb1;
DROP TABLE

-- Delete the user.
gaussdb=# DROP ROLE role_test;
DROP ROLE

-- Delete the schema.
gaussdb=# DROP SCHEMA tcpds;
DROP SCHEMA
```

Helpful Links

[CREATE VIEW](#) and [DROP VIEW](#)

7.12.6.37 ANALYZE | ANALYSE

Description

- ANALYZE collects statistics about ordinary tables in a database and stores the results in the PG_STATISTIC and PG_STATISTIC_EXT system catalogs. After you run the **ANALYZE** command, you can query the collected statistics in the system catalogs or in the system views PG_STATS and PG_EXT_STATS. The execution plan generator uses these statistics to generate the most effective execution plan.
- If no parameters are specified, ANALYZE analyzes each table and partitioned table in the database. You can also specify **table_name**, **column_name**, and **partition_name** to limit the analysis to a specified table, column, or partitioned table.
- {ANALYZE|ANALYSE} VERIFY checks whether data files of ordinary tables in a database are damaged.

- Statistics collected each time are stored in historical statistics tables ([GS_STATISTIC_EXT_HISTORY](#), [GS_STATISTIC_HISTORY](#), and [GS_TABLESTATS_HISTORY](#)). The number of historical tables and the retention period of statistics are specified by the GUC parameters `stats_history_record_limit` and `stats_history_retention_time`.

Precautions

- Non-temporary tables cannot be analyzed in an anonymous block, transaction block, function, or stored procedure. Temporary tables can be analyzed during execution of stored procedures, but statistics cannot be rolled back.
- If remote read is not involved, the remote read parameter does not take effect. If a key system catalog page is damaged, an error is reported and the detection stops.
- If no parameter to be analyzed is specified, tables on which the current user has the corresponding permission are analyzed by default. With a table specified, ANALYZE processes the table only.
- To perform ANALYZE operation to a table, you must be a table owner or a user granted the VACUUM permission on the table. By default, a system administrator has this permission. However, database owners are allowed to analyze all tables in their databases, except shared catalogs. (The restriction for shared catalogs means that a true database-wide analyze operation can only be executed by the system administrator). ANALYZE skips tables on which users do not have permissions.
- ANALYZE does not collect columns for which comparison or equivalent operations cannot be performed, for example, columns of the cursor type.

Syntax

- Collect statistics information about a table.
`{ ANALYZE | ANALYSE } [VERBOSE]
[table_name [(column_name [, ...])]] [WITH PARTITION_MODE];`
- Collect partition statistics information about a partitioned table.
`{ ANALYZE | ANALYSE } [VERBOSE]
table_name [(column_name [, ...])] PARTITION (partition_name) ;`

NOTE

- If the keyword PARTITION is used, **partition_name** must be the name of a level-1 partition.
- The distributed system does not support level-2 partitions.
- Collect statistics about global secondary indexes.
`{ ANALYZE | ANALYSE } GLOBAL INDEX index_name FOR TABLE table_name;`

 NOTE

- Before performing ANALYZE on the global secondary index, you need to perform ANALYZE on the base table to ensure the accuracy of global secondary indexes.
 - After performing the REINDEX/REBUILD operation on the global secondary indexes, you need to perform ANALYZE on the base table first before the global secondary indexes to ensure the accuracy of global secondary indexes.
 - To collect statistics from global secondary indexes, you must specify **index_name** and **table_name**, and **index_name** must be the name of a global secondary index.
 - The global secondary indexes include only the statistics (reltuple and relpages) in the pg_class system catalog.
- Collect statistics about multiple columns manually.

```
{ ANALYZE | ANALYSE } [ VERBOSE ]  
table_name (( column_1_name, column_2_name [, ...] ));
```

 NOTE

- If the GUC parameter **enable_functional_dependency** is disabled, each group of multi-column statistics supports a maximum of 32 columns.
 - You are not allowed to collect statistics about multiple columns in system catalogs.
- Collect statistics about multiple columns automatically.

After the **auto_statistic_ext_columns** parameter is enabled and the ANALYZE statement is executed, multi-column statistics are automatically created based on the index prefix of the table. The number of columns in the multi-column statistics cannot exceed the value of **auto_statistic_ext_columns**.

For example, if index (a, b, c, d) exists in table **t** and **auto_statistic_ext_columns** is set to **4**, multi-column statistics about (a, b), (a, b, c), and (a, b, c, d) are created after table **t** is analyzed.

```
{ ANALYZE | ANALYSE } [ VERBOSE ] table_name;
```

- Check the data files in the current database.

```
{ ANALYZE | ANALYSE } VERIFY { FAST | COMPLETE };
```

 NOTE

- In fast mode, DML operations need to be performed on the tables to be verified concurrently. As a result, an error is reported during the verification. In the current fast mode, data is directly read from the disk. When other threads modify files concurrently, the obtained data is incorrect. Therefore, you are advised to perform the verification offline.
 - You can perform operations on the entire database. Because a large number of tables are involved, you are advised to save the results in redirection mode.

```
gsql -d database -p port -f sqlfile> sqllog.txt 2>&1
```
 - Temporary tables and unlogged tables are not supported.
 - NOTICE is displayed only for externally visible tables. The detection of internal tables is included in the external tables on which the internal tables depend and is not displayed externally.
 - This statement can be executed with error tolerance.
 - If a key system catalog is damaged during a full database operation, an error is reported and the operation stops.
- Check data files of tables and indexes.

```
{ ANALYZE | ANALYSE } VERIFY { FAST | COMPLETE } { table_name | index_name } [ CASCADE ];
```

 **NOTE**

- Operations on ordinary tables and index tables are supported, but CASCADE operations on indexes of index tables are not supported. The CASCADE mode is used to process all index tables of the main table. When the index tables are checked separately, the CASCADE mode is not required.
- Temporary tables and unlogged tables are not supported.
- When the main table is checked, the internal tables of the main table, such as the TOAST table, are also checked.
- When the system displays a message indicating that the index table is damaged, you are advised to run the **reindex** command to rebuild the index.
- Check the data files of the table partition.

```
{ ANALYZE | ANALYSE } VERIFY { FAST | COMPLETE } table_name PARTITION (partition_name) [ CASCADE ];
```

 **NOTE**

- You can check a single partition of a table, but cannot perform the CASCADE operation on the indexes of an index table.
- Temporary tables and unlogged tables are not supported.

Parameters

- **VERBOSE**

Enables the display of progress messages.

 **NOTE**

If **VERBOSE** is specified, ANALYZE displays the progress information, indicating the table that is being processed. Statistics about tables are also displayed.

- **table_name**

Specifies the name (possibly schema-qualified) of a specific table to analyze. If omitted, all regular tables (but not foreign tables) in the current database are analyzed.

Currently, you can use ANALYZE to collect statistics on foreign tables of row-store tables.

Value range: an existing table name.

- **column_name, column_1_name, column_2_name**

Specifies the name of a specific column to analyze. All columns are analyzed by default.

Value range: An existing column name.

- **partition_name**

Assumes the table is a partitioned table. You can specify **partition_name** following the keyword PARTITION to analyze the statistics of this table.

Value range: a partition name of a table.

- **index_name**

Specifies the name of the specific index table to be analyzed (possibly schema-qualified).

Value range: an existing table name.

- **FAST|COMPLETE**

The FAST mode verifies the CRC and page header of the table. If the verification fails, an alarm is generated. In COMPLETE mode, the pointer and tuple of the table are parsed and verified.

- **CASCADE**

In CASCADE mode, all indexes of the current table are verified.

- **PARTITION_MODE**

Cascadingly collects statistics about partitioned tables. The following table describes the options and their meanings. This is not applicable to non-partitioned tables.

Table 7-236 PARTITION_MODE options

PARTITION_MODE Option	Description
ALL	Statistics about the entire table and level-1 partition are collected.
GLOBAL	Statistics about the entire table are collected.
PARTITION	Statistics about the level-1 partition are collected.
GLOBAL AND PARTITION	Statistics about the entire table and level-1 partition are collected.
ALL COMPLETE	Statistics about the entire table and level-1 partition are collected.
AUTO	Default value. The parameter configured in statistic_granularity or default_statistic_granularity prevails. The priority of the table-level parameter statistic_granularity is higher than that of the global parameter default_statistic_granularity .

A difference between **ALL** and **ALL COMPLETE** is as follows: **ALL COMPLETE** uses a higher sampling rate and takes a longer time to calculate statistics.

 **CAUTION**

- When a version earlier than 505.0.0 is upgraded to 505.0.0 or later, **PARTITION_MODE** does not take effect during the upgrade observation period. The behavior of **PARTITION_MODE** is the same as that of the source version.
- When the entire database is analyzed, the partition mode cannot be specified. That is, syntax such as **ANALYZE WITH GLOBAL** is not supported.
- When the entire database is analyzed, **default_statistic_granularity** can be set to **GLOBAL** or **ALL**. In this case, the **ANALYZE** behavior is the same as that defined in **default_statistic_granularity**. When **default_statistic_granularity** is set to other values, the **ANALYZE** behavior is degraded to the **GLOBAL** behavior.

Examples

- Collect statistics information about a table.

```
-- Create the customer_info table.
gaussdb=# CREATE TABLE customer_info(
wr_returned_date_sk INTEGER ,
wr_returned_time_sk INTEGER ,
wr_item_sk INTEGER NOT NULL
,wr_refunded_customer_sk INTEGER ) DISTRIBUTE BY HASH (wr_item_sk);

-- Run ANALYZE to update statistics.
gaussdb=# ANALYZE customer_info;

-- Run ANALYZE VERBOSE to update statistics and display information about the customer_info
table.
gaussdb=# ANALYZE VERBOSE customer_info;
INFO: analyzing "public.customer_info"(cn_5002 pid=53078)

-- Run ANALYZE VERBOSE to export the wr_returned_time_sk column information in the
customer_info table.
gaussdb=# ANALYZE VERBOSE customer_info(wr_returned_time_sk);
INFO: analyzing "public.customer_info"(cn_5002 pid=53078)
```

- Collect statistics about a partitioned table.

```
-- Create a partitioned table.
gaussdb=# CREATE TABLE customer_par(
wr_returned_date_sk INTEGER ,
wr_returned_time_sk INTEGER ,
wr_item_sk INTEGER NOT NULL,
wr_returned_customer_sk INTEGER)
DISTRIBUTE BY HASH (wr_item_sk)PARTITION BY RANGE(wr_returned_date_sk)(PARTITION P1
VALUES LESS THAN(2452275),PARTITION P2 VALUES LESS THAN(2452640),PARTITION P3 VALUES
LESS THAN(2453000),PARTITION P4 VALUES LESS THAN(MAXVALUE))ENABLE ROW MOVEMENT;

-- Run ANALYZE to update statistics.
gaussdb=# ANALYZE customer_par;

-- Run ANALYZE VERBOSE to export the information in the customer_par table.
gaussdb=# ANALYZE VERBOSE customer_par;
INFO: analyzing "public.customer_par"(cn_5001 pid=446617)

-- Run ANALYZE VERBOSE to output information about the P1 level-1 partitioned table.
gaussdb=# ANALYZE VERBOSE customer_par PARTITION(P1);
INFO: analyzing "public.customer_par"(cn_5001 pid=446617)
```

- Collect statistics about multiple columns manually.

```
-- Manually collect statistics in the wr_returned_date_sk and wr_returned_time_sk columns.
gaussdb=# ANALYZE VERBOSE customer_info (wr_returned_date_sk,wr_returned_time_sk);
INFO: analyzing "public.customer_par"(cn_5001 pid=446617)
```

- Collect statistics about multiple columns automatically.
-- Create an index for the **customer_info** table.
gaussdb=# CREATE INDEX customer_index ON customer_info USING
btree(wr_returned_date_sk,wr_returned_time_sk,wr_item_sk,wr_refunded_customer_sk);

-- Set **auto_statistic_ext_columns** to 4.
gaussdb=# set auto_statistic_ext_columns=4;

-- Collect statistics about multiple columns automatically.
gaussdb=# ANALYZE VERBOSE customer_info;
INFO: analyzing "public.customer_info"(cn_5001 pid=446617)
- Check the data files in the current database.
gaussdb=# ANALYZE VERIFY FAST;
- Check data files of tables and indexes.
-- Check the **customer_info** table.
gaussdb=# ANALYZE VERIFY FAST customer_info;

-- Check the customer_index index.
gaussdb=# ANALYZE VERIFY FAST customer_index;
- Check the data files of the table partition.
-- Check the P1 partition in the **customer_par** partitioned table.
gaussdb=# ANALYZE VERIFY FAST customer_par PARTITION (P1);
- Delete data.
-- Delete the index **customer_index**.
gaussdb=# DROP INDEX customer_index;

-- Drop the **customer_info** table.
gaussdb=# DROP TABLE customer_info;

-- Drop the **customer_par** partitioned table.
gaussdb=# DROP TABLE customer_par;

7.12.7 B

7.12.7.1 BEGIN

Description

BEGIN may be used to initiate an anonymous block or a single transaction.

An anonymous block is a structure that can dynamically create and execute stored procedure code instead of permanently storing code as a database object in the database.

Precautions

None

Syntax

- Enable an anonymous block.
[DECLARE [declare_statements]]
BEGIN
execution_statements
END;
/
- Start a transaction.
BEGIN [WORK | TRANSACTION]
[

```
{  
  ISOLATION LEVEL { READ COMMITTED | SERIALIZABLE | REPEATABLE READ }  
  | { READ WRITE | READ ONLY }  
} [, ...]  
];
```

Parameters

- **declare_statements**
Declares a variable, including its name and type, for example, **sales_cnt int**.
- **execution_statements**
Specifies the statement to be executed in an anonymous block.
Value range: an existing function name
- **WORK | TRANSACTION**
Specifies the optional keyword in the BEGIN syntax format without functions.
- **ISOLATION LEVEL**
Specifies the transaction isolation level that determines the data that a transaction can view if other concurrent transactions exist.

NOTE

The isolation level of a transaction cannot be reset after the first clause (INSERT, DELETE, UPDATE, FETCH, or COPY) for modifying data is executed in the transaction.

Value range:

- **READ COMMITTED**: Only committed data is read. This is the default action.
- **READ UNCOMMITTED**: Committed data is probably read. This isolation level is provided to handle CN breakdown emergencies. On this isolation level, you are advised to only read data to prevent inconsistency.
- **REPEATABLE READ**: Only the data committed before transaction start is read. Uncommitted data or data committed in other concurrent transactions cannot be read.
- **SERIALIZABLE**: Currently, this isolation level is not supported. Setting this isolation level is equivalent to **REPEATABLE READ**.
- **READ WRITE | READ ONLY**
Specifies the transaction access mode (read/write or read only).

Examples

- Start a transaction.
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE tbl_test1(col1 int, col2 int);
gaussdb=# INSERT INTO tbl_test1 VALUES (1,1), (2,2), (3,3);

-- Start a transaction in default mode.
gaussdb=# BEGIN;
INSERT INTO tbl_test1 VALUES (4,4);
END;

--Start a transaction with the separation level being **REPEATABLE READ**.
gaussdb=# BEGIN ISOLATION LEVEL REPEATABLE READ;
SELECT * FROM tbl_test1;
END;

```
-- Drop the table.  
gaussdb=# DROP TABLE tbl_test1;
```

- Use anonymous blocks.
-- Generate a string using anonymous blocks.

```
gaussdb=# BEGIN  
dbe_output.print_line('Hello');  
END;  
/
```

[START TRANSACTION](#)

7.12.8 C

7.12.8.1 CALL

Description

Calls defined functions and stored procedures.

Precautions

The owner of a function or stored procedure, users granted with the EXECUTE permission on the function or stored procedure, or users granted with the EXECUTE ANY FUNCTION permission can call the function or stored procedure. When separation of duties is disabled, a system administrator has the permission to use the CALL commands by default.

Syntax

```
CALL [ schema. ] { func_name | procedure_name } ( param_expr );
```

Parameters

- **schema**
Specifies the name of the schema where a function or stored procedure is located.
- **func_name**
Specifies the name of the function or stored procedure to be called.
Value range: an existing function name

NOTE

You can use database links to perform operations on remote functions or stored procedures. For details, see [DATABASE LINK](#).

- **param_expr**
Specifies a list of parameters in the function. Use := or => to separate a parameter name and its value. This method allows parameters to be placed in

any order. If only parameter values are in the list, the value order must be the same as that defined in the function or stored procedure.

Value range: an existing function parameter name or stored procedure parameter name

NOTE

- The parameters include input parameters (whose name and type are separated by **IN**) and output parameters (whose name and type are separated by **OUT**). When you run the **CALL** command to call a function or stored procedure, the parameter list must contain an output parameter for non-overloaded functions. You can set the output parameter to a variable or any constant. For details, see [Examples](#).

Examples

```
-- Create the func_add_sql function, calculate the sum of two integers, and return the result.
gaussdb=# CREATE FUNCTION func_add_sql(num1 integer, num2 integer) RETURN integer
AS
BEGIN
RETURN num1 + num2;
END;
/

-- Transfer by parameter value.
gaussdb=# CALL func_add_sql(1, 3);

-- Transfer by naming tag method.
gaussdb=# CALL func_add_sql(num1 => 1,num2 => 3);
gaussdb=# CALL func_add_sql(num2 := 2, num1 := 3);

-- Delete the function.
gaussdb=# DROP FUNCTION func_add_sql;

-- Create a function with output parameters.
gaussdb=# CREATE FUNCTION func_increment_sql(num1 IN integer, num2 IN integer, res OUT integer)
RETURN integer
AS
BEGIN
res := num1 + num2;
END;
/

-- Transfer a constant as an output parameter.
gaussdb=# CALL func_increment_sql(1,2,1);

-- Transfer a variable as an output parameter.
gaussdb=# DECLARE
res int;
BEGIN
func_increment_sql(1, 2, res);
dbe_output.print_line(res);
END;
/

-- Delete the function.
gaussdb=# DROP FUNCTION func_increment_sql;
```

Helpful Links

[CREATE FUNCTION](#) and [CREATE PROCEDURE](#)

7.12.8.2 CHECKPOINT

Function

A checkpoint is a point in the transaction log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to a disk.

It sets transaction log checkpoints. By default, WALs periodically specify checkpoints in a transaction log. You may use `gs_guc` to specify runtime parameters **checkpoint_segments**, **checkpoint_timeout**, and **incremental_checkpoint_timeout** to adjust the atomized checkpoint intervals.

Precautions

- Only the system administrator and O&M administrator can invoke CHECKPOINT.
- CHECKPOINT performs an immediate checkpoint when the related command is issued, without waiting for a regular checkpoint scheduled by the system.

Syntax

```
CHECKPOINT;
```

Examples

```
-- Set a checkpoint.  
gaussdb=# CHECKPOINT;
```

7.12.8.3 CLEAN CONNECTION

Description

Clears idle or invalid network connections between the current CN and other specified CNs or DNs. This statement is used to clear the specified database and idle or invalid connections of a specified user cached in the current CN on a specified CN.

Precautions

- In non-force mode, this function only clears connections between database cluster nodes (CNs/DNs) and does not affect client connections.
- This function clears only idle and invalid connections cached on the CN. Normal connections that are being used are not cleared.
- This function takes effect only on CNs and does not take effect on DNs.
- You can query the **PG_STAT_GET_POOLER_STATUS()** function to check the cache connection and verify the clearing effect.
- You are advised to perform this operation only when the network connection of the database is abnormal.

- If residual connections cannot be cleared on distributed DNs, O&M personnel are advised to use the `pg_terminate_session` function to clear invalid sessions.

Syntax

```
CLEAN CONNECTION  
TO { COORDINATOR ( nodename [, ... ] ) | NODE ( nodename [, ... ] ) | ALL [ CHECK ] [ FORCE ] }  
{ FOR DATABASE dbname | TO USER username | FOR DATABASE dbname TO USER username };
```

Parameters

- **CHECK**

This parameter can be specified only when the node list is specified as **TO ALL**. Setting this parameter will check whether a database is accessed by other sessions before its connections are cleared. If any sessions are detected before **DROP DATABASE** is executed, an error will be reported and the database will not be deleted.

- **FORCE**

This parameter can be specified only when the node list is **TO ALL**. If this parameter is specified, all threads related to the specified `dbname` and `username` in the current CN receive the `SIGTERM` signal, the corresponding session is forcibly closed, the transaction is terminated, and the network connection is cleared.

- **COORDINATOR (nodename ,nodename ... }) | NODE (nodename , nodename ...) | ALL**

This command is used to delete the idle or invalid connections between the current CN node and a specified node. There are three scenarios:

- **COORDINATOR**: Delete the idle or invalid connections from the current CN to a specified CN.
- **NODE**: Delete the idle or invalid connections from the current CN to a specified DN.
- **ALL**: Delete the idle or invalid connections from the current CN to all nodes, including CNs and DNs.

Value range: **nodename** is an existing node name.

- **dbname**

Deletes connections to a specified database from the current CN. If this parameter is not specified, connections to all databases will be deleted.

Value range: an existing database name

- **username**

Deletes connections to a specified user from the current CN. If this parameter is not specified, connections of all users will be deleted.

Value range: an existing username

Examples

```
-- Create the test_clean_connection database.  
gaussdb=# CREATE DATABASE test_clean_connection;  
  
-- Create user jack.  
gaussdb=# CREATE USER jack PASSWORD '*****';  
  
-- Log in to the database as the user jack in another session, and query the connection information in the
```

```
view.
gaussdb=# SELECT datname,username,application_name,waiting,state
          FROM pg_stat_activity
          WHERE datname = 'test_clean_connection';
 datname      | username | application_name | waiting | state
-----+-----+-----+-----+-----
test_clean_connection | jack   | gsql             | f       | idle
(1 row)

-- If you directly delete the test_clean_connection database, the following error information is displayed:
gaussdb=# DROP DATABASE test_clean_connection;
ERROR: Database "test_clean_connection" is being accessed by other users. You can stop all connections by
command: "clean connection to all force for database XXXX;" or wait for the sessions to end by querying
view: "pg_stat_activity".
DETAIL: There is 1 other session using the database.

-- Delete the connections between the current CN and all nodes of the test_clean_connection database.
-- If the FORCE parameter is not used, connections whose stat is not in other states cannot be deleted.
gaussdb=# CLEAN CONNECTION TO ALL FORCE FOR DATABASE test_clean_connection;

-- Query the connection for logging in to the test_clean_connection database.
gaussdb=# SELECT datname,username,application_name,waiting,state
          FROM pg_stat_activity
          WHERE datname = 'test_clean_connection';
 datname | username | application_name | waiting | state
-----+-----+-----+-----+-----
(0 rows)

-- Delete the test_clean_connection database.
gaussdb=# DROP DATABASE test_clean_connection;

-- Delete user jack.
gaussdb=# DROP USER jack;
```

7.12.8.4 CLOSE

Function

CLOSE frees the resources associated with an open cursor.

Precautions

- After a cursor is closed, no subsequent operations are allowed on it.
- A cursor should be closed when it is no longer needed.
- Every non-holdable open cursor is implicitly closed when a transaction is terminated by COMMIT or ROLLBACK.
- A holdable cursor is implicitly closed if the transaction that created it aborts by ROLLBACK.
- If the cursor creation transaction is successfully committed, the holdable cursor remains open until an explicit CLOSE operation is executed, or the client disconnects.
- GaussDB does not have an explicit OPEN cursor statement. A cursor is considered open when it is declared. You can view all available cursors by querying the pg_cursors system view.

Syntax

```
CLOSE { cursor_name | ALL } ;
```

Parameter Description

- **cursor_name**
Specifies the name of a cursor to be closed.
- **ALL**
Closes all open cursors.

Examples

See [Examples](#) in section "FETCH."

Helpful Links

[FETCH](#) and [MOVE](#)

7.12.8.5 CLUSTER

Description

- Clusters a table based on an index.
- CLUSTER instructs GaussDB to cluster the table specified by **table_name** based on the index specified by **index_name**. The index must have been defined by **table_name**.
- When a table is clustered, it is physically reordered based on the index information. Clustering is a one-time operation. When the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order.
- When a table is clustered, GaussDB records which index the table was clustered by. CLUSTER table_name reclusters the clustered index that was previously recorded in the table. You can also use ALTER TABLE table_name CLUSTER on index_name to set the index of a specified table for subsequent cluster operations, or use ALTER TABLE table_name SET WITHOUT CLUSTER to clear the previously clustered index of a specified table.
- If CLUSTER does not contain parameters, all tables that have been clustered in the database owned by the current user will be reprocessed. If a system administrator uses this command, all clustered tables are reclustered.
- When a table is clustered, an ACCESS EXCLUSIVE lock is requested on the table. This avoids that other operations (including read and write operations) are performed on the table before the CLUSTER operation is complete.

Precautions

- Only row-store B-tree indexes support CLUSTER.
- In the case where you are accessing single rows randomly within a table, the actual order of the data in the table is unimportant. However, if there are

many accesses to some data and an index groups the data, using the CLUSTER index improves performance.

- If an index you request from a table is a range, or a single indexed value that has multiple rows that match, CLUSTER will help because once the index identifies the table page for the first row that matches, all other rows that match are probably already on the same table page, and so you save disk accesses and speed up the query.
- During clustering, the system creates a temporary backup of the table created in the index sequence and a temporary backup of each index in the table. Therefore, ensure that the disk has sufficient free space during clustering, which is at least the sum of the table size and all index sizes.
- CLUSTER records which indexes have been used for clustering. Therefore, you can manually specify indexes for the first time, cluster specified tables, and set a maintenance script that will be executed periodically. You only need to run the **CLUSTER** command without parameters. In this way, tables that you want to periodically cluster can be automatically updated.
- The optimizer records table clustering statistics. After clustering a table, you need to execute the ANALYZE operation to ensure that the optimizer has the latest clustering information. Otherwise, the optimizer may select a non-optimal query plan.
- CLUSTER cannot be executed in transactions.
- If the GUC parameter **xc_maintenance_mode** is not set to **on**, the CLUSTER operation skips all system catalogs.
- For a global secondary index (GSI), after CLUSTER is executed in a single partition or CLUSTER [VERBOSE] is used to recluster a table, an error is reported when the query statement uses the global secondary index. In this case, you need to run REINDEX INDEX to rebuild the global secondary index.

Syntax

- Cluster a table.

```
CLUSTER [ VERBOSE ] table_name [ USING index_name ];
```

- Cluster a partition.

```
CLUSTER [ VERBOSE ] table_name PARTITION ( partition_name ) [ USING index_name ];
```

- Recluster a table.

```
CLUSTER [ VERBOSE ];
```

Parameters

- **VERBOSE**
(Optional) Enables the display of progress messages.
- **table_name**
Specifies the table name.
Value range: an existing table name

- **[USING index_name]**
Specifies the index name.
Value range: an existing index name
You must specify **index_name** when performing clustering on the table for the first time. If you do not specify **index_name** next time, the table will be clustered based on existing records.
- **partition_name**
Specifies the partition name.
Value range: an existing partition name

Examples

- Cluster the table.

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE test_c1(id int, name varchar(20));
gaussdb=# CREATE INDEX idx_test_c1_id ON test_c1(id);
gaussdb=# INSERT INTO test_c1 VALUES (3,'Joe'),(1,'Jack'),(2,'Scott');

-- Query.
gaussdb=# SELECT * FROM test_c1;
 id | name
----+-----
  3 | Joe
  1 | Jack
  2 | Scott
(3 rows)

-- Perform clustering.
gaussdb=# CLUSTER test_c1 USING idx_test_c1_id;

-- Query.
gaussdb=# SELECT * FROM test_c1;
 id | name
----+-----
  1 | Jack
  2 | Scott
  3 | Joe
(3 rows)

-- Delete.
gaussdb=# DROP TABLE test_c1;
```
- Recluster a table.

```
-- Create a table.
gaussdb=# CREATE TABLE test(col1 int,CONSTRAINT pk_test PRIMARY KEY (col1));

-- An error is reported when the keyword USING is not contained in the first clustering.
gaussdb=# CLUSTER test;
ERROR:  there is no previously clustered index for table "test"

-- Perform clustering.
gaussdb=# CLUSTER test USING pk_test;

-- Insert data.
gaussdb=# INSERT INTO test VALUES (1),(99),(10),(8);

-- Recluster a table.
gaussdb=# CLUSTER VERBOSE test;
INFO:  clustering "public.test" using index scan on "pk_test"(dn_6001 pid=3672)
INFO:  "test": found 0 removable, 4 nonremovable row versions in 1 pages(dn_6001 pid=3672)
DETAIL:  0 dead row versions cannot be removed yet.
CPU 0.00s/0.00u sec elapsed 0.01 sec.
CLUSTER
```

```
-- Delete.
gaussdb=# DROP TABLE test;

● Cluster a partition.
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE test_c2(id int, info varchar(4)) PARTITION BY RANGE (id)(
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (21)
);
gaussdb=# CREATE INDEX idx_test_c2_id1 ON test_c2(id);
gaussdb=# INSERT INTO test_c2 VALUES (6,'ABBB'),(2,'ABAB'),(9,'AAAA');
gaussdb=# INSERT INTO test_c2 VALUES (11,'AAAB'),(19,'BBBA'),(16,'BABA');

-- Query.
gaussdb=# SELECT * FROM test_c2;
id | info
----+-----
 6 | ABBB
 2 | ABAB
 9 | AAAA
11 | AAAB
19 | BBBA
16 | BABA
(6 rows)

-- Perform clustering on partition p2.
gaussdb=# CLUSTER test_c2 PARTITION (p2) USING idx_test_c2_id1;

-- Query.
gaussdb=# SELECT * FROM test_c2;
id | info
----+-----
 6 | ABBB
 2 | ABAB
 9 | AAAA
11 | AAAB
16 | BABA
19 | BBBA
(6 rows)

-- Delete.
gaussdb=# DROP TABLE test_c2;
```

7.12.8.6 COMMENT

Description

Defines or changes the comment of an object.

Precautions

- Each object stores only one comment. Therefore, you need to modify a comment and issue a new **COMMENT** command to the same object. To delete the comment, write **NULL** at the position of the text string. When an object is deleted, the comment is automatically deleted.
- Currently, there is no security protection for viewing comments. Any user connected to a database can view all the comments for objects in the database. For shared objects such as databases, roles, and tablespaces, comments are stored globally so any user connected to any database in the cluster can see all the comments for shared objects. Therefore, do not put security-critical information in comments.

- To comment objects, you must be an object owner or user granted the COMMENT permission. The system administrator has this permission by default.
- Roles do not have owners, so the rule for **COMMENT ON ROLE** is that you must be an administrator to comment on an administrator role, or have the CREATE ROLE permission to comment on non-administrator roles. A system administrator can comment on all objects.

Syntax

```
COMMENT ON
{
  AGGREGATE agg_name (agg_type [, ...] ) |
  CAST (source_type AS target_type) |
  COLLATION object_name |
  COLUMN { table_name.column_name | view_name.column_name } |
  CONSTRAINT constraint_name ON table_name |
  CONVERSION object_name |
  DATABASE object_name |
  DOMAIN object_name |
  EXTENSION object_name |
  FOREIGN DATA WRAPPER object_name |

  FUNCTION function_name ( [ [ argname ] [ argmode ] argtype] [, ...] ) |
  INDEX object_name |
  LARGE OBJECT large_object_oid |
  OPERATOR operator_name (left_type, right_type) |
  OPERATOR CLASS object_name USING index_method |
  OPERATOR FAMILY object_name USING index_method |
  [ PROCEDURAL ] LANGUAGE object_name |
  ROLE object_name |
  SCHEMA object_name |
  SERVER object_name |
  TABLE object_name |
  TABLESPACE object_name |
  TEXT SEARCH CONFIGURATION object_name |
  TEXT SEARCH DICTIONARY object_name |
  TEXT SEARCH PARSER object_name |
  TEXT SEARCH TEMPLATE object_name |
  TYPE object_name |
  VIEW object_name |
  TRIGGER trigger_name ON table_name
}
IS 'text';
```

Parameters

- **agg_name**
Specifies the new name of an aggregation function.
- **agg_type**
Specifies the data type of the aggregation function parameters.
- **source_type**
Specifies the source data type of the cast.
- **target_type**
Specifies the target data type of the cast.
- **object_name**
Specifies the name of an object.
- **table_name.column_name**

view_name.column_name

Specifies the column whose comment is defined or modified. You can add the table name or view name as the prefix.

- **constraint_name**
Specifies the table constraint whose comment is defined or modified.
- **table_name**
Specifies the name of a table.
- **function_name**
Specifies the function whose comment is defined or modified.
- **argmode,argname,argtype**
Specifies the schema, name, and type of the function parameters.
- **large_object_oid**
Specifies the OID of the large object whose comment is defined or modified.
- **operator_name**
Specifies the name of the operator.
- **left_type,right_type**
Specifies the data type of the operator parameters (optionally schema-qualified). If the prefix or suffix operator does not exist, the **NONE** option can be added.
- **text**
Specifies the comment content.

Examples

```
-- Create a table.
gaussdb=# CREATE TABLE emp(
  empno varchar(7),
  ename varchar(50),
  job varchar(50),
  mgr varchar(7),
  deptno int
);

-- Add comments to a table.
gaussdb=# COMMENT ON TABLE emp IS 'Department table';

-- Add comments to columns.
gaussdb=# COMMENT ON COLUMN emp.empno IS 'Employee ID';
gaussdb=# COMMENT ON COLUMN emp.ename IS 'Employee name';
gaussdb=# COMMENT ON COLUMN emp.job IS 'Job';
gaussdb=# COMMENT ON COLUMN emp.mgr IS 'Manager ID';
gaussdb=# COMMENT ON COLUMN emp.deptno IS 'Department ID';

-- View table comments.
gaussdb=# \d+
Schema | Name | Type | Owner | Size | Storage | Description
-----+-----+-----+-----+-----+-----+-----
public | emp | table | omm | 0 bytes | {orientation=row,compression=no} | Department table

-- View column comments.
gaussdb=# \d+ emp
Table "public.emp"
Column | Type | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
empno | character varying(7) | | extended | | Employee ID
ename | character varying(50) | | extended | | Employee name
```

```

job | character varying(50) | | extended | | Job
mgr | character varying(7) | | extended | | Manager ID
deptno | integer | | plain | | Department ID
Has OIDs: no
Distribute By: HASH(empno)
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no

-- Delete the emp table.
gaussdb=# DROP TABLE emp;

```

7.12.8.7 COMMIT | END

Description

COMMIT or END commits all operations of a transaction.

Precautions

Only the creator of a transaction or a system administrator can run the **COMMIT** command. The creation and commit operations must be in different sessions.

Syntax

```
{ COMMIT | END } [ WORK | TRANSACTION ] ;
```

Parameters

- COMMIT | END**
 Commits the current transaction and makes all changes made by the transaction become visible to others.
- WORK | TRANSACTION**
 Specifies an optional keyword, which has no effect except increasing readability.

Examples

```

-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Create a table.
gaussdb=# CREATE TABLE tpcds.customer_demographics_t2
(
    CD_DEMO_SK          INTEGER          NOT NULL,
    CD_GENDER           CHAR(1)          ,
    CD_MARITAL_STATUS  CHAR(1)          ,
    CD_EDUCATION_STATUS CHAR(20)         ,
    CD_PURCHASE_ESTIMATE INTEGER         ,
    CD_CREDIT_RATING   CHAR(10)         ,
    CD_DEP_COUNT        INTEGER          ,
    CD_DEP_EMPLOYED_COUNT INTEGER        ,
    CD_DEP_COLLEGE_COUNT INTEGER
)
DISTRIBUTE BY HASH (CD_DEMO_SK);

```

```
-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Insert data.
gaussdb=# INSERT INTO tpceds.customer_demographics_t2 VALUES(1,'M', 'U', 'DOCTOR DEGREE', 1200,
'GOOD', 1, 0, 0);
gaussdb=# INSERT INTO tpceds.customer_demographics_t2 VALUES(2,'F', 'U', 'MASTER DEGREE', 300, 'BAD',
1, 0, 0);

-- Commit the transaction to make all changes permanent.
gaussdb=# COMMIT;

-- Query data.
gaussdb=# SELECT * FROM tpceds.customer_demographics_t2;

-- Delete the tpceds.customer_demographics_t2 table.
gaussdb=# DROP TABLE tpceds.customer_demographics_t2;

-- Delete the schema.
gaussdb=# DROP SCHEMA tpceds;
```

[ROLLBACK](#)

7.12.8.8 COMMIT PREPARED

Description

Commits a prepared two-phase transaction. This function is for internal use only. You are advised not to use it.

Precautions

- The function is only available in maintenance mode (when GUC parameter **xc_maintenance_mode** is **on**). Exercise caution when enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.
- Only the transaction creators or system administrators can run the command. The creation and commit operations must be in different sessions.
- The transaction function is maintained automatically by the database, and should be not visible to users.

Syntax

```
COMMIT PREPARED transaction_id [ WITH commit_sequence_number ];
```

Parameters

- **transaction_id**
Specifies the identifier of the transaction to be committed. The identifier must be different from those for current prepared transactions.
- **commit_sequence_number**

Specifies the sequence number of the transaction to be committed. It is a 64-bit, incremental, unsigned number.

Examples

```
-- Start.
gaussdb=# BEGIN;

-- Prepare a transaction whose identifier is trans_test.
gaussdb=# PREPARE TRANSACTION 'trans_test';

-- Create a table.
gaussdb=# CREATE TABLE item1(id int);

--Commit the transaction whose identifier is trans_test.
gaussdb=# COMMIT PREPARED 'trans_test';

-- Delete the table.
gaussdb=# DROP TABLE item1;
```

[PREPARE TRANSACTION](#) and [ROLLBACK PREPARED](#)

7.12.8.9 COPY

Description

Copies data between tables and files.

COPY FROM copies data from a file to a table, and COPY TO copies data from a table to a file.

Precautions

- When the **enable_copy_server_files** parameter is disabled, only the initial user is allowed to run the **COPY FROM FILENAME** or **COPY TO FILENAME** command. When the **enable_copy_server_files** parameter is enabled, users with the SYSADMIN permission or users who inherit the built-in role permission **gs_role_copy_files** are allowed to run the **COPY FROM FILENAME** or **COPY TO FILENAME** command. By default, database configuration files and key files are not allowed, and you can run the **COPY FROM FILENAME** or **COPY TO FILENAME** command for certificate files and audit logs to prevent unauthorized users from viewing or modifying sensitive files. When **enable_copy_server_files** is enabled, the administrator can use the GUC parameter **safe_data_path** to set the path for common users to import and export to the subpath of the set path. If this GUC parameter is not set (by default), the path used by common users is not blocked. This parameter reports an error for ... in the path of the COPY statement.
- COPY applies only to tables but not views.
- COPY TO requires the SELECT permission on the table to be read, and COPY FROM requires the INSERT permission on the table to be inserted.
- If a list of columns is specified, COPY copies only the data of the specified columns between the file and the table. If a table has any columns that are not in the column list, **COPY FROM** inserts default values for those columns.

- If a data source file is specified, the server must be able to access the file. If **STDIN** is specified, data flows between the client and the server. When entering data, use the **TAB** key to separate the columns of the table and use a backslash and a period (\.) in a new row to indicate the end of the input.
- **COPY FROM** throws an error if any row in the data file contains more or fewer columns than expected.
- The end of the data can be represented by a line that contains only backslashes and periods (\.). If data is read from a file, the end flag is unnecessary. If data is copied between client applications, an end tag must be provided.
- In **COPY FROM**, **\N** is an empty string. To enter the actual value **\N**, use **\\N**.
- **COPY FROM** can preprocess data using column expressions, but column expressions do not support subqueries.
- When a data format error occurs during **COPY FROM** execution, the transaction is rolled back. However, the error information is insufficient, making it difficult to locate the error data from a large amount of raw data.
- **COPY FROM** and **COPY TO** apply to low concurrency and local import and export of a small amount of data.
- When **COPY** is used in binary format, transcoding in distributed mode is not supported.
- **COPY** is a server command and its execution environment is the same as that of the database server process. **\COPY** is a client meta-command and its execution environment is the same as that of **gsql** on the client. Note that when the database and **gsql** are used in the sandbox environment, the **COPY** and **\COPY** commands both use the paths in the sandbox. When the database is used in the sandbox environment and **gsql** is used outside the sandbox, the **COPY** command uses the path inside the sandbox, and the **\COPY** command uses the path outside the sandbox.
- When executing **COPY** to import data to a base table with a GSI, the **enable_stream_operator** parameter must be enabled to achieve optimal data import performance.
- During the export using **COPY TO**, if the column data in the table contains the **'\0'** character, the column data will be truncated during the export. Only the data before **'\0'** will be exported.
- The import and export statistics and error information are stored in the **gs_copy_summary** and **pgxc_copy_error_log** system catalogs, respectively. Objects that may cause privilege escalation, such as **RULE**, **TRIGGER**, index functions, row-level security, **CHECK** constraints, **GENERATED** columns, **DEFAULT** columns, and **ON UPDATE** columns, cannot be contained in the system catalogs. Otherwise, the system considers that the objects are created by unauthorized users, reports an error, and exits.

Syntax

- Copy data from a file to a table.

```
COPY table_name [ ( column_name [, ...] ) ]
FROM { 'filename' | STDIN }
[ [ USING ] DELIMITERS 'delimiters' ]
[ WITHOUT ESCAPING ]
[ LOG ERRORS ]
[ LOG ERRORS DATA ]
```

```
[ REJECT LIMIT 'limit' ]
[ [ WITH ]
  ( option [, ...] )
  | ( copy_option [, ...] )
  | [ TRANSFORM ( { column_name [ data_type ] [ AS transform_expr ] } [, ...] ) ]
  | [ FIXED FORMATTER ( { column_name( offset, length ) } [, ...] ) ]
]
```

 **NOTE**

The fixed formatter syntax is compatible with `copy_option` but incompatible with **option**. `copy_option` is incompatible with `option`. `transform` is compatible with `copy_option` and fixed formatter.

- Copy data from a table to a file.

```
COPY table_name [ ( column_name [, ...] ) ]
  TO { 'filename' | STDOUT }
  [ [ USING ] DELIMITERS 'delimiters' ]
  [ WITHOUT ESCAPING ]
  [ [ WITH ]
    ( option [, ...] )
    | ( copy_option [, ...] )
    | [ FIXED FORMATTER ( { column_name( offset, length ) } [, ...] ) ]
  ]
```

```
COPY query
  TO { 'filename' | STDOUT }
  [ WITHOUT ESCAPING ]
  [ [ WITH ]
    ( option [, ...] )
    | ( copy_option [, ...] )
    | [ FIXED FORMATTER ( { column_name( offset, length ) } [, ...] ) ]
  ]
```

 **NOTE**

- The syntax constraints of COPY TO are as follows:
(query) is incompatible with [USING] DELIMITERS. If the data comes from a query result, COPY TO cannot specify [USING] DELIMITERS.
- Use spaces to separate **copy_option** following FIXED FORMATTER.
- **copy_option** is the native parameter, while **option** is the parameter imported by a compatible foreign table.

The syntax of the optional parameter **option** is as follows:

```
FORMAT 'format_name'
| FORMAT binary
| OIDS [ boolean ]
| DELIMITER 'delimiter_character'
| NULL 'null_string'
| HEADER [ boolean ]
| USEEOF [ boolean ]
| FILEHEADER 'header_file_string'
| FREEZE [ boolean ]
| QUOTE 'quote_character'
| ESCAPE 'escape_character'
| EOL 'newline_character'
| NOESCAPING [ boolean ]
| FORCE_QUOTE { ( column_name [, ...] ) | * }
| FORCE_NOT_NULL ( column_name [, ...] )
| ENCODING 'encoding_name'
| IGNORE_EXTRA_DATA [ boolean ]
| FILL_MISSING_FIELDS [ boolean ]
| COMPATIBLE_ILLEGAL_CHARS [ boolean ]
| DATE_FORMAT 'date_format_string'
| TIME_FORMAT 'time_format_string'
| TIMESTAMP_FORMAT 'timestamp_format_string'
| SMALLDATETIME_FORMAT 'smalldatetime_format_string'
```

The syntax of the optional parameter **copy_option** is as follows:

```
OIDS
| NULL 'null_string'
| HEADER
| USEEOF
| FILEHEADER 'header_file_string'
| FREEZE
| FORCE_NOT_NULL column_name [, ...]
| FORCE_QUOTE { column_name [, ...] | * }
| BINARY
| CSV
| QUOTE [ AS ] 'quote_character'
| ESCAPE [ AS ] 'escape_character'
| EOL 'newline_character'
| ENCODING 'encoding_name'
| IGNORE_EXTRA_DATA
| FILL_MISSING_FIELDS
| COMPATIBLE_ILLEGAL_CHARS
| DATE_FORMAT 'date_format_string'
| TIME_FORMAT 'time_format_string'
| TIMESTAMP_FORMAT 'timestamp_format_string'
| SMALLDATETIME_FORMAT 'smalldatetime_format_string'
```

Parameters

- **query**
Specifies that the results will be copied.
Valid value: a **SELECT** or **VALUES** command in parentheses
- **table_name**
Specifies the name (possibly schema-qualified) of an existing table.
Value range: an existing table name
- **column_name**
Specifies an optional list of columns to be copied.
Value range: any columns. All columns will be copied if no column list is specified.
- **STDIN**
Specifies that input comes from the standard input. In the input, table columns are separated by tabs and each row ends with a backslash and a period (\.).
- **STDOUT**
Specifies that output goes to the standard output.
- **FIXED**
Fixes column length. When the column length is fixed, **DELIMITER**, **NULL**, and **CSV** cannot be specified. When **FIXED** is specified, **BINARY**, **CSV**, and **TEXT** cannot be specified by **option** or **copy_option**.

NOTE

The definition of fixed length is as follows:

- The column length of each record is the same.
 - Spaces are used for column padding. Columns of the numeric type are left-aligned and columns of the string type are right-aligned.
 - No delimiters are used between columns.
- **[USING] DELIMITERS 'delimiters'**

String that separates columns within each row (line) of the file. It cannot be larger than 10 bytes.

Value range: The delimiter in text format cannot include any of the following characters: \.abcdefghijklmnopqrstuvwxyz0123456789, but has no restriction for the CSV format.

Value range: The default value is a tab character in text format and a comma in CSV format.

 **NOTE**

Both DELIMITER and DELIMITERS can specify delimiters. DELIMITERS can be followed by brackets, but DELIMITER cannot be directly followed by brackets. Otherwise, a syntax error is reported.

- **WITHOUT ESCAPING**

Specifies, in the TEXT format, whether to escape the backslash (\) and its following characters.

Value range: text only

- **LOG ERRORS**

If this parameter is specified, the error tolerance mechanism for data type errors in the COPY FROM statement is enabled. Row errors are recorded in the **public.pgxc_copy_error_log** table in the database for future reference.

Value range: a value set while data is imported using COPY FROM.

 **NOTE**

The restrictions of this error tolerance parameter are as follows:

- This error tolerance mechanism captures only the data type errors (**DATA_EXCEPTION**) that occur during data parsing of COPY FROM on a CN. Other errors, such as network errors between CNs and DNs or expression conversion errors on DNs, are not captured.
 - Before enabling error tolerance for COPY FROM for the first time in a database, check whether the **public.pgxc_copy_error_log** table exists. If it does not, call the `copy_error_log_create()` function to create it. If it does, copy its data elsewhere, delete it, and call the `copy_error_log_create()` function to create the table. For details about columns in the **public.pgxc_copy_error_log** table, see [Table 7-121](#).
 - While a COPY FROM statement with specified LOG ERRORS is being executed, if **public.pgxc_copy_error_log** does not exist or does not have the table definitions compliant with those predefined in `copy_error_log_create()`, an error will be reported. Ensure that the error table is created using the `copy_error_log_create()` function. Otherwise, COPY FROM statements with error tolerance may fail to be run.
 - If existing error tolerance parameters (for example, **IGNORE_EXTRA_DATA**) of the COPY statement are enabled, the error of the corresponding type will be processed as specified by the parameters and no error will be reported. Therefore, the error table does not contain such error data.
- **LOG ERRORS DATA**

The differences between LOG ERRORS DATA and LOG ERRORS are as follows:

- a. LOG ERRORS DATA fills the **rawrecord** column in the error tolerance table.
- b. Only users with the super permission can use the parameter options of LOG ERRORS DATA.

 **CAUTION**

- If error content is too complex, it may fail to be written to the error tolerance table by using LOG ERRORS DATA, causing the task failure.
- For errors that cannot be read in certain code, the error codes are `ERRCODE_CHARACTER_NOT_IN_REPERTOIRE` and `ERRCODE_UNTRANSLATABLE_CHARACTER`. The `rawrecord` column is not recorded.

- **REJECT LIMIT 'limit'**

Used with the LOG ERROR options to set the upper limit of the tolerated errors in the COPY FROM statement. If the number of errors exceeds the limit, later errors will be reported based on the original mechanism.

Value range: a positive integer (1 to 2147483647) or **'unlimited'**

Default value: If LOG ERRORS is not specified, an error will be reported. If LOG ERRORS is specified, the default value is **0**.

 **NOTE**

Different from the GDS error tolerance mechanism, in the error tolerance mechanism described in LOG ERRORS, the count of REJECT LIMIT is calculated based on the number of data parsing errors on the CN where the COPY FROM statement is run, not based on the number of errors on each DN.

- **FORMATTER**

Defines the place of each column in the data file in fixed length mode.

Defines the place of each column in the data file in the **column(offset,length)** format.

Value range:

- The value of **offset** must be larger than 0. The unit is byte.
- The value of **length** must be larger than 0. The unit is byte.

The total length of all columns must be less than 1 GB.

Replace columns that are not in the file with null.

- **OPTION { option_name ' value ' }**

Specifies all types of parameters of a compatible foreign table.

- **FORMAT**

Specifies the format of the source data file in the foreign table.

Value range: **CSV**, **TEXT**, **FIXED**, and **BINARY**

- The CSV file can process newline characters efficiently, but cannot process certain special characters well.
- The TEXT file can process certain special characters efficiently, but cannot process newline characters well.
- In FIXED files, the column length of each record is the same. Spaces are used for padding, and the excessive part will be truncated.
- All data in the BINARY file is stored/read as binary format rather than as text. It is faster than the text and CSV formats, but a binary-format file is less portable.

Default value: **TEXT**

– OIDS

Specifies the internal OID to be copied for each row.

 NOTE

An error is raised if OIDs are specified for a table that does not have OIDs, or in the case of copying a query.

Value range: **true/on** or **false/off**

Default value: **false**

– DELIMITER

Specifies the character that separates columns within each row (line) of the file.

 NOTE

- The value of **delimiter** cannot be `\r` or `\n`.
- A delimiter cannot be the same as the null value. The delimiter for the CSV format cannot be same as the **quote** value.
- The delimiter for the TEXT format data cannot contain lowercase letters, digits, or special characters (`.\`).
- The data length of a single row should be less than 1 GB. A row that has many columns using long delimiters cannot contain much valid data.
- You are advised to use multi-character delimiters or invisible delimiters. For example, you can use multi-characters (such as `$^&`) and invisible characters (such as `0x07`, `0x08`, and `0x1b`).
- To use a tab to isolate CSV data, set **delimiter** to `E'\t'`.

Value range: a multi-character delimiter within 10 bytes

Default value:

- A tab character in text format
- A comma (,) in CSV format
- No delimiter in FIXED format

– NULL

Specifies the string that represents a null value.

Value range:

- A null value cannot be `\r` or `\n`. The maximum length is 100 characters.
- A null value cannot be the same as the **delimiter** or **quote** value.

Default value:

- The default value for the CSV format is an empty string without quotation marks.
- The default value for the TEXT format is `\N`.

– HEADER

Specifies whether a file contains a header with the names of each column in the file. **header** is available only for CSV and FIXED files.

When data is imported, if **header** is **on**, the first row of the data file will be identified as the header and ignored. If **header** is **off**, the first row will be identified as a data row.

When data is exported, if header is **on**, **fileheader** must be specified. If **header** is **off**, an exported file does not contain a header.

Value range: **true/on** or **false/off**

Default value: **false**

– USEEOF

The system does not report an error for "\" in the imported data.

Value range: **true/on** or **false/off**

Default value: **false**

– QUOTE

Specifies a quoted character string for a CSV file.

Default value: double quotation marks ("")

 NOTE

- The value of **quote** cannot be the same as that of the **delimiter** or **null** parameter.
- The value of **quote** must be a single-byte character.
- You are advised to set **quote** to an invisible character, such as **0x07**, **0x08**, or **0x1b**.

– ESCAPE

Specifies an escape character for a CSV file. The value must be a single-byte character.

Default value: double quotation marks (""). If the value is the same as that of **quote**, it will be replaced by '\0'.

– EOL 'newline_character'

Specifies the newline character style of the imported or exported data file.

Value range: multi-character newline characters within 10 bytes.

Common newline characters include \r (0x0D), \n (0x0A), and \r\n (0x0D0A). Special newline characters include \$ and #.

 NOTE

- The EOL parameter supports only the TEXT format for data import and export and does not support the CSV or FIXED format for data import. For forward compatibility, the EOL parameter can be set to **0x0D** or **0x0D0A** for data export in the CSV or FIXED format.
- The value of **EOL** cannot be the same as that of the **delimiter** or **null** parameter.
- The EOL parameter value cannot contain the following characters: .abcdefghijklmnopqrstuvwxyz0123456789.

– FORCE_QUOTE { (column_name [, ...]) | * }

In **CSV COPY TO** mode, forces quotation marks to be used for all non-null values in each specified column. The asterisk (*) indicates all columns. Null values are not quoted.

Value range: an existing column name

- **FORCE_NOT_NULL** (column_name [, ...])
Assigns a value to a specified column in **CSV COPY FROM** mode.
Value range: an existing column name
- **ENCODING**
Specifies the encoding format of a data file. The default value is the current database encoding format.
- **IGNORE_EXTRA_DATA**
Specifies whether to ignore excessive columns when the number of data source files exceeds the number of foreign table columns. This parameter is used only during data import.
Value range: **true/on** or **false/off**
 - **true/on**: If the number of columns in a data source file is greater than that defined by the foreign table, the extra columns at the end of a row are ignored.
 - **false/off**: If the number of columns in a data source file is greater than that defined by the foreign table, the following error message is reported:
extra data after last expected columnDefault value: **false**

NOTICE

If a newline character at the end of a row is missing and the row and another row are integrated into one, data in another row is ignored after the parameter is set to **true**.

- **COMPATIBLE_ILLEGAL_CHARS**
Specifies whether to tolerate invalid characters during data import. The parameter is valid only for data import using **COPY FROM**.
Value range: **true/on** or **false/off**
 - **true** or **on**: No error message is reported and data import is not interrupted when there are invalid characters. Invalid characters are converted into valid ones, and then imported to the database.
 - **false/off**: An error occurs when there are invalid characters, and the import stops.Default value: **false** or **off**

 NOTE

The rules for converting invalid characters are as follows:

1. '\0' is converted to a space.
2. Other invalid characters are converted to question marks.
3. When **compatible_illegal_chars** is set to **true/on**, after invalid characters such as **NULL**, **DELIMITER**, **QUOTE**, and **ESCAPE** are converted to spaces or question marks, an error message stating "illegal chars conversion may confuse COPY escape 0x20" will be displayed to remind you of possible parameter confusion caused by the conversion.
4. When the GUC parameter **copy_special_character_version** is set to 'no_error', **compatible_illegal_chars** cannot be set to **true** or **on**.
5. When the GUC parameter **copy_special_character_version** is set to 'no_error', invalid characters will not be checked during the import and will be displayed as garbled characters in query results. Exercise caution when enabling this parameter. You can use the **LOG ERRORS** or **LOG ERRORS DATA** parameter in the COPY statement to code errors to an error table.

– **FILL_MISSING_FIELDS**

Specifies how to handle the problem that the last column of a row in a source data file is lost during data import.

Value range: **true/on** or **false/off**.

Default value: **false** or **off**

– **DATE_FORMAT**

Specifies the DATE format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.

Value range: a valid DATE value. For details, see [Date and Time Processing Functions and Operators](#).

 NOTE

If Oracle is specified as the compatible database, the DATE format is **TIMESTAMP**. For details, see **timestamp_format** below.

– **TIME_FORMAT**

Specifies the TIME format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.

Value range: a valid TIME value. Time zones cannot be used. For details, see [Date and Time Processing Functions and Operators](#).

– **TIMESTAMP_FORMAT**

Specifies the **TIMESTAMP** format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.

Value range: a valid **TIMESTAMP** value. Time zones cannot be used. For details, see [Date and Time Processing Functions and Operators](#).

– **SMALLDATETIME_FORMAT**

Specifies the **SMALLDATETIME** format for data import. The BINARY format is not supported. When data of such format is imported, error

"cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.

Value range: a valid SMALLDATETIME value. For details, see [Date and Time Processing Functions and Operators](#).

- **COPY_OPTION { option_name ' value ' }**

Specifies all types of native parameters of COPY.

- OIDS

Specifies the internal OID to be copied for each row.

 **NOTE**

An error is raised if OIDs are specified for a table that does not have OIDs, or in the case of copying a query.

- NULL null_string

Specifies the string that represents a null value.

NOTICE

When using COPY FROM, any data item that matches this string will be stored as a null value, so make sure that you use the same string as you used with COPY TO.

Value range:

- A null value cannot be `\r` or `\n`. The maximum length is 100 characters.
- A null value cannot be the same as the **delimiter** or **quote** value.

Default value:

- The default value for the TEXT format is `\N`.
- The default value for the CSV format is an empty string without quotation marks.

- HEADER

Specifies whether a file contains a header with the names of each column in the file. **header** is available only for CSV and FIXED files.

When data is imported, if **header** is **on**, the first row of the data file will be identified as the header and ignored. If **header** is **off**, the first row will be identified as a data row.

When data is exported, if header is **on**, **fileheader** must be specified. If **header** is **off**, an exported file does not contain a header.

- USEEOF

The system does not report an error for `"\."` in the imported data.

- FILEHEADER

Specifies a file that defines the content in the header for exported data. The file contains data description of each column.

NOTICE

- This parameter is available only when **header** is **on** or **true**.
- **fileheader** specifies an absolute path.
- The file can contain only one row of header information, and ends with a newline character. Excess rows will be discarded. (Header information cannot contain newline characters.)
- The length of the file including the newline character cannot exceed 1 MB.

– **FREEZE**

Sets the COPY loaded data row as **frozen**, like these data have executed VACUUM FREEZE.

This is a performance option of initial data loading. The data will be frozen only when the following three requirements are met:

- The table being loaded has been created or truncated in the same transaction before copying.
- There are no cursors open in the current transaction.
- There are no original snapshots in the current transaction.

 **NOTE**

When COPY is completed, all the other sessions will see the data immediately. However, this violates the general principle of MVCC visibility, and users should understand that this may cause potential risks.

– **FORCE NOT NULL** column_name [, ...]

Assigns a value to a specified column in **CSV COPY FROM** mode.

Value range: an existing column

– **FORCE QUOTE** { column_name [, ...] | * }

In **CSV COPY TO** mode, forces quotation marks to be used for all non-null values in each specified column. The asterisk (*) indicates all columns. Null values are not quoted.

Value range: an existing column name

– **BINARY**

Specifies that data is stored and read in binary mode instead of text mode.

 NOTE

- In binary mode, you cannot declare **DELIMITER**, **NULL**, or **CSV**.
- When **BINARY** is specified, **CSV**, **FIXED**, and **TEXT** cannot be specified through **option** or **copy_option**.
- If the GUC parameter **copy_special_character_version** is set to 'no_error', invalid characters will not be checked during the import and will be displayed as garbled characters in query results. The database server code must be the same as the file code. Exercise caution when enabling this parameter. You can use the **LOG ERRORS** or **LOG ERRORS DATA** parameter in the COPY statement to code errors to an error table.
- In binary mode, **copy_special_character_version** is set to 'no_error', and it takes effect only for columns of the TEXT, CHAR, VARCHAR, NVARCHAR2, and CLOB types.

– CSV

Enables the CSV mode. When **CSV** is specified, **BINARY**, **FIXED**, and **TEXT** cannot be specified through **option** or **copy_option**.

– QUOTE [AS] 'quote_character'

Specifies a quoted character string for a CSV file.

Default value: double quotation marks ("").

 NOTE

- The value of **quote** cannot be the same as that of the **delimiter** or **null** parameter.
- The value of **quote** must be a single-byte character.
- You are advised to set **quote** to an invisible character, such as **0x07**, **0x08**, or **0x1b**.

– ESCAPE [AS] 'escape_character'

Specifies an escape character for a CSV file. The value must be a single-byte character.

Default value: double quotation marks (""). If the value is the same as that of **quote**, it will be replaced by '\0'.

– EOL 'newline_character'

Specifies the newline character style of the imported or exported data file.

Value range: multi-character newline characters within 10 bytes. Common newline characters include **\r** (0x0D), **\n** (0x0A), and **\r\n** (0x0D0A). Special newline characters include **\$** and **#**.

 NOTE

- The **EOL** parameter supports only the TEXT format for data import and export and does not support the CSV or FIXED format. For forward compatibility, the **EOL** parameter can be set to **0x0D** or **0x0D0A** for data export in the CSV or FIXED format.
- The value of **EOL** cannot be the same as that of the **delimiter** or **null** parameter.
- The EOL parameter value cannot contain the following characters: .abcdefghijklmnopqrstuvwxyz0123456789.

– ENCODING 'encoding_name'

Specifies the name of a file encoding format.

Value range: a valid encoding format

Default value: current encoding format

– IGNORE_EXTRA_DATA

Specifies that when the number of data source files exceeds the number of foreign table columns, excess columns at the end of the row are ignored. This parameter is used only during data import.

If this parameter is not used and the number of columns in the data source file is greater than that defined in the foreign table, the following error information is displayed:

extra data after last expected column

– COMPATIBLE_ILLEGAL_CHARS

Specifies that invalid characters are tolerated during data import. Invalid characters are converted and then imported to the database. No error is reported and the import is not interrupted. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.

If this parameter is not used, an error is reported when invalid characters are encountered during the import, and the import is interrupted.

 NOTE

The rules for converting invalid characters are as follows:

1. '\0' is converted to a space.
2. Other invalid characters are converted to question marks.
3. When **compatible_illegal_chars** is set to **true/on**, after invalid characters such as **NULL**, **DELIMITER**, **QUOTE**, and **ESCAPE** are converted to spaces or question marks, an error message stating "illegal chars conversion may confuse COPY escape 0x20" will be displayed to remind you of possible parameter confusion caused by the conversion.
4. When the GUC parameter **copy_special_character_version** is set to **'no_error'**, **compatible_illegal_chars** cannot be set to **true** or **on**.
5. When the GUC parameter **copy_special_character_version** is set to **'no_error'**, invalid characters will not be checked during the import and will be displayed as garbled characters in query results. Exercise caution when enabling this parameter. You can use the **LOG ERRORS** or **LOG ERRORS DATA** parameter in the COPY statement to code errors to an error table.

– FILL_MISSING_FIELDS

Specifies how to handle the problem that the last column of a row in a source data file is lost during data import.

Value range: **true/on** or **false/off**

Default value: **false** or **off**

NOTICE

Do not specify this option. Currently, it does not enable error tolerance, but will make the parser ignore the said errors during data parsing on the CN. Such errors will not be recorded in the COPY error table (enabled using LOG ERRORS REJECT LIMIT) but will be reported later by DNs. Therefore, do not specify this option.

- DATE_FORMAT 'date_format_string'
Specifies the DATE format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.
Value range: a valid DATE value For details, see [Date and Time Processing Functions and Operators](#).
-  NOTE
If Oracle is specified as the compatible database, the DATE format is TIMESTAMP. For details, see [timestamp_format](#) below.
- TIME_FORMAT 'time_format_string'
Specifies the TIME format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.
Value range: a valid TIME value. Time zones cannot be used. For details, see [Date and Time Processing Functions and Operators](#).
- TIMESTAMP_FORMAT 'timestamp_format_string'
Specifies the TIMESTAMP format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.
Value range: a valid TIMESTAMP value. Time zones cannot be used. For details, see [Date and Time Processing Functions and Operators](#).
- SMALLDATETIME_FORMAT 'smalldatetime_format_string'
Specifies the SMALLDATETIME format for data import. The BINARY format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. The parameter is valid only for data import using COPY FROM.
Value range: a valid SMALLDATETIME value. For details, see [Date and Time Processing Functions and Operators](#).
- TRANSFORM ({ column_name [data_type] [AS transform_expr] } [, ...])
Specify the conversion expression of each column in the table. **data_type** specifies the data type of the column in the expression parameter. **transform_expr** is the target expression that returns the result value whose data type is the same as that of the target column in the table. For details about the expression, see [Expressions](#).

 NOTE

COPY FROM does not support expression conversion for distribution keys.
The following special backslash sequences are recognized by COPY FROM:

- **\b**: Backslash (ASCII 8)
- **\f**: Form feed (ASCII 12)
- **\n**: Newline character (ASCII 10)
- **\r**: Carriage return character (ASCII 13)

- **\t**: Tab (ASCII 9)
- **\v**: Vertical tab (ASCII 11)
- **\digits**: Backslash followed by one to three octal digits specifies that the ASCII value is the character with that numeric code.
- **\xdigits**: Backslash followed by an x and one or two hex digits specifies the character with that numeric code.

Permission Control Examples

```
gaussdb=> copy t1 from '/home/xy/t1.csv';
ERROR: COPY to or from a file is prohibited for security concerns
HINT: Anyone can COPY to stdout or from stdin. gsql's \copy command also works for anyone.
gaussdb=> grant gs_role_copy_files to xxx;
```

This error occurs because a non-initial user does not have the COPY permission. To solve this problem, enable the **enable_copy_server_files** parameter. Then, the administrator can use the COPY function, and common users need to join the **gs_role_copy_files** group.

Examples

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Create the tpcds.ship_mode table.
gaussdb=# CREATE TABLE tpcds.ship_mode
(
    SM_SHIP_MODE_SK      INTEGER          NOT NULL,
    SM_SHIP_MODE_ID     CHAR(16)         NOT NULL,
    SM_TYPE              CHAR(30)        ,
    SM_CODE              CHAR(10)        ,
    SM_CARRIER          CHAR(20)        ,
    SM_CONTRACT          CHAR(20)
)
DISTRIBUTE BY HASH(SM_SHIP_MODE_SK);

-- Insert a single data record into the tpcds.ship_mode table.
gaussdb=# INSERT INTO tpcds.ship_mode VALUES (1,'a','b','c','d','e');

-- Copy data from tpcds.ship_mode to the /home/omm/ds_ship_mode.dat file.
gaussdb=# COPY tpcds.ship_mode TO '/home/omm/ds_ship_mode.dat';

-- Output tpcds.ship_mode to STDOUT.
gaussdb=# COPY tpcds.ship_mode TO STDOUT;

-- Output the data of tpcds.ship_mode to STDOUT. The parameters are as follows: The delimiter is ','
(delimiter',') and the encoding format is UTF8 (encoding'utf8').
gaussdb=# COPY tpcds.ship_mode TO STDOUT WITH (delimiter ',', encoding 'utf8');

-- Output the data of tpcds.ship_mode to STDOUT. The parameters are as follows: The import format is
CSV (format'CSV'), and the exported content of the SM_SHIP_MODE_SK column is enclosed in quotation
marks (force_quote(SM_SHIP_MODE_SK)).
gaussdb=# COPY tpcds.ship_mode TO STDOUT WITH (format 'CSV', force_quote(SM_SHIP_MODE_SK));

-- Create the tpcds.ship_mode_t1 table.
gaussdb=# CREATE TABLE tpcds.ship_mode_t1
(
    SM_SHIP_MODE_SK      INTEGER          NOT NULL,
    SM_SHIP_MODE_ID     CHAR(16)         NOT NULL,
    SM_TYPE              CHAR(30)        ,
    SM_CODE              CHAR(10)        ,
    SM_CARRIER          CHAR(20)        ,
    SM_CONTRACT          CHAR(20)
)
DISTRIBUTE BY HASH(SM_SHIP_MODE_SK);
```

```
-- Copy data from STDIN to the tpcds.ship_mode_t1 table.
gaussdb=# COPY tpcds.ship_mode_t1 FROM STDIN;

-- Copy data from the /home/omm/ds_ship_mode.dat file to the tpcds.ship_mode_t1 table.
gaussdb=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat';

-- Copy data from the /home/omm/ds_ship_mode.dat file to the tpcds.ship_mode_t1 table, convert the
data using the TRANSFORM expression, and insert the 10 characters on the left of the SM_TYPE column
into the table.
gaussdb=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat' TRANSFORM (SM_TYPE AS
LEFT(SM_TYPE, 10));

-- Copy data from the /home/omm/ds_ship_mode.dat file to the tpcds.ship_mode_t1 table, with the
import format set to TEXT (format 'text'), the delimiter set to \t' (delimiter E'\t'), excessive columns
ignored (ignore_extra_data 'true'), and characters not escaped (noescaping 'true').
gaussdb=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat' WITH(format 'text', delimiter
E'\t', ignore_extra_data 'true', noescaping 'true');

-- Copy data from the /home/omm/ds_ship_mode.dat file to the tpcds.ship_mode_t1 table, with the
import format set to FIXED, fixed-length format specified (FORMATTER(SM_SHIP_MODE_SK(0, 2),
SM_SHIP_MODE_ID(2,16), SM_TYPE(18,30), SM_CODE(50,10), SM_CARRIER(61,20),
SM_CONTRACT(82,20))), excessive columns ignored (ignore_extra_data), and headers included (header).
gaussdb=# COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat' FIXED
FORMATTER(SM_SHIP_MODE_SK(0, 2), SM_SHIP_MODE_ID(2,16), SM_TYPE(18,30), SM_CODE(50,10),
SM_CARRIER(61,20), SM_CONTRACT(82,20)) header ignore_extra_data;

-- Delete tables and the schema.
gaussdb=# DROP TABLE tpcds.ship_mode;
gaussdb=# DROP TABLE tpcds.ship_mode_t1;
gaussdb=# DROP SCHEMA tpcds;
```

7.12.8.10 CREATE AGGREGATE

Description

Creates an aggregate function.

Syntax

```
CREATE AGGREGATE name ( input_data_type [ , ... ] ) (
    SFUNC = sfunc,
    -- SFUNC1 = sfunc, // Earlier format, equivalent to SFUNC = sfunc.
    STYPE = state_data_type
    -- STYPE1 = state_data_type, // Earlier format, equivalent to STYPE = state_data_type.
    [ , FINALFUNC = ffunc ]
    [ , INITCOND = initial_condition ]
    -- [ , INITCOND1 = initial_condition ] // Earlier format, equivalent to INITCOND = initial_condition.
    [ , SORTOP = sort_operator ]
    [ , CFUNC = collection_func ]
    [ , INITCOLLECT = initial_collection_condition ]
    [ , IFUNC = init_func ]
    [ , SHIPPABLE = is_shippable ]
);
```

You can also use:

```
CREATE AGGREGATE name (
    BASETYPE = base_type,
    SFUNC = sfunc,
    -- SFUNC1 = sfunc, // Earlier format, equivalent to SFUNC = sfunc.
    STYPE = state_data_type
    -- STYPE1 = state_data_type, // Earlier format, equivalent to STYPE = state_data_type.
    [ , FINALFUNC = ffunc ]
    [ , INITCOND = initial_condition ]
    -- [ , INITCOND1 = initial_condition ] // Earlier format, equivalent to INITCOND = initial_condition.
    [ , SORTOP = sort_operator ]
```

```
[ , CFUNC = collection_func ]  
[ , INITCOLLECT = initial_collection_condition ]  
[ , IFUNC = init_func ]  
);
```

Parameters

- **name**
Name (optionally schema-qualified) of the aggregate function to be created.
- **input_data_type**
Data type of the input to be processed by the aggregate function. To create a zero-parameter aggregate function, you can use an asterisk (*) instead of a list of input data types. (count(*) is an instance of such aggregate function.)
- **base_type**
In the CREATE AGGREGATE syntax, the input data type is specified by the **basetype** parameter instead of following the name of the aggregate function. Note that this syntax allows only one input parameter. To create a zero-parameter aggregate function, you can set **basetype** to **ANY** instead of *.
- **sfunc**
Name of the state conversion function that will be called on each input line. For an aggregate function with *N* parameters, **sfunc** must have *N*+1 parameters. The first parameter is of the **state_data_type** type, and the other parameters match the declared input data types. The function must return a value of the **state_data_type** type. This function accepts the current state value and the current input data, and returns the next state value. The default behavior of the conversion function in an ORA-compatible database is strict, that is, the null input values are skipped. For GaussDB, you need to define the **strict** attribute of the conversion function. User-defined C functions are not supported.
- **state_data_type**
Data type of the aggregation status value.
- **ffunc**
Final processing function called after all the input lines have been converted, which calculates the result of aggregation. This function must accept a parameter of **state_data_type**. The output data type of the aggregation is defined as the return type of this function. If **ffunc** is not specified, the state value of the aggregation result is used as the aggregation result, and the output type is **state_data_type**. User-defined C functions are not supported.
- **initial_condition**
Initial setting (value) of a state value. It must be a text constant value acceptable to **state_data_type**. If the parameter is not specified, the initial state value is **null**.
- **sort_operator**
Sort operator used for MIN or MAX aggregation. This is just an operator name (optionally schema-qualified). This operator assumes that the input data type is the same as that of aggregation.
- **collection_func**
Allows users to perform distributed aggregation so as to improve performance. **collection_func** is essentially the status conversion result

generated by combining DNs. If there is no final function, the result generated by **collection_func** is the aggregation result. If you want **collection_func** to skip null values, specify **collection_func** as a strict function. If it is not specified as a strict function, ensure that null input values are processed properly. **collection_func** must have two input parameters of the type specified by **state_data_type**. The first input parameter **state_data_type** is transferred to the first parameter of the next execution of **collection_func**. If **is_shippable** is **false**, **collection_func** will not be executed. User-defined C functions are not supported.

- **initial_collection_condition**

Initial setting (value) of the state value of **collection_func**. It must be a text constant value acceptable to **state_data_type**. If it is not specified, the initial state value is **null**.

- **init_func**

Initial setting function of the **sfunc** status value. It cannot return **NULL**. It must return the **state_data_type** type and have no input parameter. If both **init_func** and **initial_condition** are set, the return value of **init_func** is preferentially used as the initial value. User-defined C functions are not supported.

- **is_shippable**

Specifies whether the aggregate function can be pushed down. The value can only be **true** or **false**. Currently, this parameter does not affect the promotion of built-in aggregate functions. It affects only the behavior of user-defined aggregate functions. The default value is **false**. User-defined aggregations can be pushed down only when **collection_func** is executed and **is_shippable** is set to **true**.

Examples

```
-- Create a user-defined function.
gaussdb=# CREATE OR REPLACE FUNCTION int_add(int,int)
         returns int as $BODY$
declare
begin
    return $1 + $2;
end;
$BODY$ language plpgsql;

-- Create an aggregate function.
gaussdb=# CREATE AGGREGATE sum_add(int)
(
    sfunc = int_add,

    stype = int,

    initcond = '0'
);

-- Create a test table and add data.
gaussdb=# CREATE TABLE test_sum(a int,b int,c int);
gaussdb=# INSERT INTO test_sum VALUES(1,2),(2,3),(3,4),(4,5);

-- Execute the aggregate function.
gaussdb=# SELECT sum_add(a) FROM test_sum;
 sum_add
-----
      10
```

```
-- Delete the aggregate function.
gaussdb=# DROP AGGREGATE sum_add(int);

-- Delete the user-defined function.
gaussdb=# DROP FUNCTION int_add(int,int);

-- Delete the test table.
gaussdb=# DROP TABLE test_sum;
```

7.12.8.11 CREATE AUDIT POLICY

Description

Creates a unified audit policy.

Precautions

- Only the user with the poladmin or sysadmin permission, or initial user has the permission to maintain audit policies.
- Before creating an audit policy, ensure that the security policy switch has been enabled. That is, the masking policy takes effect only after the GUC parameter **enable_security_policy** is set to **on**.
- A system administrator or security policy administrator can access the GS_AUDITING_POLICY, GS_AUDITING_POLICY_ACCESS, GS_AUDITING_POLICY_PRIVILEGES, and GS_AUDITING_POLICY_FILTERS system catalogs to query the created audit policies.
- The audit policy name must be unique to avoid conflicts with existing policies. You can use IF NOT EXISTS to check whether the specified audit policy exists to avoid repeated creation.

NOTICE

When you use database links to perform operations on remote objects, the client initiates a database link request. The actual sender is the server, and the attributes such as the IP address of the sender are the values of the server. For details, see [DATABASE LINK](#).

Syntax

```
CREATE AUDIT POLICY [ IF NOT EXISTS ] policy_name { { privilege_audit_clause | access_audit_clause }  
[ , ... ] [ filter_group_clause ] [ ENABLE | DISABLE ] };
```

- **privilege_audit_clause**
PRIVILEGES { DDL | ALL } [ON LABEL (resource_label_name [, ...])]
- **access_audit_clause**
ACCESS { DML | ALL } [ON LABEL (resource_label_name [, ...])]
- **filter_group_clause**
FILTER ON { FILTER_TYPE (filter_value [, ...]) } [, ...]

Parameters

- policy_name**
 Specifies the audit policy name, which must be unique.
 Value range: a string. It must comply with the [naming convention](#).
- resource_label_name**
 Specifies the resource label name.
- DDL**
 Specifies the operations that are audited in the database: **CREATE**, **ALTER**, **DROP**, **ANALYZE**, **COMMENT**, **GRANT**, **REVOKE**, **SET**, and **SHOW**.
 If this parameter is set to **ANALYZE**, both ANALYZE and VACCUUM operations are audited.
- DML**
 Specifies the operations that are audited within the database: **SELECT**, **COPY**, **DEALLOCATE**, **DELETE**, **EXECUTE**, **INSERT**, **PREPARE**, **REINDEX**, **TRUNCATE**, and **UPDATE**.
- ALL**
 Specifies all operations supported by the specified DDL or DML statements in the database. When the form is { DDL | ALL }, **ALL** indicates all DDL operations. When the form is { DML | ALL }, **ALL** indicates all DML operations.
- FILTER_TYPE**
 Specifies the types of information to be filtered by the policy, including **APP**, **ROLES**, and **IP**.
- filter_value**
 Indicates the detailed information to be filtered.
- ENABLE|DISABLE**
 Enables or disables the unified audit policy. If **ENABLE|DISABLE** is not specified, **ENABLE** is used by default.

Examples

- Creates audit policy for executing **CREATE** on the database.

```
-- Create the adt1 policy.
gaussdb=# CREATE AUDIT POLICY adt1 PRIVILEGES CREATE;

-- View the adt1 policy.
gaussdb=# SELECT * FROM GS_AUDITING_POLICY;
 polname | polcomments |      modifydate      | polenabled
-----+-----+-----+-----
 adt1    |              | 2023-11-06 16:41:40.947417 | t
```

```
-- Check the location where the audit policy is stored.
gaussdb=# SHOW audit_directory;

-- Delete the audit policy adt1.
gaussdb=# DROP AUDIT POLICY adt1;
```
- Create an audit policy to audit only the CREATE operation performed by the **dev_audit** user.

```
-- Create user dev_audit.
gaussdb=# CREATE USER dev_audit PASSWORD '*****';

-- Create the tb_for_audit table.
gaussdb=# CREATE TABLE tb_for_audit(col1 text, col2 text, col3 text);
```

```
-- Create the adt_lb0 resource label based on the tb_for_audit table.
gaussdb=# CREATE RESOURCE LABEL adt_lb0 add TABLE(public.tb_for_audit);

-- Create the adt2 audit policy for the CREATE operation on the adt_lb0 resource.
gaussdb=# CREATE AUDIT POLICY adt2 PRIVILEGES CREATE ON LABEL(adt_lb0) FILTER ON
ROLES(dev_audit);

-- Delete the audit policy adt2.
gaussdb=# DROP AUDIT POLICY adt2;

-- Delete the tb_for_audit table.
gaussdb=# DROP TABLE tb_for_audit;

-- Delete the dev_audit user.
gaussdb=# DROP USER dev_audit;
```

- Create an audit policy to audit only the SELECT, INSERT, and DELETE operations performed on the **adt_lb0** resource by user **dev_audit** using client tool gsql on the servers whose IP addresses are **10.20.30.40** and **127.0.0.0/24**, respectively.

```
-- Create user dev_audit.
gaussdb=# CREATE USER dev_audit PASSWORD '*****';

-- Create the audit policy adt3.
gaussdb=# CREATE AUDIT POLICY adt3 ACCESS SELECT ON LABEL(adt_lb0), INSERT ON
LABEL(adt_lb0), DELETE FILTER ON ROLES(dev_audit), APP(gsql), IP('10.20.30.40', '127.0.0.0/24');

-- Delete the audit policy adt3.
gaussdb=# DROP AUDIT POLICY adt3;

-- Delete the dev_audit user.
gaussdb=# DROP USER dev_audit;
```

[ALTER AUDIT POLICY](#) and [DROP AUDIT POLICY](#)

7.12.8.12 CREATE BARRIER

Description

Creates a barrier for cluster nodes. The barrier can be used for data restoration. This function is for internal use only. You are advised not to use it.

Precautions

Generally, CREATE BARRIER is used only for backup and restoration. Therefore, CREATE BARRIER can be executed only in the following scenarios:

- The database initial user can run this command.
- If the backup and restoration mode is enabled on the CN, that is, the GUC parameter **operation_mode** is set to **on**, users with the OPRADMIN permission can run this command.

Syntax

```
CREATE BARRIER 'barrier_name';
```

```
hexadecimal code.
gaussdb=> \key_info keyType=user_token,key_token=*****

-- Create a master key.
gaussdb=> CREATE CLIENT MASTER KEY alice_cmk WITH ( KEY_STORE = user_token , ALGORITHM =
AES_256_GCM );

-- Delete the master key.
gaussdb=> DROP CLIENT MASTER KEY alice_cmk;
gaussdb=> \q

-- Connect to the database, use the privileged account, and delete user alice.
gsqll -p Port number -d postgres -r
gaussdb=# DROP USER alice;
```

Helpful Links

[DROP CLIENT MASTER KEY](#)

7.12.8.14 CREATE COLUMN ENCRYPTION KEY

Description

Creates a CEK that can be used to encrypt a specified column in a table.

Precautions

- This syntax is specific to a fully-encrypted database.
- When using `gsqll` to connect to a database server, you need to use the `-C` parameter to enable the fully-encrypted database.
- The CEK object created using this syntax can be used for column-level encryption. When defining a column in a table, you can specify a CEK object to encrypt the column.

Syntax

```
CREATE COLUMN ENCRYPTION KEY column_encryption_key_name WITH VALUES(CLIENT_MASTER_KEY =
client_master_key_name, ALGORITHM = algorithm_type [, ENCRYPTED_VALUE = encrypted_value]);
```

Parameters

- **column_encryption_key_name**
Key object name. In the same namespace, the name must be unique.
Value range: a string. It must comply with the [naming convention](#).
- **CLIENT_MASTER_KEY**
Client master key, which is used to encrypt a specified CEK. The value is the name of a CMK. The CMK object is created using the CREATE CLIENT MASTER KEY syntax.
- **ALGORITHM**
Encryption algorithm to be used by the CEK. The value can be **AEAD_AES_256_CBC_HMAC_SHA256**, **AEAD_AES_128_CBC_HMAC_SHA256**, **AEAD_AES_256_CTR_HMAC_SHA256**, **AES_256_GCM**, or **SM4_SM3**.
The data expansion rates of different encryption algorithms are sorted as follows: **AEAD_AES_256_CTR_HMAC_SHA256** < **AES_256_GCM** <

AEAD_AES_256_CBC_HMAC_SHA256 = AEAD_AES_128_CBC_HMAC_SHA256 = SM4_SM3. The AEAD_AES_256_CTR_HMAC_SHA256 and AES_256_GCM encryption algorithms are recommended.

- **ENCRYPTED_VALUE (optional)**

Specifies the key password defined by the user. The key password contains 28 to 256 characters. The security strength of a key containing 28 characters complies with AES128. If AES256 is used, the key password must contain 39 characters. If this parameter is not specified, a 256-character key is automatically generated.

NOTICE

- SM algorithm constraints: SM2, SM3, and SM4 are Chinese national cryptography standards. To avoid legal risks, these algorithms must be used together. If you specify the SM4 algorithm to encrypt CEKs when creating a CMK, you must specify the SM3 and SM4 algorithms (SM4_SM3) to encrypt data when creating CEKs.
- Constraints on the **ENCRYPTED_VALUE** column: If the CMK generated by Huawei KMS is used to encrypt the CEK and the **ENCRYPTED_VALUE** column is used to transfer the key in the CREATE COLUMN ENCRYPTION KEY syntax, the length of the input key must be an integer multiple of 16 bytes.

Helpful Links

[ALTER COLUMN ENCRYPTION KEY](#) and [DROP COLUMN ENCRYPTION KEY](#)

7.12.8.15 CREATE CONVERSION

Description

Defines a new conversion between two character set encodings. This function is for internal use only. You are advised not to use it.

Precautions

- The **DEFAULT** parameter indicates that the conversion between the source encoding and the target encoding is executed by default between the client and the server. To support this usage, bidirectional conversion must be defined, that is, both conversion from A to B and conversion from B to A are supported.
- To perform conversion, you must have the EXECUTE permission on function and the CREATE permission on the target schema.
- SQL_ASCII cannot be used for either source encoding or target encoding because the server behavior is hardwired when SQL_ASCII "encoding" is involved.
- You can remove user-defined conversions using DROP CONVERSION.

Syntax

```
CREATE [ DEFAULT ] CONVERSION name  
FOR 'source_encoding' TO 'dest_encoding' FROM function_name;
```

```
→ CREATE → [ DEFAULT ] → CONVERSION → name → FOR → [ ] → source_encoding → [ ] → TO → [ ] → dest_encoding → [ ] → FROM → function_name → [ ] → ;
```

Parameters

- **DEFAULT**

Specifies that the conversion is the default conversion from the source encoding to the target encoding. There should be only one default conversion for each encoding pair in a schema.

- **name**

Specifies the name of the conversion, which can be restricted by the schema. If not restricted by a schema, the conversion is defined in the current schema. The conversion name must be unique in a schema.

- **source_encoding**

Source encoding name.

- **dest_encoding**

Target encoding name.

- **function_name**

Function used for conversion. A function name can be restricted by a schema. If not, the function is found in the path.

The function must be in the following format:

```
conv_proc(  
    integer, -- Source encoding ID  
    integer, -- Target encoding ID  
    cstring, -- Source character string (C character string ending with a null value)  
    internal, -- Target (filled with a null-terminated C character string)  
    integer -- Length of the source string  
) RETURNS void;
```

⚠ CAUTION

- Currently, only internal creation is supported.
-

7.12.8.16 CREATE DATABASE

Description

Creates a database. By default, the new database will be created only by cloning the standard system database **template0**.

Precautions

- A user who has the CREATEDB permission or a system administrator can create a database.
- It cannot be executed inside a transaction block.

- If an error message similar to "could not initialize database directory" is displayed during database creation, the possible cause is that the permission on the data directory in the file system is insufficient or the disk is full.

Syntax

```
CREATE DATABASE database_name
  [ [ WITH ] { [ OWNER [=] user_name ] |
    [ TEMPLATE [=] template ] |
    [ ENCODING [=] 'encoding' ] |
    [ LC_COLLATE [=] 'lc_collate' ] |
    [ LC_CTYPE [=] 'lc_ctype' ] |
    [ DBCOMPATIBILITY [=] 'compatibility_type' ] |
    [ TABLESPACE [=] tablespace_name ] |
    [ CONNECTION LIMIT [=] connlimit ] |
    [ DBTIMEZONE [=] 'time_zone' ] }{...} ];
```

Parameters

- **database_name**
Specifies the database name.
Value range: a string. It must comply with the [naming convention](#).
- **OWNER [=] user_name**
(Optional) Specifies the owner of the new database. If omitted, the default owner is the current user.
Value range: an existing username
- **TEMPLATE [=] template**
(Optional) Specifies a template name. That is, the template from which the database is created. GaussDB creates a database by copying data from a template database. GaussDB has two default template databases **template0** and **template1** and a default user database **postgres**.
Value range: **template0**
- **ENCODING [=] 'encoding'**
(Optional) Specifies the character encoding used by the database. The value can be a string (for example, **SQL_ASCII**) or an integer.
If this parameter is not specified, the encoding of the template database is used by default. By default, the codes of the template databases **template0** and **template1** are related to the OS environment. The character encoding of **template1** cannot be changed. To change the encoding, use **template0** to create a database.
Common values are **GBK**, **UTF8**, **Latin1**, and **GB18030**. The supported character sets are as follows:

Table 7-238 Supported character sets

Name	Description	Language	Server-side Encoding	ICU Support	Number of Bytes/Characters	Alias
BIG5	Big Five	Traditional Chinese	No	No	1–2	WIN950, Windows950
EUC_CN	Extended Unix Code-CN	Simplified Chinese	Yes	Yes	1–3	-
EUC_JP	Extended Unix Code-JP	Japanese	Yes	Yes	1–3	-
EUC_JIS_2004	Extended Unix Code-JP, JIS X 0213	Japanese	Yes	No	1–3	-
EUC_KR	Extended Unix Code-KR	Korean	Yes	Yes	1–3	-
EUC_TW	Extended Unix Code-Taiwan, China	Traditional Chinese	Yes	Yes	1–3	-
GB18030	National standards	Chinese	Yes	No	1–4	-
GB18030_2022	National standards	Chinese	Yes	No	1–4	-
GBK	Extended national standards	Simplified Chinese	Yes	No	1–2	WIN936, Windows936
ISO_8859_5	ISO 8859-5, ECMA 113	Latin/Cyrillic	Yes	Yes	1	-

Name	Description	Language	Server-side Encoding	ICU Support	Number of Bytes/Characters	Alias
ISO_8859_6	ISO 8859-6, ECMA 114	Latin/Arabic	Yes	Yes	1	-
ISO_8859_7	ISO 8859-7, ECMA 118	Latin/Greek	Yes	Yes	1	-
ISO_8859_8	ISO 8859-8, ECMA 121	Latin/Hebrew	Yes	Yes	1	-
JOHAB	JOHAB	Korean	No	No	1-3	-
KOI8R	KOI8-R	Cyrillic (Russian)	Yes	Yes	1	KOI8
KOI8U	KOI8-U	Cyrillic (Ukrainian)	Yes	Yes	1	-
LATIN1	ISO 8859-1, ECMA 94	Western European languages	Yes	Yes	1	ISO88591
LATIN2	ISO 8859-2, ECMA 94	Central European languages	Yes	Yes	1	ISO88592
LATIN3	ISO 8859-3, ECMA 94	South European languages	Yes	Yes	1	ISO88593
LATIN4	ISO 8859-4, ECMA 94	North European languages	Yes	Yes	1	ISO88594

Name	Description	Language	Server-side Encoding	ICU Support	Number of Bytes/Characters	Alias
LATIN5	ISO 8859-9, ECMA 128	Turkish	Yes	Yes	1	ISO88599
LATIN6	ISO 8859-10, ECMA 144	Germanic languages	Yes	Yes	1	ISO885910
LATIN7	ISO 8859-13	Baltic languages	Yes	Yes	1	ISO885913
LATIN8	ISO 8859-14	Celtic languages	Yes	Yes	1	ISO885914
LATIN9	ISO 8859-15	LATIN1 with Euro and accents	Yes	Yes	1	ISO885915
LATIN10	ISO 8859-16, ASRO SR 14111	Romanian	Yes	No	1	ISO885916
MULE_INTERNAL	Mule internal code	Multilingual Emacs	Yes	No	1-4	-
SJIS	Shift JIS	Japanese	No	No	1-2	Mskanji, ShiftJIS, WIN932, Windows932
SHIFT_JIS_2004	Shift JIS, JIS X 0213	Japanese	No	No	1-2	-
SQL_ASCII	Unspecified (see the text)	Any	Yes	No	1	-
UHC	Unified Hangul Code	Korean	No	No	1-2	WIN949, Windows949

Name	Description	Language	Server-side Encoding	ICU Support	Number of Bytes/Characters	Alias
UTF8	Unicode, 8-bit	<i>All</i>	Yes	Yes	1–4	Unicode
WIN866	Windows CP866	Cyrillic	Yes	Yes	1	ALT
WIN874	Windows CP874	Thai	Yes	No	1	-
WIN1250	Windows CP1250	Central European languages	Yes	Yes	1	-
WIN1251	Windows CP1251	Cyrillic	Yes	Yes	1	WIN
WIN1252	Windows CP1252	Western European languages	Yes	Yes	1	-
WIN1253	Windows CP1253	Greek	Yes	Yes	1	-
WIN1254	Windows CP1254	Turkish	Yes	Yes	1	-
WIN1255	Windows CP1255	Hebrew	Yes	Yes	1	-
WIN1256	Windows CP1256	Arabic	Yes	Yes	1	-
WIN1257	Windows CP1257	Baltic languages	Yes	Yes	1	-
WIN1258	Windows CP1258	Vietnamese	Yes	Yes	1	ABC, TCVN, TCVN5712, VSCII

Name	Description	Language	Server-side Encoding	ICU Support	Number of Bytes/Characters	Alias
ZHS16GBK	Extended national standards	Simplified Chinese	Yes	No	1-2	-

 **CAUTION**

- Note that not all client APIs support the preceding character sets.
 - The SQL_ASCII setting performs quite differently from other settings. If the character set of the server is SQL_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL_ASCII, no code conversion occurs. Therefore, this setting is not basically used to declare the specified encoding used, because this declaration ignores the encoding. In most cases, if you use any non-ASCII data, it is unwise to use the SQL_ASCII setting because the database will not be able to help you convert or verify non-ASCII characters.
-

NOTICE

- The character set encoding of the new database must be compatible with the local settings (**LC_COLLATE** and **LC_CTYPE**).
- When the specified character encoding set is **GBK** or **ZHS16GBK**, some uncommon Chinese characters cannot be directly used as object names. This is because the byte encoding overlaps with the ASCII characters `@A-Z[\]^_`a-z{}` when the second byte of the GBK ranges from `0x40` to `0x7E`. `@[\]^_`{}` is an operator in the database. If it is directly used as an object name, a syntax error will be reported. For example, the GBK hexadecimal code is **0x8240**, and the second byte is **0x40**, which is the same as the ASCII character `@`. Therefore, the character cannot be used as an object name. If you need to use this function, you can add double quotation marks (") to avoid this problem when creating and accessing objects.
- If the client code is A and the server code is B, the conversion between encoding formats A and B must exist in the database. For details about encoding format conversion supported by the database, see the system catalog [PG_CONVERSION](#). (If the encoding format cannot be converted, it is recommended that the encoding format on the client be the same as that on the server. You can change the encoding format on the client by setting the **client_encoding** parameter.)
- If you want to set the database character set encoding to `GB18030_2022` and the client encoding to `GB18030_2022`, ensure that the client OS supports `GB18030_2022`. If the `GB18030` character set versions are incompatible with each other, data inconsistency may occur. In addition, if historical data needs to be switched to the `GB18030_2022` database, follow the database switching process to migrate data.

- **LC_COLLATE [=] 'lc_collate'**

(Optional) Specifies the character set used by the new database. For example, set this parameter by using **lc_collate = 'zh_CN.gbk'**.

The use of this parameter affects the sort order of strings (for example, the order of using **ORDER BY** for execution and the order of using indexes on text columns). By default, the sorting order of the template database is used.

Value range: character sets supported by the OS.

- **LC_CTYPE [=] 'lc_ctype'**

(Optional) Specifies the character class used by the new database. For example, set this parameter by using **lc_ctype = 'zh_CN.gbk'**. The use of this parameter affects the classification of characters, such as uppercase letters, lowercase letters, and digits. By default, the character classification of the template database is used.

Value range: character classes supported by the OS.

 NOTE

- The value ranges of **lc_collate** and **lc_ctype** depend on the character sets supported by the local environment. For example, in the Linux OS, you can run the **locale -a** command to obtain the list of character sets supported by the OS. When using the **lc_collate** and **lc_ctype** parameters, you can select the required character sets and character classes.
- If you want to set the character encoding set to GB18030_2022, ensure that the value ranges of **lc_collate** and **lc_ctype** are the same as those of GB18030.
- If you want to set the character encoding set to ZHS16GBK, ensure that the value ranges of **lc_collate** and **lc_ctype** are the same as those of the GBK character set.

- **DBCCOMPATIBILITY [=] 'compatibility_type'**

(Optional) Specifies the compatible database type. The default value is **MySQL**.

Value range: **MYSQL**, **TD**, **ORA**, and **PG**. MySQL, Teradata, Oracle and PostgreSQL are compatible, respectively.

 NOTE

- For ORA compatibility, the database treats empty strings as **NULL** and replaces **DATE** with **TIMESTAMP(0) WITHOUT TIME ZONE**.
 - When a character string is converted to an integer, if the input is invalid, the input will be converted to 0 due to MySQL compatibility, and an error will be reported due to other compatibility issues.
 - For PG compatibility, CHAR and VARCHAR are counted by character. For other compatibility types, they are counted by byte. For example, for the UTF-8 character set, CHAR(3) can store three Chinese characters in PG compatibility scenarios, but can store only one Chinese character in other compatibility scenarios.
 - If an error is reported during statement execution, A-format or B-format is displayed in some error information. A-format indicates ORA-format, and B-format indicates MySQL-format.
- **TABLESPACE [=] tablespace_name**
(Optional) Specifies the tablespace of the database.
Value range: an existing tablespace name
 - **CONNECTION LIMIT [=] connlimit**
(Optional) Specifies the maximum number of concurrent connections that can be made to the new database.

NOTICE

- The system administrator is not restricted by this parameter.
- **connlimit** is calculated for each each CN. The number of connections in a cluster is calculated using the following formula: Number of connections in a cluster = **connlimit** x Number of normal CNs.

Value range: an integer in the range $[-1, 2^{31} - 1]$. The default value is **-1**, indicating that there is no limit.

The restrictions on character encoding are as follows:

- If the locale is set to **C** (or **POSIX**), all encoding types are allowed. For other locale settings, the character encoding must be the same as that of the locale.

- The encoding and region settings must match the template database, except that **template0** is used as a template. This is because other databases may contain data that does not match the specified encoding, or may contain indexes whose sorting order is affected by **LC_COLLATE** and **LC_CTYPE**. Copying this data will invalidate the indexes in the new database. **template0** does not contain any data or indexes that may be affected.
- **DBTIMEZONE [=] 'time_zone'**
Specifies the time zone of the new database. For example, you can set this parameter by setting **DBTIMEZONE** to **'+00:00'**. This parameter affects the time zone of the new database. The PRC is used by default.
Prerequisites: The current database is compatible with database ORA, **a_format_version** is set to **'10c'**, and **a_format_dev_version** is set to **'s2'**.
Value range: name and abbreviation of the time zone supported by the OS, or the timestamp ranges from -15:59 to +15:00.

Examples

```
-- Create users jim and tom.
gaussdb=# CREATE USER jim PASSWORD '*****';

-- Create the GBK-encoded database testdb1.
gaussdb=# CREATE DATABASE testdb1 ENCODING 'GBK' template = template0;
-- View information about the testdb1 database.
gaussdb=# SELECT datname,pg_encoding_to_char(encoding) FROM pg_database WHERE datname =
'testdb1';
 datname | pg_encoding_to_char
-----+-----
 testdb1 | GBK
(1 row)
-- Create the ORA-compatible database testdb2 and specify jim as the owner.
gaussdb=# CREATE DATABASE testdb2 OWNER jim DBCOMPATIBILITY = 'ORA';
-- View the information about testdb2.
gaussdb=# SELECT t1.datname,t2.username,t1.datcompatibility
          FROM pg_database t1,pg_user t2
          WHERE t1.datname = 'testdb2' AND t1.datdba=t2.usesysid;
 datname | username | datcompatibility
-----+-----+-----
 testdb2 | jim      | ORA
(1 row)
-- Switch to the ORA-compatible database testdb2 and set session parameters.
gaussdb=# \c testdb2
testdb2=# SET a_format_version='10c';
testdb2=# SET a_format_dev_version='s2';
-- Create the ORA-compatible database and specify the time zone.
testdb2=# CREATE DATABASE testdb3 DBCOMPATIBILITY 'ORA' DBTIMEZONE='+08:00';
-- View the information about testdb3.
testdb2=# SELECT datname,datcompatibility,dattimezone FROM pg_database WHERE datname = 'testdb3';
 datname | datcompatibility | dattimezone
-----+-----+-----
 testdb3 | ORA              | +08:00
(1 row)
-- Switch to the initial database.
testdb2=# \c postgres
-- Delete the database.
gaussdb=# DROP DATABASE testdb1;
gaussdb=# DROP DATABASE testdb2;
gaussdb=# DROP DATABASE testdb3;
-- Delete the user.
gaussdb=# DROP USER jim;
```

Helpful Links

[ALTER DATABASE](#) and [DROP DATABASE](#)

Suggestions

- **create database**
Database cannot be created in a transaction.
- **ENCODING**
If the new database Encoding does not match the template database (SQL_ASCII) ('GBK', 'UTF8', 'LATIN1', 'GB18030', 'GB18030_2022', or 'ZHS16GBK'), **template [=] template0** must be specified.

7.12.8.17 CREATE DATABASE LINK

Description

Creates a database link object. For details about database links, see [DATABASE LINK](#).

Precautions

- The database link feature can be used only in ORA-compatible versions.
- Do not use database links to connect to the initial user.
- Initial users are not allowed to create, modify, or delete database links.
- If the upgrade is not committed, the database link cannot be created.
- If the CURRENT_USER is used or the CONNECT TO connection string is omitted, the initial username and empty password of the current database are used for connection, resulting in connection failure.

Syntax

```
CREATE [ PUBLIC ] DATABASE LINK dblink  
[ CONNECT TO { CURRENT_USER | 'user' IDENTIFIED BY 'password' } ] [ USING ( option 'value' [...] ) ] ;
```

Parameters

- **PUBLIC**
Creates a public database link visible to all users. If this clause is omitted, the database link is private and available only to the current user.
- **dblink**
Indicates the name of the database link to be created.
- **user**
Indicates the name of the user for connecting to the remote end of the created database link.
- **password**
Indicates the password of the user for connecting to the remote end of the created database link.
- **CURRENT_USER**
Uses the initial username and empty password of the current database for connection.
- **USING (option 'value' [, ...])**

Specifies parameters such as the IP address, port number, and remote database name of the database to be connected. The supported options are as follows:

- **host**: specifies the IP addresses to be connected. IPv6 addresses are not supported. Multiple IP addresses can be specified using character strings separated by commas (,). Currently, encrypted databases, SSL settings, and certificate authentication are not supported. If no IP address is specified, this parameter is left empty by default.
- **port**: specifies the port number for connection. If this parameter is not specified, the default value **5432** is used.
- **dbname**: specifies the name of the database to be connected. If this parameter is not specified, the username used for connecting to the remote end is used by default.
- **fetch_size**: specifies the amount of data obtained from the remote end each time. The value of **fetch_size** ranges from 0 to 2147483647. The default value is **100**.

NOTICE

- You can write only part of the preceding options in the brackets after USING.
 - If the keyword USING is not written, the content in the brackets is not written as well.
 - When a database link is created, the system does not check whether the connection is successful. If related keywords are missing, an error may be reported.
 - Do not use 127.0.0.1 or local host for the **host** parameter. Otherwise, the connection fails.
-

Examples

```
-- Create an ORA-compatible database.
gaussdb=# CREATE DATABASE ora_test_db DBCOMPATIBILITY 'ORA';

-- Switch to another database.
gaussdb=# \c ora_test_db

-- Create a user with the system administrator permission.
ora_test_db=# CREATE USER user1 WITH SYSADMIN PASSWORD '*****';
ora_test_db=# SET ROLE user1 PASSWORD '*****';

-- Create a private database link.
ora_test_db=# CREATE DATABASE LINK private_dblink CONNECT TO 'user1' IDENTIFIED BY '*****' USING
(host '192.168.11.11',port '54399',dbname 'db01');

-- Delete the private database link.
ora_test_db=# DROP DATABASE LINK private_dblink;

-- Create a public database link.
ora_test_db=# CREATE PUBLIC DATABASE LINK public_dblink CONNECT TO 'user1' IDENTIFIED BY '*****'
USING (host '192.168.11.11',port '54399',dbname 'db01');

-- Delete the public database link.
ora_test_db=# DROP PUBLIC DATABASE LINK public_dblink;
```

```
-- Delete the created user.
ora_test_db=# RESET ROLE;
ora_test_db=# DROP USER user1;

-- Switch back to the initial database and delete the test database. Replace postgres with the actual
database name.
ora_test_db=# \c postgres
gaussdb=# DROP DATABASE ora_test_db;
```

[ALTER DATABASE LINK](#) and [DROP DATABASE LINK](#)

7.12.8.18 CREATE DIRECTORY

Description

CREATE DIRECTORY creates a directory. The directory defines an alias for a path in the server file system and is used to store data files used by users. Users can read and write these files through the **db_file** advanced package.

The read and write permissions for the directory can be granted to specified users to provide permission control for **db_file**.

Precautions

- When **enable_access_server_directory** is set to **off**, only the initial user is allowed to create the directory object. When **enable_access_server_directory** is set to **on**, users with the SYSADMIN permission and users inherited from the built-in role **gs_role_directory_create** can create directory objects.
- By default, the user who creates a directory has the read and write permissions on the directory.
- The default owner of a directory is the user who creates the directory.
- A directory cannot be created for the following paths:
 - The path contains special characters.
 - The path is a relative path.
- The following validity check is performed during directory creation:
 - Check whether the path exists in the OS. If it does not exist, a message is displayed, indicating the potential risks.
 - Check whether the database initial user **omm** has the read, write, and execution permissions on the created directory. If the user does not have all the permissions, a message is displayed, indicating the potential risks.
- In a cluster, ensure that the path is the same on all the nodes. Otherwise, the path may fail to be found on some nodes when the directory is used.
- You can view existing directory objects in the `pg_directory` table.

Syntax

```
CREATE [OR REPLACE] DIRECTORY directory_name
AS 'path_name';
```

→ CREATE → OR → REPLACE → DIRECTORY → directory_name → AS → ' → path_name → ' → ; →

Parameters

- **directory_name**
Specifies name of a directory.
Value range: a string. It must comply with the naming convention.
- **path_name**
Specifies the OS path for which a directory is to be created.
Value range: a valid OS path

Examples

```
-- Create a directory object.
gaussdb=# CREATE OR REPLACE DIRECTORY dir AS '/tmp/';

-- View the created directory object.
gaussdb=# select * from pg_directory;
 dirname | owner | dirpath | diracl
-----+-----+-----+-----
 dir    | 10 | /tmp |
(1 row)

-- Delete the directory object.
gaussdb=# DROP DIRECTORY dir;
```

[ALTER DIRECTORY](#) and [DROP DIRECTORY](#)

7.12.8.19 CREATE EXTENSION

NOTICE

The extended function is for internal use only. You are advised not to use it.

Description

Installs an extension.

Precautions

- Before running the **CREATE EXTENSION** command to load an extension into the database, you must install the support file for the extension first.
- The **CREATE EXTENSION** command installs a new extension to a database. Ensure that no extension with the same name has been installed.
- Installing an extension means executing an extended script file that creates an SQL entity, such as a function, data type, operator, and index-supported method.
- Installing an extension requires the same permissions as creating its component objects. For most extensions, this means that the superuser or database owner's permissions are required. For subsequent permission checks and entities created by the extension script, the role that runs the **CREATE EXTENSION** command becomes the owner of the extension.

- During the execution of `CREATE EXTENSION`, if the database contains database objects with the same name as that in the `EXTENSION`, such as synonyms, operators, directories, functions, stored procedures, views, and tables, the execution will fail.
- Do not directly create extensions for the database to avoid unexpected errors and incompatibility problems after the upgrade. To create an extension, set **`enable_extension`** to **`true`**.
- During extension creation, if **`enable_object_special_character`** is set to **`off`** and `"@extschema@"` is used in the extension script file, the value of the **`Schema`** parameter in the extension support file cannot contain any special characters in [`"$\"`].

Syntax

```
CREATE EXTENSION [ IF NOT EXISTS ] extension_name  
[ WITH ] [ SCHEMA schema_name ]  
[ VERSION version ]  
[ FROM old_version ];
```

Parameters

- **IF NOT EXISTS**
If an extension with the same name exists in the system, no error is reported. However, a message is displayed. Note that this parameter does not ensure that the existing extensions of the system are the same as those created by the script.
- **extension_name**
Specifies the name of the extension to be installed. The database creates the extension by using the information in the **`SHAREDIR/extension/extension_name.control`** file.
- **schema_name**
The extension instance is installed in this schema, and the extended content can be reinstalled. The specified schema must exist. If it is not specified, the extended control file does not specify a schema either. In this case, the default schema is used.

⚠ CAUTION

Extensions do not belong to any schema (no restriction is posed on the name of extensions within the scope of a database), but an extension instance belongs to a schema.

-
- **version**
Version of an extension to be installed, which can be written as an identifier or a string. The default version is specified in the extended control file.
 - **old_version**
If you want to upgrade the content that is not contained in the **`old style`** module, you need to specify **`FROM old_version`**. This option makes **`CREATE EXTENSION`** run an installation script to install new content into the extension instead of creating an entity. Note that **`SCHEMA`** specifies the schema that includes these existing entities.

Examples

Install an extension in the current database. For example, install **security_plugin**:

```
-- Before installing the extension, set enable_extension to true.
gaussdb=# SET enable_extension = true;

-- Install the expansion.
gaussdb=# CREATE EXTENSION IF NOT EXISTS security_plugin;

-- Delete the extension.
gaussdb=# DROP EXTENSION security_plugin;
```

7.12.8.20 CREATE FOREIGN DATA WRAPPER

Description

Creates a foreign data wrapper. The user who created the foreign data wrapper becomes its owner.

Precautions

- The name of the foreign data wrapper must be unique in the database.
- Only initial users and system administrators can create foreign data wrappers.

Syntax

```
CREATE FOREIGN DATA WRAPPER name
[ HANDLER handler_function | NO HANDLER ]
[ VALIDATOR validator_function | NO VALIDATOR ]
[ OPTIONS ( option 'value' [, ... ] ) ];
```

Parameters

- **name**
Specifies the name of the foreign data wrapper to be created.
- **HADNLER handler_function**
handler_function is the name of a registered function used to retrieve execution functions for foreign tables. The handler function must have no arguments, and its return type must be `fdw_handler`.
It is possible to create foreign data wrappers without processor functions, but foreign tables that use such wrappers can only be declared and cannot be accessed.
- **VALIDATOR validator_function**
validator_function is the name of a registered function used to check the common options provided to the foreign data wrapper, as well as the options for the foreign server, user mapping, and foreign table that use the foreign data wrapper. If there is no validator function or **NO VALIDATOR** is declared, options are not checked at creation time (foreign data wrappers may ignore or reject invalid option descriptions at runtime, depending on the implementation). The validator function must accept two arguments: one is of `text[]` type, which will contain an array of options stored in the system directory, and the other is of `OID` type, which will be the `OID` of the system directory that contains the options. The return type is ignored. The function should report invalid options using the `ereport(ERROR)` function.

- **OPTIONS (option 'value' [, ...])**

This clause declares options for the new foreign data wrapper. The allowed option names and values are specific to each foreign data wrapper and are validated by the validator function of the foreign data wrapper. The option name must be unique.

Examples

```
-- Create a useless foreign data wrapper dummy.
gaussdb=# CREATE FOREIGN DATA WRAPPER dummy;

-- Create a foreign data wrapper file with the handler function file_fdw_handler.
gaussdb=# CREATE FOREIGN DATA WRAPPER file HANDLER file_fdw_handler;

-- Create a foreign data wrapper mywrapper with some options.
gaussdb=# CREATE FOREIGN DATA WRAPPER mywrapper OPTIONS (debug 'true');
```

Helpful Links

[ALTER FOREIGN DATA WRAPPER](#) and [DROP FOREIGN DATA WRAPPER](#)

7.12.8.21 CREATE FUNCTION

Description

Creates a function.

Precautions

- If the parameters or return values of a function have precision, the precision is not checked.
- When creating a function, you are advised to explicitly specify the schemas of tables in the function definition. Otherwise, the function may fail to be executed.
- **current_schema** and **search_path** specified by SET during function creation are invalid. **search_path** and **current_schema** before and after function execution should be the same.
- If a function has output parameters, the GUC parameter **set behavior_compat_options** must be set to '**proc_outparam_override**' for the output parameters to take effect. When the function is called using SELECT or CALL, an actual parameter must be provided in the position of the output parameter. Otherwise, the function fails to be called.
- Only the functions compatible with PostgreSQL can be overloaded. After **REPLACE** is specified, a new function is created instead of replacing a function if the number of parameters, parameter type, or return value is different.
- You cannot create overloaded functions with different formal parameter names (the function name and parameter list type are the same).
- You cannot create a function that has the same name and parameter list as a stored procedure.
- Formal parameters cannot be overloaded if only the custom ref cursor type is different from the sys_refcursor type.
- Function overloading is not supported if only the returned data types are different.

- Function overloading is not supported if only the default values are different.
- When an overloaded function is called, the variable type must be specified.
- ORA-compatible functions are created for ORA-compatible databases and PG-compatible functions are created for PG-compatible databases. Hybrid creation is not recommended.
- If an undeclared variable is used in a function, an error is reported when the function is called.
- You can use the SELECT statement to specify different parameters using identical functions.
- When you create a function, you cannot insert other agg functions out of the avg function or other functions.
- In common cluster mode, return values, parameters, and variables cannot be set to the tables of the node groups that are not installed in the system by default. The internal statements of SQL functions cannot be executed on such tables.
- By default, the permissions to execute new functions are granted to PUBLIC users. For details, see [GRANT](#). By default, a user inherits the permissions of the PUBLIC role. Therefore, the user has the permission to execute a function and view the definition of the function. In addition, to execute the function, the user must have the USAGE permission on the schema to which the function locates. You can revoke the default execution permissions from the PUBLIC role when creating a function and grant the function execution permission to users as needed. To avoid the time window during which new functions can be accessed by all users, create functions and set function execution permissions in a transaction. After the database object isolation attribute is enabled, common users can view only the definitions of functions that they have permission to execute.
- If a function is defined as **IMMUTABLE** or **SHIPPABLE**, avoid **INSERT**, **UPDATE**, **DELETE**, **MERGE**, and **DDL** operations in the function because the CN needs to determine the execution node for these operations. Otherwise, an error may occur. If DDL operations are performed on a function of the IMMUTABLE or SHIPPABLE type, database objects on each node may be inconsistent. To resolve this problem, create the VOLATILE PL/SQL function on the CN, run the EXECUTE statement in the function definition to dynamically execute the DDL operation for repairing system objects, and then use the EXECUTE DIRECT ON syntax to call the repair function on the specified DN.
- When functions without parameters are called inside another function, you can omit brackets and call functions using their names directly.
- If the parameter **set behavior_compat_options** is not set to **proc_outparam_override**, the return value of the function directly called by an anonymous block or stored procedure is used as the first value of the **OUT** output parameter. As a result, the calling fails. To correctly use the **OUT** and **IN OUT** output parameters, set the parameter **set behavior_compat_options** to **proc_outparam_override**. For details, see the example.
- When other functions with output parameters are called in a function and an assignment expression, set the GUC parameter **set behavior_compat_options** to '**proc_outparam_override**', define variables of the same type as the output parameters in advance, and use the variables as output parameters to call other functions with output parameters for the output parameters to take

effect. Otherwise, the output parameters of the called functions will be ignored.

- After the GUC parameter **behavior_compat_options** is set to '**proc_outparam_override**', if the return type of the function is setof, the output parameter will not take effect.
- Oracle-compatible functions support viewing, exporting, and importing parameter comments.
- Oracle-compatible functions support viewing, exporting, and importing comments between IS/AS and plsql_body.
- Users granted with the CREATE ANY FUNCTION permission can create or replace functions in the user schemas.
- The default permission on a function is SECURITY INVOKER. To change the permission to SECURITY DEFINER, set the GUC parameter **behavior_compat_options** to '**plsql_security_definer**'.
- When a function is created, it depends on an undefined object. If **behavior_compat_options** is set to '**plpgsql_dependency**', the creation can be executed and a warning message is displayed. If **behavior_compat_options** is not set to '**plpgsql_dependency**', the creation cannot be executed.
- When **behavior_compat_options** is set to '**plpgsql_dependency**', if function A is called in the function and function B is contained in the input and output parameters of function A, function B will not establish a dependency, for example, **functionA(functionB())**. `gs_dependencies` only creates dependency with function A.
- If a view directly depends on an O-style function and the **behavior_compat_options** parameter is set to '**plpgsql_dependency**', the view can be accessed when the function is created again. However, if the **behavior_compat_options** parameter is not set to '**plpgsql_dependency**', the view cannot be accessed.
- When creating a function, you cannot use the function itself as the default value of input parameter.
- The function with **OUT** parameter cannot be called by SQL statement.
- The function with **OUT** parameter cannot be called by SELECT INTO syntax.
- Functions with **OUT** parameters cannot be called in nested mode.

Example:

```
b := func(a,func(c,1));
```

Should be changed to:

```
tmp := func(c,1); b := func(a,tmp);
```

- When a function is created, the type of the return value of the function is not checked.
- If a function with the definer specified is created in a schema of another user, the function will be executed by another user, which may cause unauthorized operations. Therefore, exercise caution when performing this operation.
- If the **out** parameter is used as the output parameter in an expression, the expression does not take effect in the following scenarios: (a) The execute immediate sqlv using func syntax is used to execute a function. (b) The select func into syntax is used to execute a function. (c) DML statements such as

INSERT and UPDATE are used to execute a function. (d) The select where a=func() statement is used. (e) When a function with the **out** output parameter is used as an input parameter, that is, **fun (func (out b), a)**, the **out b** parameter does not take effect.

- In the RETURN statement of a function, when the constructor of the composite type is called, if the actual return type is different from the defined return type, the result can be implicitly converted to the defined return type. Cross-schema call is supported. Cross-database call is not supported, for example, **RETURN package.schema.record**; In the RETURN statement of a function, when the function is called, the function with the OUT parameter in an expression of an arithmetic operation is not supported, for example, **RETURN func(c out) + 1**.
- When the complex function is called, for example, func(x).a, a composite type is returned. Cross-schema call is supported, but the database.schema.func(x).b call is not supported.
- When a stored procedure with the out parameter is called, you can set the GUC parameter **set behavior_compat_options** to **'proc_outparam_transfer_length'** to transfer the parameter length. The specifications and constraints are as follows:
 - a. The following types are supported: CHAR(n), CHARACTER(n), NCHAR(n), VARCHAR(n), VARYING(n), VARCHAR2(n), and NVARCHAR2(n).
 - b. If the out parameter does not take effect (for example, **perform**), the length does not need to be transferred.
 - c. The following types do not support precision transfer: NUMERIC, DECIMAL, NUMBER, FLOAT, DEC, INTEGER, TIME, TIMESTAMP, INTERVAL, TIME WITH TIME ZONE, TIMESTAMP WITH TIME ZONE, TIME WITHOUT TIME ZONE, and TIMESTAMP WITHOUT TIME ZONE.
 - d. The parameter length can be transferred regardless of whether the GUC parameter **set behavior_compat_options** is set to **proc_outparam_override**.
- Functions contain syntax and functions that use GUC parameters to control features. If GUC parameters are modified in a session, the result may be inconsistent with the expected result. If the parameters are modified, the function may retain the behavior before the modification. Therefore, exercise caution when modifying GUC parameters.

Syntax

- Syntax (compatible with PostgreSQL) for creating a user-defined function:

```
CREATE [ OR REPLACE ] FUNCTION function_name
( [ { argname [ argmode ] argtype [ { DEFAULT | := | = } expression ] } [, ...] ] )
[ RETURNS rettype [ DETERMINISTIC ] | RETURNS TABLE ( { column_name column_type }
[, ...] ) ]
LANGUAGE lang_name
[
  {IMMUTABLE | STABLE | VOLATILE }
  | {SHIPPABLE | NOT SHIPPABLE}
  | WINDOW
  | [ NOT ] LEAKPROOF
  | {CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
  | {[ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER | AUTHID DEFINER |
AUTHID CURRENT_USER}
  | {fenced | not fenced}
  | COST execution_cost
```

```

| ROWS result_rows
| SET configuration_parameter { {TO | =} value | FROM CURRENT }}
][...]
{
  AS 'definition'
  | AS 'obj_file', 'link_symbol'
};

```

- O-style syntax for creating a user-defined function:

```

CREATE [ OR REPLACE ] FUNCTION function_name
( [ { argname [ argmode ] argtype [ { DEFAULT | := | = } expression ] } [, ...] ] )
RETURN rettype [ DETERMINISTIC ]
[
  {IMMUTABLE | STABLE | VOLATILE }
  | {SHIPPABLE | NOT SHIPPABLE}

  | {FENCED | NOT FENCED}
  | [ NOT ] LEAKPROOF
  | {CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
  | {[ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER | AUTHID DEFINER |
AUTHID CURRENT_USER}
  | COST execution_cost
  | ROWS result_rows
  | SET configuration_parameter { {TO | =} value | FROM CURRENT }
  | LANGUAGE lang_name
][...]
{
  IS | AS
} plsql_body
/

```

Parameters

- **function_name**

Specifies the name of the function to be created (optionally schema-qualified).

Value range: a string. It must comply with the [naming convention](#). The value contains a maximum of 63 characters. If the value contains more than 63 characters, the database truncates it and retains the first 63 characters as the function name.

NOTE

You are advised not to create a function with the same name as a system function. Otherwise, you need to specify the schema of the function when calling the function.

- **argname**

Specifies the parameter name of the function.

Value range: a string. It must comply with the [naming convention](#). The value contains a maximum of 63 characters. If the value contains more than 63 characters, the database truncates it and retains the first 63 characters as the function parameter name.

- **argmode**

Specifies the parameter mode of the function.

Value range: **IN**, **OUT**, **INOUT**, and **VARIADIC**. The default value is **IN**. Only the parameter of the **OUT** mode can be followed by **VARIADIC**. The parameters of **OUT** and **INOUT** cannot be used in the function definition of RETURNS TABLE.

 NOTE

VARIADIC specifies parameters of the array type.

- **argtype**

Specifies the data type of a function parameter. You can use **%ROWTYPE** to indirectly reference the type of a table, or **%TYPE** to indirectly reference the type of a column in a table or composite type. For details, see [Variable Definition Statements](#).

- **expression**

Specifies the default expression of a parameter.

 NOTE

- If **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**, the default expression is not supported when the parameter is in INOUT mode.
- It is recommended that you define all default parameters after all non-default parameters.
- If a function with default parameters is called, input parameters are added to the function from left to right. If inputs of non-default parameters are missing, an error is reported.
- If **proc_uncheck_default_param** is enabled and a function with default parameters is called, input parameters are added to the function from left to right. The number of defaulted inputs depends on the number of default parameters. If an input of a non-default parameter is missing, the previous default value is used to fill this parameter.
- When **a_format_version** is set to **10c**, **a_format_dev_version** is set to **s1**, **proc_outparam_override** is disabled, and the function parameters include the output parameter **out** and **default**, the default value cannot be used.

- **rettype**

Specifies the return data type. Same as **argtype**, **%TYPE** or **%ROWTYPE** can also be used to indirectly reference types.

When there is **OUT** or **INOUT** parameter, the RETURNS clause can be omitted. If the clause is not omitted, the result type of the clause must be the same as that of the output parameter.

The SETOF modifier indicates that the function will return a set of items, rather than a single item.

- **column_name**

Specifies the column name.

- **column_type**

Specifies the column type.

- **definition**

Specifies a string constant defining a function. Its meaning depends on the language. It can be an internal function name, a path pointing to a target file, an SQL query, or text in a procedural language.

- **DETERMINISTIC**

Specifies an API compatible with the SQL syntax. You are advised not to use it.

- **LANGUAGE lang_name**

Specifies the name of the language that is used to implement the function. It can be **SQL**, **C**, **internal**, or the name of a customized process language. To

ensure downward compatibility, the name can use single quotation marks. Contents in single quotation marks must be capitalized.

Due to compatibility issues, no matter which language is specified when an ORA-style database is created, the language used is plpgsql.

 **NOTE**

- When an internal function is defined, if AS specifies the function as an internal system function, the parameter type, number of parameters, and return value type of the new function must be the same as those of the internal system function, and the user who creates the internal function must have the permission to execute the internal system function.
- Only users with the sysadmin permission can create internal functions.
- **WINDOW**
Specifies that the function is a window function. This is currently only useful for functions written in C. The **WINDOW** attribute cannot be changed when replacing an existing function definition.

NOTICE

For a customized window function, the value of **LANGUAGE** can only be **internal**, and the referenced internal function must be a window function.

- **IMMUTABLE**
Specifies that the function always returns the same result if the parameter values are the same.
- **STABLE**
Specifies that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same parameter value, but its result varies by SQL statements.
- **VOLATILE**
Specifies that the function value can change in a single table scan and no optimization is performed.
- **SHIPPABLE**
NOT SHIPPABLE
Specifies whether the function can be pushed down to DN for execution.
 - Functions of the IMMUTABLE type can always be pushed down to DN.
 - Functions of the STABLE or VOLATILE type can be pushed down to DN only if their attribute is **SHIPPABLE**.

NOTICE

The function or stored procedure of the SHIPPABLE/IMMUABLE type cannot contain EXCEPTION or call functions or stored procedures that contain EXCEPTION.

- **LEAKPROOF**

Specifies that the function has no side effects. **LEAKPROOF** can be set only by the system administrator.

- **CALLED ON NULL INPUT**

Declares that some parameters of the function can be called in normal mode if the parameter values are null. This parameter can be omitted.

- **RETURNS NULL ON NULL INPUT**

STRICT

Specifies that the function always returns null whenever any of its parameters is null. If this parameter is specified, the function is not executed when there are null parameters; instead a null result is returned automatically.

RETURNS NULL ON NULL INPUT and **STRICT** have the same functions.

- **EXTERNAL**

The purpose is to be compatible with SQL statements and it is optional. This feature applies to all functions, not only external functions.

- **SECURITY INVOKER**

AUTHID CURRENT_USER

Specifies that the function will be executed with the permissions of the user who calls it. This parameter can be omitted.

SECURITY INVOKER and **AUTHID CURRENT_USER** have the same functions.

- **SECURITY DEFINER**

AUTHID DEFINER

Specifies that the function will be executed with the permissions of the user who created it.

AUTHID DEFINER and **SECURITY DEFINER** have the same functions.

- **FENCED**

NOT FENCED

Specifies whether the function is executed in fenced mode or not fenced mode. In **NOT FENCED** mode, a function is executed in a CN or DN process. In **FENCED** mode, a function is executed in a new fork process, which does not affect CN or DN processes.

Application scenarios:

- Develop or debug a function in **FENCED** mode and execute it in **NOT FENCED** mode. This reduces the overhead of the fork process and communication.
- Perform complex OS operations, such as opening a file, and processing signals and threads in **FENCED** mode; otherwise, the GaussDB database execution may be affected.
- Customize PL/SQL functions. If this parameter is not specified, the default value **NOT FENCED** is used and the **FENCED** execution mode is not supported.

- **COST execution_cost**

Estimates the execution cost of a function.

The unit of **execution_cost** is **cpu_operator_cost**.

Value range: ≥ 0

- **ROWS result_rows**
Estimates the number of rows returned by the function. This is only allowed when the function is declared to return a set.
Value range: ≥ 0 . The default value is **1000**.
- **configuration_parameter**
 - **value**
Sets a specified database session parameter to a specified value. If the value is **DEFAULT** or **RESET**, the default setting is used in the new session. **OFF** disables the setting.
Value range: a string
 - **DEFAULT**
 - **OFF**
 - **RESET**
Specifies the default value.
 - **FROM CURRENT**
Uses the value of **configuration_parameter** of the current session.
- **plsql_body**
Specifies the PL/SQL stored procedure body.

NOTICE

When you perform password-related operations, such as user creation, password change, and encryption/decryption, in a function body, the password will be recorded in the system catalogs and logs in plaintext. To prevent sensitive information leakage, you are advised not to perform operations on the function body related to sensitive information, such as passwords or keys.

Examples

```
-- Create an ORA-compatible database.
gaussdb=# CREATE DATABASE ora_compatible_db DBCOMPATIBILITY 'ORA';
CREATE DATABASE

-- Switch to another database.
gaussdb=# \c ora_compatible_db

-- Define a function as SQL query.
ora_compatible_db=# CREATE FUNCTION func_add_sql(integer, integer) RETURNS integer
AS 'select $1 + $2;'
LANGUAGE SQL
IMMUTABLE
RETURNS NULL ON NULL INPUT;

-- Add an integer by parameter name using PL/pgSQL.
ora_compatible_db=# CREATE OR REPLACE FUNCTION func_increment_plsql(i integer) RETURNS integer AS
$$
BEGIN
RETURN i + 1;
END;
$$ LANGUAGE plpgsql;
```

```
-- Return the RECORD type.
ora_compatible_db=# CREATE OR REPLACE FUNCTION compute(i int, out result_1 bigint, out result_2
bigint)
  RETURNS SETOF RECORD
  AS $$
  BEGIN
    result_1 = i + 1;
    result_2 = i * 10;
  RETURN next;
  END;
  $$LANGUAGE plpgsql;

-- Return a record containing multiple output parameters.
ora_compatible_db=# CREATE FUNCTION func_dup_sql(in int, out f1 int, out f2 text)
  AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
  LANGUAGE SQL;

-- Call the func_dup_sql function.
ora_compatible_db=# SELECT * FROM func_dup_sql(42);
 f1 |   f2
-----+-----
 42 | 42 is text
(1 row)

-- Compute the sum of two integers and returning the result (if the input is null, the returned result is null):
ora_compatible_db=# CREATE FUNCTION func_add_sql2(num1 integer, num2 integer) RETURN integer
  AS
  BEGIN
    RETURN num1 + num2;
  END;
  /

-- Delete the function.

 - Do not run **ANALYZE** in a transaction or anonymous block.

- Do not run **ANALYZE** in a function or stored procedure.

7.12.8.22 CREATE GLOBAL INDEX

Description

A global secondary index (GSI) is created on a specified table.

The GSIs allow users to define indexes that are inconsistent with the distribution of base tables. In this way, single-node plans for querying non-distributed columns of base tables and unique/primary key constraints on non-distributed columns of base tables are achieved.

NOTE

You are advised to create GSIs on a base table as common indexes to improve IUD execution efficiency. In addition, after the GSIs are created on the base table, the IUD performance is affected and deteriorates.

Precautions

- Similar to the base table constraints, the distribution key of GSIs does not support the UPDATE or MERGE INTO operation.
- The GSI can be created only in GTM-lite mode. If a GSI is created in other GTM modes, an error is reported.
- Astore does not support the creation of UB-tree other than GSI and does not support the creation of partitions for GSI.
- The GSI whose distribution is the same as that of the base table cannot be created. Otherwise, an error will be reported during the execution.
- CREATE GSI CONCURRENTLY can be executed only for Ustore tables. If CREATE GSI CONCURRENTLY is executed for Astore tables, a syntax error is reported. CREATE GSI CONCURRENTLY cannot be executed for expression indexes and partial indexes. Otherwise, a syntax error is reported. Online GSI rebuild is not supported.
- Hash-based GSIs can be created for row-store Astore tables, Ustore tables, partitioned tables, hash bucket tables, and segment-page tables whose base tables are hash-based. Base tables cannot be replica,, level-2 partitioned tables, or list/range distribution tables. GSIs support hash-based distribution only.
- GSIs cannot be created for a base table when any column name, such as **ctid**, **xc_node_hash**, **xmin**, **xmax**, **tableoid** (for a partitioned table), and **tablebucketid** (for a hash bucket table) of the base table is duplicate with an existing column name after it is suffixed with "_new\$\$" or "_NEW\$\$."
- If the base table is a partitioned non-hash-bucket table, the GSI allows a maximum of 27 columns. If the base table is a non-partitioned hash bucket table, the GSI allows a maximum of 27 columns. If the base table is a partitioned hash bucket table, the GSI allows a maximum of 26 columns. If the base table is a non-partitioned non-hash-bucket table, the GSI allows a maximum of 28 columns (including index keys and distribution keys).
- For GSI creation (offline), GSI rebuild, and operations related to GSI rebuild, for example, partitioning operations (such as DROP, TRUNCATE, MERGE, SPLIT and EXCHANGE PARTITION) on a partitioned table, UPDATE

DISTRIBUTED GLOBAL INDEX, ALTER TABLE involving data rebuild, as well as ALTER SET TABLESPACE and MOVE PARTITION operations on a hash bucket table, you are advised to enable the STREAM mode to achieve optimal performance. To enable the STREAM mode, set **enable_stream_operator** to **ON** and **create_gsi_opt** to **build**.

- UPSERT is not supported. IUD returning is not supported in the base table where a GSI is created.
- If the VACUUM FULL, CLUSTER, or REINDEX operation on a table is interrupted, the GSI on the table may turn to the **UNUSABLE** state. In this case, an error will be reported when the GSI is queried. You are advised to run **REINDEX INDEX** to rebuild the GSI.
- When executing **COPY** or **GDS** to import data to a base table with a GSI, the **enable_stream_operator** parameter must be enabled to achieve optimal data import performance.
- The following operations will invalidate GSIs: database-level REINDEX, database-level/partition-level CLUSTER, ALTER TABLE PARTITION (DROP, TRUNCATE, MERGE, SPLIT, and EXCHANGE PARTITION). If **UPDATE DISTRIBUTED GLOBAL INDEX** is not specified, all GSIs on the partitioned table will be invalidated. If **UPDATE DISTRIBUTED GLOBAL INDEX** is not specified for EXCHANGE PARTITION, all GSIs on the ordinary table will be invalidated.
- TABLE ACCESS BY INDEX ROWID is based on STREAM and inherits STREAM-related constraints. Considering the STREAM communication latency, when the selectivity is too low or the number of predicate hit rows is small, the performance is not optimal. In this case, you are advised not to use TABLE ACCESS BY INDEX ROWID. Instead, you are advised to use common indexes.
- In the INSERT INTO SELECT scenario, you are advised to enable the **enable_stream_operator** parameter to insert and execute the STREAM plan. (If the base table is a segment-page table, hash bucket table, or tamper-proof table, the CN plan is still used.) If **enable_stream_operator** is disabled, the execution plan goes back to the CN, and the performance is poor (similar to the performance of creating GSIs in version 503.1.0).
- For INSERT, UPDATE, and DELETE, the execution plan is executed in distributed mode, which causes performance loss. In batch UPDATE/DELETE scenarios, the execution plan goes back to the CN, which causes poor performance.
- GSIs can contain expressions but have the following constraints:
 - Similar to the base table constraints, distribution keys cannot contain expressions. In addition, GSIs whose index column contains only an expression cannot be created either because the distribution key must be an expression. If such GSI is created, a syntax error is reported.
 - Similar to common index constraints, the **CONTAINING** column cannot contain expressions. Otherwise, a syntax error will be reported.
 - If any column name is prefixed with "expr", no GSI containing an expression can be created. Otherwise, a syntax error will be reported.

Syntax

```
CREATE GLOBAL [ UNIQUE ] INDEX [ CONCURRENTLY ] [ [schema_name.]index_name ] ON table_name  
[ USING method ]  
( { { column_name [ ( length ) ] | ( expression ) } [ COLLATE collation ] [ opclass ] [ ASC | DESC ]
```

```
[ NULLS { FIRST | LAST } ] [ , ... ] )
[ CONTAINING ( column_name [ , ... ] ) [ DISTRIBUTE BY hash( column_name [ , ... ] ) ] [ WITH
( { storage_parameter = value } [ , ... ] ) ]
[ TABLESPACE tablespace_name ] [ VISIBLE | INVISIBLE ] [ WHERE predicate];
```

Parameters

- **UNIQUE**

Creates a unique index. In this way, the system checks whether new values are unique in the index column. If the inserted or updated value causes duplicate records, an error is reported.

- **CONCURRENTLY**

Creates an index (with ShareUpdateExclusiveLock) in a mode that does not block DML statements. When an index is created, other statements cannot access the table on which the index depends. If this keyword is specified, DML statements are not blocked during the creation.

- The CREATE GLOBAL INDEX statement can be run within a transaction, but CREATE GLOBAL INDEX CONCURRENTLY cannot.
- The built-in stream accelerates creation optimization, which is controlled by the **enable_stream_operator** parameter. When this parameter is enabled, online creation is performed in stream mode, improving creation performance.
- An index may fail to be created online. The possible causes are as follows: The user instructs to terminate the online creation command. The definition of the index is modified. The definition of the base table is modified and the definition of the index is affected. When an index fails to be created online, an error message is displayed, and an unusable index is left. This index is ignored by queries, but it still consumes the IUD overhead. Therefore, you are advised to use the DROP INDEX IF EXISTS syntax to delete the index and create the index online, or use the REINDEX/REBUILD syntax to rebuild the index.

- **schema_name**

Specifies the schema name.

Value range: an existing schema name.

- **index_name**

Specifies the name of the index to be created. No schema name can be included here; the index is always created in the same schema as its parent table.

Value range: a string. It must comply with the [naming convention](#).

- **table_name**

Specifies the name of the table to be indexed (optionally schema-qualified).

Value range: an existing table name.

- **USING method**

Specifies the name of the index method to be used.

Value range: UB-tree. The multi-version B-tree index is provided. The index page contains transaction information.

- **column_name**

Specifies the name of the column on which an index is to be created.

If the index mode supports composite indexes, multiple columns can be declared. A maximum of 28 columns can be declared for a non-partitioned base table, and a maximum of 27 columns can be declared for a partitioned base table.

- **column_name (length)**

Specifies the supported prefix key. For details, see [column_name \(length \)](#).

As an expression index, the prefix index has the same constraints as the expression key in GSI.

- **expression**

Specifies an expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses can be omitted if the expression has the form of a function call. The expression index can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on upper(col) would allow the WHERE upper(col) = 'JIM' clause to use an index. If an expression contains the IS NULL clause, the index for this expression is invalid. In this case, you are advised to create a partial index.

- **COLLATE collation**

Assigns a collation to the column (which must be of a collatable data type). If no collation is specified, the default collation is used. You can run the **select * from pg_collation** command to query collation rules from the pg_collation system catalog. The default collation rule is the row starting with **default** in the query result.

- **opclass**

Specifies the name of an operator class. An operator class can be specified for each column of an index. The operator class identifies the operators to be used by the index for that column.

- **ASC**

Specifies an ascending (default) sort order.

- **DESC**

Specifies a descending sort order.

- **NULLS FIRST**

Specifies that null values appear before non-null values in the sort ordering. This is the default when **DESC** is specified.

- **NULLS LAST**

Specifies that null values appear after non-null values in the sort ordering. This is the default when **DESC** is not specified.

- **CONTAINING**

Specifies the base table attributes other than index keys contained in the GSI.

- **CONTAINING (column_name [, ...])**
Specifies the base table attributes other than the index keys contained in the GSI.
- **DISTRIBUTE BY**
Specifies the distribution key of the GSI, which is different from that of the base table, and only the hash distribution can be used.
- **DISTRIBUTE BY hash(column_name [,...])**
Specifies the distribution key of the GSI.
It needs to be included in the index key.
- **WITH ({storage_parameter = value} [, ...])**
Specifies the storage parameters of the GSI.
Value range:
 - **FILLFACTOR**
The fill factor of an index is a percentage between 10 and 100.
Value range: 10-100
 - **STORAGE TYPE**
Specifies the GSI storage type.
Value range: **USTORE**
 - **INDEXSPLIT**
Controls the method of selecting a proper split point for UB-tree, which is the same as that for B-tree.
Value range: **DEFAULT** or **INSERTPT**
 - **enable_tde**
Specifies the index as an encryption index. The database automatically encrypts the data in the encrypted index before storing it. Before using this parameter, ensure that the TDE function has been enabled using the GUC parameter **enable_tde**, the information for accessing the key service has been set using the GUC parameter **tde_key_info**, and the **enable_tde** attribute has been set for the base table. For details about how to use this parameter, see section "Transparent Data Encryption" in *Feature Guide*. This parameter supports only B-tree and UB-tree indexes. Other indexes such as hash indexes are not supported.
Value range: **on** and **off** If **enable_tde** is set to **on**, the values of **key_type**, **tde_cmk_id**, and **dek_cipher** are automatically generated in the database.
Default value: **off**
 - **encrypt_algo**
Specifies the algorithm for encrypting indexes. This parameter must be used together with **enable_tde**.
Value range: a string. The value can be **AES_128_CTR** or **SM4_CTR**.
Default value: null if **enable_tde** is not set, or **AES_128_CTR** if **enable_tde** is set.
 - **dek_cipher**

Specifies the DEK ciphertext. After you set the **enable_tde** parameter for an index, the index automatically copies the **dek_cipher** parameter of the base table. This parameter cannot be set or modified.

Value range: a string

Default value: null

– **key_type**

Specifies the type of the master key. After you set the **enable_tde** parameter for a table, the index automatically copies the **key_type** parameter of the base table. This parameter cannot be set or modified.

Default value: null

– **cmk_id**

Specifies the ID of the master key. After you set the **enable_tde** parameter for a table, the index automatically copies the **cmk_id** parameter of the base table. This parameter cannot be set or modified.

Value range: a string

Default value: null

● **TABLESPACE tablespace_name**

Specifies the tablespace for an index. If no tablespace is specified, the default tablespace is used.

Value range: an existing table name.

● **VISIBLE**

Sets the index to be visible. This is the default option.

 **NOTE**

- VISIBLE can be set only in the ORA-compatible database (that is, **sql_compatibility = 'ORA'**).
- When **disable_keyword_options** is set to **"visible"**, this keyword cannot be used.
- This keyword is not supported in the upgrade uncommitted phase.

● **INVISIBLE**

Sets the index to be invisible.

 **NOTE**

- INVISIBLE can be set only in the ORA-compatible database (that is, **sql_compatibility = 'ORA'**).
- When **disable_keyword_options** is set to **"invisible"**, this keyword cannot be used.
- This keyword is not supported in the upgrade uncommitted phase.

● **WHERE predicate**

Creates a partial index. A partial index contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small portion of the total table and yet that is an often used portion, you can improve performance by creating an index on just that portion. In addition, the WHERE clause with a UNIQUE constraint can be used to enforce uniqueness over a subset of a table.

Value range: The predicate expression can only refer to columns of the underlying table, but it can use all columns, not just the ones being indexed.

Currently, subqueries and aggregate expressions are forbidden in the WHERE clause. You are advised not to use a predicate of numeric types such as int, because such types can be implicitly converted to Boolean values (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.

Examples

```
-- Create a base table test1 that contains three columns.
gaussdb=# CREATE TABLE test1(c1 int, c2 int, c3 int);

-- Create a GSI on the c2 column of the test table containing the c3 column based on the hash distribution of the c2 column.
gaussdb=# CREATE GLOBAL INDEX idx_gsi_1 ON test1(c2) CONTAINING(c3) DISTRIBUTE BY HASH(c2);

-- Create a base table test2 that contains three columns.
gaussdb=# CREATE TABLE test2(c1 int, c2 int, c3 int);

-- Create a GSI on the c2 column of the test2 table containing the c3 column based on the hash distribution of the c2 column.
gaussdb=# CREATE GLOBAL INDEX idx_gsi_2 ON test2(c2) CONTAINING(c3);

-- Create a base table test3 that contains three columns.
gaussdb=# CREATE TABLE test3(c1 int, c2 int, c3 int);

-- Create a GSI in UNIQUE form on the c2 column of the test3 table, which is based on the hash distribution of the c2 column by default.
gaussdb=# CREATE GLOBAL UNIQUE INDEX idx_gsi_3 ON test3(c2) DISTRIBUTE BY HASH(c2);

-- Delete the index.
gaussdb=# DROP INDEX idx_gsi_1;
gaussdb=# DROP INDEX idx_gsi_2;
gaussdb=# DROP INDEX idx_gsi_3;

-- Delete the table.
gaussdb=# DROP TABLE test1;
gaussdb=# DROP TABLE test2;
gaussdb=# DROP TABLE test3;
```

7.12.8.23 CREATE GROUP

Description

Creates a user group.

Precautions

CREATE GROUP is an alias for CREATE ROLE, and it is not a standard SQL syntax and not recommended. Users can use CREATE ROLE directly.

Syntax

```
CREATE GROUP group_name [ [ WITH ] option [ ... ] ]
[ ENCRYPTED | UNENCRYPTED ] { PASSWORD | IDENTIFIED BY } { 'password' [ EXPIRED ] | DISABLE };
```

The syntax of the option clause (optional) is as follows:

```
{SYSADMIN | NOSYSADMIN}
| {MONADMIN | NOMONADMIN}
| {OPRADMIN | NOOPRADMIN}
| {POLADMIN | NOPOLADMIN}
| {AUDITADMIN | NOAUDITADMIN}
| {CREATEDB | NOCREATEDB}
| {USEFT | NOUSEFT}
| {CREATEROLE | NOCREATEROLE}
| {INHERIT | NOINHERIT}
| {LOGIN | NOLOGIN}
| {REPLICATION | NOREPLICATION}

| {PERSISTENCE | NOPERSISTENCE}
| CONNECTION LIMIT connlimit
| VALID BEGIN 'timestamp'
| VALID UNTIL 'timestamp'
| RESOURCE POOL 'respool'
| USER GROUP 'groupuser'
| PERM SPACE 'spacelimit'
| TEMP SPACE 'tmpspacelimit'
| SPILL SPACE 'spillspacelimit'
| NODE GROUP logic_group_name
| IN ROLE role_name [, ...]
| IN GROUP role_name [, ...]
| ROLE role_name [, ...]
| ADMIN role_name [, ...]
| USER role_name [, ...]
| SYSID uid
| DEFAULT TABLESPACE tablespace_name
| PROFILE DEFAULT
| PROFILE profile_name
| PGUSER
```

Parameters

See [Parameters](#) in section "CREATE ROLE."

Examples

```
-- Create a user group. The effect is the same as that of CREATE ROLE.
gaussdb=# CREATE GROUP test_group WITH PASSWORD "*****";

-- Run CREATE ROLE to create a role. You cannot log in to the database by default.
-- Run ALTER ROLE role_name WITH LOGIN to enable users to log in to the database.
gaussdb=# CREATE ROLE test_role WITH PASSWORD "*****";

-- Run CREATE USER to create a user. A schema with the same name is automatically created and the user
has the login permission.
gaussdb=# CREATE USER test_user WITH PASSWORD "*****";

-- View the user information.
gaussdb=# \du test*
          List of roles
-----+-----+-----
Role name | Attributes | Member of
-----+-----+-----
test_group | Cannot login | {}
test_role  | Cannot login | {}
test_user  |              | {}

-- Query the schema automatically created by the CREATE USER command.
gaussdb=# \dn test*
          List of schemas
-----+-----
Name      | Owner
-----+-----
test_user | test_user
```

```
(1 row)
-- Delete.
gaussdb=# DROP ROLE test_role;
gaussdb=# DROP GROUP test_group;
gaussdb=# DROP USER test_user;
```

7.12.8.24 CREATE INCREMENTAL MATERIALIZED VIEW

Description

CREATE INCREMENTAL MATERIALIZED VIEW creates a fast-refresh materialized view, and you can refresh the data of the materialized view by using REFRESH MATERIALIZED VIEW (complete-refresh) and REFRESH INCREMENTAL MATERIALIZED VIEW (fast-refresh).

CREATE INCREMENTAL MATERIALIZED VIEW is similar to CREATE TABLE AS, but it remembers the query used to initialize the view, so it can refresh data later. A materialized view has many attributes that are the same as those of a table, but does not support temporary materialized views.

Precautions

- Incremental materialized views cannot be created on database link tables, temporary tables, or global temporary tables.
- Fast-refresh materialized views support only simple filter queries and UNION ALL queries of base tables.
- The distribution key cannot be specified when a fast-refresh materialized view is created.
- After a fast-refresh materialized view is created, most DDL operations in the base table are no longer supported.
- The IUD operation cannot be performed on fast-refresh materialized views.
- After a fast-refresh materialized view is created, you need to run the **REFRESH** command to synchronize the materialized view with the base table when the base table data changes.
- The Ustore does not support the creation and use of materialized views.

Syntax

```
CREATE INCREMENTAL MATERIALIZED VIEW mv_name
  [ (column_name [, ...] ) ]
  [ TABLESPACE tablespace_name ]
  AS query;
```

Parameters

- **mv_name**

Name (optionally schema-qualified) of the materialized view to be created.
Value range: a string. It must comply with the [naming convention](#).

- **column_name**

Column name in the new materialized view. The materialized view supports specified columns. The number of specified columns must be the same as the number of columns in the result of the subsequent query statement. If no column name is provided, the column name is obtained from the output column name of the query.

Value range: a string. It must comply with the [naming convention](#).

- **TABLESPACE tablespace_name**

(Optional) Tablespace to which the new materialized view belongs. If the tablespace is not specified, the default tablespace is used.

- **AS query**

SELECT or **TABLE** command. This query will be run in a security-constrained operation.

Examples

```
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Create an ordinary table.
gaussdb=# CREATE TABLE my_table (c1 int, c2 int);

-- Create a fast-refresh materialized view.
gaussdb=# CREATE INCREMENTAL MATERIALIZED VIEW my_imv (col1,col2) TABLESPACE tbs_data1 AS
SELECT * FROM my_table;

-- Write data to the base table.
gaussdb=# INSERT INTO my_table VALUES(1,1);

-- Query fast-refresh materialized view data.
gaussdb=# SELECT * FROM my_imv;
 col1 | col2
-----+-----
(0 rows)

-- Fast refresh the fast-refresh materialized view my_imv.
gaussdb=# REFRESH INCREMENTAL MATERIALIZED VIEW my_imv;

-- Query fast-refresh materialized view data.
gaussdb=# SELECT * FROM my_imv;
 col1 | col2
-----+-----
    1 |    1
(1 row)

-- Delete a fast-refresh materialized view.
gaussdb=# DROP MATERIALIZED VIEW my_imv;

-- Delete the ordinary table my_table.
gaussdb=# DROP TABLE my_table;

-- Delete the tablespace.
gaussdb=# DROP TABLESPACE tbs_data1;
```

Helpful Links

[ALTER MATERIALIZED VIEW](#), [CREATE MATERIALIZED VIEW](#), [CREATE TABLE](#), [DROP MATERIALIZED VIEW](#), [REFRESH INCREMENTAL MATERIALIZED VIEW](#), and [REFRESH MATERIALIZED VIEW](#)

7.12.8.25 CREATE INDEX

Description

Defines a new index.

Indexes are primarily used to enhance database performance (though inappropriate use can result in database performance deterioration). You are advised to create indexes on:

- Columns that are often queried
- Join conditions. For a query on joined columns, you are advised to create a composite index on the columns. For example, for **select * from t1 join t2 on t1.a=t2.a and t1.b=t2.b**, you can create a composite index on columns **a** and **b** in table **t1**.
- Columns having filter criteria (especially scope criteria) of a WHERE clause.
- Columns that appear after ORDER BY, GROUP BY, and DISTINCT

Partitioned tables do not support partial index creation (when indexes contain the GLOBAL or LOCAL keyword or the created index is a GLOBAL index). If the GLOBAL/LOCAL keyword is declared during index creation, the index of the corresponding type is created. If the partition name is specified during index creation, a LOCAL index is created. If the index is a unique index, the index must contain a partition key. In this case, a local index is created. Otherwise, a global index is created by default.

Precautions

- If the base table is a hash-distributed table, to create a primary key or unique index that does not contain the distribution key of the base table, use a GSI (using CREATE GLOBAL INDEX); to create a primary key or unique index that contains the distribution key of the base table, use a common index (using CREATE INDEX). In single-DN deployment mode, both the GSI and common index can be successfully created. If the base table is a non-hash-distributed table, you can only create the primary key or unique index as a common index (using CREATE INDEX). That is, the index key must contain the distribution key of the base table.
- Indexes consume storage and computing resources. Creating too many indexes has negative impact on database performance (especially the performance of data import. Therefore, you are advised to import the data before creating indexes). Therefore, create indexes only when they are necessary.
- All functions and operators used in an index definition must be immutable, that is, their results must depend only on their parameters and never on any outside influence (such as the contents of another table or the current time). This restriction ensures that the behavior of the index is well-defined. To use a

user-defined function in an index or WHERE clause, mark it as an immutable function.

- Partitioned table indexes are classified into local indexes and global indexes. A local index binds to a specific partition, and a global index corresponds to the entire partitioned table.
- A user granted with the CREATE ANY INDEX permission can create indexes in both the public and user schemas.
- If the base table is distributed in HASH, RANGE, or LIST mode, the distribution key of the base table must be included when a unique index is created, and no expression is allowed.
- If a user-defined function is called in the expression index, the expression index function is executed based on the permission of the function creator.
- Data of the XML type cannot be used as common indexes, unique indexes, global indexes, local indexes, or partial indexes.
- Only B-tree and UB-tree indexes can be created online. Only common indexes of non-partitioned tables, as well as global and local indexes of partitioned tables can be created. PCR UB-tree indexes, level-2 partitions, and GSIs are not supported. Only common indexes, global indexes, and local indexes of Astore and Ustore can be created online in parallel.

Syntax

- **Create an index on a table.**

```
CREATE [ UNIQUE ] INDEX [ CONCURRENTLY ] [ IF NOT EXISTS ] [ [schema_name.] index_name ]
ON table_name [ USING method ]
    ( ( { column_name [ ( length ) ] | ( expression ) } [ COLLATE collation ] [ opclass ] [ ASC | DESC ]
    [ NULLS { FIRST | LAST } } ], ... )
    [ INCLUDE ( column_name [, ...] ) ]
    [ WITH ( { storage_parameter = value } [, ...] ) ]
    [ TABLESPACE tablespace_name ]
    { [ COMMENT 'string' ] [ ... ] }
    [ { VISIBLE | INVISIBLE } ]
    [ WHERE predicate ];
```
- **Create an index on a partitioned table.**

```
CREATE [ UNIQUE ] INDEX [ CONCURRENTLY ] [ [schema_name.] index_name ] ON table_name
[ USING method ]
    ( ( { column_name [ ( length ) ] | ( expression ) } [ COLLATE collation ] [ opclass ] [ ASC | DESC ]
    [ NULLS LAST } ], ... )
    [ LOCAL
        [ ( { PARTITION index_partition_name [ FOR { partition_name | ( partition_value [, ...] ) } ]
        [ TABLESPACE index_partition_tablespace ]
            [ ( [SUBPARTITION index_subpartition_name] [ FOR { partition_name | ( partition_value
            [, ...] ) } ] [ TABLESPACE index_partition_tablespace ]
                [, ...] ) ]
                [, ...] ) ]
            [, ...] ) ]
        | GLOBAL ]
    [ INCLUDE ( column_name [, ...] ) ]
    [ WITH ( { storage_parameter = value } [, ...] ) ]
    [ TABLESPACE tablespace_name ]
    { [ COMMENT 'string' ] [ ... ] }
    [ { VISIBLE | INVISIBLE } ];
```

Parameters

- **UNIQUE**
 Creates a unique index. In this way, the system checks whether new values are unique in the index column. Attempts to insert or update data which would result in duplicate entries will generate an error.

Currently, only B-tree indexes and UB-tree indexes in row-store tables support unique indexes.

- **CONCURRENTLY**

Creates an index (with ShareUpdateExclusiveLock) in a mode that does not block DML statements. When an index is created, other statements cannot access the table on which the index depends. If this keyword is specified, DML is not blocked during the creation.

- This option can only specify a name of one index.
- The CREATE INDEX statement can be run within a transaction, but CREATE INDEX CONCURRENTLY cannot.
- For temporary tables, you can use CONCURRENTLY to create indexes. However, indexes are created in blocking mode because no other sessions concurrently access the temporary tables and the blocking mode is more cost-effective.

 NOTE

- This keyword is specified when an index is created. The Astore needs to scan the entire table twice to build it. During the first scan, an index is created and the read and write operations are not blocked. During the second scan, changes that have occurred since the first scan are merged and updated. The Ustore needs to scan the entire table only once. During the scan, the data generated by concurrent DML operations is inserted into the temporary table **index_oid_cctmp**. After the scan is complete, the data in the temporary table is merged to the primary index and the temporary table is deleted, the index is created. You can use the GUC parameter **delete_cctmp_table** to specify whether to delete temporary tables after indexes are created online. The default value of this parameter is **on**, indicating that temporary tables are deleted by default. If this parameter is set to **off**, temporary tables are retained.
- For Astore, the table needs to be scanned and built twice, and all existing transactions that may modify the table must be completed. This means that the creation of the index takes a longer time than normal. In addition, the CPU and I/O consumption also affects other services. Although the Ustore only needs to scan the entire table once to create indexes, the preceding consumption also exists.
- Exceptions may occur during online index creation (for example, manual cancellation, duplicate index key values, insufficient resources, thread startup failure, and lock timeout). As a result, online index creation fails. In this case, indexes in the **not valid** state may be retained to avoid occupying system resources, the system automatically clears the failed index. Before clearing the failed index, wait until the transaction in the table ends. If a long transaction exists, the system may keep waiting. If you cancel the thread, the failed index remains. If the user cancels the online index creation thread, the process of clearing the failed index is started first. If the user cancels the thread again, the process of clearing the failed index is ended, and the failed index remains. For critical errors, such as FATAL, PANIC, and database faults, you need to manually clear indexes and temporary tables. If both online index creation and automatic residual clearing fail, indexes that are not valid are retained. The residual indexes may be ready or not ready (depending on the phase in which the online index creation fails. For example, the index failed in the first phase is not ready, and the index failed in the third phase is ready). If the residual indexes are ready, the DML statements still maintain the residual indexes. During the maintenance, other errors may occur (for example, the size of the index column exceeds the maximum value or the unique index constraint is violated). To prevent residual indexes from occupying system resources and generating unexpected errors, you need to manually delete them as soon as possible. In the distributed system, failed indexes in DNs are automatically cleared and those in CNs need to be manually cleared. If a critical error occurs, the metadata of the failed indexes cannot be found on some nodes in the distributed system. The DROP INDEX statement cannot be used to delete these indexes. You need to use the DROP INDEX IF EXISTS statement to delete them.
- For Astore, after the second scan, index creation must wait for any transaction that holds a snapshot earlier than the snapshot taken by the second scan to terminate. In addition, the ShareUpdateExclusiveLock (level 4) added during index creation conflicts with a lock whose level is greater than or equal to 4. Therefore, when such an index is created, the system is prone to hang or deadlock. Example:
 - If two sessions create an index by using CONCURRENTLY for the same table, a deadlock occurs.
 - If a session creates an index by using CONCURRENTLY for a table and another session drops a table, a deadlock occurs.
 - There are three sessions. Session 1 locks table **a** and does not commit it. Session 2 creates an index by using CONCURRENTLY for table **b**. Session 3 writes data to table **a**. Before the transaction of session 1 is committed, session 2 is blocked.
 - When an index is created by using CONCURRENTLY for a table concurrently with the TRUNCATE operation on the same table, a deadlock occurs.

- The transaction isolation level is set to repeatable read (read committed by default). Two sessions are started. Session 1 writes data to table **a** and does not commit it. Session 2 creates an index by using CONCURRENTLY for table **b**. Before the transaction of session 1 is committed, session 2 is blocked.
 - When an index is being created or fails to be created, you need to check the index progress or status. You can query the `gs_get_index_status('schema_name', 'index_name')` function to check the index status on all nodes. The input parameters **schema_name** and **index_name** are used to specify the index schema name and index name, respectively. The return values are **node_name**, **indisready**, and **indisvalid**, indicating the node name, whether the index can be inserted on the node, and whether the index is available on the node. The index is available only when **indisready** and **indisvalid** on all nodes are set to **true**; otherwise, wait until the index creation is complete. If the index fails to be created, delete the index and create it again.
 - When the I/O and CPU resources are not limited, the service performance deterioration caused by online index creation can be controlled within 10%. However, in special scenarios, the service performance deterioration may exceed 10%. This is because online index creation is a long transaction that consumes a large number of I/O and CPU resources. It consumes more resources than offline index creation. The longer the online index creation transaction lasts, the greater the impact on service performance. The time for creating indexes online is positively correlated with the data volume of base tables and the data volume generated by concurrent DML statements. When the I/O and CPU resources are not limited, the time for creating indexes online is about two to six times that for creating indexes offline. However, when the number of concurrent transactions is large (> 10000 TPS) or resource contention occurs, the time may be even longer. If a long transaction exists during online index creation, the long transaction running time must be added. In Astore and Ustore modes, you can create indexes in parallel to shorten the index creation time. The performance of online parallel index creation increases to a certain value and becomes stable as the number of parallel worker threads increases. Compared with the performance of creating indexes in serial mode, the performance of creating indexes in parallel online is improved by about 30%. You are advised to create indexes online during off-peak hours to avoid great impact on services. In addition, do not execute long transactions during online index creation. Although online index creation provides the capability of uninterrupted services to some extent, it still needs to be implemented with caution.
 - When a unique index is created online (by using CREATE UNIQUE INDEX CONCURRENTLY), the table is scanned to check whether the data in the table is unique. If the data in the table is not unique, an error is reported and the online index creation exits. During online index creation, whether data in the table is unique may change. Whether the creation fails depends on whether duplicate data is scanned. Consider the following situations: 1. Tuple A and tuple B are inserted during table scanning, and their index columns are the same. If both tuple A and tuple B are scanned during online index scanning, a uniqueness violation may be reported. However, if tuple B is deleted later, in this case, an error may be reported during online index creation, indicating that the uniqueness is violated. However, after the online index creation fails and exits, the data in the table is found to be unique. 2. During online index creation, if tuple A is inserted, deleted, and then inserted, and SnapshotNow is used to scan the table, tuple A may be scanned twice, which may violate the uniqueness constraint. During online index creation, Astore uses SnapshotMVCC to scan tables, and Ustore uses SnapshotNow to scan tables.
- **IF NOT EXISTS**
- When IF NOT EXISTS is specified, the system checks whether a relationship with the same name already exists in the current schema before creating an index. It is not created and a NOTICE is returned if a relationship with the same name already exists. When IF NOT EXISTS is not specified and a relationship with the same name exists in the schema, an ERROR is returned.

- **schema_name**
Specifies the schema name.
Value range: an existing schema name
- **index_name**
Specifies the name of the index to be created. No schema name can be included here; the index is always created in the same schema as its parent table.
Value range: a string. It must comply with the [naming convention](#).
- **table_name**
Specifies the name of the table to be indexed (optionally schema-qualified).
Value range: an existing table name
- **USING method**
Specifies the name of the index method to be used.
Value range:
 - **btree**: B-tree indexes store key values of data in a B+ tree structure. This structure helps users to quickly search for indexes. B-tree is applicable to comparison query and range query.
 - **ubtree**: Multi-version B-tree index used only for Ustore tables. The index page contains transaction information and can be recycled. By default, the INSERTPT function is enabled for UB-tree indexes.Row-store tables (Astore storage engine) support the following index types: **btree** (default). Row-store tables (Ustore storage engine) support the following index type: **ubtree**.

NOTICE

B-tree and UB-tree are closely related to the table storage type Astore or Ustore. When an index is created, if the specified index type does not correspond to the main table, the index type is automatically converted.

-
- **column_name**
Specifies the name of the column on which an index is to be created.
Multiple columns can be specified if the index method supports multi-column indexes. A global index supports a maximum of 31 columns, and other indexes support a maximum of 32 columns.
 - **column_name (length)**
Creates a prefix key index based on a column in the table. **column_name** indicates the column name of the prefix key, and **length** indicates the prefix length.
The prefix key uses the prefix of the specified column data as the index key value, which reduces the storage space occupied by the index. Indexes can be used for partial filter and join conditions that contain prefix key columns.

 **NOTE**

- The prefix key supports the following index methods: B-tree and UB-tree.
- The data type of the prefix key column must be binary or character (excluding special characters).
- The prefix length must be a positive integer that does not exceed 2676 and cannot exceed the maximum length of the column. For the binary type, the prefix length is measured in bytes. For non-binary character types, the prefix length is measured in characters. The actual length of the key value is restricted by the internal page. If a column contains multi-byte characters or an index has multiple keys, the length of the index line may exceed the upper limit. As a result, an error is reported. Consider this situation when setting a long prefix length.
- In the CREATE INDEX syntax, the following keywords cannot be used as prefix keys for column names: COALESCE, EXTRACT, GREATEST, LEAST, LNNVL, NULLIF, NVL, NVL2, OVERLAY, POSITION, REGEXP_LIKE, SUBSTRING, TIMESTAMPDIFF, TREAT, TRIM, XMLCONCAT, XMLELEMENT, XMLEXISTS, XMLFOREST, XMLPARSE, XMLPI, XMLROOT and XMLSERIALIZE.
- The prefix key is a special expression key. Some constraints and restrictions that are not described are the same as those of the expression key. For details, see the description of the expression index.
- As an expression index, the prefix index is the same as the expression index and cannot be used as the unique index or primary key in distributed mode.

- **expression**

Specifies an expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses can be omitted if the expression has the form of a function call.

Expression can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on upper(col) would allow the WHERE upper(col) = 'JIM' clause to use an index.

If an expression contains the IS NULL clause, the index for this expression is invalid. In this case, you are advised to create a partial index.

- **COLLATE collation**

Assigns a collation to the column (which must be of a collatable data type). If no collation is specified, the default collation is used. You can run the **SELECT * FROM pg_collation** command to query collation rules from the pg_collation system catalog. The default collation rule is the row starting with **default** in the query result.

 **NOTE**

In MySQL-compatible mode (that is, **sql_compatibility** set to 'MYSQL'), when the MySQL compatible collation is used, ensure that the index collation is the same as the column collation. Otherwise, the index fails to be created and an error is reported.

- **opclass**

Specifies the name of an operator class. An operator class can be specified for each column of an index. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on the type int4 would use int4_ops; this operator class includes comparison functions for values of type int4. In practice, the default operator class for the column's data type is sufficient. The operator class applies to data with multiple sorts. For example, users might want to sort a complex-number data type either by absolute value or by real part. They could do this by defining two operator

classes for the data type and then selecting the proper class when making an index.

- **ASC**
Specifies an ascending (default) sort order.
- **DESC**
Specifies a descending sort order.
- **NULLS FIRST**
Specifies that null values appear before non-null values in the sort ordering. This is the default when **DESC** is specified.
- **NULLS LAST**
Specifies that null values appear after non-null values in the sort ordering. This is the default when **DESC** is not specified.
- **LOCAL**
Specifies that the partitioned index to be created is a local index.
- **GLOBAL**
Specifies the partitioned index to be created as a global index. If no keyword is specified, a global index is created by default.
- **INCLUDE (column_name [, ...])**
The optional INCLUDE clause specifies that some non-key columns are included in indexes. Non-key columns cannot be used as search criteria for accelerating index scans, and they are omitted when the unique constraints of the indexes are checked.

An index-only scan can directly return content in the non-key columns without accessing the heap table corresponding to the indexes.

Exercise caution when adding non-key columns as INCLUDE columns, especially for wide columns. If the size of an index tuple exceeds the maximum size allowed by the index type, data insertion fails. Note that in any case, adding non-key columns to an index increases the space occupied by the index, which may slow down the search speed.

Currently, only UB-tree indexes access mode supports this feature. Non-key columns are stored in the index leaf tuple corresponding to the heap tuple and are not included in the tuple on the upper-layer index page.
- **PARTITION clause**
`PARTITION index_partition_name [FOR { partition_name | (partition_value [, ...]) }] [TABLESPACE index_partition_tablespace]`

If **for partition_name** or **partition_value** is specified in the PARTITION clause, the created partitioned index has the sparsely partitioned index attribute. If **for partition_name** or **partition_value** is not specified, the number of PARTITION clauses must be the same as the number of partitions in the target table.

 NOTE

- The sparsely partitioned index can be created only on a single partition.
 - The sparsely partitioned index supports only B-tree and UB-tree indexes.
 - The sparsely partitioned index does not support the UNIQUE attribute.
 - Currently, the global index is not supported.
 - Currently, level-2 partitions are not supported.
 - The created sparsely partitioned index contains the **sparsely_partitioned=true** option. Note that the CREATE TABLE or ALTER TABLE statement cannot be used to explicitly specify a non-sparsely partitioned index as a sparsely partitioned index in this option. If the created index is a sparsely partitioned index, **sparsely_partitioned=false** will be ignored.
 - If a version earlier than 505.0.0 is upgraded to 505.0.0 or later, sparsely partitioned indexes cannot be created during upgrade observation.
- **PARTITION index_partition_name**
Specifies the name of an index partition.
Value range: a string. It must comply with the [naming convention](#).
 - **FOR partition_name**
Specifies the name of the target partition. If the specified partition does not exist, an error is reported.
 - **FOR (partition_value [, ...])**
Specifies the value of the specified partition key. The partition key value must be placed in the partition key value FOR list. If there are multiple columns of partition keys, multiple **partition_value** values must be specified.
 - **TABLESPACE index_partition_tablespace**
Specifies the tablespace of an index partition.
Value range: If this parameter is not specified, the value of **index_tablespace** is used.
 - **WITH ({storage_parameter = value} [, ...])**
Specifies the storage parameter used for an index.
Value range:
For indexes other than Psort, you can also set it to **FILLFACTOR**. Only UB-tree indexes support **INDEXSPLIT**. Only non-partitioned B-tree indexes support the **DEDUPLICATION** parameter. Only UB-tree indexes support **INDEX_TXNTYPE**.
 - **STORAGE_TYPE**
Storage engine type of the table where the index is located. If **storage_type** specified by the index conflicts with the index type, the storage engine type is automatically changed to the correct one. Only B-tree and UB-tree are supported. You cannot modify this parameter after it is set.
Value range: **USTORE**, indicating that the table where the index is located uses the in-place update storage engine. **ASTORE**: indicates that the table where the index is located is an append-only storage engine.
Default value: **USTORE** for Ustore tables and **ASTORE** for Astore tables.
 - **FILLFACTOR**

The fill factor of an index is a percentage from 10 to 100. In the scenario where a large number of concurrent insertions are performed and the key value range is dense, the contention of the same index page is high during the insertion. Therefore, a smaller fill factor is more appropriate.

Value range: 10–100

– ACTIVE_PAGES

Specifies the number of index pages, which may be less than the actual number of physical file pages and can be used for optimization. Currently, this parameter is valid only for the local index of the Ustore partitioned table and will be updated by VACUUM and ANALYZE (including AUTOVACUUM). You are advised not to manually set this parameter because it is invalid in distributed mode.

– DEDUPLICATION

Specifies whether to deduplicate and compress tuples with duplicate key values. This is an index parameter. When there are a large number of indexes with duplicate key values, enabling this parameter can effectively reduce the space occupied by indexes. This parameter does not take effect for primary key indexes and unique indexes. If non-unique indexes are used and the index key value duplication rate is low or the index key values are unique, enabling this parameter will slightly deteriorate the index insertion performance. Currently, local and global indexes of partitioned tables are not supported.

Value range: Boolean value. The default value is the value of the **enable_default_index_deduplication** GUC parameter (the default value is **off**).

– INDEXSPLIT

Specifies the splitting policy of UB-tree indexes. The **DEFAULT** policy is the same as the splitting policy of B-tree indexes. The **INSERTPT** policy can significantly reduce the index space usage in some scenarios.

Value range: **INSERTPT** and **DEFAULT**

Default value: **INSERTPT**

– INDEX_TXNTYPE

Specifies the UB-tree index type (only UB-tree indexes support **INDEX_TXNTYPE**). When the value is **PCR**, flashback queries can be performed using UB-tree. PCR UB-tree indexes do not support online index creation, GSIs, ultimate RTO replay, and standby node read. If **INDEX_TXNTYPE** is not specified, the GUC parameter **index_txntype** specifies the type of the index to be created. **INDEX_TXNTYPE** cannot be modified by using ALTER INDEX INDEX_NAME SET (INDEX_TXNTYPE=PCR or RCR).

Type: character string (case insensitive)

Value range: **RCR** and **PCR**

Default value: **RCR**

For example:

```
CREATE UNIQUE INDEX t2_b_pkey ON t(b) WITH(index_txntype='pcr');
```

– STAT_STATE

Determines whether index statistics are locked. If locked, the index statistics cannot be updated. This parameter is invalid in distributed mode.

Value range: **locked** and **unlock**.

Default value: **unlock**.

– enable_tde

Specifies whether the index is encrypted. If the index is encrypted, the database automatically encrypts the data in the encrypted index before storing it. Before using this parameter, ensure that the TDE function has been enabled using the GUC parameter **enable_tde**, the information for accessing the key service has been set using the GUC parameter **tde_key_info**, and the **enable_tde** attribute has been set for the base table. For details about how to use this parameter, see section "Transparent Data Encryption" in *Feature Guide*. This parameter supports only B-tree and UB-tree indexes. Other indexes such as hash indexes are not supported.

Value range: **on** and **off** If **enable_tde** is set to **on**, the values of **key_type**, **tde_cmek_id**, and **dek_cipher** are automatically generated in the database.

Default value: **off**

– encrypt_algo

Specifies the encryption algorithm of the encryption index. This parameter must be used together with **enable_tde**.

Value range: a string. The value can be **AES_128_CTR** or **SM4_CTR**.

Default value: null if **enable_tde** and **AES_128_CTR** if **enable_tde** is set.

– dek_cipher

Specifies the DEK ciphertext. After you set the **enable_tde** parameter for an index, the index automatically copies the **dek_cipher** parameter of the base table. This parameter cannot be set or modified.

Value range: a string

Default value: null

– key_type

Specifies the type of the master key. After you set the **enable_tde** parameter for a table, the index automatically copies the **key_type** parameter of the base table. This parameter cannot be set or modified.

Default value: null

– cmek_id

Specifies the ID of the master key. After you set the **enable_tde** parameter for a table, the index automatically copies the **cmek_id** parameter of the base table. This parameter cannot be set or modified.

Value range: a string

Default value: null

– LPI_PARALLEL_METHOD

Index parameter, which is used to set the parallel creation mode of local indexes for partitioned tables.

Type: String

Value range: **PAGE**, **PARTITION**, and **AUTO PAGE** creates indexes for pages in parallel. Multiple subthreads are started to scan and sort data. Each subthread processes a data page at a time. After scanning and sorting, the main thread combines the sorting results in serial mode and inserts tuples into the indexes. **PARTITION** concurrently creates indexes at the partition level and starts multiple subthreads. Each subthread scans, sorts, and inserts indexes into a partition. **AUTO** estimates the cost of parallel index creation at the page level and partition level based on the partitioned table statistics, and selects the parallel index creation mode with a lower cost. (The statistics may be different from the actual data, resulting in inaccurate calculation results.)

Default value: **PAGE**

Setting suggestion: Set this parameter to **PARTITION** if the partitioned table data is evenly distributed in each partition. This parameter supports only the B-tree local index of Astore partitioned tables. It does not support the global index of partitioned tables, non-partitioned table indexes, segment-page table indexes, hash bucket table indexes, or online index creation.

For example:

```
CREATE INDEX idx ON tbl(col) WITH (lpi_parallel_method = 'partition');
```

- **TABLESPACE *tablespace_name***

Specifies the tablespace for an index. If no tablespace is specified, the default tablespace is used.

Value range: an existing table name

- **WHERE *predicate***

Creates a partial index. A partial index is an index that contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small fraction of the total table and yet that is an often used portion, you can improve performance by creating an index on just that portion. In addition, the WHERE clause with a UNIQUE constraint can be used to enforce uniqueness over a subset of a table.

Value range: The predicate expression can only refer to columns of the underlying table, but it can use all columns, not just the ones being indexed. Currently, subqueries and aggregate expressions are forbidden in WHERE. You are advised not to use numeric types such as int for predicate, because such types can be implicitly converted to bool values (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.

For a partitioned table index, if the created index contains the GLOBAL keyword or the created index is a GLOBAL index, the WHERE clause cannot be used to create an index.

- **COMMENT '*string*'**

COMMENT '*string*' is used to add comments to an index.

NOTICE

- This parameter is valid only in a MySQL-compatible database (that is, **sql_compatibility** set to 'MYSQL').
- An index-level comment can contain a maximum of 1024 characters.

VISIBLE

Sets the index to be visible. This is the default option.

 **NOTE**

- **VISIBLE** can be set only in an ORA-compatible database (that is, **sql_compatibility** set to 'ORA').
 - When **disable_keyword_options** is set to "visible", this keyword cannot be used.
 - This keyword is not supported in the upgrade uncommitted phase.
- **INVISIBLE**
- Sets the index to be invisible.

 **NOTE**

- **INVISIBLE** can be set only in an ORA-compatible database (that is, **sql_compatibility** set to 'ORA').
- When **disable_keyword_options** is set to "invisible", this keyword cannot be used.
- This keyword is not supported in the upgrade uncommitted phase.

Examples

- **Common index**

```
-- Create the tbl_test1 table.
gaussdb=# CREATE TABLE tbl_test1(
  id int,      -- User ID
  name varchar(50), -- Username
  postcode char(6) -- Postal code
);

-- Create the tbs_index1 tablespace.
gaussdb=# CREATE TABLESPACE tbs_index1 RELATIVE LOCATION 'test_tablespace/tbs_index1';

-- Create the idx_test1 index for the tbl_test1 table and specify a tablespace.
gaussdb=# CREATE INDEX idx_test1 ON tbl_test1(name) TABLESPACE tbs_index1;

-- Query information about the idx_test1 index.
gaussdb=# SELECT indexname,tablename,tablespace FROM pg_indexes WHERE indexname =
'idx_test1';
indexname | tablename | tablespace
-----+-----+-----
idx_test1 | tbl_test1 | tbs_index1
(1 row)

-- Delete the index.
gaussdb=# DROP INDEX idx_test1;

-- Delete the tablespace.
gaussdb=# DROP TABLESPACE tbs_index1;
```

- **Unique index**

```
-- Create the unique index idx_test2 for the tbl_test1 table.
gaussdb=# CREATE UNIQUE INDEX idx_test2 ON tbl_test1(id);

-- Query index information.
gaussdb=# \d tbl_test1
```

```

Table "public.tbl_test1"
Column | Type          | Modifiers
-----+-----+-----
id      | integer       |
name    | character varying(50) |
postcode | character(6)  |
Indexes:
    "idx_test2" UNIQUE, btree (id) TABLESPACE pg_default

-- Delete the index.
gaussdb=# DROP INDEX idx_test2;

```

- **Expression index**

```

-- Create an expression index for the tbl_test1 table.
gaussdb=# CREATE INDEX idx_test3 ON tbl_test1(substr(postcode,2));

-- Query index information.
gaussdb=# \d tbl_test1
Table "public.tbl_test1"
Column | Type          | Modifiers
-----+-----+-----
id      | integer       |
name    | character varying(50) |
postcode | character(7)  |
Indexes:
    "idx_test3" btree (substr(postcode::text, 2)) TABLESPACE pg_default

-- Delete the index.
gaussdb=# DROP INDEX idx_test3;

```

- **Partial index**

```

-- Create an index for data whose ID is not empty in the tbl_test1 table.
gaussdb=# CREATE INDEX idx_test4 ON tbl_test1(id) WHERE id IS NOT NULL;

-- Delete the index.
gaussdb=# DROP INDEX idx_test4;

-- Delete the table.
gaussdb=# DROP TABLE tbl_test1;

```

- **Partitioned index**

```

-- Create a table.
gaussdb=# CREATE TABLE student(id int, name varchar(20)) PARTITION BY RANGE (id) (
    PARTITION p1 VALUES LESS THAN (200),
    PARTITION pmax VALUES LESS THAN (MAXVALUE)
);

-- Create a local partitioned index without specifying the index partition name.
gaussdb=# CREATE INDEX idx_student1 ON student(id) LOCAL;

-- Check the index partition information. It is found that the number of local index partitions is the
same as the number of table partitions.
gaussdb=# SELECT relname FROM pg_partition WHERE parentid = 'idx_student1'::regclass;
 relname
-----
p1_id_idx
pmax_id_idx
(2 rows)

-- Delete the local partitioned index.
gaussdb=# DROP INDEX idx_student1;

-- Create a global index.
gaussdb=# CREATE INDEX idx_student2 ON student(name) GLOBAL;

-- Check the index partition information. It is found that the number of global index partitions is
different from the number of table partitions.
gaussdb=# SELECT relname FROM pg_partition WHERE parentid = 'idx_student2'::regclass;
 relname
-----
(0 rows)

```

```
-- Delete the global partitioned index.
gaussdb=# DROP INDEX idx_student2;

-- Create a local expression index without specifying the index partition name.
gaussdb=# CREATE INDEX idx_student3 ON student(lower(name)) LOCAL;

-- Check the index partition information. It is found that the number of local index partitions is the
same as the number of table partitions.
gaussdb=# SELECT relname FROM pg_partition WHERE parentid = 'idx_student3'::regclass;
 relname
-----
p1_id_idx
pmax_id_idx
(2 rows)

-- Delete the expression index of the LOCAL partition.
gaussdb=# DROP INDEX idx_student3;

-- Create a global expression index.
gaussdb=# CREATE INDEX idx_student4 ON student(lower(name)) GLOBAL;

-- Check the index partition information. It is found that the number of global expression index
partitions is different from the number of table partitions.
gaussdb=# SELECT relname FROM pg_partition WHERE parentid = 'idx_student4'::regclass;
 relname
-----
(0 rows)

-- Delete the expression index of the global partition.
gaussdb=# DROP INDEX idx_student4;

-- Delete the table.
gaussdb=# DROP TABLE student;
```

Helpful Links

[ALTER INDEX](#) and [DROP INDEX](#)

Suggestions

- create index
Constraints:
 - An index of an ordinary table supports a maximum of 32 columns. A GLOBAL index of a partitioned table supports a maximum of 31 columns.
 - The size of a single index cannot exceed the size of the index page (8 KB). The size of a B-tree or UB-tree index cannot exceed one-third of the page size.
 - Partial indexes cannot be created in a partitioned table.
 - When a GLOBAL index is created on a partitioned table, the following constraints apply:
 - Expression indexes and partial indexes are not supported.
 - Only B-tree indexes are supported.
 - In the same attribute column, the local index and global index of a partition cannot coexist.
 - If the ALTER statement does not contain UPDATE GLOBAL INDEX, the original global index is invalid. In this case, other indexes are used for

query. If the ALTER statement contains UPDATE GLOBAL INDEX, the original global index is still valid and the index function is correct.

7.12.8.26 CREATE LANGUAGE

This version does not support this syntax.

7.12.8.27 CREATE MASKING POLICY

Description

Creates a masking policy.

Precautions

- Only users with the poladmin or sysadmin permission, or the initial user can perform this operation.
- The masking policy takes effect only after the security policy is enabled, that is, **enable_security_policy** is set to **on**.

CAUTION

When you use database links to perform operations on remote objects, the client initiates a database link request. The actual sender is the server, and the attributes such as the IP address of the sender are the values of the server. For details, see [DATABASE LINK](#).

Syntax

```
CREATE MASKING POLICY policy_name masking_clause[, ...] [ policy_filter_clause ] [ENABLE | DISABLE];
```

- **masking_clause**
masking_function ON LABEL(label_name[, ...])
- **masking_function**
maskall is not a preset function and cannot be displayed by running `\df`.
The masking methods during presetting are as follows:
{ maskall | randommasking | creditcardmasking | basicemailmasking | fullemailmasking | shufflemasking | alldigitsmasking | regexpmasking }
- **policy_filter_clause**:
FILTER ON { FILTER_TYPE (filter_value [, ...]) } [, ...]
- **FILTER_TYPE**:
{ APP | ROLES | IP }

Parameters

- **policy_name**
Specifies the masking policy name, which must be unique.
Value range: a string. It must comply with the [naming convention](#).
- **label_name**
Specifies the resource label name.

- **masking_clause**
Specifies the masking function to be used to anonymize database resources labeled by **label_name**. **schema.function** can be used to specify the masking function.
- **policy_filter**
Specifies the users for which the masking policy takes effect. If this parameter is left empty, the masking policy takes effect for all users.
- **FILTER_TYPE**
Specifies the types of information to be filtered by the policy, including **IP**, **APP**, and **ROLES**.
- **filter_value**
Indicates the detailed information to be filtered, such as the IP address, app name, and username.
- **ENABLE|DISABLE**
Enables or disables the masking policy. If **ENABLE|DISABLE** is not specified, **ENABLE** is used by default.

Examples

- Create a masking policy using maskall. (All values of the character string type are masked as **x**, and other types are displayed as the default values of this type.)

```
-- Create table tb_for_masking.
gaussdb=# CREATE TABLE tb_for_masking(idx int, col1 text, col2 text, col3 text, col4 text, col5 text,
col6 text, col7 text,col8 text);

-- Insert data into the tb_for_masking table.
gaussdb=# INSERT INTO tb_for_masking VALUES(1, '9876543210', 'usr321usr', 'abc@huawei.com',
'abc@huawei.com', '1234-4567-7890-0123', 'abcdef 123456 ui 323 jsfd321 j3k2l3',
'4880-9898-4545-2525', 'this is a llt case');

-- View data.
gaussdb=# SELECT * FROM tb_for_masking;
idx | col1 | col2 | col3 | col4 | col5 | col6
    | col7 | col8
-----+-----+-----+-----+-----+-----+-----
1 | 9876543210 | usr321usr | abc@huawei.com | abc@huawei.com | 1234-4567-7890-0123 | abcdef
123456 ui 323 jsfd321 j
3k2l3 | 4880-9898-4545-2525 | this is a llt case
(1 row)

-- Create a resource label for sensitive column col1.
gaussdb=# CREATE RESOURCE LABEL mask_lb1 ADD COLUMN(tb_for_masking.col1);

-- Create a data masking policy named maskpol1.
gaussdb=# CREATE MASKING POLICY maskpol1 maskall ON LABEL(mask_lb1);

-- Access the tb_for_masking table. The masking policy is triggered for the col1 column.
gaussdb=# SELECT col1 FROM tb_for_masking;
col1
-----
xxxxxxxxx
(1 row)
```

- Create a data masking policy that uses randommasking to mask values of the character string type to random numbers. The masked values are different each time.

```
-- Create a resource label for sensitive column col2.
gaussdb=# CREATE RESOURCE LABEL mask_lb2 ADD COLUMN(tb_for_masking.col2);

-- Create a data masking policy named maskpol2.
gaussdb=# CREATE MASKING POLICY maskpol2 randommasking ON LABEL(mask_lb2);

-- Access the tb_for_masking table. The masking policy is triggered for the col2 column.
gaussdb=# SELECT col2 FROM tb_for_masking;
 col2
-----
0e8612d9a
(1 row)
```

- Create a data masking policy that uses basicemailmasking to set all data content before the at sign (@) in the mailbox format value of the character string type to **x**.

```
-- Create a resource label for sensitive column col3.
gaussdb=# CREATE RESOURCE LABEL mask_lb3 ADD COLUMN(tb_for_masking.col3);

-- Create a data masking policy named maskpol3.
gaussdb=# CREATE MASKING POLICY maskpol3 basicemailmasking ON LABEL(mask_lb3);

-- Access the tb_for_masking table. The masking policy is triggered for the col3 column.
gaussdb=# SELECT col3 FROM tb_for_masking;
 col3
-----
xxx@huawei.com
(1 row)
```

- Create a data masking policy that uses fullemailmasking to retain only the at sign (@) and **.com** in the email address format of the character string type, and set other parameters to **x**.

```
-- Create a resource label for sensitive column col4.
gaussdb=# CREATE RESOURCE LABEL mask_lb4 ADD COLUMN(tb_for_masking.col4);

-- Create a data masking policy named maskpol4.
gaussdb=# CREATE MASKING POLICY maskpol4 fullemailmasking ON LABEL(mask_lb4);

-- Access the tb_for_masking table. The masking policy is triggered for the col4 column.
gaussdb=# SELECT col4 FROM tb_for_masking;
 col4
-----
xxx@xxxxxx.com
(1 row)
```

- Create a masking policy that uses creditcardmasking to retain the hyphen (-) and the last four digits for values of the string type, and set the rest to **x**.

```
-- Create a resource label for sensitive column col5.
gaussdb=# CREATE RESOURCE LABEL mask_lb5 ADD COLUMN(tb_for_masking.col5);

-- Create a data masking policy named maskpol5.
gaussdb=# CREATE MASKING POLICY maskpol5 creditcardmasking ON LABEL(mask_lb5);

-- Access the tb_for_masking table. The masking policy is triggered for the col5 column.
gaussdb=# SELECT col5 FROM tb_for_masking;
 col5
-----
xxxx-xxxx-xxxx-0123
(1 row)
```

- Create a data masking policy that uses shufflemasking to shuffle the positions of characters in the value of the character string type.

```
-- Create a resource label for sensitive column col6.
gaussdb=# CREATE RESOURCE LABEL mask_lb6 ADD COLUMN(tb_for_masking.col6);

-- Create a data masking policy named maskpol6.
gaussdb=# CREATE MASKING POLICY maskpol6 shufflemasking ON LABEL(mask_lb6);

-- Access the tb_for_masking table. The masking policy is triggered for the col6 column.
```

```
gaussdb=# SELECT col6 FROM tb_for_masking;
          col6
-----
2 b6jusfd54c3312 13d23lk3jf3 2eai
(1 row)
```

- Create a masking policy that uses `regexprmasking` to mask values of the string type using regular expressions.

```
-- Create a resource label for sensitive column col7.
gaussdb=# CREATE RESOURCE LABEL mask_lb7 ADD COLUMN(tb_for_masking.col7);

-- Create a data masking policy named maskpol7.
gaussdb=# CREATE MASKING POLICY maskpol7 regexprmasking('[\d+]','*',2, 9) ON LABEL(mask_lb7);

-- Access the tb_for_masking table. The masking policy is triggered for the col7 column.
gaussdb=# SELECT col7 FROM tb_for_masking;
          col7
-----
48**_****_*545-2525
(1 row)
```

- Create a masking policy that takes effect only for scenarios where users are `dev_mask` and `bob_mask`, the client tool `gsqL` is used, and IP addresses are `172.31.17.160` and `127.0.0.0/24`.

```
-- Create users dev_mask and bob_mask.
gaussdb=# CREATE USER dev_mask PASSWORD '*****';
gaussdb=# CREATE USER bob_mask PASSWORD '*****';

-- Create a resource label for sensitive column col8.
gaussdb=# CREATE RESOURCE LABEL mask_lb8 ADD COLUMN(tb_for_masking.col8);

-- Create a data masking policy named maskpol8.
gaussdb=# CREATE MASKING POLICY maskpol8 randommasking ON LABEL(mask_lb8) FILTER ON
ROLES(dev_mask, bob_mask), APP(gsqL), IP('172.31.17.160', '127.0.0.0/24');

-- Access the tb_for_masking table. The masking policy is triggered for the col8 column.
gaussdb=# SELECT * FROM tb_for_masking;

-- Use the gsqL tool, set the IP address to 172.31.17.160, and view tb_for_masking as user dev_mask.
gaussdb=# GRANT ALL PRIVILEGES TO dev_mask;

-- Use maskpol8 for data masking. The result is random and different each time.
gaussdb=# SELECT col8 FROM tb_for_masking;
          col8
-----
cf32a9aa427f219ab0
(1 row)

gaussdb=# SELECT col8 FROM tb_for_masking;
          col8
-----
13efa056dda1e1a474
(1 row)
```

- Delete data.

```
-- Delete a masking policy.
gaussdb=# DROP MASKING POLICY maskpol1, maskpol2, maskpol3, maskpol4, maskpol5, maskpol6,
maskpol7, maskpol8;

-- Delete a resource label.
gaussdb=# DROP RESOURCE LABEL mask_lb1, mask_lb2, mask_lb3, mask_lb4, mask_lb5, mask_lb6,
mask_lb7, mask_lb8;

-- Delete the tb_for_masking table.
gaussdb=# DROP TABLE tb_for_masking;

-- Delete the dev_mask and bob_mask users.
gaussdb=# DROP USER dev_mask, bob_mask;
```

7.12.8.28 CREATE MATERIALIZED VIEW

CREATE MATERIALIZED VIEW creates a complete-refresh materialized view, and you can use REFRESH MATERIALIZED VIEW (full refresh) to refresh the data in the materialized view.

CREATE MATERIALIZED VIEW is similar to CREATE TABLE AS, but it remembers the query used to initialize the view, so it can refresh data later. A materialized view has many attributes that are the same as those of a table, but does not support temporary materialized views.

Precautions

- Complete-refresh materialized views cannot be created in temporary tables or global temporary tables.
- Complete-refresh materialized views do not support NodeGroups.
- After a complete-refresh materialized view is created, most DDL operations in the base table are no longer supported.
- IUD operations cannot be performed on complete-refresh materialized views.
- After a complete-refresh materialized view is created, if the base table data changes, you need to run the refresh command to synchronize the materialized view with the base table.
- The Ustore engine does not support the creation and use of materialized views.
- The segment-page does not support the creation and use of materialized views.

Syntax

```
CREATE MATERIALIZED VIEW mv_name  
  [ (column_name [, ...] ) ]  
  [ WITH ( {storage_parameter = value} [, ...] ) ]  
  [ TABLESPACE tablespace_name ]  
  AS query  
  [ WITH [ NO ] DATA ];
```

Parameters

- **mv_name**
Name (optionally schema-qualified) of the materialized view to be created.
Value range: a string. It must comply with the [naming convention](#).
- **column_name**
Specifies a column name in the new materialized view. The materialized view supports specified columns. The number of specified columns must be the same as that of columns in the result of the subsequent query statement. If no column name is provided, the column name is obtained from the output column name of the query.
Value range: a string. It must comply with the [naming convention](#).

- **WITH (storage_parameter [= value] [, ...])**
Specifies an optional storage parameter for a table or an index. For details, see [CREATE TABLE](#).
- **TABLESPACE tablespace_name**
Tablespace to which the new materialized view belongs. If the tablespace is not specified, the default tablespace is used.
- **AS query**
A **SELECT**, **TABLE**, or **VALUES** command. This query will be run in a security-constrained operation.

Examples

```
-- Change the default table type.
gaussdb=# set enable_default_ustore_table=off;

-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_data1 RELATIVE LOCATION 'tablespace1/tbs_data1';

-- Create an ordinary table.
gaussdb=# CREATE TABLE my_table (c1 int, c2 int);

-- Create a complete-refresh materialized view.
gaussdb=# CREATE MATERIALIZED VIEW my_mv TABLESPACE tbs_data1 AS SELECT * FROM my_table;

-- Write data to the base table.
gaussdb=# INSERT INTO my_table VALUES(1,1),(2,2);

-- Query the complete-refresh materialized view.
gaussdb=# SELECT * FROM my_mv;
c1 | c2
----+----
(0 rows)

-- Completely refresh the complete-refresh materialized view my_mv.
gaussdb=# REFRESH MATERIALIZED VIEW my_mv;

-- Query the complete-refresh materialized view.
gaussdb=# SELECT * FROM my_mv;
c1 | c2
----+----
 1 |  1
 2 |  2
(2 rows)

-- Delete the complete-refresh materialized view.
gaussdb=# DROP MATERIALIZED VIEW my_mv;

-- Delete the ordinary table my_table.
gaussdb=# DROP TABLE my_table;

-- Delete the tablespace.
gaussdb=# DROP TABLESPACE tbs_data1;
```

7.12.8.29 CREATE MODEL

This syntax is not supported in distributed scenarios.

7.12.8.30 CREATE NODE

Function

Creates a cluster node.

Precautions

CREATE NODE is an API of the cluster management tool. You are advised not to use this API, because doing so affects the cluster. Only the administrator has the permission to use this API.

Syntax

```
CREATE NODE nodename WITH
(
  [ TYPE = nodetype,]
  [ HOST = hostname,]
  [ PORT = portnum,]
  [ HOST1 = 'hostname',]
  [ PORT1 = portnum,]
  [ HOSTPRIMARY [ = boolean ],]
  [ PRIMARY [ = boolean ],]
  [ PREFERRED [ = boolean ],]
  [ SCTP_PORT = portnum,]
  [ CONTROL_PORT = portnum,]
  [ SCTP_PORT1 = portnum,]
  [ CONTROL_PORT1 = portnum ]
);
```

Parameters

- **nodename**
Specifies the node name.
Value range: a string. It must comply with the [naming convention](#).
- **TYPE = nodetype**
Specifies the type of a node.
Value range:
 - 'coordinator'
 - 'datanode'
- **HOST = hostname**
Specifies the host name or IP address of a node.
- **PORT = portnum**
Specifies the port number of the primary node to which a node is bound.
- **HOST1 = hostname**
Specifies the name or IP address of the standby node corresponding to a node.
- **PORT1 = portnum**
Specifies the port number of the standby node to which a node is bound.
- **HOSTPRIMARY**
- **PRIMARY = boolean**

Specifies whether the node is a primary node or not. A primary node allows read/write operations. A non-primary node allows only read operations.

Value range:

- **true**
- **false** (default value)

- **PREFERRED = boolean**

Specifies whether the node is a preferred node for read operations.

Value range:

- **true**
- **false** (default value)

- **SCTP_PORT = portnum**

Specifies the port used by the TCP proxy communications library of the primary node to listen on the data transmission channel. TCP is used to listen on connections.

- **CONTROL_PORT = portnum**

Specifies the port used by the TCP proxy communications library of the primary node to listen on the control transmission channel. The TCP protocol is used to listen on connections.

- **SCTP_PORT1 = portnum**

Specifies the port used by the TCP proxy communications library of the standby node to listen on the data transmission channel. TCP is used to listen on connections.

- **CONTROL_PORT 1= portnum**

Specifies the port used by the TCP proxy communications library of the standby node to listen on the control transmission channel. The TCP protocol is used to listen on connections.

Examples

```
-- Create cluster nodes.
gaussdb=# CREATE NODE datanode1 WITH(
  TYPE = datanode,
  PREFERRED = false
);
gaussdb=# CREATE NODE datanode2 WITH(
  TYPE = datanode,
  PREFERRED = false
);

-- Query the initial cluster DN status.
gaussdb=# SELECT node_name, nodeis_preferred FROM pgxc_node WHERE node_type = 'D' ORDER BY 1;
 node_name | nodeis_preferred
-----+-----
 datanode1 | f
 datanode2 | f
(2 rows)

-- Set datanode1 as the preferred DN.
gaussdb=# ALTER NODE datanode1 WITH(preferred = true);
-- Query the cluster DN status after the change.
gaussdb=# SELECT node_name, nodeis_preferred FROM pgxc_node WHERE node_type = 'D' ORDER BY 1;
 node_name | nodeis_preferred
-----+-----
 datanode1 | t
```

```
datanode2 | f
(2 rows)

-- Delete nodes from the cluster.
gaussdb=# DROP NODE datanode1;
gaussdb=# DROP NODE datanode2;
```

Helpful Links

[ALTER NODE](#) and [DROP NODE](#)

7.12.8.31 CREATE NODE GROUP

Description

Creates a cluster node group.

Precautions

- CREATE NODE GROUP is an API of the cluster management tool.
- Only a system administrator has the permission.

Syntax

```
CREATE NODE GROUP groupname
WITH ( nodename [, ... ] )
[ BUCKETS [ ( bucketnumber [, ... ] ) ] ];
```

Parameters

- **groupname**
Specifies the name of a node group.
Value range: a string. It must comply with the [naming convention](#). A value can contain a maximum of 63 characters.

NOTE

A node group name supports all ASCII characters, but you are advised to name a node group according to the naming convention.

- **nodename**
Node name.
Value range: a string. It must comply with the [naming convention](#). A value can contain a maximum of 63 characters.
- **BUCKETS [(bucketnumber [, ...])]**
The BUCKETS clause is an internal use of the cluster management tool and can be called only during scale-out.

Examples

```
-- Query the initial cluster DN status.
gaussdb=# SELECT node_name, nodeis_preferred FROM pgxc_node WHERE node_type = 'D' ORDER BY 1;
node_name | nodeis_preferred
-----+-----
dn_6001_6002_6003 | f
dn_6004_6005_6006 | f
dn_6007_6008_6009 | f
```

```
(3 rows)
-- Create a node group and replace dn_6001_6002_6003 with the actual node name obtained in the
previous step.
gaussdb=# CREATE NODE GROUP test_group WITH ( dn_6001_6002_6003 );

-- Query the node group.
gaussdb=# SELECT group_name, group_members FROM pgxc_group;

-- Delete the node group.
gaussdb=# DROP NODE GROUP test_group;
```

Helpful Links

[ALTER NODE GROUP](#) and [DROP NODE GROUP](#)

7.12.8.32 CREATE PROCEDURE

Description

Creates a stored procedure.

Precautions

- If the parameters or return values of a stored procedure have precision, the precision is not checked.
- When creating a stored procedure, you are advised to explicitly specify the schemas of all operations on table objects in the stored procedure definition. Otherwise, the stored procedure may fail to be executed.
- When a stored procedure is created, a write lock is added only to the CREATE stored procedure, and a read lock is added only to the functions during compilation and execution.
- **current_schema** and **search_path** specified by SET during stored procedure creation are invalid. **search_path** and **current_schema** before and after function execution should be the same.
- When the function is called by SELECT or CALL, an argument must be provided in the output parameter. The argument does not take effect.
- Do not create an overloaded stored procedure with different parameter names but same stored procedure name and parameter list type.
- Do not create a stored procedure that has the same name and parameter list as the function.
- Do not overload stored procedures with different default values.
- Only the in, out, and inout parameters of the stored procedure cannot be reloaded after the GUC parameter **behavior_compat_options** is set to '**proc_outparam_override**'. They can be reloaded after the parameter is disabled.
- ORA-compatible functions are created for ORA-compatible databases and PG-compatible functions are created for PG-compatible databases. Hybrid creation is not recommended.
- When an overloaded stored procedure is called, the variable type must be specified.
- If an undeclared variable is used in a stored procedure, an error is reported when the stored procedure is called.

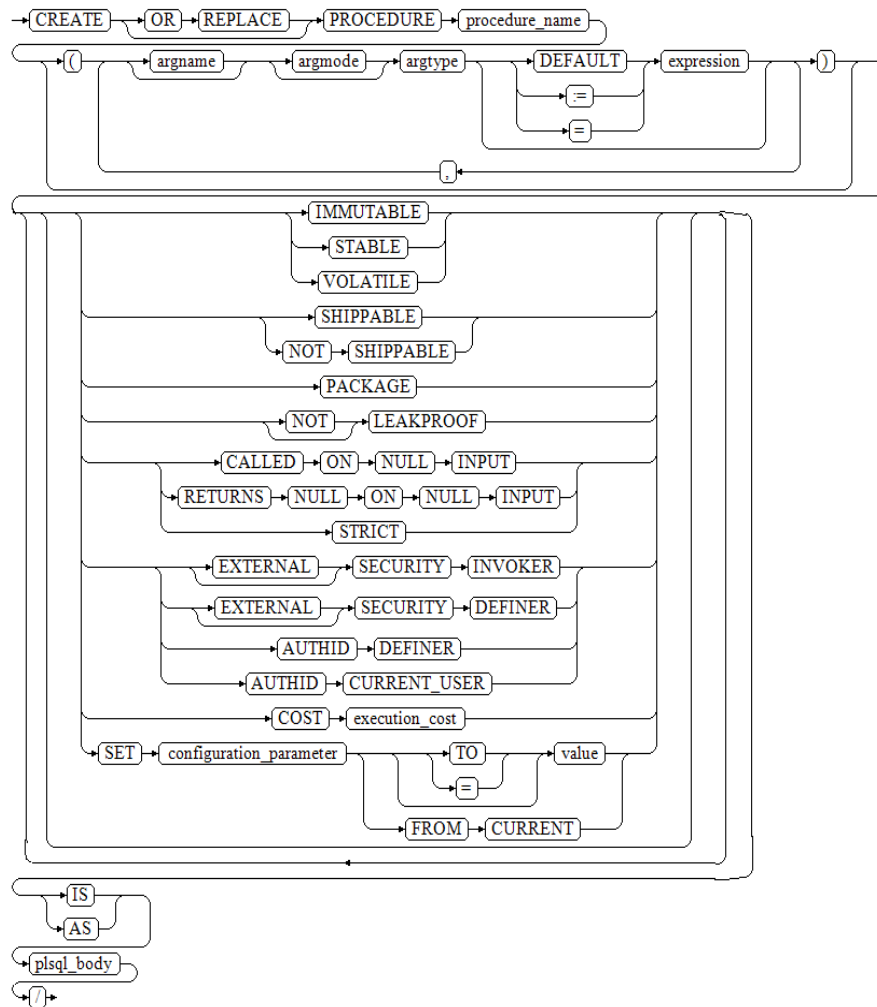

- When you create a procedure, you cannot insert aggregate functions or other functions out of the average function.
- If a function is defined as IMMUTABLE or SHIPPABLE, avoid INSERT, UPDATE, DELETE, MERGE, and DDL operations in the function because the CN needs to determine the execution node for these operations. Otherwise, an error may occur.
- The stored procedure does not support operations that will return a set.
- When stored procedures without parameters are called in another stored procedure, you can omit brackets and call stored procedures using their names directly.
- When other functions with output parameters are called in a stored procedure and an assignment expression, set the GUC parameter **set behavior_compat_options** to '**proc_outparam_override**', define variables of the same type as the output parameters in advance, and use the variables as output parameters to call other functions with output parameters for the output parameters to take effect. Otherwise, the output parameters of the called function will be ignored.
- The stored procedure supports viewing, exporting, and importing parameter comments.
- The stored procedure supports viewing, exporting, and importing parameter comments between IS/AS and plsql_body.
- Users granted with the CREATE ANY FUNCTION permission can create or replace stored procedures in the user schemas.
- **out/inout** must be set to a variable but not a constant.
- The default permission on a stored procedure is SECURITY INVOKER. To change the default permission to SECURITY DEFINER, set the GUC parameter **behavior_compat_options** to '**plsql_security_definer**'.
- When a stored procedure is created, it depends on an undefined object. If **behavior_compat_options** is set to '**plpgsql_dependency**', the creation can be executed, and a warning message is displayed. If **behavior_compat_options** is not set to '**plpgsql_dependency**', the creation cannot be executed.
- When separation of duties is enabled, the stored procedure of the definer permission can be rebuilt only by the current user.
- If a stored procedure with the definer specified is created in a schema of another user, the stored procedure will be executed by another user, which may cause unauthorized operations. Therefore, exercise caution when performing this operation.
- If the **out** parameter is used as the output parameter in an expression, the expression does not take effect in the following scenarios: The execute immediate sqlv using func syntax is used to execute a function. The select func into syntax is used to execute a function. DML statements such as INSERT and UPDATE are used to execute a function. When a function with the **out** output parameter is used as an input parameter, that is, **fun (func (out b), a)**, the **out b** parameter does not take effect.
- When the complex function is called in a stored procedure, for example, func(x).a, a composite type is returned. Cross-schema call is supported, but the database.schema.func(x).b call is not supported.

- When a stored procedure with the out parameter is called, you can set the GUC parameter **set behavior_compat_options = 'proc_outparam_transfer_length'** to transfer the parameter length. The specifications and constraints are as follows:
 - a. The following types are supported: CHAR(n), CHARACTER(n), NCHAR(n), VARCHAR(n), VARYING(n), VARCHAR2(n), and NVARCHAR2(n).
 - b. If the out parameter does not take effect (for example, **perform**), the length does not need to be transferred.
 - c. The following types do not support precision transfer: NUMERIC, DECIMAL, NUMBER, FLOAT, DEC, INTEGER, TIME, TIMESTAMP, INTERVAL, TIME WITH TIME ZONE, TIMESTAMP WITH TIME ZONE, TIME WITHOUT TIME ZONE, and TIMESTAMP WITHOUT TIME ZONE.
 - d. The parameter length can be transferred regardless of whether the GUC parameter **set behavior_compat_options** is set to **proc_outparam_override**.
- Functions contain syntax and functions that use GUC parameters to control features. If GUC parameters are modified in a session, the function may retain the behavior before the modification. Therefore, exercise caution when modifying GUC parameters.

Syntax

```
CREATE [ OR REPLACE ] PROCEDURE procedure_name
  [ ( ( [ argname ] [ argmode ] argtype [ { DEFAULT | := | = } expression ] ) [, ... ] ) ]
  [
    { IMMUTABLE | STABLE | VOLATILE }
    | { SHIPPABLE | NOT SHIPPABLE }

    | [ NOT ] LEAKPROOF
    | { CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
    | { [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER | AUTHID DEFINER | AUTHID
CURRENT_USER }
    | COST execution_cost
    | SET configuration_parameter { [ TO | = ] value | FROM CURRENT }
  ] [ ... ]
  { IS | AS }
  plsql_body
/
```

Parameters

- OR REPLACE**
 Replaces the original definition when two stored procedures are with the same name.
- procedure_name**
 Specifies the name of the stored procedure that is created (optionally with schema names).
 Value range: a string. It must comply with the [naming convention](#).

NOTE

You are advised not to create a function with the same name as a system function. Otherwise, you need to specify the schema of the function when calling the function.

- argmode**
 Specifies the mode of an argument.

NOTICE

VARIADIC specifies parameters of the array type.

Value range: **IN**, **OUT**, **INOUT**, and **VARIADIC**. The default value is **IN**. Only the parameter of the **OUT** mode can be followed by **VARIADIC**. The parameters of **OUT** and **INOUT** cannot be used in procedure definition of **RETURNS TABLE**.

- **argname**

Specifies the argument name.

Value range: a string. It must comply with the [naming convention](#).

- **argtype**

Specifies the type of an argument. You can use **%ROWTYPE** to indirectly reference the type of a table, or **%TYPE** to indirectly reference the type of a column in a table or composite type.

Value range: a valid data type

- **expression**

Specifies the default expression of a parameter.

 **NOTE**

- If **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**, the default expression is not supported when the parameter is in **INOUT** mode.
- It is recommended that you define all default parameters after all non-default parameters.
- If a function with default parameters is called, input parameters are added to the function from left to right. If inputs of non-default parameters are missing, an error is reported.
- If **proc_uncheck_default_param** is enabled and a function with default parameters is called, input parameters are added to the function from left to right. The number of defaulted inputs depends on the number of default parameters. If an input of a non-default parameter is missing, the previous default value is used to fill this parameter.
- When **a_format_version** is set to **10c**, **a_format_dev_version** is set to **s1**, **proc_outparam_override** is disabled, and the function parameters include the output parameter **out** and **default**, the default value cannot be used.
- **IMMUTABLE, STABLE,...**
Specifies a constraint. The function of each parameter is similar to that of **CREATE FUNCTION**. For details, see [CREATE FUNCTION](#).
- **plsql_body**
Specifies the PL/SQL stored procedure body.

NOTICE

When you perform password-related operations, such as user creation, password change, and encryption/decryption, in a stored procedure, the password will be recorded in the system catalogs and logs in plaintext. To prevent sensitive information leakage, you are advised not to perform password-related operations in a stored procedure.

 NOTE

No specific order is applied to **argname** and **argname**. The following order is advised: **argname**, **argmode**, and **argtype**.

Examples

- Create a stored procedure.

```
-- Create a stored procedure and return the sum of the input parameters.
gaussdb=# CREATE OR REPLACE PROCEDURE proc_add(i int, j int)
AS
BEGIN
    dbe_output.print_line('result is: || i+j);
END;
/

-- Use CALL to call a stored procedure.
gaussdb=# CALL proc_add(16,17);

-- Use a program block to call a stored procedure.
gaussdb=# BEGIN
    proc_add(16,17);
END;
/

-- Delete.
gaussdb=# DROP PROCEDURE proc_add;
```
- Create a stored procedure whose parameter model is VARIADIC.

```
-- Create the stored procedure pro_variadic.
gaussdb=# CREATE OR REPLACE PROCEDURE pro_variadic (var1 VARCHAR2(10) DEFAULT 'hello!',var4
VARIADIC int4[])
AS
BEGIN
    dbe_output.print_line(var1);
    for i in 1..array_length(var4,1) loop
        dbe_output.print_line(var4[i]);
    end loop;
END;
/

-- Execute the stored procedure.
gaussdb=# SELECT pro_variadic(var1=>'hello', VARIADIC var4=> array[3,5,11,2]);

-- Delete.
gaussdb=# DROP PROCEDURE pro_variadic;
```
- Parameter models: **IN** and **OUT**
 - **IN** (default) indicates that the parameter is an input parameter.
 - **OUT** indicates that the parameter is an output parameter.
 - **IN OUT** indicates that the parameter is an input and output parameter

```
-- Create the stored procedure proc_add1. num1 and num2 are input parameters, and num3 is an
output parameter.
gaussdb=# CREATE PROCEDURE proc_add1 (num1 in int, num2 in int, num3 out int)
AS
BEGIN
    num3 := num1 + num2;
END;
/

-- Use a program block to call the stored procedure and use variable c to receive the parameters sent
by the stored procedure.
gaussdb=# DECLARE
    a int := 20;
    b int := 32;
    c int := 0;
```

```
BEGIN
  proc_add1(a,b,c);
  db_output.put_line(c);
END;
/

-- Delete.
gaussdb=# DROP PROCEDURE proc_add1;
```

DROP PROCEDURE

Suggestions

- analyse | analyze
 - Do not run **ANALYZE** in a transaction or anonymous block.
 - Do not run **ANALYZE** in a function or stored procedure.

7.12.8.33 CREATE RESOURCE LABEL

Description

CREATE RESOURCE LABEL is used to create a resource label.

Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.

Syntax

```
CREATE RESOURCE LABEL [IF NOT EXISTS] label_name ADD label_item_list[, ...];
```

- `label_item_list`
`resource_type(resource_path[, ...])`

- `resource_type`
{ TABLE | COLUMN | SCHEMA | VIEW | FUNCTION }

Parameters

- **IF NOT EXISTS**
If a resource label with the same name already exists, no error is generated. Instead, a message is displayed, indicating that the resource label already exists.
- **label_name**
Specifies the resource label name, which must be unique.
Value range: a string. It must comply with the [naming convention](#).
- **resource_type**
Specifies the type of database resources to be labeled.
Value range: **TABLE**, **COLUMN**, **SCHEMA**, **VIEW**, and **FUNCTION**.
- **resource_path**
Specifies the path of database resources.

Examples

```
-- Create table tb_for_label.
gaussdb=# CREATE TABLE tb_for_label(col1 text, col2 text, col3 text);

-- Create a resource label based on a table.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS table_label add TABLE(public.tb_for_label);

-- Create an existing table resource label again and compare the differences between adding IF NOT EXISTS
and not adding IF NOT EXISTS.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS table_label add TABLE(public.tb_for_label);
NOTICE: table_label label already defined, skipping
CREATE RESOURCE LABEL
gaussdb=# CREATE RESOURCE LABEL table_label add TABLE(public.tb_for_label);
ERROR: table_label label already defined

-- Create a resource label based on columns.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS column_label add COLUMN(public.tb_for_label.col1);

-- Create schema schema_for_label.
gaussdb=# CREATE SCHEMA schema_for_label;

-- Create a resource label based on a schema.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS schema_label add SCHEMA(schema_for_label);

-- Create view view_for_label.
gaussdb=# CREATE VIEW view_for_label AS SELECT 1;

-- Create a resource label based on a view.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS view_label add VIEW(view_for_label);

-- Create function func_for_label.
gaussdb=# CREATE FUNCTION func_for_label RETURNS TEXT AS $$ SELECT col1 FROM tb_for_label; $$
LANGUAGE SQL;

-- Create a resource label based on a function.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS func_label add FUNCTION(func_for_label);

-- Delete the table resource label table_label.
gaussdb=# DROP RESOURCE LABEL IF EXISTS table_label;

-- Delete the column resource label column_label.
gaussdb=# DROP RESOURCE LABEL IF EXISTS column_label;

-- Delete the function resource label func_for_label.
gaussdb=# DROP FUNCTION func_for_label;
```

```
-- Delete the view resource label view_for_label.
gaussdb=# DROP VIEW view_for_label;

-- Delete the schema resource label schema_for_label.
gaussdb=# DROP SCHEMA schema_for_label;

-- Delete the tb_for_label table.
gaussdb=# DROP TABLE tb_for_label;
```

[ALTER RESOURCE LABEL](#) and [DROP RESOURCE LABEL](#)

7.12.8.34 CREATE RESOURCE POOL

Description

Creates a resource pool and specifies the Cgroup of the resource pool.

Precautions

Only users with the sysadmin permission, or the initial user can perform this operation.

Syntax

```
CREATE RESOURCE POOL pool_name
  [WITH ({MEM_PERCENT=pct | CONTROL_GROUP="group_name" | ACTIVE_STATEMENTS=stmt |
  MAX_DOP = dop | MEMORY_LIMIT="memory_size" | io_limits=io_limits | io_priority="io_priority" |
  max_workers=max_workers | max_connections=max_connections |
  max_dynamic_memory="max_dynamic_memory" | max_shared_memory="max_shared_memory" |
  max_concurrency=concurrency}], ... ]);
```

Parameters

- **pool_name**
Specifies the name of a resource pool.
The name of the resource pool cannot be same as that of an existing resource pool.
Value range: a string. It must comply with the [naming convention](#).
- **group_name**
Specifies the name of a Cgroup.

 NOTE

- You can use either double quotation marks (""") or single quotation marks (") in the syntax when setting the name of a Cgroup.
- The value of **group_name** is case-sensitive.
- If **group_name** is not specified, the string "Medium" will be used by default in the syntax, indicating the **Medium** Timeshare Cgroup under **DefaultClass**.
- If an administrator specifies a Workload Cgroup under Class, for example, **control_group** set to **class1:workload1**, the resource pool will be associated with the **workload1** Cgroup under **class1**. The level of **Workload** can also be specified. For example, **control_group** is set to **class1:workload1:1**.
- If a database user specifies the Timeshare string (**Rush**, **High**, **Medium**, or **Low**) in the syntax, for example, **control_group** is set to **High**, the resource pool will be associated with the **High** Timeshare Cgroup under **DefaultClass**.
- In multi-tenant scenarios, the Cgroup associated with a group resource pool is a Class Cgroup, and that associated with a service resource pool is a Workload Cgroup. Additionally, switching Cgroups between different resource pools is not allowed.

Value range: a string. It must comply with the rule in the description, which specifies the created Cgroup.

- **dop**

Specifies the maximum statement concurrency degree for a resource pool, equivalent to the number of threads that can be created for executing a statement.

Value range: numeric data ranging from 1 to 2147483647

- **memory_size**

Specifies the maximum memory size of a resource pool.

Value range: a string from 1 KB to 2047 GB

- **mem_percent**

Specifies the proportion of available resource pool memory to the total memory or group user memory.

In multi-tenant scenarios, **mem_percent** of group users or service users ranges from 1 to 100. The default value is **20**.

In common scenarios, **mem_percent** of common users ranges from 0 to 100. The default value is **0**.

 NOTE

When both of **mem_percent** and **memory_limit** are specified, only **mem_percent** takes effect.

- **io_limits**

Specifies the upper limit of IOPS in a resource pool.

It is counted by 10 thousands per second.

- **io_priority**

Specifies the I/O priority for jobs that consume many I/O resources. It takes effect when the I/O usage reaches 90%.

There are three priorities: **Low**, **Medium**, and **High**. If you do not want to control I/O resources, use the default value **None**.

 NOTE

The settings of **io_limits** and **io_priority** are valid only for complex jobs, such as batch import (using **INSERT INTO SELECT**, **COPY FROM**, or **CREATE TABLE AS**), complex queries involving over 500 MB data on each DN, and **VACUUM FULL**.

- **max_workers**

Concurrency in a table during data redistribution. This column is used only for scaling.

- **max_connections**

Limits the maximum number of connections that can be used by a resource pool.

 NOTE

The total maximum number of connections in all resource pools cannot exceed the maximum number of connections specified by **max_connections** of the entire GaussDB process.

- **max_dynamic_memory**

Specifies the maximum dynamic memory that can be used by a resource pool.

- **max_shared_memory**

Specifies the maximum shared memory that can be used by a resource pool.

- **max_concurrency**

Specifies the maximum concurrent requests that can be used by a resource pool.

Examples

This example assumes that Cgroups have been created by users in advance. Contact the administrator create a Cgroup.

```
-- Create a default resource pool, and associate it with the Medium Timeshare Cgroup under Workload under DefaultClass.
gaussdb=# CREATE RESOURCE POOL pool1;

-- Create a resource pool and specify the High Timeshare Workload Cgroup under the DefaultClass Cgroup.
gaussdb=# CREATE RESOURCE POOL pool2 WITH (CONTROL_GROUP="High");

-- Create a resource pool, and associate it with the Low Timeshare Cgroup under Workload under class1.
gaussdb=# CREATE RESOURCE POOL pool3 WITH (CONTROL_GROUP="class1:Low");

-- Create a resource pool, and associate it with the wg1 Workload Cgroup under class1.
gaussdb=# CREATE RESOURCE POOL pool4 WITH (CONTROL_GROUP="class1:wg1");

-- Create a resource pool, and associate it with the wg2 Workload Cgroup under class1.
gaussdb=# CREATE RESOURCE POOL pool5 WITH (CONTROL_GROUP="class1:wg2:3");

-- Delete the resource pool.
gaussdb=# DROP RESOURCE POOL pool1;
gaussdb=# DROP RESOURCE POOL pool2;
gaussdb=# DROP RESOURCE POOL pool3;
gaussdb=# DROP RESOURCE POOL pool4;
gaussdb=# DROP RESOURCE POOL pool5;
```

[7.13.6.25-ALTER RESOURCE POOL](#) and [7.13.9.29-DROP RESOURCE POOL](#)

7.12.8.35 CREATE ROLE

Description

Creates a role.

A role is an entity that owns database objects and permissions. In different environments, a role can be considered a user, a group, or both.

Precautions

- If a role is added to the database, the role does not have the login permission.
- Only the user who has the CREATE ROLE permission or a system administrator is allowed to create roles.

Syntax

```
CREATE ROLE role_name [ [ WITH ] option [ ... ] ] [ ENCRYPTED | UNENCRYPTED ] { PASSWORD | IDENTIFIED BY } { 'password' [EXPIRED] | DISABLE };
```

The syntax of role information configuration clause **option** is as follows:

```
{SYSADMIN | NOSYSADMIN}
| {MONADMIN | NOMONADMIN}
| {OPRADMIN | NOOPRADMIN}
| {POLADMIN | NOPOLADMIN}
| {AUDITADMIN | NOAUDITADMIN}
| {CREATEDB | NOCREATEDB}
| {USEFT | NOUSEFT}
| {CREATEROLE | NOCREATEROLE}
| {INHERIT | NOINHERIT}
| {LOGIN | NOLOGIN}
| {REPLICATION | NOREPLICATION}
| {PERSISTENCE | NOPERSISTENCE}
| CONNECTION LIMIT connlimit
| VALID BEGIN 'timestamp'
| VALID UNTIL 'timestamp'
| RESOURCE POOL 'respool'
| USER GROUP 'groupuser'
| PERM SPACE 'spacelimit'
| TEMP SPACE 'tmpspacelimit'
| SPILL SPACE 'spillspacelimit'
| NODE GROUP logic_cluster_name
| IN ROLE role_name [, ...]
| IN GROUP role_name [, ...]
| ROLE role_name [, ...]
| ADMIN role_name [, ...]
| USER role_name [, ...]
| SYSID uid
| DEFAULT TABLESPACE tablespace_name
| PROFILE DEFAULT
| PROFILE profile_name
| PGUSER
```

Parameters

- **role_name**
Specifies the name of a role.
Value range: a string. It must comply with the [naming convention](#). A value can contain a maximum of 63 characters. If the value contains more than 63

characters, the database truncates it and retains the first 63 characters as the role name. If a role name contains uppercase letters, the database automatically converts the uppercase letters into lowercase letters. To create a role name that contains uppercase letters, enclose the role name with double quotation marks ("").

 **NOTE**

The identifier must be letters, underscores (_), digits (0-9), or dollar signs (\$) and must start with a letter (a-z) or underscore (_).

- **password**

Specifies the login password.

A new password must:

- Contain at least eight characters. This is the default length.
- Differ from the role name or the role name spelled backward.
- Contain at least three of the following character types: uppercase characters, lowercase characters, digits, and special characters (limited to ~!@#%&^&*()-_+=\|[]{};,:<.>/?).
- The password can also be a ciphertext character string that meets the format requirements. This mode is mainly used to import user data. You are advised not to use it directly. If a ciphertext password is used, the user must know the plaintext corresponding to the ciphertext password and ensure that the password meets the complexity requirements. The database does not verify the complexity of the ciphertext password. Instead, the security of the ciphertext password is ensured by the user.
- Be enclosed by single quotation marks when a role is created.

Value range: a character string that cannot be empty.

- **EXPIRED**

When creating a user, you can select **EXPIRED**. That is, you can create a user whose password is invalid. The user cannot perform simple query or extended query. The statement can be executed only after the password is changed.

- **DISABLE**

By default, you can change your password unless it is disabled. To disable the password of a user, use this parameter. After the password of a user is disabled, the password will be deleted from the system. The user can connect to the database only through external authentication, for example, Kerberos authentication. Only administrators can enable or disable a password. Common users cannot disable the password of an initial user. To enable a password, run **ALTER USER** and specify the password.

- **ENCRYPTED | UNENCRYPTED**

Determines whether a password stored in a system catalog is encrypted. According to product security requirement, the password must be stored encrypted. Therefore, **UNENCRYPTED** is forbidden in GaussDB. If the password string has already been encrypted in the SHA256 format, it is stored as it was, regardless of whether **ENCRYPTED** or **UNENCRYPTED** is specified (since the system cannot decrypt the specified encrypted password string). This allows reloading of encrypted passwords during dump/restore.

- **SYSADMIN | NOSYSADMIN**

Specifies whether a new role is a system administrator. Roles with the SYSADMIN attribute have the highest permission.

Value range: If not specified, **NOSYSADMIN** is the default.

When separation of duties is disabled, users with the SYSADMIN permission can create users with the SYSADMIN, REPLICATION, CREATEROLE, AUDITADMIN, MONADMIN, POLADMIN, or CREATEDB permission and common users.

When separation of duties is enabled, users with the SYSADMIN permission do not have the permission to create users.

- **MONADMIN | NOMONADMIN**

Specifies whether a role is a monitor administrator.

Value range: If not specified, **NOMONADMIN** is the default.

- **OPRADMIN | NOOPRADMIN**

Specifies whether a role is an O&M administrator.

Value range: If not specified, **NOOPRADMIN** is the default.

- **POLADMIN | NOPOLADMIN**

Specifies whether a role is a security policy administrator.

Value range: If not specified, **NOPOLADMIN** is the default.

- **AUDITADMIN | NOAUDITADMIN**

Specifies whether a role has the audit and management attributes.

If not specified, **NOAUDITADMIN** is the default.

- **CREATEDB | NOCREATEDB**

Specifies a role's permission to create databases.

A new role does not have the permission to create databases.

Value range: If not specified, **NOCREATEDB** is the default.

- **USEFT | NOUSEFT**

This parameter is reserved and not used in this version.

- **CREATEROLE | NOCREATEROLE**

Specifies whether a role will be permitted to create new roles (that is, execute **CREATE ROLE** and **CREATE USER**). A role with the CREATEROLE permission can also modify and delete other roles.

Value range: If not specified, **NOCREATEROLE** is the default.

- When separation of duties is disabled, users with the CREATEROLE permission can create users with the CREATEROLE, AUDITADMIN, MONADMIN, POLADMIN, or CREATEDB permission and common users.

- When separation of duties is enabled, users with the CREATEROLE permission can create users with the CREATEROLE, MONADMIN, POLADMIN, or CREATEDB permission and common users.

- **INHERIT | NOINHERIT**

Specifies whether a role "inherits" the permissions of roles in the same group. It is not recommended.

- **LOGIN | NOLOGIN**

Specifies whether a role is allowed to log in to a database. A role having the **LOGIN** attribute can be considered as a user.

Value range: If not specified, **NOLOGIN** is the default.

- **REPLICATION | NOREPLICATION**

Specifies whether a role is allowed to initiate streaming replication or put the system in and out of backup mode. A role having the **REPLICATION** attribute is specific to replication.

If not specified, **NOREPLICATION** is the default.

- **PERSISTENCE | NOPERSISTENCE**

Defines a permanent user. Only the initial user is allowed to create, modify, and delete permanent users with the **PERSISTENCE** attribute.

- **CONNECTION LIMIT connlimit**

Specifies how many concurrent connections the role can make.

NOTICE

- The system administrator is not restricted by this parameter.
- **connlimit** is calculated for each CN. The number of connections in a cluster is calculated using the following formula: Number of connections in a cluster = **connlimit** x Number of normal CNs.

Value range: an integer in the range $[-1, 2^{31} - 1]$. The default value is **-1**, which means unlimited.

- **VALID BEGIN 'timestamp'**

Sets the timestamp when a role takes effect. If this clause is omitted, the role has no valid start time. **timestamp** indicates the start time. The format is 'YYYY-MM-DD HH:mm:ss'.

- **VALID UNTIL 'timestamp'**

Sets a date and time after which the role's password is no longer valid. If this clause is omitted, the role has no valid end time. **timestamp** indicates the end time. The format is 'YYYY-MM-DD HH:mm:ss'.

- **RESOURCE POOL 'respool'**

Sets the name of resource pool used by the role. The name belongs to the system catalog `pg_resource_pool`.

- **USER GROUP 'groupuser'**

Creates a sub-user.

- **PERM SPACE 'SPACELIMIT'**

Sets the space available for a user.

- **TEMP SPACE 'tmpspacelimit'**

Sets the space allocated to the temporary table of a user.

- **SPILL SPACE 'spillspacelimit'**

Sets the operator disk flushing space of a user.

- **IN ROLE role_name**

Lists one or more existing roles whose permissions will be inherited by a new role. It is not recommended.

- **IN GROUP role_name**
Specifies an obsolete spelling of IN ROLE. It is not recommended.
- **ROLE role_name**
Lists one or more existing roles which are automatically added as members of the new role.
- **ADMIN role_name**
Similar to ROLE. However, ADMIN grants permissions of new roles to other roles.
- **USER role_name**
Specifies an obsolete spelling of the ROLE clause.
- **SYSID uid**
The SYSID clause is ignored.
- **DEFAULT TABLESPACE tablespace_name**
The DEFAULT TABLESPACE clause is ignored.
- **PROFILE profile_name**
The PROFILE clause is ignored.
- **PGUSER**
In the current version, this attribute is reserved only for forward compatibility.

Examples

- Differences between CREATE ROLE and CREATE USER:

```
-- Run CREATE ROLE to create role test_role.
gaussdb=# CREATE ROLE test_role PASSWORD '*****';
-- Run CREATE USER to create user test_user.
gaussdb=# CREATE USER test_user PASSWORD '*****';

-- View the information. Roles created by CREATE ROLE are not allowed to log in to the database by default.
gaussdb=# \du test*
      List of roles
Role name | Attributes | Member of
-----+-----+-----
test_role | Cannot login | {}
test_user |           | {}

-- Enable the test_role role to log in to the database.
gaussdb=# ALTER ROLE test_role WITH LOGIN;

gaussdb=# \du test*
      List of roles
Role name | Attributes | Member of
-----+-----+-----
test_role |           | {}
test_user |           | {}

-- View schema information. When CREATE USER is executed to create a user, a schema with the same name is automatically created.
gaussdb=# \dn test*
      List of schemas
Name | Owner
-----+-----
test_user | test_user
(1 row)

-- Delete.
gaussdb=# DROP ROLE test_role;
gaussdb=# DROP USER test_user;
```

- **Creating password invalidation role:**

```
-- Create the password invalidation role test_role2.
gaussdb=# CREATE ROLE test_role2 PASSWORD '*****' EXPIRED;
gaussdb=# ALTER ROLE test_role2 WITH LOGIN;

-- test_role2 cannot perform any operation after logging in to the database. You can perform
operations only after changing the password as prompted.
gaussdb=# SET ROLE test_role2 PASSWORD '*****';
gaussdb=> \d
ERROR: Please use "ALTER ROLE user_name IDENTIFIED BY 'password' REPLACE 'old password';" to
modify the expired password of user test_role2 before operation!

-- Change the password of test_role2.
gaussdb=> ALTER ROLE test_role2 IDENTIFIED BY '*****' REPLACE '*****';

-- Delete.
gaussdb=> RESET ROLE;
gaussdb=# DROP ROLE test_role2;
```
- **Creating a role and specifying the effective date and expiration date:**

```
-- Create a role with its validity from January 1, 2015 to January 1, 2026.
gaussdb=# CREATE ROLE test_role3 WITH LOGIN PASSWORD '*****' VALID BEGIN '2015-01-01'
VALID UNTIL '2026-01-01';
-- Delete.
gaussdb=# DROP ROLE test_role3;
```

[SET ROLE](#), [ALTER ROLE](#), [DROP ROLE](#), [GRANT](#), and [REVOKE](#)

7.12.8.36 CREATE ROW LEVEL SECURITY POLICY

Description

Creates a row-level security policy for a table.

The policy takes effect only after row-level security is enabled (by running **ALTER TABLE ... ENABLE ROW LEVEL SECURITY**). Otherwise, this statement does not take effect.

Currently, row-level security affects the read (SELECT, UPDATE, and DELETE) of data tables and does not affect the write (INSERT and MERGE INTO) of data tables. The table owner or system administrators can create an expression in the USING clause. When the client reads the data table, the database server combines the expressions that meet the condition and applies it to the execution plan in the statement rewriting phase of a query. For each tuple in a data table, if the USING expression returns **TRUE**, the tuple is visible to the current user; if the USING expression returns **FALSE** or **NULL**, the tuple is invisible to the current user.

A row-level security policy name is specific to a table. A data table cannot have row-level security policies with the same name. Different data tables can have the same row-level security policy.

Row-level security policies can be applied to specified operations (**SELECT**, **UPDATE**, **DELETE**, and **ALL**). **ALL** indicates that SELECT, UPDATE, and DELETE will be affected. For a new row-level security policy, the default value **ALL** will be used if you do not specify the operations that will be affected.

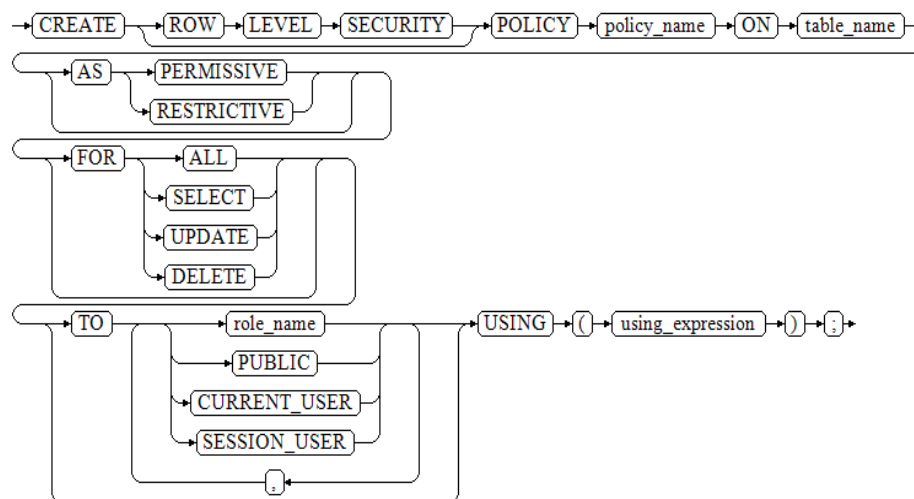

Row-level security policies can be applied to a specified user (role) or to all users (**PUBLIC**). For a new row-level security policy, the default value **PUBLIC** will be used if you do not specify the user who will be affected.

Precautions

- Row-level security policies can be defined for row-store tables, row-store partitioned tables, replication tables, unlogged tables, and hash tables.
- Row-level security policies cannot be defined for foreign tables and temporary tables.
- Row-level security policies cannot be defined for views.
- A maximum of 100 row-level security policies can be defined for a table.
- System administrators are not affected by row-level security policies and can view all data in a table.
- Tables queried by using SQL statements, views, functions, and stored procedures are affected by row-level security policies.
- The data type of a table column to which a row-level security policy has been added cannot be changed.

Syntax

```
CREATE [ ROW LEVEL SECURITY ] POLICY policy_name ON table_name
[ AS { PERMISSIVE | RESTRICTIVE } ]
[ FOR { ALL | SELECT | UPDATE | DELETE } ]
[ TO { role_name | PUBLIC | CURRENT_USER | SESSION_USER } [, ... ] ]
USING ( using_expression );
```

Parameters

- **policy_name**
Specifies the name of a row-level security policy to be created. The names of row-level security policies for a table must be unique.
- **table_name**
Specifies the name of a table to which a row-level security policy is applied.
- **PERMISSIVE | RESTRICTIVE**
PERMISSIVE enables the permissive policy for row-level security. The conditions of the permissive policy are joined through the OR expression. **RESTRICTIVE** enables the restrictive policy for row-level security. The conditions of the restrictive policy are joined through the AND expression. The join methods are as follows:

(using_expression_permissive_1 OR using_expression_permissive_2 ...) AND
(using_expression_restrictive_1 AND using_expression_restrictive_2 ...)

The default value is **PERMISSIVE**.

- **command**

Specifies the SQL operations affected by a row-level security policy, including **ALL**, **SELECT**, **UPDATE**, and **DELETE**. If this parameter is not specified, the default value **ALL** will be used, covering **SELECT**, **UPDATE**, and **DELETE**.

If **command** is set to **SELECT**, only tuple data that meets the condition (the return value of **using_expression** is **TRUE**) can be queried. The operations that are affected include **SELECT**, **SELECT FOR UPDATE/SHARE**, **UPDATE ... RETURNING**, and **DELETE ... RETURNING**.

If **command** is set to **UPDATE**, only tuple data that meets the condition (the return value of **using_expression** is **TRUE**) can be updated. The operations that are affected include **UPDATE**, **UPDATE ... RETURNING**, and **SELECT ... FOR UPDATE/SHARE**.

If **command** is set to **DELETE**, only tuple data that meets the condition (the return value of **using_expression** is **TRUE**) can be deleted. The operations that are affected include **DELETE** and **DELETE ... RETURNING**.

The following table describes the relationship between row-level security policies and SQL statements.

Table 7-239 Relationship between the ROW LEVEL SECURITY policy and SQL statements

Command	SELECT/ALL Policy	UPDATE/ALL Policy	DELETE/ALL Policy
SELECT	Existing row	No	No
SELECT FOR UPDATE/SHARE	Existing row	Existing row	No
UPDATE	No	Existing row	No
UPDATE RETURNING	Existing row	Existing row	No
DELETE	No	No	Existing row
DELETE RETURNING	Existing row	No	Existing row

- **role_name**

Specifies database users affected by a row-level security policy.

CURRENT_USER indicates the username in the current operating environment. **SESSION_USER** indicates the session username. If this parameter is not specified, the default value **PUBLIC** is used, indicating that all database users are affected. You can specify multiple affected database users.

NOTICE

System administrators are not affected by row-level security.

- **using_expression**

Specifies an expression defined for a row-level security policy (return type: Boolean).

The expression cannot contain aggregate functions or window functions. In the statement rewriting phase of a query, if row-level security for a data table is enabled, the expressions that meet the specified conditions will be added to the plan tree. The expression is calculated for each tuple in the data table. For SELECT, UPDATE, and DELETE, row data is visible to the current user only when the return value of the expression is **TRUE**. If the expression returns **FALSE**, the tuple is invisible to the current user. In this case, the user cannot view the tuple through the SELECT statement, update the tuple through the UPDATE statement, or delete the tuple through the DELETE statement.

Examples

```
-- Create user alice.
gaussdb=# CREATE USER alice PASSWORD '*****!';

-- Create user bob.
gaussdb=# CREATE USER bob PASSWORD '*****!';

-- Create data table all_data.
gaussdb=# CREATE TABLE public.all_data(id int, role varchar(100), data varchar(100));

-- Insert data into the data table.
gaussdb=# INSERT INTO all_data VALUES(1, 'alice', 'alice data');
gaussdb=# INSERT INTO all_data VALUES(2, 'bob', 'bob data');
gaussdb=# INSERT INTO all_data VALUES(3, 'peter', 'peter data');

-- Grant the read permission on the all_data table to users alice and bob.
gaussdb=# GRANT SELECT ON all_data TO alice, bob;

-- Enable the row-level security policy.
gaussdb=# ALTER TABLE all_data ENABLE ROW LEVEL SECURITY;

-- Create a row-level security policy to specify that the current user can view only their own data.
gaussdb=# CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role = CURRENT_USER);

-- View information about the all_data table.
gaussdb=# \d+ all_data
          Table "public.all_data"
  Column |          Type          | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
  id     | integer                |           |         |              |
  role   | character varying(100) |           | extended |              |
  data   | character varying(100) |           | extended |              |
Row Level Security Policies:
  POLICY "all_data_rls" FOR ALL

[DROP ROW LEVEL SECURITY POLICY](#)

7.12.8.37 CREATE SCHEMA

Description

Creates a schema.

Named objects are accessed either by "qualifying" their names with the schema name as a prefix, or by setting a search path that includes the desired schema. When creating named objects, you can also use the schema name as a prefix.

Optionally, CREATE SCHEMA can include sub-commands to create objects within the new schema. The sub-commands are treated essentially the same as separate commands issued after creating the schema. If the AUTHORIZATION clause is used, all the created objects are owned by this user.

Precautions

- Only a user with the **CREATE** permission on the current database can perform this operation.
- The owner of an object created by a system administrator in a schema with the same name as a common user is the common user, not the system administrator.

Syntax

- Create a schema based on a specified name.

```
CREATE SCHEMA schema_name
[ AUTHORIZATION user_name ] [ WITH BLOCKCHAIN ] [ schema_element [ ... ] ];
```

- Create a schema based on a username.

```
CREATE SCHEMA AUTHORIZATION user_name [ schema_element [ ... ] ];
```

- Create a schema and specify the default character set and collation.

```
CREATE SCHEMA schema_name
[ [ DEFAULT ] CHARACTER SET | CHARSET [=] default_charset ] [ [ DEFAULT ] COLLATE [=]
default_collation ];
```

Parameters

- **schema_name**
Specifies the schema name.

NOTICE

- The schema name must be unique in the current database.
- The schema name cannot be the same as the initial username of the current database.
- The schema name cannot start with **pg_**.
- The schema name cannot start with **gs_role_**.

Value range: a string. It must comply with the [naming convention](#).

- **AUTHORIZATION user_name**
Specifies the owner of a schema. If **schema_name** is not specified, **user_name** will be used as the schema name. In this case, **user_name** can only be a role name.

Value range: an existing username or role name

- **WITH BLOCKCHAIN**
Specifies the tamper-proof attribute of a schema. A common row-store table in tamper-proof mode is a tamper-proof user table.

 **NOTE**

To create a tamper-proof schema, set the GUC parameter **enable_ledger** to **on**. The default value is **off**, and the level is **SIGHUP**.

- **schema_element**

Specifies an SQL statement defining an object to be created within the schema. Currently, only the **CREATE TABLE**, **CREATE VIEW**, **CREATE INDEX**, **CREATE TABLE PARTITION**, **CREATE SEQUENCE**, **CREATE TRIGGER**, and **GRANT** clauses are supported.

Objects created by sub-commands are owned by the user specified by **AUTHORIZATION**.

 **NOTE**

If objects in the schema on the current search path are with the same name, specify the schemas for different objects. You can run **SHOW SEARCH_PATH** to check the schemas on the current search path.

- **default_charset**

Specifies the default character set of a schema. If this parameter is specified separately, the default collation of the schema is set to the default collation of the specified character set.

This syntax is supported only in MySQL-compatible mode (that is, **sql_compatibility** set to **'MYSQL'**).

- **default_collation**

Specifies the default collation of a schema. If this parameter is specified separately, the default character set of the schema is set to the character set corresponding to the specified collation.

This syntax is supported only in MySQL-compatible mode (that is, **sql_compatibility** set to **'MYSQL'**). For details about the supported collations, see [Table 1 Supported character sets](#).

Examples

```
-- Create the role1 role.
gaussdb=# CREATE ROLE role1 IDENTIFIED BY '*****';

-- Create a schema named role1 for the role1 role. The owner of the films and winners tables created by
the clause is role1.
gaussdb=# CREATE SCHEMA AUTHORIZATION role1
CREATE TABLE films (title text, release date, awards text[])
CREATE VIEW winners AS SELECT title, release FROM films WHERE awards IS NOT NULL;

-- Delete the schema.
gaussdb=# DROP SCHEMA role1 CASCADE;
-- Delete the user.
gaussdb=# DROP USER role1 CASCADE;
```

Helpful Links

[ALTER SCHEMA](#) and [DROP SCHEMA](#)

7.12.8.38 CREATE SECURITY LABEL

Description

CREATE SECURITY LABEL creates a security label for the specified security policy in the current database.

Precautions

An initial user, a user with the SYSADMIN permission, or a user who inherits the gs_role_seclabel permission of the built-in role can create security labels.

Syntax

```
CREATE SECURITY LABEL label_name 'label_content';
```

→ CREATE → SECURITY → LABEL → label_name → ' → label_content → ' → ; →

Parameters

- **label_name**
Security label name, which must be unique in the database.
Value range: a string of a maximum of 63 characters. Only lowercase letters (a to z), uppercase letters (A to Z), digits, underscores (_), and dollar signs (\$) are allowed. If the length exceeds 63 characters, the database retains only the first 63 characters as the security label name.
- **label_content**
Security label content. The requirements are as follows:
A security label consists of only one level and at least one range, which are separated by a colon (:). The format is "level:range", for example, "L1:G2,G41,G6-G27".
 - There are 1024 levels named L_i , where $1 \leq i \leq 1024$. The levels meet a partial order relationship (if $i \leq j$, then $L_i \leq L_j$). For example, L_1 is lower than L_3 .
 - There are 1024 ranges named G_i , where $1 \leq i \leq 1024$. You cannot compare sizes between ranges, but you can perform set operations. Multiple ranges are separated by commas (,), and a hyphen (-) is used to specify the interval. For example, {G2-G5} indicates {G2,G3,G4,G5}. {G1} is a subset of {G1, G6}.
 - The letters L and G must be capitalized and followed by at least one non-zero digit. Other characters are not allowed. In the {Gxxx-Gyyy} format, yyy must be greater than or equal to xxx.
 - If the input levels and ranges do not meet the requirements, the system reports an error.

CAUTION

Example:
gaussdb=# CREATE SECURITY LABEL sec_label3 'L3:;' // The label must contain at least one content range category.
ERROR: in label text "L3:", there at least have one level and one group

Examples

```
-- Create a security label sec_label.
gaussdb=# CREATE SECURITY LABEL sec_label 'L1:G4';

-- Create security label sec_label with the content of 'L1:G2,G4'.
gaussdb=# CREATE SECURITY LABEL sec_label 'L1:G2,G4';
ERROR: security label "sec_label" already exists
-- Create security label sec_label1 with the content of 'L1:G2,G4'.
gaussdb=# CREATE SECURITY LABEL sec_label1 'L1:G2,G4';

-- Create security label sec_label2 with the content of 'L3:G1-G5'.
gaussdb=# CREATE SECURITY LABEL sec_label2 'L3:G1-G5';

-- View the security labels created in the system.
gaussdb=# SELECT * FROM gs_security_label;
 label_name | label_content
-----+-----
 sec_label  | L1:G4
 sec_label1 | L1:G2,G4
 sec_label2 | L3:G1-G5
(3 rows)

-- Delete the existing security labels sec_label, sec_label1, and sec_label2.
gaussdb=# DROP SECURITY LABEL sec_label;
gaussdb=# DROP SECURITY LABEL sec_label1;
gaussdb=# DROP SECURITY LABEL sec_label2;

-- View the security labels created in the system again.
gaussdb=# SELECT * FROM gs_security_label;
 label_name | label_content
-----+-----
(0 rows)
```

Helpful Links

[DROP SECURITY LABEL](#) and [SECURITY LABEL ON](#)

7.12.8.39 CREATE SEQUENCE

Description

CREATE SEQUENCE adds a sequence to the current database. The owner of a sequence is the user who creates the sequence.

Precautions

- A sequence is a special table that stores arithmetic progressions. It has no actual meaning and is usually used to generate unique identifiers for rows or tables.
- If a schema name is given, the sequence is created in the specified schema; otherwise, it is created in the current schema. The sequence name must be different from the names of other sequences, tables, indexes, views in the same schema.
- After the sequence is created, functions `nextval()` and `generate_series(1,N)` insert data to the table. Make sure that the number of times for calling `nextval` is greater than or equal to `N+1`. Otherwise, errors will be reported because the number of times for calling function `generate_series()` is `N+1`.
- A user granted with the CREATE ANY SEQUENCE permission can create sequences in the public and user schemas.

Syntax

```
CREATE SEQUENCE [ IF NOT EXISTS ] name [ INCREMENT [ BY ] increment ]
  [ MINVALUE minvalue | NO MINVALUE | NOMINVALUE ] [ MAXVALUE maxvalue | NO MAXVALUE |
  NOMAXVALUE ]
  [ START [ WITH ] start ] [ CACHE cache ] [ [ NO ] CYCLE | NOCYCLE ]
  [ OWNED BY { table_name.column_name | NONE } ];
```

Parameters

- **IF NOT EXISTS**

When IF NOT EXISTS is specified, the system checks whether a relationship with the same name already exists in the current schema before creating a sequence. It is not created and a NOTICE is returned if a relationship with the same name already exists. When IF NOT EXISTS is not specified and a relationship with the same name exists in the schema, an ERROR is returned.

- **name**

Specifies the name of a sequence to be created.

Value range: a string containing only lowercase letters, uppercase letters, special characters #_\$, and digits.

- **increment**

Optional. Specifies the step for a sequence. A positive number generates an ascending sequence, and a negative number generates a decreasing sequence. The default value is 1.

NOTE

In MySQL compatibility mode, if the step is a floating-point number, the value is automatically converted to an integer. In other modes, this parameter cannot be set to a floating-point number.

- **MINVALUE minvalue | NO MINVALUE| NOMINVALUE**

Optional. Specifies the minimum value of the sequence. If **MINVALUE** is not declared, or **NO MINVALUE** is declared, the default value of the ascending sequence is 1, and that of the descending sequence is $-2^{63}-1$. **NOMINVALUE** is equivalent to **NO MINVALUE**.

- **MAXVALUE maxvalue | NO MAXVALUE| NOMAXVALUE**

Optional. Specifies the maximum value of the sequence. If **MAXVALUE** is not declared, or **NO MAXVALUE** is declared, the default value of the ascending sequence is $2^{63}-1$, and that of the descending sequence is -1. **NOMAXVALUE** is equivalent to **NO MAXVALUE**.

- **start**

Optional. Specifies the start value of the sequence. The default value for an ascending sequence is **minvalue** and that for a descending sequence is **maxvalue**.

- **cache**

Optional. Specifies the number of sequences stored in the memory for quick access purposes.

Default value **1** indicates that one sequence can be generated each time.

 **NOTE**

- It is not recommended that you define **cache** and **maxvalue** or **minvalue** at the same time. The continuity of sequences cannot be ensured after **cache** is defined because unacknowledged sequences may be generated, causing waste of sequences. If there are requirements on the concurrency performance, see the **session_sequence_cache** parameter.
- **cache** specifies the value that a single CN/DN applies for from the GTM at a time. **session_sequence_cache** specifies the value of the cache that a single session applies for from the CN/DN at a time. The value is automatically discarded after the session ends.

- **CYCLE**

Optional. Recycles sequences after the number of sequences reaches **maxvalue** or **minvalue**.

If **NO CYCLE** is specified, any calling of nextval would return an error after the number of sequences reaches **maxvalue** or **minvalue**.

- **NOCYCLE** is equivalent to **NO CYCLE**. The default value is **NO CYCLE**.
- If **CYCLE** is specified, the sequence uniqueness cannot be ensured.

- **OWNED BY**

Optional. Associates a sequence with a specified column included in a table. In this way, the sequence will be deleted when you delete its associated column or the table where the column belongs to. The associated table and sequence must be owned by the same user and in the same schema. **OWNED BY** only establishes the association between a table column and the sequence. Sequences on the column do not increase automatically when data is inserted.

The default value **OWNED BY NONE** indicates that such association does not exist.

NOTICE

You are advised not to use the sequence created using **OWNED BY** in other tables. If multiple tables need to share a sequence, the sequence must not belong to a specific table.

Examples

- Create an ascending sequence named **seq1**. The sequence starts from 101 and the step is 10.

```
gaussdb=# CREATE SEQUENCE seq1
START 101
INCREMENT 10;
```

```
-- Select the next number from the sequence.
```

```
gaussdb=# SELECT nextval('seq1');
nextval
```

```
-----
    101
(1 row)
```

```
gaussdb=# SELECT nextval('seq1');
nextval
```

```
-----
    111
```

```
-- Delete the sequence.
```

```
gaussdb=# DROP SEQUENCE seq1;
```

- Implement the auto-increment column.

```
-- Create a table.
```

```
gaussdb=# CREATE TABLE test1(id int PRIMARY KEY, name varchar(20));
```

```
-- Create a sequence joined with the table.
```

```
gaussdb=# CREATE SEQUENCE test_seq2
START 1
NO CYCLE
OWNED BY test1.id;
```

```
-- Set the default value of a column.
```

```
gaussdb=# ALTER TABLE test1 ALTER COLUMN id SET DEFAULT nextval('test_seq2'::regclass);
```

```
-- Insert data.
```

```
gaussdb=# INSERT INTO test1 (name) values ('Joe'),('Scott'),('Ben');
```

```
-- Query.
```

```
gaussdb=# SELECT * FROM test1;
```

```
id | name
-----+-----
 3 | Ben
 1 | Joe
 2 | Scott
(3 rows)
```

```
-- Delete the sequence and the table.
```

```
gaussdb=# DROP SEQUENCE test_seq2 CASCADE;
```

```
gaussdb=# DROP TABLE test1;
```

[DROP SEQUENCE](#) and [ALTER SEQUENCE](#)

7.12.8.40 CREATE SERVER

Description

Creates a foreign server.

A foreign server stores other homogeneous cluster information.

Precautions

Only a system administrator and users with permission to use a specified FOREIGN DATA WRAPPER can create a foreign server. The authorization syntax is as follows:

```
GRANT USAGE ON FOREIGN DATA WRAPPER fdw_name TO username
```

fdw_name is the name of the FOREIGN DATA WRAPPER, and **username** is the name of the user creating a foreign server.

When multi-layer quotation marks are used for sensitive columns (such as **password**) in **OPTIONS**, the semantics is different from that in the scenario where quotation marks are not used. Therefore, sensitive columns are not identified for anonymization.

Syntax

```
CREATE SERVER server_name  
  FOREIGN DATA WRAPPER fdw_name  
  [ OPTIONS ( { option_name ' value ' } [, ...] ) ] ;
```

Parameters

- **server_name**
Specifies the server name.
Value range: a string containing no more than 63 bytes.
- **FOREIGN DATA WRAPPER fdw_name**
Specifies the name of the foreign data wrapper.
Value range: **fdw_name** is the data wrapper created by the system during database initialization. Currently, **fdw_name** can only be **gc_fdw** for other homogeneous clusters. You can also create **dist_fdw**, **file_fdw**, and **log_fdw**. **log_fdw** is used only for syntax compatibility and can be used to create foreign tables, but it is meaningless. **dist_fdw** is used to import GDS data. You do not need to manually create a server using **dist_fdw** because **gsmpp_server** is already built in.
- **OPTIONS ({ option_name ' value ' } [, ...])**
Specifies the parameters for the foreign server. The detailed parameters are as follows:
 - address
Address of the foreign server.
 - dbname
Database name of the foreign server.
 - username
Username of a foreign server.
 - password
Password of the foreign server.

Examples

Create a server, in which **file_fdw** is the FOREIGN DATA WRAPPER existing in the database.

```
-- Create a server.  
gaussdb=# CREATE SERVER my_server FOREIGN DATA WRAPPER file_fdw;
```

```
-- Delete the server.  
gaussdb=# DROP SERVER my_server;
```

You are advised to create another server in the homogeneous cluster, where **gc_fdw** is the foreign data wrapper in the database.

```
-- Create a server.  
gaussdb=# CREATE SERVER server_remote FOREIGN DATA WRAPPER GC_FDW OPTIONS  
  (address '10.146.187.231:8000,10.180.157.130:8000',  
   dbname 'test',  
   username 'test',  
   password '*****'  
  );  
  
-- Delete the server.  
gaussdb=# DROP SERVER server_remote;
```

Helpful Links

[ALTER SERVER](#) and [DROP SERVER](#)

7.12.8.41 CREATE SYNONYM

Description

Creates a synonym object. A synonym is an alias of a database object and is used to record the mapping between database object names. You can use synonyms to access associated database objects.

Precautions

- The user who creates the synonym will be the owner of the synonym.
- If the schema name is specified, create a synonym in the specified schema. Otherwise, a synonym is created in the current schema.
- Database objects that can be accessed using synonyms include tables, views, types, packages, functions, stored procedures, sequences, or other synonyms.
- To use synonyms, you must have the required permissions on associated objects.
- The following DML statements support synonyms: SELECT, INSERT, UPDATE, DELETE, EXPLAIN, and CALL.
- The CREATE SYNONYM statement of an associated function or stored procedure cannot be used in a stored procedure. You are advised to use synonyms existing in the pg_synonym system catalog in the stored procedure.
- You are advised not to create synonyms for temporary tables. To create a synonym, you need to specify the schema name of the target temporary table. Otherwise, the synonym cannot be used normally. In addition, you need to run the **DROP SYNONYM** command before the current session ends.
- After an original object is deleted, the synonym associated with the object will not be deleted in cascading mode. If you continue to access the synonym, for accessed tables, a message is displayed indicating that the synonym has expired; for accessed functions, stored procedures, and packages, a message is displayed indicating that the objects do not exist.
- Users granted the CREATE ANY SYNONYM permission can create synonyms in user schemas.

- Synonyms cannot be created for encrypted tables that contain encrypted columns and views, functions, and stored procedures based on encrypted tables.
- If the schema of a synonym is the schema to which the user belongs, the owner of the synonym is also the owner of the schema. In other scenarios, the owner of the synonym is the creator of the synonym by default.
- If **SEARCH_PATH** is set and no synonym schema is specified, for stored procedures and functions, the PG_PROC table is preferentially searched by name. If no function with the same name exists, synonyms are searched based on **SEARCH_PATH**. For other objects, **SEARCH_PATH** is preferentially searched, if their schemas are the same as that of synonyms, the objects are accessed prior to synonyms.
- Objects associated with synonyms cannot be accessed using DDL statements, such as CREATE, DROP, and ALTER.
- Nested synonyms are supported. When you search for a synonym, if the synonym is associated with another synonym, the system continues to search for the associated synonym until the last associated object is found.
- You cannot use \d, \df, or \sf to access information about associated objects through synonyms.

Syntax

```
CREATE [ OR REPLACE ] [PUBLIC] SYNONYM synonym_name
FOR object_name;
```

Parameters

- **OR REPLACE**
(Optional) Redefines the synonym if it already exists.
- **PUBLIC**
(Optional) Creates a PUBLIC synonym.

NOTE

- PUBLIC synonyms must be unique in the same database.
- If the database is upgraded from a version that does not support PUBLIC synonyms to a version that supports PUBLIC synonyms, PUBLIC synonyms cannot be created or deleted before the upgrade is committed.
- All users can access PUBLIC synonyms. Except the initial users and system administrators, you must have the CREATE PUBLIC SYNONYM and DROP PUBLIC SYNONYM permissions to create and delete PUBLIC synonyms, respectively.
- For the PUBLIC synonym, the values of **synnamespace** and **synowner** in the PG_SYNONYM system catalog are **0**, the value of **owner** in the ADM_SYNONYMS and DB_SYNONYMS system views is **PUBLIC**, and the value of **schema_name** is **NULL**.
- If no synonym schema is specified, the system searches for objects with the same name to determine whether the objects exist. Then, the system searches for synonyms by **SEARCH_PATH**. Finally, the system searches for PUBLIC synonyms. If a synonym schema is specified, PUBLIC synonyms are not retrieved.

- **synonym_name**
Specifies the name of the synonym to be created, which can contain the schema name.
Value range: a string. It must comply with the [naming convention](#).
- **object_name**
Specifies the name of an object that is associated (optionally with schema names).
Value range: a string. It must comply with the [naming convention](#).

 **NOTE**

- **object_name** can be the name of an object that does not exist.
- **object_name** can be the name of a remote object accessed by using a database link. For details about how to use database links, see [DATABASE LINK](#).

 **CAUTION**

Do not create aliases for functions that contain passwords and other sensitive information, such as the encryption functions `gs_encrypt` and `gs_encrypt_bytera`, and the decryption functions `gs_decrypt` and `gs_decrypt_bytea` or use aliases to call the functions to prevent sensitive information leakage.

Examples

```
-- Create schema ot.
gaussdb=# CREATE SCHEMA ot;

-- Create a table ot.test_tbl1.
gaussdb=# CREATE TABLE ot.test_tbl1(c1 INT, c2 INT);
gaussdb=# INSERT INTO ot.test_tbl1 values(1,1);

-- View the current value of search_path.
gaussdb=# SHOW search_path;
 search_path
-----
"$user",public
(1 row)

-- The current value of search_path does not contain ot, and the current user is not ot. Therefore, an error
is reported when you directly view the table name.
gaussdb=# SELECT * FROM test_tbl1;
ERROR: relation "test_tbl1" does not exist
LINE 1: SELECT * FROM test_tbl1;
                        ^

-- Create a synonym.
gaussdb=# CREATE OR REPLACE SYNONYM test_tbl1 FOR ot.test_tbl1;

-- Use the synonym.
gaussdb=# SELECT * FROM test_tbl1;
 c1 | c2
----+----
  1 |  1
(1 row)
gaussdb=# INSERT INTO test_tbl1 VALUES (2,2);

-- Query a created synonym.
gaussdb=# SELECT synname,synobjschema,synobjname FROM pg_synonym WHERE synname = 'test_tbl1';
 synname | synobjschema | synobjname
-----+-----+-----
```

```
test_tbl1 | ot      | test_tbl1
(1 row)

-- Delete.
gaussdb=# DROP SYNONYM test_tbl1;
gaussdb=# DROP TABLE ot.test_tbl1;
gaussdb=# DROP SCHEMA ot CASCADE;
```

Helpful Links

[ALTER SYNONYM](#) and [DROP SYNONYM](#)

7.12.8.42 CREATE TABLE

Description

Creates an initially empty table in the current database. The table will be owned by the creator. Row-store tables are created by default.

Precautions

- If a primary key constraint or unique constraint is added to a non-distribution key, a global secondary index is created by default.
- By default, **HASH(column_name)** is used in a distributed system. **column_name** is the primary key column or unique constraint column (if any) of the table, or the first column of a data type that can be used as the distribution key. The priority is as follows: primary key column > unique constraint column > first column of a data type that can be used as the distribution key. If a primary key column and multiple unique constraint columns exist and the distribution mode of the table is not specified, GSIs are created for other unique constraint columns by default after the distribution key of the table is determined based on the priority.
- The distribution keys can be updated only when **enable_update_distkey** is set to **on** and constraints are met. Otherwise, distribution keys do not support the UPDATE operation.

 **NOTE**

The constraints on updating distribution keys are as follows:

- Distribution keys can be updated only when **enable_update_distkey** is set to **on**.
- The UPDATE statement cannot be pushed down to DN for execution. The PGXC plan is directly generated and is not changed based on the values before and after the distribution key is updated.
- Tables with row-level UPDATE TRIGGER are not supported. Otherwise, the execution fails and an error message is displayed. The row-level INSERT/DELETE TRIGGER does not take effect, and the update-statement-level TRIGGER is executed normally.
- Concurrent update of the same row is not supported. You need to obtain a lock first. The result (returning 0 or reporting an error) of obtaining a lock on DN depends on the setting of the GUC parameter **concurrent_dml_mode**. An error will be reported in the following cases: (1) The error message "update distribute column conflict" is displayed. (2) When the time spent for obtaining a lock exceeds the threshold, an error message is displayed, indicating that the lock times out.
- Tables with global secondary indexes (GSIs) are not supported. Otherwise, an error is reported.
- Only Hash distribution is supported. LIST/RANGE distribution tables are not supported. Otherwise, an error is reported.
- MERGE INTO and UPSERT cannot be used to update distribution keys. Otherwise, an error is reported.
- GTM_FREE is not supported. Otherwise, an error is reported.
- UPDATE RETURNING is not supported. Otherwise, an error is reported.
- Statements with joined tables are not supported. Otherwise, an error is reported.
- UPDATE+LIMIT is not supported. Otherwise, an error is reported.
- If an error occurs during table creation, after it is fixed, the system may fail to delete the empty disk files (whose size is 0) created before the last automatic clearance. This problem seldom occurs and does not affect system running of the database.
- When JDBC is used, the **DEFAULT** value can be set through **PrepareStatement**.
- Row-store tables do not support foreign key as the table-level constraint.
- A user granted with the CREATE ANY TABLE permission can create tables in the public and user schemas. To create a table that contains serial columns, you must also obtain the CREATE ANY SEQUENCE permission to create sequences.
- The XML type cannot be used as a primary key or foreign key.
- If you add a row-level expression when adding or changing an ILM policy for a data object, note that the row-level expression supports only the functions listed in the whitelist. For details about the whitelist function list, see [Row Expression Function Whitelist](#).

NOTICE

If the database creates unlimited tables, CNs may be affected as follows:

- **Resource exhaustion:** Each table occupies certain disk space. Unlimited table creation will occupy a large amount of memory and disk space, which may exhaust CN resources. As a result, the system breaks down or becomes unstable.
- **Performance deterioration:** Unlimited table creation causes a large number of I/O operations and CPU computing, and the metadata information of the database becomes large, which may deteriorate the CN performance, including operations such as insert, query, update, and deletion. As a result, the system responds slowly or cannot meet service requirements.
- **Security issues:** Excessive tables make database management and maintenance difficult. Creating unlimited tables may cause security issues such as data leakage or data loss. Database stability decreases, causing immeasurable loss to enterprises.

Therefore, plan the number and size of tables in the database properly to avoid unlimited table creation and ensure system stability, reliability, and security.

- The number of table constraints cannot exceed 32,767.

Syntax

- Create a table.

```
CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } | UNLOGGED ] TABLE [ IF NOT EXISTS ]
table_name
  ( ( { column_name data_type [ CHARACTER SET | CHARSET charset ] [ compress_mode ] [ COLLATE
collation ] [ column_constraint [ ... ] ]
    | table_constraint
    | LIKE source_table [ like_option [ ... ] ] }
    [, ... ] )
  | LIKE source_table }
[ table_option [ [ , ] ... ] ]
[ WITH ( { storage_parameter = value } [, ... ] ) ]
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS } ]
[ COMPRESS | NOCOMPRESS ]
[ ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year }
OF { NO MODIFICATION } [ ON ( EXPR ) ] ]
[ TABLESPACE tablespace_name ]
[ DISTRIBUTE BY { REPLICATION | HASH ( column_name [, ... ] )
| MURMURHASH ( expression )
| RANGE ( column_name [, ... ] ) { SLICE REFERENCES tablename | ( slice_less_than_item [, ... ] ) |
( slice_start_end_item [, ... ] ) }
| LIST ( column_name [, ... ] ) { SLICE REFERENCES tablename | ( slice_values_item [, ... ] ) }
} ]
[ TO { GROUP groupname | NODE ( nodename [, ... ] ) } ] ;
```

- **table_option** is as follows:

```
{ COMMENT [ = ] 'string' |
  AUTO_INCREMENT [ = ] value |
  [ DEFAULT ] CHARACTER SET | CHARSET [ = ] default_charset |
  [ DEFAULT ] COLLATE [ = ] default_collation |
  ENGINE [ = ] { InnoDB | 'InnoDB' | "InnoDB" } }
```

- **column_constraint** is as follows:

```
[ CONSTRAINT constraint_name ]
{ NOT NULL |
  NULL |
  CHECK ( expression ) |
```

- ```

DEFAULT default_expr |
ON UPDATE update_expr |
GENERATED ALWAYS AS (generation_expr) [STORED] |
AUTO_INCREMENT |
COMMENT 'string' |
UNIQUE [KEY] index_parameters |
PRIMARY KEY index_parameters |
ENCRYPTED WITH (COLUMN_ENCRYPTION_KEY = column_encryption_key,
ENCRYPTION_TYPE = encryption_type_value) |
REFERENCES reftable [(refcolumn)] [MATCH FULL | MATCH PARTIAL | MATCH SIMPLE]
[ON DELETE action] [ON UPDATE action] }
[DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE]

```
- **compress\_mode** of a column is as follows:  
{ DELTA | PREFIX | DICTIONARY | NUMSTR | NOCOMPRESS }
  - **table\_constraint** is as follows:  
[ CONSTRAINT [ constraint\_name ] ]  
{ CHECK ( expression ) |  
UNIQUE [ index\_name ][ USING method ] ( { {column\_name [ ( length ) ] | ( expression ) }  
[ ASC | DESC ] }[, ... ] ) index\_parameters |  
PRIMARY KEY [ USING method ] ( { column\_name [ ASC | DESC ] }[, ... ] ) index\_parameters  
}  
[ DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE ]  
{ [ COMMENT 'string' ] [ ... ] }
  - **like\_option** is as follows:  
{ INCLUDING | EXCLUDING } { DEFAULTS | GENERATED | CONSTRAINTS | INDEXES | STORAGE |  
COMMENTS | PARTITION | REOPTIONS | DISTRIBUTION | UPDATE | ALL }
  - **index\_parameters** is as follows:  
[ WITH ( {storage\_parameter = value} [, ... ] ) ]  
[ USING INDEX TABLESPACE tablespace\_name ]
  - **Range distribution rules**  
For **slice\_less\_than\_item**:  
SLICE name VALUES LESS THAN ( { expression | MAXVALUE } [, ...] ) [ DATANODE  
datanode\_name | ( datanode\_name\_list [, ... ] ) ]  
For **slice\_start\_end\_item**:  
SLICE name {  
{ START ( expression ) END ( expression ) EVERY ( expression ) } |  
{ START ( literal ) END ( { literal | MAXVALUE } ) } |  
{ START ( literal ) } |  
{ END ( { literal | MAXVALUE } ) }  
}
  - The LIST distribution rule **slice\_values\_item** is as follows:  
[ ( SLICE name VALUES (expression [, ... ] ) [DATANODE datanode\_name |  
( datanode\_name\_list )  
[, ... ] ) ]  
( SLICE name VALUES (DEFAULT) [DATANODE datanode\_name] | ( datanode\_name\_list ) )  
]
  - **update\_expr** is as follows:  
{ CURRENT\_TIMESTAMP | LOCALTIMESTAMP | NOW() }

## Parameters

- **UNLOGGED**

If this keyword is specified, the created table is an unlogged table. Data written to unlogged tables is not written to the WALs, which makes them considerably faster than ordinary tables. However, an unlogged table is automatically truncated after conflicts, OS restart, database restart, switchover, power-off, or abnormal shutdown, incurring data loss risks. Contents of an unlogged table are also not replicated to standby nodes. Any indexes created on an unlogged table are not automatically logged as well.

Usage scenario: Unlogged tables do not ensure data security. Users can back up data before using unlogged tables; for example, users should back up the data before a system upgrade.

Troubleshooting: If data is missing in the indexes of unlogged tables due to some unexpected operations such as an unclean shutdown, users should rebuild the indexes with errors.

- **GLOBAL | LOCAL**

When creating a temporary table, you can specify the **GLOBAL** or **LOCAL** keyword before **TEMP** or **TEMPORARY**. Currently, the two keywords are used to be compatible with the SQL standard. A local temporary table will be created by the GaussDB regardless of whether **GLOBAL** or **LOCAL** is specified.

- **TEMPORARY | TEMP**

If **TEMP** or **TEMPORARY** is specified, the created table is a temporary table. A temporary table is automatically dropped at the end of the current session. Therefore, you can create and use temporary tables in the current session as long as the connected CN in the session is normal. Temporary tables are created only in the current session. If a DDL statement involves operations on temporary tables, a DDL error will be generated. Therefore, you are advised not to perform operations on temporary tables in DDL statements. **TEMP** is equivalent to **TEMPORARY**.

---

**NOTICE**

- Temporary tables are visible to the current session through a schema starting with **pg\_temp**. Therefore, do not delete schemas starting with **pg\_temp** or **pg\_toast\_temp**.
- If **TEMPORARY** or **TEMP** is not specified when you create a table but its schema is set to that starting with **pg\_temp** in the current session, the table will be created as a temporary table.
- A temporary table is visible only to the current session. Therefore, it cannot be used together with **\parallel on**.
- Temporary tables do not support DN faults or primary/standby switchovers.

---

- **IF NOT EXISTS**

Sends a notice, but does not throw an error, if a table with the same name exists.

- **[ ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year } OF { NO MODIFICATION } [ ON ( EXPR ) ] ]**

When creating a table, you can call **ILM ADD POLICY ROW STORE COMPRESS ADVANCED ROW** to add an advanced compression policy for row store. For example, **CREATE TABLE t1 (a int) ILM ADD POLICY ROW STORE COMPRESS ADVANCED ROW AFTER 3 DAY OF NO MODIFICATION ON (a != 0)** indicates that the **t1** table is created and the advanced compression policy is added: rows that are not modified in three days and **a != 0** is specified.

- **AFTER n { day | month | year } OF NO MODIFICATION**: indicates the rows that are not modified in *n* days, months, or years.
- **ON (EXPR)**: indicates the row-level expression, which is used to determine whether a row is hot or cold.

- **table\_name**  
Specifies the name of the table to be created.

---

**NOTICE**

Some processing logic of materialized views determines whether a table is the log table of a materialized view or a table associated with a materialized view based on the table name prefix. Therefore, do not create a table whose name prefix is **mlog\_** or **matviewmap\_**. Otherwise, some functions of the table are affected.

- 
- **column\_name**  
Specifies the name of a column to be created in the new table.
  - **data\_type**  
Specifies the data type of the column.
  - **compress\_mode**  
Specifies whether to compress a table column. The option specifies the algorithm preferentially used by table columns. Row-store tables do not support compression.  
Value range: **DELTA**, **PREFIX**, **DICTIONARY**, **NUMSTR**, and **NOCOMPRESS**
  - **CHARACTER SET | CHARSET charset**  
Specifies the character set of a table column. If this parameter is specified separately, the collation of the table column is set to the default collation of the specified character set.  
This syntax is supported only in a MySQL-compatible database (that is, **sql\_compatibility** set to 'MYSQL').
  - **COLLATE collation**  
Assigns a collation to the column (which must be of a collatable data type). If no collation is specified, the default collation is used. You can run the **SELECT \* FROM pg\_collation** command to query collation rules from the **pg\_collation** system catalog. The default collation rule is the row starting with **default** in the query result. In a MySQL-compatible database (that is, **sql\_compatibility** set to 'MYSQL'), **utf8mb4\_bin**, **utf8mb4\_general\_ci**, **utf8mb4\_unicode\_ci**, **binary**, **gbk\_chinese\_ci**, **gbk\_bin**, **gb18030\_chinese\_ci**, and **gb18030\_bin** are also supported.

 **NOTE**

- Only the character type supports the specified character set. If the binary character set or collation is specified, the character type is converted to the corresponding binary type. If the type mapping does not exist, an error is reported. Currently, only the mapping from the TEXT type to the BLOB type is available.
- Except the binary character set and collation, only the character set that is the same as the database encoding can be specified.
- If the character set or collation of a column is not explicitly specified and the default character set or collation of the table is specified, the character set or collation of the column is inherited from the table. If the default character set or collation of a table does not exist, the character set and collation of table columns inherit the character set and collation of the current database when **b\_format\_behavior\_compat\_options** contains 'default\_collation'.

**Table 7-240** Character sets and collation supported in MySQL-compatible mode (sql\_compatibility set to 'MYSQL')

| Collation          | Character Set  | Description                                                                    |
|--------------------|----------------|--------------------------------------------------------------------------------|
| utf8mb4_general_ci | utf8mb4 (utf8) | The general collation is used, which is case insensitive.                      |
| utf8mb4_unicode_ci | utf8mb4 (utf8) | The general collation is used, which is case insensitive.                      |
| utf8mb4_bin        | utf8mb4 (utf8) | The binary collation is used, which is case sensitive.                         |
| binary             | binary         | The binary collation is used.                                                  |
| gbk_chinese_ci     | gbk            | The Chinese collation is used.                                                 |
| gbk_bin            | gbk            | The binary collation is used, which is case sensitive.                         |
| gb18030_chinese_ci | gb18030        | The Chinese collation is used.                                                 |
| gb18030_bin        | gb18030        | The binary collation is used, which is case sensitive.                         |
| utf8mb4_0900_ai_ci | utf8mb4        | The unicode collation algorithm (UCA) rule is used, which is case-insensitive. |
| utf8_general_ci    | utf8           | The general collation is used, which is case insensitive.                      |
| utf8_bin           | utf8           | The binary collation is used, which is case sensitive.                         |

- **LIKE source\_table [ like\_option ... ]**

Specifies a table from which the new table automatically inherits all column names, their data types, and their not-null constraints, as well as the default expression declared as serial.

The new table and the original table are decoupled after creation is complete. Changes to the original table will not be applied to the new table, and it is not possible to include data of the new table in scans of the original table.

The copied columns and constraints are not merged with similarly named columns and constraints. If the same name is specified explicitly or in another LIKE clause, an error is reported.

- The default expressions are copied from the original table to the new table only if INCLUDING DEFAULTS is specified. The **serial** column is not copied. The default behavior is to exclude default expressions, resulting in the copied columns in the new table having default values **NULL**.
- If **INCLUDING UPDATE** is specified, the **ON UPDATE CURRENT\_TIMESTAMP** attribute of the source table column is copied to the new table column. By default, the generated expression is not copied.

- The **CHECK** constraints are copied from the original table to the new table only when **INCLUDING CONSTRAINTS** is specified. Other types of constraints are never copied to the new table. Not-null constraints are always copied to the new table. These rules also apply to column constraints and table constraints.
- Any indexes on the original table will not be created on the new table, unless the **INCLUDING INDEXES** clause is specified.
- **STORAGE** settings for the source column definitions are copied only if **INCLUDING STORAGE** is specified. The default behavior is to exclude **STORAGE** settings.
- If **INCLUDING COMMENTS** is specified, comments for the copied columns, constraints, and indexes are copied. The default behavior is to exclude comments.
- If **INCLUDING PARTITION** is specified, the partition definitions of the source table are copied to the new table, and the new table no longer uses the **PARTITION BY** clause. By default, the partition definition of the source table is not copied.
- If **INCLUDING REOPTIONS** is specified, the new table will copy the storage parameter (that is, **WITH** clause) of the source table. The default behavior is to exclude partition definition of the storage parameter of the original table.
- If **INCLUDING DISTRIBUTION** is specified, the distribution information of the original table is copied to the new table, including distribution type and key, and the new table no longer use the **DISTRIBUTE BY** clause. The default behavior is to exclude distribution information of the original table.
- **INCLUDING ALL** contains the content of **INCLUDING DEFAULTS**, **INCLUDING UPDATE**, **INCLUDING CONSTRAINTS**, **INCLUDING INDEXES**, **INCLUDING STORAGE**, **INCLUDING COMMENTS**, **INCLUDING PARTITION**, **INCLUDING REOPTIONS**, and **INCLUDING DISTRIBUTION**.

---

**NOTICE**

- If the original table contains a sequence with the serial, bigserial, or smallserial data type, or a column in the original table is a sequence by default and the sequence is created for this table (created by using CREATE SEQUENCE ... OWNED BY), these sequences will not be copied to the new table, and another sequence specific to the new table will be created. This is different from earlier versions. To share a sequence between the source table and new table, create a shared sequence (do not use **OWNED BY**) and set a column in the source table to this sequence.
  - You are advised not to set a column in the source table to the sequence specific to another table especially when the table is distributed in specific node groups, because doing so may result in CREATE TABLE ... LIKE execution failures. In addition, doing so may cause the sequence to become invalid in the source sequence because the sequence will also be deleted from the source table when it is deleted from the table that the sequence is specific to. To share a sequence among multiple tables, you are advised to create a shared sequence for them.
  - The CREATE TABLE table\_name LIKE source\_table syntax is supported only when **sql\_compatibility** is set to 'MYSQL' (MySQL-compatible database), **b\_format\_version** is set to 5.7, and **b\_format\_dev\_version** is set to s2.
  - In a MySQL-compatible database, if **b\_format\_version** is set to 5.7 and **b\_format\_dev\_version** is set to s2, **INCLUDING** and **EXCLUDING** cannot be specified. In this case, it is equivalent to specify **INCLUDING ALL** by default.
- 
- **AUTO\_INCREMENT [ = ] value**  
This clause specifies an initial value for an auto-increment column. The value must be a positive number and cannot exceed  $2^{127} - 1$ .

---

**NOTICE**

This clause takes effect only when **sql\_compatibility** is set to 'MYSQL'.

- 
- **COMMENT [ = ] 'string'**
    - The COMMENT [ = ] 'string' clause is used to add comments to a table.
    - The COMMENT 'string' in column\_constraint indicates that comments are added to a column.
    - The COMMENT 'string' in table\_constraint indicates that comments are added to the indexes corresponding to the primary key and unique key.

---

**NOTICE**

- This clause is valid only when **sql\_compatibility** is set to 'MYSQL'.
  - A table-level comment can contain a maximum of 2048 characters, and a column-level or index-level comment can contain a maximum of 1024 characters.
  - Comments in table\_constraint support only primary keys and unique keys.
- 
- **ENGINE**  
Supported in MySQL-compatible mode and used only for syntax adaptation. Only InnoDB can be set and no actual effect is achieved.

---

**NOTICE**

The ENGINE syntax cannot be used in the CREATE TABLE table\_name LIKE source\_table syntax.

- 
- **WITH ( { storage\_parameter = value } [, ... ] )**  
Specifies an optional storage parameter for a table or an index. The WITH clause used for tables can also contain **OIDS=FALSE** to specify that rows of the new table should not contain OIDs.

** NOTE**

When using **Numeric** of any precision to define a column, specify precision **p** and scale **s**. When precision and scale are not specified, the input will be displayed.

The description of parameters is as follows:

– **FILLFACTOR**

The fill factor of a table is a percentage from 10 to 100. **100** (complete filling) is the default value. If the Ustore is used, the default value is **92**. When a smaller fill factor is specified, **INSERT** operations fill table pages only to the indicated percentage. The remaining space on each page is reserved for updating rows on that page. This gives UPDATE a chance to place the updated copy of a row on the same page, which is more efficient than placing it on a different page. For a table whose entries are never updated, setting the fill factor to **100** (complete filling) is the best choice, but in heavily updated tables a smaller fill factor would be appropriate.

Value range: 10–100

– **ORIENTATION**

Specifies the storage mode of table data. This parameter cannot be modified once it is set.

Value range:

- **ROW** indicates that table data is stored in rows.

Row store applies to the OLTP service, which has many interactive transactions. An interaction involves many columns in the table. Using row store can improve the efficiency.

Default value:

If an ordinary tablespace is specified, the default is **ROW**.

– STORAGE\_TYPE

Specifies the storage engine type. This parameter cannot be modified once it is set.

Value range:

- **USTORE** indicates that tables support the in-place update storage engine. Note that the **track\_counts** and **track\_activities** parameters must be enabled when the Ustore table is used. Otherwise, space bloating may occur.
- **ASTORE** indicates that tables support the append-only storage engine.

Default value:

If **ORIENTATION** and **STORAGE\_TYPE** are not specified, **ASTORE** is used by default, indicating that the table supports the append-only storage engine.

– INIT\_TD

Specifies the number of TDs to be initialized when a Ustore table is created. This parameter can be modified by running the **ALTER TABLE** command. Note that this parameter affects the maximum size of a single tuple stored on the data page. The conversion method is **MAX\_TUPLE\_SIZE = BLCKSZ – INIT\_TD x TD\_SIZE**. For example, if you change the number of **INIT\_TD** from 4 to 8, the maximum size of a single tuple decreases by 4 x **INIT\_TD**.

Value ranges: 2–128. The default value is **4**.

– COMPRESSION

Specifies the compression level of table data. It determines the compression ratio and time. Generally, the higher the level of compression, the higher the ratio, the longer the time; and the lower the level of compression, the lower the ratio, the shorter the time. The actual compression ratio depends on the distribution mode of table data loaded. Row-store tables do not support compression.

Value range: For row-store tables, the valid values are **YES** and **NO**.

Default value: **NO**

– COMPRESSLEVEL

Specifies the table data compression ratio and duration at the same compression level. This divides a compression level into sublevels, providing more choices for compression ratio and duration. As the value becomes greater, the compression ratio becomes higher and duration longer at the same compression level.

Value range: 0 to 3

Default value: **0**

– segment

The data is stored in segment-page mode. This parameter supports only row-store tables. Column-store tables are not supported. Protection against unauthorized deletion and damage of physical files 1 to 5 is not supported.

Value range: **on** and **off**

Default value: **off**

– hashbucket

Creates a hash table that uses buckets. This parameter supports only row-store tables.

Value range: **on** and **off**

Default value: **off**

---

**NOTICE**

- For details about constraints on hash bucket tables, see section "Online Scale-Out Based on Hash Bucket Tables" in *Administrator Guide*.
- When creating a hash bucket table, ensure that the current database is bound to the default node group of the cluster. For details about how to bind a database to a group, see [ALTER DATABASE](#).
- In current version, DDL operations on hash bucket tables are affected. Therefore, you are advised not to frequently perform DDL operations on hash bucket tables.
- Hash bucket tables are bound to segmented paging storage, that is, when **hashbucket** is set to **on**, **segment** is set to **on**.
- You are advised not to create a small table (ordinary table: < 8 MB; partitioned table: < 8 MB x Number of partitions) as a hash bucket table. The sequential scan performance deteriorates twice that of an ordinary table.

---

– enable\_tde

Indicates that the table is an encrypted table. The database automatically encrypts the data in the encryption table before storing it. Before using this parameter, ensure that TDE has been enabled using the GUC parameter **enable\_tde** and the information for accessing the key service has been set using the GUC parameter **tde\_key\_info**. For details about how to use this parameter, see "Transparent Data Encryption" in *Feature Guide*. This parameter applies only to row-store tables, segment-page tables, hash bucket tables, temporary tables, and unlogged tables.

Value range: **on** and **off** When **enable\_tde** is set to **on**, **key\_type**, **tde\_cmk\_id**, and **dek\_cipher** are automatically generated by the database and cannot be manually specified or modified.

Default value: **off**

– encrypt\_algo

Specifies the encryption algorithm of the encryption table. This parameter must be used together with **enable\_tde**.

Value range: a string. The value can be **AES\_128\_CTR** or **SM4\_CTR**.

Default value: null if **enable\_tde** is not set, or **AES\_128\_CTR** if **enable\_tde** is set.

– parallel\_workers

Number of bgworker threads started when an index is created. For example, value **2** indicates that two bgworker threads are started to create indexes concurrently.

Value range: [0,32], int type. The value **0** indicates that concurrent index creation is disabled.

Default value: If this parameter is not set, the concurrent index creation function is disabled.

– dek\_cipher

Specifies the DEK ciphertext. After a user sets the **enable\_tde** parameter for a table, the database automatically generates a data key.

Value range: a string

Default value: null

– key\_type

Specifies the type of the master key. After the **enable\_tde** parameter is set for a table, the database automatically obtains the master key type from the GUC parameter **tde\_key\_info**.

Value range: a string

Default value: null

– cmk\_id

Specifies the ID of the master key. After the **enable\_tde** parameter is set for a table, the database automatically obtains the master key ID from the GUC parameter **tde\_key\_info**.

Value range: a string

Default value: null

– hasuids

If this parameter is set to **on**, a unique table-level ID is allocated to a tuple when the tuple is updated.

Value range: **on** and **off**

Default value: **off**

– logical\_repl\_node

Name of the DN that returns logical logs to the CN during logical decoding of a distributed replication table. For the replication table, if this parameter is not specified, the first node in the node group where the current table is located is used by default. When the RESET operation is performed on this option, **logical\_repl\_node** is reset to the first node of current table.

Value range: a string

Default value: For the non-replication table, this parameter is empty by default. For the replication table, this parameter is set to the name of the first node by default.

– STAT\_STATE

Determines whether table statistics are locked. If locked, the table statistics cannot be updated. This parameter is invalid in distributed mode.

Value range: **locked** and **unlock**

Default value: **unlock**

- `statistic_granularity`

Records the default **partition\_mode** when the table analyzes statistics. For details about **partition\_mode**, see [ANALYZE | ANALYSE](#). This parameter is invalid for non-partitioned tables.

Value range: See the value range of **partition\_mode**.

Default value: **AUTO**

- `enable_update_distkey`

Determines whether the table supports the UPDATE operation on distribution keys. The distribution keys can be updated only when this attribute of the table is set to **on** and constraints are met. Otherwise, distribution keys do not support the UPDATE operation.

Value range: **on** and **off**

Default value: **off**

#### NOTE

For details about the constraints on updating distributed columns, see [Precautions](#) in this section.

- **WITHOUT OIDS**

It is equivalent to **WITH(OIDS=FALSE)**.

- **ON COMMIT { PRESERVE ROWS | DELETE ROWS }**

**ON COMMIT** determines what to do when you commit a temporary table creation operation. Currently, **PRESERVE ROWS** and **DELETE ROWS** are supported.

- **PRESERVE ROWS** (default): No special action is taken at the ends of transactions. The temporary table and its table data are unchanged.
- **DELETE ROWS**: All rows in the temporary table will be deleted at the end of each transaction block.

- **COMPRESS | NOCOMPRESS**

If you specify **COMPRESS** in the CREATE TABLE statement, the compression feature is triggered in case of a bulk insert operation. If this feature is enabled, a scan is performed for all tuple data within the page to generate a dictionary and then the tuple data is compressed and stored. If

**NOCOMPRESS** is specified, the table is not compressed. Row-store tables do not support compression.

Default value: **NOCOMPRESS**, that is, tuple data is not compressed before storage.

- **TABLESPACE tablespace\_name**

Specifies the tablespace where the new table is created. If not specified, the default tablespace is used.

- **DISTRIBUTE BY**

Specifies how the table is distributed or replicated between DN's.

Value range:

- **REPLICATION**: Each row in the table exists on all DN's, that is, each DN has complete table data.

- **HASH ( column\_name )**: Each row of the table will be placed into specified DNs based on the hash value of the specified column.
- **MURMURHASH ( diskey\_expr )**: Hash operations are performed on specified columns. The MURMURHASH algorithm is used to distribute data to corresponding DNs through mapping. **diskey\_expr** can be a single column name or a column name modified by the **lpad\_s(string text, length int [, fill text])** function. When this function is used, only the first parameter can be a column name, for example, `lpad_s(a,10,'0')`. When **lpad\_s** is used as a distribution key expression, the third parameter cannot be omitted.
- **RANGE(column\_name)**: maps a specified column based on the range and distributes data to the corresponding DNs.
- **LIST(column\_name)**: maps a specified column based on a specific value and distributes data to the corresponding DNs.

 NOTE

- For HASH distribution, the maximum number of distribution keys is the same as that of columns. A maximum of 1600 distribution keys are supported. For MURMURHASH distribution, the distribution key supports only one column (an expression or a column in a table). For RANGE (VALUE LESS THAN) and LIST distributions, the distribution key supports a maximum of four columns. For RANGE (START END) distribution, the distribution key supports only one column.
- Only the MURMURHASH distribution supports an expression as the distribution key. The distribution key expression supports only the `lpad_s(string text, length int [, fill text])` function.
- The restrictions on MURMURHASH distribution are as follows:
  - The stream plan, FQS plan, and PGXC plan are not supported.
  - Scaling, hash bucket tables, GSIs, and materialized views are not supported.
  - When two hash tables are joined and the distribution key has an INNER JOIN condition, the FQS plan is not supported.
  - A node group (user-defined node group) must be specified for a MURMURHASH distributed table, and the node group must be a non-installation node group.
  - Tables cannot be created using CREATE TABLE AS.
  - The distribution key of the MURMURHASH distribution table must contain the NOT NULL constraint.
- For a RANGE distribution policy using the VALUE LESS THAN clause, the distribution rules are as follows:
  - The comparison starts from the first column of values to be inserted.
  - If the value of the inserted first column is smaller than the boundary value of the current column in the local slice, the values are directly inserted.
  - If the value of the inserted first column is equal to the boundary value of the current column in the local slice, compare the value of the inserted second column with the boundary value of the next column in the local slice. If the value of the inserted second column is smaller than the boundary value of the next column in the local slice, the values are directly inserted. If they are equal, the comparison of the next columns between the source and target continues.
  - If the value of the inserted first column is greater than the boundary value of the current column in the local slice, compare the value with that in the next slice.
- If the shard of the RANGE distribution table corresponds to multiple DNs, the hash value of the distribution key is calculated to perform modulo operation on the number of DN and map a new DN. For details, see the example.
- If the shard of the list distribution table corresponds to multiple DNs, the hash value of the distribution key is calculated for the default shards. Then, use the calculated hash value to perform modulo operation on the number of DN and map a new DN. For non-default shards, the round robin method is used to map values in the values list to DNs. For details, see the example.
- The RANGE/LIST distribution tables support only scale-out but not scale-in. For details about the slice scale-out rule, contact the administrator.

For the hash distribution, **column\_name** supports the following data types:

- Integer types: TINYINT, SMALLINT, INT, BIGINT, and NUMERIC/DECIMAL
- Character types: CHAR, BPCHAR, VARCHAR, VARCHAR2, NVARCHAR2, and TEXT

- Date/time types: DATE, TIME, TIMETZ, TIMESTAMP, TIMESTAMPTZ, INTERVAL, and SMALLDATETIME

For the MURMURHASH distribution, the data type of the column name in **diskey\_expr** must be one of the following:

- Integer types: TINYINT, SMALLINT, INT, and BIGINT
- Character types: CHAR, BPCHAR, VARCHAR, VARCHAR2, and NVARCHAR2

For the RANGE (VALUES LESS THAN) or LIST distribution, **column\_name** supports the following data types:

- Integer types: TINYINT, SMALLINT, INT, BIGINT, and NUMERIC/DECIMAL
- Character types: CHAR, BPCHAR, VARCHAR, VARCHAR2, NVARCHAR2, and TEXT
- Date/time types: DATE, TIMESTAMP, and TIMESTAMPTZ

For the range (start end) distribution, the data type of **column\_name** must be one of the following:

- Integer types: TINYINT, SMALLINT, INT, BIGINT, and NUMERIC/DECIMAL
- Date/time types: DATE, TIMESTAMP, and TIMESTAMPTZ

 NOTE

When you create a table, the choices of distribution keys and partition keys have major impact on SQL query performance. Therefore, select appropriate distribution keys and partition keys with strategies.

- Select appropriate distribution keys.

A hash table's distribution key should evenly distribute data on each DN to prevent skewing the data or distributing it unevenly across DNs. Determine appropriate distribution keys based on the following principles:

1. Determine whether data is skewed.

Connect to the database and check the number of tuples on each DN. Replace *tablename* with the actual name of the table to be analyzed.

```
gaussdb=# SELECT a.count,b.node_name FROM (SELECT count(*) AS
count,xc_node_id FROM tablename GROUP BY xc_node_id) a, pgxc_node b WHERE
a.xc_node_id=b.node_id ORDER BY a.count DESC;
```

If tuple numbers vary greatly (several times or tenfold) on each DN, a data skew occurs. Change the data distribution key based on the following principles:

2. Rebuild a table to change its distribution keys. ALTER TABLE cannot change distribution keys. Therefore, you need to rebuild a table when changing its distribution keys.

Principles for selecting distribution keys are as follows:

The value of the distribution key should be discrete so that data can be evenly distributed on each DN. You can select the primary key of the table as the distribution key. For example, for a person information table, choose the ID card number column as the distribution key.

With the above principles are met, you can select join conditions as distribution keys so that join tasks can be pushed down to DNs, reducing the amount of data transferred between the DNs.

- Select appropriate partition keys.

In range partitioning, a table is partitioned based on ranges defined by one or more columns, with no overlap between the ranges of values assigned to different partitions. Each range has a dedicated partition for data storage.

Modify partition keys to make the query result stored in the same or least partitions (partition pruning). Obtain consecutive I/O to improve the query performance.

In actual services, time is used to filter query objects. Therefore, you can use time as a partition key, and change the key value based on the total data volume and data volume of a single query.

- RANGE/LIST distribution

If no DN is specified for the shards of a RANGE/LIST distribution table, the database uses the Round Robin algorithm to allocate DNs to the shards. In addition, if RANGE/LIST distribution is used, you are advised to define as many shards as possible when creating a table for future capacity expansion. If the defined number of shards is less than the number of DNs before scale-out, data redistribution cannot be performed on new DNs. Note that the sharding rules are designed by users. In some extreme cases, scale-out may not solve the problem of insufficient storage space.

- **TO { GROUP *groupname* | NODE ( *nodename* [, ... ] ) }**

**TO GROUP** specifies the node group to which the table to be created belongs. **TO NODE** is used for internal scale-out tools.

- **CONSTRAINT [*constraint\_name*]**

Specifies the name of a column or table constraint. The optional constraint clauses specify constraints that new or updated rows must satisfy for an INSERT or UPDATE operation to succeed.

There are two ways to define constraints:

- A column constraint is defined as part of a column definition, and it is bound to a particular column.
- A table constraint is not bound to a particular column but can apply to more than one column.

---

**NOTICE**

For a table constraint, **constraint\_name** is optional in a MySQL-compatible database (that is, **sql\_compatibility** set to 'MYSQL'). In other databases, **constraint\_name** must be added.

---

- **NOT NULL**

Forbids NULL values in columns.

- **NULL**

Allows to contain NULL values. This is the default setting.

This clause is only provided for compatibility with non-standard SQL databases. It is not recommended.

- **CHECK ( expression )**

Specifies an expression producing a Boolean result where the INSERT or UPDATE operation of rows can succeed only when the expression result is **TRUE** or **UNKNOWN**; otherwise, an error is thrown and the database is not altered.

A CHECK constraint specified as a column constraint should reference only the column's value, while an expression in a table constraint can reference multiple columns.

 **NOTE**

<>NULL and !=NULL are invalid in an expression. Change them to **IS NOT NULL**.

- **DEFAULT default\_expr**

Assigns a default data value to a column. The value can be any variable-free expressions. (Subqueries and cross-references to other columns in the current table are not allowed.) The data type of the default expression must match the data type of the column.

The default expression will be used in any insert operation that does not specify a value for the column. If there is no default value for a column, then the default value is **NULL**.

- **ON UPDATE update\_expr**

The ON UPDATE clause is an attribute constraint of a column.

When an UPDATE operation is performed on a tuple in a table, if new values of updated columns are different from old values in the table, column values with this attribute but not in updated columns are automatically updated to the current timestamp. If new values of updated columns are the same as old values in the table, column values with this attribute but not in updated

columns remain unchanged. If columns with this attribute are in updated columns, column values are updated according to the specified update value.

 **NOTE**

- This attribute can be specified only in MySQL 5.7 (that is, **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1').
- In terms of syntax, **update\_expr** supports three keywords: CURRENT\_TIMESTAMP, LOCALTIMESTAMP, and NOW(). You can also specify or not specify the precision of a keyword with parentheses. For example, ON UPDATE CURRENT\_TIMESTAMP(), ON UPDATE CURRENT\_TIMESTAMP(5), ON UPDATE LOCALTIMESTAMP(), and ON UPDATE LOCALTIMESTAMP(6). If the keyword does not contain parentheses or contains empty parentheses, the precision is 0. The NOW keyword cannot contain parentheses. The three types of keywords are synonyms of each other and have the same attribute effect.
- This attribute can be specified only for columns of the following types: timestamp, datetime, date, time without time zone, smalldatetime, and abstime.
- The CREATE TABLE AS syntax does not inherit the column attributes.
- The CREATE TABLE LIKE syntax can use INCLUDING UPDATE or EXCLUDING UPDATE to inherit or exclude a constraint. The LIKE syntax is inherited from the LIKE syntax of PostgreSQL. Currently, the ILM policy information of the old table cannot be copied.
- The precision specified by this attribute can be different from the precision specified by the type in the corresponding column. After the column value is updated through this attribute, the minimum precision is displayed. For example, CREATE TABLE t1 (col1 timestamp(6) ON UPDATE CURRENT\_TIMESTAMP(3));. If the UPDATE syntax triggers the attribute to take effect, three decimal places in the value of **col1** are displayed after the update.
- The same column cannot be specified for this attribute and the generated column constraint at the same time.
- This attribute cannot be specified for the partition key in a partitioned table.
- In distributed scenarios, this attribute cannot be specified for distribution keys and primary keys.

- **AUTO\_INCREMENT**

Specifies an auto-increment column.

Currently, the auto-increment column is a local auto-increment column by default. The auto-increment column increases independently on each DN and does not affect each other. The auto-increment column is not unique globally.

If the value of this column is not specified (or the value of this column is set to **0**, **NULL**, or **DEFAULT**), the value of this column is automatically increased by the auto-increment counter.

If this column is inserted or updated to a value greater than the current auto-increment counter, the auto-increment counter is updated to this value after the command is executed successfully.

The initial auto-increment value is set by the AUTO\_INCREMENT [= ] value clause. If it is not set, the default value **1** is used.

 NOTE

- The auto-increment column can be specified only when **sql\_compatibility** is set to 'MYSQL'.
- The data type of the auto-increment column can only be integer, 4-byte or 8-byte floating point, or Boolean.  
An error occurs if the auto-increment continues after an auto-increment value reaches the maximum value of a column data type.
- Each table can have only one auto-increment column.
- It is recommended that the local auto-increment column be the first column of a non-global secondary index. Otherwise, errors may occur when some operations are performed on a table that contains auto-increment columns, for example, ALTER TABLE EXCHANGE PARTITION.
- The DEFAULT value cannot be specified for an auto-increment column.
- The expression of the CHECK constraint cannot contain auto-increment columns.
- You can specify that the auto-increment column can be NULL. If it is not specified, the auto-increment column contains the NOT NULL constraint by default.
- When a table containing a local auto-increment column is created, a sequence that depends on the column is created on each DN as an auto-increment counter. You are not allowed to modify or delete the sequence using sequence-related functions. You can view the value of the sequence.
- The auto-increment and refresh operations of the auto-increment counter are not rolled back.
  - Before data is inserted into a table, **0** or **NULL** triggers auto-increment. After data is inserted or updated to a table, the auto-increment counter is updated. If an error is reported after auto-increment, and data is not inserted or updated to the table, the auto-increment counter does not roll back. Subsequent insert statements trigger auto-increment based on the auto-increment counter. As a result, the values of the auto-increment columns in the table are discontinuous.
  - If you insert or import reserved auto-increment cache values in batches, the values in the auto-increment column may be discontinuous. For details, see the description of the **auto\_increment\_cache** parameter.
- An auto-increment column cannot be used as a distribution key.
- Currently, local temporary tables do not support auto-increment columns.
- DISTRIBUTE BY REPLICATION does not support auto-increment columns.
- **UNIQUE [KEY] index\_parameters**  
Specifies that a group of one or more columns of a table can contain only unique values.  
For the purpose of a unique constraint, null is not considered equal.  
UNIQUE KEY can be used only when **sql\_compatibility** is set to 'MYSQL', which has the same semantics as UNIQUE.
- **UNIQUE [ index\_name ][ USING method ] ( { {column\_name | ( expression ) } [ ASC | DESC ] }, ... ) index\_parameters**  
Specifies that a group of one or more columns of a table can contain only unique values.  
For the purpose of a unique constraint, null is not considered equal.  
**index\_name** indicates the index name.

---

**NOTICE**

- The **index\_name** parameter is supported only in a MySQL-compatible database (that is, **sql\_compatibility** set to 'MYSQL').
- For a unique key constraint, if both **constraint\_name** and **index\_name** are specified, the value of **index\_name** is used as the index name.

---

- **PRIMARY KEY index\_parameters**

**PRIMARY KEY [ USING method ] ( { column\_name [ ASC | DESC ] } [, ... ] )  
index\_parameters**

Specifies that a column or columns of a table can contain only unique (non-duplicate) and non-null values.

Only one primary key can be specified for a table.

- **REFERENCES**

The current version does not support the REFERENCES clause.

- **USING method**

Specifies the name of the index method to be used.

For details about the value range, see the USING method in [Parameters](#).

---

**NOTICE**

- The USING method is supported only in a MySQL-compatible database (that is, **sql\_compatibility** set to 'MYSQL').
- In MySQL-compatible mode, if USING method is not specified, the default index method is B-tree for Astore or UB-tree for Ustore.
- For the constraint of building a global secondary index by default, the bottom layer of the global secondary index uses UB-tree storage, even if the storage mode specified by the user is B-tree.
- If the storage mode of a table is Ustore and the constraint in the SQL statement is specified as USING BTREE, the underlying layer automatically creates the constraint as USING UBTREE.

---

- **ASC | DESC**

**ASC** specifies an ascending (default) sort order. **DESC** specifies a descending sort order.

---

**NOTICE**

ASC|DESC is supported only in a MySQL-compatible database (that is, **sql\_compatibility** set to 'MYSQL').

---

- **expression**

Specifies an expression index constraint based on one or more columns of the table. It must be written in parentheses.

## NOTICE

Expression indexes in the UNIQUE constraint are supported only in a MySQL-compatible database (that is, `sql_compatibility` set to 'MYSQL').

- **DEFERRABLE | NOT DEFERRABLE**

Determines whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction using the **SET CONSTRAINTS** command. **NOT DEFERRABLE** is the default value. Currently, only **UNIQUE** and **PRIMARY KEY** constraints accept this clause. All the other constraints are not deferrable.

- **INITIALLY IMMEDIATE | INITIALLY DEFERRED**

If a constraint is deferrable, this clause specifies the default time to check the constraint.

- If the constraint is **INITIALLY IMMEDIATE** (default value), it is checked after each statement.
- If the constraint is **INITIALLY DEFERRED**, it is checked only at the end of the transaction.

The constraint check time can be altered using the **SET CONSTRAINTS** statement.

- **USING INDEX TABLESPACE tablespace\_name**

Allows selection of the tablespace in which the index associated with a **UNIQUE** or **PRIMARY KEY** constraint will be created. If not specified, the index is created in **default\_tablespace**. If **default\_tablespace** is empty, the default tablespace of the database is used.

- **ENCRYPTION\_TYPE = encryption\_type\_value**

For the encryption type in the **ENCRYPTED WITH** constraint, the value of **encryption\_type\_value** is **DETERMINISTIC** or **RANDOMIZED**.

- **[DEFAULT] CHARACTER SET | CHARSET [=] default\_charset**

Specifies the default character set of a table. If you specify a character set separately, the default collation of the table is set to the default collation of the specified character set.

This syntax is supported only when `sql_compatibility` is set to 'MYSQL'.

- **[DEFAULT] COLLATE [=] default\_collation**

Specifies the default collation of a table. If you specify a collation separately, the default character set of the table is set to the character set corresponding to the specified collation.

This syntax is supported only when `sql_compatibility` is set to 'MYSQL'. For details about the collation, see [Table 7-240](#).

## NOTE

If the character set or collation of a table is not explicitly specified and the default character set or collation of the schema is specified, the character set or collation of the table is inherited from the schema. If the default character set or collation of a schema does not exist, the character set and collation of the table inherit the character set and collation of the current database when `b_format_behavior_compat_options` contains 'default\_collation'.

## Examples

- Temporary table

```
-- Create a temporary table.
gaussdb=# CREATE TEMP TABLE test_t1(
 id CHAR(7),
 name VARCHAR(20),
 province VARCHAR(60), -- Province
 country VARCHAR(30) DEFAULT 'China' -- Country
);

-- Insert data into the current session.
gaussdb=# INSERT INTO test_t1 VALUES ('0000009','Jack','Guangzhou','China');

-- The data in the temporary table is visible only in the current session. Therefore, the table does not
contain data in another session.
gaussdb=# SELECT * FROM test_t1;
 id | name | age
----+-----+-----
(0 rows)

-- Create a temporary table and specify that this table is deleted when the transaction is committed.
gaussdb=# CREATE TEMPORARY TABLE test_t2(
 id CHAR(7),
 name VARCHAR(20),
 province VARCHAR(60), -- Province
 country VARCHAR(30) DEFAULT 'China' -- Country
) ON COMMIT DELETE ROWS;
-- Drop the table.
gaussdb=# DROP TABLE test_t1;
gaussdb=# DROP TABLE test_t2;
```

- Specifying the character set and collation during table creation

```
-- Create table t1. Set the default character set of t1 to utf8mb4 and the default collation to
utf8mb4_bin. Set the character set and collation of the c1 column to the default values of the table.
Set the character set of the c2 column to utf8mb4, and its collation to utf8mb4_unicode_ci.
gaussdb=# CREATE TABLE t1(c1 text, c2 text charset utf8mb4 collate utf8mb4_unicode_ci) charset
utf8mb4 collate utf8mb4_bin;
```

- IF NOT EXISTS keyword

If this keyword is used, NOTICE is reported when the table does not exist. If this keyword is not used, ERROR is reported. In either case, the table fails to be created.

```
gaussdb=# CREATE TABLE test_t3(id INT);
-- Create a table named test_t3.
gaussdb=# CREATE TABLE test_t3(id INT);
ERROR: relation "test_t3" already exists in schema "public"
DETAIL: creating new table with existing name in the same schema

-- Use the IF NOT EXISTS keyword.
gaussdb=# CREATE TABLE IF NOT EXISTS test_t3(id INT);
NOTICE: relation "test_t3" already exists, skipping
CREATE TABLE

-- Drop the table.
gaussdb=# DROP TABLE test_t3;
```

- Specifying a tablespace during table creation

```
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE ds_tbs1 RELATIVE LOCATION 'tablespace/tablespace_1';

-- Specify a tablespace when creating a table.
gaussdb=# CREATE TABLE test(id CHAR(7), name VARCHAR(20)) TABLESPACE ds_tbs1;

-- Delete the table and tablespace.
gaussdb=# DROP TABLE test;
gaussdb=# DROP TABLESPACE ds_tbs1;
```

- Specifying the AUTO\_INCREMENT column during table creation

```
-- The local auto-increment column is not used as the distribution key. The value starts from 10 for
each DN. (Change the DN name by running SELECT node_name FROM pgxc_node WHERE
node_type = 'D' based on the actual situation.)
gaussdb=# CREATE TABLE local_autoinc(col int AUTO_INCREMENT, col1 int) AUTO_INCREMENT = 10
DISTRIBUTE BY LIST(col1)(
 SLICE s1 VALUES (1) DATANODE datanode1,
 SLICE s2 VALUES (2) DATANODE datanode2
);

-- You are advised to use the auto-increment column as the first column of the index to create an
index.
gaussdb=# CREATE INDEX local_autoinc_ai ON local_autoinc(col);

-- Distribute data to DN1. The value NULL triggers auto-increment, and the auto-increment value is
10.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(NULL,1);

-- Distribute data to DN2. The value 0 triggers auto-increment, and the auto-increment value is 10.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(1 - 1,2);

-- Distribute data to DN1. The value 100 does not trigger auto-increment. After data is inserted
successfully, the auto-increment value is updated to 100.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(100,1);

-- Distribute data to DN1. The value 0 triggers auto-increment, and the auto-increment value is 101.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(0,1);

-- Distribute data to DN2. The value DEFAULT triggers auto-increment, and the auto-increment value
is 11.
gaussdb=# INSERT INTO local_autoinc(col, col1) VALUES(DEFAULT,2);

gaussdb=# SELECT col,col1 FROM local_autoinc ORDER BY 2,1;
 col | col1
-----+-----
 10 | 1
 100 | 1
 10 | 1
 10 | 2
 11 | 2
(5 rows)

-- Delete.
gaussdb=# DROP TABLE local_autoinc;
```

- **Creating a table using CREATE TABLE ... LIKE**

```
-- Create the source table t1.
gaussdb=# CREATE TABLE t1(col INT);
CREATE TABLE

gaussdb=# \d t1
 Table "public.t1"
 Column | Type | Modifiers
-----+-----+-----
 col | integer |

-- Create the target table t2.
gaussdb=# CREATE TABLE t2(LIKE t1);
CREATE TABLE

gaussdb=# \d t2
 Table "public.t2"
 Column | Type | Modifiers
-----+-----+-----
 col | integer |

-- Delete.
gaussdb=# DROP TABLE t1,t2;
```

## Examples of Creating a Table and Adding Constraints to the Table

- Non-null constraints

If no value is specified for a column with a non-null constraint when data is added, an error is reported. You can add non-null constraints to multiple columns in a table.

```
-- Create a table and add a non-null constraint to the id column.
```

```
gaussdb=# CREATE TABLE test_t4(
 id CHAR(7) NOT NULL,
 name VARCHAR(20),
 province VARCHAR(60), -- Province
 country VARCHAR(30) DEFAULT 'China' -- Country
);
```

```
-- If the value of id is not specified or is NULL during data insertion, the non-null constraint is triggered. As a result, the insertion fails.
```

```
gaussdb=# INSERT INTO test_t4 (name,province) VALUES ('scott','Shanghai');
ERROR: null value in column "id" violates not-null constraint
DETAIL: Failing row contains (null, scott, Shanghai, China)
```

```
-- Drop the table.
```

```
gaussdb=# DROP TABLE test_t4;
```

- Unique constraint

The keyword UNIQUE is used to add a unique constraint to a column. When data is inserted, the constraint is triggered if the column is duplicate. Multiple **NULL** values are not duplicate values. When a unique constraint is added, a unique index is automatically added. You can add unique constraints to multiple columns in a table.

```
-- Create a table to add unique constraints.
```

```
gaussdb=# CREATE TABLE test_t5(
 id CHAR(7) UNIQUE USING INDEX TABLESPACE pg_default, -- You can specify a tablespace or
 use the default tablespace.
 name VARCHAR(20),
 province VARCHAR(60), -- Province
 country VARCHAR(30) DEFAULT 'China' -- Country
);
```

```
-- You can also use the following method to manually name a unique constraint and add constraints for multiple columns:
```

```
gaussdb=# CREATE TABLE test_t6(
 id CHAR(7),
 name VARCHAR(20),
 province VARCHAR(60), -- Province
 country VARCHAR(30) DEFAULT 'China', -- Country
 CONSTRAINT unq_test_id UNIQUE (id,name)
);
```

```
-- When data with duplicate IDs is inserted, constraints are triggered. As a result, the insertion fails.
```

```
gaussdb=# INSERT INTO test_t5(id) VALUES('0000010');
INSERT 0 1
gaussdb=# INSERT INTO test_t5(id) VALUES('0000010');
ERROR: duplicate key value violates unique constraint "test_t5_id_key"
DETAIL: Key (id)=(0000010) already exists.
```

```
-- The constraint is not triggered when data whose id is NULL is inserted for multiple times.
```

```
gaussdb=# INSERT INTO test_t5(id) VALUES (NULL);
INSERT 0 1
gaussdb=# INSERT INTO test_t5(id) VALUES (NULL);
INSERT 0 1
```

```
gaussdb=# SELECT * FROM test_t5;
```

```
 id | name | province | country
-----+-----+-----+-----
0000010 | | | China
 | | | China
 | | | China
```

```
-- Drop the table.
gaussdb=# DROP TABLE test_t5;
gaussdb=# DROP TABLE test_t6;
```

- Primary key constraints

The keyword PRIMARY KEY is used to add a unique constraint to a column. The column must be unique and cannot be empty. When a primary key constraint is added, a unique index is automatically created for the table, and a non-null constraint is automatically added for the column.

Only one primary key constraint can be defined in each table.

```
-- Create a table and add a primary key constraint to the table.
gaussdb=# CREATE TABLE test_t6(
 id CHAR(7) PRIMARY KEY,
 name VARCHAR(20),
 province VARCHAR(60), -- Province
 country VARCHAR(30) DEFAULT 'China' -- Country
);
gaussdb=# INSERT INTO test_t6 (id,name,province) VALUES ('0000001','july','Beijing');
```

-- You can also use the following method to manually name a unique constraint and add constraints for multiple columns:

```
gaussdb=# CREATE TABLE test_t7(
 id CHAR(7),
 name VARCHAR(20),
 province VARCHAR(60), -- Province
 country VARCHAR(30) DEFAULT 'China', -- Country
 CONSTRAINT pk_test_t6_id PRIMARY KEY (id,name)
);
-- Insert data whose id is NULL to trigger the constraint.
gaussdb=# INSERT INTO test_t6 (id,name,province) VALUES (NULL,'july','Beijing');
ERROR: null value in column "id" violates not-null constraint
DETAIL: Failing row contains (null, july, Beijing, China).
```

-- Insert data with duplicate **id** values to trigger the constraint.

```
gaussdb=# INSERT INTO test_t6 (id,name,province) VALUES ('0000001','ben','Shanghai');
ERROR: duplicate key value violates unique constraint "test_t6_pkey"
DETAIL: Key (id)=(0000001) already exists.
```

```
-- Drop the table.
gaussdb=# DROP TABLE test_t6;
gaussdb=# DROP TABLE test_t7;
```

- Check constraints

The keyword CHECK adds a check constraint to a column. The check constraint must reference one or more columns in the table, and the result returned by the expression must be a Boolean value. Currently, expressions cannot contain subqueries. Both check and non-null constraints can be defined for the same column.

```
-- Create a table and add check constraints.
gaussdb=# CREATE TABLE test_t8 (
 id CHAR(7),
 name VARCHAR(20),
 age INT CHECK(age > 0 AND age < 150)
);
```

-- You can also use the following SQL statements to name a check constraint and add the check constraint for one or more columns:

```
gaussdb=# CREATE TABLE test_t9 (
 id CHAR(7),
 name VARCHAR(20),
 age INT,
 CONSTRAINT chek_test_t8_age CHECK(age > 0 AND age < 150)
);
```

-- If a value that does not comply with the expression is inserted, the check constraint is triggered. As a result, the insertion fails.

```
gaussdb=# INSERT INTO test_t8 (id,name,age) VALUES ('0000007','scott',200);
```

```
ERROR: new row for relation "test_t8" violates check constraint "test_t8_age_check"
DETAIL: N/A
-- Drop the table.
gaussdb=# DROP TABLE test_t8;
gaussdb=# DROP TABLE test_t9;
```

## Data Distribution Example

- **REPLICATION**

```
gaussdb=# CREATE TABLE test_replication(
 id CHAR(7),
 name VARCHAR(20),
 province VARCHAR(60), -- Province
 country VARCHAR(30) DEFAULT 'China' -- Country
)DISTRIBUTE BY REPLICATION;

-- Query table information.
gaussdb=# \d+ test_replication
Table "public.test_replication"
Column | Type | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
id | character(7) | | extended | |
name | character varying(20) | | extended | |
province | character varying(60) | | extended | |
country | character varying(30) | default 'China':character varying | extended |
Has OIDs: no
Distribute By: REPLICATION
Location Nodes: ALL DATANODES
Options: orientation=row, logical_repl_node=-1, compression=no

-- Delete.
gaussdb=# DROP TABLE test_replication;
```

- **HASH**

```
-- Define a hash table.
gaussdb=# CREATE TABLE test_hash(
 id CHAR(7),
 name VARCHAR(20),
 province VARCHAR(60), -- Province
 country VARCHAR(30) DEFAULT 'China' -- Country
)DISTRIBUTE BY HASH(id);

-- Insert data.
gaussdb=# INSERT INTO test_hash VALUES ('0000001', 'Bob', 'Shanghai', 'China'),
('0000002', 'Jack', 'Beijing', 'China'),
('0000003', 'Scott', 'Beijing', 'China');

-- View data distribution.
gaussdb=# SELECT a.count,b.node_name
FROM (SELECT COUNT(*) AS count, xc_node_id FROM test_hash GROUP BY xc_node_id) a,
pgxc_node b
WHERE a.xc_node_id=b.node_id ORDER BY a.count DESC;

count | node_name
-----+-----
2 | dn_6001_6002_6003
1 | dn_6004_6005_6006
-- Drop the table.
gaussdb=# DROP TABLE test_hash;
```

- **MURMURHASH**

```
-- The test environment contains one CN and six DNs.
-- Create a node group. You can run the SELECT node_name FROM PGXC_NODE WHERE node_type = 'D' command to query the DN name in the node group. In the query result, replace the DN name following WITH in the CREATE NODE GROUP statement as required.
gaussdb=# CREATE NODE GROUP NG1 WITH(datanode1, datanode2, datanode3, datanode4, datanode5, datanode6);
-- Define a table using MURMURHASH.
gaussdb=# CREATE TABLE test_murmurhash1 (a int NOT NULL, b int) DISTRIBUTE BY MURMURHASH(a) TO GROUP NG1;
gaussdb=# CREATE TABLE test_murmurhash2 (a int NOT NULL, b int) DISTRIBUTE BY
```

```

MURMURHASH(lpad_s(a,10,'0')) TO GROUP NG1;
-- Insert data.
gaussdb=# INSERT INTO test_murmurhash1 VALUES(0,1);
gaussdb=# INSERT INTO test_murmurhash2 VALUES(1,2);
-- Query data.
gaussdb=# SELECT * FROM test_murmurhash1;
 a | b
----+---
 0 | 1
(1 row)
gaussdb=# SELECT * FROM test_murmurhash2;
 a | b
----+---
 1 | 2
(1 row)
-- Drop the table.
gaussdb=# DROP TABLE test_murmurhash1;
gaussdb=# DROP TABLE test_murmurhash2;

-- Delete a node group.
gaussdb=# DROP NODE GROUP NG1;

```

- **RANGE**

-- Define a range-distributed table. (Change the DN name based on the actual situation. You can run the **SELECT node\_name FROM PGXC\_NODE WHERE node\_type = 'D'** command to query the DN name.)

```

gaussdb=# CREATE TABLE test_range(
 id INT,
 name VARCHAR(20),
 province VARCHAR(60), -- Province
 country VARCHAR(30) DEFAULT 'China' -- Country
)DISTRIBUTE BY RANGE(id)(

## Helpful Links

[ALTER TABLE](#), [DROP TABLE](#), and [CREATE TABLESPACE](#)

## Suggestions

- UNLOGGED
  - The unlogged table and its indexes do not use the WAL log mechanism during data writing. Their write speed is much higher than that of ordinary tables. Therefore, they can be used for storing intermediate result sets of complex queries to improve query performance.
  - The unlogged table has no primary/standby mechanism. In case of system faults or abnormal breakpoints, data loss may occur. Therefore, the unlogged table cannot be used to store basic data.
- TEMPORARY | TEMP
  - A temporary table is automatically dropped at the end of a session.
  - The temporary table is visible only to the current CN.
- LIKE
  - The new table automatically inherits all column names, data types, and not-null constraints from this table. The new table is irrelevant to the original table after the creation.
- LIKE INCLUDING DEFAULTS
  - The default expressions are copied from the original table to the new table only if INCLUDING DEFAULTS is specified. The default behavior is to exclude default expressions, resulting in the copied columns in the new table having default values **NULL**.

- LIKE INCLUDING CONSTRAINTS
  - The CHECK constraints are copied from the original table to the new table only when INCLUDING CONSTRAINTS is specified. Other types of constraints are never copied to the new table. Not-null constraints are always copied to the new table. These rules also apply to column constraints and table constraints.
- LIKE INCLUDING INDEXES
  - Any indexes on the original table will not be created on the new table, unless the INCLUDING INDEXES clause is specified.
- LIKE INCLUDING STORAGE
  - STORAGE settings for the copied column definitions are copied only if INCLUDING STORAGE is specified. The default behavior is to exclude STORAGE settings.
- LIKE INCLUDING COMMENTS
  - If INCLUDING COMMENTS is specified, comments for the copied columns, constraints, and indexes are copied. The default behavior is to exclude comments.
- LIKE INCLUDING PARTITION
  - If **INCLUDING PARTITION** is specified, the partition definitions of the source table are copied to the new table, and the new table no longer uses the **PARTITION BY** clause. By default, the partition definition of the source table is not copied.
- LIKE INCLUDING REOPTIONS
  - If INCLUDING REOPTIONS is specified, the new table will copy the storage parameter (that is, WITH clause) of the source table. The default behavior is to exclude partition definition of the storage parameter of the original table.
- LIKE INCLUDING DISTRIBUTION
  - If **INCLUDING DISTRIBUTION** is specified, the distribution information of the original table is copied to the new table, including distribution type and key, and the new table no longer use the **DISTRIBUTE BY** clause. The default behavior is to exclude distribution information of the original table.
- LIKE INCLUDING ALL
  - INCLUDING ALL contains the content of INCLUDING DEFAULTS, INCLUDING CONSTRAINTS, INCLUDING INDEXES, INCLUDING STORAGE, INCLUDING COMMENTS, INCLUDING PARTITION, INCLUDING REOPTIONS, and INCLUDING DISTRIBUTION.
- ORIENTATION ROW
  - Creates a row-store table. Row store applies to the OLTP service, which has many interactive transactions. An interaction involves many columns in the table. Using row store can improve the efficiency.
- DISTRIBUTE BY
  - It is recommended that a fact table or dimension table containing a large amount of data be created as a distribution table. Each row of the table will be placed into specified DNs based on the hash value of the specified column. The syntax is DISTRIBUTE BY HASH(column\_name).

- It is recommended that a dimension table containing a small amount of data be created as a replication table. Each row in the table exists on all DNs. That is, each DN has complete table data. The syntax is DISTRIBUTE BY REPLICATION.

### 7.12.8.43 CREATE TABLESPACE

#### Description

Creates a tablespace in a database.

#### Precautions

- The system administrator or a user who inherits the `gs_role_tablespace` permission of the built-in role can create a tablespace.
- Do not run **CREATE TABLESPACE** in a transaction block.
- If running **CREATE TABLESPACE** fails but the internal directory (or file) has been created, the directory (or file) will remain. You need to manually clear it before creating the tablespace again. If there are residual files of soft links for the tablespace in the data directory, delete the residual files, and then perform O&M operations.
- **CREATE TABLESPACE** cannot be used for two-phase transactions. If it fails on some nodes, the execution cannot be rolled back.
- You are advised not to use user-defined tablespaces in the Huawei Cloud scenario.

This is because user-defined tablespaces are usually used with storage media other than the main storage (storage device where the default tablespace is located, such as a disk) to isolate I/O resources that can be used by different services. Storage devices use standard configurations and do not have other available storage media in the Huawei Cloud scenario. If the user-defined tablespaces are not properly used, the system cannot run stably for a long time and the overall performance is affected. Therefore, you are advised to use the default tablespace.

#### Syntax

```
CREATE TABLESPACE tablespace_name
[OWNER user_name] [RELATIVE] LOCATION 'directory' [MAXSIZE 'space_size']
[with_option_clause];
```

**with\_option\_clause** for creating a general tablespace is as follows:

```
WITH ({{filesystem= { ' general ' | " general " | general } | address = { ' ip:port [, ...] ' | " ip:port [, ...] " } |
cfgpath = { ' path ' | " path " } | storepath = { ' rootpath ' | " rootpath " } | random_page_cost = { ' value ' | "
value " | value } | seq_page_cost = { ' value ' | " value " | value }}, ...)
```

#### Parameters

- **tablespace\_name**  
Specifies name of the tablespace to be created.

The tablespace name must be distinct from the name of any existing tablespace in the database and cannot start with "pg", which are reserved for system catalogs.

Value range: a string. It must comply with the [naming convention](#).

- **OWNER user\_name**

Specifies the name of the user who will own the tablespace. If omitted, the default owner is the current user.

Only system administrators can create tablespaces, but they can use the OWNER clause to assign ownership of tablespaces to non-system-administrators.

Value range: a string. It must be an existing user.

- **RELATIVE**

Specifies a relative path. The **LOCATION** directory is relative to each CN/DN data directory.

Directory hierarchy: relative path of the CNs and DNs directory `/pg_location/`. A relative path contains a maximum of two levels.

If this parameter is not specified, the absolute tablespace path is used. The **LOCATION** directory must be an absolute path.

- **LOCATION directory**

Specifies the directory for the table space. When creating an absolute tablespace path, ensure that the directory meets the following requirements:

- The system user must have the read and write permissions on the directory, and the directory must be empty. If the directory does not exist, the system automatically creates it.
- The directory must be an absolute path, and does not contain special characters, such as dollar sign (\$) and greater-than sign (>).
- The directory cannot be specified under the database data directory.
- The directory must be a local path.

Value range: a string. It must be a valid directory.

- **MAXSIZE 'space\_size'**

Specifies the maximum size of a tablespace on a single DN.

Value range: a string consisting of a positive integer and unit. The unit can be KB, MB, GB, TB, or PB currently. The unit of parsed value is KB and cannot exceed the range that can be expressed in 64 bits, which is 1 KB to 9007199254740991 KB.

- **filesystem**

Specifies the file system used by the tablespace.

Value range:

**general**: general file system.

**hdfs**: Hadoop distributed file system. It is not supported in the current version.

Default value: **general**

- **random\_page\_cost**

Specifies the time and resources required for randomly reading pages.

Value range: 0 to 1.79769e+308

Default value: value of the GUC parameter **random\_page\_cost**

- **seq\_page\_cost**

Specifies the time and resources required for reading pages in sequence.

Value range: 0 to 1.79769e+308

Default value: value of GUC parameter **seq\_page\_cost**

## Examples

```
-- Create a tablespace.
gaussdb=# CREATE TABLESPACE tbs_location1 RELATIVE LOCATION 'test_tablespace/test_tablespace_1';

-- Create a tablespace and specify the maximum value.
gaussdb=# CREATE TABLESPACE tbs_location2 RELATIVE LOCATION 'test_tablespace/test_tablespace_2'
MAXSIZE '10G';

-- Query tablespace information.
gaussdb=# SELECT * FROM pg_tablespace WHERE spcname = 'tbs_location2';
 spcname | spcowner | spcacl | spcoptions | spcmaxsize | relative
-----+-----+-----+-----+-----+-----
 tbs_location2 | 10 | | | 10485760 K | t
(1 row)

-- Create user joe.
gaussdb=# CREATE ROLE joe IDENTIFIED BY '*****';

-- Create a tablespace and set its owner to user joe.
gaussdb=# CREATE TABLESPACE tbs_location3 OWNER joe RELATIVE LOCATION 'test_tablespace/
test_tablespace_3';

-- Delete tablespaces and users.
gaussdb=# DROP TABLESPACE tbs_location1;
gaussdb=# DROP TABLESPACE tbs_location2;
gaussdb=# DROP TABLESPACE tbs_location3;
gaussdb=# DROP ROLE joe;
```

## Helpful Links

[CREATE DATABASE](#), [CREATE TABLE](#), [CREATE INDEX](#), [DROP TABLESPACE](#), and [ALTER TABLESPACE](#)

## Suggestions

You are advised not to create tablespaces in a transaction using CREATE TABLESPACE.

### 7.12.8.44 CREATE TABLE AS

#### Description

Creates a table from the results of a query.

It creates a table and fills it with data obtained using SELECT. The table columns have the names and data types associated with the output columns of SELECT (except that you can override the SELECT output column names by giving an explicit list of new column names).

CREATE TABLE AS queries a source table once and writes the data in a new table. The result in the query view changes with the source table. In contrast, the view re-computes and defines its SELECT statement at each query.

## Precautions

- This statement cannot be used to create a partitioned table.
- If an error occurs during table creation, after it is fixed, the system may fail to delete the disk files that are created before the last automatic clearance and whose size is not 0. This problem seldom occurs and does not affect system running of the database.
- If you add a row-level expression when adding or changing an ILM policy for a data object, note that the row-level expression supports only the functions listed in the whitelist. For details about the whitelist function list, see [Row Expression Function Whitelist](#).

## Syntax

```
CREATE [[GLOBAL | LOCAL] [TEMPORARY | TEMP] | UNLOGGED] TABLE [IF NOT EXISTS] table_name
 [(column_name [, ...])]
 [{ ENGINE [=] { InnoDB | 'InnoDB' | "InnoDB" } } [[, ...]]]
 [WITH ({storage_parameter = value} [, ...])]
 [ON COMMIT { PRESERVE ROWS | DELETE ROWS }]
 [COMPRESS | NOCOMPRESS]
 [ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year } OF
{ NO MODIFICATION } [ON (EXPR)]]
 [TABLESPACE tablespace_name]
 [DISTRIBUTE BY { REPLICATION | { [HASH] (column_name) } }]
 [TO { GROUP groupname | NODE (nodename [, ...]) }]
AS query
[WITH [NO] DATA];
```

For details about each field, see [Syntax](#).

## Parameters

- **UNLOGGED**  
Specifies that the table is created as an unlogged table. Data written to unlogged tables is not written to the WALs, which makes them considerably faster than ordinary tables. However, they are not crash-safe. An unlogged table is automatically truncated after a crash or unclean shutdown. The contents of an unlogged table are also not replicated to standby servers. Any indexes created on an unlogged table are automatically unlogged as well.
  - Usage scenario: Unlogged tables do not ensure data security. Users can back up data before using unlogged tables; for example, users should back up the data before a system upgrade.
  - Troubleshooting: If data is missing in the indexes of unlogged tables due to some unexpected operations such as an unclean shutdown, users should rebuild the indexes with errors.
- **GLOBAL | LOCAL**  
When creating a temporary table, you can specify the **GLOBAL** or **LOCAL** keyword before **TEMP** or **TEMPORARY**. Currently, the two keywords are used to be compatible with the SQL standard. A local temporary table will be created by the GaussDB regardless of whether **GLOBAL** or **LOCAL** is specified.
- **TEMPORARY | TEMP**  
If **TEMP** or **TEMPORARY** is specified, the created table is a temporary table. A temporary table is automatically dropped at the end of the current session. Therefore, you can create and use temporary tables in the current session when CNs, except for the one connected to the current session, are faulty.

Temporary tables are created only in the current session. If a DDL statement involves operations on temporary tables, a DDL error will be generated. Therefore, you are advised not to perform operations on temporary tables in DDL statements. **TEMP** is equivalent to **TEMPORARY**.

---

#### NOTICE

- Temporary tables are visible to the current session through a schema starting with **pg\_temp**. Therefore, do not delete schemas starting with **pg\_temp** or **pg\_toast\_temp**.
- If **TEMPORARY** or **TEMP** is not specified when you create a table but its schema is set to that starting with **pg\_temp** in the current session, the table will be created as a temporary table.
- A temporary table is visible only to the current session. Therefore, it cannot be used together with **\parallel on**.
- Temporary tables do not support DN faults or primary/standby switchovers.

---

- **IF NOT EXISTS**

When **IF NOT EXISTS** is specified, the system checks whether a relationship with the same name already exists in the current schema before creating a table. It is not created and a **NOTICE** is returned if a relationship with the same name already exists. When **IF NOT EXISTS** is not specified and a relationship with the same name exists in the schema, an **ERROR** is returned.

- **table\_name**

Specifies the name of the table to be created.

Value range: a string. It must comply with the [naming convention](#).

- **column\_name**

Optional. Specifies the name of a column to be created in the new table. If no column name is specified, the columns in the new table are the same as those entered in the **SELECT** statement.

Value range: a string. It must comply with the [naming convention](#).

- **ENGINE**

Supported in MySQL-compatible mode and used only for syntax adaptation. Only InnoDB can be set and no actual effect is achieved.

- **WITH ( storage\_parameter [= value] [, ... ] )**

Specifies an optional storage parameter for a table or an index. See details of parameters below.

- **FILLFACTOR**

The fill factor of a table is a percentage from 10 to 100. If the Ustore storage engine is used, the default value is **92**. **100** (complete filling) is the default value. When a smaller fill factor is specified, **INSERT** operations fill table pages only to the indicated percentage. The remaining space on each page is reserved for updating rows on that page. This gives **UPDATE** a chance to place the updated copy of a row on the same page, which is more efficient than placing it on a different page. For a table whose entries are never updated, setting the fill factor

to **100** (complete filling) is the best choice, but in heavily updated tables a smaller fill factor would be appropriate. The parameter is only valid for row-store tables.

Value range: 10–100

– **ORIENTATION**

Value range:

**COLUMN**: The data will be stored in columns.

**ROW** (default value): The data will be stored in rows.

– **COMPRESSION**

Specifies the compression level of table data. It determines the compression ratio and time. Generally, the higher the level of compression, the higher the ratio, the longer the time; and the lower the level of compression, the lower the ratio, the shorter the time. The actual compression ratio depends on the distribution mode of table data loaded.

Value range:

Row-store tables do not support compression.

– **hashbucket**

Creates a hash table that uses buckets. This parameter supports only row-store tables, including row-store range tables.

Value range: **on** and **off**

Default value: **off**

---

**NOTICE**

In current version, DDL operations on hash bucket tables are affected. Therefore, you are advised not to frequently perform DDL operations on hash bucket tables.

---

● **ON COMMIT { PRESERVE ROWS | DELETE ROWS }**

**ON COMMIT** determines what to do when you commit a temporary table creation operation. Currently, only **PRESERVE ROWS** and **DELETE ROWS** are supported.

– **PRESERVE ROWS** (default): No special action is taken at the ends of transactions. The temporary table and its table data are unchanged.

– **DELETE ROWS**: All rows in the temporary table will be deleted at the end of each transaction block.

● **COMPRESS / NOCOMPRESS**

Specifies keyword **COMPRESS** during the creation of a table, so that the compression feature is triggered in case of bulk insert operations. If this feature is enabled, a scan is performed for all tuple data within the page to generate a dictionary and then the tuple data is compressed and stored. If **NOCOMPRESS** is specified, the table is not compressed. Row-store tables do not support compression.

Default value: **NOCOMPRESS**, that is, tuple data is not compressed before storage.

- **[ ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year } OF { NO MODIFICATION } [ ON ( EXPR ) ] ]**  
When creating a table, you can call ILM ADD POLICY ROW STORE COMPRESS ADVANCED ROW to add an advanced compression policy for row store.
  - AFTER n { day | month | year } OF NO MODIFICATION: indicates the rows that are not modified in *n* days, months, or years.
  - ON (EXPR): indicates the row-level expression, which is used to determine whether a row is hot or cold.
- **TABLESPACE tablespace\_name**  
Specifies that the new table will be created in the **tablespace\_name** tablespace. If not specified, the default tablespace is used.
- **DISTRIBUTE BY**  
For details, see [DISTRIBUTE BY](#).
- **TO { GROUP groupname | NODE ( nodename [, ... ] ) }**  
**TO GROUP** specifies the node group to which the table to be created belongs. **TO NODE** is used for internal scale-out tools.
- **AS query**  
Specifies a **SELECT** or **VALUES** command, or an **EXECUTE** command that runs a prepared **SELECT** or **VALUES** query.
- **[ WITH [ NO ] DATA ]**  
Specifies whether the data produced by the query should be copied to the new table. By default, the data will be copied. If the value **NO** is used, only the table structure will be copied.

## Examples

- If no column name is specified, the columns in the new table are the same as those queried in the SELECT statement.  

```
-- Create the test1 table and insert two records into the table.
gaussdb=# CREATE TABLE test1(col1 int PRIMARY KEY,col2 varchar(10));
gaussdb=# INSERT INTO test1 VALUES (1,'col1'),(101,'col101');
-- Query the data whose col1 is less than 100 in the table.
gaussdb=# SELECT * FROM test1 WHERE col1 < 100;
col1 | col2
-----+-----
 1 | col1
(1 row)
```

```
-- Create the test2 table and insert the queried data into the table.
gaussdb=# CREATE TABLE test2 AS SELECT * FROM test1 WHERE col1 < 100;

-- Query the structure of the test2 table.
gaussdb=# \d test2;
Column | Type | Modifiers
-----+-----+-----
col1 | integer |
col2 | character varying(10) |
```
- Specify column names for the new table.  

```
-- Use test1 to copy a new table test3 and specify column names.
gaussdb=# CREATE TABLE test3(c1,c2) AS SELECT * FROM test1;

-- Query the structure of the test3 table.
gaussdb=# \d test3
 Table "public.test3"
Column | Type | Modifiers
```

```
-----+-----+-----
c1 | integer |
c2 | character varying(10) |

-- Delete.
gaussdb=# DROP TABLE test1,test2,test3;

● Create a table with the ILM policy enabled.
-- Create an ORA-compatible database.
gaussdb=# CREATE DATABASE ilmtabledb WITH dbcompatibility = 'ORA';
gaussdb=# \c ilmtabledb

-- Enable the ILM feature of the database.
ilmtabledb=# ALTER DATABASE SET ILM = on;

-- Create a table ilm_table with the ILM policy enabled and insert the value of old_table.
ilmtabledb=# CREATE TABLE old_table (a int);
ilmtabledb=# CREATE TABLE ilm_table
ILM ADD POLICY ROW STORE COMPRESS ADVANCED
ROW AFTER 3 MONTHS OF NO MODIFICATION
AS (SELECT * FROM old_table);

-- Delete.
ilmtabledb=# DROP TABLE old_table,ilm_table;
ilmtabledb=# \c postgres
gaussdb=# DROP DATABASE ilmtabledb;
```

## Helpful Links

[CREATE TABLE](#) and [SELECT](#)

### 7.12.8.45 CREATE TABLE PARTITION

#### Description

Creates a partitioned table. Partitioning refers to splitting what is logically one large table into smaller physical pieces based on specific schemes. The table based on the logic is called a partitioned table, and each physical piece is called a partition. Data is stored on these physical partitions, instead of the logical partitioned table.

The common forms of partitioning include range partitioning, interval partitioning, hash partitioning, list partitioning, and value partitioning. Currently, row-store tables support range partitioning, hash/key partitioning, and list partitioning.

In range partitioning, a table is partitioned based on ranges defined by one or more columns, with no overlap between the ranges of values assigned to different partitions. Each range has a dedicated partition for data storage.

The partitioning policy for range partitioning refers to how data is inserted into partitions.

In range partitioning, a table is partitioned based on partition key values. If a record can be mapped to a partition, it is inserted into the partition; if it cannot, an error message is returned. Range partitioning is the most commonly used partitioning policy.

In hash partitioning, a modulus and a remainder are specified for each partition based on a column in the table, and records to be inserted into the table are allocated to the corresponding partition, the rows in each partition must meet the

following condition: The value of the partition key divided by the specified modulus generates the remainder specified for the partition key.

In hash partitioning, table is partitioned based on partition key values. If a record can be mapped to a partition, it is inserted into the partition; if it cannot, an error message is returned.

List partitioning is to allocate the records to be inserted into a table to the corresponding partition based on the key values in each partition. The key values do not overlap in different partitions. A partition is created for each group of key values to store corresponding data.

In list partitioning, table is partitioned based on partition key values. If a record can be mapped to a partition, it is inserted into the partition; if it cannot, an error message is returned.

Partitioning can provide several benefits:

- Query performance can be improved drastically in certain situations, particularly when most of the heavily accessed rows of the table are in a single partition or a small number of partitions. Partitioning narrows the range of data search and improves data access efficiency.
- In the case of an INSERT or UPDATE operation on most portions of a single partition, performance can be improved by taking advantage of continuous scan of that partition instead of partitions scattered across the whole table.
- Frequent loading or deletion operations on records in a separate partition can be accomplished by reading or deleting that partition. This not only improves performance but also avoids the VACUUM overload caused by bulk DELETE operations (hash partitions cannot be deleted).

## Precautions

- If the constraint key of the unique constraint and primary key constraint contains all partition keys, a local index is created for the constraints. Otherwise, a global index is created.
- Currently, hash partitioning supports only single-column partition keys, and does not support multi-column partition keys.
- In the PARTITION FOR (values) syntax for partitioned tables, values can only be constants.
- In the PARTITION FOR (values) syntax for partitioned tables, if data type conversion is required for values, you are advised to use forcible type conversion to prevent the implicit type conversion result from being inconsistent with the expected result.
- The maximum number of partitions is 104,8575. Generally, it is impossible to create so many partitions, because too many partitions may cause insufficient memory. Create partitions based on the value of **local\_syscache\_threshold**. The memory used by the partitioned tables is about (number of partitions x 3/1024) MB. Theoretically, the memory occupied by the partitions cannot be greater than the value of **local\_syscache\_threshold**. In addition, some space must be reserved for other functions.
- Considering the impact on performance, it is recommended that the maximum number of partitions in a single table be less than or equal to 2000 and the number of subpartitions multiplied by (Number of local indexes + 1) be less than or equal to 10000.

- If the memory is insufficient due to too many partitions, the performance deteriorates sharply.
- Currently, the statement specifying a partition cannot perform global index scan.
- Data of the XML type cannot be used as partition keys or level-2 partition keys.
- When UPDATE or DELETE is performed on a partitioned table, if the generated plan is not an FQS or Stream plan, the statement execution efficiency is low. You are advised to check statements and eliminate factors that cannot be pushed down to generate FQS or Stream plans.
- If you add a row-level expression when adding or changing an ILM policy for a data object, note that the row-level expression supports only the functions listed in the whitelist. For details about the whitelist function list, see [Row Expression Function Whitelist](#).

## Syntax

```
CREATE TABLE [IF NOT EXISTS] partition_table_name
{ ([
 { column_name data_type [CHARACTER SET | CHARSET charset] [COLLATE collation]
 [column_constraint [...]]
 | table_constraint
 | LIKE source_table [like_option [...]] }
[, ...]
])
| LIKE source_table }
[table_option [[,] ...]]
[WITH ({storage_parameter = value} [, ...])]
[COMPRESS | NOCOMPRESS]
[ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year } OF
{ NO MODIFICATION } [ON (EXPR)]]
[TABLESPACE tablespace_name]

}]
[TO { GROUP groupname | NODE (nodename [, ...]) }]
PARTITION BY {
 {RANGE [COLUMNS] (partition_key) [PARTITIONS integer] (partition_less_than_item [, ...])} |
 {RANGE [COLUMNS] (partition_key) [PARTITIONS integer] (partition_start_end_item [, ...])} |
 {LIST [COLUMNS] (partition_key) [PARTITIONS integer] (PARTITION partition_name VALUES [IN
(list_values) [ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month |
year } OF { NO MODIFICATION } [ON (EXPR)]] [TABLESPACE [=] tablespace_name][, ...])} |
 { HASH (partition_key) [PARTITIONS integer] (PARTITION partition_name [ILM ADD POLICY ROW
STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year } OF { NO MODIFICATION } [ON
(EXPR)]] [TABLESPACE [=] tablespace_name][, ...])}
} [{ ENABLE | DISABLE } ROW MOVEMENT];
```

- **table\_option** is as follows:

```
{ COMMENT [=] 'string' |
 AUTO_INCREMENT [=] value |
 [DEFAULT] CHARACTER SET | CHARSET [=] default_charset |
 [DEFAULT] COLLATE [=] default_collation }
```

- **column\_constraint** is as follows:

```
[CONSTRAINT constraint_name]
{ NOT NULL |
 NULL |
 CHECK (expression) |
 AUTO_INCREMENT |
 COMMENT 'string' |
 DEFAULT default_expr |
```

```
ON UPDATE update_expr |
UNIQUE [KEY] [index_parameters] |
PRIMARY KEY [index_parameters] }
[DEFERRABLE | NOT DEFERRABLE][INITIALLY DEFERRED | INITIALLY IMMEDIATE]
```

- **table\_constraint** is as follows:

```
[CONSTRAINT constraint_name]
{ CHECK (expression) |
UNIQUE (column_name [, ...]) [index_parameters] |
PRIMARY KEY (column_name [, ...]) [index_parameters] }
[DEFERRABLE | NOT DEFERRABLE][INITIALLY DEFERRED | INITIALLY IMMEDIATE]
{ [COMMENT 'string'] [...] }
```

- **like\_option** is as follows:

```
{ INCLUDING | EXCLUDING } { DEFAULTS | CONSTRAINTS | INDEXES | STORAGE | COMMENTS |
REOPTIONS | DISTRIBUTION | UPDATE | ALL }
```

- **index\_parameters** is as follows:

```
[WITH ({storage_parameter = value} [, ...])]
[USING INDEX TABLESPACE tablespace_name]
```

- **partition\_less\_than\_item:**

```
PARTITION partition_name VALUES LESS THAN ({ partition_value | MAXVALUE }) [ILM ADD POLICY
ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year } OF { NO
MODIFICATION } [ON (EXPR)] [TABLESPACE tablespace_name]
```

- **partition\_start\_end\_item:**

```
PARTITION partition_name {
 {START(partition_value) END (partition_value) EVERY (interval_value)} |
 {START(partition_value) END ({partition_value | MAXVALUE})} |
 {START(partition_value)} |
 {END({partition_value | MAXVALUE})}
} [ILM ADD POLICY ROW STORE { COMPRESS ADVANCED } { ROW } AFTER n { day | month | year }
OF { NO MODIFICATION } [ON (EXPR)] [TABLESPACE tablespace_name]
```

- **update\_expr:**

```
{ CURRENT_TIMESTAMP | LOCALTIMESTAMP | NOW() }
```

## Parameters

- **IF NOT EXISTS**

Sends a notice instead of throwing an error, if a table with the same name exists.

- **partition\_table\_name**

Specifies the name of a partitioned table.

Value range: a string. It must comply with the [naming convention](#).

- **column\_name**

Specifies the name of a column to be created in the new table.

Value range: a string. It must comply with the [naming convention](#).

- **data\_type**

Specifies the data type of the column.

- **COLLATE collation**

Assigns a collation to the column (which must be of a collatable data type). If no collation is specified, the default collation is used. You can run the **SELECT \* FROM pg\_collation** command to query collation rules from the pg\_collation system catalog. The default collation rule is the row starting with **default** in the query result.

- **CONSTRAINT constraint\_name**

Specifies the name of a column or table constraint. The optional constraint clauses specify constraints that new or updated rows must satisfy for an

INSERT or UPDATE operation to succeed. You can run the **SELECT \* FROM pg\_collation** command to query collation rules from the pg\_collation system catalog. The default collation rule is the row starting with **default** in the query result.

There are two ways to define constraints:

- A column constraint is defined as part of a column definition, and it is bound to a particular column.
- A table constraint is not bound to a particular column but can apply to more than one column.

- **LIKE source\_table [ like\_option ... ]**

Specifies a table from which the new table automatically copies all column names, their data types, and their not-null constraints.

The new table and original table are decoupled after creation is complete. Changes to the original table will not be applied to the new table, and it is not possible to include data of the new table in scans of the original table.

- Default expressions for the copied column definitions will be copied only if **INCLUDING DEFAULTS** is specified. The default behavior is to exclude default expressions, resulting in the copied columns in the new table having default values **NULL**.
- Not-null constraints are always copied to the new table. **CHECK** constraints will only be copied if **INCLUDING CONSTRAINTS** is specified; other types of constraints will never be copied. These rules also apply to column constraints and table constraints.

The copied columns and constraints are not merged with similarly named columns and constraints. If the same name is specified explicitly or in another **LIKE** clause, an error is reported.

- If **INCLUDING UPDATE** is specified, the **ON UPDATE CURRENT\_TIMESTAMP** attribute of the original table column is copied to the new table column. By default, this attribute is not copied.
- Any indexes on the original table will not be created on the new table, unless the **INCLUDING INDEXES** clause is specified.
- If **INCLUDING STORAGE** is specified, the **STORAGE** setting of the original table column is also copied. By default, the **STORAGE** setting is not included.
- If **INCLUDING COMMENTS** is specified, comments of the original table columns, constraints, and indexes are also copied. The default behavior is to exclude comments.
- If **INCLUDING REOPTIONS** is specified, the storage parameters (**WITH** clauses) of the original table are also copied to the new table. The default behavior is to exclude partition definition of the storage parameter of the original table.
- If **INCLUDING DISTRIBUTION** is specified, the new table will copy the distribution information of the original table, including distribution type and key, and the new table cannot use the **DISTRIBUTE BY** clause. The default behavior is to exclude distribution information of the original table.
- **INCLUDING ALL** contains the meaning of **INCLUDING DEFAULTS**, **INCLUDING UPDATE**, **INCLUDING CONSTRAINTS**, **INCLUDING INDEXES**,

INCLUDING STORAGE, INCLUDING COMMENTS, INCLUDING REOPTIONS, and INCLUDING DISTRIBUTION.

---

#### NOTICE

- The CREATE TABLE table\_name LIKE source\_table syntax is supported only when **sql\_compatibility** is set to 'MYSQL' (MySQL-compatible database), **b\_format\_version** is set to 5.7, and **b\_format\_dev\_version** is set to s2.
- In a MySQL-compatible database, if **b\_format\_version** is set to 5.7 and **b\_format\_dev\_version** is set to s2, **INCLUDING** and **EXCLUDING** cannot be specified. In this case, it is equivalent to specify **INCLUDING ALL** by default.

---

- **AUTO\_INCREMENT [ = ] value**

This clause specifies an initial value for an auto-increment column. The value must be a positive number and cannot exceed  $2^{127} - 1$ .

---

#### NOTICE

This clause takes effect only when **sql\_compatibility** is set to 'MYSQL'.

---

- **COMMENT [ = ] 'string'**

- The COMMENT [ = ] 'string' clause is used to add comments to a table.
- The COMMENT 'string' in column\_constraint indicates that comments are added to a column.
- The COMMENT 'string' in table\_constraint indicates that comments are added to the indexes corresponding to the primary key and unique key.

For details, see [COMMENT \[ = \] 'string'](#).

- **CHARACTER SET | CHARSET charset**

Specifies the character set of a table column. If this parameter is specified separately, the collation of the table column is set to the default collation of the specified character set.

This syntax is supported only in a MySQL-compatible database (that is, **sql\_compatibility** set to 'MYSQL').

- **COLLATE collation**

Assigns a collation to the column (which must be of a collatable data type). If no collation is specified, the default collation is used. You can run the **SELECT \* FROM pg\_collation** command to query collation rules from the pg\_collation system catalog. The default collation rule is the row starting with **default** in the query result. In a MySQL-compatible database (that is, **sql\_compatibility** set to 'MYSQL'), **utf8mb4\_bin**, **utf8mb4\_general\_ci**, **utf8mb4\_unicode\_ci**, **binary**, **gbk\_chinese\_ci**, **gbk\_bin**, **gb18030\_chinese\_ci**, and **gb18030\_bin** are also supported.

- **WITH ( storage\_parameter [= value] [, ... ] )**

Specifies an optional storage parameter for a table or an index. Optional parameters are as follows:

- **FILLFACTOR**  
The fill factor of a table is a number from 10 to 100. **100** (complete filling) is the default value. When a smaller fill factor is specified, INSERT operations fill table pages only to the indicated percentage. The remaining space on each page is reserved for updating rows on that page. This gives UPDATE a chance to place the updated copy of a row on the same page, which is more efficient than placing it on a different page. For a table whose entries are never updated, setting the fill factor to **100** (complete filling) is the best choice, but in heavily updated tables a smaller fill factor would be appropriate.

Value range: 10–100

- **ORIENTATION**  
Determines the data storage mode of the table.  
Value range:

- **ROW** (default value): The data will be stored in rows.

---

**NOTICE**

**orientation** cannot be modified.

---

- **STORAGE\_TYPE**  
Specifies the storage engine type. This parameter cannot be modified once it is set.  
Value range:
- **USTORE** indicates that tables support the in-place update storage engine. Note that the **track\_counts** and **track\_activities** parameters must be enabled when the Ustore table is used. Otherwise, space bloating may occur.

- **ASTORE** indicates that tables support the append-only storage engine.

Default value:

If this parameter is not specified, the **enable\_default\_ustore\_table** parameter determines the storage engine mode. The default value is append-only storage.

- **COMPRESSION**

- Row-store tables do not support compression.

- **statistic\_granularity**

Specifies the default value of **partition\_mode** of a table during statistics analysis. For details about **partition\_mode**, see [ANALYZE|ANALYSE](#). This parameter is invalid for non-partitioned tables.

Value range: See the value range of **partition\_mode**.

Default value: **AUTO**.

- **enable\_tde**

Specifies that the table is an encrypted table. The database automatically encrypts the data in the encryption table before storing it. Before using

this parameter, ensure that TDE function has been enabled using the GUC parameter **enable\_tde** and the information for accessing the key service has been set using the GUC parameter **tde\_key\_info**. For details about how to use this parameter, see section "Transparent Data Encryption" in *Feature Guide*. This parameter applies only to row-store tables, segment-page tables, hash bucket tables, temporary tables, and unlogged tables.

Value range: **on** and **off** When **enable\_tde** is set to **on**, **key\_type**, **tde\_cmk\_id**, and **dek\_cipher** are automatically generated by the database and cannot be manually specified or modified.

Default value: **off**

– encrypt\_algo

Specifies the encryption algorithm of the encryption table. This parameter must be used together with **enable\_tde**.

Value range: a string. The value can be **AES\_128\_CTR** or **SM4\_CTR**.

Default value: null if **enable\_tde** is not set, or **AES\_128\_CTR** if **enable\_tde** is set.

– dek\_cipher

Specifies the DEK ciphertext. After a user sets the **enable\_tde** parameter for a table, the database automatically generates a data key.

Value range: a string

Default value: null

– key\_type

Specifies the type of the master key. After the **enable\_tde** parameter is set for a table, the database automatically obtains the master key type from the GUC parameter **tde\_key\_info**.

Value range: a string

Default value: null

– cmk\_id

Specifies the ID of the master key. After the **enable\_tde** parameter is set for a table, the database automatically obtains the master key ID from the GUC parameter **tde\_key\_info**.

Value range: a string

Default value: null

– hashbucket

Creates a hash table that uses buckets. This parameter supports only row-store tables, including row-store range tables.

Value range: **on** and **off**

Default value: **off**

---

**NOTICE**

In current version, DDL operations on hash bucket tables are affected. Therefore, you are advised not to frequently perform DDL operations on hash bucket tables.

---

- **COMPRESS / NOCOMPRESS**  
Specifies keyword COMPRESS during the creation of a table, so that the compression feature is triggered in case of BULK INSERT operations. If this feature is enabled, a scan is performed for all tuple data within the page to generate a dictionary and then the tuple data is compressed and stored. If **NOCOMPRESS** is specified, the table is not compressed.  
Default value: **NOCOMPRESS**, that is, tuple data is not compressed before storage. Row-store tables do not support compression.
- **TABLESPACE tablespace\_name**  
Specifies that the new table will be created in the **tablespace\_name** tablespace. If not specified, the default tablespace is used.
- **DISTRIBUTE BY**  
Specifies how the table is distributed or replicated between nodes.  
For the value range and details, see **DISTRIBUTE BY**.
- **TO { GROUP groupname | NODE ( nodename [, ... ] ) }**  
**TO GROUP** specifies the node group to which the table to be created belongs. **TO NODE** is used for internal scale-out tools.
- **PARTITION BY RANGE [COLUMNS] (partition\_key)**  
Creates a range partition. **partition\_key** is the name of the partition key.  
The COLUMNS keyword can be used only when **sql\_compatibility** is set to 'MYSQL'. The semantics of PARTITION BY RANGE COLUMNS is the same as that of PARTITION BY RANGE.  
(1) Assume that the VALUES LESS THAN syntax is used.

---

**NOTICE**

If the VALUE LESS THAN clause is used, a range partitioning policy supports a partition key with up to 16 columns.

---

Data types supported by the partition keys are as follows: TINYINT, SMALLINT, INTEGER, BIGINT, DECIMAL, NUMERIC, REAL, FLOAT4, FLOAT8, DOUBLE PRECISION, CHARACTER VARYING(n), VARCHAR(n), CHARACTER(n), CHAR(n), CHARACTER, CHAR, TEXT, NVARCHAR2, NAME, TIMESTAMP[(p)] [WITHOUT TIME ZONE], TIMESTAMP[(p)] [WITH TIME ZONE], and DATE.

(2) Assume that the START END syntax is used.

---

**NOTICE**

In this case, only one partition key is supported.

---

Data types supported by the partition key are as follows: TINYINT, SMALLINT, INTEGER, BIGINT, DECIMAL, NUMERIC, REAL, FLOAT4, FLOAT8, DOUBLE PRECISION, TIMESTAMP[(p)] [WITHOUT TIME ZONE], TIMESTAMP[(p)] [WITH TIME ZONE], and DATE.

- **PARTITION partition\_name VALUES LESS THAN (( { partition\_value | MAXVALUE } [,...] ) | MAXVALUE }**

Specifies the information of partitions. **partition\_name** is the name of a range partition. **partition\_value** is the upper limit of a range partition, and the value depends on the type of **partition\_key**. *MAXVALUE* usually specifies the upper limit of the last range partition.

---

**NOTICE**

- Each partition requires an upper limit.
  - The data type of the upper limit must be the same as that of the partition key.
  - In a partition list, partitions are arranged in ascending order of upper limits. A partition with a smaller upper limit value is placed before another partition with a larger one.
  - *MAXVALUE* that is not in parentheses can be used only when **sql\_compatibility** is set to 'MYSQL' and can have only one partition key.
- 
- **PARTITION partition\_name {START (partition\_value) END (partition\_value) EVERY (interval\_value)} | {START (partition\_value) END (partition\_value|MAXVALUE)} | {START(partition\_value)} | {END (partition\_value | MAXVALUE)}**

Specifies the information of partitions.

- **partition\_name**: name or name prefix of a range partition. It is the name prefix only in the following cases (assuming that **partition\_name** is **p1**):
  - If **START+END+EVERY** is used, the names of partitions will be defined as **p1\_1**, **p1\_2**, and the like. For example, if **PARTITION p1 START(1) END(4) EVERY(1)** is defined, the generated partitions are [1, 2), [2, 3), and [3, 4), and their names are **p1\_1**, **p1\_2**, and **p1\_3**. In this case, **p1** is a name prefix.
  - If the defined statement is in the first place and has **START** specified, the range (*MINVALUE*, **START**) will be automatically used as the first actual partition, and its name will be **p1\_0**. The other partitions are then named **p1\_1**, **p1\_2**, and the like. For example, if **PARTITION p1 START(1), PARTITION p2 START(2)** is defined, generated partitions are (*MINVALUE*, 1), [1, 2), and [2, *MAXVALUE*), and their names will be **p1\_0**, **p1\_1**, and **p2**. In this case, **p1** is a name prefix and **p2** is a partition name. *MINVALUE* means the minimum value.
- **partition\_value**: start value or end value of a range partition. The value depends on **partition\_key** and cannot be *MAXVALUE*.
- **interval\_value**: width of each partition for dividing the [**START**, **END**) range. It cannot be *MAXVALUE*. If the value of (**END** - **START**) divided by **EVERY** has a remainder, the width of only the last partition is less than the value of **EVERY**.
- *MAXVALUE* usually specifies the upper limit of the last range partition.

## NOTICE

1. If the defined statement is in the first place and has **START** specified, the range (*MINVALUE*, **START**) will be automatically used as the first actual partition.
2. The **START END** syntax must comply with the following rules:
  - The value of **START** (if any, same for the following situations) in each **partition\_start\_end\_item** must be smaller than that of **END**.
  - In two adjacent **partition\_start\_end\_item** statements, the value of the first **END** must be equal to that of the second **START**.
  - The value of **EVERY** in each **partition\_start\_end\_item** must be a positive number (in ascending order) and must be smaller than **END** minus **START**.
  - Each partition includes the start value (unless it is *MINVALUE*) and excludes the end value. The format is as follows: [**START**, **END**).
  - Partitions created by the same **partition\_start\_end\_item** belong to the same tablespace.
  - If **partition\_name** is a name prefix of a partition, the length must not exceed 57 bytes. If there are more than 57 bytes, the prefix will be automatically truncated.
  - When creating or modifying a partitioned table, ensure that the total number of partitions in the table does not exceed the maximum value **1048575**.
3. In statements for creating partitioned tables, **START END** and **LESS THAN** cannot be used together.
4. The **START END** syntax in a partitioned table creation SQL statement will be replaced by the **VALUES LESS THAN** syntax when `gs_dump` is executed.

---

- **PARTITION BY LIST [COLUMNS] (partition\_key)**

Create a list partition. **partition\_key** is the name of the partition key.

The **COLUMNS** keyword can be used only when **sql\_compatibility** is set to **'MYSQL'**. The semantics of **PARTITION BY LIST COLUMNS** is the same as that of **PARTITION BY LIST**.

- A list partitioning policy supports a partition key with up to 16 columns.
- For the clause syntax **VALUES [IN] (list\_values)**, if **list\_values** contains the key values of the corresponding partition, it is recommended that the number of key values of each partition be less than or equal to 64.
- The clause **VALUES IN** can be used only when **sql\_compatibility** is set to **'MYSQL'**. The semantics is the same as that of **VALUES**.

Partition keys support the following data types: **TINYINT**, **SMALLINT**, **INTEGER**, **BIGINT**, **NUMERIC**, **VARCHAR(n)**, **CHAR**, **BPCHAR**, **NVARCHAR2**, **TIMESTAMP[(p)] [WITHOUT TIME ZONE]**, **TIMESTAMP[(p)] [WITH TIME ZONE]**, and **DATE**. The number of partitions cannot exceed 1048575.

- **PARTITION BY HASH(partition\_key)**

Create a hash partition. **partition\_key** is the name of the partition key.

For **partition\_key**, the hash partitioning policy supports only one column of partition keys.

Partition keys support the following data types: TINYINT, SMALLINT, INTEGER, BIGINT, NUMERIC, VARCHAR(n), CHAR, BPCHAR, TEXT, NVARCHAR2, TIMESTAMP[(p)] [WITHOUT TIME ZONE], TIMESTAMP[(p)] [WITH TIME ZONE], and DATE. The number of partitions cannot exceed 1048575.

- **PARTITIONS integer**

Specifies the number of partitions.

**integer** indicates the number of partitions. The value must be an integer greater than 0 and cannot be greater than 1048575.

- When this clause is specified after the range and list partitions, each partition must be explicitly defined, and the number of defined partitions must be equal to the integer value. This clause can be specified after the range and list partitions only when **sql\_compatibility** is set to 'MYSQL'.
- When this clause is specified after the hash and key partitions, if the definition of each partition is not listed, an *integer* number of partitions are automatically generated. The automatically generated partition name is "p+number", and the number ranges from 0 to *integer* minus 1. The tablespace of the partition is the tablespace of the table by default. If each partition definition is explicitly defined, the number of defined partitions must be the same as the value of *integer*. If neither the partition definition nor the number of partitions is specified, a unique partition is created.

- **{ ENABLE | DISABLE } ROW MOVEMENT**

Sets row movement.

If the tuple value is updated on the partition key during the UPDATE operation, the partition where the tuple is located is altered. Setting this parameter enables error messages to be reported or movement of the tuple between partitions.

Value range:

- **ENABLE**: Row movement is enabled.
- **DISABLE** (default value): Row movement is disabled.

If the row movement is enabled, an error may be reported when UPDATE and DELETE operations are performed concurrently. The causes are as follows:

The old data is marked as deleted in the UPDATE and DELETE operations. If the row movement is enabled, the cross-partition update occurs when the partition key is updated. The kernel marks the old data in the old partition as deleted and adds a data to the new partition. As a result, the new data cannot be found by querying the old data.

If data in the same row is concurrently operated, the cross-partition and non-cross-partition data results have different behaviors in the following three concurrency scenarios: UPDATE and UPDATE concurrency, DELETE and DELETE concurrency, as well as UPDATE and DELETE concurrency.

- a. For non-cross-partition data, no error is reported for the second operation after the first operation is performed.

If the first operation is UPDATE, the latest data can be found and operated after the second operation is performed.

If the first operation is DELETE, the second operation is terminated if the current data is deleted and the latest data cannot be found.

- b. For the cross-partition data result, an error is reported for the second operation after the first operation is performed.

If the first operation is UPDATE, the second operation cannot find the latest data because the new data is in the new partition. Therefore, the second operation fails and an error is reported.

If the first operation is DELETE, performing the second operation can find that the current data is deleted and the latest data cannot be found, but cannot determine whether the operation of deleting the old data is UPDATE or DELETE. If the operation is UPDATE, an error is reported. If the operation is DELETE, the operation is terminated. To ensure the data correctness, an error is reported.

If the UPDATE and UPDATE concurrency, and UPDATE and DELETE concurrency are performed, the error can be solved only when the operations are performed serially. If the DELETE and DELETE concurrency are performed, the error can be solved by disabling the row movement.

- **NOT NULL**

Forbids NULL values in columns. **ENABLE** can be omitted.

- **NULL**

Allows to contain NULL values. This is the default setting.

This clause is only provided for compatibility with non-standard SQL databases. It is not recommended.

- **CHECK (condition) [ NO INHERIT ]**

Specifies an expression producing a Boolean result where the INSERT or UPDATE operation of new or updated rows can succeed only when the expression result is **TRUE** or **UNKNOWN**; otherwise, an error is thrown and the database is not altered.

A check constraint specified as a column constraint should reference only the column's values, while an expression in a table constraint can reference multiple columns.

A constraint marked with **NO INHERIT** will not propagate to child tables.

**ENABLE** can be omitted.

- **DEFAULT default\_expr**

Assigns a default data value to a column. The value can be any variable-free expressions. (Subqueries and cross-references to other columns in the current table are not allowed.) The data type of the default expression must match the data type of the column.

The default expression will be used in any insert operation that does not specify a value for the column. If there is no default value for a column, then the default value is **NULL**.

- **ON UPDATE update\_expr**

The ON UPDATE clause is an attribute constraint of a column.

When an UPDATE operation is performed on a tuple in a table, if new values of updated columns are different from old values in the table, column values with this attribute but not in updated columns are automatically updated to the current timestamp. If new values of updated columns are the same as old values in the table, column values with this attribute but not in updated

columns remain unchanged. If columns with this attribute are in updated columns, column values are updated according to the specified update value.

#### NOTE

- This attribute can be specified only in MySQL 5.7 (that is, **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** is set to '5.7', and **b\_format\_dev\_version** is set to 's1').
  - In terms of syntax, **update\_expr** supports three keywords: CURRENT\_TIMESTAMP, LOCALTIMESTAMP, and NOW(). You can also specify or not specify the precision of a keyword with parentheses. For example, ON UPDATE CURRENT\_TIMESTAMP(), ON UPDATE CURRENT\_TIMESTAMP(5), ON UPDATE LOCALTIMESTAMP(), and ON UPDATE LOCALTIMESTAMP(6). If the keyword does not contain parentheses or contains empty parentheses, the precision is 0. The NOW keyword cannot contain parentheses. The three types of keywords are synonyms of each other and have the same attribute effect.
  - This attribute can be specified only for columns of the following types: timestamp, datetime, date, time without time zone, smalldatetime, and abstime.
  - The CREATE TABLE AS syntax does not inherit the column attributes.
  - The CREATE TABLE LIKE syntax can use INCLUDING UPDATE or EXCLUDING UPDATE to inherit or exclude a constraint. The LIKE syntax is inherited from the LIKE syntax of PostgreSQL. Currently, the ILM policy information of the old table cannot be copied.
  - The precision specified by this attribute can be different from the precision specified by the type in the corresponding column. After the column value is updated through this attribute, the minimum precision is displayed. For example, CREATE TABLE t1 (col1 timestamp(6) ON UPDATE CURRENT\_TIMESTAMP(3));. If the UPDATE syntax triggers the attribute to take effect, three decimal places in the value of **col1** are displayed after the update.
  - The same column cannot be specified for this attribute and the generated column constraint at the same time.
  - This attribute cannot be specified for the partition key in a partitioned table.
  - In distributed scenarios, this attribute cannot be specified for distribution keys and primary keys.
- **AUTO\_INCREMENT**  
Specifies an auto-increment column.  
For details, see [•AUTO\\_INCREMENT](#).
  - **UNIQUE [KEY] index\_parameters**  
**UNIQUE ( column\_name [, ... ] ) index\_parameters**  
Specifies that a group of one or more columns of a table can contain only unique values.  
For the purpose of a unique constraint, null is not considered equal.  
UNIQUE KEY can be used only when **sql\_compatibility** is set to 'MYSQL', which has the same semantics as UNIQUE.
  - **PRIMARY KEY index\_parameters**  
**PRIMARY KEY ( column\_name [, ... ] ) index\_parameters**  
Specifies that a column or columns of a table can contain only unique (non-duplicate) and non-null values.  
Only one primary key can be specified for a table.
  - **DEFERRABLE | NOT DEFERRABLE**  
Determines whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of

constraints that are deferrable can be postponed until the end of the transaction using the **SET CONSTRAINTS** command. **NOT DEFERRABLE** is the default value. Currently, only **UNIQUE** and **PRIMARY KEY** constraints accept this clause. All the other constraints are not deferrable.

- **INITIALLY IMMEDIATE | INITIALLY DEFERRED**

If a constraint is deferrable, this clause specifies the default time to check the constraint.

- If the constraint is **INITIALLY IMMEDIATE** (default value), it is checked after each statement.
- If the constraint is **INITIALLY DEFERRED**, it is checked only at the end of the transaction.

The constraint check time can be altered using the **SET CONSTRAINTS** command.

- **USING INDEX TABLESPACE tablespace\_name**

Allows selection of the tablespace in which the index associated with a **UNIQUE** or **PRIMARY KEY** constraint will be created. If not specified, the index is created in **default\_tablespace**. If **default\_tablespace** is empty, the default tablespace of the database is used.

## Range Partitioning

- **VALUES LESS THAN**

```
-- Create a tablespace.
CREATE TABLESPACE tbs_test_range1_p1 RELATIVE LOCATION 'tbs_test_range1/tablespace_1';
CREATE TABLESPACE tbs_test_range1_p2 RELATIVE LOCATION 'tbs_test_range1/tablespace_2';
CREATE TABLESPACE tbs_test_range1_p3 RELATIVE LOCATION 'tbs_test_range1/tablespace_3';
CREATE TABLESPACE tbs_test_range1_p4 RELATIVE LOCATION 'tbs_test_range1/tablespace_4';

-- Create a partitioned table test_range1.
CREATE TABLE test_range1(
 id INT,
 info VARCHAR(20)
) PARTITION BY RANGE (id) (
 PARTITION p1 VALUES LESS THAN (200) TABLESPACE tbs_test_range1_p1,
 PARTITION p2 VALUES LESS THAN (400) TABLESPACE tbs_test_range1_p2,
 PARTITION p3 VALUES LESS THAN (600) TABLESPACE tbs_test_range1_p3,
 PARTITION pmax VALUES LESS THAN (MAXVALUE) TABLESPACE tbs_test_range1_p4
);

-- Insert 1000 data records.
INSERT INTO test_range1 VALUES(GENERATE_SERIES(1,1000),'abcd');

-- Check that the number of rows in the p1 partition is 199, that is, the record range is [1, 200).
SELECT COUNT(*) FROM test_range1 PARTITION (p1);
count

 199
(1 row)

-- Check that the number of rows in the p2 partition is 200, that is, the record range is [200, 400).
SELECT COUNT(*) FROM test_range1 PARTITION (p2);
count

 200
(1 row)

-- View the partition information.
SELECT a.relname, a.boundaries, b.spcname
FROM pg_partition a, pg_tablespace b
WHERE a.reltablespace = b.oid AND a.parentid = 'test_range1'::regclass;
relname | boundaries | spcname
```

```
-----+-----+-----
p1 | {200} | tbs_test_range1_p1

### 7.12.8.46 CREATE TRIGGER

#### Description

CREATE TRIGGER is used to create a trigger. A trigger is a special type of stored procedure, and is used for complex service rules and requirements and help ensure reference integrity. A trigger is associated with a specified table or view and executes a specified function under specific conditions, this allows you to retain the relationships defined in the table when you add, update, or delete rows in the table.

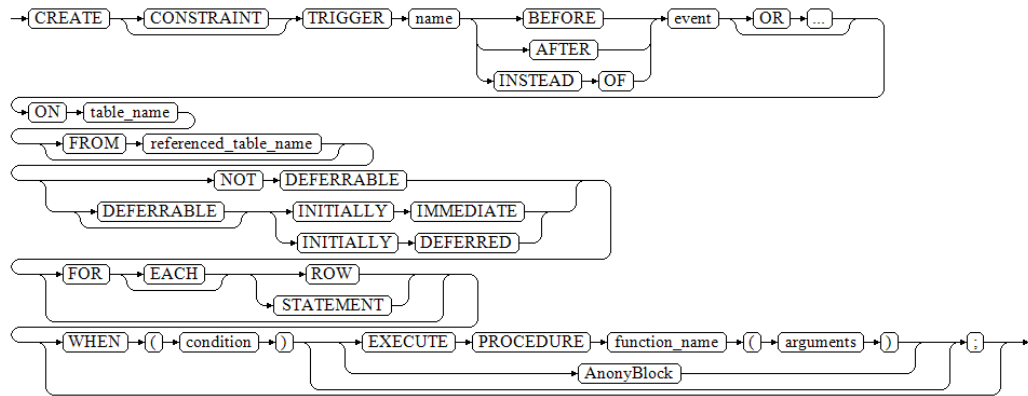

#### Precautions

- Currently, triggers can be created only on ordinary row-store tables, instead of on temporary tables or unlogged tables.
- If multiple triggers of the same kind are defined for the same event, they will be fired in alphabetical order by name.
- Triggers are usually used for data association and synchronization between multiple tables. SQL execution performance is greatly affected. Therefore, you are advised not to use this statement when a large amount of data needs to be synchronized and performance requirements are high.

- When a trigger meets the following conditions, the trigger statement and trigger itself can be pushed together down to a DN for execution, improving the trigger execution performance:
  - The GUC parameters **enable\_trigger\_shipping** and **enable\_fast\_query\_shipping** are enabled.
  - The trigger function used by the source table is a PL/pgSQL function (recommended).
  - The source and target tables have the same type and number of distribution keys, are both row-store tables, and belong to the same node group.
  - The **INSERT**, **UPDATE**, or **DELETE** statement on the source table contains an expression about equality comparison between all the distribution keys and the *NEW* or *OLD* variable.
  - The **INSERT**, **UPDATE**, or **DELETE** statement on the source table can be used to query shipping without a trigger.
  - There are only six types of triggers (**INSERT BEFORE FOR EACH ROW**, **INSERT AFTER FOR EACH ROW**, **UPDATE BEFORE FOR EACH ROW**, **UPDATE AFTER FOR EACH ROW**, **DELETE BEFORE FOR EACH ROW**, and **DELETE AFTER FOR EACH ROW**) on the source table, and all the triggers can be pushed down.
- When a trigger statement is executed, the permission is determined by the trigger creator.
- To create a trigger, you must have the TRIGGER permission on the specified table or have the CREATE ANY TRIGGER permission.
- A row-level trigger function triggered by BEFORE can return a **NULL** value, indicating that operations on the row are ignored. Subsequent triggers will not be executed and no **INSERT**, **UPDATE**, or **DELETE** action will be generated on the row. The return value of the trigger function triggered by AFTER is not affected.
- For a **DELETE BEFORE** trigger, the return value **NEW** indicates **NULL**. For an **INSERT BEFORE** trigger, the return value **OLD** indicates **NULL**. For an **UPDATE BEFORE** trigger, the return value of the trigger function is **NULL** only when it is displayed as **NULL**.
- For a trigger function whose event is **INSERT** or **UPDATE**, the normal return value is **NEW**. If a non-NULL row is returned, the inserted or updated row is modified. For a trigger function whose event is **DELETE**, the normal return value is **OLD**.
- **INSTEAD OF** triggers can only work on views. Their trigger functions can also return **NULL**, indicating that subsequent triggers will not be executed.

## Syntax

```
CREATE [OR REPLACE] [CONSTRAINT] TRIGGER name { BEFORE | AFTER | INSTEAD OF } { event [OR ...] }
ON table_name
[FROM referenced_table_name]
{ NOT DEFERRABLE | [DEFERRABLE] { INITIALLY IMMEDIATE | INITIALLY DEFERRED } }
[FOR [EACH] { ROW | STATEMENT }]
[WHEN (condition)]
[EXECUTE PROCEDURE function_name (arguments) | AnonyBlock];
```

Events include:

INSERT

UPDATE [ OF column\_name [, ... ] ]

DELETE

TRUNCATE

## Parameters

- OR REPLACE**  
 (Optional) If this parameter is specified, the existing trigger will be modified. Constraint triggers and internal triggers cannot be created or modified using the OR REPLACE syntax. A constraint trigger is a trigger created using CREATE CONSTRAINT TRIGGER. An internal trigger is a trigger implicitly created by some SQL statements. For example, if a foreign key constraint is added to a table, four triggers are implicitly created. The four triggers are internal triggers.
- CONSTRAINT**  
 (Optional) Creates a constraint trigger. That is, the trigger is used as a constraint. This is the same as a regular trigger except that the timing of the trigger firing can be adjusted using SET CONSTRAINTS. Constraint triggers must be AFTER ROW triggers.
- name**  
 Specifies the name of the trigger to be created. This must be distinct from the name of any other trigger for the same table. The name cannot be schema-

qualified — the trigger inherits the schema of its table. For a constraint trigger, this is also the name to use when modifying the trigger's behavior using [SET CONSTRAINTS](#).

Value range: a string, which complies with the [naming convention](#). A value can contain a maximum of 63 characters.

- **BEFORE**

Specifies that the function is called before the event.

- **AFTER**

Specifies that the function is called after the event. A constraint trigger can only be specified as **AFTER**.

- **INSTEAD OF**

Specifies that the function is called instead of the event.

- **event**

Specifies the event that will fire the trigger. Values are **INSERT**, **UPDATE**, **DELETE**, and **TRUNCATE**. Multiple events can be specified using **OR**.

For UPDATE events, it is possible to specify a list of columns using this syntax:

```
UPDATE OF column_name1 [, column_name2 ...]
```

The trigger will only fire if at least one of the listed columns is mentioned as a target of the UPDATE statement. **INSTEAD OF UPDATE** events do not allow a list of columns. If the column specified by **UPDATE OF** contains a generated column, the trigger is also fired when the column on which the generated column depends is the target column of the UPDATE statement.

- **table\_name**

Specifies the name of the table for which the trigger is created.

Value range: name of an existing table in the database

- **referenced\_table\_name**

Specifies the name of another table referenced by the constraint. This option is used for foreign-key constraints. It can only be specified for constraint triggers. Because foreign keys are not supported currently, this option is not recommended for general use.

Value range: name of an existing table in the database

- **DEFERRABLE | NOT DEFERRABLE**

Specifies the start time of the trigger. It can only be specified for constraint triggers. They determine whether the constraint is deferrable.

For details, see [CREATE TABLE](#).

- **INITIALLY IMMEDIATE | INITIALLY DEFERRED**

If the constraint is deferrable, the two clauses specify the default time to check the constraint. It can only be specified for constraint triggers.

For details, see [CREATE TABLE](#).

- **FOR EACH ROW | FOR EACH STATEMENT**

Specifies the frequency of firing the trigger.

- **FOR EACH ROW** indicates that the trigger should be fired once for every row affected by the trigger event.

- **FOR EACH STATEMENT** indicates that the trigger should be fired just once per SQL statement.

If neither is specified, the default is **FOR EACH STATEMENT**. Constraint triggers can only be marked as **FOR EACH ROW**.

- **condition**

Specifies whether the trigger function will actually be executed. If **WHEN** is specified, the function will be called only when **condition** returns **true**.

In **FOR EACH ROW** triggers, the **WHEN** condition can refer to columns of the old and/or new row values by writing **OLD.column name** or **NEW.column name** respectively. In addition, **INSERT** triggers cannot refer to **OLD**, and **DELETE** triggers cannot refer to **NEW**.

**INSTEAD OF** triggers do not support **WHEN** conditions.

Currently, **WHEN** expressions cannot contain subqueries.

Note that for constraint triggers, evaluation of the **WHEN** condition is not deferred, but occurs immediately after the row update operation is performed. If the condition does not evaluate to **true**, then the trigger is not queued for deferred execution.

- **function\_name**

Specifies a user-defined function, which must be declared as taking no parameters and returning type trigger. This is executed when a trigger fires.

- **arguments**

Specifies an optional comma-separated list of parameters to be provided to the function when the trigger is executed. The parameters are literal string constants. Simple names and numeric constants can also be written here, but they will all be converted to strings. Check the description of the implementation language of the trigger function to find out how these parameters can be accessed within the function.

 **NOTE**

The following details trigger types:

- **INSTEAD OF** triggers must be marked as **FOR EACH ROW** and can be defined only on views.
- **BEFORE** and **AFTER** triggers on a view must be marked as **FOR EACH STATEMENT**.
- **TRUNCATE** triggers must be marked as **FOR EACH STATEMENT**.

**Table 7-241** Types of triggers supported on tables and views

| When       | Event                | Row-Level      | Statement-Level  |
|------------|----------------------|----------------|------------------|
| BEFORE     | INSERT/UPDATE/DELETE | Tables         | Tables and views |
|            | TRUNCATE             | Not supported. | Tables           |
| AFTER      | INSERT/UPDATE/DELETE | Tables         | Tables and views |
|            | TRUNCATE             | Not supported. | Tables           |
| INSTEAD OF | INSERT/UPDATE/DELETE | Views          | Not supported.   |

| When | Event    | Row-Level      | Statement-Level |
|------|----------|----------------|-----------------|
|      | TRUNCATE | Not supported. | Not supported.  |

**Table 7-242** Special variables in PL/pgSQL functions

| Variable        | Description                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------|
| NEW             | New tuple for INSERT and UPDATE operations. This variable is <b>NULL</b> for <b>DELETE</b> operations and statement-level triggers. |
| OLD             | Old tuple for UPDATE and DELETE operations. This variable is <b>NULL</b> for <b>INSERT</b> operations and statement-level triggers. |
| TG_NAME         | Trigger name.                                                                                                                       |
| TG_WHEN         | Trigger timing ( <b>BEFORE</b> , <b>AFTER</b> , or <b>INSTEAD OF</b> ).                                                             |
| TG_LEVEL        | Trigger frequency ( <b>ROW</b> or <b>STATEMENT</b> ).                                                                               |
| TG_OP           | Trigger event ( <b>INSERT</b> , <b>UPDATE</b> , <b>DELETE</b> , or <b>TRUNCATE</b> ).                                               |
| TG_RELID        | OID of the table where the trigger resides.                                                                                         |
| TG_RELNAME      | Name of the table where the trigger resides. (This variable has been replaced by <b>TG_TABLE_NAME</b> .)                            |
| TG_TABLE_NAME   | Name of the table where the trigger resides.                                                                                        |
| TG_TABLE_SCHEMA | Schema of the table where the trigger resides.                                                                                      |
| TG_NARGS        | Number of parameters for the trigger function.                                                                                      |
| TG_ARGV[]       | List of parameters for the trigger function.                                                                                        |

## Examples

```
-- Create a source table and a destination table.
gaussdb=# CREATE TABLE test_trigger_src_tbl(id1 INT, id2 INT, id3 INT);
gaussdb=# CREATE TABLE test_trigger_des_tbl(id1 INT, id2 INT, id3 INT);
```

### Using the INSERT trigger

```
-- Create an INSERT trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION tri_insert_func() RETURNS TRIGGER AS
$$
DECLARE
BEGIN
 INSERT INTO test_trigger_des_tbl VALUES(NEW.id1, NEW.id2, NEW.id3);
 RETURN NEW;
END
$$ LANGUAGE plpgsql;

-- Create an INSERT trigger.
gaussdb=# CREATE TRIGGER insert_trigger
BEFORE INSERT ON test_trigger_src_tbl
FOR EACH ROW
EXECUTE PROCEDURE tri_insert_func();

-- Execute the INSERT event and check the trigger results.
gaussdb=# INSERT INTO test_trigger_src_tbl VALUES(100,200,300);

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 300
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 300
(1 row)
```

### Using the UPDATE trigger

```
-- Create an UPDATE trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION tri_update_func() RETURNS TRIGGER AS
$$
DECLARE
BEGIN
UPDATE test_trigger_des_tbl SET id3 = NEW.id3 WHERE id1=OLD.id1;
RETURN OLD;
END
$$ LANGUAGE plpgsql;

-- Create an UPDATE trigger.
gaussdb=# CREATE TRIGGER update_trigger
AFTER UPDATE ON test_trigger_src_tbl
FOR EACH ROW
EXECUTE PROCEDURE tri_update_func();

-- Execute the UPDATE event and check the trigger results.
gaussdb=# UPDATE test_trigger_src_tbl SET id3=400 WHERE id1=100;

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 400
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 400
(1 row)
```

### Using the DELETE trigger

```
-- Create a DELETE trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION TRI_DELETE_FUNC() RETURNS TRIGGER AS
```

```
$$
DECLARE
BEGIN
 DELETE FROM test_trigger_des_tbl WHERE id1=OLD.id1;
 RETURN OLD;
END
$$ LANGUAGE plpgsql;

-- Create a DELETE trigger.
gaussdb=# CREATE TRIGGER delete_trigger BEFORE DELETE ON test_trigger_src_tbl FOR EACH ROW
EXECUTE PROCEDURE tri_delete_func();

-- Execute the DELETE event and check the trigger results.
gaussdb=# DELETE FROM test_trigger_src_tbl WHERE id1=100;

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----
(0 rows)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----
(0 rows)
```

### Renaming a trigger

```
-- Rename a trigger.
gaussdb=# ALTER TRIGGER delete_trigger ON test_trigger_src_tbl RENAME TO delete_trigger_renamed;
```

### Disabling a trigger

```
-- Disable insert_trigger.
gaussdb=# ALTER TABLE test_trigger_src_tbl DISABLE TRIGGER insert_trigger;

gaussdb=# INSERT INTO test_trigger_src_tbl VALUES(100,200,300);

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----
 100 | 200 | 300
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // View that the trigger does not take effect.
 id1 | id2 | id3
-----+-----
(0 rows)

-- Disable all triggers on the current table.
gaussdb=# ALTER TABLE test_trigger_src_tbl DISABLE TRIGGER ALL;
```

### Deleting a trigger

```
gaussdb=# DROP TRIGGER insert_trigger ON test_trigger_src_tbl;

gaussdb=# DROP TRIGGER update_trigger ON test_trigger_src_tbl;

gaussdb=# DROP TRIGGER delete_trigger_renamed ON test_trigger_src_tbl;
```

### Deleting a function

```
gaussdb=# DROP FUNCTION tri_insert_func;

gaussdb=# DROP FUNCTION tri_update_func;

gaussdb=# DROP FUNCTION tri_delete_func;
-- Delete the source table and destination table.
gaussdb=# DROP TABLE test_trigger_src_tbl;
gaussdb=# DROP TABLE test_trigger_des_tbl;
```

[ALTER TRIGGER](#), [DROP TRIGGER](#), and [ALTER TABLE](#)

### 7.12.8.47 CREATE TYPE

#### Description

Defines a new data type for use in the current database. The user who defines a type becomes its owner. Types are designed only for row-store tables.

The following data types can be created: composite type, base type, shell type, and enumerated type.

- **Composite type**  
A composite type is specified by a list of attribute names and data types. If the data type of an attribute is collatable, the attribute's collation rule can also be specified. This is essentially the same as the row type of a table, but using CREATE TYPE avoids the need to create an actual table when all that is wanted is to define a type. A stand-alone composite type is useful as the parameter or return type of a function.  
To create a composite type, you must have the USAGE permission on all of its attribute types.
- **Base type**  
You can create a base type (scalar type). Generally, the functions required by a base type have to be coded in C or another low-level language.
- **Shell type**  
A shell type is simply a placeholder for a type to be defined later; it is created by issuing CREATE TYPE with no parameters except for the type name. Shell types are needed as forward references when base types are created.
- **Enumerated type**  
An enumerated type is a list of one or more quoted labels, each of which must be 1 to 64 bytes long.
- A user granted with the CREATE ANY TYPE permission can create types in the public and user schemas.

#### Precautions

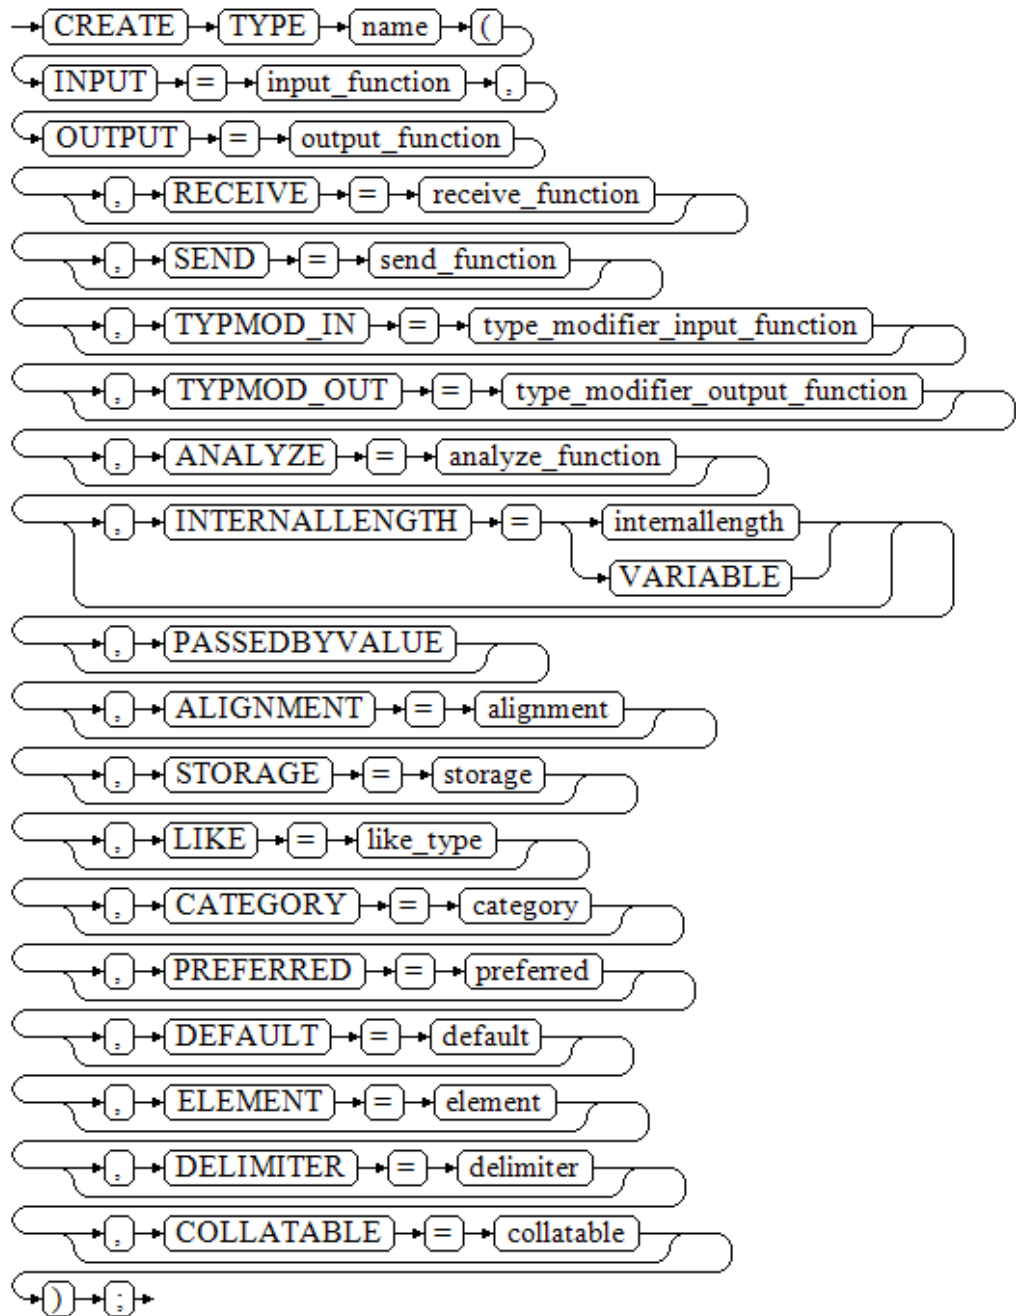

- If a schema name is given then the type is created in the specified schema. Otherwise, it is created in the current schema. The type name must be distinct from the name of any existing type or domain in the same schema. (Because tables have associated data types, the type name must also be distinct from the name of any existing table in the same schema.)
- When creating a non-system type by associating a function, the user needs to understand the definition of the type and the function associated with the type. If this function is not properly used, permissions may be exploited due to the associated function.

#### Syntax

```
CREATE TYPE name AS
([attribute_name data_type [COLLATE collation] [, ...]]);
```

```
CREATE TYPE name (
 INPUT = input_function,
 OUTPUT = output_function
 [, RECEIVE = receive_function]
 [, SEND = send_function]
 [, TYPMOD_IN = type_modifier_input_function]
 [, TYPMOD_OUT = type_modifier_output_function]
 [, ANALYZE = analyze_function]
 [, INTERNALLENGTH = { internallength | VARIABLE }]
 [, PASSEDBYVALUE]
 [, ALIGNMENT = alignment]
 [, STORAGE = storage]
 [, LIKE = like_type]
 [, CATEGORY = category]
 [, PREFERRED = preferred]
 [, DEFAULT = default]
 [, ELEMENT = element]
 [, DELIMITER = delimiter]
 [, COLLATABLE = collatable]
);
```

CREATE TYPE name;

CREATE TYPE name AS ENUM  
( ['label' [ ... ] ] );

## Parameters

### Composite type

- **name**  
Specifies the name (optionally schema-qualified) of the type to be created.
- **attribute\_name**  
Specifies the name of an attribute (column) for the composite type.
- **data\_type**  
Specifies the name of an existing data type to become a column of the composite type. You can use **%ROWTYPE** to indirectly reference the type of a table, or **%TYPE** to indirectly reference the type of a column in a table or composite type.
- **collation**  
Specifies the name of an existing collation rule to be associated with a column of the composite type. You can run the **SELECT \* FROM pg\_collation** command to query collation rules from the `pg_collation` system catalog. The default collation rule is the row starting with **default** in the query result.

### NOTE

The constructor of the composite type can use the `=>` to assign values. The restrictions are as follows:

- The `=>` function is used when the constructor of a composite type assigns values. This function is supported only in an ORA-compatible database (**sql\_compatibility** set to 'ORA').
- The constructor of the composite type uses the `=>` function to assign values. This function is supported only when `=>` is consecutively used to assign values to input parameters, for example, **composite\_name(ename1 => val1, ename2 => val2, ename3 => val3)** or **composite\_name(val1, ename2 => val2, ename3 => val3)**. Discontinuous use of `=>` or `=>` is not supported. The last input parameter, for example, **composite\_name(ename1 => val1, ename2 => val2, val3)** or **composite\_name(val1, ename2 => val2, val3)**, is not assigned a value.

### Base type

When creating a base type, you can place parameters in any order. The `input_function` and `output_function` parameters are required, and other parameters are optional.

- **input\_function**  
Specifies the name of a function that converts data from the type's external textual form to its internal form.  
The input function may be declared as taking one parameter of type `cstring` or taking three parameters of types `cstring`, `oid`, and `integer`.
  - The `cstring`-type parameter is the input text as a C string.
  - The `oid`-type parameter is the type's own OID (except for array types, which instead receive their element type's OID).
  - The `integer`-type parameter is `typmod` of the destination column, if known (`-1` will be passed if not known).The input function must return a value of the data type itself. Usually, an input function should be declared as **STRICT**. Otherwise, when a **NULL** input

value is read and the input function is called, the first parameter is **NULL**. The function must still return **NULL** in this case, unless it raises an error. (This case is mainly meant to support domain input functions, which might need to reject **NULL** inputs.)

 **NOTE**

- The input and output functions can be declared to have results or parameters of the new type, when they have to be created before the new type can be created. The type should first be defined as a shell type, which is a placeholder type that has no attributes except a name and an owner. This is done by issuing the **CREATE TYPE name** statement, with no additional parameters. Then, the I/O functions written in C can be defined as referencing the shell type. Finally, **CREATE TYPE** with a full definition replaces the shell entry with a complete, valid type definition, after which the new type can be used normally.
- If the input and output functions are internal functions and are specified as internal system functions, the parameter types of the input and output functions must be the same, and the parameter types of **INTERNALLENGTH** and **PASSEDBYVALUE** of the new type must be the same as those of the input and output functions.
- **output\_function**  
Specifies the name of a function that converts data from the type's internal form to its external textual form.  
The output function must be declared as taking one parameter of the new data type. The output function must return type cstring. Output functions are not called for **NULL** values.
- **receive\_function**  
(Optional) Specifies the name of a function that converts data from the type's external binary form to its internal form.  
If this function is not supplied, the type cannot participate in binary input. The binary representation should be chosen to be cheap to convert to internal form, while being reasonably portable. (For example, the standard integer data types use network byte order as the external binary representation, while the internal representation is in the machine's native byte order.) The receive function should perform adequate checking to ensure that the value is valid.  
The receive function may be declared as taking one parameter of type internal or taking three parameters of types internal, oid, integer.
  - The internal-type parameter is a pointer to a StringInfo buffer holding the received byte strings.
  - The oid- and integer-type parameters are the same as those of the text input function.The receive function must return a value of the data type itself. Usually, a receive function should be declared as **STRICT**. Otherwise, when a **NULL** input value is read and the receive function is called, the first parameter is **NULL**. The function must still return **NULL** in this case, unless it raises an error. (This case is mainly meant to support domain receive functions, which might need to reject **NULL** inputs.)
- **send\_function**  
(Optional) Specifies the name of a function that converts data from the type's internal form to its external binary form.  
If this function is not supplied, the type cannot participate in binary output. The send function must be declared as taking one parameter of the new data

type. The send function must return type bytea. Send functions are not called for **NULL** values.

- **type\_modifier\_input\_function**

(Optional) Specifies the name of a function that converts an array of modifiers for a type to its internal format.

- **type\_modifier\_output\_function**

(Optional) Specifies the name of a function that converts the internal format of modifiers for a type to its external text format.

 **NOTE**

**type\_modifier\_input\_function** and **type\_modifier\_output\_function** are needed if the type supports modifiers, that is optional constraints attached to a type declaration, such as `char(5)` or `numeric(30,2)`. GaussDB allows user-defined types to take one or more simple constants or identifiers as modifiers. However, this information must be capable of being packed into a single non-negative integer value for storage in the system catalogs. Declared modifiers are passed to **type\_modifier\_input\_function** in the cstring array format. It must check the values for validity (throwing an error if they are wrong), and if they are correct, return a single non-negative integer value that will be stored as the column "typmod". Type modifiers will be rejected if the type does not have a **type\_modifier\_input\_function**. The **type\_modifier\_output\_function** converts the internal integer typmod value back to the correct form for user display. It must return a cstring value that is the exact string to append to the type name. For example, a numeric function may return (30,2). It is allowed to omit the **type\_modifier\_output\_function**, in which case the default display format is just the stored typmod integer value enclosed in parentheses.

- **analyze\_function**

(Optional) Specifies the name of a function that performs statistical analysis for the data type.

By default, ANALYZE will attempt to gather statistics using the type's "equals" and "less-than" operators, if there is a default B-tree operator class for the type. For non-scalar types, this behavior is likely to be unsuitable, so it can be overridden by specifying a custom analysis function. The analysis function must be declared to take one parameter of type internal and return a boolean result.

- **internallength**

(Optional) Specifies the length in bytes of the new type's internal representation. The default assumption is that it is variable-length.

While the details of the new type's internal representation are only known to the I/O functions and other functions you create to work with the type, there are several attributes of the internal representation that must be declared to GaussDB. Foremost of these is **internallength**. Base data types can be fixed-length, in which case **internallength** is a positive integer, or variable length, indicated by setting **internallength** to **VARIABLE**. (Internally, this is represented by setting **typlen** to **-1**.) The internal representation of all variable-length types must start with a 4-byte integer giving the total length of this value of the type.

- **PASSEDBYVALUE**

(Optional) Indicates that values of this data type are passed by value, rather than by reference. You cannot pass by value types whose internal representation is larger than the size of the Datum type (4 bytes on most machines, 8 bytes on a few).

- **alignment**

(Optional) Specifies the storage alignment requirement of the data type. If specified, it must be **char**, **int2**, **int4**, or **double**; the default is **int4**.

The allowed values equate to alignment on 1, 2, 4, or 8 byte boundaries. Note that variable-length types must have an alignment of at least 4, since they necessarily contain an int4 as their first component.

- **storage**

(Optional) Specifies the storage strategy for the data type.

If specified, it must be **plain**, **external**, **extended**, or **main**; the default is **plain**.

- **plain** specifies that data of the type will always be stored in-line and not compressed. (Only **plain** is allowed for fixed-length types.)
- **extended** specifies that the system will first try to compress a long data value, and will move the value out of the main table row if it is still too long.
- **external** allows the value to be moved out of the main table, but the system will not try to compress it.
- **main** allows compression, but discourages moving the value out of the main table. (Data items with this storage strategy might still be moved out of the main table if there is no other way to make a row fit, but they will be kept in the main table preferentially over **extended** and **external** items.)

All **storage** values other than **plain** imply that the functions of the data type can handle values that have been toasted. The specific other value given merely determines the default TOAST storage strategy for columns of a TOAST data type; users can pick other strategies for individual columns using ALTER TABLE SET STORAGE.

- **like\_type**

(Optional) Specifies the name of an existing data type that the new type will have the same representation as. The values of **internallength**, **passedbyvalue**, **alignment**, and **storage** are copied from that type, unless overridden by explicit specification elsewhere in this CREATE TYPE statement.

Specifying representation in this way is especially useful when the low-level implementation of a new type references an existing type.

- **category**

(Optional) Specifies the category code (a single ASCII character) for this type. The default is **U** for a user-defined type. You may also choose other ASCII characters to create custom categories.

- **preferred**

(Optional) Specifies whether a type is preferred within its type category. If it is, the value will be **TRUE**, else **FALSE**. The default is **FALSE**. Be very careful about creating a preferred type within an existing type category, as this could cause surprising changes in behavior.

 **NOTE**

The **category** and **preferred** parameters can be used to help control which implicit cast will be applied in ambiguous situations. Each data type belongs to a category named by a single ASCII character, and each type is either preferred or not within its category. The parser will prefer casting to preferred types (but only from other types within the same category) when this rule is helpful in resolving overloaded functions or operators. For types that have no implicit casts to or from any other types, it is sufficient to leave these settings at the defaults. However, for a group of related types that have implicit casts, it is often helpful to mark them all as belonging to a category and select one or two of the most general types as being preferred within the category. The **category** parameter is especially useful when adding a user-defined type to an existing built-in category, such as the numeric or string types. However, it is also possible to create entirely-user-defined type categories. Select any ASCII character other than an uppercase letter to name such a category.

- **default**

(Optional) Specifies the default value for the data type. If this is omitted, the default is null.

A default value can be specified, in case a user wants columns of the data type to default to something other than the null value. Specify the default with the **DEFAULT** keyword. (Such a default can be overridden by an explicit **DEFAULT** clause attached to a particular column.)

- **element**

(Optional) Specifies the type of array elements when an array type is created. For example, to define an array of 4-byte integers (**int4**), specify **ELEMENT = int4**.

- **delimiter**

(Optional) Specifies the delimiter character to be used between values in arrays made of this type.

**delimiter** can be set to a specific character. The default delimiter is the comma (,). Note that the delimiter is associated with the array element type, not the array type itself.

- **collatable**

(Optional) Specifies whether this type's operations can use collation information. If they can, the value will be **TRUE**, else **FALSE** (default).

If **collatable** is **TRUE**, column definitions and expressions of the type may carry collation information through use of the **COLLATE** clause. It is up to the implementations of the functions operating on the type to actually make use of the collation information; this does not happen automatically merely by marking the type collatable.

- **label**

(Optional) Represents the textual label associated with one value of an enumerated type. It is a string of 1 to 63 characters.

 **NOTE**

Whenever a user-defined type is created, GaussDB automatically creates an associated array type whose name consists of the element type's name prefixed with an underscore (\_).

## Examples

```
-- Create a composite type, create a table, insert data, and make a query.
gaussdb=# CREATE TYPE compfoo AS (f1 int, f2 text);
```

```
gaussdb=# CREATE TABLE t1_compfoo(a int, b compfoo);
gaussdb=# CREATE TABLE t2_compfoo(a int, b compfoo);
gaussdb=# INSERT INTO t1_compfoo values(1,(1,'demo'));
gaussdb=# INSERT INTO t2_compfoo SELECT * FROM t1_compfoo;
gaussdb=# SELECT (b).f1 FROM t1_compfoo;
gaussdb=# SELECT * FROM t1_compfoo t1 JOIN t2_compfoo t2 ON (t1.b).f1=(t1.b).f1;

-- Rename the data type.
gaussdb=# ALTER TYPE compfoo RENAME TO compfoo1;

-- Change the owner of the user-defined type compfoo1 to usr1.
gaussdb=# CREATE USER usr1 PASSWORD '*****';
gaussdb=# ALTER TYPE compfoo1 OWNER TO usr1;

-- Change the schema of the user-defined type compfoo1 to usr1.
gaussdb=# ALTER TYPE compfoo1 SET SCHEMA usr1;

-- Add a new attribute to the data type.
gaussdb=# ALTER TYPE usr1.compfoo1 ADD ATTRIBUTE f3 int;

-- Delete the compfoo1 type.
gaussdb=# DROP TYPE usr1.compfoo1 CASCADE;

-- Delete related tables and users.
gaussdb=# DROP TABLE t1_compfoo;
gaussdb=# DROP TABLE t2_compfoo;
gaussdb=# DROP SCHEMA usr1;
gaussdb=# DROP USER usr1;

-- Create an enumerated type.
gaussdb=# CREATE TYPE bugstatus AS ENUM ('create', 'modify', 'closed');

-- Add a label.
gaussdb=# ALTER TYPE bugstatus ADD VALUE IF NOT EXISTS 'regress' BEFORE 'closed';

-- Rename a label.
gaussdb=# ALTER TYPE bugstatus RENAME VALUE 'create' TO 'new';

-- Compile the .so file and create a shell type.
gaussdb=# CREATE TYPE complex;
-- This statement creates a placeholder for the type to be defined so that the type can be referenced when
its I/O functions are defined. Then, you can define I/O functions. Note that the functions must be declared
to take the NOT FENCED mode during creation.
gaussdb=# CREATE FUNCTION
complex_in(cstring)
RETURNS complex
AS 'filename'
LANGUAGE C IMMUTABLE STRICT not fenced;

gaussdb=# CREATE FUNCTION
complex_out(complex)
RETURNS cstring
AS 'filename'
LANGUAGE C IMMUTABLE STRICT not fenced;

gaussdb=# CREATE FUNCTION
complex_rcv(internal)

RETURNS complex

AS 'filename'

LANGUAGE C IMMUTABLE STRICT not fenced;

gaussdb=# CREATE FUNCTION
complex_send(complex)

RETURNS bytea
```

```
AS 'filename'

LANGUAGE C IMMUTABLE STRICT not fenced;
-- Finally, provide a complete definition of the data type.
gaussdb=# CREATE TYPE complex (

internallength = 16,

input = complex_in,

output = complex_out,

receive = complex_rcv,

send = complex_send,

alignment = double
);

-- Delete the type and functions.
gaussdb=# DROP TYPE complex;
gaussdb=# DROP FUNCTION complex_send;
gaussdb=# DROP FUNCTION complex_rcv;
gaussdb=# DROP FUNCTION complex_out;
gaussdb=# DROP FUNCTION complex_in;

-- Delete an enumerated type.
gaussdb=# DROP TYPE bugstatus CASCADE;
```

The C functions corresponding to the input, output, receive, and send functions are defined as follows:

```
-- Define a structure body Complex.
typedef struct Complex {
 double x;
 double y;
} Complex;

-- Define an input function.
PG_FUNCTION_INFO_V1(complex_in);

Datum
complex_in(PG_FUNCTION_ARGS)
{
 char *str = PG_GETARG_CSTRING(0);
 double x,
 y;
 Complex *result;

 if (sscanf(str, " (%lf , %lf)", &x, &y) != 2)
 ereport(ERROR,
 (errmsg("invalid input syntax for complex: \"%s\"",
 str)));

 result = (Complex *) palloc(sizeof(Complex));
 result->x = x;
 result->y = y;
 PG_RETURN_POINTER(result);
}

-- Define an output function.
PG_FUNCTION_INFO_V1(complex_out);

Datum
complex_out(PG_FUNCTION_ARGS)
{
 Complex *complex = (Complex *) PG_GETARG_POINTER(0);
 char *result;
```

```
 result = (char *) palloc(100);
 snprintf(result, 100, "(%g,%g)", complex->x, complex->y);
 PG_RETURN_CSTRING(result);
 }

 -- Define a receive function.
 PG_FUNCTION_INFO_V1(complex_recv);

 Datum
 complex_recv(PG_FUNCTION_ARGS)
 {
 StringInfo buf = (StringInfo) PG_GETARG_POINTER(0);
 Complex *result;

 result = (Complex *) palloc(sizeof(Complex));
 result->x = pq_getmsgfloat8(buf);
 result->y = pq_getmsgfloat8(buf);
 PG_RETURN_POINTER(result);
 }

 -- Define a send function.
 PG_FUNCTION_INFO_V1(complex_send);

 Datum
 complex_send(PG_FUNCTION_ARGS)
 {
 Complex *complex = (Complex *) PG_GETARG_POINTER(0);
 StringInfoData buf;

 pq_begintypsend(&buf);
 pq_sendfloat8(&buf, complex->x);
 pq_sendfloat8(&buf, complex->y);
 PG_RETURN_BYTEA_P(pq_endtypsend(&buf));
 }

[ALTER TYPE](#) and [DROP TYPE](#)

### 7.12.8.48 CREATE USER

#### Description

Creates a user with a specified password. A user is a basic element for GaussDB authentication. You can use the correct username and password to log in to the GaussDB and grant different permissions to different users so that different users can perform different operations.

#### Precautions

- A user created using the CREATE USER statement has the LOGIN permission by default.
- When you run the **CREATE USER** command to create a user, the system creates a schema with the same name as the user in the database where the command is executed.
- The owner of an object created by a system administrator in a schema with the same name as a common user is the common user, not the system administrator.

#### Syntax

```
CREATE USER user_name [[WITH] option [...]] [ENCRYPTED | UNENCRYPTED] { PASSWORD | IDENTIFIED BY } { 'password' [EXPIRED] | DISABLE };
```

The option clause is used to configure information, including permissions and properties.

```
{SYSADMIN | NOSYSADMIN}
| {MONADMIN | NOMONADMIN}
| {OPRADMIN | NOOPRADMIN}
| {POLADMIN | NOPOLADMIN}
| {AUDITADMIN | NOAUDITADMIN}
| {CREATEDB | NOCREATEDB}
| {USEFT | NOUSEFT}
| {CREATEROLE | NOCREATEROLE}
| {INHERIT | NOINHERIT}
| {LOGIN | NOLOGIN}
| {REPLICATION | NOREPLICATION}
| {PERSISTENCE | NOPERSISTENCE}
| CONNECTION LIMIT connlimit
| VALID BEGIN 'timestamp'
| VALID UNTIL 'timestamp'
| RESOURCE POOL 'respool'
| USER GROUP 'groupuser'
| PERM SPACE 'spacelimit'
| TEMP SPACE 'tmpspacelimit'
| SPILL SPACE 'spillspacelimit'
| NODE GROUP logic_cluster_name
| IN ROLE role_name [, ...]
| IN GROUP role_name [, ...]
| ROLE role_name [, ...]
| ADMIN role_name [, ...]
| USER role_name [, ...]
| SYSID uid
| DEFAULT TABLESPACE tablespace_name
| PROFILE DEFAULT
| PROFILE profile_name
| PGUSER
```

## Parameters

- **user\_name**

Name of the user to be created.

Value range: a string. It must comply with the [naming convention](#). A value can contain a maximum of 63 characters.

---

 **CAUTION**

If a username contains uppercase letters, the database automatically converts the uppercase letters into lowercase letters. To create a username that contains uppercase letters, enclose the username with double quotation marks ("").

- **password**

Specifies the login password.

The new password must:

- Contain at least eight characters. This is the default length.
- Differ from the username or the username spelled backward.
- Contain at least three of the following character types: uppercase characters, lowercase characters, digits, and special characters (limited to ~!@#\$\$%^&\*()-\_+=\|[{]};,;<.>/?). If the password contains characters other

than the preceding characters, an error will be reported during statement execution.

- The password can also be a ciphertext character string that meets the format requirements. This mode is mainly used to import user data. You are advised not to use it directly. If a ciphertext password is used, the user must know the plaintext corresponding to the ciphertext password and ensure that the password meets the complexity requirements. The database does not verify the complexity of the ciphertext password. Instead, the security of the ciphertext password is ensured by the user.
- Be enclosed by single quotation marks when a user is created.

Value range: a string

For details about other parameters, see [Parameters](#) in "CREATE ROLE".

## Examples

```
-- Create user jim whose login password is *****
gaussdb=# CREATE USER jim PASSWORD '*****';

-- Create user kim whose login password is *****.
gaussdb=# CREATE USER kim IDENTIFIED BY '*****';

-- Create user tom.
gaussdb=# CREATE USER TOM PASSWORD '*****';

-- Create user TOM.
gaussdb=# CREATE USER "TOM" PASSWORD '*****';

-- To create a user with the CREATEDB permission, add the CREATEDB keyword.
gaussdb=# CREATE USER dim CREATEDB PASSWORD '*****';

-- Query the permissions of the dim user.
gaussdb=# \du dim
List of roles
Role name | Attributes | Member of
-----+-----+-----
dim | Create DB | {}
(You can see that the dim user has the CREATEDB permission.)

-- Change the password of user jim.
gaussdb=# ALTER USER jim IDENTIFIED BY '*****' REPLACE '*****';

-- Add the CREATEROLE permission to jim.
gaussdb=# ALTER USER jim CREATEROLE;

-- View the CREATEROLE permission added to user jim.
gaussdb=# \du jim
List of roles
Role name | Attributes | Member of
-----+-----+-----
jim | Create role | {}

-- Lock jim.
gaussdb=# ALTER USER jim ACCOUNT LOCK;

-- Unlock jim.
gaussdb=# ALTER USER jim ACCOUNT UNLOCK;

-- Change the user password.
gaussdb=# ALTER USER dim WITH PASSWORD '*****';

-- Change the username.
gaussdb=# ALTER USER dim RENAME TO lisa;

-- Delete the user.
```

```
gaussdb=# DROP USER kim CASCADE;
gaussdb=# DROP USER jim CASCADE;
gaussdb=# DROP USER lisa CASCADE;
gaussdb=# DROP USER TOM CASCADE;
gaussdb=# DROP USER "TOM" CASCADE;
```

[ALTER USER](#), [CREATE ROLE](#), and [DROP USER](#)

### 7.12.8.49 CREATE VIEW

#### Description

Creates a view. A view is a virtual table, not a base table. Only view definition is stored in the database and view data is not. The data is stored in a base table. If data in the base table changes, the data in the view changes accordingly. In this sense, a view is like a window through which users can know their interested data and data changes in the database.

- You can define frequently used data as views to encapsulate complex query SQL statements, which simplifies operations.
- You can query only data defined in a view, which is secure. Columns in a base table are hidden to protect the data structure of the database.
- User permission management is simplified. Only the permission to use views is granted to users.

#### Precautions

A user granted with the CREATE ANY TABLE permission can create views in the public and user schemas.

#### Syntax

```
CREATE [OR REPLACE] [TEMP | TEMPORARY] VIEW view_name [(column_name [, ...])]
[WITH ({view_option_name [= view_option_value]} [, ...])]
AS query
[WITH [CASCADED | LOCAL] CHECK OPTION | WITH READ ONLY];
```

#### NOTE

You can use WITH(security\_barrier) to create a relatively secure view. This prevents attackers from printing base table data by using the RAISE statement of low-cost functions. After a view is created, you are not allowed to use REPLACE to modify column names in the view or delete the columns.

## Parameters

- **OR REPLACE**  
Optional. Redefines the view if it already exists.
- **TEMP | TEMPORARY**  
(Optional) Creates a temporary view. The view is automatically deleted when the current session ends. If any table referenced by a view is a temporary table, the view is created as a temporary view (regardless of whether **TEMP | TEMPORARY** is specified in the SQL statement).
- **view\_name**  
Specifies the name (optionally schema-qualified) of the view to be created.  
Value range: a string. It must comply with the [naming convention](#).
- **column\_name**  
Specifies an optional list of names to be used for columns of the view. If not given, the column names are deduced from the query.  
Value range: a string. It must comply with the [naming convention](#).
- **view\_option\_name [= view\_option\_value]**  
Specifies an optional parameter for a view.  
Currently, `view_option_name` supports only **security\_barrier** and **check\_option**.  
**security\_barrier**: This parameter is used when the view attempts to provide row-level security. Value range: Boolean (**true** or **false**).  
**check\_option**: Controls the behavior of updating a view. Value range: **CASCADED** and **LOCAL**.
- **query**  
Specifies a **SELECT** or **VALUES** statement that will provide the columns and rows of the view.

---

### NOTICE

If **query** contains a clause specifying the partition of a partitioned table, the OID of the specified partition is fixed to the system catalog when the view is created. If the partition DDL syntax that causes the change in the OID of the specified partition is used, for example, **DROP**, **SPLIT**, or **MERGE**, the view is unavailable. In this case, you need to create a view.

- 
- **WITH [ CASCADED | LOCAL ] CHECK OPTION**  
Controls the behavior of updatable views. **INSERT** and **UPDATE** on the view will be checked to ensure that new rows meet the view-defining condition, that is, the new rows are visible through the view. If the check fails, the modification is rejected. If this option is not added, **INSERT** and **UPDATE** on the view are allowed to create rows that are not visible through the view. When **DELETE** is performed on a view, if the base table from which data is to be deleted is duplicate in a multi-table join view and the duplicate base tables are not all key-reserved tables in the view, data cannot be deleted when **WITH CHECK OPTION** is specified. The **WITH CHECK OPTION** option can be specified as **CASCADED** or **LOCAL**.

**CASCADED:** New rows are checked against the conditions of the view and all underlying views. If **CHECK OPTION** is specified, and neither **LOCAL** nor **CASCADED** is specified, then **CASCADED** is used by default.

**LOCAL:** Only the conditions directly defined by the view itself are checked. If **CHECK OPTION** is also defined in the underlying views, the conditions defined in the underlying views are checked.

- **WITH READ ONLY**

A read-only view is defined. You cannot insert, update, or delete data in the view.

 NOTE

- The concepts involved in the constraints on updating, inserting, and deleting views are described as follows:
  - Join view: view created with multiple tables using JOIN.
  - Key-preserved table: Insertion, update, and deletion of multi-table join views are restricted by key-preserved tables. In a multi-table view, if each row in the source table corresponds to each row in the view, and a row in the source table does not correspond to multiple rows in the view after the JOIN, the source table is a key-preserved table.
  - Relationship between the top layer and the bottom layer: A view may be nested at multiple layers. For example, a view consists of one or more views or subqueries. The view that is directly operated by the DML is called the top layer. The tables and views that form the view and the tables and views in the WITH clause are called the corresponding bottom layer.
  - Columns that can be updated: Columns that are not system columns or whole-row references and directly reference user columns in the base table can be updated. You can query the **is\_updatable** column in **information\_schema.columns** to check whether a column in a view or table can be updated.
  - Updatable view: view that can be inserted, updated, or deleted. Updatable views do not contain DISTINCT, GROUP BY, HAVING, LIMIT and OFFSET clauses, set operations (UNION, INTERSECT, and EXCEPT), aggregate functions, window functions, and return set functions (array\_agg, json\_agg, and generate\_series). **WITH CHECK OPTION** can be defined only on updatable views. To check whether a view can be updated, query the **is\_updatable** and **is\_insertable\_into** columns in **information\_schema.views** or the **information\_schema.tables.is\_insertable\_into** column. In **information\_schema.views**, **is\_updatable** specifies whether a view can be updated or deleted, **is\_insertable\_into** specifies whether data can be inserted into a view, and **information\_schema.tables.is\_insertable\_into** specifies whether data can be inserted into a relationship.
- If an updatable view has an INSTEAD OF trigger or INSTEAD rule, using CHECK OPTION does not check the conditions on that view.
- If an underlying view of an updatable view has an INSTEAD OF trigger and the updatable view defines the **CHECK OPTION** option of the CASCADED type, in non-ORA-compatible mode, the conditions of the underlying view with the INSTEAD OF trigger are recursively checked, and the conditions of the underlying view with the trigger are not checked. In ORA-compatible mode, the **CHECK OPTION** option of all views is invalid and no check is performed.
- If an updatable view or any of its underlying relationships has an INSTEAD rule that causes INSERT or UPDATE rewriting, specifying **CHECK OPTION** will not check the conditions on all views.
- If **CASCADED CHECK OPTION** is defined in the upper-layer view and **LOCAL CHECK OPTION** is defined in the lower-layer view, **LOCAL CHECK OPTION** in the lower-layer view is overwritten by **CASCADED CHECK OPTION** in the upper-layer view.
- If **CHECK OPTION** is specified, insert and update operations cannot be performed on join columns in multi-table join views or multi-table join subqueries.
- If **CHECK OPTION** is specified, duplicate base tables exist in a multi-table join view or multi-table join subquery, and the duplicate base tables are not all key-preserved tables, the view or subquery cannot be deleted.

## Examples

- Common view

```
-- Create the test_tb1 table and insert 100 data records into the table.
gaussdb=# CREATE TABLE test_tb1(col1 int, col2 int);
```

```

gaussdb=# INSERT INTO test_tb1 VALUES (generate_series(1,100),generate_series(1,100));
-- Create a view whose value of col1 is less than 3.
gaussdb=# CREATE VIEW test_v1 AS SELECT * FROM test_tb1 WHERE col1 < 3;
-- Query a view.
gaussdb=# SELECT * FROM test_v1;
 col1 | col2
-----+-----
 1 | 1
 2 | 2
(2 rows)

-- Delete the table and the view.
gaussdb=# DROP VIEW test_v1;
gaussdb=# DROP TABLE test_tb1;

```

- **Temporary view**

```

-- Create a table and a temporary view.
gaussdb=# CREATE TABLE test_tb2(c1 int, c2 int);
gaussdb=# CREATE TEMP VIEW test_v2 AS SELECT * FROM test_tb2;
-- Query the table and view information. (The temporary table belongs to a schema starting with
pg_temp instead of public.)
gaussdb=# \d

```

| Schema                     | Name     | Type  | Owner | Storage                          |
|----------------------------|----------|-------|-------|----------------------------------|
| pg_temp_cn_5001_6_2_187504 | test_v2  | view  | omm   |                                  |
| public                     | test_tb2 | table | omm   | {orientation=row,compression=no} |

(2 rows)

```

-- Exit the current session and log in again. Check whether the temporary view is deleted.
gaussdb=# \d

```

### 7.12.8.50 CREATE WEAK PASSWORD DICTIONARY

#### Description

CREATE WEAK PASSWORD DICTIONARY creates a weak password dictionary, which is empty by default. You can use this syntax to add one or more weak passwords to the gs\_global\_config system catalog.

#### Precautions

- Only the initial user, system administrator, and security administrator have the permission to execute this syntax.
- Passwords in the weak password dictionary are stored in the gs\_global\_config system catalog.

- The weak password dictionary is empty by default. You can use this syntax to add one or more weak passwords.
- When a user attempts to execute this syntax to insert a weak password that already exists in the `gs_global_config` catalog, only one weak password is retained in the table.

## Syntax

```
CREATE WEAK PASSWORD DICTIONARY
 [WITH VALUES] ({'weak_password'} [, ...]);
```

## Parameters

- **weak\_password**  
Specifies a weak password.  
Value range: a string.

## Examples

```
-- Insert a single weak password into the gs_global_config system catalog.
gaussdb=# CREATE WEAK PASSWORD DICTIONARY WITH VALUES ('*****');

-- Check weak passwords in the gs_global_config system catalog.
gaussdb=# SELECT * FROM gs_global_config WHERE NAME LIKE 'weak_password';
 name | value
-----+-----
weak_password | *****
(1 rows)

-- Insert multiple weak passwords into the gs_global_config system catalog.
gaussdb=# CREATE WEAK PASSWORD DICTIONARY WITH VALUES ('*****'),('*****');

-- Check the weak password in the gs_global_config system catalog again. The asterisk (*) in a weak
password does not represent the password content.
gaussdb=# SELECT * FROM gs_global_config WHERE NAME LIKE 'weak_password';
 name | value
-----+-----
weak_password | *****
weak_password | *****
weak_password | *****
(3 rows)

-- Clear all weak passwords in the gs_global_config system catalog.
gaussdb=# DROP WEAK PASSWORD DICTIONARY;

-- View existing weak passwords.
gaussdb=# SELECT * FROM gs_global_config WHERE NAME LIKE 'weak_password';
 name | value
-----+-----
(0 rows)
```

## 7.12.8.51 CURSOR

### Function

This statement is used to create a cursor and retrieve specified rows of data from a query.

To process SQL statements, the stored procedure thread assigns a memory segment to store context association. Cursors are handles or pointers pointing to context regions. With cursors, stored procedures can control alterations in context regions.

### Precautions

- CURSOR is used only in transaction blocks.
- Generally, CURSOR and SELECT both have text returns. Since data is stored in binary format in the system, the system needs to convert the data from the binary format to the text format. If data is returned in text format, client applications need to convert the data back to the binary format for processing. FETCH implements conversion between binary data and text data.
- Binary cursors should be used carefully. Text usually occupies larger space than binary data. A binary cursor returns internal binary data, which is easier to operate. A text cursor returns text, which is easier to retrieve and therefore reduces workload on the client. As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor, whereas with a binary cursor you would get a 4-byte field containing the internal representation of the value (in big-endian byte order).
- Parameters can be defined for static cursors. The parameters support default values.
- The definition of a cursor generates a query object. Currently, stored procedures do not support the creation of dependencies on query objects.

### Syntax

```
CURSOR cursor_name
[BINARY] [NO SCROLL] [{ WITH | WITHOUT } HOLD]
FOR query;
```

### Parameters

- **cursor\_name**  
Specifies the name of the cursor to be created.  
Value range: a string. It must comply with the naming convention.
- **BINARY**  
Specifies that data retrieved by a cursor will be returned in binary format, not in text format.

- **NO SCROLL**  
Specifies how the cursor retrieves rows.
  - **NO SCROLL**: specifies that the cursor cannot be used to retrieve rows in a nonsequential fashion.
  - Unspecified: Based on the query's execution plan, the system automatically determines whether the cursor can be used to retrieve rows in a nonsequential fashion.
- **WITH HOLD | WITHOUT HOLD**  
Specifies whether a cursor can be used after the transaction that created it ends.
  - **WITH HOLD**: The cursor can be used after the transaction that created it ends.
  - **WITHOUT HOLD**: The cursor cannot be used outside of the transaction that created it.
  - If neither **WITH HOLD** nor **WITHOUT HOLD** is specified, the default is **WITHOUT HOLD**.
  - Cross-node transactions (for example, DDL-contained transactions created in a cluster with multiple Coordinators) do not support **WITH HOLD**.
- **query**  
Uses the SELECT or VALUES clause to specify the rows to be returned by a cursor.  
Value range: SELECT or VALUES clause

## Examples

### Example 1:

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE tbl_test(c1 int);
gaussdb=# INSERT INTO tbl_test VALUES (generate_series(1,20));

-- Set up cursor1.
gaussdb=# BEGIN;
gaussdb=# CURSOR cursor1 FOR SELECT * FROM tbl_test ORDER BY 1;

-- Run the FETCH command to retrieve three rows of data.
gaussdb=# FETCH FORWARD 3 FROM cursor1;
c1

 1
 2
 3
(3 rows)

-- Run the MOVE command to move the cursor backwards by two rows. No result is returned.
gaussdb=# MOVE FORWARD 2 FROM cursor1;
MOVE 2

-- Run the FETCH command to retrieve two rows of data.
gaussdb=# FETCH FORWARD 2 FROM cursor1;
c1

 6
 7
(2 rows)
```

```
-- Close the cursor and end the transaction.
gaussdb=# CLOSE cursor1;
gaussdb=# END;
```

#### Example 2: Cursor with the WITH HOLD attribute

```
-- Set up a WITH HOLD cursor named cursor2.
gaussdb=# BEGIN;
gaussdb=# CURSOR cursor2 WITH HOLD FOR SELECT * FROM tbl_test ORDER BY 1;

-- Run the FETCH command to retrieve three rows of data.
gaussdb=# FETCH FORWARD 3 FROM cursor2;
c1

1
2
3
(3 rows)

-- Different from common cursors, cursors with the WITH HOLD attribute can still be used after a
transaction ends.
gaussdb=# END;
gaussdb=# FETCH FORWARD 2 FROM cursor2;
c1

4
5
(2 rows)

-- Close the cursor.
gaussdb=# CLOSE cursor2;

-- Delete.
gaussdb=# DROP TABLE tbl_test;
```

## 7.12.9 D

### 7.12.9.1 DEALLOCATE

#### Description

Deallocates prepared statements.

#### Precautions

- If you do not explicitly deallocate a prepared statement, the statement is deallocated when the session ends.
- The PREPARE keyword in the syntax is always ignored.

#### Syntax

```
DEALLOCATE [PREPARE] { name | ALL };
```

## Parameters

- **name**  
Specifies the name of a prepared statement to be deallocated.
- **ALL**  
Deallocates all prepared statements.

## Examples

```
-- View existing prepared statements.
gaussdb=# SELECT name, statement, parameter_types FROM pg_prepared_statements;
name | statement | parameter_types
-----+-----+-----
(0 rows)

-- Create four prepared statements q1, q2, q3, and q4.
gaussdb=# PREPARE q1 AS SELECT 1 AS a;
PREPARE
gaussdb=# PREPARE q2 AS SELECT 1 AS a;
PREPARE
gaussdb=# PREPARE q3 AS SELECT 1 AS a;
PREPARE
gaussdb=# PREPARE q4 AS SELECT 1 AS a;
PREPARE

-- View existing prepared statements again.
gaussdb=# SELECT name, statement, parameter_types FROM pg_prepared_statements;
name | statement | parameter_types
-----+-----+-----
q1 | PREPARE q1 AS SELECT 1 AS a; | {}
q4 | PREPARE q4 AS SELECT 1 AS a; | {}
q3 | PREPARE q3 AS SELECT 1 AS a; | {}
q2 | PREPARE q2 AS SELECT 1 AS a; | {}
(4 rows)

-- Delete the prepared statements q4 and view the remaining prepared statements.
gaussdb=# DEALLOCATE q4;
gaussdb=# SELECT name, statement, parameter_types FROM pg_prepared_statements;
name | statement | parameter_types
-----+-----+-----
q1 | PREPARE q1 AS SELECT 1 AS a; | {}
q3 | PREPARE q3 AS SELECT 1 AS a; | {}
q2 | PREPARE q2 AS SELECT 1 AS a; | {}
(3 rows)

-- Delete all prepared statements and view the remaining prepared statements.
gaussdb=# DEALLOCATE ALL;
DEALLOCATE ALL
gaussdb=# SELECT name, statement, parameter_types FROM pg_prepared_statements;
name | statement | parameter_types
-----+-----+-----
(0 rows)
```

### 7.12.9.2 DECLARE

#### Description

DECLARE defines a cursor to retrieve a small number of rows at a time out of a larger query and can be the start of an anonymous block.

This section describes usage of cursors. The usage of anonymous blocks is available in [BEGIN](#).

To process SQL statements, the stored procedure thread assigns a memory segment to store context association. Cursors are handles or pointers pointing to context regions. With cursors, stored procedures can control alterations in context regions.

Generally, CURSOR and SELECT both have text returns. Since data is stored in binary format in the system, the system needs to convert the data from the binary format to the text format. If data is returned in text format, client applications need to convert the data back to the binary format for processing. FETCH implements conversion between binary data and text data.

## Precautions

- CURSOR is used only in transaction blocks.
- Binary cursors should be used carefully. Text usually occupies larger space than binary data. A binary cursor returns internal binary data, which is easier to operate. A text cursor returns text, which is easier to retrieve and therefore reduces workload on the client. As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor, whereas with a binary cursor you would get a 4-byte value containing the internal representation of the value (in big-endian byte order).

## Syntax

- Define a cursor.  

```
DECLARE cursor_name [BINARY] [NO SCROLL]
 CURSOR [{ WITH | WITHOUT } HOLD] FOR query;
```

- Enable an anonymous block.

```
[DECLARE [declare_statements]]
BEGIN
execution_statements
END;
/
```

## Parameters

- **cursor\_name**  
 Specifies the name of the cursor to be created.  
 Value range: a string. It must comply with the naming convention.
- **BINARY**

Specifies that data retrieved by a cursor will be returned in binary format, not in text format.

- **NO SCROLL**

Specifies how the cursor retrieves rows.

- **NO SCROLL**: specifies that the cursor cannot be used to retrieve rows in a nonsequential fashion.
- Unspecified: Based on the query's execution plan, the system automatically determines whether the cursor can be used to retrieve rows in a nonsequential fashion.

- **WITH HOLD**

**WITHOUT HOLD**

Specifies whether a cursor can be used after the transaction that created it ends.

- **WITH HOLD**: The cursor can be used after the transaction that created it ends.
- **WITHOUT HOLD**: The cursor cannot be used outside of the transaction that created it.
- If neither **WITH HOLD** nor **WITHOUT HOLD** is specified, the default is **WITHOUT HOLD**.

---

**NOTICE**

For a cursor declared as **WITH HOLD**, all data of the cursor is cached when a transaction ends. If the cursor has a large amount of data, this process may take a long time.

---

- **query**

Uses the **SELECT** or **VALUES** clause to specify the rows to be returned by a cursor.

Value range: **SELECT** or **VALUES** clause

- **declare\_statements**

Declares a variable, including its name and type, for example, **sales\_cnt int**.

- **execution\_statements**

Specifies the statement to be executed in an anonymous block.

Value range: an existing function name

## Examples

For details about how to start an anonymous block, see [Examples](#) in section "BEGIN."

For details about how to define a cursor, see [Examples](#) in section "FETCH."

## Helpful Links

[BEGIN](#) and [FETCH](#)

### 7.12.9.3 DELETE

#### Description

Deletes rows that satisfy the WHERE clause from the specified table. If the WHERE clause is absent, the effect is to delete all rows in the table. The result is a valid, but an empty table.

#### Precautions

- The owner of a table, users granted the DELETE permission on the table or the DELETE ANY TABLE permission can delete data from the table. When separation of duties is disabled, system administrators have this permission by default. To perform the DELETE operation, you must have the SELECT permission on the table referenced by the USING clause and the table read in the condition.
- For row-store replication tables, DELETE can be performed only in the following scenarios:
  - Scenarios with primary key constraints.
  - Scenarios where the execution plan can be pushed down.
- For a DELETE statement whose subquery is a STREAM plan, UPDATE cannot be performed on the deleted row data.

#### Syntax

```
[WITH [RECURSIVE] with_query [, ...]]
DELETE [/*+ plan_hint */] [FROM] [ONLY] { table_name [*] subquery [[AS] alias] | view_name [[AS]
alias] }
 [USING using_list]
 [WHERE condition | WHERE CURRENT OF cursor_name]
 [ORDER BY { expression [ASC | DESC | USING operator] }]
 [LIMIT row_count]
 [RETURNING { * | { output_expr [[AS] output_name] } [, ...] }] ;
```

Format of **with\_query**:

```
with_query_name [(column_name [, ...])] AS [[NOT] MATERIALIZED]
({ select | values | insert | update | delete })
```

#### Parameters

- **WITH [ RECURSIVE ] with\_query [, ...]**

Specifies one or more subqueries that can be referenced by name in the main query, which is equivalent to a temporary table.

If RECURSIVE is specified, it allows a SELECT subquery to reference itself by name.

  - **with\_query\_name** specifies the name of the result set generated by a subquery. Such names can be used to access the result sets of subqueries in a query.
  - **column\_name** specifies the column name displayed in the subquery result set.
  - Each subquery can be a SELECT, VALUES, INSERT, UPDATE, or DELETE statement.

- You can use **MATERIALIZED** or **NOT MATERIALIZED** to modify the CTE.
  - If **MATERIALIZED** is specified, the WITH query will be materialized, and a copy of the subquery result set is generated. The copy is directly queried at the reference point. Therefore, the WITH subquery cannot be jointly optimized with the SELECT statement trunk (for example, predicate pushdown and equivalence class transfer). In this scenario, you can use **NOT MATERIALIZED** for modification. If the WITH query can be executed as a subquery inline, the preceding optimization can be performed.
  - If the user does not explicitly declare the materialized attribute, comply with the following rules: If the CTE is referenced only once in the trunk statement to which it belongs and semantically supports inline execution, it will be rewritten as subquery inline execution. Otherwise, the materialized execution will be performed in CTE Scan mode.
- **plan\_hint**  
Follows the **DELETE** keyword in the */\*+ \*/* format. It is used to optimize the plan of a DELETE statement block. For details, see [Hint-based Tuning](#). In each statement, only the first */\*+ plan\_hint \*/* comment block takes effect as a hint. Multiple hints can be written.
- **ONLY**  
If **ONLY** is specified before the table name, matching rows are deleted from the named table only. If **ONLY** is not specified, matching rows are also deleted from any tables inheriting from the named table.
- **table\_name**  
Specifies the name (optionally schema-qualified) of the target table.  
Value range: an existing table name

 **NOTE**

You can use database links to perform operations on remote tables. For details, see [DATABASE LINK](#).

- **subquery**  
The object to be deleted can be a subquery. When data in a subquery is deleted, the subquery is regarded as a temporary view. The **CHECK OPTION** option can be added to the end of the subquery.

```
[WITH [RECURSIVE] with_query [, ...]
SELECT /*+ plan_hint */ [ALL]
{ * | {expression [[AS] output_name]} [, ...] }
[into_option]
[FROM from_item [, ...]]
[WHERE condition]
[[START WITH condition] CONNECT BY [NOCYCLE] condition [ORDER SIBLINGS BY expression]]
[ORDER BY {expression [[ASC | DESC | USING operator] | nlssort_expression_clause } [NULLS
{ FIRST | LAST }]} [, ...]]
[FETCH { FIRST | NEXT } [count] { ROW | ROWS } ONLY]
[into_option];
```

The specified subquery source **from\_item** is as follows:

```
{ [ONLY] {table_name | view_name} [*] [[AS] alias [(column_alias [, ...])]]
| (select) [AS] alias [(column_alias [, ...])]
|with_query_name [[AS] alias [(column_alias [, ...])]]
|from_item [NATURAL] join_type from_item [ON join_condition | USING (join_column [, ...])] }
```

If there is only one table in the subquery, the table is deleted. If there are multiple tables or nested tables in the subquery, the system determines whether the table can be deleted by checking whether there is a key-preserved table. For details about key-preserved tables and **WITH CHECK OPTION**, see [CREATE VIEW](#).

- **view\_name**

Name of the target view.

 **NOTE**

The restrictions on deleting views and subqueries are as follows:

- The DELETE operation can be performed only on columns that directly reference user columns in the base table.
  - A subquery or view must contain at least one updatable column. For details about updatable columns, see [CREATE VIEW](#).
  - Views and subqueries that contain the DISTINCT, GROUP BY, HAVING, LIMIT or OFFSET clause at the top layer are not supported.
  - Views and subqueries that contain set operations (UNION, INTERSECT, EXCEPT, and MINUS) at the top layer are not supported.
  - Views and subqueries whose target lists contain aggregate functions, window functions, or return set functions (such as array\_agg, json\_agg, and generate\_series) are not supported.
  - Views with BEFORE or AFTER triggers but without INSTEAD OF triggers or INSTEAD rules are not supported.
  - Table types supported in views and subqueries include ordinary tables, temporary tables, global temporary tables, partitioned tables, level-2 partitioned tables, Ustore tables, and Astore tables.
  - A join view or subquery can delete only the key-preserved tables in the view or subquery. If there is only one key-preserved table, the data in the table is deleted. If there are multiple key-preserved tables, only the data in the first key-preserved table following FROM is deleted.
  - If the **CHECK OPTION** option is specified in the join view or subquery, the base table is duplicate, and the duplicate base table retains inconsistent key table attributes in the view or subquery, rows cannot be deleted from the join view or subquery. For details about the key-preserved table, see [CREATE VIEW](#).
  - System views cannot be deleted.
  - Deleting multiple tables is not supported.
- **alias**  
Specifies a substitute name for the target table.  
Value range: a string. It must comply with the [naming convention](#).
  - **using\_list**  
Specifies the USING clause.
  - **condition**  
Specifies an expression that returns a value of type Boolean. Only rows for which this expression returns **true** will be deleted. You are advised not to use numeric types such as int as conditions, because such types can be implicitly converted to bool values (non-zero values are implicitly converted to **true** and 0 is implicitly converted to **false**), which may cause unexpected results.
  - **WHERE CURRENT OF cursor\_name**  
When the cursor points to a row in a table, you can use this syntax to delete the row. For details about the restrictions, see [UPDATE](#).

- **ORDER BY**  
For details about the keywords, see [SELECT](#).
- **LIMIT**  
For details about the keywords, see [SELECT](#).
- **output\_expr**  
Specifies an expression to be computed and returned by the DELETE statement after each row is deleted. The expression can use any column names of the table. Write \* to return all columns.
- **output\_name**  
Specifies a name to use for a returned column.  
Value range: a string. It must comply with the [naming convention](#).

## Examples

- **Deleting some data records**  

```
-- Create a table.
gaussdb=# CREATE TABLE test_t1(col1 INT,col2 INT);
gaussdb=# INSERT INTO test_t1 VALUES (1, 1), (2, 2), (3, 3), (4, 4), (4, 6);

-- Delete some data records from the table.
gaussdb=# DELETE FROM test_t1 WHERE col1 = 4;

-- Query.
gaussdb=# SELECT * FROM test_t1;
col1 | col2
-----+-----
 1 | 1
 2 | 2
 3 | 3
(3 rows)
```
- **Deleting all data**  

```
--Delete all data.
gaussdb=# DELETE FROM test_t1;

-- Query.
gaussdb=# SELECT * FROM test_t1;
col1 | col2
-----+-----
(0 rows)

-- Drop the table.
gaussdb=# DROP TABLE test_t1;
```
- **WITH [ RECURSIVE ] with\_query [, ...]**  

```
-- Create a student table.
gaussdb=# CREATE TABLE student(id INT,name varchar(50));

-- Create a score table.
gaussdb=# CREATE TABLE grade(id INT,score CHAR);

gaussdb=# INSERT INTO student VALUES (1, 'tom'), (2, 'jerry'), (3, 'david');
gaussdb=# INSERT INTO grade VALUES (1, 'A'), (2, 'B'), (3, 'b');

-- Delete the data whose id is 2 from the student table and delete the data of the student from the grade table.
gaussdb=# WITH del_stu AS(DELETE FROM student WHERE id = 2 RETURNING id)
DELETE FROM grade WHERE id = (SELECT id FROM del_stu);

-- Query data.
gaussdb=# SELECT * FROM student;
id | name
----+-----
```

```

1 | tom
3 | david
(2 rows)

gaussdb=# SELECT * FROM grade;
 id | score
----+-----
 1 | A
 3 | b
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE grade;
gaussdb=# DROP TABLE student;

```

- Deleting a view or subquery

#### Example 1: Deleting a subquery

```

-- Create a schema.
gaussdb=# CREATE SCHEMA del_subqry;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = 'del_subqry';
SET

-- Create tables and insert data into the tables.
gaussdb=# CREATE TABLE t1 (x1 int, y1 int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'x1' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# CREATE TABLE t2 (x2 int PRIMARY KEY, y2 int);
NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "t2_pkey" for table "t2"
CREATE TABLE
gaussdb=# CREATE TABLE tdata (x INT PRIMARY KEY, y INT);
NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "tdata_pkey" for table "tdata"
CREATE TABLE
gaussdb=# CREATE TABLE tinfo (z INT PRIMARY KEY, comm VARCHAR2(20));
NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "tinfo_pkey" for table "tinfo"
CREATE TABLE
gaussdb=# INSERT INTO t1 VALUES (1, 1), (2, 2), (3, 3), (5, 5);
INSERT 0 4
gaussdb=# INSERT INTO t2 VALUES (1, 1), (2, 2), (3, 3), (5, 5);
INSERT 0 4
gaussdb=# INSERT INTO tdata VALUES (1, 1), (2, 2), (3, 3);
INSERT 0 3
gaussdb=# INSERT INTO tinfo VALUES (1,'one'), (2, 'two'), (3, 'three'), (5, 'wrong three');
INSERT 0 4

-- Delete data from t1 using a subquery.
gaussdb=# DELETE FROM (SELECT * FROM t1) where y1 = 3;
DELETE 1

-- The subquery is read-only, and data cannot be deleted.
gaussdb=# DELETE FROM (SELECT * FROM t1 WITH READ ONLY) WHERE y1 = 1;
ERROR: cannot perform a DML operation on a read-only subquery.

-- Delete a subquery of a multi-table join.
gaussdb=# SELECT * FROM t1, t2 WHERE x1 = x2;
 x1 | y1 | x2 | y2
----+----+----+----
 1 | 1 | 1 | 1
 2 | 2 | 2 | 2
 5 | 5 | 5 | 5
(3 rows)

gaussdb=# DELETE FROM (SELECT * FROM t1, t2 WHERE x1 = x2) WHERE y2 = 5;
DELETE 1
gaussdb=# SELECT * FROM t1, t2 WHERE x1 = x2;
 x1 | y1 | x2 | y2
----+----+----+----
 1 | 1 | 1 | 1

```

```
2 | 2 | 2 | 2
(2 rows)
```

-- The subquery contains **CHECK OPTION**, and the **tdata** table is duplicate. **td1** is not a key-preserved table, and **td2** is a key-preserved table.

```
gaussdb=# DELETE FROM (SELECT td1.x x1, td1.y y1, td2.x x2, td2.y y2 FROM tdata td1, tdata td2,
tinfo WHERE td2.y=tinfo.z AND td1.x=td2.y WITH CHECK OPTION) WHERE y1 = 2;
ERROR: cannot delete from view without exactly one key-preserved table
```

-- If **CHECK OPTION** is not specified, a subquery with the same structure is created and deleted successfully.

```
gaussdb=# DELETE FROM (SELECT td1.x x1, td1.y y1, td2.x x2, td2.y y2 FROM tdata td1, tdata td2,
tinfo WHERE td2.y=tinfo.z AND td1.x=td2.y) WHERE y1 = 2;
```

```
DELETE 1
```

-- Delete a schema.

```
gaussdb=# RESET CURRENT_SCHEMA;
RESET
```

```
gaussdb=# DROP SCHEMA del_subqry CASCADE;
```

NOTICE: drop cascades to 5 other objects

DETAIL: drop cascades to table del\_subqry.t1

drop cascades to table del\_subqry.t2

drop cascades to table del\_subqry.tdata

drop cascades to table del\_subqry.tinfo

drop cascades to view del\_subqry.vv\_wco

```
DROP SCHEMA
```

## Example 2: Deleting a view

-- Create a schema.

```
gaussdb=# CREATE SCHEMA del_view;
```

```
CREATE SCHEMA
```

```
gaussdb=# SET CURRENT_SCHEMA = 'del_view';
```

```
SET
```

-- Create tables and insert data into the tables.

```
gaussdb=# CREATE TABLE t1 (x1 int, y1 int);
```

NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'x1' as the distribution column by default.

HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.

```
CREATE TABLE
```

```
gaussdb=# CREATE TABLE t2 (x2 int PRIMARY KEY, y2 int);
```

NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "t2\_pkey" for table "t2"

```
CREATE TABLE
```

```
gaussdb=# CREATE TABLE tdata (x INT PRIMARY KEY, y INT);
```

NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "tdata\_pkey" for table "tdata"

```
CREATE TABLE
```

```
gaussdb=# CREATE TABLE tinfo (z INT PRIMARY KEY, comm VARCHAR2(20));
```

NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "tinfo\_pkey" for table "tinfo"

```
CREATE TABLE
```

```
gaussdb=# INSERT INTO t1 VALUES (1, 1), (2, 2), (3, 3), (5, 5);
```

```
INSERT 0 4
```

```
gaussdb=# INSERT INTO t2 VALUES (1, 1), (2, 2), (3, 3), (5, 5);
```

```
INSERT 0 4
```

```
gaussdb=# INSERT INTO tdata VALUES (1, 1), (2, 2), (3, 3);
```

```
INSERT 0 3
```

```
gaussdb=# INSERT INTO tinfo VALUES (1,'one'), (2, 'two'), (3, 'three'), (5, 'wrong three');
```

```
INSERT 0 4
```

-- Create a single table view.

```
gaussdb=# CREATE VIEW v_del1 AS SELECT * FROM t1;
```

```
CREATE VIEW
```

```
gaussdb=# CREATE VIEW v_del_read AS SELECT * FROM t1 WITH READ ONLY;
```

```
CREATE VIEW
```

-- Delete data from **t1** using a view.

```
gaussdb=# DELETE FROM v_del1 where y1 = 3;
```

```
DELETE 1
```

-- The view is read-only, and data cannot be deleted.

```
gaussdb=# DELETE FROM v_del_read WHERE y1 = 1;
```

```
ERROR: cannot perform a DML operation on a read-only subquery.
```

```
-- Create multi-table join views.
gaussdb=# CREATE VIEW vvt1t2 AS SELECT * FROM t1, t2 WHERE x1 = x2;
CREATE VIEW
gaussdb=# CREATE VIEW vv_dup AS SELECT td1.x x1, td1.y y1, td2.x x2, td2.y y2 FROM tdata td1,

drop cascades to view del_view.vvt1t2
drop cascades to view del_view.vv_dup
drop cascades to view del_view.vv_dup_wco
DROP SCHEMA
```

## Suggestions

- **DELETE**  
To delete all records in a table, use the **TRUNCATE** syntax.

### 7.12.9.4 DO

#### Function

Executes an anonymous code block.

A code block is regarded as a function body without parameters. The return value type is void. It is parsed and executed a single time.

## Precautions

- Before using a procedural language, you must install it in the current database by running the **CREATE LANGUAGE** command. PL/pgSQL is installed by default. To install another language, you must specify it.
- To use an untrusted language, you must have the USAGE permission on the programming language or the system administrator permission.

## Syntax

```
DO [LANGUAGE lang_name] code;
```

## Parameter Description

- **lang\_name**  
Specifies the name of the procedural language the code is written in. If omitted, the default is **plpgsql**.
- **code**  
Specifies the programming language code that can be executed. The value must be a character string.

## Examples

```
-- Create the webuser user.
gaussdb=# CREATE USER webuser PASSWORD '*****';

-- Grant all permissions on all views in the tpcds schema to the webuser user.
gaussdb=# DO $$DECLARE r record;
BEGIN
 FOR r IN SELECT c.relname,n.nspname FROM pg_class c,pg_namespace n
 WHERE c.relnamespace = n.oid AND n.nspname = 'tpcds' AND relkind IN ('r','v')
 LOOP
 EXECUTE 'GRANT ALL ON ' || quote_ident(r.table_schema) || '.' || quote_ident(r.table_name) || ' TO
webuser';
 END LOOP;
END$$;

-- Delete the webuser user.
gaussdb=# DROP USER webuser CASCADE;
```

### 7.12.9.5 DROP AGGREGATE

#### Description

Deletes an aggregate function.

#### Precautions

DROP AGGREGATE deletes an existing aggregate function. Only the owner of the aggregate function can run this command.

## Syntax

```
DROP AGGREGATE [IF EXISTS] name (argtype [, ...]) [CASCADE | RESTRICT];
```

## Parameters

- **IF EXISTS**  
If the specified aggregate function does not exist, a NOTICE prompt is generated, but no error is generated.
- **name**  
Name of an existing aggregate function (optionally schema-qualified).
- **argtype**  
Input data type of the aggregate function. To reference a zero-parameter aggregate function, replace the input data type list using \*.
- **CASCADE**  
Cascadingly deletes objects that depend on the aggregate function.
- **RESTRICT**  
Refuses to delete the aggregate function if any objects depend on it. This is a default processing.

## Examples

```
-- Create a user-defined function.
gaussdb=# CREATE OR REPLACE FUNCTION int_add(int,int)
 RETURNS int AS $BODY$
DECLARE
BEGIN
 RETURN $1 + $2;
END;
$BODY$ language plpgsql;

-- Create an aggregate function.
gaussdb=# CREATE AGGREGATE myavg (int)
(
 sfunc = int_add,
 stype = int,
 initcond = '0'
);

-- Delete the aggregate function myavg of the int type.
gaussdb=# DROP AGGREGATE myavg(int);

-- Delete the user-defined function.
gaussdb=# DROP FUNCTION int_add(int,int);
```

## Helpful Links

[ALTER AGGREGATE](#) and [CREATE AGGREGATE](#)

## Compatibility

The SQL standard does not provide the **DROP AGGREGATE** statement.

## 7.12.9.6 DROP AUDIT POLICY

### Description

Deletes an audit policy.

### Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial users can perform this operation.

### Syntax

```
DROP AUDIT POLICY [IF EXISTS] policy_name;
```

### Parameters

- **policy\_name**  
Specifies the audit policy name, which must be unique.  
Value range: a string. It must comply with the [naming convention](#).
- **IF EXISTS**  
Checks whether the audit policy exists. If yes, the deletion is successful. If no, a NOTICE message is sent.

### Examples

```
-- Create the adt1 policy.
gaussdb=# CREATE AUDIT POLICY adt1 PRIVILEGES CREATE;
CREATE AUDIT POLICY

-- Delete the audit policy adt1.
gaussdb=# DROP AUDIT POLICY adt1;
DROP AUDIT POLICY

-- When you delete the audit policy adt0 that does not exist, the system displays a message indicating that
the deletion fails because the audit policy does not exist.
gaussdb=# DROP AUDIT POLICY adt0;
ERROR: adt0 policy does not exist, drop failed
```

### Helpful Links

[CREATE AUDIT POLICY](#) and [ALTER AUDIT POLICY](#)

## 7.12.9.7 DROP CLIENT MASTER KEY

### Description

Deletes a CMK.

## Precautions

- Only the CMK owner or a user who has been granted the DROP permission can run this command. By default, the system administrator has this permission.
- This command can only be used to delete the metadata information recorded in the system catalog of the database, but cannot be used to delete the CMK file. You need to use KeyTool to delete the CMK file.

## Syntax

```
DROP CLIENT MASTER KEY [IF EXISTS] client_master_key_name [, ...] [CASCADE | RESTRICT];
```

## Parameters

- **IF EXISTS**  
If a specified CMK does not exist, a notice rather than an error is issued.
- **client\_master\_key\_name**  
Specifies the name of a CMK to be deleted.  
Value range: a string. It is the name of an existing CMK.
- **CASCADE | RESTRICT**  
Allows/Restricts to cascadingly delete objects that depend on the CMK.

## Helpful Links

[CREATE CLIENT MASTER KEY](#)

### 7.12.9.8 DROP COLUMN ENCRYPTION KEY

## Description

Deletes a column encryption key (CEK).

## Precautions

Only the CEK owner or a user who has been granted the DROP permission can run this command. System administrators have this permission by default.

## Syntax

```
DROP COLUMN ENCRYPTION KEY [IF EXISTS] client_column_key_name [, ...] [CASCADE | RESTRICT];
```

## Parameters

- **IF EXISTS**  
If a specified CEK does not exist, a notice rather than an error is issued.

- **client\_column\_key\_name**  
Name of a CEK to be deleted.  
Value range: a string. It is the name of an existing CEK.
- **CASCADE | RESTRICT**  
For fully-encrypted databases, this syntax is high-risk operation. Actually, encrypted columns that depend on CEKs cannot be deleted.

## Helpful Links

[ALTER COLUMN ENCRYPTION KEY](#) and [CREATE COLUMN ENCRYPTION KEY](#)

### 7.12.9.9 DROP DATABASE

#### Function

Deletes a database.

#### Precautions

- Only the database owner or a user granted with the DROP permission can run the **DROP DATABASE** command. The system administrator has this permission by default.
- The preinstalled POSTGRES, TEMPLATE0, and TEMPLATE1 databases are protected and therefore cannot be deleted. To check databases in the current service, run the gsql statement `\l`.
- If any users are connected to the database, the database cannot be deleted. You can view the DV\_SESSIONS view to check the database connections.
- **DROP DATABASE** cannot be executed within a transaction block.
- Before deleting a database, run the **CLEAN CONNECTION TO ALL FORCE FOR DATABASE XXXX** command to forcibly stop the existing user connections and backend threads, preventing database deletion failures caused by running backend threads. Forcibly stopping backend threads may cause data inconsistency in the current database. Therefore, execute this command only when you are sure to delete the database.
- If **DROP DATABASE** fails to be run and the transaction is rolled back, run **DROP DATABASE IF EXISTS** again.

---

#### NOTICE

DROP DATABASE cannot be undone.

---

#### Syntax

```
DROP DATABASE [IF EXISTS] database_name;
```

## Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified database does not exist.
- **database\_name**  
Specifies the name of the database to be deleted.  
Value range: an existing database name

## Examples

See [Examples](#) in section "CREATE DATABASE."

## Helpful Links

[CREATE DATABASE](#)

## Suggestions

- **DROP DATABASE**  
Do not delete databases during transactions.

### 7.12.9.10 DROP DATABASE LINK

## Description

Deletes database link objects.

## Syntax

```
DROP [PUBLIC] DATABASE LINK [IF EXISTS] dblink_name;
```

## Parameters

- **dblink\_name**  
Name of a connection object.
- **IF EXISTS**  
Reports a notice instead of an error if the specified **DATABASE LINK** does not exist.
- **PUBLIC**  
Specifies the connection type. If **PUBLIC** is not specified, the database link is private by default.

## Examples

```
-- Create an ORA-compatible database.
gaussdb=# CREATE DATABASE ora_test_db DBCOMPATIBILITY 'ORA';

-- Switch to another database.
gaussdb=# \c ora_test_db
```

```
-- Create a user with the system administrator permission.
ora_test_db=# CREATE USER user1 WITH SYSADMIN PASSWORD '*****';
ora_test_db=# SET ROLE user1 PASSWORD '*****';

-- Create a private database link.
ora_test_db=# CREATE DATABASE LINK private_dblink CONNECT TO 'user1' IDENTIFIED BY '*****' USING
(host '192.168.11.11',port '54399',dbname 'db01');

-- Delete the private database link.
ora_test_db=# DROP DATABASE LINK private_dblink;

-- Create a public database link.
ora_test_db=# CREATE PUBLIC DATABASE LINK public_dblink CONNECT TO 'user1' IDENTIFIED BY '*****'
USING (host '192.168.11.11',port '54399',dbname 'db01');

-- Delete the public database link.
ora_test_db=# DROP PUBLIC DATABASE LINK public_dblink;

-- Delete the created user.
ora_test_db=# RESET ROLE;
ora_test_db=# DROP USER user1;

-- Switch back to the initial database and delete the test database. Replace postgres with the actual
database name.
ora_test_db=# \c postgres
gaussdb=# DROP DATABASE ora_test_db;
```

## Helpful Links

[ALTER DATABASE LINK](#) and [CREATE DATABASE LINK](#)

### 7.12.9.11 DROP DIRECTORY

#### Function

Deletes a directory.

#### Precautions

- When **enable\_access\_server\_directory** is set to **off**, only the initial user is allowed to delete the directory object.
- When **enable\_access\_server\_directory** is set to **on**, a user with the SYSADMIN permission, a directory object owner, a user granted with the DROP permission for a directory, or a user inherited from the built-in role `gs_role_directory_drop` can delete a directory object.

#### Syntax

```
DROP DIRECTORY [IF EXISTS] directory_name;
```

#### Parameters

- **directory\_name**  
Specifies the name of the directory to be deleted.  
Value range: an existing directory name

- **IF EXISTS**  
Does not report an error if the specified directory object does not exist. A notice is issued in this case.

## Examples

```
-- Create a directory object.
gaussdb=# CREATE OR REPLACE DIRECTORY dir as '/tmp/';

-- Delete the directory object.
gaussdb=# DROP DIRECTORY dir;
```

## Helpful Links

[CREATE DIRECTORY](#) and [ALTER DIRECTORY](#)

### 7.12.9.12 DROP FOREIGN DATA WRAPPER

#### Description

Deletes a specified foreign data wrapper.

#### Precautions

The DROP statement can be successfully executed only when **support\_extended\_features** is set to **on**.

#### Syntax

```
DROP FOREIGN DATA WRAPPER [IF EXISTS] name [CASCADE | RESTRICT];
```

#### Parameters

- **IF EXISTS**  
Sends a notification instead of throwing an error if the foreign data wrapper does not exist.
- **name**  
Specifies the name of an existing foreign data wrapper.
- **CASCADE**  
Automatically drops objects (such as servers) that depend on the foreign data wrapper.
- **RESTRICT**  
If there are objects that depend on the foreign data wrapper, the foreign data wrapper cannot be deleted. This is the default behavior.

#### Example

```
-- Delete the foreign data wrapper dbi.
gaussdb=# DROP FOREIGN DATA WRAPPER dbi;
```

## Helpful Links

[CREATE FOREIGN DATA WRAPPER](#) and [ALTER FOREIGN DATA WRAPPER](#)

### 7.12.9.13 DROP FUNCTION

#### Description

Deletes a function.

#### Precautions

If a function involves operations on temporary tables, DROP FUNCTION cannot be used.

Only the function owner or a user granted with the DROP permission can run the **DROP FUNCTION** command. The system administrator has this permission by default.

#### Syntax

```
DROP FUNCTION [IF EXISTS] function_name
[([{ [argname] [argmode] argtype } [, ...]]) [CASCADE | RESTRICT]] ;
```

#### Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified function does not exist.
- **function\_name**  
Specifies the name of the function to be deleted.  
Value range: an existing function name
- **argmode**  
Specifies the parameter mode of the function.
- **argname**  
Specifies the parameter name of the function.
- **argtype**  
Specifies the parameter type of the function.
- **CASCADE | RESTRICT**
  - **CASCADE**: automatically deletes the objects that depend on the function.
  - **RESTRICT**: refuses to delete the function if any objects depend on it. This is the default action.

#### Examples

- Delete the list of parameters that can be omitted when a function.

```
-- Create a function.
gaussdb=# CREATE FUNCTION func_test(varchar) RETURN VARCHAR AS
BEGIN
 RETURN $1||'_test';
END;
/

-- Delete the function.
gaussdb=# DROP FUNCTION func_test;
```

- Delete a function with the same name.

If a function with the same name exists, add a parameter list when deleting the function. Otherwise, an error is reported.

```
-- Create a function.
gaussdb=# CREATE FUNCTION func_add(int) RETURNS int AS $$
BEGIN
 RETURN $1+10;
END;
$$ LANGUAGE PLPGSQL;

-- Reload the func_add function.
gaussdb=# CREATE FUNCTION func_add(int,int) RETURNS int AS $$
BEGIN
 RETURN $1+$2;
END;
$$ LANGUAGE PLPGSQL;

-- Delete the function.
gaussdb=# DROP FUNCTION func_add(int);
gaussdb=# DROP FUNCTION func_add(int,int);
```

## Helpful Links

[ALTER FUNCTION](#) and [CREATE FUNCTION](#)

### 7.12.9.14 DROP GLOBAL CONFIGURATION

#### Function

Deletes parameter values from the `gs_global_config` system catalog.

#### Precautions

- Only the initial database user can run this command.
- The parameter name cannot be **weak\_password** or **undostoragetype**.

#### Syntax

```
DROP GLOBAL CONFIGURATION name [, ...];
```

#### Parameter Description

- **name**  
The parameter must exist in the `gs_global_config` system catalog. If you delete a parameter that does not exist, an error will be reported.

## Examples

For details, see [Examples](#) in section "ALTER GLOBAL CONFIGURATION."

## Helpful Links

[ALTER GLOBAL CONFIGURATION](#)

### 7.12.9.15 DROP GROUP

#### Function

Deletes a user group. DROP GROUP is an alias for DROP ROLE.

#### Precautions

It is available only to users with the CREATE ROLE permission granted by the administrator.

#### Syntax

```
DROP GROUP [IF EXISTS] group_name [, ...];
```

#### Parameter Description

- **IF EXISTS**  
If a role does not exist, no error is reported. Instead, a notification is sent, indicating that the role does not exist.
- **group\_name**  
Specifies the name of the role to be deleted.  
Value range: an existing role name.

## Helpful Links

[CREATE GROUP](#), [ALTER GROUP](#), and [DROP ROLE](#)

### 7.12.9.16 DROP INDEX

#### Description

Deletes an index.

#### Precautions

Only the index owner, owner of the schema where the index resides, a user who has the INDEX permission on the table where the index resides, or a user who has the DROP ANY INDEX permission can run the **DROP INDEX** command. When

separation of duties is disabled, system administrators have this permission by default.

## Syntax

```
DROP INDEX [IF EXISTS]
index_name [, ...] [CASCADE | RESTRICT];
```

## Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified index does not exist.
- **index\_name**  
Specifies the name of the index to be deleted.  
Value range: an existing index
- **CASCADE | RESTRICT**
  - **CASCADE**: cascadingly deletes the objects that depend on the index.
  - **RESTRICT**: refuses to delete the index if any objects depend on it. This is the default action.

## Examples

```
-- Create a table.
gaussdb=# CREATE TABLE test1_index (id INT, name VARCHAR(20));

-- Create an index.
gaussdb=# CREATE INDEX idx_test1 (id);

-- Delete the index.
gaussdb=# DROP INDEX IF EXISTS idx_test1 CASCADE;

-- Delete the table.
gaussdb=# DROP TABLE test1_index;
```

## Helpful Links

[ALTER INDEX](#) and [CREATE INDEX](#)

### 7.12.9.17 DROP LANGUAGE

This version does not support this syntax.

### 7.12.9.18 DROP MASKING POLICY

## Description

Deletes a masking policy.

## Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.

## Syntax

```
DROP MASKING POLICY [IF EXISTS] policy_name;
```

## Parameters

- **policy\_name**  
Specifies the audit policy name, which must be unique.  
Value range: A string indicating an existing policy name.

## Examples

```
-- Create table tb_for_masking.
gaussdb=# CREATE TABLE tb_for_masking(idx int, col1 text, col2 text, col3 text, col4 text, col5 text, col6
text, col7 text,col8 text);

-- Insert data into the tb_for_masking table.
gaussdb=# INSERT INTO tb_for_masking VALUES(1, '9876543210', 'usr321usr', 'abc@huawei.com',
'abc@huawei.com', '1234-4567-7890-0123', 'abcdef 123456 ui 323 jsfd321 j3k2l3', '4880-9898-4545-2525',
'this is a llt case');

-- Create a resource label for sensitive column col1.
gaussdb=# CREATE RESOURCE LABEL mask_lb1 ADD COLUMN(tb_for_masking.col1);

-- Create a resource label for sensitive column col2.
gaussdb=# CREATE RESOURCE LABEL mask_lb2 ADD COLUMN(tb_for_masking.col2);

-- Create a resource label for sensitive column col3.
gaussdb=# CREATE RESOURCE LABEL mask_lb3 ADD COLUMN(tb_for_masking.col3);

-- Create a data masking policy named maskpol1.
gaussdb=# CREATE MASKING POLICY maskpol1 maskall ON LABEL(mask_lb1);

-- Create a data masking policy named maskpol2.
gaussdb=# CREATE MASKING POLICY maskpol2 randommasking ON LABEL(mask_lb2);

-- Create a data masking policy named maskpol3.
gaussdb=# CREATE MASKING POLICY maskpol3 basicemailmasking ON LABEL(mask_lb3);

-- Delete a masking policy.
gaussdb=# DROP MASKING POLICY IF EXISTS maskpol1;

-- Delete a group of masking policies.
gaussdb=# DROP MASKING POLICY IF EXISTS maskpol2, maskpol3;

-- Delete a resource label.
gaussdb=# DROP RESOURCE LABEL mask_lb1;
gaussdb=# DROP RESOURCE LABEL mask_lb2;
gaussdb=# DROP RESOURCE LABEL mask_lb3;

-- Delete the table.
gaussdb=# DROP TABLE tb_for_masking;
```

## Helpful Links

[ALTER MASKING POLICY](#) and [CREATE MASKING POLICY](#)

## 7.12.9.19 DROP MATERIALIZED VIEW

### Function

Deletes an existing materialized view from the database.

### Precautions

The owner of a materialized view, owner of the schema of the materialized view, users granted with the DROP permission on the materialized view, or users granted with the DROP ANY TABLE permission can run the **DROP MATERIALIZED VIEW** command. By default, the system administrator has the permission to run the command.

### Syntax

```
DROP MATERIALIZED VIEW [IF EXISTS] mv_name [, ...] [CASCADE | RESTRICT];
```

### Parameter Description

- **IF EXISTS**  
Reports a notice instead of an error if the specified materialized view does not exist.
- **mv\_name**  
Name of the materialized view to be deleted.
- **CASCADE | RESTRICT**
  - **CASCADE**: automatically deletes the objects that depend on a materialized view.
  - **RESTRICT**: refuses to delete a materialized view if any objects depend on it. This is the default value.

### Examples

```
-- Create a table.
gaussdb=# CREATE TABLE my_table (c1 int, c2 int)
WITH(STORAGE_TYPE=ASTORE);

-- Create a materialized view named my_mv.
gaussdb=# CREATE MATERIALIZED VIEW my_mv AS SELECT * FROM my_table;

-- Delete the materialized view named my_mv.
gaussdb=# DROP MATERIALIZED VIEW my_mv;

-- Delete the table.
gaussdb=# DROP TABLE my_table;
```

### Helpful Links

[ALTER MATERIALIZED VIEW](#), [CREATE INCREMENTAL MATERIALIZED VIEW](#), [CREATE MATERIALIZED VIEW](#), [CREATE TABLE](#), [REFRESH INCREMENTAL MATERIALIZED VIEW](#), and [REFRESH MATERIALIZED VIEW](#)

### 7.12.9.20 DROP MODEL

This syntax is not supported in distributed scenarios.

→ DROP → MODEL → model\_name → ; →

### 7.12.9.21 DROP NODE

#### Function

Deletes a node.

#### Precautions

**DROP NODE** is an interface of the cluster management tool. You are not advised to use this interface, because doing so affects the cluster. Only the administrator has the permission to use this interface.

#### Syntax

```
DROP NODE [IF EXISTS] nodename [WITH (cnnodename [, ...])];
```

#### Parameter Description

- **IF EXISTS**  
Reports a notice instead of an error if the specified node does not exist.
- **nodename**  
Specifies the name of the node to be deleted.  
Value range: an existing node name
- **cnnodename**  
Specifies the CN name. If this parameter is defined, the command will be executed on this node in addition to the current connected CN. If it is not specified, DN deletion must be performed on all CNs, and CN deletion must be performed on all CNs except the CN to be deleted.  
Value range: an existing CN name

#### Examples

See [Examples](#) in **CREATE NODE**.

#### Helpful Links

- [CREATE NODE](#)
- [ALTER NODE](#)

### 7.12.9.22 DROP NODE GROUP

#### Description

Deletes a node group.

## Precautions

- DROP NODE GROUP is an interface of the cluster management tool.
- Only the system administrator or a user who has the DROP permission can perform this operation.

## Syntax

```
DROP NODE GROUP groupname
[TO ELASTIC GROUP];
```

## Parameters

### groupname

Specifies the name of the node group to be deleted.

Value range: an existing node group name

## Examples

For details, see [Examples](#) in section "CREATE NODE GROUP."

## Helpful Links

[ALTER NODE GROUP](#) and [CREATE NODE GROUP](#)

## 7.12.9.23 DROP OWNED

### Function

Deletes the database objects owned by a database role.

### Precautions

- This interface will revoke the role's permissions on all objects in the current database and shared objects (databases and tablespaces).
- DROP OWNED is often used to prepare for removing one or more roles. Because DROP OWNED affects only the objects in the current database, you need to run this statement in each database that contains the objects owned by the role to be removed.
- Using the **CASCADE** option may cause this statement to recursively remove objects owned by other users.
- The databases and tablespaces owned by the role will not be removed.
- Private database links owned by a role can be deleted only after the **CASCADE** option is added.

### Syntax

```
DROP OWNED BY name [, ...] [CASCADE | RESTRICT];
```

## Parameter Description

- **name**  
Specifies the role name.
- **CASCADE | RESTRICT**
  - **CASCADE**: automatically deletes the objects that depend on the objects to be deleted.
  - **RESTRICT** (default): refuses to delete the object if any objects depend on it.

## Examples

```
-- Create user jim.
gaussdb=# CREATE USER jim PASSWORD '*****';

-- Revoke user jim's permissions on all objects in the current database and on shared objects (databases
and tablespaces).
gaussdb=# DROP OWNED BY jim;

-- Delete user jim.
gaussdb=# DROP USER jim;
```

## Helpful Links

[REASSIGN OWNED](#)

### 7.12.9.24 DROP PROCEDURE

## Function

Deletes a stored procedure.

## Syntax

```
DROP PROCEDURE [IF EXISTS] procedure_name;
```

## Parameter Description

- **IF EXISTS**  
Reports a notice instead of an error if the specified stored procedure does not exist.
- **procedure\_name**  
Specifies the name of the stored procedure to be deleted.  
Value range: an existing stored procedure name

## Examples

See [Examples](#) in section "CREATE PROCEDURE."

## Helpful Links

[CREATE PROCEDURE](#)

### 7.12.9.25 DROP RESOURCE LABEL

#### Description

DROP RESOURCE LABEL is used to delete a resource label.

#### Precautions

Only users with the POLADMIN or SYSADMIN permission, or the initial user can perform this operation.

#### Syntax

```
DROP RESOURCE LABEL [IF EXISTS] label_name[, ...];
```

#### Parameters

- **label\_name**  
Specifies the resource label name.  
Value range: a string. It must comply with the [naming convention](#).

#### Examples

```
-- Create table tb_for_label.
gaussdb=# CREATE TABLE tb_for_label(col1 text, col2 text, col3 text);

-- Create a resource label based on a table.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS table_label add TABLE(public.tb_for_label);

-- Create an existing table resource label again and compare the differences between adding IF NOT EXISTS
and not adding IF NOT EXISTS.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS table_label add TABLE(public.tb_for_label);
NOTICE: table_label label already defined, skipping
CREATE RESOURCE LABEL
gaussdb=# CREATE RESOURCE LABEL table_label add TABLE(public.tb_for_label);
ERROR: table_label label already defined

-- Create a resource label based on columns.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS column_label add COLUMN(public.tb_for_label.col1);

-- Create schema schema_for_label.
gaussdb=# CREATE SCHEMA schema_for_label;

-- Create a resource label based on a schema.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS schema_label add SCHEMA(schema_for_label);

-- Create view view_for_label.
gaussdb=# CREATE VIEW view_for_label AS SELECT 1;

-- Create a resource label based on a view.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS view_label add VIEW(view_for_label);
```

```
-- Create function func_for_label.
gaussdb=# CREATE FUNCTION func_for_label RETURNS TEXT AS $$ SELECT col1 FROM tb_for_label; $$
LANGUAGE SQL;

-- Create a resource label based on a function.
gaussdb=# CREATE RESOURCE LABEL IF NOT EXISTS func_label add FUNCTION(func_for_label);

-- Delete the table resource label table_label.
gaussdb=# DROP RESOURCE LABEL IF EXISTS table_label;

-- Delete the column resource label column_label.
gaussdb=# DROP RESOURCE LABEL IF EXISTS column_label;

-- Delete the function resource label func_for_label.
gaussdb=# DROP FUNCTION func_for_label;

-- Delete the view resource label view_for_label.
gaussdb=# DROP VIEW view_for_label;

-- Delete the schema resource label schema_for_label.
gaussdb=# DROP SCHEMA schema_for_label;

-- Delete the tb_for_label table.
gaussdb=# DROP TABLE tb_for_label;
```

## Helpful Links

[ALTER RESOURCE LABEL](#) and [CREATE RESOURCE LABEL](#)

### 7.12.9.26 DROP RESOURCE POOL

#### Description

Deletes a resource pool.

#### NOTE

The resource pool cannot be deleted if it is associated with a role.

#### Precautions

Only users with the SYSADMIN permission, or the initial user can perform this operation.

#### Syntax

```
DROP RESOURCE POOL [IF EXISTS] pool_name;
```

#### Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified resource pool does not exist.
- **pool\_name**  
Specifies the name of the resource pool to be deleted.

Value range: a string. It must comply with the [naming convention](#).

 **NOTE**

In a multi-tenant scenario, deleting a group resource pool also deletes the related service resource pools. A resource pool can be deleted only when it is not associated with any users.

## Examples

See [Examples](#) in section "CREATE RESOURCE POOL."

## Helpful Links

[7.13.6.25-ALTER RESOURCE POOL](#) and [7.13.8.37-CREATE RESOURCE POOL](#)

## 7.12.9.27 DROP ROLE

### Function

Deletes a role.

### Syntax

```
DROP ROLE [IF EXISTS] role_name [, ...];
```

### Parameter Description

- **IF EXISTS**  
Reports a notice instead of an error if the specified role does not exist.
- **role\_name**  
Specifies the name of the role to be deleted.  
Value range: an existing role name

## Examples

See [Examples](#) in section "CREATE ROLE."

## Helpful Links

[CREATE ROLE](#), [ALTER ROLE](#), and [SET ROLE](#)

## 7.12.9.28 DROP ROW LEVEL SECURITY POLICY

### Function

Deletes a row-level security policy from a table.

## Precautions

Only the table owner or administrators can delete a row-level security policy from the table.

## Syntax

```
DROP [ROW LEVEL SECURITY] POLICY [IF EXISTS] policy_name ON table_name [CASCADE | RESTRICT];
```

## Parameter Description

- **IF EXISTS**  
Reports a notice instead of an error if the specified row-level security policy does not exist.
- **policy\_name**  
Specifies the name of the row-level security policy to be deleted.
- **table\_name**  
Specifies the name of the table containing the row-level security policy.
- **CASCADE | RESTRICT**  
Currently, no objects depend on row-level security policies. Therefore, **CASCADE** is equivalent to **RESTRICT**, and they are reserved to ensure backward compatibility.

## Examples

```
-- Create the data table all_data.
gaussdb=# CREATE TABLE all_data(id int, role varchar(100), data varchar(100));

-- Create a row-level security policy.
gaussdb=# CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role = CURRENT_USER);

-- Delete the row-level security policy.
gaussdb=# DROP ROW LEVEL SECURITY POLICY all_data_rls ON all_data;

-- Delete the all_data table.
gaussdb=# DROP TABLE all_data;
```

## Helpful Links

[ALTER ROW LEVEL SECURITY POLICY](#) and [CREATE ROW LEVEL SECURITY POLICY](#)

### 7.12.9.29 DROP SCHEMA

#### Description

Deletes a schema from the current database.

#### Precautions

- Only the owner of a schema or a user granted the DROP permission for a schema has the permission to run the **DROP SCHEMA** command. If

separation of duties is disabled, the system administrator has this permission by default.

- Users except the initial user and O&M administrator cannot drop the schema of the O&M administrator.
- You are not allowed to delete DBE\_PLDEVELOPER when **allow\_system\_table\_mods** is disabled.

## Syntax

```
DROP SCHEMA [IF EXISTS] schema_name [, ...] [CASCADE | RESTRICT];
```

## Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified schema does not exist.
- **schema\_name**  
Specifies the schema name.  
Value range: an existing schema name
- **CASCADE | RESTRICT**
  - **CASCADE**: automatically deletes all the objects contained in the schema.
  - **RESTRICT**: refuses to delete the schema if the schema contains objects. This is the default action.

### NOTICE

Schemas beginning with **pg\_temp** or **pg\_toast\_temp** are for internal use. Do not delete them. Otherwise, unexpected consequences may be incurred.

### NOTE

The schema currently being used cannot be deleted. To delete it, switch to another schema first.

## Examples

See [Examples](#) in section "CREATE SCHEMA."

## Helpful Links

[ALTER SCHEMA](#) and [CREATE SCHEMA](#)

### 7.12.9.30 DROP SECURITY LABEL

## Description

`DROP SECURITY LABEL` is used to delete security labels from the current database.

## Precautions

An initial user, a user with the SYSADMIN permission, or a user who inherits the gs\_role\_seclabel permission of the built-in role can delete security labels.

## Syntax

```
DROP SECURITY LABEL label_name;
```

## Parameters

- **label\_name**  
Security label name. The security label to be deleted must exist in the database.

## Examples

```
-- Create a security label sec_label.
gaussdb=# CREATE SECURITY LABEL sec_label 'L1:G4';

-- Delete the security label sec_label2 that does not exist.
gaussdb=# DROP SECURITY LABEL sec_label2;
ERROR: security label "sec_label2" does not exist

-- Delete the existing security label sec_label.
gaussdb=# DROP SECURITY LABEL sec_label;
```

## Helpful Links

[CREATE SECURITY LABEL](#) and [SECURITY LABEL ON](#)

### 7.12.9.31 DROP SEQUENCE

## Description

Deletes a sequence from the current database.

## Precautions

Only the owner of a sequence, the owner of the schema to which the sequence belongs, or a user granted the DROP permission on a sequence or a user granted the DROP ANY SEQUENCE permission can delete a sequence. When separation of duties is disabled, a system administrator has this permission by default.

## Syntax

```
DROP SEQUENCE [IF EXISTS] { [schema.] sequence_name } [, ...] [CASCADE | RESTRICT];
```

## Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified sequence does not exist.

- **sequence\_name**  
Specifies the name of the sequence to be deleted.
- **CASCADE**  
Cascadingly deletes the objects that depend on the sequence.
- **RESTRICT**  
Refuses to delete the sequence if any objects depend on it. This is the default action.

## Examples

```
-- Create an ascending sequence named serial, starting from 101.
gaussdb=# CREATE SEQUENCE serial START 101;

-- Delete a sequence.
gaussdb=# DROP SEQUENCE serial;
```

## Helpful Links

[ALTER SEQUENCE](#) and [DROP SEQUENCE](#)

### 7.12.9.32 DROP SERVER

#### Description

Deletes an existing data server.

#### Precautions

Only the server owner or a user granted with the DROP permission can run the **DROP SERVER** command. A system administrator has this permission by default.

#### Syntax

```
DROP SERVER [IF EXISTS] server_name [CASCADE | RESTRICT];
```

#### Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified data server does not exist.
- **server\_name**  
Specifies the name of the data server to be deleted.
- **CASCADE | RESTRICT**
  - **CASCADE**: cascadingly deletes the objects that depend on the data server.
  - **RESTRICT**: refuses to delete the server if any objects depend on it. This is the default action.

## Example

```
-- Create a server.
gaussdb=# CREATE SERVER my_server FOREIGN DATA WRAPPER log_fdw;
CREATE SERVER

-- Delete the server.
gaussdb=# DROP SERVER my_server;
DROP SERVER
```

## Helpful Links

[ALTER SERVER](#) and [CREATE SERVER](#)

### 7.12.9.33 DROP SYNONYM

## Description

Deletes a synonym.

## Precautions

Only the synonym owner or a user granted with the DROP ANY SYNONYM permission can run the **DROP SYNONYM** command. System administrators have this permission by default.

## Syntax

```
DROP [PUBLIC] SYNONYM [IF EXISTS] synonym_name [CASCADE | RESTRICT];
```

## Parameters

- **PUBLIC**  
(Optional) Deletes PUBLIC synonyms.
- **IF EXISTS**  
Reports a notice instead of an error if the specified synonym does not exist.
- **synonym\_name**  
Specifies the name (optionally schema-qualified) of the synonym to be deleted.
- **CASCADE | RESTRICT**
  - **CASCADE**: automatically deletes the objects (such as views) that depend on the synonym.
  - **RESTRICT**: refuses to delete the synonym if any objects depend on it. This is the default action.

## Examples

See [Examples](#) in section "CREATE SYNONYM."

## Helpful Links

[ALTER SYNONYM](#) and [CREATE SYNONYM](#)

### 7.12.9.34 DROP TABLE

#### Description

Deletes a table.

#### Precautions

- After DROP TABLE deletes the table, the indexes depending on the table are deleted, and the functions and stored procedures that need to use this table cannot be executed. Deleting a partitioned table also deletes all partitions in the table.
- The owner of a table, the owner of the schema of the table, users granted with the DROP permission on the table, or users granted with the DROP ANY TABLE permission can delete the specified table. When separation of duties is disabled, system administrators have this permission by default.

#### Syntax

```
DROP TABLE [IF EXISTS]
{ [schema.]table_name } [, ...] [CASCADE | RESTRICT] [PURGE];
```

#### Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified table does not exist.
- **schema**  
Specifies the schema name.
- **table\_name**  
Specifies the table name.
- **CASCADE | RESTRICT**
  - **CASCADE**: allows to cascadingly delete the objects (such as views) that depend on the table.
  - **RESTRICT**: refuses to delete the table if any objects depend on it. This is the default action.
- **PURGE**  
Specifies that even if the recycle bin function is enabled, the table is physically dropped instead of being moved to the recycle bin when you use DROP TABLE to delete tables.

#### Examples

```
-- Create the test table.
gaussdb=# CREATE TABLE test(c1 int, c2 int);
-- Drop the test table.
gaussdb=# DROP TABLE IF EXISTS test;

-- Create the test1 table.
gaussdb=# CREATE TABLE test1(c1 int, c2 int);
```

```
-- Create the v_test1 view.
gaussdb=# CREATE VIEW v_test1 AS SELECT * FROM test1 WHERE c1 < 20;
-- An error is reported when the table is deleted.
gaussdb=# DROP TABLE test1;
ERROR: cannot drop table test1 because other objects depend on it
DETAIL: view v_test1 depends on table test1
HINT: Use DROP ... CASCADE to drop the dependent objects too.

-- Use the CASCADE parameter to drop the test1 table, which will automatically delete the views.
gaussdb=# DROP TABLE test1 CASCADE;
NOTICE: drop cascades to view v_test1
DROP TABLE
```

## Helpful Links

[ALTER TABLE](#) and [CREATE TABLE](#)

### 7.12.9.35 DROP TABLESPACE

#### Function

Deletes a tablespace.

#### Precautions

- Only the tablespace owner or a user granted with the DROP permission can run the **DROP TABLESPACE** command. The system administrator has this permission by default.
- The tablespace to be deleted should not contain any database objects. Otherwise, an error will be reported.
- DROP TABLESPACE cannot be rolled back and therefore cannot be run in transaction blocks.
- During execution of DROP TABLESPACE, database queries by other sessions using **\db** may fail and need to be reattempted.
- If DROP TABLESPACE fails to be executed, execute DROP TABLESPACE IF EXISTS.

#### Syntax

```
DROP TABLESPACE [IF EXISTS] tablespace_name;
```

#### Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified tablespace does not exist.
- **tablespace\_name**  
Specifies the name of the tablespace to be deleted.  
Value range: an existing tablespace name

#### Examples

See [Examples](#) in section "CREATE TABLESPACE."

## Helpful Links

[ALTER TABLESPACE](#) and [CREATE TABLESPACE](#)

## Suggestions

Do not delete tablespaces during transactions using DROP TABLESPACE.

### 7.12.9.36 DROP TRIGGER

## Description

DROP TRIGGER is used to delete a trigger.

## Precautions

Only the trigger owner or a user granted with the DROP ANY TRIGGER permission can run the **DROP TRIGGER** command. System administrators have this permission by default.

## Syntax

```
DROP TRIGGER [IF EXISTS] name ON table_name [CASCADE | RESTRICT];
```

## Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified trigger does not exist.
- **trigger\_name**  
Specifies the name of the trigger to be deleted.  
Value range: an existing trigger name
- **table\_name**  
Specifies the name of the table containing the trigger.  
Value range: name of the table containing the trigger
- **CASCADE | RESTRICT**
  - **CASCADE**: automatically deletes the objects that depend on the trigger.
  - **RESTRICT**: refuses to delete the trigger if any objects depend on it. This is the default action.

## Examples

```
-- Create a source table and a destination table.
gaussdb=# CREATE TABLE test_trigger_src_tbl(id1 INT, id2 INT, id3 INT);
gaussdb=# CREATE TABLE test_trigger_des_tbl(id1 INT, id2 INT, id3 INT);
```

Using the INSERT trigger

```
-- Create an INSERT trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION tri_insert_func() RETURNS TRIGGER AS
```

```
$$
DECLARE
BEGIN
 INSERT INTO test_trigger_des_tbl VALUES(NEW.id1, NEW.id2, NEW.id3);
 RETURN NEW;
END
$$ LANGUAGE plpgsql;

-- Create an INSERT trigger.
gaussdb=# CREATE TRIGGER insert_trigger
 BEFORE INSERT ON test_trigger_src_tbl
 FOR EACH ROW
 EXECUTE PROCEDURE tri_insert_func();

-- Execute the INSERT event and check the trigger results.
gaussdb=# INSERT INTO test_trigger_src_tbl VALUES(100,200,300);

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 300
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 300
(1 row)
```

### Using the UPDATE trigger

```
-- Create an UPDATE trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION tri_update_func() RETURNS TRIGGER AS
$$
DECLARE
BEGIN
UPDATE test_trigger_des_tbl SET id3 = NEW.id3 WHERE id1=OLD.id1;
RETURN OLD;
END
$$ LANGUAGE plpgsql;

-- Create an UPDATE trigger.
gaussdb=# CREATE TRIGGER update_trigger
 AFTER UPDATE ON test_trigger_src_tbl
 FOR EACH ROW
 EXECUTE PROCEDURE tri_update_func();

-- Execute the UPDATE event and check the trigger results.
gaussdb=# UPDATE test_trigger_src_tbl SET id3=400 WHERE id1=100;

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 400
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 400
(1 row)
```

### Using the DELETE trigger

```
-- Create a DELETE trigger function.
gaussdb=# CREATE OR REPLACE FUNCTION TRI_DELETE_FUNC() RETURNS TRIGGER AS
$$
DECLARE
BEGIN
DELETE FROM test_trigger_des_tbl WHERE id1=OLD.id1;
```

```
 RETURN OLD;
 END
 $$ LANGUAGE plpgsql;

-- Create a DELETE trigger.
gaussdb=# CREATE TRIGGER delete_trigger BEFORE DELETE ON test_trigger_src_tbl FOR EACH ROW
EXECUTE PROCEDURE tri_delete_func();

-- Execute the DELETE event and check the trigger results.
gaussdb=# DELETE FROM test_trigger_src_tbl WHERE id1=100;

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
(0 rows)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // Check whether the trigger operation takes effect.
 id1 | id2 | id3
-----+-----+-----
(0 rows)
```

### Renaming a trigger

```
-- Rename a trigger.
gaussdb=# ALTER TRIGGER delete_trigger ON test_trigger_src_tbl RENAME TO delete_trigger_renamed;
```

### Disabling a trigger

```
-- Disable insert_trigger.
gaussdb=# ALTER TABLE test_trigger_src_tbl DISABLE TRIGGER insert_trigger;

gaussdb=# INSERT INTO test_trigger_src_tbl VALUES(100,200,300);

gaussdb=# SELECT * FROM test_trigger_src_tbl;
 id1 | id2 | id3
-----+-----+-----
 100 | 200 | 300
(1 row)

gaussdb=# SELECT * FROM test_trigger_des_tbl; // View that the trigger does not take effect.
 id1 | id2 | id3
-----+-----+-----
(0 rows)

-- Disable all triggers on the current table.
gaussdb=# ALTER TABLE test_trigger_src_tbl DISABLE TRIGGER ALL;
```

### Deleting a trigger

```
gaussdb=# DROP TRIGGER insert_trigger ON test_trigger_src_tbl;

gaussdb=# DROP TRIGGER update_trigger ON test_trigger_src_tbl;

gaussdb=# DROP TRIGGER delete_trigger_renamed ON test_trigger_src_tbl;
```

### Deleting a function

```
gaussdb=# DROP FUNCTION tri_insert_func;

gaussdb=# DROP FUNCTION tri_update_func;

gaussdb=# DROP FUNCTION tri_delete_func;
-- Delete the source table and destination table.
gaussdb=# DROP TABLE test_trigger_src_tbl;
gaussdb=# DROP TABLE test_trigger_des_tbl;
```

## Helpful Links

[CREATE TRIGGER](#), [ALTER TRIGGER](#), and [ALTER TABLE](#)

### 7.12.9.37 DROP TYPE

#### Description

Deletes a user-defined data type.

#### Precautions

Only the owner of a type, a user granted the DROP permission on a type, or a user granted the DROP ANY TYPE permission on a sequence can run the **DROP TYPE** command. When separation of duties is disabled, a system administrator has this permission by default.

#### Syntax

```
DROP TYPE [IF EXISTS] name [, ...] [CASCADE | RESTRICT] ;
```

#### Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified type does not exist.
- **name**  
Specifies the name (optionally schema-qualified) of the type to be deleted.
- **CASCADE**  
Automatically deletes the objects (such as columns, functions, and operators) that depend on the type.
- **RESTRICT**  
Refuses to delete the type if any objects depend on it. This is the default action.

#### Examples

See [Examples](#) in section "CREATE TYPE."

#### Helpful Links

[CREATE TYPE](#) and [ALTER TYPE](#)

### 7.12.9.38 DROP USER

#### Description

DROP USER deletes users in GaussDB. This permission can be executed only when you have the permission to create users. After the command for deleting a user is executed successfully, the schema with the same name is deleted.

## Precautions

- **CASCADE** is used to cascadingly delete the objects (excluding databases) that depend on the user. It cannot delete locked objects unless the objects are unlocked or the threads locking the objects are terminated.
- If the dependent objects are other databases or reside in other databases, manually delete them before deleting the user from the current database. **DROP USER** cannot delete objects across databases.
- Before deleting a user, you need to delete all the objects owned by the user and revoke the user's permissions on other objects. Alternatively, you can specify **CASCADE** to delete the objects owned by the user and the granted permissions.
- In a multi-tenant scenario, the service user will also be deleted when you delete a user group. If you want to use **CASCADE**, set **CASCADE** for the service user as well. If any error is reported for one user, other users cannot be deleted either.
- If the user has an error table specified when the GDS foreign table is created, the user cannot be deleted by specifying the **CASCADE** keyword in the **DROP USER** statement.

## Syntax

```
DROP USER [IF EXISTS] user_name [, ...] [CASCADE | RESTRICT];
```

## Parameters

- **IF EXISTS**  
When this parameter is used, if the specified user does not exist, a notice instead of an error is sent. Therefore, this parameter can be used to avoid errors.
- **user\_name**  
Specifies the name of the user to be deleted.  
Value range: an existing username in the database.
- **CASCADE | RESTRICT**
  - **CASCADE**: automatically deletes objects that depend on the user and revokes the permissions granted to the user.
  - **RESTRICT**: refuses to delete the user if any objects depend on it. This is the default action.

### NOTE

In GaussDB, the **enable\_kill\_query** configuration parameter exists in the **gaussdb.conf** file. This parameter affects **CASCADE**.

- If **enable\_kill\_query** is **on** and **CASCADE** is used, the statement automatically kills the threads locking dependent objects and then deletes the specified user.
- If **enable\_kill\_query** is **off** and **CASCADE** is used, the statement waits until the threads locking dependent objects end and then deletes the specified user.

## Examples

```
-- Create user jim whose login password is *****.
gaussdb=# CREATE USER jim PASSWORD '*****';

-- Create user kim whose login password is *****.
gaussdb=# CREATE USER kim IDENTIFIED BY '*****';

-- Create user tom.
gaussdb=# CREATE USER TOM PASSWORD '*****';

-- Create user TOM.
gaussdb=# CREATE USER "TOM" PASSWORD '*****';

-- To create a user with the CREATEDB permission, add the CREATEDB keyword.
gaussdb=# CREATE USER dim CREATEDB PASSWORD '*****';

-- Query the permissions of the dim user.
gaussdb=# \du dim
List of roles
Role name | Attributes | Member of
-----+-----+-----
dim | Create DB | {}
(You can see that the dim user has the CREATEDB permission.)

-- Change the password of user jim.
gaussdb=# ALTER USER jim IDENTIFIED BY '*****' REPLACE '*****';

-- Add the CREATEROLE permission to jim.
gaussdb=# ALTER USER jim CREATEROLE;

-- View the CREATEROLE permission added to user jim.
gaussdb=# \du jim
List of roles
Role name | Attributes | Member of
-----+-----+-----
jim | Create role | {}

-- Lock jim.
gaussdb=# ALTER USER jim ACCOUNT LOCK;

-- Unlock jim.
gaussdb=# ALTER USER jim ACCOUNT UNLOCK;

-- Change the user password.
gaussdb=# ALTER USER dim WITH PASSWORD '*****';

-- Change the username.
gaussdb=# ALTER USER dim RENAME TO lisa;

-- Delete the user.
gaussdb=# DROP USER kim CASCADE;
gaussdb=# DROP USER jim CASCADE;
gaussdb=# DROP USER lisa CASCADE;
gaussdb=# DROP USER TOM CASCADE;
gaussdb=# DROP USER "TOM" CASCADE;
```

## Helpful Links

[ALTER USER](#) and [CREATE USER](#)

### 7.12.9.39 DROP VIEW

## Function

DROP VIEW deletes a view from a database.

## Precautions

The owner of a view, owner of the schema of the view, users granted with the DROP permission on the view, or users granted with the DROP ANY TABLE permission can run the **DROP VIEW** command. When separation of duties is disabled, system administrators have this permission by default.

## Syntax

```
DROP VIEW [IF EXISTS] view_name [...] [CASCADE | RESTRICT];
```

## Parameters

- **IF EXISTS**  
Reports a notice instead of an error if the specified view does not exist.
- **view\_name**  
Specifies the name of the view to be deleted.  
Value range: an existing view name
- **CASCADE | RESTRICT**
  - **CASCADE**: cascadingly deletes the objects (such as other views) that depend on the view.
  - **RESTRICT**: refuses to delete the view if any objects depend on it. This is the default action.

## Examples

See [Examples](#) in **CREATE VIEW**.

## Helpful Links

[ALTER VIEW](#) and [CREATE VIEW](#)

### 7.12.9.40 DROP WEAK PASSWORD DICTIONARY

## Description

DROP WEAK PASSWORD DICTIONARY is used to clear the weak password dictionary. You can run this statement to clear all weak passwords in the gs\_global\_config system catalog.

## Precautions

Only the initial user, system administrators, and security administrators have the permission to execute this syntax.

## Syntax

```
DROP WEAK PASSWORD DICTIONARY;
```

## Examples

```
-- Insert a single weak password into the gs_global_config system catalog.
gaussdb=# CREATE WEAK PASSWORD DICTIONARY WITH VALUES ('*****');

-- Check weak passwords in the gs_global_config system catalog.
gaussdb=# SELECT * FROM gs_global_config WHERE NAME LIKE 'weak_password';
 name | value
-----+-----
weak_password | *****
(1 rows)

-- Clear all weak passwords in the gs_global_config system catalog.
gaussdb=# DROP WEAK PASSWORD DICTIONARY;

-- View existing weak passwords.
gaussdb=# SELECT * FROM gs_global_config WHERE NAME LIKE 'weak_password';
 name | value
-----+-----
(0 rows)
```

## Helpful Links

[13.14.82-CREATE WEAK PASSWORD DICTIONARY](#)

## 7.12.10 E

### 7.12.10.1 EXECUTE

#### Description

Executes a prepared statement. Because a prepared statement exists only in the lifetime of the session, the prepared statement must be created earlier in the current session by using the PREPARE statement.

#### Precautions

If the PREPARE statement declares some parameters when the prepared statement is created, the parameter set passed to the EXECUTE statement must be compatible. Otherwise, an error occurs.

#### Syntax

```
EXECUTE name [(parameter [, ...])] ;
```

#### Parameters

- **name**  
Specifies the name of the prepared statement to be executed.

- **parameter**

Specifies a parameter of the prepared statement. It must be an expression that generates a value compatible with the data type of the parameter specified when the prepared statement was created. **ROWNUM** cannot be used as a parameter.

## Examples

```
-- Create the reason table.
gaussdb=# CREATE TABLE reason (
 CD_DEMO_SK int NOT NULL,
 CD_GENDER varchar(10),
 CD_MARITAL_STATUS varchar(10)
);

-- Create a prepared statement for an INSERT statement and execute the prepared statement.
gaussdb=# PREPARE insert_reason(int,varchar(10),varchar(10)) AS INSERT INTO reason VALUES($1,$2,$3);
gaussdb=# EXECUTE insert_reason(52, 'AAAAAAAADD', 'reason 52');

-- Query data.
gaussdb=# SELECT * FROM reason;
 cd_demo_sk | cd_gender | cd_marital_status
-----+-----+-----
 52 | AAAAAAAD | reason 52
(1 row)

-- Delete the reason table.
gaussdb=# DROP TABLE reason;
```

## Helpful Links

[7.13.16.2-PREPARE](#) and [DEALLOCATE](#)

## 7.12.10.2 EXECUTE DIRECT

### Description

Executes an SQL statement on a specified node. Generally, the cluster automatically allocates an SQL statement to proper nodes. EXECUTE DIRECT is mainly used for database maintenance and testing.

### Precautions

- When **enable\_nonsysadmin\_execute\_direct** is **off**, only a system administrator has the EXECUTE DIRECT permission.
- To ensure data consistency across nodes, only the SELECT statement can be used. Transaction statements, DDL, and DML cannot be used.
- When the stddev aggregation calculation is performed on the specified DN using such statements, the result set is returned in triplet. For example, {3, 8, 30} indicates that the count result is 3, the sum result is 8, and the sum of squares is 30. When the AVG aggregation calculation is performed on the specified DN using such statements, the result set is returned in a binary tuple, for example, {4,2}. The result of count is 4, and that of sum is 2.
- When multiple nodes are specified, aggregate functions are not supported. If the query contains an aggregate function, the message "EXECUTE DIRECT on multinode not support agg functions." is returned.

- CN nodes do not store user table data. Therefore, do not execute SELECT for querying user tables on a CN.
- If the SQL statement to be executed is also EXECUTE DIRECT, do not nest it into EXECUTE DIRECT; instead, directly execute the inner EXECUTE DIRECT.
- The query result of the **agg** function is inconsistent with that on the CN. Multiple pieces of information are returned. The **array\_avg** function is not supported.
- If the **nodeoid** or **nodeoid list** parameter is specified, this parameter takes effect only when the **enable\_direct\_standby\_datanodes** parameter is successfully set in distributed mode. To query data on a specified DN, invalid or duplicate **nodeoid** values are not supported, and **nodeoid** and **nodename** cannot be used together.

## Syntax

```
EXECUTE DIRECT ON (nodename [, ...]) query ;
EXECUTE DIRECT ON (nodeoid [, ...]) query;
EXECUTE DIRECT ON { COORDINATORS | DATANODES | ALL } query;
```

## Parameters

- **nodename**  
Node name.  
Value range: an existing node name
- **nodeoid**  
Node OID.  
Value range: an existing DN OID, which can be obtained from the **PGXC\_NODE** system catalog.
- **query**  
Specifies the SQL statement to be executed.
- **COORDINATORS**  
Runs the query statement on all CNs.
- **DATANODES**  
Runs the query statement on all DNs.
- **ALL**  
Runs the query statement on all CNs and DNs.

## Examples

```
-- Query the name of the current node in the cluster.
gaussdb=# SELECT node_name,oid FROM pgxc_node WHERE node_type IN ('C','D') ORDER BY 1;
 node_name | oid
-----+-----
cn_5001 | 15517
cn_5002 | 16387
cn_5003 | 16391
dn_6001_6002_6003 | 16384
dn_6004_6005_6006 | 16388
dn_6007_6008_6009 | 16392
(6 rows)

-- Create a range-distributed table and insert data into the table.
```

```
gaussdb=# CREATE TABLE tbl_range(
 id INT,
 name VARCHAR(20),
 province VARCHAR(60), -- Province
 country VARCHAR(30) DEFAULT 'China' -- Country
)DISTRIBUTE BY RANGE(id)(
 SLICE s1 VALUES LESS THAN (100) DATANODE dn_6001_6002_6003,
 SLICE s2 VALUES LESS THAN (200) DATANODE dn_6004_6005_6006,
 SLICE s3 VALUES LESS THAN (MAXVALUE) DATANODE dn_6007_6008_6009
);
gaussdb=# INSERT INTO tbl_range VALUES (52,'Bob','Beijing','China'),
 (100,'Ben','Shanghai','China'),
 (150,'Scott','Guangzhou','China'),
 (300,'Jordan','Beijing','China');

-- Query the table data distributed on the dn_6007_6008_6009 node.
gaussdb=# EXECUTE DIRECT ON(dn_6007_6008_6009) 'SELECT * FROM tbl_range';
 id | name | province | country
-----+-----+-----+-----
 300 | Jordan | Beijing | China
(1 row)

-- Delete the tbl_range table.
gaussdb=# DROP TABLE tbl_range;
```

### 7.12.10.3 EXPDP DATABASE

#### Function

**EXPDP DATABASE** exports all physical files in a database.

#### Syntax

```
EXPDP DATABASE db_name LOCATION = 'directory';
```

#### Parameter Description

- **db\_name**  
Name of the database to be exported.
- **directory**  
Directory for storing exported files.

#### Examples

```
-- The EXPDP DATABASE syntax is used for fine-grained backup and restoration and is called by the backup and restoration tool. If you directly call the syntax, an error message may be displayed, indicating that the directory does not exist. Therefore, you are not advised to directly call the syntax.
gaussdb=# EXPDP DATABASE test LOCATION = '/data1/expdp/database';
```

### 7.12.10.4 EXPDP TABLE

#### Function

**EXPDP TABLE** exports all table-related index, sequence, partition, toast, and toast index files.

#### Syntax

```
EXPDP TABLE table_name LOCATION = 'directory';
```

## Parameter Description

- **table\_name**  
Name of the table to be exported.
- **directory**  
Directory for storing exported files.

## Examples

```
-- The EXPDP TABLE syntax is used for fine-grained backup and restoration and is called by the backup and restoration tool. If you directly call the syntax, an error message may be displayed, indicating that the directory does not exist. Therefore, you are not advised to directly call the syntax.
gaussdb=# EXPDP TABLE test_t LOCATION = '/data1/expdp/table0';
```

## 7.12.10.5 EXPLAIN

### Description

Shows the execution plan of an SQL statement.

The execution plan shows how the tables referenced by the SQL statement will be scanned, for example, by plain sequential scan or index scan. If multiple tables are referenced, the execution plan also shows what join algorithms will be used to bring together the required rows from each input table.

The most critical part of the display is the estimated statement execution cost, which is the planner's guess at how long it will take to run the statement.

The **ANALYZE** option causes the statement to be actually executed, not only planned. The total elapsed time expended within each plan node (in milliseconds) and total number of rows it actually returned are added to the display. This is useful for determining whether the planner's estimates are close to reality.

### Precautions

The statement is actually executed when ANALYZE is used. If you want to use EXPLAIN ANALYZE on an INSERT, UPDATE, DELETE, CREATE TABLE AS, or EXECUTE statement without letting the statement affect your data, use this approach:

```
START TRANSACTION;
EXPLAIN ANALYZE ...;
ROLLBACK;
```

### Syntax

- Display the execution plan of an SQL statement, which supports multiple options and has no requirements for the order of options.

```
EXPLAIN [(option [, ...])] statement;
```

The syntax of the option clause is as follows:

```
ANALYZE [boolean] |
ANALYSE [boolean] |
VERBOSE [boolean] |
COSTS [boolean] |
CPU [boolean] |
DETAIL [boolean] |
NODES [boolean] |
NUM_NODES [boolean] |
BUFFERS [boolean] |
```

```
TIMING [boolean] |
PLAN [boolean] |
BLOCKNAME [boolean] |
FORMAT { TEXT | XML | JSON | YAML }
```

- Display the execution plan of an SQL statement, where options are in order.  
EXPLAIN { [ ANALYZE | ANALYSE ] [ VERBOSE ] [ PERFORMANCE ] statement;

## Parameters

- **statement**  
Specifies the SQL statement to explain.
- **ANALYZE boolean | ANALYSE boolean**  
Specifies whether to display actual run times and other statistics. When two parameters are used at the same time, the latter option takes effect.  
Value range:
  - **TRUE** (default): displays them.
  - **FALSE**: does not display them.
- **VERBOSE boolean**  
Specifies whether to display additional information regarding the plan.  
Value range:
  - **TRUE** (default): displays it.
  - **FALSE**: does not display it.
- **COSTS boolean**  
Specifies whether to display the estimated total cost of each plan node, estimated number of rows, estimated width of each row.  
Value range:
  - **TRUE** (default): displays them.
  - **FALSE**: does not display them.
- **CPU boolean**  
Specifies whether to display CPU usage. This parameter must be used together with ANALYZE or ANALYSE.  
Value range:
  - **TRUE** (default): displays it.
  - **FALSE**: does not display it.
- **DETAIL boolean**  
Specifies whether to display DN information. This parameter must be used together with ANALYZE or ANALYSE.  
Value range:
  - **TRUE** (default): displays it.
  - **FALSE**: does not display it.
- **NODES boolean**  
Specifies whether to display information about the nodes executed by query.  
Value range:
  - **TRUE** (default): displays it.

- **FALSE**: does not display it.
- **NUM\_NODES boolean**

Specifies whether to display the number of executing nodes.

Value range:

  - **TRUE** (default): displays it.
  - **FALSE**: does not display it.
- **BUFFERS boolean**

Specifies whether to display buffer usage. This parameter must be used together with **ANALYZE** or **ANALYSE**.

Value range:

  - **TRUE**: displays it.
  - **FALSE** (default): does not display it.
- **TIMING boolean**

Specifies whether to display the actual startup time and time spent on the output node. This parameter must be used together with **ANALYZE** or **ANALYSE**.

Value range:

  - **TRUE** (default): displays them.
  - **FALSE**: does not display them.
- **PLAN boolean**

Specifies whether to store the execution plan in **PLAN\_TABLE**. If this parameter is set to **on**, the execution plan is stored in **PLAN\_TABLE** and is not displayed on the screen. Therefore, this parameter cannot be used together with other parameters when it is set to **on**.

Value range:

  - **TRUE** (default): The execution plan is stored in **PLAN\_TABLE** and not displayed on the screen. If the plan is stored successfully, "EXPLAIN SUCCESS" is returned.
  - **FALSE**: The execution plan is not stored but is printed on the screen.
- **BLOCKNAME boolean**

Specifies whether to display the query block where each operation of the plan is located. When this option is enabled, the name of the query block where each operation is performed is displayed in the **Query Block** column. This helps users obtain the query block name and use hints to modify the execution plan.

  - **TRUE** (default value): When the plan is displayed, the name of the query block where each operation is located is displayed in the **Query Block** column. This option must be used in the pretty mode. For details, see [Hint Specifying the Query Block Where the Hint Is Located](#).
  - **FALSE**: The plan display is not affected.
- **FORMAT**

Specifies the output format.

Value range: **TEXT**, **XML**, **JSON**, and **YAML**

Default value: **TEXT**

- **PERFORMANCE**

Prints all relevant information in execution. Some information is described as follows:

- **ex c/r**: indicates the average number of CPU cycles used by each row, which is equal to **(ex cyc) / (ex row)**.
- **ex row**: indicates the number of executed rows.
- **ex cyc**: indicates the number of used CPU cycles.
- **inc cyc**: indicates the total number of CPU cycles used by subnodes.
- **shared hit**: indicates the shared buffer hits of the operator.
- **loops**: indicates the number of operator loop execution times.
- **total\_calls**: indicates the total number of generated elements.
- **remote query poll time stream gather**: indicates the operator used to listen to the network poll time when data on each DN reaches the CN.
- **deserialize time**: indicates the time required for deserialization.
- **estimated time**: indicates the estimated time.
- **Network Poll Time**: indicates the duration for the libcomm receiver to wait for data during distributed stream network communication.
- **Stream Send time**: indicates the time consumed by libcomm or libpq to send data during distributed stream network communication.
- **OS Kernel Send time**: indicates the time required for the OS layer to send data during distributed stream network communication. This parameter is displayed only when the value is greater than **0**.
- **Wait Quota time**: indicates the duration for libcomm to wait for the peer end to send the quota traffic control size during distributed stream network communication. This parameter is displayed only when the value is greater than **0**.
- **Data Serialize time**: indicates the data serialization time during distributed stream network communication.
- **Data Copy time**: indicates the data replication time during distributed stream network communication. This parameter is displayed only when the value is greater than **0**.

## Examples

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Create the tpcds.customer_address table.
gaussdb=# CREATE TABLE tpcds.customer_address
(
ca_address_sk INTEGER NOT NULL,
ca_address_id CHARACTER(16) NOT NULL
);

-- Insert multiple records into the table.
gaussdb=# INSERT INTO tpcds.customer_address VALUES (5000, 'AAAAAAAAABAAAAAAA'),(10000,
'AAAAAAAAACAAAAAAAA');

-- Create the tpcds.customer_address_p1 table.
gaussdb=# CREATE TABLE tpcds.customer_address_p1 AS TABLE tpcds.customer_address;

-- Change the value of explain_perf_mode to normal.
gaussdb=# SET explain_perf_mode=normal;
```

```

-- Display an execution plan for simple queries in the table.
gaussdb=# EXPLAIN SELECT * FROM tpcds.customer_address_p1;
QUERY PLAN

Data Node Scan (cost=0.00..0.00 rows=0 width=0)
Node/s: All DNs
(2 rows)

-- Use the ANALYZE option to add runtime statistics to the output.
gaussdb=# EXPLAIN ANALYZE SELECT * FROM tpcds.customer_address_p1;
QUERY PLAN

Data Node Scan (cost=0.00..0.00 rows=0 width=0) (actual time=1.754..3.218 rows=2 loops=1)
Node/s: All DNs
Total runtime: 3.272 ms
(3 rows)

-- Use the ANALYZE and CPU options to output the CPU usage information.
gaussdb=# EXPLAIN (ANALYZE,CPU)SELECT * FROM tpcds.customer_address_p1;
QUERY PLAN

Data Node Scan (cost=0.00..0.00 rows=0 width=0) (actual time=1.996..2.214 rows=2 loops=1)
Node/s: All DNs
(CPU: ex c/r=25694795469106248, ex row=2, ex cyc=51389590938212496, inc cyc=51389590938212496)
Total runtime: 2.251 ms
(4 rows)

-- Generate an execution plan in JSON format (with explain_perf_mode being normal).
gaussdb=# EXPLAIN(FORMAT JSON) SELECT * FROM tpcds.customer_address_p1;
QUERY PLAN

[
 {
 "Plan": {
 "Node Type": "Data Node Scan",+
 "Startup Cost": 0.00, +
 "Total Cost": 0.00, +
 "Plan Rows": 0, +
 "Plan Width": 0, +
 "Node/s": "All DNs" +
 }
 }
]
(1 row)

-- Generate an execution plan in YAML format (with explain_perf_mode being normal).
gaussdb=# EXPLAIN(FORMAT YAML) SELECT * FROM tpcds.customer_address_p1 WHERE
ca_address_sk=10000;
QUERY PLAN

- Plan:
 Node Type: "Data Node Scan"+
 Startup Cost: 0.00 +
 Total Cost: 0.00 +
 Plan Rows: 0 +
 Plan Width: 0 +
 Node/s: "dn_6005_6006"
(1 row)

-- Suppress the execution plan of cost estimation.
gaussdb=# EXPLAIN(COSTS FALSE)SELECT * FROM tpcds.customer_address_p1 WHERE
ca_address_sk=10000;
QUERY PLAN

Data Node Scan
Node/s: dn_6005_6006
(2 rows)

```

```
-- Generate an execution plan with aggregate functions for a query.
gaussdb=# EXPLAIN SELECT SUM(ca_address_sk) FROM tpcds.customer_address_p1 WHERE

[ANALYZE | ANALYSE](#)

### 7.12.10.6 EXPLAIN PLAN

#### Description

EXPLAIN PLAN saves information about an execution plan into the **PLAN\_TABLE** table. Different from the EXPLAIN statement, EXPLAIN PLAN only saves plan information and does not print information on the screen.

#### Precautions

- EXPLAIN PLAN cannot be executed on a DN.
- Plan information cannot be collected for SQL statements that failed to be executed.
- Data in **PLAN\_TABLE** is in a session-level lifecycle. Sessions are isolated from users, and therefore users can only view the data of the current session and current user.
- **PLAN\_TABLE** cannot be joined with GDS foreign tables.
- For a query that cannot be pushed down, only such information as **REMOTE\_QUERY** and **CTE** can be collected from **PLAN\_TABLE** after **EXPLAIN PLAN** is executed. For details, see [Example 2](#).
- **PLAN**: saves plan information into **PLAN\_TABLE**. If information is stored successfully, "EXPLAIN SUCCESS" is returned.
- **STATEMENT\_ID**: tags each query. The tag information will be stored in **PLAN\_TABLE**.
- After the EXPLAIN PLAN statement is executed, plan information is automatically stored in **PLAN\_TABLE**. INSERT, UPDATE, and ANALYZE cannot be performed on **PLAN\_TABLE**. For details about **PLAN\_TABLE**, see [PLAN\\_TABLE](#).

## Syntax

```
EXPLAIN PLAN
[SET STATEMENT_ID = name]
FOR statement ;
```

## Parameters

- **name**  
Specifies a query tag.  
Value range: a string

### NOTE

If **STATEMENT\_ID** is not set when the EXPLAIN PLAN statement is executed, **STATEMENT\_ID** is left empty by default. In addition, the value of **STATEMENT\_ID** cannot exceed 30 bytes. Otherwise, an error will be reported.

- **statement**  
Specifies the SQL statement to explain.

## Example 1

```
-- Create tables foo1 and foo2.
gaussdb=# CREATE TABLE foo1(f1 int, f2 text, f3 text[]);
gaussdb=# CREATE TABLE foo2(f1 int, f2 text, f3 text[]);

-- Run EXPLAIN PLAN.
gaussdb=# EXPLAIN PLAN SET STATEMENT_ID = 'TPCH-Q4' FOR SELECT f1, count(*) FROM foo1 WHERE f1
> 1 AND f1 < 3 AND EXISTS (SELECT * FROM foo2) GROUP BY f1;

-- Query PLAN_TABLE.
gaussdb=# SELECT * FROM plan_table;

-- Delete data from the PLAN_TABLE table and delete tables foo1 and foo2.
gaussdb=# DELETE FROM plan_table WHERE STATEMENT_ID = 'TPCH-Q4';
gaussdb=# DROP TABLE foo1;
gaussdb=# DROP TABLE foo2;
```

## Example 2

```
-- Disable enable_stream_recursive so that associated WITH RECURSIVE queries cannot be pushed down.
gaussdb=# SET enable_stream_recursive = off;

-- Create the chinamap table.
gaussdb=# CREATE TABLE chinamap
(
 id integer,
 pid integer,
 name text
) DISTRIBUTE BY hash(id);

-- Plan collected by plan_table.
gaussdb=# EXPLAIN PLAN SET statement_id = 'cte can not be push down'
FOR
WITH RECURSIVE rq AS
(
 SELECT id, name FROM chinamap WHERE id = 11
 UNION ALL
 SELECT origin.id, rq.name || ' > ' || origin.name
 FROM rq JOIN chinamap origin ON origin.pid = rq.id
)
SELECT id, name FROM rq ORDER BY 1;

-- Query PLAN_TABLE.
```

```
gaussdb=# SELECT * FROM plan_table;

-- Delete the chinamap table.
gaussdb=# DROP TABLE chinamap;
```

## 7.12.11 F

### 7.12.11.1 FETCH

#### Description

FETCH retrieves rows using a previously created cursor.

A cursor has an associated position, which is used by FETCH. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result.

- When created, a cursor is positioned before the first row.
- After fetching some rows, the cursor is positioned on the row most recently retrieved.
- If FETCH runs off the end of the available rows then the cursor is left positioned after the last row, or before the first row if fetching backward.
- FETCH ALL or FETCH BACKWARD ALL will always leave the cursor positioned after the last row or before the first row.

#### Precautions

- If the cursor is declared with **NO SCROLL**, backward fetches like FETCH BACKWARD are not allowed.
- The forms **NEXT**, **PRIOR**, **FIRST**, **LAST**, **ABSOLUTE**, and **RELATIVE** fetch a single row after moving the cursor appropriately. If there is no such row, an empty result is returned, and the cursor is left positioned before the first row (backward fetch) or after the last row (forward fetch) as appropriate.
- The forms using **FORWARD** and **BACKWARD** retrieve the indicated number of rows moving in the forward or backward direction, leaving the cursor positioned on the last-returned row or after (backward fetch)/before (forward fetch) all rows if the **count** exceeds the number of rows available.
- **RELATIVE 0**, **FORWARD 0**, and **BACKWARD 0** all request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This action will succeed unless the cursor is positioned before the first row or after the last row. If the cursor is positioned before the first row or after the last row, no row is returned.
- If the cursor of FETCH involves a non-system catalog, backward fetches like **BACKWARD**, **PRIOR**, and **FIRST** are not allowed.

#### Syntax

```
FETCH [direction { FROM | IN }] cursor_name;
```

The direction clause specifies optional parameters.

```
NEXT
| PRIOR
| FIRST
| LAST
| ABSOLUTE count
| RELATIVE count
| count
| ALL
| FORWARD
| FORWARD count
| FORWARD ALL
| BACKWARD
| BACKWARD count
| BACKWARD ALL
```

## Parameters

- **direction**  
Defines the fetch direction.  
Value range:
  - **NEXT** (default value)  
Fetches the next row.
  - **PRIOR**  
Fetches the prior row.
  - **FIRST**  
Fetches the first row of the query (same as **ABSOLUTE 1**).

- **LAST**  
Fetches the last row of the query (same as **ABSOLUTE -1**).
- **ABSOLUTE** *count*  
Fetches the *count*'th row of the query.  
**ABSOLUTE** fetches are not any faster than navigating to the desired row with a relative move: the underlying implementation must traverse all the intermediate rows anyway.  
Value range: a possibly-signed integer
  - If *count* is positive, the *count*'th row of the query will be fetched. If *count* is less than the current cursor position, rewind is required, which is currently not supported.
  - If *count* is negative or 0, backward scan is required, which is currently not supported.
- **RELATIVE** *count*  
Fetches the *count*'th succeeding row or the *count*'th prior row if *count* is negative.  
Value range: a possibly-signed integer
  - If *count* is positive, the *count*'th succeeding row will be fetched.
  - If *count* is negative or 0, backward scan is required, which is currently not supported.
  - If the current row contains no data, **RELATIVE 0** returns null.
- **count**  
Fetches the next *count* rows (same as **FORWARD count**).
- **ALL**  
Fetches all remaining rows (same as **FORWARD ALL**).
- **FORWARD**  
Fetches the next row (same as **NEXT**).
- **FORWARD count**  
Fetches the next or prior *count* rows (same as **RELATIVE count**).
- **FORWARD ALL**  
Fetches all remaining rows.
- **BACKWARD**  
Fetches the prior row (same as **PRIOR**).
- **BACKWARD count**  
Fetches the prior *count* rows (scanning backwards).  
Value range: a possibly-signed integer
  - If **count** is a positive integer, fetches the (count)'th prior row.
  - If **count** is a negative integer, fetches the abs(count)'th succeeding row.

- **BACKWARD 0** re-fetches the current row, if any.
- **BACKWARD ALL**  
Fetches all prior rows (scanning backwards).
- **{ FROM | IN } cursor\_name**  
Specifies the cursor name using the keyword **FROM** or **IN**.  
Value range: an existing cursor name

## Examples

```
-- Create the test table and insert 20 data records into the table.
gaussdb=# CREATE TABLE test(c1 int, c2 int);
gaussdb=# INSERT INTO test VALUES (generate_series(1,20),generate_series(1,20));

-- Start a transaction and create a cursor named cursor1.
gaussdb=# START TRANSACTION;
gaussdb=# CURSOR cursor1 FOR SELECT * FROM test ORDER BY 1;

-- The cursor retrieves three rows of data from the associated position.
gaussdb=# FETCH FORWARD 3 FROM cursor1;
c1 | c2
----+----
 1 | 1
 2 | 2
 3 | 3
(3 rows)

-- Close the cursor and commit the transaction.
gaussdb=# CLOSE cursor1;
gaussdb=# END;

-- Delete the table.
gaussdb=# DROP TABLE test;
```

## 7.12.12 G

### 7.12.12.1 GRANT

#### Description

Grants permissions to roles and users.

GRANT is used in the following scenarios:

- **Granting system permissions to roles or users**

System permissions are also called user attributes, including SYSADMIN, CREATEDB, CREATEROLE, AUDITADMIN, MONADMIN, OPRADMIN, POLADMIN, INHERIT, REPLICATION, and LOGIN.

They can be specified only by the CREATE ROLE or ALTER ROLE statement. The SYSADMIN permissions can be granted and revoked using GRANT ALL PRIVILEGE and REVOKE ALL PRIVILEGE, respectively. System permissions cannot be inherited by a user from a role, and cannot be granted using PUBLIC.

- **Granting database object permissions to roles or users**

Grant permissions on a database object (table, view, column, database, function, schema, or tablespace) to a role or user.

GRANT gives specific permissions on a database object to one or more roles. These permissions are added to those already granted, if any.

The keyword PUBLIC indicates that the permissions are to be granted to all roles, including those that might be created later. PUBLIC can be thought of as an implicitly defined group that always includes all roles. Any particular role will have the sum of permissions granted directly to it, permissions granted to any role it is presently a member of, and permissions granted to PUBLIC.

If WITH GRANT OPTION is specified, the recipient of the permission can in turn grant it to others. Without a grant option, the recipient cannot do that. This option cannot be granted to PUBLIC, which is a unique GaussDB attribute.

GaussDB grants the permissions on certain types of objects to PUBLIC. By default, permissions on tables, columns, sequences, foreign data sources, foreign servers, schemas, and tablespaces are not granted to PUBLIC, but the following permissions are granted to PUBLIC: CONNECT and CREATE TEMP TABLE permissions on databases, EXECUTE permission on functions, and USAGE permission on languages and data types (including domains). An object owner can revoke the default permissions granted to PUBLIC and grant permissions to other users as needed. For security purposes, you are advised to create an object and set its permissions in the same transaction so that other users do not have time windows to use the object. These default permissions can be modified by running the **ALTER DEFAULT PRIVILEGES** command.

By default, an object owner has all permissions on the object. For security purposes, the owner can discard some permissions. However, the ALTER, DROP, COMMENT, INDEX, VACUUM, and re-grantable permissions of the object are inherent permissions implicitly owned by the owner.

- **Granting the permissions of one role or user to others**

Grant the permissions of one role or user to others. In this case, every role or user can be regarded as a set of one or more database permissions.

If WITH ADMIN OPTION is specified, the recipients can in turn grant the permissions to other roles or users or revoke the permissions they have granted to other roles or users. If recipients' permissions are changed or revoked later, the grantees' permissions will also change.

When separation-of-duty is disabled, the system administrator can grant or revoke the permissions of any non-permanent user, O&M administrator, or private user role. Security administrators can grant or revoke permissions of any non-system administrator, built-in role, permanent user, O&M administrator, or private user role.

- **Granting ANY permissions to roles or users**

Grant ANY permissions to a specified role or user. For details about the value range of the ANY permissions, see the syntax. If WITH ADMIN OPTION is specified, the grantee can grant the ANY permissions to or revoke them from other roles or users. The ANY permissions can be inherited by a role but cannot be granted to PUBLIC. An initial user and the system administrator

when separation of duties is disabled can grant the ANY permissions to or revoke them from any role or user.

Currently, the following ANY permissions are supported: CREATE ANY TABLE, ALTER ANY TABLE, DROP ANY TABLE, SELECT ANY TABLE, INSERT ANY TABLE, UPDATE ANY TABLE, DELETE ANY TABLE, CREATE ANY SEQUENCE, CREATE ANY INDEX, CREATE ANY FUNCTION, EXECUTE ANY FUNCTION, CREATE ANY TYPE, ALTER ANY TYPE, DROP ANY TYPE, ALTER ANY SEQUENCE, DROP ANY SEQUENCE, SELECT ANY SEQUENCE, ALTER ANY INDEX, DROP ANY INDEX, CREATE ANY SYNONYM, DROP ANY SYNONYM, CREATE ANY TRIGGER, ALTER ANY TRIGGER, and DROP ANY TRIGGER. For details about the ANY permission scope, see [Table 7-243](#).

## Precautions

- It is not allowed to grant the ANY permissions to PUBLIC or revoke the ANY permissions from PUBLIC.
- The ANY permissions are database permissions and are valid only for database objects that are granted with the permissions. For example, SELECT ANY TABLE only allows a user to view all user table data in the current database, but the user does not have the permission to view user tables in other databases.
- The ANY permissions and the original permissions do not affect each other.
- If a user is granted with the CREATE ANY TABLE permission, the owner of a table created in a schema with the same name as the user is the creator of the schema. When the user performs other operations on the table, the user needs to be granted with the corresponding operation permission. Similarly, if a user is granted with the CREATE ANY FUNCTION, CREATE ANY TYPE, CREATE ANY SEQUENCE, or CREATE ANY INDEX permission, the owner of an object created in a schema with the same name is the owner of the schema. If a user is granted with the CREATE ANY TRIGGER or CREATE ANY SYNONYM permission, the owner of an object created in a schema with the same name is the creator.
- Exercise caution when granting the CREATE ANY FUNCTION permission to users to prevent other users from using DEFINER functions for privilege escalation.
- When GRANT is used to grant a user the permission to use a table, if the permission is not properly used, ALTER may be used to add expressions to the default values and constraints of the table, or indexes may be created to add expressions to INDEX. In this case, the permission may be exploited.
- When GRANT is used to grant the TRIGGER permission, if the permission is not properly used, the WHEN condition may be used to create expressions. When the trigger is triggered, the permission may be exploited.
- When granting permissions to users, pay special attention to the definer permission on functions. The definer permission is executed as the owner of the functions. If the permission is not properly granted (including GRANT ROLE TO ROLE), the permission may be exploited.
- Do not grant object permissions to too many users. You can use roles or PUBLIC based on service requirements.

## Syntax

- Grant the table or view access permission to a user or role.  

```
GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER | ALTER | DROP
| COMMENT | INDEX | VACUUM } [, ...]
| ALL [PRIVILEGES] }
ON { [TABLE] table_name [, ...]
| ALL TABLES IN SCHEMA schema_name [, ...] }
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```
- Grant the column access permission to a user or role.  

```
GRANT { { SELECT | INSERT | UPDATE | REFERENCES | COMMENT } (column_name [, ...]) } [, ...]
| ALL [PRIVILEGES] (column_name [, ...]) }
ON [TABLE] table_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

### NOTE

If you have the permission to access a table, you have the permission to access all columns in the table by default. To grant only the access permission on a column in a table, you need to revoke the access permission on the table.

- Grant the sequence access permission to a specified user or role.  

```
GRANT { { SELECT | UPDATE | USAGE | ALTER | DROP | COMMENT } [, ...]
| ALL [PRIVILEGES] }
ON { [SEQUENCE] sequence_name [, ...]
| ALL SEQUENCES IN SCHEMA schema_name [, ...] }
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```
- Grant the database access permission to a user or role.  

```
GRANT { { CREATE | CONNECT | TEMPORARY | TEMP | ALTER | DROP | COMMENT } [, ...]
| ALL [PRIVILEGES] }
ON DATABASE database_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```
- Grant the domain access permission to a user or role.  

```
GRANT { USAGE | ALL [PRIVILEGES] }
ON DOMAIN domain_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

### NOTE

In the current version, the domain access permission cannot be granted.

- Grant the CMK access permission to a specified user or role.  

```
GRANT { { USAGE | DROP } [, ...] | ALL [PRIVILEGES] }
ON { CLIENT_MASTER_KEY client_master_key
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```
- Grant the column encryption key (CEK) access permission to a specified user or role.  

```
GRANT { { USAGE | DROP } [, ...] | ALL [PRIVILEGES] }
ON { COLUMN_ENCRYPTION_KEY column_encryption_key
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```
- Grant the foreign data source access permission to a user or role.  

```
GRANT { USAGE | ALL [PRIVILEGES] }
ON FOREIGN_DATA_WRAPPER fdw_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```
- Grant the foreign server access permission to a user or role.  

```
GRANT { { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON FOREIGN_SERVER server_name [, ...]
```

```
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

- **Grant the function access permission to a user or role.**  

```
GRANT { { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON { FUNCTION {function_name ([{ [argmode] [arg_name] arg_type } [, ...]) } [, ...]
| ALL FUNCTIONS IN SCHEMA schema_name [, ...] }
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```
- **Grant the procedural procedure access permission to a user or role.**  

```
GRANT { { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON PROCEDURE {proc_name ([{ [argmode] [arg_name] arg_type } [, ...]) } [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```
- **Grant the procedural language access permission to a user or role.**  

```
GRANT { USAGE | ALL [PRIVILEGES] }
ON LANGUAGE lang_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

 **NOTE**

In the current version, all users can create C functions, whereas only users with the sysadmin permission can create Java and internal functions.

- When a user with the sysadmin permission grants the permission for creating C functions to others, the user must specify a recipient and cannot use GRANT USAGE ON LANGUAGE c TO PUBLIC.
- When a user with the sysadmin permission grants the permission for creating C functions to others, the user cannot specify WITH GRANT OPTION.
- **Grant the sub-cluster access permission to a user or role.**  

```
GRANT { { CREATE | USAGE | COMPUTE | ALTER | DROP } [, ...] | ALL [PRIVILEGES] }
ON NODE GROUP group_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

 **NOTE**

When the CREATE permission of a sub-cluster is granted to a specified user or role, the USAGE and COMPUTE permissions are granted to the specified user or role by default.

- **Grant the schema access permission to a user or role.**  

```
GRANT { { CREATE | USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON SCHEMA schema_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

 **NOTE**

When you grant table or view permissions to other users, you also need to grant the USAGE permission on the schema that the tables and views belong to. Without the USAGE permission, the users with table or view permissions can only see the object names, but cannot access them.

- **Grant the large object access permission to a specified user or role.**  

```
GRANT { { SELECT | UPDATE } [, ...] | ALL [PRIVILEGES] }
ON LARGE OBJECT loid [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

 **NOTE**

In the current version, the large object access permission cannot be granted.

- **Grant the tablespace access permission to a user or role.**

```
GRANT { { CREATE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON TABLESPACE tablespace_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

- Grant the type access permission to a user or role.

```
GRANT { { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON TYPE type_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

 **NOTE**

In the current version, the type access permission cannot be granted.

- Grant the DIRECTORY permission to a role.

```
GRANT { { READ | WRITE | ALTER | DROP } [, ...] | ALL [PRIVILEGES] }
ON DIRECTORY directory_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

- Grant a role's permissions to another user or role.

```
GRANT role_name [, ...]
TO role_name [, ...]
[WITH ADMIN OPTION];
```

- Grant the SYSADMIN permission to a role.

```
GRANT ALL { PRIVILEGES | PRIVILEGE }
TO role_name;
```

- Grant the ANY permissions to another user or role.

```
GRANT { CREATE ANY TABLE | ALTER ANY TABLE | DROP ANY TABLE | SELECT ANY TABLE |
INSERT ANY TABLE | UPDATE ANY TABLE | DELETE ANY TABLE | CREATE ANY SEQUENCE |
CREATE ANY INDEX | CREATE ANY FUNCTION | EXECUTE ANY FUNCTION |
CREATE ANY TYPE | ALTER ANY TYPE | DROP ANY TYPE |
ALTER ANY SEQUENCE | DROP ANY SEQUENCE | SELECT ANY SEQUENCE | ALTER ANY INDEX |
DROP ANY INDEX | CREATE ANY SYNONYM | DROP ANY SYNONYM | CREATE ANY TRIGGER | ALTER
ANY TRIGGER |
DROP ANY TRIGGER } [, ...]
TO [GROUP] role_name [, ...]
[WITH ADMIN OPTION];
```

- Grant the database link object permission to a specified user.

```
GRANT { CREATE | ALTER | DROP } [PUBLIC] DATABASE LINK TO role_name;
```

 **NOTE**

- **PUBLIC:** creates a public database link visible to all users. If this clause is omitted, the database link is private and used only as a compatible API. The data that can be accessed on the remote database depends on the identity used by the database link during connection.
- When the permission to create a database link is granted to a user, the user can remotely access a database by using the IP address of the remote database. Exercise caution when granting this permission to users.
- In addition to the statement for directly granting the database link permission, you can also obtain the database link permission by inheriting permission and granting permission to an administrator.
- For details about database links, see [DATABASE LINK](#).
- Grant the permission to create PUBLIC synonyms to a specified user.

```
GRANT { CREATE | DROP } PUBLIC SYNONYM TO role_name [WITH ADMIN OPTION];
```

Built-in roles (`gs_role_public_synonym_create` and `gs_role_public_synonym_drop`) can also be used to grant users the permission to create and delete PUBLIC synonyms.

- Grant the permission to create PUBLIC synonyms to a user.

```
GRANT gs_role_public_synonym_create TO role_name;
```

- Grant the permission to delete PUBLIC synonyms to a user.  
`GRANT gs_role_public_synonym_drop TO role_name;`

## Parameters

GRANT permissions are classified as follows:

- **SELECT**  
Allows SELECT from any table, view, or sequence. The SELECT permission on the corresponding column is also required for UPDATE or DELETE.
- **INSERT**  
Allows INSERT of a new row into a table.
- **UPDATE**  
Allows you to execute the UPDATE statement on any column in the specified table. The UPDATE statement also requires the SELECT permission to query which rows need to be updated. SELECT ... FOR UPDATE and SELECT ... FOR SHARE also require this permission on at least one column, in addition to the SELECT permission.
- **DELETE**  
Allows DELETE of a row from a table. DELETE also requires the SELECT permission to query which rows need to be deleted.
- **TRUNCATE**  
Allows TRUNCATE on a table.
- **REFERENCES**  
Allows to create a foreign key constraint referencing a table. This permission is required on both referencing and referenced tables. This function is not supported in distributed mode.
- **TRIGGER**  
Allows the creation of a trigger on the specified table.
- **CREATE**
  - For databases, allows new schemas to be created within the database.
  - For schemas, allows new objects to be created within the schema. To rename an existing object, you must own the object and have the CREATE permission on the schema of the object.
  - For tablespaces, allows tables to be created within the tablespace, and allows databases and schemas to be created that have the tablespace as their default tablespace.
  - For sub-clusters, allows tables to be created within the sub-cluster.
- **CONNECT**  
Allows the grantee to connect to the database.
- **EXECUTE**  
Allows calling a function, including use of any operators that are implemented on top of the function.
- **USAGE**
  - For procedural languages, allows use of the language for the creation of functions in that language.

- For schemas, allows access to objects contained in the schema. Without this permission, it is still possible to see the object names.
- For sequences, allows use of the nextval function.
- For sub-clusters, allows users who can access objects contained in the schema to access tables in the sub-cluster.
- For a key object, USAGE is the permission to use the key.
- **COMPUTE**  
For computing sub-clusters, allows users to perform elastic computing in the sub-cluster that they have the compute permission on.
- **ALTER**  
Allows users to modify the attributes of a specified object, excluding the owner and schema of the object.
- **DROP**  
Allows users to delete specified objects.
- **COMMENT**  
Allows users to define or modify comments of a specified object.
- **INDEX**  
Allows users to create indexes on specified tables, manage indexes on the tables, and perform REINDEX and CLUSTER operations on the tables.
- **VACUUM**  
Allows users to perform ANALYZE and VACUUM operations on specified tables.
- **ALL PRIVILEGES**  
Grants all available permissions to a user or role at a time. Only a system administrator has the GRANT ALL PRIVILEGES permission.

**GRANT** parameters are as follows:

- **role\_name**  
Specifies the username.
- **table\_name**  
Specifies the table name.
- **column\_name**  
Specifies the column name.
- **schema\_name**  
Specifies the schema name.
- **database\_name**  
Specifies the database name.
- **function\_name**  
Specifies the function name.
- **sequence\_name**  
Specifies the sequence name.
- **domain\_name**  
Specifies the domain type name.

- **fdw\_name**  
Specifies the foreign data wrapper name.
- **lang\_name**  
Specifies the language name.
- **type\_name**  
Specifies the type name.
- **group\_name**  
Specifies the sub-cluster name.
- **argmode**  
Specifies the parameter mode.  
Value range: a string. It must comply with the [naming convention](#).
- **arg\_name**  
Specifies the parameter name.  
Value range: a string. It must comply with the [naming convention](#).
- **arg\_type**  
Specifies the parameter type.  
Value range: a string. It must comply with the [naming convention](#).
- **loid**  
Specifies the identifier of the large object that includes this page.  
Value range: a string. It must comply with the [naming convention](#).
- **tablespace\_name**  
Specifies the tablespace name.
- **client\_master\_key**  
Name of the CMK.  
Value range: a string. It must comply with the [naming convention](#).
- **column\_encryption\_key**  
Name of the column encryption key.  
Value range: a string. It must comply with the [naming convention](#).
- **directory\_name**  
Specifies the directory name.  
Value range: a string. It must comply with the [naming convention](#).
- **WITH GRANT OPTION**  
If WITH GRANT OPTION is specified, the recipient of the permission can in turn grant it to others. Without a grant option, the recipient cannot do that. Grant options cannot be granted to PUBLIC.

When a non-owner of an object attempts to grant permissions on the object:

- The statement will fail outright if the user has no permissions whatsoever on the object.
- As long as some permission is available, the statement will proceed, but it will grant only those permissions for which the user has grant options.

- The GRANT ALL PRIVILEGES forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the permissions specifically named in the statement are not held.

 **NOTE**

When separation of duties is disabled, database administrators can access all objects, regardless of object permission settings. It is unwise to operate as a system administrator except when necessary.

- **WITH ADMIN OPTION**

If WITH ADMIN OPTION is specified for a role, the grantee can grant the role to other roles or users or revoke the role from other roles or users.

For the ANY permissions, if WITH ADMIN OPTION is specified, the grantee can grant the ANY permissions to or revoke them from other roles or users.

**Table 7-243** ANY permissions

| Permission           | Description                                                                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CREATE ANY TABLE     | Users can create tables or views in the public and user schemas. The users must be granted with the permission to create sequences to create a table that contains serial columns.                                                                                      |
| ALTER ANY TABLE      | Users' ALTER permission on tables or views in the public and user schemas. If the users want to modify the unique index of a table to add a primary key constraint or unique constraint to the table, the users must be granted with the index permission on the table. |
| DROP ANY TABLE       | Users' DROP permission on tables or views in the public and user schemas.                                                                                                                                                                                               |
| SELECT ANY TABLE     | Users' SELECT permission on tables or views in the public and user schemas, which is still subject to row-level security.                                                                                                                                               |
| UPDATE ANY TABLE     | Users' UPDATE permission on tables or views in the public and user schemas, which is still subject to row-level security.                                                                                                                                               |
| INSERT ANY TABLE     | Users' INSERT permission on tables or views in the public and user schemas.                                                                                                                                                                                             |
| DELETE ANY TABLE     | Users' DELETE permission on tables or views in the public and user schemas, which is still subject to row-level security.                                                                                                                                               |
| CREATE ANY FUNCTION  | Users can create functions or stored procedures in the user schemas.                                                                                                                                                                                                    |
| EXECUTE ANY FUNCTION | Users' EXECUTE permission on functions or stored procedures in the public and user schemas.                                                                                                                                                                             |
| CREATE ANY TYPE      | Users can create types in the public and user schemas.                                                                                                                                                                                                                  |
| CREATE ANY SEQUENCE  | Users can create sequences in the public and user schemas.                                                                                                                                                                                                              |

| Permission          | Description                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CREATE ANY INDEX    | Users can create indexes in the public and user schemas. The users must be granted with the permission to create tablespaces to create a partitioned table index in a tablespace.                                                                                                                                                                                                         |
| ALTER ANY TYPE      | Users have the ALTER permission on types in public and user schemas, excluding modifying the owner of a type or modifying the schema of a type.                                                                                                                                                                                                                                           |
| DROP ANY TYPE       | Users' DROP permission on types in the public and user schemas.                                                                                                                                                                                                                                                                                                                           |
| ALTER ANY SEQUENCE  | Users have the ALTER permission on sequences in public and user schemas, excluding modifying the owner of a sequence.                                                                                                                                                                                                                                                                     |
| DROP ANY SEQUENCE   | Users' DROP permission on sequences in the public and user schemas.                                                                                                                                                                                                                                                                                                                       |
| SELECT ANY SEQUENCE | Users' SELECT, USAGE, and UPDATE permissions on sequences in the public and user schemas.                                                                                                                                                                                                                                                                                                 |
| ALTER ANY INDEX     | Users' ALTER permission on indexes in the public and user schemas. To rename an index, users also need the permission to create objects in the schema where the index is located. If tablespace operations are involved, users need to have the corresponding operation permission on the tablespace. To set an index to <b>UNUSABLE</b> , users must have the DROP ANY INDEX permission. |
| DROP ANY INDEX      | Users' DROP permission on indexes in the public and user schemas.                                                                                                                                                                                                                                                                                                                         |
| CREATE ANY TRIGGER  | Users can create triggers in the public and user schemas.                                                                                                                                                                                                                                                                                                                                 |
| ALTER ANY TRIGGER   | Users' ALTER permission on triggers in the public and user schemas.                                                                                                                                                                                                                                                                                                                       |
| DROP ANY TRIGGER    | Users' DROP permission on triggers in the public and user schemas.                                                                                                                                                                                                                                                                                                                        |
| CREATE ANY SYNONYM  | Users can create synonyms in user schema.                                                                                                                                                                                                                                                                                                                                                 |
| DROP ANY SYNONYM    | Users' DROP permission on synonyms in the public and user schemas.                                                                                                                                                                                                                                                                                                                        |

 **NOTE**

If a user is granted with any ANY permission, the user has the USAGE permission on the public and user schemas but does not have the USAGE permission on the system schemas except public listed in [Table 13-1](#).

## Examples

### Example 1: Grant system permissions to a user or role.

Create the **joe** user and grant the sysadmin permission to it.

```
gaussdb=# CREATE USER joe PASSWORD 'xxxxxxxxxx';
gaussdb=# GRANT ALL PRIVILEGES TO joe;
```

Then **joe** has the sysadmin permission.

### Example 2: Grant object permissions to a user or role.

1. Revoke the sysadmin permission from the **joe** user. Grant the usage permission of the **tpcds** schema and all permissions on the **tpcds.reason** table to **joe**.

```
gaussdb=# CREATE SCHEMA tpcds;
gaussdb=# CREATE TABLE tpcds.reason (
 r_reason_sk INTEGER NOT NULL,
 r_reason_id CHAR(16) NOT NULL,
 r_reason_desc VARCHAR(20)
);
gaussdb=# REVOKE ALL PRIVILEGES FROM joe;
gaussdb=# GRANT USAGE ON SCHEMA tpcds TO joe;
gaussdb=# GRANT ALL PRIVILEGES ON tpcds.reason TO joe;
```

Then **joe** has all permissions on the **tpcds.reason** table, including create, retrieve, update, and delete.

2. Grant the retrieve permission of **r\_reason\_sk**, **r\_reason\_id**, and **r\_reason\_desc** columns and the update permission of the **r\_reason\_desc** column in the **tpcds.reason** table to **joe**.

```
gaussdb=# GRANT select (r_reason_sk,r_reason_id,r_reason_desc),update (r_reason_desc) ON
tpcds.reason TO joe;
```

Then **joe** has the retrieve permission on the **r\_reason\_sk**, **r\_reason\_id**, and **r\_reason\_desc** columns in the **tpcds.reason** table. To enable **joe** to grant these permissions to other users, execute the following statement:

```
gaussdb=# GRANT select (r_reason_sk, r_reason_id) ON tpcds.reason TO joe WITH GRANT OPTION;
```

Grant the connection and schema creation permissions of the **testdb** database to **joe**, and allow **joe** to grant these permissions to other users.

```
gaussdb=# CREATE DATABASE testdb;
gaussdb=# GRANT create,connect on database testdb TO joe WITH GRANT OPTION;
```

Create the **tpcds\_manager** role, grant the access and object creation permissions of the **tpcds** schema to **tpcds\_manager**, but do not allow **tpcds\_manager** to grant these permissions to others.

```
gaussdb=# CREATE ROLE tpcds_manager PASSWORD 'xxxxxxxxxx';
gaussdb=# GRANT USAGE,CREATE ON SCHEMA tpcds TO tpcds_manager;
```

Grant all permissions on the **tpcds\_tbspc** tablespace to **joe**, but do not allow **joe** to grant these permissions to others.

```
gaussdb=# CREATE TABLESPACE tpcds_tbspc RELATIVE LOCATION 'tablespace/tablespace_1';
gaussdb=# GRANT ALL ON TABLESPACE tpcds_tbspc TO joe;
```

3. Create the fun1 function in the tpcds schema, and grants the ALTER permission of the fun1 function to **joe**.

```
gaussdb=# CREATE or replace FUNCTION tpcds.fun1() RETURN boolean AS
BEGIN
 SELECT current_user;
 RETURN true;
END;
/
gaussdb=# GRANT ALTER ON FUNCTION tpcds.fun1() TO joe;
```

**Example 3: Grant a user's or role's permissions to other users or roles.**

1. Create the **manager** role, grant **joe's** permissions to **manager**, and allow **manager** to grant these permissions to others.

```
gaussdb=# CREATE ROLE manager PASSWORD 'xxxxxxxxxx';
gaussdb=# GRANT joe TO manager WITH ADMIN OPTION;
```

2. Create the **senior\_manager** user and grant **manager's** permissions to it.

```
gaussdb=# CREATE ROLE senior_manager PASSWORD 'xxxxxxxxxx';
gaussdb=# GRANT manager TO senior_manager;
```

3. Revoke permissions and delete users.

```
gaussdb=# REVOKE manager FROM joe;
gaussdb=# REVOKE senior_manager FROM manager;
gaussdb=# DROP USER manager;
gaussdb=# DROP DATABASE testdb;
```

**Example 4: Grant the CMK or CEK permission to other users or roles.**

1. Connect to an encrypted database.

```
-- Use the -C parameter to enable the encrypted database function.
```

```
gsqll -p 57101 postgres -r -C
gaussdb=# CREATE CLIENT MASTER KEY MyCMK1 WITH (KEY_STORE = xxx , KEY_PATH = xxx ,
ALGORITHM = AES_256_CBC);
CREATE CLIENT MASTER KEY
gaussdb=# CREATE COLUMN ENCRYPTION KEY MyCEK1 WITH VALUES (CLIENT_MASTER_KEY =
MyCMK1, ALGORITHM = AEAD_AES_256_CBC_HMAC_SHA256);
CREATE COLUMN ENCRYPTION KEY
```

2. Create a role **newuser** and grant the key permission to **newuser**.

```
gaussdb=# CREATE USER newuser PASSWORD 'xxxxxxxxxx';
CREATE ROLE
gaussdb=# GRANT ALL ON SCHEMA public TO newuser;
GRANT
gaussdb=# GRANT USAGE ON COLUMN_ENCRYPTION_KEY MyCEK1 to newuser;
GRANT
gaussdb=# GRANT USAGE ON CLIENT_MASTER_KEY MyCMK1 to newuser;
GRANT
```

3. Set the user to connect to a database and use a CEK to create an encrypted table.

```
gaussdb=# SET ROLE newuser PASSWORD 'xxxxxxxxxx';
gaussdb=> CREATE TABLE acctest1 (x int, x2 varchar(50) ENCRYPTED WITH
(COLUMN_ENCRYPTION_KEY = MyCEK1, ENCRYPTION_TYPE = DETERMINISTIC));
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'x' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=> SELECT has_cek_privilege('newuser', 'MyCEK1', 'USAGE');
has_cek_privilege

t
(1 row)
```

4. Revoke permissions and delete users.

```
gaussdb=# RESET ROLE;
gaussdb=# REVOKE USAGE ON COLUMN_ENCRYPTION_KEY MyCEK1 FROM newuser;
gaussdb=# REVOKE USAGE ON CLIENT_MASTER_KEY MyCMK1 FROM newuser;
gaussdb=# DROP TABLE newuser.acctest1;
gaussdb=# DROP COLUMN ENCRYPTION KEY MyCEK1;
gaussdb=# DROP CLIENT MASTER KEY MyCMK1;
gaussdb=# DROP SCHEMA IF EXISTS newuser CASCADE;
gaussdb=# REVOKE ALL ON SCHEMA public FROM newuser;
gaussdb=# DROP ROLE IF EXISTS newuser;
```

**Example 5: Revoke permissions and delete roles and users.**

```
gaussdb=# REVOKE ALTER ON FUNCTION tpceds.fun1 () FROM joe;
gaussdb=# REVOKE ALL PRIVILEGES ON tpceds.reason FROM joe;
gaussdb=# REVOKE ALL PRIVILEGES ON SCHEMA tpceds FROM joe;
gaussdb=# REVOKE ALL ON TABLESPACE tpceds_tbsp FROM joe;
```

```
gaussdb=# DROP TABLESPACE tpcds_tbspc;
gaussdb=# REVOKE USAGE,CREATE ON SCHEMA tpcds FROM tpcds_manager;
gaussdb=# DROP ROLE tpcds_manager;
gaussdb=# DROP ROLE senior_manager;
gaussdb=# DROP USER joe CASCADE;
gaussdb=# DROP TABLE tpcds.reason;
gaussdb=# DROP FUNCTION tpcds.fun1();
gaussdb=# DROP SCHEMA tpcds CASCADE;
```

## 7.12.13 I

### 7.12.13.1 IMPDP DATABASE CREATE

#### Function

**IMPDP DATABASE CREATE** specifies the preparation phase for importing a database.

#### Syntax

```
IMPDP DATABASE [db_name] CREATE SOURCE = 'directory' OWNER = user [LOCAL];
```

#### Parameter Description

- **db\_name**  
Name of the new database after the import. If this parameter is not specified, the original database name is retained after the import.
- **directory**  
Data source directory of the imported database.
- **user**  
Owner of the imported database.
- **LOCAL**  
If this column is specified, data is imported to the original cluster. If this column is not specified, data is imported to a new cluster.

#### Examples

```
-- The IMPDP DATABASE CREATE syntax is used for fine-grained backup and restoration and is called by the
backup and restoration tool. If you directly call the syntax, an error message may be displayed, indicating
that the directory does not exist. Therefore, you are not advised to directly call the syntax.
gaussdb=# IMPDP DATABASE test CREATE SOURCE = '/data1/impdp/database' OWNER = admin;
```

### 7.12.13.2 IMPDP RECOVER

#### Function

**IMPDP RECOVER** specifies the execution phase of importing a database.

## Syntax

```
IMPDP DATABASE RECOVER SOURCE = 'directory' OWNER = user [LOCAL];
```

## Parameter Description

- **directory**  
Data source directory of the imported database.
- **user**  
Owner of the imported database.
- **LOCAL**  
If this column is specified, data is imported to the original cluster. If this column is not specified, data is imported to a new cluster.

## Examples

```
-- The IMPDP DATABASE RECOVER syntax is used for fine-grained backup and restoration and is called by the backup and restoration tool. If you directly call the syntax, an error message may be displayed, indicating that the directory does not exist. Therefore, you are not advised to directly call the syntax.
gaussdb=# IMPDP DATABASE RECOVER SOURCE = '/data1/impdp/database' owner=admin;
```

### 7.12.13.3 IMPDP TABLE

## Function

**IMPDP TABLE** specifies the execution phase of importing a table.

## Syntax

```
IMPDP TABLE [AS table_name] SOURCE = 'directory' OWNER = user;
```

## Parameter Description

- **table\_name**  
Name of the new table after the import. If this parameter is not specified, the original table name is retained after the import.
- **directory**  
Data source directory of the imported table.
- **user**  
Owner of the imported table.

## Examples

```
-- The IMPDP TABLE syntax is used for fine-grained backup and restoration and is called by the backup and restoration tool. If you directly call the syntax, an error message may be displayed, indicating that the directory does not exist. Therefore, you are not advised to directly call the syntax.
gaussdb=# IMPDP TABLE SOURCE = '/data1/impdp/table0' OWNER=admin;
```

### 7.12.13.4 IMPDP TABLE PREPARE

## Function

**IMPDP TABLE PREPARE** specifies the preparation phase for importing a table.

## Syntax

```
IMPDP TABLE PREPARE SOURCE = 'directory' OWNER = user;
```

## Parameter Description

- **directory**  
Data source directory of the imported table.
- **user**  
Owner of the imported table.

## Examples

```
-- The IMPDP TABLE PREPARE syntax is used for fine-grained backup and restoration and is called by the backup and restoration tool. If you directly call the syntax, an error message may be displayed, indicating that the directory does not exist. Therefore, you are not advised to directly call the syntax.
gaussdb=# IMPDP TABLE PREPARE SOURCE = '/data1/impdp/table0' OWNER=admin;
```

### 7.12.13.5 INSERT

## Description

Inserts one or more rows of data into a table.

## Precautions

- The owner of a table, users granted with the INSERT permission on the table, or users granted with the INSERT ANY TABLE permission can insert data into the table. The system administrator has the permission to insert data into the table by default when separation of duties is disabled.
- Use of the RETURNING clause requires the SELECT permission on all columns mentioned in RETURNING.
- If ON DUPLICATE KEY UPDATE is used, you must have the INSERT and UPDATE permissions on the table and the SELECT permission on the columns of the UPDATE clause.
- If you use the query clause to insert rows from a query, you need to have the SELECT permission on any table or column used in the query.
- If you use the query clause to insert data from the dynamic data anonymization column, the inserted result is the anonymized value and cannot be restored.
- When you connect to a database compatible to Teradata and **td\_compatible\_truncation** is **on**, a long string will be automatically truncated. If later INSERT statements (not involving foreign tables) insert long strings to columns of CHAR- and VARCHAR-typed columns in the target table, the system will truncate the long strings to ensure no strings exceed the maximum length defined in the target table.

### NOTE

If inserting multi-byte character data (such as Chinese characters) into a database with the character set byte encoding (SQL\_ASCII, LATIN1), and the character data crosses the truncation position, the string is truncated based on its bytes instead of characters. Unexpected result will occur in tail after the truncation. If you want correct truncation result, you are advised to adopt encoding set such as UTF8, which has no character data crossing the truncation position.

## Syntax

```
[WITH [RECURSIVE] with_query [, ...]]
INSERT [/*+ plan_hint */] [IGNORE] INTO table_name [{ [alias_name] [(column_name [, ...])] } |
{ [partition_clause] [AS alias] [(column_name [, ...])] }]
{ DEFAULT VALUES
| { VALUES | VALUE } { ({ expression | DEFAULT } [, ...]) }, ...
| query }
[ON DUPLICATE KEY UPDATE { NOTHING | { column_name = { expression | DEFAULT } } [, ...] [WHERE
condition] }]
[RETURNING { * | {output_expression [[AS] output_name] }, ...}];
```

Insert subqueries and views.

```
[WITH [RECURSIVE] with_query [, ...]]
INSERT [/*+ plan_hint */] INTO {subquery | view_name} [AS alias] [(column_name [, ...])]
{ DEFAULT VALUES
| { VALUES | VALUE } { ({ expression | DEFAULT } [, ...]) }, ...
| query }
[RETURNING { * | {output_expression [[AS] output_name] }, ...}];
```

## Parameters

- **WITH [ RECURSIVE ] with\_query [, ...]**

Specifies one or more subqueries that can be referenced by name in the main query, which is equivalent to a temporary table.

If **RECURSIVE** is specified, a SELECT subquery can be referenced by name.

Format of **with\_query**:

```
with_query_name [(column_name [, ...])] AS [[NOT] MATERIALIZED]
({SELECT | VALUES | INSERT | UPDATE | DELETE})
```

- **with\_query\_name** specifies the name of the result set generated by a subquery. Such names can be used to access the result sets of subqueries in a query.

- **column\_name** specifies the column name displayed in the subquery result set.

- Each subquery can be a SELECT, VALUES, INSERT, UPDATE or DELETE statement.

### NOTICE

If a subquery is a DML statement with a RETURNING statement, the number of command output records of the INSERT statement is determined by the subquery. Assume that table **T1** exists. Run the following statement:

```
WITH CTE AS (INSERT INTO T1 VALUES(1,2) RETURNING *) INSERT INTO T1 SELECT * FROM CTE;
```

The number of command output records of the preceding statement is determined by the following part instead of the entire statement. That is, the command output is "INSERT 0 1" instead of "INSERT 0 2".

```
INSERT INTO T1 VALUES(1,2) RETURNING *
```

- You can use **MATERIALIZED** or **NOT MATERIALIZED** to modify the CTE.

- If **MATERIALIZED** is specified, the WITH query will be materialized, and a copy of the subquery result set is generated. The copy is directly queried at the reference point. Therefore, the WITH subquery cannot be jointly optimized with the SELECT statement trunk (for example, predicate pushdown and equivalence class transfer). In this scenario, you can use

**NOT MATERIALIZED** for modification. If the WITH query can be executed as a subquery inline, the preceding optimization can be performed.

- If the user does not explicitly declare the materialized attribute, comply with the following rules: If the CTE is referenced only once in the trunk statement to which it belongs and semantically supports inline execution, it will be rewritten as subquery inline execution. Otherwise, the materialized execution will be performed in CTE Scan mode.

 **NOTE**

INSERT ON DUPLICATE KEY UPDATE does not support the WITH or WITH RECURSIVE clauses.

- **plan\_hint** clause

Follows the INSERT keyword in the */\*+ \*/* format. It is used to optimize the plan of an INSERT statement block. For details, see [Hint-based Tuning](#). In each statement, only the first */\*+ plan\_hint \*/* comment block takes effect as a hint. Multiple hints can be written.

- **IGNORE**

When the INSERT statement uses the IGNORE keyword, some ERROR-level errors can be degraded to WARNING-level errors, and invalid values can be adjusted to the closest values based on error scenarios. GaussDB supports the following error codes for error downgrade:

- Damage to the NOT NULL constraint
- UNIQUE KEY conflict
- No partition found for the inserted value
- Unmatch between the inserted data and the specified partition
- Multiple rows returned for a subquery
- Oversized data
- Time function overflow
- Division by 0
- Incorrect value

 NOTE

1. INSERT IGNORE is supported only when **sql\_compatibility** is set to 'MySQL', **b\_format\_version** set to '5.7', and **b\_format\_dev\_version** set to 's1'.
2. INSERT IGNORE does not support encrypted tables and foreign tables.
3. INSERT IGNORE does not support PRIMARY KEY constraints or UNIQUE KEY constraints that take effect with a delay.
4. The OIDs of each data type that supports damage to NOT NULL constraints with NULL values are TIMESTAMPOID, TIMESTAMPTZOID, TIMEOID, TIMETZOID, RELTIMEOID, INTERVALOID, TINTERVALOID, SMALLDATETIMEOID, DATEOID, NAMEOID, POINTOID, PATHOID, POLYGONOID, CIRCLEOID, LSEGOID, BOXOID, JSONOID, JSONBOID, XMLOID, XMLTYPEOID, VARBITOID, NUMERICOID, CIDROID, INETOID, MACADDROID, NUMRANGEOID, INT8RANGEOID, INT4RANGEOID, TSRANGEOID, TSTZRANGEOID, DATERANGEOID, ABSTIMEOID, BOOLOID, INT8OID, INT4OID, INT2OID, INT1OID, FLOAT4OID, FLOAT8OID, CASHOID, UINT1OID, UINT2OID, UINT4OID, UINT8OID, BPCHAROID, VARCHAROID, NVARCHAR2OID, CHAROID, BYTEAOID, RAWOID, BLOBOID, CLOBOID, TEXTOID, and YEAROID. [Table 7-244](#) lists the zero values of each data type.
5. When the default zero value is used for calculation, exercise caution when using IGNORE to ignore the NOT NULL constraint.
6. INSERT IGNORE does not support tables with global secondary indexes.
7. An error generated on a CN is degraded to the warning information while an error generated on a DN is not degraded to the warning information.

**Table 7-244** Default zero values for the data type

| OID of Each Data Type                                                                                         | Default Zero Value                                                                |
|---------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| INT8OID, INT4OID, INT2OID, INT1OID, UINT1OID, UINT2OID, UINT4OID, UINT8OID, FLOAT4OID, FLOAT8OID, NUMERICOID  | 0 or 0.00 (The number of 0s after the decimal point is specified by a parameter.) |
| BPCHAROID, VARCHAROID, CHAROID, BYTEAOID, RAWOID, BLOBOID, NVARCHAR2OID, CLOBOID, TEXTOID, VARBITOID, NAMEOID | Empty string                                                                      |
| NUMRANGEOID, INT8RANGEOID, INT4RANGEOID, TSRANGEOID, TSTZRANGEOID, DATERANGEOID                               | empty                                                                             |
| TIMEOID                                                                                                       | time '00:00:00'                                                                   |
| TIMETZOID                                                                                                     | timetz '00:00:00'                                                                 |
| INTERVALOID                                                                                                   | interval '00:00:00'                                                               |
| TINTERVALOID                                                                                                  | tinterval(abstime '1970-01-01 00:00:00', abstime '1970-01-01 00:00:00')           |
| SMALLDATETIMEOID                                                                                              | smalldatetime '1970-01-01 00:00:00'                                               |
| ABSTIMEOID                                                                                                    | abstime '1970-01-01 00:00:00'                                                     |

| OID of Each Data Type        | Default Zero Value  |
|------------------------------|---------------------|
| RELTIMEOID                   | reltime '00:00:00'  |
| TIMESTAMPOID, TIMESTAMPTZOID | 1970-01-01 00:00:00 |
| DATEOID                      | 1970-01-01          |
| YEAROID                      | 0000                |
| POINTOID                     | (0,0)               |
| PATHOID, POLYGONOID          | ((0,0))             |
| CIRCLEOID                    | <(0,0),0>           |
| LSEGOID                      | [(0,0),(0,0)]       |
| BOXOID                       | (0,0),(0,0)         |
| JSONOID, JSONBOID, XMLOID    | 'null'              |
| XMLTYPEOID                   | '<null/>'           |
| CIDROID                      | 0.0.0.0/32          |
| INETOID                      | 0.0.0.0             |
| MACADDROID                   | 00:00:00:00:00:00   |
| BOOLOID                      | f                   |
| CASHOID                      | \$0.00              |

- **table\_name**

Specifies the name of the target table where data will be inserted.

Value range: an existing table name

 **NOTE**

You can use database links to perform operations on remote tables. For details, see [DATABASE LINK](#).

- **subquery**

The inserted object can be a subquery. When a subquery is inserted, the subquery is regarded as a temporary view. The **CHECK OPTION** option can be added to the end of the subquery.

```
[WITH [RECURSIVE] with_query [, ...]]
SELECT [/*+ plan_hint */] [ALL]
{ * | {expression [[AS] output_name]} [, ...] }
[into_option]
[FROM from_item [, ...]]
[WHERE condition]
[[START WITH condition] CONNECT BY [NOCYCLE] condition [ORDER SIBLINGS BY expression]]
[ORDER BY {expression [[ASC | DESC | USING operator] | nlssort_expression_clause] [NULLS
{ FIRST | LAST } }] [, ...]]
[FETCH { FIRST | NEXT } [count] { ROW | ROWS } ONLY]
[into_option];
```

The specified subquery source **from\_item** is as follows:

```
{[ONLY] {table_name | view_name} [*] [partition_clause] [[AS] alias [(column_alias [, ...])]]
{ (select) [AS] alias [(column_alias [, ...])]
|with_query_name [[AS] alias [(column_alias [, ...])]]
|from_item [NATURAL] join_type from_item [ON join_condition | USING (join_column [, ...])] }
```

If a subquery contains only one table, data is inserted into the table. If a subquery contains multiple tables or has nested relationships, check whether a key-preserved table exists to determine whether data can be inserted. For details about key-preserved tables and **WITH CHECK OPTION**, see [CREATE VIEW](#).

- **view\_name**

Indicates the target view to be inserted.

 **NOTE**

The restrictions on inserting views and subqueries are as follows:

- The INSERT operation can be performed only on columns that directly reference user columns in the base table.
  - A subquery or view must contain at least one updatable column. For details about updatable columns, see [CREATE VIEW](#).
  - Views and subqueries that contain the DISTINCT, GROUP BY, HAVING, LIMIT or OFFSET clause at the top layer are not supported.
  - Views and subqueries that contain set operations (UNION, INTERSECT, EXCEPT, and MINUS) at the top layer are not supported.
  - Views and subqueries whose target lists contain aggregate functions, window functions, or return set functions (such as array\_agg, json\_agg, and generate\_series) are not supported.
  - Views with BEFORE/AFTER triggers but without INSTEAD OF triggers or INSTEAD rules are not supported.
  - The ON DUPLICATE KEY UPDATE function is not supported.
  - Table types supported in views and subqueries include ordinary tables, temporary tables, global temporary tables, partitioned tables, level-2 partitioned tables, Ustore tables, and Astore tables.
  - For a multi-table join view or subquery, only one base table can be inserted at a time.
  - When INSERT joins a view or subquery, explicitly specified columns to be inserted or implicitly specified columns (columns specified during view or subquery creation) cannot reference columns of non-key-preserved tables; if the WITH CHECK OPTION clause is used, INSERT operations cannot be performed on join columns in join views or subqueries. For details about the key-preserved table, see [CREATE VIEW](#).
  - The INSERT operation cannot be performed on the system view.
- **alias\_name**

Specifies the table alias when the INSERT statement is used without AS alias.

 **NOTE**

1. When the INSERT statement is used without AS alias, the table alias cannot be a keyword (such as SELECT and VALUE) or an expression. The alias must comply with the identifier naming rule.
2. When the INSERT statement is used without AS alias, the table alias cannot be in the INSERT INTO table\_name alias\_name(alias\_name.col1, ...,alias\_name.coln) VALUES(xxx); format.
3. When the INSERT statement is used without AS alias, data cannot be inserted into the specified partition.

- **partition\_clause**

Inserts data to a specified partition.

```
PARTITION { (partition_name) | FOR (partition_value [, ...]) }
```

For details about the keywords, see [SELECT](#).

If the value of the VALUE clause is inconsistent with that of the specified partition, an exception is displayed.

- **column\_name**

Specifies the name of a column in a table.

- The column name can be qualified with a subcolumn name or array index, if needed.
- Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or **NULL** if there is none. Inserting data into only some columns of a composite type leaves the other columns **NULL**.
- The target column names **column\_name** can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order.
- The target columns are the first *N* column names, if there are only *N* columns provided by the VALUE clause and QUERY.
- The values provided by the VALUE clause and QUERY are joined with the corresponding columns from left to right in the table.

Value range: an existing column

- **expression**

Specifies an expression or a value to assign to the corresponding column.

- In the INSERT ON DUPLICATE KEY UPDATE statement, expression can be **VALUES(column\_name)** or **EXCLUDED.column\_name**, indicating that the value of **column\_name** corresponding to the conflict row is referenced. **VALUES(column\_name)** can be nested in a compound expression, for example, **VALUES(column\_name)+1**, **VALUES(column\_name)+VALUES(column\_name)**, and **function\_name(VALUES(column\_name))**.

 **NOTE**

- **VALUES(column\_name)** can be used only in the ON DUPLICATE KEY UPDATE clause.
- **VALUES(column\_name)** cannot be used in the IN or NOT IN expressions.
- If single-quotation marks are inserted into a column, the single-quotation marks need to be used for escape.
- If the expression for any column is not of the correct data type, automatic type conversion will be attempted. If the attempt fails, data insertion fails, and the system returns an error message.

- **DEFAULT**

Specifies the default value of a column. The value is **NULL** if no default value is assigned to it.

- **query**

Specifies a query statement (SELECT statement) that uses the query result as the inserted data.

- **RETURNING**  
Returns the inserted rows. The syntax of the RETURNING list is identical to that of the output list of SELECT.
- **output\_expression**  
Specifies an expression used to calculate the output result of the INSERT statement after each row is inserted.  
Value range: The expression can use any column in the table. You can use the asterisk (\*) to return all columns of the inserted row.
- **output\_name**  
Specifies a name to use for a returned column.  
Value range: a string. It must comply with the [naming convention](#).
- **ON DUPLICATE KEY UPDATE**  
For a table with a unique constraint (UNIQUE INDEX or PRIMARY KEY), if the inserted data violates the unique constraint, the UPDATE clause is executed to update the conflicting rows. If **NOTHING** is specified for the UPDATE clause, no operation will be performed. You can use **EXCLUDED.** or **VALUES()** to select the column corresponding to the source data.  
For a table without a unique constraint, only insert is performed.
  - Triggers are supported. The execution sequence of triggers is determined by the actual execution process.
    - Executing INSERT will trigger the BEFORE INSERT and AFTER INSERT triggers.
    - Executing UPDATE will trigger the BEFORE INSERT, BEFORE UPDATE, and AFTER UPDATE triggers.
    - Executing UPDATE NOTHING will trigger the BEFORE INSERT trigger.
  - The unique constraint or primary key of DEFERRABLE is not supported.
  - If a table has multiple unique constraints and the inserted data violates multiple unique constraints, only the first row that has a conflict is updated. (The check sequence is closely related to index maintenance. Generally, the conflict check is performed on the index that is created first.)
  - Primary keys and unique index columns cannot be updated.
  - Foreign tables are not supported.
  - The WHERE clause and expression of UPDATE cannot contain sublinks.

## Examples

- **Insert a data record.**

**Example:**

```
-- Create a table.
gaussdb=# CREATE TABLE test_t1(col1 INT,col2 VARCHAR);

-- Insert data.
gaussdb=# INSERT INTO test_t1 (col1, col2) VALUES (1,'AB');

-- Add values to some columns of the table.
gaussdb=# INSERT INTO test_t1 (col1) VALUES (2);
```

```
-- There is no parenthesis on the left of the VALUES keyword. Values must be added to all fields in
the parenthesis on the right according to the table structure sequence.
gaussdb=# INSERT INTO test_t1 VALUES (3,'AC');

-- Query the table.
gaussdb=# SELECT * FROM test_t1;
 col1 | col2
-----+-----
 1 | AB
 2 |
 3 | AC
(3 rows)

-- Delete.
gaussdb=# DROP TABLE test_t1;
```

- **Insert multiple data records.**

**Example:**

```
-- Create a table.
gaussdb=# CREATE TABLE test_t2(col1 INT,col2 VARCHAR);
gaussdb=# CREATE TABLE test_t3(col1 INT,col2 VARCHAR);

-- Insert multiple data records.
gaussdb=# INSERT INTO test_t2 (col1, col2) VALUES (10,'AA'),(20,'BB'),(30,'CC');

-- Query.
gaussdb=# SELECT * FROM test_t2;
 col1 | col2
-----+-----
 10 | AA
 20 | BB
 30 | CC
(3 rows)

-- Insert data in test_t2 into test_t3.
gaussdb=# INSERT INTO test_t3 SELECT * FROM test_t2;

-- Query.
gaussdb=# SELECT * FROM test_t3;
 col1 | col2
-----+-----
 10 | AA
 20 | BB
 30 | CC
(3 rows)

-- Delete.
gaussdb=# DROP TABLE test_t2;
DROP TABLE test_t3;
```

- **ON DUPLICATE KEY UPDATE**

**Example:**

```
-- Create a table.
gaussdb=# CREATE TABLE test_t4 (id INT PRIMARY KEY, info VARCHAR(10));
gaussdb=# INSERT INTO test_t4 VALUES (1, 'AA'), (2,'BB'), (3, 'CC');

-- Use the ON DUPLICATE KEY UPDATE keyword.
gaussdb=# INSERT INTO test_t4 VALUES (3, 'DD'), (4, 'EE') ON DUPLICATE KEY UPDATE info =
VALUES(info);

-- Query.
gaussdb=# SELECT * FROM test_t4;
 id | info
----+----
 1 | AA
 2 | BB
 4 | EE
 3 | DD
```

```
-- Delete.
gaussdb=# DROP TABLE test_t4;
```

- **INSERT IGNORE**

**Example 1: Damage to the NOT NULL constraint**

```
-- Create a table.
gaussdb=# CREATE TABLE test_t5(f1 INT NOT NULL);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
```

```
-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t5 VALUES(NULL);
WARNING: null value in column "f1" violates not-null constraint
DETAIL: Failing row contains (null).
INSERT 0 1
```

```
-- Query the table.
gaussdb=# SELECT * FROM test_t5;
f1

0
(1 row)
```

```
-- Drop the table.
gaussdb=# DROP TABLE test_t5;
DROP TABLE
```

**Example 2: UNIQUE KEY conflict**

```
-- Create a table.
gaussdb=# CREATE TABLE test_t6(f1 INT PRIMARY KEY);
NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "test_t6_pkey" for table "test_t6"
CREATE TABLE
```

```
-- Insert data.
gaussdb=# INSERT INTO test_t6 VALUES(1);
INSERT 0 1
```

```
-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t6 VALUES(1);
INSERT 0 0
```

```
-- Query the table.
gaussdb=# SELECT * FROM test_t6;
f1

1
(1 row)
```

```
-- Drop the table.
gaussdb=# DROP TABLE test_t6;
DROP TABLE
```

**Example 3: No partition found for the inserted value**

```
-- Create a table.
gaussdb=# CREATE TABLE test_t7(f1 INT, f2 INT) PARTITION BY LIST(f1) (PARTITION p0 VALUES(1, 4, 7), PARTITION p1 VALUES (2, 5, 8));
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
```

```
-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t7 VALUES(3, 5);
INSERT 0 0
```

```
-- Query the table.
gaussdb=# SELECT * FROM test_t7;
f1 | f2
----+----
```

```
(0 rows)
-- Drop the table.
gaussdb=# DROP TABLE test_t7;
DROP TABLE
```

#### Example 4: Unmatch between the inserted data and the specified partition

```
-- Create a table.
gaussdb=# CREATE TABLE test_t8(f1 INT NOT NULL, f2 TEXT, f3 INT) PARTITION BY RANGE(f1)
(PARTITION p0 VALUES LESS THAN(5), PARTITION p1 VALUES LESS THAN(10), PARTITION p2
VALUES LESS THAN(15), PARTITION p3 VALUES LESS THAN(MAXVALUE));
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t8 PARTITION(p2) VALUES(20, 'Jan', 1);
INSERT 0 0

-- Query the table.
gaussdb=# SELECT * FROM test_t8;
 f1 | f2 | f3
----+----+----
(0 rows)

-- Drop the table.
gaussdb=# DROP TABLE test_t8;
DROP TABLE
```

#### Example 5: Multiple rows returned for a subquery

```
-- Create a table.
gaussdb=# CREATE TABLE test_t9(f1 INT, f2 INT);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

-- Insert data.
gaussdb=# INSERT INTO test_t9 VALUES(1, 1), (2, 2), (3, 3);
INSERT 0 3

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t9 VALUES((SELECT f1 FROM test_t9), 0);
WARNING: more than one row returned by a subquery used as an expression
CONTEXT: referenced column: f1
INSERT 0 1

-- Query the table.
gaussdb=# SELECT * FROM test_t9 WHERE f2 = 0;
 f1 | f2
----+----
 | 0
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE test_t9;
DROP TABLE
```

#### Example 6: Oversized data

```
-- Create a table.
gaussdb=# CREATE TABLE test_t10(f1 VARCHAR(5));
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t10 VALUES('aaaaaaaaa');
WARNING: value too long for type character varying(5)
CONTEXT: referenced column: f1
```

```
INSERT 0 1
-- Query the table.
gaussdb=# SELECT * FROM test_t10;
 f1

aaaaa
(1 row)
-- Drop the table.
gaussdb=# DROP TABLE test_t10;
DROP TABLE
```

### Example 7: Time function overflow

```
-- Create a table.
gaussdb=# CREATE TABLE test_t11(f1 DATETIME);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'f1' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t11 VALUES(date_sub('2000-01-01', INTERVAL 2001 YEAR));
WARNING: Datetime function: datetime field overflow
CONTEXT: referenced column: f1
INSERT 0 1
-- Query the table.
gaussdb=# SELECT * FROM test_t11;
 f1

(1 row)
-- Drop the table.
gaussdb=# DROP TABLE test_t11;
DROP TABLE
```

### Example 8: Division by 0

```
-- Create a table.
gaussdb=# CREATE TABLE test_t12(f1 INT);
CREATE TABLE
-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t12 VALUES(1/0);
WARNING: division by zero
CONTEXT: referenced column: f1
INSERT 0 1
-- Query the table.
gaussdb=# SELECT * FROM test_t12;
 f1

(1 row)
-- Drop the table.
gaussdb=# DROP TABLE test_t12;
DROP TABLE
```

### Example 9: Incorrect value

```
-- Create a table.
gaussdb=# CREATE TABLE test_t13(f0 INT, f1 FLOAT);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'f0' as the distribution column by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
-- Use the IGNORE keyword.
gaussdb=# INSERT IGNORE INTO test_t13 VALUES(1, '1.11aaa');
WARNING: invalid input syntax for type real: "1.11aaa"
LINE 1: INSERT IGNORE INTO test_t13 VALUES(1, '1.11aaa');
```

```

 ^
CONTEXT: referenced column: f1
INSERT 0 1

-- Query the table.
gaussdb=# SELECT * FROM test_t13;
 f0 | f1
-----+-----
 1 | 1.11
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE test_t13;
DROP TABLE

```

- **WITH [ RECURSIVE ] with\_query [, ...]**

**Example:**

```

-- Grade table.
gaussdb=# CREATE TABLE grade (
 sid INT,
 course VARCHAR(20),
 score FLOAT
);
-- Student table.
gaussdb=# CREATE TABLE student(
 sid INT PRIMARY KEY,
 class INT,
 name VARCHAR(50),
 sex INT CHECK (sex = 0 or sex = 1)
);
-- Insert data.
gaussdb=# WITH student_sid AS (INSERT INTO student (sid, CLASS, NAME, sex) VALUES (1, 1,
'scott', 1) RETURNING sid)
 INSERT INTO grade (sid, course, score)
 VALUE ((SELECT sid FROM student_sid), 'match', '96'),
 ((SELECT sid FROM student_sid), 'chinese', '82'),
 ((SELECT sid FROM student_sid), 'english', '86');

-- Query data.
gaussdb=# SELECT * FROM student;
 sid | class | name | sex
-----+-----+-----+----
 1 | 1 | scott | 1
(1 row)

gaussdb=# SELECT * FROM grade;
 sid | course | score
-----+-----+-----
 1 | match | 96
 1 | chinese | 82
 1 | english | 86
(3 rows)

-- Delete.
gaussdb=# DROP TABLE student;
gaussdb=# DROP TABLE grade;

```

- **Insert data into a view or subquery.**

**Example 1: Insert a subquery.**

```

-- Create a schema.
gaussdb=# CREATE SCHEMA ins_subqry;
CREATE SCHEMA
gaussdb=# SET CURRENT_SCHEMA = 'ins_subqry';
SET

-- Create tables.
gaussdb=# CREATE TABLE t1 (x1 int, y1 int);

```

```
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using 'x1' as the distribution column by default.

drop cascades to view ins_view.vv_ins
DROP SCHEMA
```

## Suggestions

- **VALUES**

When you run the INSERT statement to insert data in batches, you are advised to combine multiple records into one statement to improve data loading performance.

Example:

```
INSERT INTO sections VALUES (30, 'Administration', 31, 1900),(40, 'Development', 35, 2000), (50, 'Development', 60, 2001);
```

If values of an INSERT statement are distributed on a DN, GaussDB can push the statement down to the corresponding DN for execution. Currently, only constants, simple expressions, and pushdown functions (**provolatile** in **pg\_proc** is set to 'i') are supported. If a column in the table has a default value, the value must be a constant or a simple expression. Neither a single-value statement nor a multi-value statement can be pushed down to a single DN.

## 7.12.14 L

### 7.12.14.1 LOAD DATA

#### Description

Imports data from a file to a specified table in the database.

#### Precautions

- The LOAD DATA syntax is supported only when **sql\_compatibility** is set to 'MYSQL'.
- The LOAD DATA syntax is the same as that of database MySQL only when **b\_format\_version** is set to '5.7' and **b\_format\_dev\_version** is set to 's2'.

- The GUC parameters related to the LOAD DATA syntax are the same as those of the COPY FROM syntax. For details, see [Precautions](#).
- The LOAD DATA syntax requires the INSERT and DELETE permissions on tables.
- If the data written to a table by running **LOAD DATA** cannot be converted to the data type of the table, the import fails.
- LOAD DATA applies only to tables but not views.

## Syntax

```
LOAD DATA
 [LOCAL]
 INFILE 'file_name'
 [REPLACE | IGNORE]
 INTO TABLE tbl_name
 [PARTITION (partition_name [, partition_name] ...)]
 [CHARACTER SET charset_name]
 [{FIELDS | COLUMNS}
 [TERMINATED BY 'string']
 [[OPTIONALLY] ENCLOSED BY 'char']
 [ESCAPED BY 'char']
]
 [LINES
 [STARTING BY 'string']
 [TERMINATED BY 'string']
]
 [IGNORE number {LINES | ROWS}]
 [(col_name_or_user_var
 [, col_name_or_user_var] ...)]
 [SET col_name={expr | DEFAULT}
 [, col_name={expr | DEFAULT}] ...]
```

## Parameters

- **LOCAL**  
Specifies the location of the file to be imported.  
If **LOCAL** is not specified and **file\_name** is a relative path, data is imported to the data directory by default.  
If the **LOCAL** parameter is specified, **file\_name** must be set to an absolute path. If **file\_name** is set to a relative path, data is imported to the location of the database binary file by default, that is, *\$GAUSSHOME/bin/*.

### NOTE

If the imported data conflicts with the table data or the number of columns in the file is less than the number of columns in the specified table, the function of specifying **LOCAL** is the same as that of specifying **IGNORE**.

- **REPLACE | IGNORE**  
If the data to be imported conflicts with the original data in the table, specifying **REPLACE** replaces the conflicting data, and specifying **IGNORE** skips the conflicting data and continues the import. If data conflicts occur but none of **REPLACE**, **IGNORE**, or **LOCAL** is specified, the import stops and an error is reported.

### NOTE

If the number of columns in the file is less than that in the specified table, specifying **IGNORE** or **LOCAL** will assign default values to the remaining columns. If **IGNORE** or **LOCAL** is not specified, an error is reported.

- **PARTITION**

If the table to be imported is a partitioned table, this parameter specifies a partition. If the data is inconsistent with the specified partition range, an error is reported.
- **CHARACTER SET**

Specifies the encoding format of a data file. The default value is the current client encoding format.
- **FIELDS | COLUMNS**
  - **TERMINATED BY**

Specifies the delimiter between columns. The default value is "\t".

 **NOTE**

The specified newline character cannot be the same as the delimiter.
  - **[OPTIONALLY] ENCLOSED BY**

Specifies the quotation mark character. The default value is "".

The **OPTIONALLY** parameter is optional and does not take effect.

The quotation mark can only be a single character and cannot be a character string.
  - **ESCAPED BY**

Specifies the escape character. The default value is "\".

The escape character can only be a single character and cannot be a character string.
- **LINES**
  - **STARTING BY**

Specifies the style of the starting field in the data file to be imported.
  - **TERMINATED BY**

Specifies the newline character style of the imported data file.
- **IGNORE**

Specifies that the first *number* rows of the data file are skipped during data import.
- **col\_name\_or\_user\_var**

Specifies an optional list of columns to be copied.

Value range: any columns. All columns will be copied if no column list is specified.

 **NOTE**

  - The parameter for specifying columns cannot be used to specify a column repeatedly.
  - When columns are specified using the LOAD DATA syntax, **col\_name\_or\_user\_var** can only be specified as existing columns but not user variables.
- **SET**

Specifies the column value, which can be an expression or **DEFAULT**.

 NOTE

- The expression does not support column names.
- If no implicit conversion exists between the expression result type and the type of the assigned column, an error is reported.

## Examples

```
-- Create a table.
gaussdb=# CREATE TABLE load_data_tbl1(load_col1 INT UNIQUE, load_col2 INT, load_col3 CHAR(10));

-- Insert a data record into a table.
gaussdb=# INSERT INTO load_data_tbl1 VALUES(0,0,'load0');

-- Copy data from the /home/omm/load1.csv file to the load_data_tbl1 table, specify a column name, and
set the value of the load_col3 column to load.
gaussdb=# LOAD DATA INFILE '/home/omm/load1.csv' INTO TABLE load_data_tbl1(load_col1, load_col2)
SET load_col3 = 'load';
-- The values imported to the load_col3 column later are all load.
gaussdb=# SELECT * FROM load_data_tbl1;
load_col1 | load_col2 | load_col3
-----+-----+-----
0 | 0 | load0
3 | 3 | load
1 | 1 | load
2 | 2 | load
(4 rows)

-- Copy data from the /home/omm/load2.csv file to the load_data_tbl1 table and specify IGNORE to
ignore conflicts.
gaussdb=# LOAD DATA INFILE '/home/omm/load2.csv' IGNORE INTO TABLE load_data_tbl1;
-- Data in the load_data_tbl1 table remains unchanged, and conflicting data is skipped.
gaussdb=# SELECT * FROM load_data_tbl1;
load_col1 | load_col2 | load_col3
-----+-----+-----
0 | 0 | load0
3 | 3 | load
1 | 1 | load
2 | 2 | load
(4 rows)

-- Create a partitioned table.
gaussdb=# CREATE TABLE load_data_tbl2
(
 load_col_col1 INT,
 load_col_col2 INT
) PARTITION BY RANGE (load_col_col2)
(
 PARTITION load_p1 VALUES LESS THAN(3),
 PARTITION load_p2 VALUES LESS THAN(9),
 PARTITION load_p3 VALUES LESS THAN(MAXVALUE)
);

-- Copy data from the /home/omm/load3.csv file to the load_data_tbl2 table and specify a partition.
gaussdb=# LOAD DATA INFILE '/home/omm/load3.csv' INTO TABLE load_data_tbl2 PARTITION (load_p2);
-- Import data to the specified partition in the load_data_tbl2 table.
gaussdb=# SELECT * FROM load_data_tbl2;
load_col_col1 | load_col_col2
-----+-----
4 | 4
5 | 5
(2 rows)

-- Create a table.
gaussdb=# CREATE TABLE load_data_tbl3(load_col_col1 CHAR(30));

-- Copy data from the /home/omm/load4.csv file to the load_data_tbl3 table and specify FIELDS
ENCLOSED BY.
```

```
gaussdb=# LOAD DATA INFILE '/home/omm/load4.csv' INTO TABLE load_data_tbl3 FIELDS ENCLOSED BY '"';
-- The double quotation marks of "load test quote" are removed, and the single quotation marks of 'load
test single_quote' are retained.
gaussdb=# select * from load_data_tbl3;
load_col_col1

load test quote
'load test single_quote'
(2 rows)
-- Delete the table.
gaussdb=# drop table load_data_tbl1;
gaussdb=# DROP TABLE load_data_tbl2;
gaussdb=# DROP TABLE load_data_tbl3;
```

## 7.12.14.2 LOCK

### Description

LOCK TABLE obtains a table-level lock.

GaussDB always tries to select the lock mode with minimum constraints when automatically requesting a lock for a statement referenced by a table. Use **LOCK** if users need a more strict lock mode. For example, suppose an application runs a transaction at the Read Committed isolation level and needs to ensure that data in a table remains stable in the duration of the transaction. To achieve this, you could obtain **SHARE** lock mode over the table before the query. This can prevent concurrent data changes and ensure subsequent reads of the table see a stable view of committed data. It is because the **SHARE** lock mode conflicts with the **ROW EXCLUSIVE** lock acquired by writers, and your **LOCK TABLE name IN SHARE MODE** statement will wait until any concurrent holders of **ROW EXCLUSIVE** mode locks commit or roll back. Therefore, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

### Precautions

- **LOCK TABLE** is useless outside a transaction block: the lock would remain held only to the completion of the statement. If **LOCK TABLE** is out of any transaction block, an error is reported.
- If no lock mode is specified, then **ACCESS EXCLUSIVE**, the most restrictive mode, is used.
- **LOCK TABLE ... IN ACCESS SHARE MODE** requires the **SELECT** permission on the target table. All other forms of **LOCK** require table-level **UPDATE** and/or the **DELETE** permission.
- There is no **UNLOCK TABLE** statement. Locks are always released at transaction end.
- **LOCK TABLE** only deals with table-level locks, and so the mode names involving **ROW** are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, **ROW EXCLUSIVE** mode is a shareable table lock. Note that all lock modes have the same semantics as long as **LOCK TABLE** is involved. The only difference lies in whether locks conflict with each other. For details about the rules, see [Table 7-245](#).
- If the `xc_maintenance_mode` parameter is not enabled, an error is reported when an **ACCESS EXCLUSIVE** lock is applied for a system catalog.

- Only the redistribution tool can use the automatic CANCEL service interface.

## Syntax

```
LOCK [TABLE] {[ONLY] name [, ...]} {name [*]} [, ...]
 [IN {ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE | SHARE | SHARE
ROW EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE} MODE]
 [NOWAIT][CANCELABLE];
```

## Parameters

**Table 7-245** Lock mode conflicts

| Requested Lock Mode/<br>Current Lock Mode | ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE | SHARE | SHARE ROW EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE |
|-------------------------------------------|--------------|-----------|---------------|------------------------|-------|---------------------|-----------|------------------|
| ACCESS SHARE                              | -            | -         | -             | -                      | -     | -                   | -         | X                |
| ROW SHARE                                 | -            | -         | -             | -                      | -     | -                   | X         | X                |
| ROW EXCLUSIVE                             | -            | -         | -             | -                      | X     | X                   | X         | X                |
| SHARE UPDATE EXCLUSIVE                    | -            | -         | -             | X                      | X     | X                   | X         | X                |
| SHARE                                     | -            | -         | X             | X                      | -     | X                   | X         | X                |
| SHARE ROW EXCLUSIVE                       | -            | -         | X             | X                      | X     | X                   | X         | X                |
| EXCLUSIVE                                 | -            | X         | X             | X                      | X     | X                   | X         | X                |
| ACCESS EXCLUSIVE                          | X            | X         | X             | X                      | X     | X                   | X         | X                |

**LOCK** parameters are as follows:

- **name**

Specifies the name (optionally schema-qualified) of an existing table to lock. Tables are locked one-by-one in the order specified in the **LOCK TABLE** statement.

Value range: an existing table name

 **NOTE**

You can use database links to perform operations on remote tables. For details, see [DATABASE LINK](#).
- **ONLY**

If **ONLY** is specified, only that table is locked. If it is not specified, the table and all its sub-tables are locked.
- **ACCESS SHARE**

Allows only read operations on a table. In general, any SQL statements that only read a table and do not modify it will acquire this lock mode. The **SELECT** statement acquires an **ACCESS SHARE** lock on referenced tables.
- **ROW SHARE**

Allows concurrent read of a table but does not allow any other operations on the table.

**SELECT FOR UPDATE** and **SELECT FOR SHARE** automatically acquire the **ROW SHARE** lock on the target table and add the **ACCESS SHARE** lock to other referenced tables except **FOR SHARE** and **FOR UPDATE**.

For a partitioned table, **SELECT FOR SHARE** obtains the **ROW EXCLUSIVE** lock of the partition object on the DN for concurrency control.
- **ROW EXCLUSIVE**

Allows concurrent read of a table but does not allow modification of data in the table. **ROW EXCLUSIVE** is the same as **ROW SHARE**. **UPDATE**, **DELETE**, and **INSERT** automatically acquire this lock on the target table and add the **ACCESS SHARE** lock to other referenced tables. Generally, all statements that modify table data acquire the **ROW EXCLUSIVE** lock for tables.
- **SHARE UPDATE EXCLUSIVE**

Protects a table against concurrent schema changes and **VACUUM** runs. The **VACUUM** (without **FULL**), **ANALYZE**, and **CREATE INDEX CONCURRENTLY** statements automatically request this lock.
- **SHARE**

Allows concurrent queries of a table but does not allow modification of the table.

The **CREATE INDEX** (without **CONCURRENTLY**) statement automatically requests this lock.
- **SHARE ROW EXCLUSIVE**

Protects a table against concurrent data changes, and is self-exclusive so that only one session can hold it at a time.

No SQL statements automatically acquire this lock mode.
- **EXCLUSIVE**

Allows concurrent queries of the target table but does not allow any other operations.

This mode allows only concurrent **ACCESS SHARE** locks; that is, only reads from the table can proceed in parallel with a transaction holding this lock mode.

No SQL statements automatically acquire this lock mode on user tables. However, it will be acquired on some system catalogs in case of some operations.

- **ACCESS EXCLUSIVE**

Guarantees that the holder is the only transaction accessing the table in any way.

Acquired by the **ALTER TABLE**, **DROP TABLE**, **TRUNCATE**, **REINDEX**, **CLUSTER**, and **VACUUM FULL** commands.

This is also the default lock mode for **LOCK TABLE** statements that do not specify a mode explicitly.

- **NOWAIT**

Specifies that **LOCK TABLE** should not wait for any conflicting locks to be released: if the specified lock(s) cannot be acquired immediately without waiting, the transaction is aborted.

If a table-level lock is obtained without specifying **NOWAIT** and other mutex locks exist, the system waits for other locks to be released.

- **CANCELABLE**

Allows the waiting thread to send CANCEL signals to the holding threads and waiting threads.

Only the redistribution tool can use this parameter. An error message is displayed when the parameter is used by users.

## Examples

- **SHARE ROW EXCLUSIVE**

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Create the tpcds.reason table.
gaussdb=# CREATE TABLE tpcds.reason (
r_reason_sk INTEGER NOT NULL,
r_reason_id CHAR(16) NOT NULL,
r_reason_desc INTEGER
);

-- Insert multiple records into the table.
gaussdb=# INSERT INTO tpcds.reason VALUES (1, 'AAAAAAAAABAAAAAAA', '18'),(5,
'AAAAAAAACAAAAAAA', '362'),(7, 'AAAAAAAADAAAAAAA', '585');

-- Create a table named reason_t1.
gaussdb=# CREATE TABLE tpcds.reason_t1 AS TABLE tpcds.reason;

-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Use the SHARE ROW EXCLUSIVE MODE lock mode to lock a table.
gaussdb=# LOCK TABLE tpcds.reason_t1 IN SHARE ROW EXCLUSIVE MODE;

-- If you perform the DELETE operation on another device, the operation is blocked.
gaussdb=# DELETE FROM tpcds.reason_t1 WHERE r_reason_sk = 7;

-- End the transaction and release the lock.
gaussdb=# COMMIT;
```

- **ROW EXCLUSIVE**  
-- Start a transaction.  
gaussdb=# START TRANSACTION;  
  
-- After the UPDATE statement is executed, request a ROW EXCLUSIVE lock on the referenced table.  
gaussdb=# UPDATE tpcds.reason\_t1 SET r\_reason\_desc=180 WHERE r\_reason\_sk=1;  
  
-- When the ALTER TABLE statement is executed on another device, the operation is blocked.  
gaussdb=# ALTER TABLE tpcds.reason\_t1 ADD r\_reason\_asc int;  
  
-- End the transaction and release the lock.  
gaussdb=# COMMIT;
- **ACCESS EXCLUSIVE**  
-- Start a transaction.  
gaussdb=# START TRANSACTION;  
  
-- After the TRUNCATE statement is executed, request an ACCESS SHARE lock on the referenced table.  
gaussdb=# TRUNCATE tpcds.reason\_t1;  
  
-- When the SELECT statement is executed on another device, the operation is blocked.  
gaussdb=# SELECT \* FROM tpcds.reason\_t1;  
  
-- End the transaction and release the lock.  
gaussdb=# COMMIT;  
  
-- Delete the **tpcds.reason\_t1** table.  
gaussdb=# DROP TABLE tpcds.reason\_t1;  
  
-- Delete the **tpcds.reason** table.  
gaussdb=# DROP TABLE tpcds.reason;  
  
-- Delete a schema.  
gaussdb=# DROP SCHEMA tpcds CASCADE;

### 7.12.14.3 LOCK BUCKETS

#### Description

Bucket-based lock.

#### Precautions

It can be called only during hash bucket scaling out.

LOCK BUCKETS is useless outside a transaction block: the lock would remain held only to the completion of the statement. If LOCK BUCKETS is out of any transaction block, an error is reported.

#### Syntax

```
LOCK BUCKETS (bucketlist) IN {ACCESS SHARE|ACCESS EXCLUSIVE} MODE [CANCELABLE];
```

#### Parameters

Parameters of LOCK BUCKETS are as follows:

- **bucketlist**  
Specifies the list of buckets to be locked.  
Value range: For each bucket, the value range is [0,1023].
- **ACCESS SHARE**

Allows only read operations on a bucket.

- **ACCESS EXCLUSIVE**

Guarantees that the holder is the only transaction accessing the bucket in any way.

- **CANCELABLE**

Allows the waiting thread to send CANCEL signals to the holding threads and waiting threads.

## Examples

```
gaussdb=# START TRANSACTION;
gaussdb=# LOCK BUCKETS (0,1,2,3) IN ACCESS EXCLUSIVE MODE;
gaussdb=# COMMIT;
```

## 7.12.15 M

### 7.12.15.1 MARK BUCKETS

#### Function

Used by the scale-out tool to notify the kernel of the buckets that have been migrated.

#### Precautions

It can be called by administrators only during hashbucket scale-out.

#### Syntax

```
MARK BUCKETS (bucketlist) FINISH FROM datanode_name TO datanode_name;
```

#### Parameter Description

Parameters of MARK BUCKETS are as follows:

- **bucketlist**  
Specifies the list of buckets that have been migrated.  
Value range: For each bucket, the value range is [0,1023].
- **datanode\_name**  
Specifies the name of the node involved in bucket migration.  
Value range: a string. It must comply with the [naming convention](#).

## Examples

```
gaussdb=# MARK BUCKETS (0,1,2,3) FINISH FROM datanode1 TO datanode3;
```

## 7.12.15.2 MERGE INTO

### Function

MERGE INTO conditionally matches data in a target table with that in a source table. If data matches, UPDATE is executed on the target table; if data does not match, INSERT is executed. You can use this syntax to run **UPDATE** and **INSERT** at a time for convenience.

### Precautions

- You have the INSERT and UPDATE permissions for the target table and the SELECT permission for the source table.
- MERGE INTO cannot be executed during redistribution.
- If the source table of the MERGE INTO operation contains data columns that are dynamically anonymized, the result of inserting data to or updating data in the target table is the anonymized value and cannot be restored.

### Syntax

```
MERGE [/*+ plan_hint */] INTO table_name [[AS] alias]
USING { { table_name | view_name } | subquery } [[AS] alias]
ON (condition)
[
 WHEN MATCHED THEN
 UPDATE SET { column_name = { expression | subquery | DEFAULT } |
 (column_name [, ...]) = ({ expression | subquery | DEFAULT } [, ...]) } [, ...]
 [WHERE condition]
]
[
 WHEN NOT MATCHED THEN
 INSERT { DEFAULT VALUES |
 ((column_name [, ...]) VALUES ({ expression | subquery | DEFAULT } [, ...]) [, ...] [WHERE condition]) }
];
NOTICE: 'subquery' in the UPDATE and INSERT clauses are only available in CENTRALIZED mode!
```

### Parameter Description

- **plan\_hint** clause  
Follows the MERGE keyword in the */\*+ \*/* format. It is used to optimize the plan of a MERGE statement block. For details, see [Hint-based Tuning](#). In each statement, only the first */\*+ plan\_hint \*/* comment block takes effect as a hint. Multiple hints can be written.
- **INTO** clause  
Specifies the target table that is being updated or has data being inserted. If the target table is a replication table, the default value of a column (such as auto-increment column) in the target table cannot be the volatile function. If **enable\_stream\_operator** is set to **off**, the target table must contain a primary key or UNIQUE and NOT NULL constraints.
  - **table\_name**  
Specifies the name of the target table.
  - **alias**  
Specifies the alias of the target table.  
Value range: a string. It must comply with the [naming convention](#).

- **USING clause**  
Specifies the source table, which can be a table, view, or subquery. If the target table is a replication table, the **USING** clause cannot contain non-replication tables.
- **ON clause**  
Specifies the condition used to match data between the source and target tables. Columns in the condition cannot be updated.
- **WHEN MATCHED clause**  
Performs **UPDATE** if data in the source table matches that in the target table based on the condition.  
Distribution keys cannot be updated. System catalogs and system columns cannot be updated.
- **WHEN NOT MATCHED clause**  
Performs **INSERT** if data in the source table does not match that in the target table based on the condition.  
An **INSERT** clause cannot contain multiple **VALUES**.  
The order of **WHEN MATCHED** and **WHEN NOT MATCHED** clauses can be reversed. One of them can be used by default, but they cannot be both used at one time. Two **WHEN MATCHED** or **WHEN NOT MATCHED** clauses cannot be specified at the same time.
- **DEFAULT**  
Specifies the default value of a column.  
The value is **NULL** if no default value is assigned to it.
- **WHERE condition**  
Specifies the conditions for the **UPDATE** and **INSERT** clauses. The two clauses will be executed only when the conditions are met. The default value can be used. System columns cannot be referenced in **WHERE** condition. You are advised not to use numeric types such as **int** as conditions, because such types can be implicitly converted to **bool** values (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.

## Examples

```
-- Create the target table products and source table newproducts, and insert data to them.
gaussdb=# CREATE TABLE products
(
product_id INTEGER,
product_name VARCHAR2(60),
category VARCHAR2(60)
);

gaussdb=# INSERT INTO products VALUES (1501, 'vivitar 35mm', 'electrncs');
gaussdb=# INSERT INTO products VALUES (1502, 'olympus is50', 'electrncs');
gaussdb=# INSERT INTO products VALUES (1600, 'play gym', 'toys');
gaussdb=# INSERT INTO products VALUES (1601, 'lamaze', 'toys');
gaussdb=# INSERT INTO products VALUES (1666, 'harry potter', 'dvd');

gaussdb=# CREATE TABLE newproducts
(
product_id INTEGER,
product_name VARCHAR2(60),
category VARCHAR2(60)
```

```

);

gaussdb=# INSERT INTO newproducts VALUES (1502, 'olympus camera', 'electrncs');
gaussdb=# INSERT INTO newproducts VALUES (1601, 'lamaze', 'toys');
gaussdb=# INSERT INTO newproducts VALUES (1666, 'harry potter', 'toys');
gaussdb=# INSERT INTO newproducts VALUES (1700, 'wait interface', 'books');

-- Run MERGE INTO.
gaussdb=# MERGE INTO products p
USING newproducts np
ON (p.product_id = np.product_id)
WHEN MATCHED THEN
 UPDATE SET p.product_name = np.product_name, p.category = np.category WHERE p.product_name !=
'play gym'
WHEN NOT MATCHED THEN
 INSERT VALUES (np.product_id, np.product_name, np.category) WHERE np.category = 'books';
MERGE 4

-- Query updates.
gaussdb=# SELECT * FROM products ORDER BY product_id;
 product_id | product_name | category
-----+-----+-----
 1501 | vivitar 35mm | electrncs
 1502 | olympus camera | electrncs
 1600 | play gym | toys
 1601 | lamaze | toys
 1666 | harry potter | toys
 1700 | wait interface | books
(6 rows)

-- Delete the table.
gaussdb=# DROP TABLE products;
gaussdb=# DROP TABLE newproducts;

```

### 7.12.15.3 MOVE

#### Description

MOVE repositions a cursor without retrieving any data. MOVE works exactly like the **FETCH** statement, except MOVE only repositions the cursor and does not return rows.

#### Syntax

```
MOVE [direction [FROM | IN]] cursor_name;
```

The direction clause specifies optional parameters.

```

NEXT
| PRIOR
| FIRST
| LAST
| ABSOLUTE count
| RELATIVE count
| count
| ALL
| FORWARD
| FORWARD count
| FORWARD ALL
| BACKWARD

```

| BACKWARD count  
| BACKWARD ALL

## Parameters

The parameters of **MOVE** and **FETCH** are the same. For details, see [Parameters](#) in **FETCH**.

### NOTE

On successful completion, a **MOVE** statement returns a tag of the form **MOVE count**. The **count** is the number of rows that a **FETCH** statement with the same parameters would have returned (possibly zero).

## Examples

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE tbl_test(c1 int);
gaussdb=# INSERT INTO tbl_test VALUES (generate_series(1,20));

-- Set up cursor1.
gaussdb=# BEGIN;
gaussdb=# CURSOR cursor1 FOR SELECT * FROM tbl_test ORDER BY 1;

-- Run the MOVE command to move the cursor backwards by five rows. No result is returned.
gaussdb=# MOVE FORWARD 5 FROM cursor1;
MOVE 5

-- Run the FETCH command to retrieve two rows of data.
gaussdb=# FETCH FORWARD 2 FROM cursor1;
c1

6
```

```

7
(2 rows)

-- Close the cursor and end the transaction.
gaussdb=# CLOSE cursor1;
gaussdb=# END;

-- Delete.
gaussdb=# DROP TABLE tbl_test;

```

## Helpful Links

## 7.12.16 P

### 7.12.16.1 PREDICT BY

This syntax is not supported in distributed scenarios.

### 7.12.16.2 PREPARE

#### Description

Creates a prepared statement.

A prepared statement is a performance optimizing object on the server. When the **PREPARE** statement is executed, the specified query is parsed, analyzed, and rewritten. When **EXECUTE** is executed, the prepared statement is planned and executed. This avoids repetitive parsing and analysis. After the **PREPARE** statement is created, it exists throughout the database session. Once it is created (even if in a transaction block), it will not be deleted when a transaction is rolled back. It can only be deleted by explicitly calling [DEALLOCATE](#) or automatically deleted when the session ends.

#### Syntax

```
PREPARE name [(data_type [, ...])] AS statement;
```

#### Parameters

- name**  
 Specifies the name of a prepared statement. It must be unique in the session.
- data\_type**  
 Specifies the type of an argument.
- statement**  
 Specifies a SELECT, INSERT, UPDATE, DELETE, MERGE INTO, or VALUES statement.

## Examples

See [Examples](#) in section "EXECUTE."

## Helpful Links

[DEALLOCATE](#) and [7.13.10.1-EXECUTE](#)

### 7.12.16.3 PREPARE TRANSACTION

#### Description

Prepares the current transaction for two-phase commit.

After this statement, the transaction is no longer associated with the current session; instead, its state is fully stored on disk, and there is a high probability that it can be committed successfully, even if a database crash occurs before the commit is requested.

Once prepared, a transaction can later be committed or rolled back with [COMMIT PREPARED](#) or [ROLLBACK PREPARED](#), respectively. Those statements can be issued from any session, not only the one that executed the original transaction.

From the point of view of the issuing session, **PREPARE TRANSACTION** is not unlike a **ROLLBACK** statement: after executing it, there is no active current transaction, and the effects of the prepared transaction are no longer visible. (The effects will become visible again if the transaction is committed.)

If the **PREPARE TRANSACTION** statement fails for any reason, it becomes a **ROLLBACK** and the current transaction is canceled.

#### Precautions

- The transaction function is maintained automatically by the database, and should be not visible to users.
- The distributed system does not allow users to call the customized **PREPARE TRANSACTION** operation.
- When running the **PREPARE TRANSACTION** statement, increase the value of **max\_prepared\_transactions** in configuration file **gaussdb.conf**. You are advised to set it to a value not less than that of **max\_connections** so that one pending prepared transaction is available for each session.

#### Syntax

```
PREPARE TRANSACTION transaction_id;
```

The diagram shows the syntax of the **PREPARE TRANSACTION** statement. It consists of the keyword **PREPARE**, followed by the keyword **TRANSACTION**, then the identifier **transaction\_id**, and finally a semicolon **;**. Each element is enclosed in a rounded rectangular box, and the boxes are connected by right-pointing arrows. The entire sequence is flanked by a left-pointing arrow on the left and a right-pointing arrow on the right.

#### Parameters

- **transaction\_id**  
Specifies an arbitrary identifier that later identifies this transaction for **COMMIT PREPARED** or **ROLLBACK PREPARED**. The identifier must be different from those for current prepared transactions.

Value range: The identifier must be written as a string literal, and must be less than 200 bytes long.

## Helpful Links

[COMMIT PREPARED](#) and [ROLLBACK PREPARED](#)

### 7.12.16.4 PURGE

#### Description

The **PURGE** statement can be used to:

- Clear tables or indexes from the recycle bin and release all space related to the objects.
- Clear the recycle bin.
- Clear the objects of a specified tablespace in the recycle bin.

#### Precautions

- The PURGE operation supports tables (**PURGE TABLE**), indexes (**PURGE INDEX**), and recycle bins (**PURGE RECYCLEBIN**).
- The permission requirements for performing the PURGE operation are as follows:
  - **PURGE TABLE**: The user must be the owner of the table and must have the USAGE permission on the schema to which the table belongs. When the separation of duties is disabled, system administrators have this permission by default.
  - **PURGE INDEX**: The user must be the owner of the index and have the USAGE permission on the schema to which the index belongs. When the separation of duties is disabled, system administrators have this permission by default.
  - **PURGE RECYCLEBIN**: Common users can clear only the objects owned by themselves in the recycle bin. In addition, the user must have the USAGE permission of the schema to which the objects belong. When the separation of duties is disabled, system administrators can clear all objects in the recycle bin by default.

#### Prerequisites

- The **enable\_recyclebin** parameter has been enabled to enable the recycle bin. Contact the administrator for details about how to use the parameter.
- The **recyclebin\_retention\_time** parameter has been set for specifying the retention period of objects in the recycle bin. The objects will be automatically deleted after the retention period expires. Contact the administrator for details about how to use the parameter.

#### Syntax

```
PURGE { TABLE [schema_name.]table_name
 | INDEX index_name
 | RECYCLEBIN
 };
```

## Parameters

- schema\_name**  
 Schema name
- TABLE [ schema\_name. ] table\_name**  
 Clears a specified table in the recycle bin. The table can be schema-qualified.
- INDEX index\_name**  
 Clears a specified index in the recycle bin.
- RECYCLEBIN**  
 Clears all objects in the recycle bin.

## Examples

```

-- Create the reason_t1 table.
gaussdb=# CREATE TABLE reason_t1(
 r_reason_sk integer,
 r_reason_id character(16),
 r_reason_desc character(100)
) WITH(STORAGE_TYPE = ustore);

-- Create the reason_t2 table:
gaussdb=# CREATE TABLE reason_t2(
 r_reason_sk integer,
 r_reason_id character(16),
 r_reason_desc character(100)
) WITH(STORAGE_TYPE = ustore);

-- Add indexes to the reason_t1 and reason_t2 tables.
gaussdb=# CREATE INDEX idx_t1 on reason_t1(r_reason_id);
gaussdb=# CREATE INDEX idx_t2 on reason_t2(r_reason_id);
gaussdb=# DROP TABLE reason_t1;
gaussdb=# DROP TABLE reason_t2;

-- View the recycle bin.
gaussdb=# SELECT rcyname,rcyoriginname,rcytablespace FROM GS_RECYCLEBIN;
-----+-----+-----
rcyname | rcyoriginname | rcytablespace
-----+-----+-----
BIN$31C94EB4207$8001$0==$0 | reason_t1 | 0
BIN$31C94EB420D$8001$0==$0 | idx_t1 | 0
BIN$31C94EB420A$8004$0==$0 | reason_t2 | 0
BIN$31C94EB420E$8004$0==$0 | idx_t2 | 0
(4 rows)

-- Purge the table.
gaussdb=# PURGE TABLE reason_t1;
gaussdb=# SELECT rcyname,rcyoriginname,rcytablespace FROM GS_RECYCLEBIN;
-----+-----+-----
rcyname | rcyoriginname | rcytablespace
-----+-----+-----
BIN$31C94EB420A$8004$0==$0 | reason_t2 | 0
BIN$31C94EB420E$8004$0==$0 | idx_t2 | 0
(2 rows)

-- Purge the index.
gaussdb=# PURGE INDEX idx_t2;

```

```
gaussdb=# SELECT rcyname,rcyoriginname,rcytablespace FROM GS_RECYCLEBIN;
rcyname | rcyoriginname | rcytablespace
-----+-----+-----
BIN$31C94EB420A$8004$0==$0 | reason_t2 | 0
(1 row)

-- Purge all objects in the recycle bin.
gaussdb=# PURGE recyclebin;
gaussdb=# SELECT rcyname,rcyoriginname,rcytablespace FROM GS_RECYCLEBIN;
rcyname | rcyoriginname | rcytablespace
-----+-----+-----
(0 rows)
```

## 7.12.17 R

### 7.12.17.1 REASSIGN OWNED

#### Function

Changes the owner of the database object.

REASSIGN OWNED changes the database object owner of an old role to a new role.

#### Precautions

- REASSIGN OWNED is often executed before role deletion.
- To run the REASSIGN OWNED statement, you must have the permissions of the original and target roles.

#### Syntax

```
REASSIGN OWNED BY old_role [, ...] TO new_role;
```

#### Parameters

- **old\_role**  
Specifies the role name of the old owner.
- **new\_role**  
Specifies the role name of the new owner. Note: Only the initial user can use the REASSIGN OWNED syntax to change the owner to the initial user.

#### Examples

```
-- Create the test_jim and test_tom users.
gaussdb=# CREATE USER test_jim PASSWORD '*****';
gaussdb=# CREATE USER test_tom PASSWORD '*****';

-- View the user with the same name as owner of the automatically created schema.
gaussdb=# \dn test*
List of schemas
Name | Owner
-----+-----
```

```
test_jim | test_jim
test_tom | test_tom
(2 rows)

-- Change the owner of all database objects owned by test_jim to test_tom.
gaussdb=# REASSIGN OWNED BY test_jim TO test_tom;

-- View the schema information. The owner of the test_jim schema is changed to test_tom.
gaussdb=# \dn test*
List of schemas
Name | Owner
-----+-----
test_jim | test_tom
test_tom | test_tom
(2 rows)

-- Delete the test_jim and test_tom users.
gaussdb=# DROP USER test_jim, test_tom CASCADE;
```

## Helpful Links

[DROP OWNED](#)

### 7.12.17.2 REFRESH INCREMENTAL MATERIALIZED VIEW

#### Description

REFRESH INCREMENTAL MATERIALIZED VIEW refreshes a materialized view in incremental mode.

#### Precautions

- Incremental refresh supports only fast-refresh materialized views.
- To refresh a materialized view, you must have the SELECT permission on the base table.

#### Syntax

```
REFRESH INCREMENTAL MATERIALIZED VIEW mv_name;
```

#### Parameters

- **mv\_name**  
Name of the materialized view to be refreshed.

#### Examples

```
-- Create an ordinary table.
gaussdb=# CREATE TABLE my_table (c1 int, c2 int);

-- Create a fast-refresh materialized view.
gaussdb=# CREATE INCREMENTAL MATERIALIZED VIEW my_imv AS SELECT * FROM my_table;

-- Write data to the base table.
gaussdb=# INSERT INTO my_table VALUES(1,1),(2,2);

-- Fast refresh the fast-refresh materialized view my_imv.
gaussdb=# REFRESH INCREMENTAL MATERIALIZED VIEW my_imv;

-- View the fast-refresh materialized view.
gaussdb=# SELECT * FROM my_imv;
```

```
c1 | c2
----+----
 1 | 1
 2 | 2
(2 rows)

-- Delete the fast-refresh materialized view.
gaussdb=# DROP MATERIALIZED VIEW my_imv;

-- Delete the my_table table.
gaussdb=# DROP TABLE my_table;
```

## Helpful Links

[ALTER MATERIALIZED VIEW](#), [CREATE INCREMENTAL MATERIALIZED VIEW](#), [CREATE MATERIALIZED VIEW](#), [CREATE TABLE](#), [DROP MATERIALIZED VIEW](#), and [REFRESH MATERIALIZED VIEW](#)

### 7.12.17.3 REFRESH MATERIALIZED VIEW

#### Function

**REFRESH MATERIALIZED VIEW** refreshes materialized views in complete-refresh mode.

#### Precautions

- Full refreshing can be performed on both complete- and fast-refresh materialized views.
- To refresh a materialized view, you must have the SELECT permission on the base table.

#### Syntax

```
REFRESH MATERIALIZED VIEW mv_name;
```

#### Parameter Description

- **mv\_name**  
Name of the materialized view to be refreshed.

#### Examples

```
-- Create an ordinary table.
gaussdb=# CREATE TABLE my_table (c1 int, c2 int);

-- Create a complete-refresh materialized view.
gaussdb=# CREATE MATERIALIZED VIEW my_mv AS SELECT * FROM my_table;

-- Create a fast-refresh materialized view.
gaussdb=# CREATE INCREMENTAL MATERIALIZED VIEW my_imv AS SELECT * FROM my_table;

-- Write data to the base table.
gaussdb=# INSERT INTO my_table VALUES(1,1),(2,2);

-- Completely refresh the complete-refresh materialized view my_mv.
gaussdb=# REFRESH MATERIALIZED VIEW my_mv;

-- Completely refresh the fast-refresh materialized view my_imv.
gaussdb=# REFRESH MATERIALIZED VIEW my_imv;
```

```
-- Delete a fast-refresh materialized view.
gaussdb=# DROP MATERIALIZED VIEW my_imv;

-- Delete a complete-refresh materialized view.
gaussdb=# DROP MATERIALIZED VIEW my_mv;

-- Delete the my_table table.
gaussdb=# DROP TABLE my_table;
```

## Helpful Links

[ALTER MATERIALIZED VIEW](#), [CREATE INCREMENTAL MATERIALIZED VIEW](#), [CREATE MATERIALIZED VIEW](#), [CREATE TABLE](#), [DROP MATERIALIZED VIEW](#), and [REFRESH INCREMENTAL MATERIALIZED VIEW](#)

### 7.12.17.4 REINDEX

#### Description

Rebuilds an index using the data stored in the index's table, replacing the old copy of the index.

There are several scenarios in which REINDEX can be used:

- An index has become corrupted, and no longer contains valid data.
- An index has become "bloated", that is, it contains many empty or nearly-empty pages.
- You have altered a storage parameter (such as a fill factor) for an index, and wish that the change takes full effect.

#### Precautions

- REINDEX DATABASE and REINDEX SYSTEM cannot be performed in transaction blocks.
- Currently, only REINDEX INDEX and REINDEX TABLE are supported for global secondary indexes.
- If the index contains the **lpi\_parallel\_method** option and the value is **PARTITION**, and the **parallel\_workers** value of the index's table is greater than 0, the index cannot be rebuilt in parallel. If the index does not contain the **lpi\_parallel\_method** option or the value of the option is set to **AUTO**, page-level parallel index is rebuilt by default. For details, see [LPI\\_PARALLEL\\_METHOD](#).

#### Syntax

- Rebuild a general index.  
REINDEX { INDEX | TABLE | DATABASE | SYSTEM } [CONCURRENTLY] name [ FORCE ];
- Rebuild the index and convert the type.  
REINDEX [ ( option [, ...] ) ] { INDEX } [ CONCURRENTLY ] name [ FORCE ];

- Rebuild an index partition.  

```
REINDEX { INDEX| TABLE} name
PARTITION partition_name [FORCE];
```

## Parameters

- **INDEX**  
Rebuilds the specified index.
- **TABLE**  
Rebuilds all indexes of a specified table. If a table has a TOAST table, the table will also be reindexed. If an index on the table has been invalidated by running **alter unusable**, the index cannot be rebuilt. Indexes in the TOAST table cannot be rebuilt when specifying the **CONCURRENTLY** option.
- **DATABASE**  
Rebuilds all indexes within the current database. Indexes in the TOAST table within the current database cannot be rebuilt when specifying the **CONCURRENTLY** option.
- **SYSTEM**  
Rebuilds all indexes on system catalogs within the current database. Indexes on user tables are not processed.
- **option**  
Currently, only **CROSSBUCKET** is supported, and the value can only be **ON** or **OFF**. This parameter is used to control whether the index of a hash bucket table is converted to a cross-bucket index (CBI) or local-bucket index (LBI). This conversion supports only the index of the distributed hash bucket table and does not support the GSI index. In the current version, only the session of the scale-out process can use the online index type conversion.
- **CONCURRENTLY**  
Rebuilds an index (with ShareUpdateExclusiveLock) in non-blocking DML mode. When an index is rebuilt, other statements cannot access the table on which the index depends. If this keyword is specified, DML is not blocked during the rebuilding. Indexes in system catalogs cannot be rebuilt online. **REINDEX INTERNAL TABLE CONCURRENTLY**, **REINDEX SYSTEM CONCURRENTLY**, and **REINDEX INVALID INDEX CONCURRENTLY** are not supported. When **REINDEX DATABASE CONCURRENTLY** is executed, all indexes on user tables in the current database are rebuilt online (indexes on system catalogs are not processed). **REINDEX CONCURRENTLY** cannot be executed within a transaction. Online index rebuilding supports only B-tree and UB-tree indexes, common indexes, global indexes, and local indexes. PCR UB-tree indexes, level-2 partitions, and GSIs are not supported. Online concurrent index rebuilding supports only common indexes, global indexes, and local indexes of Astore and Ustore. Other online index rebuilding specifications are inherited from the current version. If online index rebuilding fails, the system automatically clears new indexes to prevent resource occupation in scenarios such as manual cancellation, duplicate unique index key values, insufficient resources, thread startup failure, and lock timeout. If the system cannot automatically clear invalid new indexes (for example, the database breaks down, PATAL, or PANIC), you need to manually clear invalid new indexes (using the **DROP INDEX** statement) and temporary tables (using the **DROP TABLE** statement) as soon as possible to prevent more resources from being occupied. Generally, the extension of an invalid index name is

**\_ccnew**. In the distributed system, failed indexes in DNs are automatically cleared and those in CNs need to be manually cleared. If a critical error occurs, the metadata of the failed indexes cannot be found on some nodes in the distributed system. The DROP INDEX statement cannot be used to delete these indexes. You need to use the DROP INDEX IF EXISTS statement to delete them. The execution of REINDEX INDEX CONCURRENTLY adds a four-level session lock to the table and its first several phases are similar to those of CREATE INDEX CONCURRENTLY. Therefore, the execution may be suspended or deadlocked, which is similar to that of CREATE INDEX CONCURRENTLY. For example, if two sessions perform the REINDEX CONCURRENTLY operation on the same index or table at the same time, a deadlock occurs. For details, see [CONCURRENTLY](#).

#### NOTE

This keyword is specified when an index is rebuilt. For Astore, you need to complete two full table scans for building. During the first scan, a new index is created without blocking read and write operations. During the second scan, the changes in the first scan are merged and updated. For Ustore, you need to complete a full table scan. During the scan, data generated by concurrent DML operations is inserted into the temporary table named **index\_oid\_cctmp**. After the scan is complete, you merge the temporary table to the new index suffixed with **\_ccnew{n}**, delete the temporary table, exchange the old and new indexes, mark the old index as dead, enable the new index, and rebuild the index.

- **name**

Specifies the name of the index, table, or database whose index needs to be rebuilt. Tables and indexes can be schema-qualified.

#### NOTE

REINDEX DATABASE and REINDEX SYSTEM can create indexes for only the current database. Therefore, **name** must be the same as the current database name.

- **FORCE**

Discarded parameter. It is currently reserved for compatibility with earlier versions.

- **partition\_name**

Specifies the name of the partition or index partition to be rebuilt.

Value range:

- If **REINDEX INDEX** is used, specify the name of an index partition.
- If it is **REINDEX TABLE**, specify the name of a partition.

---

#### NOTICE

- REINDEX DATABASE and REINDEX SYSTEM cannot be performed in transaction blocks.
  - REINDEX and REINDEX CONCURRENTLY do not support separate operations on TOAST tables or TOAST indexes.
- 

## Examples

```
-- Create the table tbl_test and insert data into the tables.
gaussdb=# CREATE TABLE tbl_test(c1 int,c2 varchar);
```

```
gaussdb=# INSERT INTO tbl_test VALUES (1, 'AAAAAAA'),(5, 'AAAAAAB'),(10, 'AAAAAAC');
-- Create an index and check the index size.
gaussdb=# CREATE INDEX idx_test_c1 ON tbl_test(c1);
gaussdb=# SELECT pg_size_pretty(pg_total_relation_size('idx_test_c1')) AS size;
 size

64 kB
(1 row)
-- Insert 10,000 data records and then delete the data. It is found that the index becomes larger.
gaussdb=# INSERT INTO tbl_test VALUES (generate_series(1,10000),'test');
gaussdb=# DELETE FROM tbl_test WHERE c2 = 'test';
gaussdb=# SELECT pg_size_pretty(pg_total_relation_size('idx_test_c1')) AS size;
 size

376 kB
(1 row)
-- After an independent index is rebuilt, the index size is restored to the initial size.
gaussdb=# REINDEX INDEX idx_test_c1;
gaussdb=# SELECT pg_size_pretty(pg_total_relation_size('idx_test_c1')) AS size;
 size

64 kB
(1 row)
-- Rebuild a single index online.
gaussdb=# REINDEX INDEX CONCURRENTLY idx_test_c1;
-- Rebuild all indexes in the table tbl_test.
gaussdb=# REINDEX TABLE tbl_test;
-- Rebuild all indexes in the table tbl_test online.
gaussdb=# REINDEX TABLE CONCURRENTLY tbl_test;
-- Delete the tbl_test table.
gaussdb=# DROP TABLE tbl_test;
```

## Suggestions

- INTERNAL TABLE  
This scenario is used for fault recovery. You are advised not to perform concurrent operations.
- DATABASE  
You are advised not to reindex a database in a transaction.
- SYSTEM  
You are advised not to reindex a system catalog in a transaction.

## 7.12.17.5 RELEASE SAVEPOINT

### Description

**RELEASE SAVEPOINT** destroys a savepoint previously defined in the current transaction.

Destroying a savepoint makes it unavailable as a rollback point, but it has no other user visible behavior. It does not undo the effects of statements executed after the savepoint was established. To do that, use **ROLLBACK TO SAVEPOINT**. Destroying a savepoint when it is no longer needed allows the system to reclaim some resources earlier than transaction end.

**RELEASE SAVEPOINT** also destroys all savepoints that were established after the named savepoint was established.

## Precautions

- Releasing a savepoint name that was not previously defined will cause an error.
- It is not possible to release a savepoint when the transaction is in an aborted state.
- If multiple savepoints have the same name, only the one that was most recently defined is released.

## Syntax

```
RELEASE [SAVEPOINT] savepoint_name;
```

## Parameters

- **savepoint\_name**  
Specifies the name of the savepoint you want to destroy.

## Examples

```
-- Create a schema.
gaussdb=# CREATE SCHEMA tpcds;

-- Create a table.
gaussdb=# CREATE TABLE tpcds.table1(a int);

-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Insert data.
gaussdb=# INSERT INTO tpcds.table1 VALUES (3);

-- Establish a savepoint.
gaussdb=# SAVEPOINT my_savepoint;

-- Insert data.
gaussdb=# INSERT INTO tpcds.table1 VALUES (4);

-- Delete the savepoint.
gaussdb=# RELEASE SAVEPOINT my_savepoint;

-- Commit the transaction.
gaussdb=# COMMIT;

-- Query the table content, which should contain both 3 and 4.
gaussdb=# SELECT * FROM tpcds.table1;

-- Delete the table.
gaussdb=# DROP TABLE tpcds.table1;

-- Delete a schema.
gaussdb=# DROP SCHEMA tpcds CASCADE;
```

## Helpful Links

[SAVEPOINT](#) and [ROLLBACK TO SAVEPOINT](#)

## 7.12.17.6 RENAME TABLE

### Description

In the same statement, changing the name of a single table or multiple tables does not affect the stored data.

### Precautions

- To change the name of a single table, this syntax is equivalent to RENAME in ALTER TABLE.
- Changing the names of multiple tables is equivalent to running RENAME in ALTER TABLE for multiple times. However, changing the names of local and non-local temporary tables at the same time is not supported.

### Syntax

Modify the table name.

```
RENAME { TABLE | TABLES } table_name TO new_table_name [, table_name2 TO new_table_name2, ...];
```

#### NOTE

If you run this command when **sql\_compatibility** is set to 'MYSQL', **b\_format\_version** set to '5.7', and **b\_format\_dev\_version** set to 's2', the following situations may occur:

- If the new table name starts with "#mysql50#" and is followed by other characters, "#mysql50#" will be ignored.
- If the old and new table names are the same, no error is reported.

### Parameters

- **TABLE | TABLES**  
TABLE and TABLES can be used interchangeably, regardless of the number of tables operated in the statement.
- **table\_name TO new\_table\_name [, table\_name2 TO new\_table\_name2, ...]**  
**table\_name** and **table\_name2** indicate the names of the tables to be modified.  
**new\_table\_name** and **new\_table\_name2** indicate the new table names.  
TO is the connection word.

### Examples of Modifying Tables

- Rename a single table.

```
gaussdb=# CREATE TABLE aa(c1 int, c2 int);
gaussdb=# RENAME TABLE aa TO test_alt1;
gaussdb=# DROP TABLE test_alt1;
```
- Rename multiple tables.

```
gaussdb=# CREATE TABLE aa(c1 int, c2 int);
gaussdb=# CREATE TABLE bb(c1 int, c2 int);
gaussdb=# RENAME TABLE aa TO test_alt1, bb TO test_alt2;
gaussdb=# DROP TABLE test_alt1,test_alt2;
```

## Helpful Links

### [ALTER TABLE](#)

## 7.12.17.7 REPLACE

### Function

The REPLACE statement is used to insert data into a table or replace existing data in a table. If the data to be inserted has the primary key or unique key conflicts with the existing data, the REPLACE statement deletes the existing data and then inserts the new data.

You can use REPLACE in the following ways:

- Replace or insert values. That is, VALUES or VALUE is used to construct a row of records and insert the row into the table.
- Replace or insert the query. One or more rows of records are constructed based on the result set returned by SELECT and inserted into a table.
- Set the value of a specified column. Similar to value insertion, the default value is used for columns that are not specified.

### Precautions

- To execute this statement, you must have the DELETE and INSERT permissions on the table.
- If the primary key or unique key does not conflict, you can directly insert the data. If the primary key or unique key conflicts, delete the original data and then insert the new data.
- The return format of the REPLACE operation is **REPLACE 0 X**, where *X* indicates the number of DELETE and INSERT operations.
- In the REPLACE...SELECT syntax, the number of columns in **select\_list** must be the same as the number of columns to be inserted.
- In the REPLACE...SET syntax:
  - If **col\_name** has a default value, **SET col\_name = col\_name + 1** is equivalent to **SET col\_name = Default value of col\_name + 1**.
  - If **col\_name** has neither default value nor NOT NULL constraint, **SET col\_name = col\_name + 1** is equivalent to **col\_name = NULL**.
  - If **col\_name** does not have a default value but has a NOT NULL constraint, the data types that support a default value are timestamp, timestamp with time zone, time, time with time zone, interval, tinterval, smalldatetime, date, uuid, name, point, polygon, circle, lseg, box, json, jsonb, xml, varbit, numeric, cidr, inet, macaddr, numrange, int8range, int4range, tsrange, tstzrange, daterange, hash16, hash32, bool, bytea, char, bigint, int, smallint, tinyint, text, raw, blob, clob, float4, float8, abstime, reltime, bpchar, varchar, nvarchar, money, uint1, uint2, uint4, uint8, and enum. The default values are as follows:

| Data Type                | Default Value of col_name           |
|--------------------------|-------------------------------------|
| timestamp with time zone | timestamptz '1970-01-01 00:00:00'   |
| date                     | date '1970-01-01'                   |
| time                     | time '00:00:00'                     |
| time with time zone      | timetz '00:00:00'                   |
| smalldatetime            | smalldatetime '1970-01-01 00:00:00' |

 NOTE

- The default value of the enumerated type (ENUM) is the first element. If the first element does not exist, NULL is returned.
- In an ORA database (**sql\_compatibility = 'ORA'**), an empty string of the text, clob, blob, raw, bytea, varchar, nvarchar2, bpchar, char, name, byteawithoutorderwithqualcol, or byteawithoutordercol type is equivalent to null. If a column has a NOT NULL constraint, an error is reported when a reference column is used to insert data into a table.
- In MySQL-compatible mode (**sql\_compatibility = 'MYSQL'**), if **b\_format\_version** is set to '5.7', **b\_format\_dev\_version** is set to 's1', and **sql\_mode** does not contain **strict\_tans\_tables**, **only\_full\_group\_by**, **no\_zero\_in\_date**, **no\_zero\_date**, or **error\_for\_division\_by\_zero**, then the default values of **timestamp** and **datetime** are **0000-00-00 00:00:00**, and the default value of **DATE** is **0000-00-00** under the NOT NULL constraint.
- The uint1, uint2, uint4, and uint8 data types are supported only in the MySQL-compatible mode (**sql\_compatibility = 'MYSQL'**).
- If the default value of the function expression can be calculated during parsing, the default value is the calculated constant. Otherwise, the value is **NULL**.
- In other scenarios, the default value is **NULL**.
- In the REPLACE... SET syntax, the current **col\_name** value depends on the previous **col\_name** value. If there is no previous **col\_name** value, the default value is used. For example, in the **SET f1 = f1 + 1, f2 = f1** scenario, **f1** is equal to the default value of **f1** (assumed to **1**) plus 1, and **f2** is equal to the calculated value of **f1**, that is **2**.
- Triggers are not supported. The INSERT or DELETE trigger of the target table is not fired.
- The unique constraint or primary key of DEFERRABLE is not supported.
- If a table has multiple unique constraints and the inserted data violates multiple unique constraints, all the data that violates the constraints is deleted and new data is inserted. In this scenario, data may be deleted by mistake. Therefore, exercise caution when performing this operation.
- If multiple rows are inserted and these rows have unique constraint conflicts with data in the same row in the table, the REPLACE operation is performed in sequence.
- In **SET col\_name = col\_name + 1**, the length of **col\_name** cannot exceed 1. For example, in **SET col\_name = table\_name.col\_name + 1**, the length of

**table\_name.col\_name** is 2. Formats such as B.A, C.B.A, and D.C.B.A are not supported.

- Tables containing global secondary indexes do not support the REPLACE syntax.
- When comparing floating-point data, note that precision loss may occur.
- If a row-level security policy is created on a table, REPLACE INTO is not supported.
- Foreign tables are not supported.
- Encrypted tables are not supported.
- Memory tables are not supported.

## Syntax

- Replace or insert values.  
REPLACE [ INTO ] table\_name  
[ PARTITION ( partition\_name [, ... ] ) ]  
[ ( col\_name [, ... ] ) ]  
{ VALUES | VALUE } ( value [, ... ] ) [, ... ];

- Replace or insert the query.  
REPLACE [ INTO ] table\_name  
[ PARTITION ( partition\_name [, ... ] ) ]  
[ ( col\_name [, ... ] ) ]  
query;

- Set the value of a specified column.  
REPLACE [INTO] table\_name  
[ PARTITION ( partition\_name [, ... ] ) ]  
SET col\_name = value [, ... ];

## Parameters

- **table\_name**  
Specifies the name of the target table where data will be inserted.  
Value range: an existing table name.
- **col\_name**  
Specifies the name of a column in a table.
  - The column name can be qualified with a subcolumn name or array index, if needed.
  - Each column not present in the column list will be filled with a default value, either its declared default value or **NULL** if there is none. Inserting data into only some columns of a composite type leaves the other columns **NULL**.
  - The target column names (specified by **col\_name**) can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order.
  - The target columns are the first *N* column names, if there are only *N* columns provided by the VALUE clause and QUERY.
  - The values provided by the VALUE clause and QUERY are joined with the corresponding columns from left to right in the table.Value range: an existing column.
- **PARTITION ( partition\_name [, ... ] )**

Inserts data to a specified partition. **partition\_name** indicates the partition name.

If the value of the VALUE clause is inconsistent with that of the specified partition, an exception is displayed.

- **value**

Specifies the value to be inserted. The value format is as follows:

```
{ expression | DEFAULT }
```

- a. **expression** indicates that a valid expression or value is assigned to the corresponding column.

If single-quotation marks are inserted into a column, the single-quotation marks need to be used for escape.

If the expression for any column is not of the correct data type, automatic type conversion will be attempted. If the attempt fails, data insertion fails, and the system returns an error message.

- b. **DEFAULT** indicates the default value of the corresponding column name. The value is **NULL** if no default value is assigned to it.

- **query**

Specifies a query statement (SELECT statement) that uses the query result as the inserted data.

## Examples

```
-- Create a table.
gaussdb=# CREATE TABLE test(f1 int primary key, f2 int, f3 int);

-- Insert data.
gaussdb=# INSERT INTO test VALUES(1, 1, 1), (2, 2, 2), (3, 3, 3);
INSERT 0 3

-- Replace or insert values.
gaussdb=# REPLACE INTO test VALUES(1, 11, 11);
REPLACE 0 2

-- Query the result.
gaussdb=# SELECT * FROM test WHERE f1 = 1;
 f1 | f2 | f3
-----+-----
 1 | 11 | 11
(1 row)

-- Replace or insert the query.
gaussdb=# REPLACE INTO test SELECT 2, 22, 22;
REPLACE 0 2

-- Query the result.
gaussdb=# SELECT * FROM test WHERE f1 = 2;
 f1 | f2 | f3
-----+-----
 2 | 22 | 22
(1 row)

-- Replace or insert the specified column.
gaussdb=# REPLACE INTO test SET f1 = f1 + 3, f2 = f1 * 10 + 3, f3 = f2;
REPLACE 0 2

-- Query the result.
gaussdb=# SELECT * FROM test WHERE f1 = 3;
 f1 | f2 | f3
-----+-----
```

```
3 | 33 | 33
(1 row)

-- Delete the table.
gaussdb=# DROP TABLE test;
```

## 7.12.17.8 RESET

### Description

Restores GUC parameters to their default values. The default values are parameter default values compiled in the **gaussdb.conf** configuration file.

RESET is an alternative spelling for:

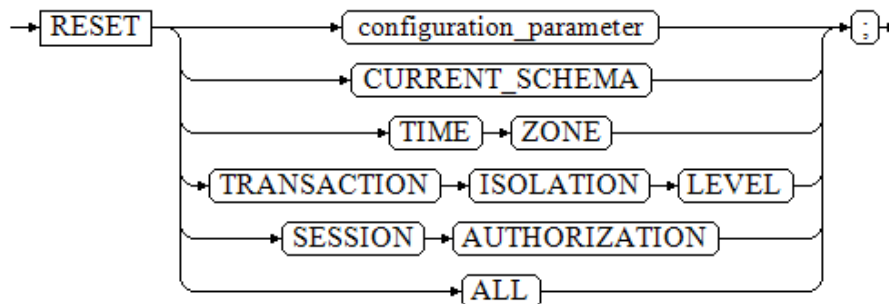

```
SET configuration_parameter TO DEFAULT;
```

### Precautions

RESET and SET have the same transaction behavior. Their impact will be rolled back.

### Syntax

```
RESET {configuration_parameter | CURRENT_SCHEMA | TIME ZONE | TRANSACTION ISOLATION LEVEL |
SESSION AUTHORIZATION | ALL };
```

### Parameters

- **configuration\_parameter**  
Specifies the name of a GUC parameter.  
Value range: GUC parameters. You can view them by running the **SHOW ALL** statement.  
**NOTE**  
Some parameters that viewed by **SHOW ALL** cannot be set by **SET**, for example, **max\_datanodes**.
- **CURRENT\_SCHEMA**  
Specifies the current schema.
- **TIME ZONE**  
Specifies the time zone.
- **TRANSACTION ISOLATION LEVEL**  
Specifies the transaction isolation level.

- **SESSION AUTHORIZATION**  
Specifies the current user identifier of the current session.
- **ALL**  
Resets all GUC parameters to default values.

## Examples

```
-- Set the time zone to Italy.
gaussdb=# SET timezone TO 'Europe/Rome';
-- View the current time zone.
gaussdb=# SHOW timezone;
 TimeZone

Europe/Rome
(1 row)

-- Set the time zone to the default value.
gaussdb=# RESET timezone;
-- View the current time zone.
gaussdb=# SHOW timezone;
 TimeZone

PRC
(1 row)

-- The preceding SQL statement is equivalent to the following two SQL statements. Set the time zone to
the default value.
gaussdb=# SET timezone TO DEFAULT;
gaussdb=# ALTER SESSION SET timezone to DEFAULT;
```

[SET](#) and [SHOW](#)

### 7.12.17.9 REVOKE

## Description

Revokes permissions from one or more roles.

## Precautions

If a non-owner user of an object attempts to REVOKE permission on the object, the statement is executed based on the following rules:

- If the user has no permissions whatsoever on the object, the statement will fail outright.
- If an authorized user has some permissions, only the permissions with authorization options are revoked.
- If the authorized user does not have the authorization option, the REVOKE ALL PRIVILEGES form will issue an error message. For other forms of statements, if the permission specified in the statement does not have the corresponding authorization option, the statement will issue a warning.

## Syntax

- Revoke the permission on a specified table or view.

```
REVOKE [GRANT OPTION FOR]
{ { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | ALTER | DROP | COMMENT |
INDEX | VACUUM }[, ...]
| ALL [PRIVILEGES] }
ON { [TABLE] table_name [, ...]
| ALL TABLES IN SCHEMA schema_name [, ...] }
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified field in a table.

```
REVOKE [GRANT OPTION FOR]
{ { SELECT | INSERT | UPDATE | REFERENCES | COMMENT } (column_name [, ...])[, ...]
| ALL [PRIVILEGES] (column_name [, ...]) }
ON [TABLE] table_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified sequence.

```
REVOKE [GRANT OPTION FOR]
{ { SELECT | UPDATE | ALTER | DROP | COMMENT }[, ...]
| ALL [PRIVILEGES] }
ON { [SEQUENCE] sequence_name [, ...]
| ALL SEQUENCES IN SCHEMA schema_name [, ...] }
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified database.

```
REVOKE [GRANT OPTION FOR]
{ { CREATE | CONNECT | TEMPORARY | TEMP | ALTER | DROP | COMMENT } [, ...]
| ALL [PRIVILEGES] }
ON DATABASE database_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified domain.

```
REVOKE [GRANT OPTION FOR]
{ USAGE | ALL [PRIVILEGES] }
ON DOMAIN domain_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the specified CMK permission.

```
REVOKE [GRANT OPTION FOR]
{ { USAGE | DROP } [, ...] | ALL [PRIVILEGES] }
ON CLIENT_MASTER_KEYS client_master_keys_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the specified CEK permission.

```
REVOKE [GRANT OPTION FOR]
{ { USAGE | DROP } [, ...] | ALL [PRIVILEGES]}
ON COLUMN_ENCRYPTION_KEYS column_encryption_keys_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified directory.

```
REVOKE [GRANT OPTION FOR]
{ { READ | WRITE | ALTER | DROP } [, ...] | ALL [PRIVILEGES] }
ON DIRECTORY directory_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified external data source.

```
REVOKE [GRANT OPTION FOR]
{ USAGE | ALL [PRIVILEGES] }
ON FOREIGN_DATA_WRAPPER fdw_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified external server.

```
REVOKE [GRANT OPTION FOR]
{ { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
```

```
ON FOREIGN SERVER server_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified function.

```
REVOKE [GRANT OPTION FOR]
{ { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON { FUNCTION {function_name ([{ argmode } [arg_name] arg_type } [, ...]) } [, ...]
 | ALL FUNCTIONS IN SCHEMA schema_name [, ...] }
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified stored procedure.

```
REVOKE [GRANT OPTION FOR]
{ { EXECUTE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON { PROCEDURE {proc_name ([{ argmode } [arg_name] arg_type } [, ...]) } [, ...]
 | ALL PROCEDURE IN SCHEMA schema_name [, ...] }
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified procedural language.

```
REVOKE [GRANT OPTION FOR]
{ USAGE | ALL [PRIVILEGES] }
ON LANGUAGE lang_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified large object.

```
REVOKE [GRANT OPTION FOR]
{ { SELECT | UPDATE } [, ...] | ALL [PRIVILEGES] }
ON LARGE OBJECT loid [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified schema.

```
REVOKE [GRANT OPTION FOR]
{ { CREATE | USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON SCHEMA schema_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified tablespace.

```
REVOKE [GRANT OPTION FOR]
{ { CREATE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON TABLESPACE tablespace_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified type.

```
REVOKE [GRANT OPTION FOR]
{ { USAGE | ALTER | DROP | COMMENT } [, ...] | ALL [PRIVILEGES] }
ON TYPE type_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke the permission on a specified sub-cluster.

```
REVOKE [GRANT OPTION FOR]
{ { CREATE | USAGE | COMPUTE | ALTER | DROP } [, ...] | ALL [PRIVILEGES] }
ON NODE GROUP group_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

#### NOTE

When the CREATE permission on a sub-cluster is revoked, the USAGE and COMPUTE permissions are revoked by default.

- Revoke the permission on a directory object.

```
REVOKE [GRANT OPTION FOR]
{ { READ | WRITE } [, ...] | ALL [PRIVILEGES] }
ON DIRECTORY directory_name [, ...]
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT];
```

- Revoke permissions from a role.  

```
REVOKE [ADMIN OPTION FOR]
 role_name [, ...] FROM role_name [, ...]
 [CASCADE | RESTRICT];
```
- Revoke the sysadmin permission from a role.  

```
REVOKE ALL { PRIVILEGES | PRIVILEGE } FROM role_name;
```
- Revoke the ANY permissions.  

```
REVOKE [ADMIN OPTION FOR]
 { CREATE ANY TABLE | ALTER ANY TABLE | DROP ANY TABLE | SELECT ANY TABLE | INSERT ANY
 TABLE | UPDATE ANY TABLE |
 DELETE ANY TABLE | CREATE ANY SEQUENCE | CREATE ANY INDEX | CREATE ANY FUNCTION |
 EXECUTE ANY FUNCTION |
 CREATE ANY TYPE | ALTER ANY TYPE | DROP ANY TYPE | ALTER ANY SEQUENCE | DROP ANY
 SEQUENCE |
 SELECT ANY SEQUENCE | ALTER ANY INDEX | DROP ANY INDEX | CREATE ANY SYNONYM | DROP
 ANY SYNONYM | CREATE ANY TRIGGER | ALTER ANY TRIGGER |
 DROP ANY TRIGGER
 } [, ...]
 FROM [GROUP] role_name [, ...];
```
- Revoke the permission on database links.  

```
REVOKE { CREATE | ALTER | DROP } [PUBLIC] DATABASE LINK FROM role_name;
```

#### NOTE

For details about database links, see [DATABASE LINK](#).

- Revoke the permission on PUBLIC synonyms.  

```
REVOKE { CREATE | DROP } PUBLIC SYNONYM FROM role_name;
```

Built-in roles (`gs_role_public_synonym_create` and `gs_role_public_synonym_drop`) can also be used to revoke the permission on PUBLIC synonyms.

  - Revoke the permission to create PUBLIC synonyms.  

```
REVOKE gs_role_public_synonym_create FROM role_name;
```
  - Revoke the permission to delete PUBLIC synonyms.  

```
REVOKE gs_role_public_synonym_drop FROM role_name;
```

## Parameters

The keyword PUBLIC indicates an implicitly defined group that has all roles.

For details about permission types and parameters, see [Parameters](#) in section "GRANT."

Permissions of a role include the permissions directly granted to the role, permissions inherited from the parent role, and permissions granted to PUBLIC. Therefore, revoking the SELECT permission on an object from PUBLIC users does not necessarily mean that the SELECT permission on the object has been revoked from all roles, because the SELECT permission directly granted to roles and inherited from parent roles remains. Similarly, if the SELECT permission is revoked from a user but is not revoked from PUBLIC users, the user can still run the SELECT statement.

If GRANT OPTION FOR is specified, the permission cannot be granted to others, but permission itself is not revoked.

If user A holds the UPDATE permissions on a table and the **WITH GRANT OPTION** option and has granted them to user B, the permissions that user B holds are called dependent permissions. If the permissions or the grant option held by

user A is revoked, the dependent permissions still exist. Those dependent permissions are also revoked if CASCADE is specified.

A user can only revoke permissions that were granted directly by that user. For example, if user A has granted permission with grant option (**WITH ADMIN OPTION**) to user B, and user B has in turn granted it to user C, then user A cannot revoke the permission directly from C. However, user A can revoke the grant option held by user B and use CASCADE. In this way, the permission of user C is automatically revoked. For another example, if both user A and user B have granted the same permission to C, A can revoke his own grant but not B's grant, so C will still effectively have the permission.

If the role executing REVOKE holds permissions indirectly by using more than one role membership path, it is unspecified which containing role will be used to execute the statement. In such cases, you are advised to use SET ROLE to become the specific role, and then execute REVOKE. Failure to do so may lead to deleting permissions not intended to delete, or not deleting any permissions at all.

## Examples

- Revoke the permission of role **jerry** from user **tom**.  

```
gaussdb=# REVOKE jerry FROM tom;
REVOKE ROLE
```
- Revoke the SELECT permission for the **t1** table in schema **jerry** from user **tom**.  

```
gaussdb=# REVOKE SELECT ON TABLE jerry.t1 FROM tom;
REVOKE
```
- Revoke the EXECUTE permission for the fun1 function in schema **jerry** from user **tom**.  

```
gaussdb=# REVOKE EXECUTE ON FUNCTION jerry.fun1() FROM tom;
REVOKE
```
- Revoke the CONNECT permission on database **DB1** from user **tom**.  

```
gaussdb=# REVOKE CONNECT ON database DB1 FROM tom;
REVOKE
```

For more examples, see [Examples](#) in section "GRANT."

[GRANT](#)

### 7.12.17.10 ROLLBACK

#### Description

Rolls back the current transaction and backs out all updates in the transaction.

If a fault occurs during the running of a transaction, the transaction cannot be executed. The system cancels all completed operations on the database in the transaction, and the database status returns to the time when the transaction starts.

#### Precautions

If a ROLLBACK statement is executed out of a transaction, no error occurs, but a notice is displayed.

## Syntax

```
ROLLBACK [WORK | TRANSACTION] ;
```

## Parameters

### WORK | TRANSACTION

Specifies the optional keyword that more clearly illustrates the syntax.

## Examples

```
-- Create a table.
gaussdb=# CREATE TABLE test (id int, name text);

-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Alter the table structure.
gaussdb=# ALTER TABLE test ADD COLUMN score int;

-- View the table structure.
gaussdb=# \d test;
Table "public.test"
Column | Type
-----+-----
id | integer
name | text
score | integer

-- Perform rollback.
gaussdb=# ROLLBACK;

-- The table structure is restored to the initial state.
gaussdb=# \d test;
Table "public.test"
Column | Type
-----+-----
id | integer
name | text
```

## Helpful Links

[COMMIT | END](#)

### 7.12.17.11 ROLLBACK PREPARED

## Description

Cancels a transaction ready for two-phase committing.

## Precautions

- The function is only available in maintenance mode (when the GUC parameter **xc\_maintenance\_mode** is set to **on**). Exercise caution when

enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.

- Only the user who initiates a transaction or a system administrator can roll back the transaction.
- The transaction function is maintained automatically by the database, and should be not visible to users.

## Syntax

```
ROLLBACK PREPARED transaction_id;
```

### NOTE

The distributed environment does not support the ROLLBACK PREPARED syntax.

## Parameters

### **transaction\_id**

Specifies the identifier of the transaction to be committed. The identifier must be different from those for current prepared transactions.

## Helpful Links

[COMMIT PREPARED](#) and [PREPARE TRANSACTION](#)

## 7.12.17.12 ROLLBACK TO SAVEPOINT

### Function

Rolls back to a savepoint. It implicitly destroys all savepoints that were established after the named savepoint.

Rolls back all statements that were executed after the savepoint was established. The savepoint remains valid and can be rolled back to again later, if needed.

### Precautions

- Specifying a savepoint name that has not been established is an error.
- Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a FETCH or MOVE statement inside a savepoint that is later rolled back, the cursor remains at the position that FETCH left it pointing to (that is, the cursor motion caused by FETCH is not rolled back). Closing a cursor is not undone by rolling back, either. A cursor whose execution causes a transaction to abort is put in a cannot-execute state, so while the transaction can be restored using **ROLLBACK TO SAVEPOINT**, the cursor can no longer be used.
- Use **ROLLBACK TO SAVEPOINT** to roll back to a savepoint. Use **RELEASE SAVEPOINT** to destroy a savepoint but keep the effects of the statements executed after the savepoint was established.

## Syntax

```
ROLLBACK [WORK | TRANSACTION] TO [SAVEPOINT] savepoint_name;
```

## Parameters

- **savepoint\_name**  
Rolls back to a savepoint.

## Examples

```
-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Set the savepoint my_savepoint.
gaussdb=# SAVEPOINT my_savepoint;

-- Roll back to the savepoint my_savepoint.
gaussdb=# ROLLBACK TO SAVEPOINT my_savepoint;

-- Cursor positions are not affected by savepoint rollback.
gaussdb=# DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;

-- Set the savepoint foo.
gaussdb=# SAVEPOINT foo;

-- Read a data record, which is the first one.
gaussdb=# FETCH 1 FROM foo;
?column?

 1
-- Roll back to the savepoint foo.
gaussdb=# ROLLBACK TO SAVEPOINT foo;

-- Read a data record, which is the second one.
gaussdb=# FETCH 1 FROM foo;
?column?

 2
-- Release a savepoint.
gaussdb=# RELEASE SAVEPOINT my_savepoint;

-- End the transaction.
gaussdb=# COMMIT;
```

## Helpful Links

[SAVEPOINT](#) and [RELEASE SAVEPOINT](#)

## 7.12.18 S

### 7.12.18.1 SAVEPOINT

#### Description

**SAVEPOINT** establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction. It allows all statements that are executed after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

## Precautions

- Use **ROLLBACK TO SAVEPOINT** to roll back to a savepoint. Use **RELEASE SAVEPOINT** to destroy a savepoint but keep the effects of the statements executed after the savepoint was established.
- Savepoints can only be established when inside a transaction block. Multiple savepoints can be defined in a transaction.
- In the case of an unexpected termination of a distributed thread or process caused by a node or connection failure, or of an error caused by the inconsistency between source and destination table structures in a COPY FROM operation, the transaction cannot be rolled back to the established savepoint. Instead, the entire transaction will be rolled back.
- According to the SQL standard, when a savepoint with the same name is created, the previous savepoint with the same name is automatically deleted. In GaussDB, the old savepoint is retained, but only the latest one is used during rollback or release. If the latest savepoint is released, the previous savepoint will again become accessible to ROLLBACK TO SAVEPOINT and RELEASE SAVEPOINT. In addition, **SAVEPOINT** fully complies with the SQL standard.

## Syntax

```
SAVEPOINT savepoint_name;
```

## Parameters

### savepoint\_name

Specifies the name of the new savepoint.

### NOTICE

When using SAVEPOINT, you are advised to release SAVEPOINT promptly to avoid too many nested subtransactions. It is recommended that the number of nested subtransactions be less than or equal to 10,000. If the number of nested subtransactions is too large, the current transaction performance may deteriorate.

## Examples

```
-- Create a table.
gaussdb=# CREATE TABLE table1(a int);

-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Insert data.
gaussdb=# INSERT INTO table1 VALUES (1);

-- Create a savepoint.
gaussdb=# SAVEPOINT my_savepoint;

-- Insert data.
```

```
gaussdb=# INSERT INTO table1 VALUES (2);
-- Roll back the savepoint.
gaussdb=# ROLLBACK TO SAVEPOINT my_savepoint;

-- Insert data.
gaussdb=# INSERT INTO table1 VALUES (3);

-- Commit the transaction.
gaussdb=# COMMIT;

-- Query the content of the table. You can see 1 and 3 at the same time, but cannot see 2 because 2 is
rolled back.
gaussdb=# SELECT * FROM table1;

-- Delete the table.
gaussdb=# DROP TABLE table1;

-- Create a table.
gaussdb=# CREATE TABLE table2(a int);

-- Start a transaction.
gaussdb=# START TRANSACTION;

-- Insert data.
gaussdb=# INSERT INTO table2 VALUES (3);

-- Create a savepoint.
gaussdb=# SAVEPOINT my_savepoint;

-- Insert data.
gaussdb=# INSERT INTO table2 VALUES (4);

-- Roll back the savepoint.
gaussdb=# RELEASE SAVEPOINT my_savepoint;

-- Commit the transaction.
gaussdb=# COMMIT;

-- Query the table content. You can see 3 and 4 at the same time.
gaussdb=# SELECT * FROM table2;

-- Delete the table.
gaussdb=# DROP TABLE table2;
```

### 7.12.18.2 SECURITY LABEL ON

#### Function

Applies, updates, or cancels a security label.

#### Precautions

An initial user, a user with the SYSADMIN permission, or a user who inherits the gs\_role\_seclabel permission of the built-in role can update or cancel security labels.

#### Syntax

```
SECURITY LABEL ON { ROLE | USER | TABLE | COLUMN } objname IS {'label_name' | NULL};
```

## Parameter Description

- **objname**
  - For **ROLE** and **USER**, **objname** indicates the user/role name.
  - For **TABLE**, **objname** indicates the table name, which can be prefixed with a schema name.
  - For **COLUMN**, **objname** indicates the name in the format of "table name.column name", which can be prefixed with a schema name.
- **label\_name**

Specifies the security label name.
- **NULL**

Specifies that the security label is canceled.

## Examples

```
-- Create a security label.
gaussdb=# CREATE SECURITY LABEL sec_label 'L1:G4';
-- Create a table.
gaussdb=# CREATE TABLE tbl(c1 int, c2 int);
-- Create a user.
gaussdb=# CREATE USER bob WITH PASSWORD '*****';
-- Apply a security label to the user.
gaussdb=# SECURITY LABEL ON ROLE bob IS 'sec_label';
-- Apply a security label to the table.
gaussdb=# SECURITY LABEL ON TABLE tbl IS 'sec_label';
-- Apply a security label to a column of the table.
gaussdb=# SECURITY LABEL ON COLUMN tbl.c1 IS 'sec_label';
-- Cancel the security label of the user.
gaussdb=# SECURITY LABEL ON ROLE bob IS NULL;
-- Cancel the security label of the table.
gaussdb=# SECURITY LABEL ON TABLE tbl IS NULL;
-- Cancel the security label of the column of the table.
gaussdb=# SECURITY LABEL ON COLUMN tbl.c1 IS NULL;
-- Delete the existing security label sec_label.
gaussdb=# DROP SECURITY LABEL sec_label;
-- Delete table tbl.
gaussdb=# DROP TABLE tbl;
-- Delete user bob.
gaussdb=# DROP USER bob;
```

[CREATE SECURITY LABEL](#) and [DROP SECURITY LABEL](#)

### 7.12.18.3 SELECT

#### Description

Retrieves data from a table or view.

Serving as an overlaid filter for a database table, **SELECT** filters required data from the table using SQL keywords.

#### Precautions

- The owner of the table, users granted with the **SELECT** permission on the table, and users granted with the **SELECT ANY TABLE** permission can read

data in the table or view. When the separation of duties is disabled, system administrators have this permission by default.

- SELECT can join ordinary tables, but cannot join ordinary and GDS foreign tables. That is, the SELECT statement cannot contain both an ordinary table and a GDS foreign table.
- You must have the SELECT permission on each field used in the SELECT statement.
- Using FOR UPDATE or FOR SHARE requires the UPDATE permission in addition to the SELECT permission.

## Syntax

- Query data.

```
[WITH [RECURSIVE] with_query [, ...]]
SELECT [/*+ plan_hint */] [ALL | DISTINCT [ON (expression [, ...])]]
 { * | {expression [[AS] output_name]} [, ...] }
 [FROM from_item [, ...]]
 [WHERE condition]
 [GROUP BY grouping_element [, ...]]
 [HAVING condition [, ...]]
 [WINDOW {window_name AS (window_definition)} [, ...]]
 [{ UNION | INTERSECT | EXCEPT | MINUS } [ALL | DISTINCT] select]
 [ORDER BY {expression [[ASC | DESC | USING operator] | nlssort_expression_clause] [NULLS { FIRST |
LAST }]} [, ...]]
 [LIMIT { [offset,] count | ALL }]
 [OFFSET start [ROW | ROWS]]
 [FETCH { FIRST | NEXT } [count] { ROW | ROWS } ONLY]
 [{FOR { UPDATE | SHARE } [OF table_name [, ...]] [NOWAIT | WAIT n | SKIP LOCKED]} [...]]
TABLE { ONLY { (table_name) | table_name } | table_name [*]};
```

### NOTE

In condition and expression, you can use the aliases of expressions in **targetlist** in compliance with the following rules:

- Reference only within the same level.
- Only reference aliases in **targetlist**.
- Reference a prior expression in a subsequent expression.
- The **volatile** function cannot be used.
- The **Window** function cannot be used.
- Aliases cannot be referenced in the **JOIN ON** condition.
- An error is reported if the target list contains multiple aliases to be referenced.

### NOTICE

In the scenario where the SELECT statement plan is cached, the WHERE IN candidate subset cannot be too large. It is recommended that the number of conditions be less than or equal to 100 to prevent high dynamic memory.

- If the WHERE IN candidate subset is too large, the memory usage of the generated plan increases.
- If the WHERE IN subsets constructed by concatenated SQL statements are different, the SQL template of the cache plan cannot be reused. A large number of different plans are generated, and the plans cannot be shared. As a result, a large amount of memory is occupied.

- The subquery **with\_query** is as follows:  
with\_query\_name [ ( column\_name [, ...] ) ]  
AS [ [ NOT ] MATERIALIZED ] ( {select | values | insert | update | delete} )
- The specified query source **from\_item** is as follows:  
{ [ ONLY ] table\_name [ \* ] [ partition\_clause ] [ [ AS ] alias [ ( column\_alias [, ...] ) ] ]  
[ TABLESAMPLE sampling\_method ( argument [, ...] ) [ REPEATABLE ( seed ) ] ]  
[ TIMECAPSULE {TIMESTAMP | CSN} expression ]  
( select ) [ AS ] alias [ ( column\_alias [, ...] ) ]  
|with\_query\_name [ [ AS ] alias [ ( column\_alias [, ...] ) ] ]  
|function\_name ( [ argument [, ...] ] ) [ AS ] alias [ ( column\_alias [, ...] | column\_definition [, ...] ) ]  
|function\_name ( [ argument [, ...] ] ) AS ( column\_definition [, ...] )  
|xmltable\_clause  
|from\_item unpivot\_clause  
|from\_item pivot\_clause  
|from\_item [ NATURAL ] join\_type from\_item [ ON join\_condition | USING ( join\_column [, ...] ) ] }
- The **group** clause is as follows:  
( )  
| expression  
| ( expression [, ...] )  
| ROLLUP ( { expression | ( expression [, ...] ) } [, ...] )  
| CUBE ( { expression | ( expression [, ...] ) } [, ...] )  
| GROUPING SETS ( grouping\_element [, ...] )
- The specified partition **partition\_clause** is as follows:  
PARTITION { ( partition\_name [, ...] ) | FOR ( partition\_value [, ...] ) }

 **NOTE**

- The specified partition applies only to partitioned tables.
- If PARTITION specifies multiple partition names, the partition names can be the same. The union set of the partition ranges is used.
- The sorting order **nlssort\_expression\_clause** is as follows:  
NLSSORT ( column\_name, ' NLS\_SORT = { SCHINESE\_PINYIN\_M | generic\_m\_ci } ' )  
The second parameter can be **generic\_m\_ci**, which supports only the case-insensitive order for English characters.
- Simplified query syntax, equivalent to **select \* from table\_name**.  
TABLE { ONLY {(table\_name)| table\_name} | table\_name [ \* ]};

## Parameters

- **WITH [ RECURSIVE ] with\_query [, ...]**  
Specifies one or more subqueries that can be referenced by name in the main query, which is equivalent to a temporary table. This subquery statement structure is called the common table expression (CTE) structure. When this structure is used, the execution plan contains the CTE SCAN content.  
If **RECURSIVE** is specified, it allows a **SELECT** subquery to reference itself by name.  
The detailed format of **with\_query** is as follows: **with\_query\_name** [ ( column\_name [, ...] ) ] AS [ [ NOT ] MATERIALIZED ] ( {select | values | insert | update | delete} )
  - **with\_query\_name** specifies the name of the result set generated by a subquery. Such names can be used to access the result sets of subqueries in a query.
  - **column\_name** specifies the column name displayed in the subquery result set.
  - Each subquery can be a SELECT, VALUES, INSERT, UPDATE or DELETE statement.

- RECURSIVE can appear only after WITH. In the case of multiple CTEs, you only need to declare RECURSIVE at the first CTE.
- You can use **MATERIALIZED** or **NOT MATERIALIZED** to modify the CTE. Currently, only inline execution is supported for stream plans. In this case, this syntax does not take effect.
  - If **MATERIALIZED** is specified, the WITH query will be materialized, and a copy of the subquery result set is generated. The copy is directly queried at the reference point. Therefore, the WITH subquery cannot be jointly optimized with the SELECT statement trunk (for example, predicate pushdown and equivalence class transfer). In this scenario, you can use **NOT MATERIALIZED** for modification. If the WITH query can be executed as a subquery inline, the preceding optimization can be performed.
  - If the user does not explicitly declare the materialized attribute, comply with the following rules: If the CTE is referenced only once in the SELECT statement trunk to which it belongs and semantically supports inline execution, it will be rewritten as subquery inline execution. Otherwise, the materialized execution will be performed in CTE Scan mode.
- **plan\_hint** clause  
Follows the SELECT keyword in the */\*+<Plan hint> \*/* format. It is used to optimize the plan of a SELECT statement block. For details, see [Hint-based Tuning](#). In each statement, only the first */\*+ plan\_hint\*/* comment block takes effect as a hint. Multiple hints can be written.
- **ALL**  
Specifies that all rows that meet the conditions are returned. This is the default behavior and can be omitted.
- **DISTINCT [ ON ( expression [, ...] ) ]**  
Removes all duplicate rows from the **SELECT** result set so one row is kept from each group of duplicates.  
Only the first row in the set of rows that have the same result calculated on the given expression **ON ( expression [, ...] )** is retained.

---

**NOTICE**

**DISTINCT ON** expression is explained with the same rule of **ORDER BY**. Unless you use **ORDER BY** to ensure that the required row appears first, you cannot know what the first row is.

- 
- **SELECT list**  
Specifies the name of a column in the table to be queried. The value can be a part of the column name or all of the column names. The wildcard (\*) is used to represent the column name.  
You may use the **AS output\_name** clause to give an alias for an output column. The alias is used for the displaying of the output column. The name, value, and type keywords can be used as column aliases.  
Column names can be expressed in the following formats:

- Manually input column names which are separated by commas (,)
- Columns computed in the FROM clause.

- **FROM clause**

Specifies one or more source tables for SELECT.

The FROM clause can contain the following elements:

- `table_name`

Specifies the name of a table or view. The schema name can be added before the table name or view name, for example, `schema_name.table_name`.

 **NOTE**

You can use database link to perform operations on remote tables and synonyms. For details, see [DATABASE LINK](#).

- `alias`

Gives a temporary alias to a table to facilitate the quotation by other queries.

An alias is used for brevity or to eliminate ambiguity for self-joins. If an alias is provided, it completely replaces the actual name of the table.

---

**NOTICE**

If an alias is specified for the *joined\_table* table created by JOIN and *joined\_table* is wrapped with "()", that is, (*joined\_table*), non-reserved keywords UNPIVOT and PIVOT cannot be used as aliases.

- TABLESAMPLE `sampling_method` ( `argument` [, ...] ) [ REPEATABLE ( `seed` ) ]

The TABLESAMPLE clause following *table\_name* specifies that the specified *sampling\_method* should be used to retrieve the subset of rows in the table.

The optional REPEATABLE clause specifies the number of seeds used to generate random numbers in the sampling method. The seed value can be any non-null constant value. If the table was not changed during the query, the two queries having the same seed and *argument* values will select the same sampling in this table. However, different seed values usually generate different samples. If **REPEATABLE** is not specified, a new random sample will be selected for each query based on the seed generated by the system.

- TIMECAPSULE { `TIMESTAMP` | `CSN` } `expression`

Queries the table data of a specified CSN or at a specified time point.

Currently, the following tables do not support flashback query: system catalogs, DFS tables, global temporary tables, local temporary tables, unlogged tables, views, sequence tables, hash bucket tables, shared tables, and inherited tables.

- TIMECAPSULE `TIMESTAMP`

Searches for the result set of a specified time point based on the date as the flashback query flag. *date* must be a valid past timestamp.

- **TIMECAPSULE CSN**

Searches for the result set of a specified CSN based on the CSN flashback of the table as the flashback query flag. The CSN can be obtained from **snpcsn** recorded in **gs\_txn\_snapshot**.

- **expression**

Constants, functions, or SQL expressions.

 **NOTE**

- A flashback query cannot span statements that affect the table structure or physical storage. Otherwise, an error is reported. Between the flashback point and the current point, if a statement (TRUNCATE, DDL, DCL, or VACUUM FULL) has been executed to modify the table structure or affect physical storage, the flashback fails.
- Flashback query supports scanning PCR UB-tree indexes. If no such indexes, flashback query supports only seqScan for full table scanning.
- When the flashback point is too old, the old version cannot be obtained because the flashback version is recycled. As a result, the flashback fails and the error message "Restore point too old" is displayed.
- The flashback point is specified by time. The maximum difference between the flashback point and the actual time is 3 seconds.
- After truncating a table, perform a flashback query or flashback on the table. The error message "Snapshot too old" is displayed when a flashback is performed at a specified time point. Data cannot be found or the error message "Snapshot too old" is reported during the CSN-based flashback.
- In the GTM-free scenario, each node uses the local CSN and does not have a globally unified CSN. Therefore, flashback in CSN mode is not supported.

- **column\_alias**

Specifies the column alias.

- **PARTITION**

Queries data in the specified partition in a partitioned table.

- **partition\_name**

Specifies the name of a partition.

- **partition\_value**

Specifies the value of the specified partition key. If there are many partition keys, use the **PARTITION FOR** clause to specify the value of the only partition key you want to use.

- **subquery**

Performs a subquery in the **FROM** clause. A temporary table is created to save subquery results.

- **with\_query\_name**

Specifies that the **WITH** clause can also be used as the source of the **FROM** clause and can be referenced by the name of the **WITH** query.

- function\_name  
Function name. Function calls can appear in the **FROM** clause.
- join\_type  
The options are as follows:
  - [ INNER ] JOIN  
A **JOIN** clause combines two **FROM** items. You can use parentheses to determine the order of nesting. In the absence of parentheses, **JOIN** nests left-to-right.
  - LEFT [ OUTER ] JOIN  
Returns all rows that meet join conditions in the Cartesian product, plus those rows that do not match the right table rows in the left table by join conditions. This left-hand row is extended to the full width of the joined table by inserting **NULL** values for the right-hand columns. Note that only the **JOIN** clause's own condition is considered while the system decides which rows have matches. Outer conditions are applied afterward.
  - RIGHT [ OUTER ] JOIN  
Returns all the joined rows, plus one row for each unmatched right-hand row (extended with **NULL** on the left).  
This is just a notational convenience, since you could convert it to a **LEFT OUTER JOIN** by switching the left and right inputs.
  - FULL [ OUTER ] JOIN  
Returns all the joined rows, pluses one row for each unmatched left-hand row (extended with **NULL** on the right), and pluses one row for each unmatched right-hand row (extended with **NULL** on the left).
  - CROSS JOIN  
Is equivalent to **INNER JOIN ON (TRUE)**, which means no rows are removed by qualification. These join types are just a notational convenience, since they do nothing you could not do with plain **FROM** and **WHERE**.

 **NOTE**

For the **INNER** and **OUTER** join types, a join condition must be specified, namely exactly one of **NATURAL ON**, **join\_condition**, or **USING (join\_column [, ...])**. For **CROSS JOIN**, none of these clauses can appear.

**CROSS JOIN** and **INNER JOIN** produce a simple Cartesian product, the same result as you get from listing the two items at the top level of **FROM**.

- ON join\_condition  
Defines which rows have matches in joins. Example: ON left\_table.a = right\_table.a You are advised not to use numeric types such as int for **join\_condition**, because such types can be implicitly converted to bool values (non-zero values are implicitly converted to **true** and **0** is implicitly converted to **false**), which may cause unexpected results.
- USING(join\_column[, ...])

ON left\_table.a = right\_table.a AND left\_table.b = right\_table.b ...  
abbreviation. Corresponding columns must have the same name.

- NATURAL

Is a shorthand for a **USING** list that mentions all columns in the two tables that have the same names.

- from item

Specifies the name of the query source object connected.

- xmltable\_clause

Currently, xmltable\_clause can be used only in ORA or PG compatibility mode. xmltable\_clause produces a virtual table based on data of the given XMLTYPE (in ORA compatibility mode) or XML (in PG compatibility mode) type. The syntax format is as follows:

```
XMLTABLE(
 xmlnamespaces_clause
 row_expression
 passing_clause
 columns_clause
)
```

■ For xmlnamespaces\_clause:

```
[
 XMLNAMESPACES(
 {string AS identifier }
 |
 { DEFAULT string }
 [, { string AS identifier } | { DEFAULT string }]...
),
]
```

The optional xmlnamespaces\_clause is a clause that starts with XMLNAMESPACES followed by a comma-separated XML namespace declaration. **string** indicates the full name of the namespace for which single quotation marks are used as boundary characters. **identifier** indicates the namespace alias for which double quotation marks are used as boundary characters. The alias can be used in row\_expression and columns\_clause. In the current version, DEFAULT cannot be used to declare the default namespace.

■ row\_expression

The required **row\_expression** is an XPath 1.0 expression with English single quotation marks as boundary characters. The document\_expression in the subsequent passing\_clause is used as its context to obtain a group of XML nodes. These nodes are processed by columns\_clause to generate each row of the virtual table.

■ For passing\_clause:

```
PASSING [BY { REF | VALUE }] document_expression [BY { REF | VALUE }]
```

The required **passing\_clause** starts with PASSING, where **document\_expression** is the data of the XMLTYPE (in ORA compatibility mode) or XML (in PG compatibility mode) type that is processed in the transferred **XMLTABLE**. Currently, only single-root data is supported. In ORA compatibility mode, an error is reported regardless of whether BY VALUE or BY REF in the first or second place is used. In PG compatibility mode, although BY VALUE or BY REF in the first and second places can be identified and received, no functional processing is performed.

- For `columns_clause`:

```
[
 COLUMNS
 name { type [PATH column_expression] [DEFAULT default_expression] [NOT NULL |
 NULL] | FOR ORDINALITY }
 [, ...]
]
```

The optional **columns\_clause** is used to specify the information required for the columns to be generated in the virtual table.

**name**: indicates the name of a column.

**type**: indicates the column type.

**PATH**: **column\_expression** in the optional **PATH** part is an expression of XPath 1.0. A node in the node set obtained by **row\_expression** is used as the context of the node, and the data required by the value of the corresponding column in the row data generated by the node is obtained through processing by the node. There is an implicit conversion when it is converted to a result of the **TYPE** type. If the **PATH** part is not provided, **name** is regarded as **column\_expression**.

**DEFAULT**: **default\_expression** in the optional **DEFAULT** part is an expression. If a **NULL** value is obtained after **column\_expression** processing, the result obtained by calculating **default\_expression** is used to generate the value of the column. Note that **default\_expression** is calculated only when necessary. If the expression is stable, **default\_expression** is calculated only once when necessary.

**NOT NULL | NULL**: In PG compatibility mode, the optional **NOT NULL** or **NULL** is used to indicate whether the column value can be **NULL**. If the column value is inconsistent with the specified option, an error is reported.

**FOR ORDINALITY**: indicates that the column is a row number column. Row numbers starting from 1 are filled for generated rows. Only one column can be marked as **FOR ORDINALITY**.

In ORA compatibility mode, **columns\_clause** can be omitted. After **columns\_clause** is omitted, the default **columns\_clause**: **COLUMNS column\_value XMLTYPE PATH '.'** is generated internally for subsequent processing. In PG compatibility mode, **columns\_clause** cannot be omitted.

**NOTICE**

Currently, `xmldata_clause` has the following restrictions:

- The involved XPath expressions are XPath 1.0.
- Currently, XPath expressions such as `'..'` cannot be used in **column\_expression**.
- When the data obtained through **column\_expression** is converted to the data of the TYPE type, in ORA compatibility mode, if the obtained data is too long and exceeds the typmod of the type, the data will be truncated. Currently, long data is truncated only when the typmod of the CHAR, CHARACTER, NCHAR, BPCHAR, VARCHAR, CHARACTER VARYING, VARCHAR2 and NVARCHAR2 data types (including those attached with (n)) is greater than 0. In PG compatibility mode, an error is reported.
- Currently, the maximum size of the input XMLTYPE (in ORA compatibility mode) or XML (in PG compatibility mode) type data is 1 GB.
- For upgrade from a version that does not support XMLTABLE to a version that supports XMLTABLE, the XMLTABLE syntax cannot be used during the upgrade observation period.
- The following expression is supported in XPath only in ORA compatibility mode: `*:nodename`, where **nodename** indicates the node name. This expression indicates that the namespace of the node specified by **nodename** is ignored when the node is selected.
- The non-reserved keyword XMLTABLE cannot be used as the name of a function of the Functions as Table Sources type.

 **NOTE**

When non-constructed XMLTYPE (in ORA compatibility mode) data is entered, spaces and carriage return characters that are at the same level as the non-constructed part and are used to control the writing format between nodes are parsed as text nodes. For example, in the following text, the space and carriage return between the end label of **node2** and the start label of **node3** are parsed as text nodes, which is different from that in database ORA.

Input:

```
<root>
<node1>node1</node1>
malform
<node2>node2</node2>
<node3>node3</node3>
</root>
```

Actual situation:

```
<root><node1>node1</node1>
malform
<node2>node2</node2>
<node3>node3</node3>
</root>
```

Currently, the functions implemented by `xmldata_clause` are different from those implemented by databases ORA and PG. Pay attention to the differences. For details, see [Table 7-246](#).

**Table 7-246** Comparison between GaussDB Kernel and databases ORA and PG

GaussDB Kernel	PostgreSQL	ORA
XPath 1.0 expressions are used at <b>row_expression</b> and <b>PATH</b> in <b>columns_clause</b> .	Same as that in GaussDB Kernel.	XQuery 1.0 expressions are used at <b>row_expression</b> and <b>PATH</b> in <b>columns_clause</b> .
The default namespace function is not supported.	Same as that in GaussDB Kernel.	The default namespace function is supported.
A single data record can be transferred through <b>passing_clause</b> , but the alias cannot be used.	Same as that in GaussDB Kernel. (Note that the input data is of the XML type.)	Multiple data records can be transferred through the corresponding clause and aliases can be used.
The <b>passing_clause</b> cannot be omitted.	Same as that in GaussDB Kernel.	The corresponding clause can be omitted.
The RETURNING SEQUENCE BY REF clause cannot be used after <b>passing_clause</b> .	Same as that in GaussDB Kernel.	The RETURNING SEQUENCE BY REF clause can be used after the corresponding clause.
In <b>columns_clause</b> , ( SEQUENCE ) BY REF cannot be used to modify the returned data of the XML type.	Same as that in GaussDB Kernel.	You can use ( SEQUENCE ) BY REF in the corresponding clause to modify the returned data of the XML type.
If the <b>PATH</b> part in <b>columns_clause</b> is omitted and the column name is not enclosed using double quotation marks (""), the node can be correctly found for subsequent operations when the node name in the data transferred to XMLTABLE is in lowercase.	Same as that in GaussDB Kernel.	If the corresponding part is omitted and the column name is not enclosed using double quotation marks (""), the node can be correctly found for subsequent operations when the node name in the data transferred to XMLTABLE is in uppercase.

GaussDB Kernel	PostgreSQL	ORA
The declaration of the column type in <b>columns_clause</b> cannot be omitted.	Same as that in GaussDB Kernel.	The declaration of the column type in the corresponding clause can be omitted.
In ORA compatibility mode, the <b>columns_clause</b> can be omitted. In PG compatibility mode, the <b>columns_clause</b> cannot be omitted.	The corresponding clause cannot be omitted.	The corresponding clause can be omitted.
In ORA compatibility mode, if the returned data length exceeds the typmod of the type, the data is truncated. In PG compatibility mode, if the returned data length exceeds the typmod of the type, an error is reported.	An error is reported when the length of the returned data exceeds the typmod of the type.	If the length of the returned data exceeds the value of typmod, the data is truncated.

Example:

```
gaussdb=# CREATE DATABASE test DBCOMPATIBILITY = 'ORA';
gaussdb=# \c test
test=# SELECT * FROM XMLTABLE(
test(# XMLNAMESPACES('namespace1' AS "ns1", 'namespace2' AS "ns2"), -- Declare two XML
namespaces 'namespace1' and 'namespace2' and the corresponding aliases "ns1" and "ns2".
test(# '/ns1:root/*:child' -- Select the root node whose namespace is 'namespace1' from the
transferred data through row_expression, select all child nodes under the root node, and ignore
the child namespaces. ns1 is the alias of 'namespace1'.
test(# PASSING xmltype(
test(# '<root xmlns="namespace1">
test'# <child>
test'# <name>peter</name>
test'# <age>11</age>
test'# </child>
test'# <child xmlns="namespace1">
test'# <name>qiqi</name>
test'# <age>12</age>
test'# </child>
test'# <child xmlns="namespace2">
test'# <name>hacker</name>
test'# <age>15</age>
test'# </child>
test'# </root>')
test(# COLUMNS
test(# columns FOR ORDINALITY, -- Row number column
test(# name varchar(10) path 'ns1:name', -- Select the name node whose namespace is
'namespace1' from each child node obtained by row_expression, convert the value in the node to
varchar(10), and return the value. ns1 is the alias of namespace1.
test(# age int); -- Select the age node from each child node obtained by row_expression,
convert the value in the node to int, and return the value. The first child node does not explicitly
specify the namespace. Therefore, the namespace of the parent node root is followed.
```

Therefore, no value in this column is returned.

```
column | name | age
-----+-----
 1 | peter |
 2 | qiqi |
 3 | |
(3 rows)
```

-- Switch to the default database and delete the *test* database. Change the database name as required.

```
gaussdb=# \c postgres
gaussdb=# DROP DATABASE test;
```

#### – unpivot\_clause

Converts a column to a row. The syntax format is as follows:

```
UNPIVOT [{INCLUDE | EXCLUDE} NULLS]
(
 unpivot_col_clause
 unpivot_for_clause
 unpivot_in_clause
)
```

- {INCLUDE | EXCLUDE} NULLS

Controls whether the converted result contains NULL rows. **INCLUDE NULLS** indicates that the converted results contain NULL rows. **EXCLUDE NULLS** indicates that the converted results do not contain NULL rows. If this clause is ignored, the unpivot operation removes NULL rows from the converted results by default.

- unpivot\_col\_clause

```
unpivot_col_element
```

**unpivot\_col\_element** specifies the output column names. These columns store the values to be converted.

- unpivot\_col\_element

```
{ column | (column [, column]...) }
```

**unpivot\_col\_element** has two forms: column and ( column [, column]... ).

- unpivot\_for\_clause

```
FOR { unpivot_col_element }
```

**unpivot\_col\_element** contained in the **unpivot\_for\_clause** is used to specify the output column names. These columns store the alias and names of the column to be converted.

- unpivot\_in\_clause

```
IN (unpivot_in_element [,unpivot_in_element...])
```

**unpivot\_in\_clause** specifies the columns to be converted. The column names and column values are saved in the previously specified output columns.

```
unpivot_in_element
```

```
{ unpivot_col_element } [AS { unpivot_alias_element }]
```

**unpivot\_col\_element** specifies the column to be converted. If ( column [, column]... ) is used to specify the column to be converted, the *column* names are connected by underscores ( `_` ) and saved in the output columns. For example, IN ((col1, col2)) generates the column name **col1\_col2** and saves it in the output column specified by **unpivot\_for\_clause**. In addition, the AS keyword can be used to specify an alias for the column to be converted. Once an alias is

specified, the alias is saved in the output column instead of the name of column to be converted.

- `unpivot_alias_element`  
{ alias | ( alias [, alias]... ) }

Similar to **unpivot\_col\_element**, **unpivot\_alias\_element** has two forms. **alias** indicates the specified alias.

#### NOTICE

Currently, **unpivot\_clause** has the following restrictions:

- This parameter can be used only in ORA compatibility mode.
- The **unpivot\_clause** clause cannot be used with hints.
- For **unpivot\_col\_clause**, the number of output columns specified by **unpivot\_col\_element** must be the same as that of **unpivot\_col\_element** contained in **unpivot\_in\_clause**.
- For **unpivot\_for\_clause**, the number of output columns specified by **unpivot\_col\_element** must be the same as the number of aliases specified by **unpivot\_alias\_element** contained in **unpivot\_in\_clause**.
- For **unpivot\_in\_clause**, the alias must be a constant or an expression that can be converted to a constant.
- For **unpivot\_in\_clause**, constant expressions support only IMMUTABLE functions.
- For all **unpivot\_col\_element** parameters contained in **unpivot\_in\_clause**, if the column types in the same position of these **unpivot\_col\_element** parameters are different, UNPIVOT attempts to convert the column types in order to convert the values of columns to be converted to a public type. Similarly, for all **unpivot\_alias\_element** parameters, if the alias types of these **unpivot\_alias\_element** parameters in the same position are different, UNPIVOT attempts to do the similar type conversion.

For example, assume that there is an **unpivot\_in\_clause** in the form of IN (col1, col2), where col1 is of the int type and col2 is of the float type, UNPIVOT attempts to convert the column value of col1 to the public type float during the calculation.

#### – pivot\_clause

Converts a row into column. The syntax format is as follows:

```
PIVOT [XML]
(aggregate_function (expr) [[AS] alias]
 [, aggregate_function (expr) [[AS] alias]]...
 pivot_for_clause
 pivot_in_clause
)
```

- `aggregate_function ( expr ) [[AS] alias ]`  
Aggregates calculation on a given expression. The calculation result is saved in the output column specified by **pivot\_in\_clause**. [AS] alias (The AS keyword can be omitted.) can be used to specify an alias for **aggregate\_function**. The alias is added to the end of output column name specified by **pivot\_in\_clause** in the format of "*\_alias*".

- **pivot\_for\_clause**

```
FOR { column
 | (column [, column]...)
}
```

Specifies the row to be converted. The **column** indicates a column of the row to be converted.

- **pivot\_in\_clause**

```
IN ({ { { expr
 | (expr [, expr]...)
 } [[AS] alias
 } ...
 }
)
```

Specifies the name of the output column. The column name can consist of one or more expressions, for example, (expr1, expr2). When a column name consists of multiple expressions, these expressions are connected by underscores ( \_ ) in sequence. That is, the output column name corresponding to (expr1, expr2) is "expr1\_expr2". These expressions not only generate output column names, but also determine the time when the aggregate function is triggered. If the values of row to be converted is the same as the value of these expressions, the results calculated by **aggregate\_function** are saved in the output column names that consist of these expressions. Assume that expr1 is "1" and expr2 is "2". For row "1 2", **aggregate\_function** is used for calculation. For row "1 1", the calculation is not triggered.

---

**NOTICE**

Currently, **pivot\_clause** has the following restrictions:

- This parameter can be used only in ORA compatibility mode.
- The **pivot\_clause** clause cannot be used with hints.
- If more than one **aggregate\_function** is specified, at most one **aggregate\_function** is allowed to have no alias, the rest of the **aggregate\_function** functions are required to specify an alias.
- XML supports only syntax but does not support functions.
- The expression in **pivot\_in\_clause** can be a constant or an expression that can be converted to a constant. If the expression is not a unary expression, specify an alias for the expression.
- For **pivot\_in\_clause**, constant expressions support only IMMUTABLE functions.
- For the expression in **pivot\_in\_clause**, when the keyword AS is used to specify an alias for the expression, only the non-reserved keywords can be used as aliases.
- If the length of an output column name exceeds 63 characters, an error is reported.

---

- **WHERE clause**

Forms an expression for row selection to narrow down the query range of **SELECT**. **condition** indicates any expression that returns a value of Boolean

type. Rows that do not meet this condition will not be retrieved. You are advised not to use numeric types such as int for **condition**, because such types can be implicitly converted to bool values (non-zero values are implicitly converted to **true** and 0 is implicitly converted to **false**), which may cause unexpected results.

In the **WHERE** clause, you can use the operator (+) to convert a table join to an outer join. However, this method is not recommended because it is not the standard SQL syntax and may raise syntax compatibility issues during platform migration. There are many restrictions on using the operator (+):

- a. It can appear only in the **WHERE** clause.
- b. If a table join has been specified in the **FROM** clause, the operator (+) cannot be used in the **WHERE** clause.
- c. The operator (+) can work only on columns of tables or views, instead of on expressions.
- d. If table A and table B have multiple join conditions, the operator (+) must be specified in all the conditions. Otherwise, the operator (+) will not take effect, and the table join will be converted into an inner join without any prompt information.
- e. Tables specified in a join condition where the operator (+) works cannot cross queries or subqueries. If tables where the operator (+) works are not in the **FROM** clause of the current query or subquery, an error will be reported. If a peer table for the operator (+) does not exist, no error will be reported and the table join will be converted into an inner join.
- f. Expressions where the operator (+) is used cannot be directly connected through **OR**.
- g. If a column where the operator (+) works is compared with a constant, the expression becomes a part of the JOIN condition.
- h. A table cannot have multiple foreign tables.
- i. The operator (+) can appear only in the following expressions: comparison, NOT, ANY, ALL, IN, NULLIF, IS DISTINCT FROM, and IS OF. It is not allowed in other types of expressions. In addition, these expressions cannot be connected through **AND** or **OR**.
- j. The operator (+) can be used to convert a table join only to a left or right outer join, instead of a full join. That is, the operator (+) cannot be specified on both tables of an expression.

---

#### NOTICE

For the **WHERE** clause, if special character "%", "\_", or "\" is queried in **LIKE**, add the slash "\" before each character.

---

- **GROUP BY clause**

Condenses query results into a single row all selected rows that share the same values for the grouped expressions.

- CUBE ( { expression | ( expression [, ...] ) } [, ...] )

A CUBE grouping is an extension to the **GROUP BY** clause that creates subtotals for all of the possible combinations of the given list of grouping columns (or expressions). In terms of multidimensional analysis, CUBE

generates all the subtotals that could be calculated for a data cube with the specified dimensions. For example, given three expressions ( $n=3$ ) in the CUBE clause, the operation results in  $2^n = 2^3 = 8$  groupings. Rows grouped on the values of  $n$  expressions are called regular rows, and the rest are called superaggregate rows.

- GROUPING SETS ( grouping\_element [, ...] )

Another extension to the GROUP BY clause. It allows users to specify multiple GROUP BY options. This improves efficiency by trimming away unnecessary data group. After you specify the required data group, the database does not need to compute a whole ROLLUP or CUBE.

#### NOTICE

- If a SELECT list expression references ungrouped columns and no aggregate function is used, an error is reported. This is because multiple values may be returned for ungrouped columns.
- If a SELECT list expression references a constant, the GROUP BY clause does not need to group the constant. Otherwise, an error is reported.

- **HAVING clause**

Selects special groups by working with the **GROUP BY** clause. The **HAVING** clause compares some attributes of groups with a constant. Only groups that matching the logical expression in the **HAVING** clause are extracted.

- **WINDOW clause**

The general format is **WINDOW window\_name AS ( window\_definition ) [, ...]**. **window\_name** is a name can be referenced by **window\_definition**. **window\_definition** can be expressed in the following forms:

```
[existing_window_name]
[PARTITION BY expression [, ...]]
[ORDER BY expression [ASC | DESC | USING operator] [NULLS { FIRST | LAST }] [, ...]]
[frame_clause]
```

**frame\_clause** defines a **window frame** for the window function. The window function (not all window functions) depends on **window frame** and **window frame** is a set of relevant rows of the current query row. **frame\_clause** can be expressed in the following forms:

```
[RANGE | ROWS] frame_start
[RANGE | ROWS] BETWEEN frame_start AND frame_end
```

**frame\_start** and **frame\_end** can be expressed in the following forms:

```
UNBOUNDED PRECEDING
VALUE PRECEDING
CURRENT ROW
VALUE FOLLOWING
UNBOUNDED FOLLOWING
```

- **UNION clause**

Computes the set union of the rows returned by the involved SELECT statements.

The UNION clause has the following constraints:

- By default, the result of UNION does not contain any duplicate rows unless the ALL clause is declared.
- Multiple UNION operators in the same SELECT statement are evaluated left to right, unless otherwise specified by parentheses.

- **FOR UPDATE** cannot be specified either for a UNION result or for any input of a UNION.

General expression:

```
select_statement UNION [ALL] select_statement
```

- **select\_statement** can be any SELECT statement without an ORDER BY, LIMIT, or FOR UPDATE clause.
- ORDER BY and LIMIT can be attached to the subexpression if it is enclosed in parentheses.

- **INTERSECT clause**

Computes the set intersection of rows returned by the involved SELECT statements. The result of INTERSECT does not contain any duplicate rows.

The INTERSECT clause has the following constraints:

- Multiple INTERSECT operators in the same SELECT statement are evaluated left to right, unless otherwise specified by parentheses.
- Processing INTERSECT preferentially when UNION and INTERSECT operations are executed for results of multiple SELECT statements.

General format:

```
select_statement INTERSECT select_statement
```

**select\_statement** can be any SELECT statement without a FOR UPDATE clause.

- **EXCEPT clause**

Has the following common form:

```
select_statement EXCEPT [ALL] select_statement
```

**select\_statement** can be any SELECT statement without a FOR UPDATE clause.

The EXCEPT operator computes the set of rows that are in the result of the left SELECT statement but not in the result of the right one.

The result of EXCEPT does not contain any duplicate rows unless the ALL clause is declared. To execute **ALL**, a row that has  $m$  duplicates in the left table and  $n$  duplicates in the right table will appear  $\text{MAX}(m-n, 0)$  times in the result set.

Multiple **EXCEPT** operators in the same **SELECT** statement are evaluated left to right, unless parentheses dictate otherwise. **EXCEPT** binds at the same level as **UNION**.

Currently, **FOR UPDATE** cannot be specified either for an **EXCEPT** result or for any input of an **EXCEPT**.

- **MINUS clause**

Has the same function and syntax as **EXCEPT** clause.

- **ORDER BY clause**

Sorts data retrieved by **SELECT** in descending or ascending order. If the **ORDER BY** expression contains multiple columns:

- If two columns are equal according to the leftmost expression, they are compared according to the next expression and so on.
- If they are equal according to all specified expressions, they are returned in an implementation-dependent order.

- When used with the **DISTINCT** keyword, the columns to be sorted in **ORDER BY** must be included in the columns of the result set retrieved by the SELECT statement.
- When used with the **GROUP BY** clause, the columns to be sorted in **ORDER BY** must be included in the columns of the result set retrieved by the SELECT statement.

When the clause is not used with the GROUP BY clause and the columns of the result set retrieved by the SELECT statement contain aggregate functions:

- The ORDER BY clause is ignored if the columns of the retrieved result set do not contain any set returning functions.
- Only the sorting of the columns that contain set returning functions is retained if the columns of the retrieved result set contain set returning functions.

#### NOTE

To support Chinese pinyin order, set the encoding format to **UTF-8**, **GB18030**, **GB18030\_2022**, **GBK**, or **ZHS16GBK** when initializing the database. The statements are as follows:

```
initdb -E UTF8 -D ../data -locale=zh_CN.UTF-8
initdb -E GB18030 -D ../data -locale=zh_CN.GB18030
initdb -E GB18030_2022 -D ../data -locale=zh_CN.GB18030
initdb -E GBK -D ../data -locale=zh_CN.GBK
initdb -E ZHS16GBK -D ../data -locale=zh_CN.GBK
```

- **LIMIT clause**

Consists of two independent sub-clauses:

**LIMIT { count | ALL }** limits the number of rows to be returned. **count** specifies the number of rows to be returned. The effect of **LIMIT ALL** is the same as that of omitting the LIMIT clause.

**OFFSET start count** specifies the maximum number of rows to return, while **start** specifies the number of rows to skip before starting to return rows. When both are specified, **start** rows are skipped before starting to count the **count** rows to be returned.

ROWNUM cannot be used as count or offset in the LIMIT clause.

- **OFFSET clause**

The SQL: 2008 standard has introduced a different clause:

OFFSET start { ROW | ROWS }

**start** specifies the number of rows to skip before starting to return rows.

- **FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } ONLY**

If **count** is omitted in a **FETCH** clause, it defaults to 1.

- **FOR UPDATE clause**

The FOR UPDATE clause locks the rows retrieved by SELECT. This ensures that the rows cannot be modified or deleted by other transactions until the current transaction ends. That is, other transactions that attempt UPDATE, DELETE, or SELECT FOR UPDATE of these rows will be blocked until the current transaction ends.
