Parameter	Description	Default Value
GC_OPTS	JVM parameter used for garbage collection (GC). This parameter is valid only when **GC_PROFILE** is set to **custom**. Ensure that the **GC_OPT** parameter is set correctly. Otherwise, the process will fail to be started. **NOTICE** Exercise caution when you modify the configuration. If the configuration is incorrect, the services are unavailable.	-Xms2G -Xmx4G -XX:NewSize=128M -XX:MaxNewSize=256M -XX:MetaspaceSize=128M -XX:MaxMetaspaceSize=128M -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:CMSInitiatingOccupancyFraction=65 -XX:+PrintGCDetails -Dsun.rmi.dgc.client.gcInterval=0x7FFFFFFFFFFFFE -Dsun.rmi.dgc.server.gcInterval=0x7FFFFFFFFFFFFE -XX:-OmitStackTraceInFastThrow -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M -Djdk.tls.ephemeralDHKeySize=2048

12.9.3 Creating an HDFS Role

Scenario

This section describes how to create and configure an HDFS role on FusionInsight Manager. The HDFS role is granted the rights to read, write, and execute HDFS directories or files.

A user has the complete permission on the created HDFS directories or files, that is, the user can directly read data from and write data to as well as authorize others to access the HDFS directories or files.

NOTE

- This section applies to MRS 3.*x* or later.
- An HDFS role can be created only in security mode.
- If the current component uses Ranger for permission control, HDFS policies must be configured based on Ranger for permission management. For details, see **Adding a Ranger Access Permission Policy for HDFS**.

Prerequisites

The system administrator has understood the service requirements.

Procedure

Step 1 Log in to FusionInsight Manager, and choose **System** > **Permission** > **Role**.

Step 2 On the displayed page, click **Create Role** and fill in **Role Name** and **Description**.

Step 3 Configure the resource permission. For details, see **Table 12-190**.

File System: HDFS directory and file permission

Common HDFS directories are as follows:

- **flume**: Flume data storage directory
- **hbase**: HBase data storage directory
- **mr-history**: MapReduce task information storage directory
- **tmp**: temporary data storage directory
- **user**: user data storage directory

Table 12-190 Setting a role

Task	Operation
Setting the HDFS administrator permission	In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS, and select **Cluster Admin Operations**. **NOTE** The setting takes effect after the HDFS service is restarted.
Setting the permission for users to check and recover HDFS	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the save path of specified directories or files on HDFS. 3. In the **Permission** column of the specified directories or files, select **Read** and **Execute**.
Setting the permission for users to read directories or files of other users	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the save path of specified directories or files on HDFS. 3. In the **Permission** column of the specified directories or files, select **Read** and **Execute**.

Task	Operation
Setting the permission for users to write data to files of other users	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the save path of specified files on HDFS. 3. In the **Permission** column of the specified files, select **Write** and **Execute**.
Setting the permission for users to create or delete sub-files or sub-directories in the directory of other users	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the path where the specified directory is saved in the HDFS. 3. In the **Permission** column of the specified directories, select **Write** and **Execute**.
Setting the permission for users to execute directories or files of other users	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the save path of specified directories or files on HDFS. 3. In the **Permission** column of the specified directories or files, select **Execute**.
Setting the permission for allowing subdirectories to inherit all permissions of their parent directories	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the save path of specified directories or files on HDFS. 3. In the **Permission** column of the specified directories or files, select **Recursive**.

Step 4 Click **OK**, and return to the **Role** page.

----End

12.9.4 Using the HDFS Client

Scenario

This section describes how to use the HDFS client in an O&M scenario or service scenario.

Prerequisites

- The client has been installed.

  For example, the installation directory is **/opt/hadoopclient**. The client directory in the following operations is only an example. Change it to the actual installation directory.

- Service component users are created by the administrator as required. In security mode, machine-machine users need to download the keytab file. A human-machine user needs to change the password upon the first login. (This operation is not required in normal mode.)

Using the HDFS Client

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, run the following command to authenticate the user. In normal mode, user authentication is not required.

kinit *Component service user*

Step 5 Run the HDFS Shell command. Example:

hdfs dfs -ls /

----End

Common HDFS Client Commands

The following table lists common HDFS client commands.

For more commands, see **https://hadoop.apache.org/docs/stable/hadoop-project-dist/hadoop-common/CommandsManual.html#User_Commands**.

Table 12-191 Common HDFS client commands

Command	Description	Example
hdfs dfs -mkdir *Folder name*	Used to create a folder.	**hdfs dfs -mkdir /tmp/mydir**
hdfs dfs -ls *Folder name*	Used to view a folder.	**hdfs dfs -ls /tmp**
hdfs dfs -put *Local file on the client node Specified HDFS path*	Used to upload a local file to a specified HDFS path.	**hdfs dfs -put /opt/test.txt /tmp** Upload the **/opt/test.txt** file on the client node to the **/tmp** directory of HDFS.
hdfs dfs -get *Specified file on HDFS Specified path on the client node*	Used to download the HDFS file to the specified local path.	**hdfs dfs -get /tmp/test.txt /opt/** Download the **/tmp/test.txt** file on HDFS to the **/opt** path on the client node.

Command	Description	Example
hdfs dfs -rm -r -f *Specified folder on HDFS*	Used to delete a folder.	**hdfs dfs -rm -r -f /tmp/mydir**
hdfs dfs -chmod *Permission parameter File directory*	Used to configure the HDFS directory permission for a user.	**hdfs dfs -chmod 700 /tmp/test**

Client-related FAQs

1. What do I do when the HDFS client exits abnormally and error message "java.lang.OutOfMemoryError" is displayed after the HDFS client command is running?

   This problem occurs because the memory required for running the HDFS client exceeds the preset upper limit (128 MB by default). You can change the memory upper limit of the client by modifying **CLIENT_GC_OPTS** in *<Client installation path>***/HDFS/component_env**. For example, if you want to set the upper limit to 1 GB, run the following command:

   ```
   CLIENT_GC_OPTS="-Xmx1G"
   ```

   After the modification, run the following command to make the modification take effect:

   source <*Client installation path*>/**/bigdata_env**

2. How do I set the log level when the HDFS client is running?

   By default, the logs generated during the running of the HDFS client are printed to the console. The default log level is INFO. To enable the DEBUG log level for fault locating, run the following command to export an environment variable:

   export HADOOP_ROOT_LOGGER=DEBUG,console

   Then run the HDFS Shell command to generate the DEBUG logs.

   If you want to print INFO logs again, run the following command:

   export HADOOP_ROOT_LOGGER=INFO,console

3. How do I delete HDFS files permanently?

   HDFS provides a recycle bin mechanism. Typically, after an HDFS file is deleted, the file is moved to the recycle bin of HDFS. If the file is no longer needed and the storage space needs to be released, clear the corresponding recycle bin directory, for example, **hdfs://hacluster/user/xxx/.Trash/Current/***xxx*.

12.9.5 Running the DistCp Command

Scenario

DistCp is a tool used to perform large-amount data replication between clusters or in a cluster. It uses MapReduce tasks to implement distributed copy of a large amount of data.

Prerequisites

- The Yarn client or a client that contains Yarn has been installed. For example, the installation directory is **/opt/client**.
- Service users of each component are created by the system administrator based on service requirements. In security mode, machine-machine users need to download the keytab file. A human-machine user must change the password upon the first login. (Not involved in normal mode)
- To copy data between clusters, you need to enable the inter-cluster data copy function on both clusters.

Procedure

Step 1 Log in to the node where the client is installed.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, the user group to which the user executing the DistCp command belongs must be **supergroup** and the user run the following command to perform user authentication. In normal mode, user authentication is not required.

kinit *Component service user*

Step 5 Run the DistCp command. The following provides an example:

hadoop distcp hdfs://hacluster/source hdfs://hacluster/target

----End

Common Usage of DistCp

1. The following is an example of the commonest usage of DistCp:
   ```
   hadoop distcp -numListstatusThreads 40 -update -delete -prbugpaxtq hdfs://cluster1/source hdfs://cluster2/target
   ```

   NOTE

   In the preceding command:

   - **-numListstatusThreads** specifies the number of threads for creating the list of 40 copied files.
   - **-update -delete** specifies that files at the source location and the target location are synchronized, and that files with excessive target locations are deleted. If you need to copy files incrementally, delete **-delete**.
   - If **-prbugpaxtq** and **-update** are used, it indicates that the status information of the copied file is also updated.
   - **hdfs://cluster1/source** indicates the source location, and **hdfs://cluster2/target** indicates the target location.

2. The following is an example of data copy between clusters:
   ```
   hadoop distcp hdfs://cluster1/foo/bar hdfs://cluster2/bar/foo
   ```

NOTE

The network between cluster1 and cluster2 must be reachable, and the two clusters must use the same HDFS version or compatible HDFS versions.

3. The following are multiple examples of data copy in a source directory:

```
hadoop distcp hdfs://cluster1/foo/a \
hdfs://cluster1/foo/b \
hdfs://cluster2/bar/foo
```

The preceding command is used to copy the folders a and b of cluster1 to the **/bar/foo** directory of cluster2. The effect is equivalent to that of the following commands:

```
hadoop distcp -f hdfs://cluster1/srclist \
hdfs://cluster2/bar/foo
```

The content of **srclist** is as follows. Before running the DistCp command, upload the **srclist** file to HDFS.

```
hdfs://cluster1/foo/a
hdfs://cluster1/foo/b
```

4. **-update** indicates that a to-be-copied file does not exist in the target location, or the content of the copied file in the target location is updated; and **-overwrite** is used to overwrite existing files in the target location.

The following is an example of the difference between no option and any one of the two options (either **update** or **overwrite**) that is added:

Assume that the structure of a file at the source location is as follows:

```
hdfs://cluster1/source/first/1
hdfs://cluster1/source/first/2
hdfs://cluster1/source/second/10
hdfs://cluster1/source/second/20
```

Commands without options are as follows:

```
hadoop distcp hdfs://cluster1/source/first  hdfs://cluster1/source/second  hdfs://cluster2/target
```

By default, the preceding command creates the **first** and **second** folders at the target location. Therefore, the copy results are as follows:

```
hdfs://cluster2/target/first/1
hdfs://cluster2/target/first/2
hdfs://cluster2/target/second/10
hdfs://cluster2/target/second/20
```

The command with any one of the two options (for example, **update**) is as follows:

```
hadoop distcp -update hdfs://cluster1/source/first  hdfs://cluster1/source/second  hdfs://cluster2/target
```

The preceding command copies only the content at the source location to the target location. Therefore, the copy results are as follows:

```
hdfs://cluster2/target/1
hdfs://cluster2/target/2
hdfs://cluster2/target/10
hdfs://cluster2/target/20
```

NOTE

- If files with the same name exist in multiple source locations, the DistCp command fails.
- If neither **update** nor **overwrite** is used and the file to be copied already exists in the target location, the file will be skipped.
- When **update** is used, if the file to be copied already exists in the target location but the file content is different, the file content in the target location is updated.
- When **overwrite** is used, if the file to be copied already exists in the target location, the file in the target location is still overwritten.

5. The following table describes other command options:

Table 12-192 Other command options

Option	Description
-p[rbugpcaxtq]	When **-update** is also used, the status information of a copied file is updated even if the content of the copied file is not updated. **r**: number of copies **b**: size of a block **u**: user to which the files belong **g**: user group to which the user belongs **p**: permission **c**: check and type **a**: access control **t**: timestamp **q**: quota information
-i	Failures ignored during copying
-log <logdir>	Path of the specified log
-v	Additional information in the specified log
-m <num_maps>	Maximum number of concurrent copy tasks that can be executed at the same time
-numListstatusThreads	Number of threads for constituting the list of copied files. This option increases the running speed of DistCp.
-overwrite	File at the target location that is to be overwritten
-update	A file at the target location is updated if the size and check of a file at the source location are different from those of the file at the target location.
-append	When **-update** is also used, the content of the file at the source location is added to the file at the target location.

Option	Description
-f <urilist_uri>	Content of the **<urilist_uri>** file is used as the file list to be copied.
-filters	A local file is specified whose content contains multiple regular expressions. If the file to be copied matches a regular expression, the file is not copied.
-async	The **distcp** command is run asynchronously.
-atomic {-tmp <tmp_dir>}	An atomic copy can be performed. You can add a temporary directory during copying.
-bandwidth	The transmission bandwidth of each copy task. Unit: MB/s.
-delete	The files that exist in the target location is deleted but do not exist in the source location. This option is usually used with **-update**, and indicates that files at the source location are synchronized with those at the target location and the redundant files at the target location are deleted.
-diff <oldSnapshot> <newSnapshot>	The differences between the old and new versions are copied to a file in the old version at the target location.
-skipcrccheck	Whether to skip the cyclic redundancy check (CRC) between the source file and the target file.
-strategy {dynamic| uniformsize}	The policy for copying a task. The default policy is **uniformsize**, that is, each copy task copies the same number of bytes.

FAQs of DistCp

1. When you run the DistCp command, if the content of some copied files is large, you are advised to change the timeout period of MapReduce that executes the copy task. It can be implemented by specifying the **mapreduce.task.timeout** in the DistCp command. For example, run the following command to change the timeout to 30 minutes:

   ```
   hadoop distcp -Dmapreduce.task.timeout=1800000 hdfs://cluster1/source hdfs://cluster2/target
   ```

   Or, you can also use **filters** to exclude the large files out of the copy process. The command example is as follows:

   ```
   hadoop distcp -filters /opt/client/filterfile hdfs://cluster1/source hdfs://cluster2/target
   ```

   In the preceding command, *filterfile* indicates a local file, which contains multiple expressions used to match the path of a file that is not copied. The following is an example:

   ```
   .*excludeFile1.*
   .*excludeFile2.*
   ```

2. If the DistCp command unexpectedly quits, the error message "java.lang.OutOfMemoryError" is displayed.

This is because the memory required for running the copy command exceeds the preset memory limit (default value: 128 MB). You can change the memory upper limit of the client by modifying **CLIENT_GC_OPTS** in *<Client installation path>***/HDFS/component_env**. For example, if you want to set the memory upper limit to 1 GB, refer to the following configuration:

```
CLIENT_GC_OPTS="-Xmx1G"
```

After the modification, run the following command to make the modification take effect:

source {*Client installation path*}**/bigdata_env**

3. When the dynamic policy is used to run the DistCp command, the command exits unexpectedly and the error message "Too many chunks created with splitRatio" is displayed.

   The cause of this problem is that the value of **distcp.dynamic.max.chunks.tolerable** (default value: 20,000) is less than the value of **distcp.dynamic.split.ratio** (default value: 2) multiplied by the number of Maps. This problem occurs when the number of Maps exceeds 10,000. You can use the **-m** parameter to reduce the number of Maps to less than 10,000.

   ```
   hadoop distcp -strategy dynamic -m 9500 hdfs://cluster1/source hdfs://cluster2/target
   ```

   Alternatively, you can use the **-D** parameter to set **distcp.dynamic.max.chunks.tolerable** to a large value.

   ```
   hadoop distcp -Ddistcp.dynamic.max.chunks.tolerable=30000 -strategy dynamic hdfs://cluster1/source hdfs://cluster2/target
   ```

12.9.6 Overview of HDFS File System Directories

This section describes the directory structure in HDFS, as shown in the following table.

Table 12-193 HDFS directory structure (applicable to versions earlier than MRS 3.x)

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/tmp/spark/sparkhive-scratch	Fixed directory	Stores temporary files of metastore sessions in Spark JDBCServer.	No	Failed to run the task.
/tmp/sparkhive-scratch	Fixed directory	Stores temporary files of metastore session that are executed using Spark CLI.	No	Failed to run the task.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/tmp/carbon/	Fixed directory	Stores the abnormal data in this directory if abnormal CarbonData data exists during data import.	Yes	Error data is lost.
/tmp/Loader-${*Job name*}_${*MR job ID*}	Temporary directory	Stores the region information about Loader HBase bulkload jobs. The data is automatically deleted after the job running is completed.	No	Failed to run the Loader HBase Bulkload job.
/tmp/logs	Fixed directory	Stores the collected MR task logs.	Yes	MR task logs are lost.
/tmp/archived	Fixed directory	Archives the MR task logs on HDFS.	Yes	MR task logs are lost.
/tmp/hadoop-yarn/staging	Fixed directory	Stores the run logs, summary information, and configuration attributes of ApplicationMaster running jobs.	No	Services are running improperly.
/tmp/hadoop-yarn/staging/history/done_intermediate	Fixed directory	Stores temporary files in the **/tmp/hadoop-yarn/staging** directory after all tasks are executed.	No	MR task logs are lost.
/tmp/hadoop-yarn/staging/history/done	Fixed directory	The periodic scanning thread periodically moves the **done_intermediate** log file to the **done** directory.	No	MR task logs are lost.
/tmp/mr-history	Fixed directory	Stores the historical record files that are pre-loaded.	No	Historical MR task log data is lost.
/tmp/hive	Fixed directory	Stores Hive temporary files.	No	Failed to run the Hive task.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/tmp/hive-scratch	Fixed directory	Stores temporary data (such as session information) generated during Hive running.	No	Failed to run the current task.
/user/{user}/.sparkStaging	Fixed directory	Stores temporary files of the SparkJDBCServer application.	No	Failed to start the executor.
/user/spark/jars	Fixed directory	Stores running dependency packages of the Spark executor.	No	Failed to start the executor.
/user/loader	Fixed directory	Stores dirty data of Loader jobs and data of HBase jobs.	No	Failed to execute the HBase job. Or dirty data is lost.
/user/loader/etl_dirty_data_dir				
/user/loader/etl_hbase_putlist_tmp				
/user/loader/etl_hbase_tmp				
/user/mapred	Fixed directory	Stores Hadoop-related files.	No	Failed to start Yarn.
/user/hive	Fixed directory	Stores Hive-related data by default, including the depended Spark lib package and default table data storage path.	No	User data is lost.
/user/omm-bulkload	Temporary directory	Stores HBase batch import tools temporarily.	No	Failed to import HBase tasks in batches.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/user/hbase	Temporary directory	Stores HBase batch import tools temporarily.	No	Failed to import HBase tasks in batches.
/sparkJobHistory	Fixed directory	Stores Spark event log data.	No	The History Server service is unavailable, and the task fails to be executed.
/flume	Fixed directory	Stores data collected by Flume from HDFS.	No	Flume runs improperly.
/mr-history/tmp	Fixed directory	Stores logs generated by MapReduce jobs.	Yes	Log information is lost.
/mr-history/done	Fixed directory	Stores logs managed by MR JobHistory Server.	Yes	Log information is lost.
/tenant	Created when a tenant is added.	Directory of a tenant in the HDFS. By default, the system automatically creates a folder in the **/tenant** directory based on the tenant name. For example, the default HDFS storage directory for **ta1** is **tenant/ta1**. When a tenant is created for the first time, the system creates the **/tenant** directory in the HDFS root directory. You can customize the storage path.	No	The tenant account is unavailable.
/apps{1~5}/	Fixed directory	Stores the Hive package used by WebHCat.	No	Failed to run the WebHCat tasks.
/hbase	Fixed directory	Stores HBase data.	No	HBase user data is lost.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/hbaseFileStream	Fixed directory	Stores HFS files.	No	The HFS file is lost and cannot be restored.
/ats/active	Fixed directory	HDFS path used to store the timeline data of running applications.	No	Failed to run the **tez** task after the directory deletion.
/ats/done	Fixed directory	HDFS path used to store the timeline data of completed applications.	No	Automatically created after the deletion.
/flink	Fixed directory	Stores the checkpoint task data.	No	Failed to run tasks after the deletion.

Table 12-194 Directory structure of the HDFS file system (applicable to MRS 3.x or later)

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/tmp/spark2x/sparkhive-scratch	Fixed directory	Stores temporary files of metastore session in Spark2x JDBCServer.	No	Failed to run the task.
/tmp/sparkhive-scratch	Fixed directory	Stores temporary files of metastore sessions that are executed in CLI mode using Spark2x CLI.	No	Failed to run the task.
/tmp/logs/	Fixed directory	Stores container log files.	Yes	Container log files cannot be viewed.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/tmp/carbon/	Fixed directory	Stores the abnormal data in this directory if abnormal CarbonData data exists during data import.	Yes	Error data is lost.
/tmp/Loader-${*Job name*}_${*MR job ID*}	Temporary directory	Stores the region information about Loader HBase bulkload jobs. The data is automatically deleted after the job running is completed.	No	Failed to run the Loader HBase Bulkload job.
/tmp/hadoop-omm/yarn/system/rmstore	Fixed directory	Stores the ResourceManager running information.	Yes	Status information is lost after ResourceManager is restarted.
/tmp/archived	Fixed directory	Archives the MR task logs on HDFS.	Yes	MR task logs are lost.
/tmp/hadoop-yarn/staging	Fixed directory	Stores the run logs, summary information, and configuration attributes of ApplicationMaster running jobs.	No	Services are running improperly.
/tmp/hadoop-yarn/staging/history/done_intermediate	Fixed directory	Stores temporary files in the **/tmp/hadoop-yarn/staging** directory after all tasks are executed.	No	MR task logs are lost.
/tmp/hadoop-yarn/staging/history/done	Fixed directory	The periodic scanning thread periodically moves the **done_intermediate** log file to the **done** directory.	No	MR task logs are lost.
/tmp/mr-history	Fixed directory	Stores the historical record files that are pre-loaded.	No	Historical MR task log data is lost.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/tmp/hive-scratch	Fixed directory	Stores temporary data (such as session information) generated during Hive running.	No	Failed to run the current task.
/user/{user}/.sparkStaging	Fixed directory	Stores temporary files of the SparkJDBCServer application.	No	Failed to start the executor.
/user/spark2x/jars	Fixed directory	Stores running dependency packages of the Spark2x executor.	No	Failed to start the executor.
/user/loader	Fixed directory	Stores dirty data of Loader jobs and data of HBase jobs.	No	Failed to execute the HBase job. Or dirty data is lost.
/user/loader/etl_dirty_data_dir				
/user/loader/etl_hbase_putlist_tmp				
/user/loader/etl_hbase_tmp				
/user/oozie	Fixed directory	Stores dependent libraries required for Oozie running, which needs to be manually uploaded.	No	Failed to schedule Oozie.
/user/mapred/hadoop-mapreduce-*3.1.1*.tar.gz	Fixed files	Stores JAR files used by the distributed MR cache.	No	The MR distributed cache function is unavailable.
/user/hive	Fixed directory	Stores Hive-related data by default, including the depended Spark lib package and default table data storage path.	No	User data is lost.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/user/omm-bulkload	Temporary directory	Stores HBase batch import tools temporarily.	No	Failed to import HBase tasks in batches.
/user/hbase	Temporary directory	Stores HBase batch import tools temporarily.	No	Failed to import HBase tasks in batches.
/spark2xJobHistory2x	Fixed directory	Stores Spark2x eventlog data.	No	The History Server service is unavailable, and the task fails to be executed.
/flume	Fixed directory	Stores data collected by Flume from HDFS.	No	Flume runs improperly.
/mr-history/tmp	Fixed directory	Stores logs generated by MapReduce jobs.	Yes	Log information is lost.
/mr-history/done	Fixed directory	Stores logs managed by MR JobHistory Server.	Yes	Log information is lost.
/tenant	Created when a tenant is added.	Directory of a tenant in the HDFS. By default, the system automatically creates a folder in the **/tenant** directory based on the tenant name. For example, the default HDFS storage directory for **ta1** is **tenant/ta1**. When a tenant is created for the first time, the system creates the **/tenant** directory in the HDFS root directory. You can customize the storage path.	No	The tenant account is unavailable.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/apps{1~5}/	Fixed directory	Stores the Hive package used by WebHCat.	No	Failed to run the WebHCat tasks.
/hbase	Fixed directory	Stores HBase data.	No	HBase user data is lost.
/hbaseFileStream	Fixed directory	Stores HFS files.	No	The HFS file is lost and cannot be restored.

12.9.7 Changing the DataNode Storage Directory

Scenario

NOTE

This section applies to MRS 3.*x* or later.

If the storage directory defined by the HDFS DataNode is incorrect or the HDFS storage plan changes, the system administrator needs to modify the DataNode storage directory on FusionInsight Manager to ensure that the HDFS works properly. Changing the ZooKeeper storage directory includes the following scenarios:

- Change the storage directory of the DataNode role. In this way, the storage directories of all DataNode instances are changed.
- Change the storage directory of a single DataNode instance. In this way, only the storage directory of this instance is changed, and the storage directories of other instances remain the same.

Impact on the System

- The HDFS service needs to be stopped and restarted during the process of changing the storage directory of the DataNode role, and the cluster cannot provide services before it is completely started.
- The DataNode instance needs to stopped and restarted during the process of changing the storage directory of the instance, and the instance at this node cannot provide services before it is started.
- The directory for storing service parameter configurations must also be updated.

Prerequisites

- New disks have been prepared and installed on each data node, and the disks are formatted.
- New directories have been planned for storing data in the original directories.
- The HDFS client has been installed.
- The system administrator user **hdfs** is available.
- When changing the storage directory of a single DataNode instance, ensure that the number of active DataNode instances is greater than the value of **dfs.replication**.

Procedure

Check the environment.

Step 1 Log in to the server where the HDFS client is installed as user **root**, and run the following command to configure environment variables:

source *Installation directory of the HDFS client*/**bigdata_env**

Step 2 If the cluster is in security mode, run the following command to authenticate the user:

kinit hdfs

Step 3 Run the following command on the HDFS client to check whether all directories and files in the HDFS root directory are normal:

hdfs fsck /

Check the fsck command output.

- If the following information is displayed, no file is lost or damaged. Go to **Step 4**.
  ```
  The filesystem under path '/' is HEALTHY
  ```
- If other information is displayed, some files are lost or damaged. Go to **Step 5**.

Step 4 Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services**, and check whether **Running Status** of HDFS is **Normal**.

- If yes, go to **Step 6**.
- If no, the HDFS status is unhealthy. Go to **Step 5**.

Step 5 Rectify the HDFS fault.. The task is complete.

Step 6 Determine whether to change the storage directory of the DataNode role or that of a single DataNode instance:

- To change the storage directory of the DataNode role, go to **Step 7**.
- To change the storage directory of a single DataNode instance, go to **Step 12**.

Changing the storage directory of the DataNode role

Step 7 Choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Stop Instance** to stop the HDFS service.

Step 8 Log in to each data node where the HDFS service is installed as user **root** and perform the following operations:

1. Create a target directory (**data1** and **data2** are original directories in the cluster).

   For example, to create a target directory **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following command:

   mkdir -p ${BIGDATA_DATA_HOME}/hadoop/data3/dn

2. Mount the target directory to the new disk. For example, mount **${BIGDATA_DATA_HOME}/hadoop/data3** to the new disk.
3. Modify permissions on the new directory.

   For example, to create a target directory **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following commands:

   chmod 700 ${BIGDATA_DATA_HOME}/hadoop/data3/dn -R and **chown omm:wheel ${BIGDATA_DATA_HOME}/hadoop/data3/dn -R**

4. Copy the data to the target directory.

   For example, if the old directory is **${BIGDATA_DATA_HOME}/hadoop/data1/dn** and the target directory is **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following command:

   cp -af ${BIGDATA_DATA_HOME}/hadoop/data1/dn/* ${BIGDATA_DATA_HOME}/hadoop/data3/dn

Step 9 On FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Configurations** > **All Configurations** to go to the HDFS service configuration page.

Change the value of **dfs.datanode.data.dir** from the default value **%{@auto.detect.datapart.dn}** to the new target directory, for example, **${BIGDATA_DATA_HOME}/hadoop/data3/dn**.

For example, the original data storage directories are **/srv/BigData/hadoop/data1**, **/srv/BigData/hadoop/data2**. To migrate data from the **/srv/BigData/hadoop/data1** directory to the newly created **/srv/BigData/hadoop/data3** directory, replace the whole parameter with **/srv/BigData/hadoop/data2, /srv/BigData/hadoop/data3**. Separate multiple storage directories with commas (,). In this example, changed directories are **/srv/BigData/hadoop/data2**, **/srv/BigData/hadoop/data3**.

Step 10 Click **Save**. Choose **Cluster** > *Name of the desired cluster* > **Services**. On the page that is displayed, start the services that have been stopped.

Step 11 After the HDFS is started, run the following command on the HDFS client to check whether all directories and files in the HDFS root directory are correctly copied:

hdfs fsck /

Check the fsck command output.

- If the following information is displayed, no file is lost or damaged, and data replication is successful. No further action is required.

  ```
  The filesystem under path '/' is HEALTHY
  ```

- If other information is displayed, some files are lost or damaged. In this case, check whether **8.4** is correct and run the **hdfs fsck** *Name of the damaged file* **-delete** command.

Changing the storage directory of a single DataNode instance

Step 12 Choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Instance**. Select the HDFS instance whose storage directory needs to be modified, and choose **More** > **Stop Instance**.

Step 13 Log in to the DataNode node as user **root**, and perform the following operations:

1. Create a target directory.

   For example, to create a target directory **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following command:

   mkdir -p ${BIGDATA_DATA_HOME}/hadoop/data3/dn

2. Mount the target directory to the new disk.

   For example, mount **${BIGDATA_DATA_HOME}/hadoop/data3** to the new disk.

3. Modify permissions on the new directory.

   For example, to create a target directory **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following commands:

   chmod 700 ${BIGDATA_DATA_HOME}/hadoop/data3/dn -R and **chown omm:wheel ${BIGDATA_DATA_HOME}/hadoop/data3/dn -R**

4. Copy the data to the target directory.

   For example, if the old directory is **${BIGDATA_DATA_HOME}/hadoop/data1/dn** and the target directory is **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following command:

   cp -af ${BIGDATA_DATA_HOME}/hadoop/data1/dn/* ${BIGDATA_DATA_HOME}/hadoop/data3/dn

Step 14 On FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Service** > **HDFS** > **Instance**. Click the specified DataNode instance and go to the **Configurations** page.

Change the value of **dfs.datanode.data.dir** from the default value **%{@auto.detect.datapart.dn}** to the new target directory, for example, **${BIGDATA_DATA_HOME}/hadoop/data3/dn**.

For example, the original data storage directories are **/srv/BigData/hadoop/data1,/srv/BigData/hadoop/data2**. To migrate data from the **/srv/BigData/hadoop/data1** directory to the newly created **/srv/BigData/hadoop/data3** directory, replace the whole parameter with **/srv/BigData/hadoop/data2,/srv/BigData/hadoop/data3**.

Step 15 Click **Save**, and then click **OK**.

Operation succeeded is displayed. click **Finish**.

Step 16 Choose **More** > **Restart Instance** to restart the DataNode instance.

----End

12.9.8 Configuring HDFS Directory Permission

Scenario

The permission for some HDFS directories is **777** or **750** by default, which brings potential security risks. You are advised to modify the permission for the HDFS directories after the HDFS is installed to increase user security.

Procedure

Log in to the HDFS client as the administrator and run the following command to modify the permission for the **/user** directory.

The permission is set to **1777**, that is, **1** is added to the original permission. This indicates that only the user who creates the directory can delete it.

hdfs dfs -chmod 1777 */user*

To ensure security of the system file, you are advised to harden the security for non-temporary directories. The following directories are examples:

- /user:777
- /mr-history:777
- /mr-history/tmp:777
- /mr-history/done:777
- /user/mapred:755

12.9.9 Configuring NFS

Scenario

NOTE

This section applies to MRS 3.*x* or later.

Before deploying a cluster, you can deploy a Network File System (NFS) server based on requirements to store NameNode metadata to enhance data reliability.

If the NFS server has been deployed and NFS services are configured, you can follow operations in this section to configure NFS on the cluster. These operations are optional.

Procedure

Step 1 Check the permission of the shared NFS directories on the NFS server to ensure that the server can access NameNode in the MRS cluster.

Step 2 Log in to the active NameNode as user **root**.

Step 3 Run the following commands to create a directory and assign it write permissions:

mkdir ${BIGDATA_DATA_HOME}/namenode-nfs

chown omm:wheel ${BIGDATA_DATA_HOME}/namenode-nfs

chmod 750 ${BIGDATA_DATA_HOME}/namenode-nfs

Step 4 Run the following command to mount the NFS to the active NameNode:

mount -t nfs -o rsize=8192,wsize=8192,soft,nolock,timeo=3,intr *IP address of the NFS server*:*Shared directory* **${BIGDATA_DATA_HOME}/namenode-nfs**

For example, if the IP address of the NFS server is **192.168.0.11** and the shared directory is **/opt/Hadoop/NameNode**, run the following command:

mount -t nfs -o rsize=8192,wsize=8192,soft,nolock,timeo=3,intr 192.168.0.11:/opt/Hadoop/NameNode ${BIGDATA_DATA_HOME}/namenode-nfs

Step 5 Perform **Step 2** to **Step 4** on the standby NameNode.

NOTE

The names of the shared directories (for example, **/opt/Hadoop/NameNode**) created on the NFS server by the active and standby NameNodes must be different.

Step 6 Log in to FusionInsight Manager, and choose **Cluster** > *Name of the desired cluster* > **Service** > **HDFS** > **Configuration** > **All Configurations**.

Step 7 In the search box, search for **dfs.namenode.name.dir**, add **${BIGDATA_DATA_HOME}/namenode-nfs** to **Value**, and click **Save**. Separate paths with commas (,).

Step 8 Click **OK**. On the **Dashboard** tab page, choose **More** > **Restart Service** to restart the service.

----End

12.9.10 Planning HDFS Capacity

In HDFS, DataNode stores user files and directories as blocks, and file objects are generated on the NameNode to map each file, directory, and block on the DataNode.

The file objects on the NameNode require certain memory capacity. The memory consumption linearly increases as more file objects generated. The number of file objects on the NameNode increases and the objects consume more memory when the files and directories stored on the DataNode increase. In this case, the existing hardware may not meet the service requirement and the cluster is difficult to be scaled out.

Capacity planning of the HDFS that stores a large number of files is to plan the capacity specifications of the NameNode and DataNode and to set parameters according to the capacity plans.

Capacity Specifications

- NameNode capacity specifications

  Each file object on the NameNode corresponds to a file, directory, or block on the DataNode.

  A file uses at least one block. The default size of a block is **134,217,728**, that is, 128 MB, which can be set in the **dfs.blocksize** parameter. By default, a file whose size is less than 128 MB occupies only one block. If the file size is greater than 128 MB, the number of occupied blocks is the file size divided by

128 MB (Number of occupied blocks = File size/128). The directories do not occupy any blocks.

Based on **dfs.blocksize**, the number of file objects on the NameNode is calculated as follows:

Table 12-195 Number of NameNode file objects

Size of a File	Number of File Objects
< 128 MB	1 (File) + 1 (Block) = 2
> 128 MB (for example, 128 GB)	1 (File) + 1,024 (128 GB/128 MB = 1,024 blocks) = 1,025

The maximum number of file objects supported by the active and standby NameNodes is 300,000,000 (equivalent to 150,000,000 small files). **dfs.namenode.max.objects** specifies the number of file objects that can be generated in the system. The default value is **0**, which indicates that the number of generated file objects is not limited.

- DataNode capacity specifications

  In HDFS, blocks are stored on the DataNode as copies. The default number of copies is **3**, which can be set in the **dfs.replication** parameter.

  The number of blocks stored on all DataNode role instances in the cluster can be calculated based on the following formula: Number of HDFS blocks x 3 Average number of saved blocks = Number of HDFS blocks x 3/Number of DataNodes

  Table 12-196 DataNode specifications

Item	Specifications
Maximum number of blocks supported by a DataNode instance	5,000,000
Maximum number of blocks supported by a disk on a DataNode instance	500,000
Minimum number of disks required when the number of blocks supported by a DataNode instance reaches the maximum	10

  Table 12-197 Number of DataNodes

Number of HDFS Blocks	Minimum Number of DataNode Roles
10,000,000	10,000,000 *3/5,000,000 = 6
50,000,000	50,000,000 *3/5,000,000 = 30

Number of HDFS Blocks	Minimum Number of DataNode Roles
100,000,000	100,000,000 *3/5,000,000 = 60

Setting Memory Parameters

- Configuration rules of the NameNode JVM parameter

  Default value of the NameNode JVM parameter **GC_OPTS**:

  -Xms2G -Xmx4G -XX:NewSize=128M -XX:MaxNewSize=256M -XX:MetaspaceSize=128M -XX:MaxMetaspaceSize=128M -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:CMSInitiatingOccupancyFraction=65 -XX:+PrintGCDetails -Dsun.rmi.dgc.client.gcInterval=0x7FFFFFFFFFFFFE -Dsun.rmi.dgc.server.gcInterval=0x7FFFFFFFFFFFFE -XX:-OmitStackTraceInFastThrow -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M -Djdk.tls.ephemeralDHKeySize=3072 -Djdk.tls.rejectClientInitiatedRenegotiation=true -Djava.io.tmpdir=${Bigdata_tmp_dir}

  The number of NameNode files is proportional to the used memory size of the NameNode. When file objects change, you need to change **-Xms2G -Xmx4G -XX:NewSize=128M --XX:MaxNewSize=256M** in the default value. The following table lists the reference values.

  Table 12-198 NameNode JVM configuration

Number of File Objects	Reference Value
10,000,000	-Xms6G -Xmx6G -XX:NewSize=512M -XX:MaxNewSize=512M
20,000,000	-Xms12G -Xmx12G -XX:NewSize=1G -XX:MaxNewSize=1G
50,000,000	-Xms32G -Xmx32G -XX:NewSize=3G -XX:MaxNewSize=3G
100,000,000	-Xms64G -Xmx64G -XX:NewSize=6G -XX:MaxNewSize=6G
200,000,000	-Xms96G -Xmx96G -XX:NewSize=9G -XX:MaxNewSize=9G
300,000,000	-Xms164G -Xmx164G -XX:NewSize=12G -XX:MaxNewSize=12G

- Configuration rules of the DataNode JVM parameter

  Default value of the DataNode JVM parameter **GC_OPTS**:

  -Xms2G -Xmx4G -XX:NewSize=128M -XX:MaxNewSize=256M -XX:MetaspaceSize=128M -XX:MaxMetaspaceSize=128M -

XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:CMSInitiatingOccupancyFraction=65 -XX:+PrintGCDetails -Dsun.rmi.dgc.client.gcInterval=0x7FFFFFFFFFFFFE -Dsun.rmi.dgc.server.gcInterval=0x7FFFFFFFFFFFFE -XX:-OmitStackTraceInFastThrow -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M -Djdk.tls.ephemeralDHKeySize=3072 -Djdk.tls.rejectClientInitiatedRenegotiation=true -Djava.io.tmpdir=${Bigdata_tmp_dir}

The average number of blocks stored in each DataNode instance in the cluster is: Number of HDFS blocks x 3/Number of DataNodes. If the average number of blocks changes, you need to change **-Xms2G -Xmx4G -XX:NewSize=128M -XX:MaxNewSize=256M** in the default value. The following table lists the reference values.

Table 12-199 DataNode JVM configuration

Average Number of Blocks in a DataNode Instance	Reference Value
2,000,000	-Xms6G -Xmx6G -XX:NewSize=512M -XX:MaxNewSize=512M
5,000,000	-Xms12G -Xmx12G -XX:NewSize=1G -XX:MaxNewSize=1G

Xmx specifies memory which corresponds to the threshold of the number of DataNode blocks, and each GB memory supports a maximum of 500,000 DataNode blocks. Set the memory as required.

Viewing the HDFS Capacity Status

- NameNode information

  For versions earlier than MRS 3.*x*: Log in to the MRS console, and choose **Components** > **HDFS** > **NameNode (Active)**. Click **Overview** and check the number of file objects, files, directories, or blocks in the HDFS in **Summary**.

  For MRS 3.*x* or later: Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **NameNode(Active)**, and click **Overview** to view information like the number of file objects, files, directories, and blocks in HDFS in **Summary** area.

- DataNode information

  For versions earlier than MRS 3.*x*: Log in to the MRS console and choose **Components** > **HDFS** > **NameNode (Active)**. Click **DataNodes** and check the number of blocks of all DataNodes that report alarms.

  For MRS 3.*x* or later: Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **NameNode(Active)**, and click **DataNodes** to view the number of blocks on all DataNodes that report alarms.

- Alarm information

Check whether the alarms whose IDs are 14007, 14008, and 14009 are generated and change the alarm thresholds as required.

12.9.11 Configuring ulimit for HBase and HDFS

Symptom

When you open an HDFS file, an error occurs due to the limit on the number of file handles. Information similar to the following is displayed.

```
IOException (Too many open files)
```

Procedure

You can contact the administrator to add file handles for each user. This is a configuration on the OS instead of HBase or HDFS. It is recommended that the administrator configure the number of file handles based on the service traffic of HBase and HDFS and the rights of each user. If a user performs a large number of operations frequently on the HDFS that has large service traffic, set the number of file handles of this user to a large value.

Step 1 Log in to the OSs of all nodes or clients in the cluster as user **root**, and go to the **/etc/security** directory.

Step 2 Run the following command to edit the **limits.conf** file:

vi limits.conf

Add the following information to the file.

```
hdfs -       nofile  32768
hbase -      nofile  32768
```

hdfs and **hbase** indicate the usernames of the OSs that are used during the services.

NOTE

- Only user **root** has the rights to edit the **limits.conf** file.
- If this modification does not take effect, check whether other nofile values exist in the **/etc/security/limits.d** directory. Such values may overwrite the values set in the **/etc/security/limits.conf** file.
- If a user needs to perform operations on HBase, set the number of file handles of this user to a value greater than **10000**. If a user needs to perform operations on HDFS, set the number of file handles of this user based on the service traffic. It is recommended that the value not be too small. If a user needs to perform operations on both HBase and HDFS, set the number of file handles of this user to a large value, such as **32768**.

Step 3 Run the following command to check the limit on the number of file handles of a user:

su - *user_name*

ulimit -n

The limit on the number of file handles of this user is displayed as follows.

```
8194
```

----End

12.9.12 Balancing DataNode Capacity

Scenario

NOTE

This section applies to MRS 3.*x* or later.

In the HDFS cluster, unbalanced disk usage among DataNodes may occur, for example, when new DataNodes are added to the cluster. Unbalanced disk usage may result in multiple problems. For example, MapReduce applications cannot make full use of local computing advantages, network bandwidth usage between data nodes cannot be optimal, or node disks cannot be used. Therefore, the system administrator needs to periodically check and maintain DataNode data balance.

HDFS provides a capacity balancing program Balancer. By running Balancer, you can balance the HDFS cluster and ensure that the difference between the disk usage of each DataNode and that of the HDFS cluster does not exceed the threshold. DataNode disk usage before and after balancing is shown in **Figure 12-18** and **Figure 12-19**, respectively.

Figure 12-18 DataNode disk usage before balancing

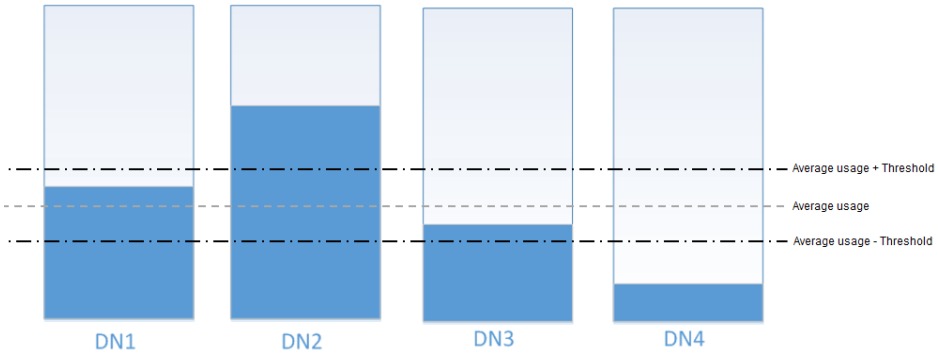

Figure 12-19 DataNode disk usage after balancing

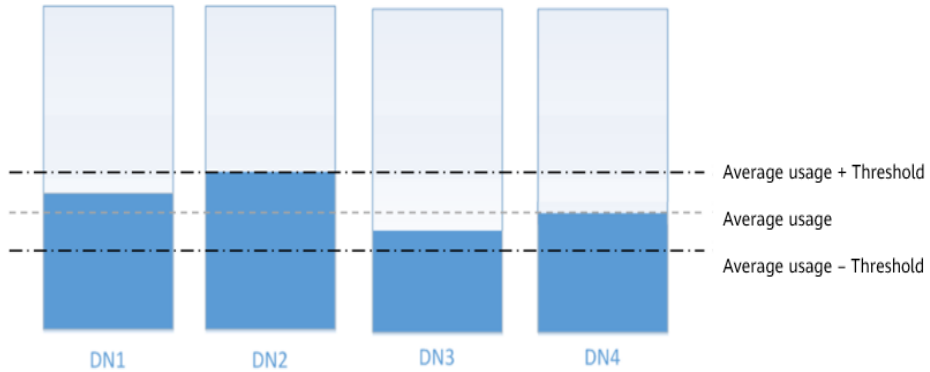


The time of the balancing operation is affected by the following two factors:

1. Total amount of data to be migrated:

   The data volume of each DataNode must be greater than (Average usage - Threshold) x Average data volume and less than (Average usage + Threshold)

x Average data volume. If the actual data volume is less than the minimum value or greater than the maximum value, imbalance occurs. The system sets the largest deviation volume on all DataNodes as the total data volume to be migrated.

2. Balancer migration is performed in sequence in iteration mode. The amount of data to be migrated in each iteration does not exceed 10 GB, and the usage of each iteration is recalculated.

Therefore, for a cluster, you can estimate the time consumed by each iteration (by observing the time consumed by each iteration recorded in balancer logs) and divide the total data volume by 10 GB to estimate the task execution time.

The balancer can be started or stopped at any time.

Impact on the System

- The balance operation occupies network bandwidth resources of DataNodes. Perform the operation during maintenance based on service requirements.
- The balance operation may affect the running services if the bandwidth traffic (the default bandwidth control is 20 MB/s) is reset or the data volume is increased.

Prerequisites

The client has been installed.

Procedure

Step 1 Log in to the node where the client is installed as a client installation user. Run the following command to switch to the client installation directory, for example, **/opt/client**:

cd /opt/client

NOTE

If the cluster is in normal mode, run the **su - omm** command to switch to user **omm**.

Step 2 Run the following command to configure environment variables:

source bigdata_env

Step 3 If the cluster is in security mode, run the following command to authenticate the HDFS identity:

kinit hdfs

Step 4 Determine whether to adjust the bandwidth control.

- If yes, go to **Step 5**.
- If no, go to **Step 6**.

Step 5 Run the following command to change the maximum bandwidth of Balancer, and then go to **Step 6**.

hdfs dfsadmin -setBalancerBandwidth ***<bandwidth in bytes per second>***

<bandwidth in bytes per second> indicates the bandwidth control value, in bytes. For example, to set the bandwidth control to 20 MB/s (the corresponding value is 20971520), run the following command:

hdfs dfsadmin -setBalancerBandwidth 20971520

NOTE

- The default bandwidth control is 20 MB/s. This value is applicable to the scenario where the current cluster uses the 10GE network and services are being executed. If the service idle time window is insufficient for balance maintenance, you can increase the value of this parameter to shorten the balance time, for example, to 209715200 (200 MB/s).
- The value of this parameter depends on the networking. If the cluster load is high, you can change the value to 209715200 (200 MB/s). If the cluster is idle, you can change the value to 1073741824 (1 GB/s).
- If the bandwidth of the DataNodes cannot reach the specified maximum bandwidth, modify the HDFS parameter **dfs.datanode.balance.max.concurrent.moves** on FusionInsight Manager, and change the number of threads for balancing on each DataNode to **32** and restart the HDFS service.

Step 6 Run the following command to start the balance task:

bash /opt/client/HDFS/hadoop/sbin/start-balancer.sh -threshold *<threshold of balancer>*

-threshold specifies the deviation value of the DataNode disk usage, which is used for determining whether the HDFS data is balanced. When the difference between the disk usage of each DataNode and the average disk usage of the entire HDFS cluster is less than this threshold, the system considers that the HDFS cluster has been balanced and ends the balance task.

For example, to set deviation rate to 5%, run the following command:

bash /opt/client/HDFS/hadoop/sbin/start-balancer.sh -threshold 5

NOTE

- The preceding command executes the task in the background. You can query related logs in the **hadoop-root-balancer-***host name***.out log** file in the **/opt/client/HDFS/hadoop/logs** directory of the host.
- To stop the balance task, run the following command:

  bash /opt/client/HDFS/hadoop/sbin/stop-balancer.sh
- If only data on some nodes needs to be balanced, you can add the **-include** parameter in the script to specify the nodes to be migrated. You can run commands to view the usage of different parameters.
- **/opt/client** is the client installation directory. If the directory is inconsistent, replace it.
- If the command fails to be executed and the error information **Failed to APPEND_FILE /system/balancer.id** is displayed in the log, run the following command to forcibly delete **/system/balancer.id** and run the **start-balancer.sh** script again:

  hdfs dfs -rm -f /system/balancer.id

Step 7 If the following information is displayed, the balancing is complete and the system automatically exits the task:

```
Apr 01, 2016 01:01:01 PM  Balancing took 23.3333 minutes
```

After you run the script in **Step 6**, the **hadoop-root-balancer-***Host name***.out log** file is generated in the client installation directory **/opt/client/HDFS/hadoop/logs**. You can view the following information in the log:

- Time Stamp
- Bytes Already Moved
- Bytes Left To Move
- Bytes Being Moved

----End

Related Tasks

Enable automatic execution of the balance task

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Configurations**, select **All Configurations**, search for the following parameters, and change the parameter values.

- **dfs.balancer.auto.enable** indicates whether to enable automatic balance task execution. The default value **false** indicates that automatic balance task execution is disabled. The value **true** indicates that automatic execution is enabled.
- **dfs.balancer.auto.cron.expression** indicates the task execution time. The default value **0 1 * * 6** indicates that the task is executed at 01:00 every Saturday. This parameter is valid only when the automatic execution is enabled.

  Table 12-200 describes the expression for modifying this parameter. * indicates consecutive time segments.

  Table 12-200 Parameters in the execution expression

Column	Description
1	Minute. The value ranges from 0 to 59.
2	Hour. The value ranges from 0 to 23.
3	Date. The value ranges from 1 to 31.
4	Month. The value ranges from 1 to 12.
5	Week. The value ranges from 0 to 6. **0** indicates Sunday.

- **dfs.balancer.auto.stop.cron.expression** indicates the task ending time. The default value is empty, indicating that the running balance task is not automatically stopped. For example, **0 5 * * 6** indicates that the balance task is stopped at 05:00 every Saturday. This parameter is valid only when the automatic execution is enabled.

  Table 12-200 describes the expression for modifying this parameter. * indicates consecutive time segments.

Step 3 Running parameters of the balance task that is automatically executed are shown in Table 12-201.

Table 12-201 Running parameters of the automatic balancer

Parameter	Parameter description	Default Value
dfs.balancer.auto.threshold	Specifies the balancing threshold of the disk capacity percentage. This parameter is valid only when **dfs.balancer.auto.enable** is set to **true**.	10
dfs.balancer.auto.exclude.datanodes	Specifies the list of DataNodes on which automatic disk balancing is not required. This parameter is valid only when **dfs.balancer.auto.enable** is set to **true**.	The value is left blank by default.
dfs.balancer.auto.bandwidthPerSec	Specifies the maximum bandwidth (MB/s) of each DataNode for load balancing.	20
dfs.balancer.auto.maxIdleIterations	Specifies the maximum number of consecutive idle iterations of Balancer. An idle iteration is an iteration without moving blocks. When the number of consecutive idle iterations reaches the maximum number, the balance task ends. The value **-1** indicates infinity.	5
dfs.balancer.auto.maxDataNodesNum	Controls the number of DataNodes that perform automatic balance tasks. Assume that the value of this parameter is *N*. If *N* is greater than 0, data is balanced between *N* DataNodes with the highest percentage of remaining space and *N* DataNodes with the lowest percentage of remaining space. If *N* is 0, data is balanced among all DataNodes in the cluster.	5

Step 4 Click **Save** to make configurations take effect. You do not need to restart the HDFS service.

Go to the **/var/log/Bigdata/hdfs/nn/hadoop-omm-balancer-***Host name***.log** file to view the task execution logs saved in the active NameNode.

----End

12.9.13 Configuring Replica Replacement Policy for Heterogeneous Capacity Among DataNodes

Scenario

By default, NameNode randomly selects a DataNode to write files. If the disk capacity of some DataNodes in a cluster is inconsistent (the total disk capacity of some nodes is large and of some nodes is small), the nodes with small disk capacity will be fully written. To resolve this problem, change the default disk selection policy for data written to DataNode to the available space block policy. This policy increases the probability of writing data blocks to the node with large available disk space. This ensures that the node usage is balanced when disk capacity of DataNodes is inconsistent.

Impact on the System

The disk selection policy is changed to **org.apache.hadoop.hdfs.server.blockmanagement.AvailableSpaceBlockPlacementPolicy**. It is proven that the HDFS file write performance optimizes by 3% after the modification.

NOTE

The default replica storage policy of the NameNode is as follows:

1. First replica: stored on the node where the client resides.
2. Second replica: stored on DataNodes of the remote rack.
3. Third replica: stored on different nodes of the same rack for the node where the client resides.

If there are more replicas, randomly store them on other DataNodes.

The replica selection mechanism (**org.apache.hadoop.hdfs.server.blockmanagement.AvailableSpaceBlockPlacementPolicy**) is as follows:

1. First replica: stored on the DataNode where the client resides (the same as the default storage policy).
2. Second replica:
   - When selecting a storage node, select two data nodes that meet the requirements.
   - Compare the disk usages of the two DataNodes. If the difference is smaller than 5%, store the replicas to the first node.
   - If the difference exceeds 5%, there is a 60% probability (specified by **dfs.namenode.available-space-block-placement-policy.balanced-space-preference-fraction** and default value is **0.6**) that the replica is written to the node whose disk space usage is low.
3. As for the storage of the third replica and subsequent replicas, refer to that of the second replica.

Prerequisites

The total disk capacity deviation of DataNodes in the cluster cannot exceed 100%.

Procedure

Step 1 Go to the **All Configurations** page of HDFS by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 Modify the disk selection policy parameters when HDFS writes data. Search for the **dfs.block.replicator.classname** parameter and change its value to **org.apache.hadoop.hdfs.server.blockmanagement.AvailableSpaceBlockPlacementPolicy**.

Step 3 Save the modified configuration. Restart the expired service or instance for the configuration to take effect.

----End

12.9.14 Configuring the Number of Files in a Single HDFS Directory

Scenario

Generally, multiple services are deployed in a cluster, and the storage of most services depends on the HDFS file system. Different components such as Spark and Yarn or clients are constantly writing files to the same HDFS directory when the cluster is running. However, the number of files in a single directory in HDFS is limited. Users must plan to prevent excessive files in a single directory and task failure.

You can set the number of files in a single directory using the **dfs.namenode.fs-limits.max-directory-items** parameter in HDFS.

Procedure

Step 1 Go to the **All Configurations** page of HDFS by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 Search for the configuration item **dfs.namenode.fs-limits.max-directory-items**.

Table 12-202 Parameter description

Parameter	Description	Default Value
dfs.namenode.fs-limits.max-directory-items	Maximum number of items in a directory Value range: 1 to 6,400,000	1048576

Step 3 Set the maximum number of files that can be stored in a single HDFS directory. Save the modified configuration. Restart the expired service or instance for the configuration to take effect.

NOTE

Plan data storage in advance based on time and service type categories to prevent excessive files in a single directory. You are advised to use the default value, which is about 1 million pieces of data in a single directory.

----End

12.9.15 Configuring the Recycle Bin Mechanism

Scenario

On HDFS, deleted files are moved to the recycle bin (trash can) so that the data deleted by mistake can be restored.

You can set the time threshold for storing files in the recycle bin. Once the file storage duration exceeds the threshold, it is permanently deleted from the recycle bin. If the recycle bin is cleared, all files in the recycle bin are permanently deleted.

Configuration Description

If a file is deleted from HDFS, the file is saved in the trash space rather than cleared immediately. After the aging time is due, the deleted file becomes an aging file and will be cleared based on the system mechanism or manually cleared by users.

Parameter portal:

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-203 Parameter description

Parameter	Description	Default Value
fs.trash.interval	Trash collection time, in minutes. If data in the trash station exceeds the time, the data will be deleted. Value range: 1440 to 259200	1440
fs.trash.checkpoint.interval	Interval between trash checkpoints, in minutes. The value must be less than or equal to the value of **fs.trash.interval**. The checkpoint program creates a checkpoint every time it runs and removes the checkpoint created **fs.trash.interval** minutes ago. For example, the system checks whether aging files exist every 10 minutes and deletes aging files if any. Files that are not aging are stored in the checkpoint list waiting for the next check. If this parameter is set to 0, the system does not check aging files and all aging files are saved in the system. Value range: 0 to *fs.trash.interval* **NOTE** It is not recommended to set this parameter to 0 because aging files will use up the disk space of the cluster.	60

12.9.16 Setting Permissions on Files and Directories

Scenario

HDFS allows users to modify the default permissions of files and directories. The default mask provided by the HDFS for creating file and directory permissions is **022**. If you have special requirements for the default permissions, you can set configuration items to change the default permissions.

Configuration Description

Parameter portal:

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-204 Parameter description

Parameter	Description	Default Value
fs.permissions.umask-mode	This **umask** value (user mask) is used when the user creates files and directories in the HDFS on the clients. This parameter is similar to the file permission mask on Linux. The parameter value can be in octal or in symbolic, for example, **022** (octal, the same as **u=rwx,g=r-x,o=r-x** in symbolic), or **u=rwx,g=rwx,o=** (symbolic, the same as **007** in octal). **NOTE** The octal mask is opposite to the actual permission value. You are advised to use the symbol notation to make the description clearer.	022

12.9.17 Setting the Maximum Lifetime and Renewal Interval of a Token

Scenario

In security mode, users can flexibly set the maximum token lifetime and token renewal interval in HDFS based on cluster requirements.

Configuration Description

Navigation path for setting parameters:

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-205 Parameter description

Parameter	Description	Default Value
dfs.namenode.delegation.token.max-lifetime	This parameter is a server parameter. It specifies the maximum lifetime of a token. Unit: milliseconds. Value range: 10,000 to 10,000,000,000,000	604,800,000
dfs.namenode.delegation.token.renew-interval	This parameter is a server parameter. It specifies the maximum lifetime to renew a token. Unit: milliseconds. Value range: 10,000 to 10,000,000,000,000	86,400,000

12.9.18 Configuring the Damaged Disk Volume

Scenario

In the open source version, if multiple data storage volumes are configured for a DataNode, the DataNode stops providing services by default if one of the volumes is damaged. You can change the value of **dfs.datanode.failed.volumes.tolerated** to specify the number of damaged disk volumes that are allowed. If the number of damaged volumes does not exceed the threshold, DataNode continues to provide services.

Configuration Description

Navigation path for setting parameters:

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-206 Parameter description

Parameter	Description	Default Value
dfs.datanode.failed.volumes.tolerated	Specifies the number of damaged volumes that are allowed before the DataNode stops providing services. By default, there must be at least one valid volume. The value **-1** indicates that the minimum value of a valid volume is **1**. The value greater than or equal to **0** indicates the number of damaged volumes that are allowed.	Versions earlier than MRS 3.x: 0 MRS 3.*x* or later: -1

12.9.19 Configuring Encrypted Channels

Scenario

Encrypted channel is an encryption protocol of remote procedure call (RPC) in HDFS. When a user invokes RPC, the user's login name will be transmitted to RPC through RPC head. Then RPC uses Simple Authentication and Security Layer (SASL) to determine an authorization protocol (Kerberos and DIGEST-MD5) to complete RPC authorization. When users deploy security clusters, they need to use encrypted channels and configure the following parameters. For details about the secure Hadoop RPC, visit **https://hadoop.apache.org/docs/r3.1.1/hadoop-project-dist/hadoop-common/SecureMode.html#Data_Encryption_on_RPC**.

Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-207 Parameter description

Parameter	Description	Default Value
hadoop.rpc.protection	**NOTICE** • The setting takes effect only after the service is restarted. Rolling restart is not supported. • After the setting, you need to download the client configuration again. Otherwise, the HDFS cannot provide the read and write services. Whether the RPC channels of each module in Hadoop are encrypted. The channels include: • RPC channels for clients to access HDFS • RPC channels between modules in HDFS, for example, RPC channels between DataNode and NameNode • RPC channels for clients to access Yarn • RPC channels between NodeManager and ResourceManager • RPC channels for Spark to access Yarn and HDFS • RPC channels for MapReduce to access Yarn and HDFS • RPC channels for HBase to access HDFS **NOTE** You can set this parameter on the HDFS component configuration page. The parameter setting takes effect globally, that is, the setting of whether the RPC channel is encrypted takes effect on all modules in Hadoop. There are three encryption modes. • **authentication**: This is the default value in normal mode. In this mode, data is directly transmitted without encryption after being authenticated. This mode ensures performance but has security risks. • **integrity**: Data is transmitted without encryption or authentication. To ensure data security, exercise caution when using this mode. • **privacy**: This is the default value in security mode, indicating that data is transmitted after authentication and encryption. This mode reduces the performance.	• Security mode: privacy • Normal mode: authentication

12.9.20 Reducing the Probability of Abnormal Client Application Operation When the Network Is Not Stable

Scenario

Clients probably encounter running errors when the network is not stable. Users can adjust the following parameter values to improve the running efficiency.

Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-208 Parameter description

Parameter	Description	Default Value
ha.health-monitor.rpc-timeout.ms	Timeout interval during the NameNode health check performed by ZKFC. Increasing this value can prevent dual active NameNodes and reduce the probability of application running exceptions on clients. Unit: millisecond. Value range: 30,000 to 3,600,000	180,000
ipc.client.connect.max.retries.on.timeouts	Number of retry times when the socket connection between a server and a client times out. Value range: 1 to 256	45
ipc.client.connect.timeout	Timeout interval of the socket connection between a client and a server. Increasing the value of this parameter increases the timeout interval for setting up a connection. Unit: millisecond. Value range: 1 to 3,600,000	20,000

12.9.21 Configuring the NameNode Blacklist

Scenario

NOTE

This section applies to MRS 3.*x* or later.

In the existing default DFSclient failover proxy provider, if a NameNode in a process is faulty, all HDFS client instances in the same process attempt to connect to the NameNode again. As a result, the application waits for a long time and timeout occurs.

When clients in the same JVM process connect to the NameNode that cannot be accessed, the system is overloaded. The NameNode blacklist is equipped with the MRS cluster to avoid this problem.

In the new Blacklisting DFSClient failover provider, the faulty NameNode is recorded in a list. The DFSClient then uses the information to prevent the client from connecting to such NameNodes again. This function is called NameNode blacklisting.

For example, there is a cluster with the following configurations:

namenode: nn1, nn2

dfs.client.failover.connection.retries: 20

Processes in a single JVM: 10 clients

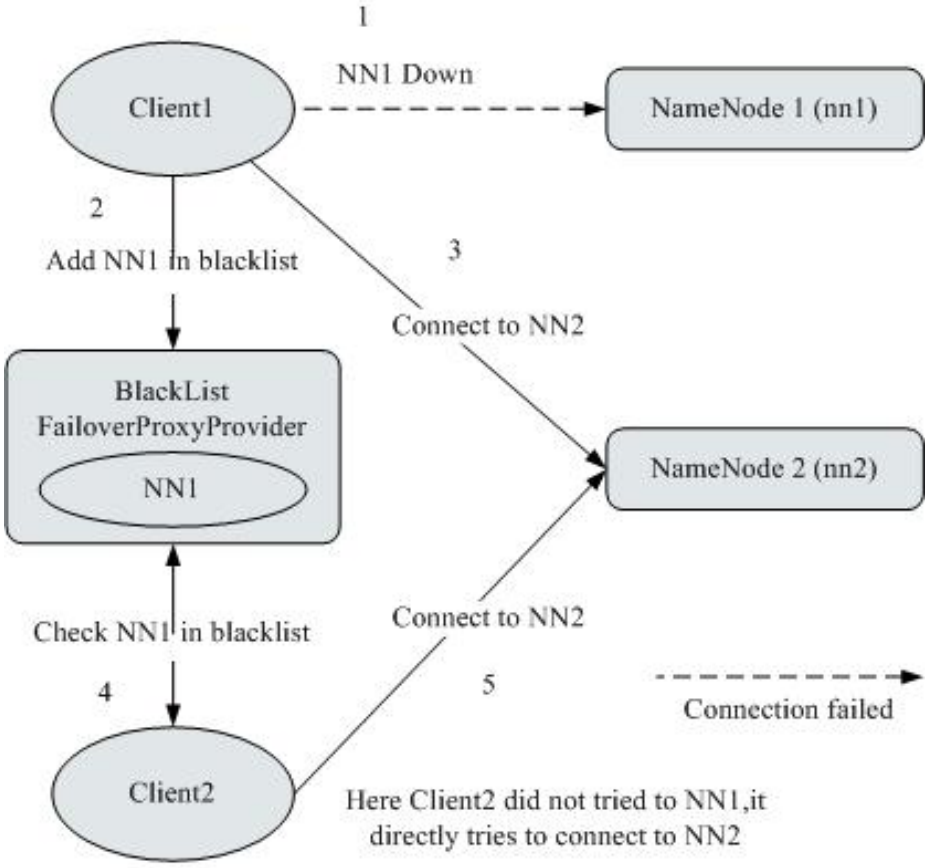
In the preceding cluster, if the active **nn1** cannot be accessed, client1 will retry the connection for 20 times. Then, a failover occurs, and client1 will connect to **nn2**. In the same way, other clients also connect to **nn2** when the failover occurs after retrying the connection to **nn1** for 20 times. Such process prolongs the fault recovery of NameNode.

In this case, the NameNode blacklisting adds **nn1** to the blacklist when client1 attempts to connect to the active **nn1** which is already faulty. Therefore, other clients will avoid trying to connect to **nn1** but choose **nn2** directly.

NOTE

If, at any time, all NameNodes are added to the blacklist, the content in the blacklist will be cleared, and the client attempts to connect to the NameNodes based on the initial NameNode list. If any fault occurs again, the NameNode is still added to the blacklist.

Figure 12-20 NameNode blacklisting working principle



Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-209 NameNode blacklisting parameters

Parameter	Description	Default Value
dfs.client.failover.proxy.provider.*[nameserviceID]*	Client Failover proxy provider class which creates the NameNode proxy using the authenticated protocol. Set this parameter to **org.apache.hadoop.hdfs.server.namenode.ha.BlackListingFailoverProxyProvider**. You can configure the observer NameNode to process read requests.	org.apache.hadoop.hdfs.server.namenode.ha.AdaptiveFailoverProxyProvider

12.9.22 Optimizing HDFS NameNode RPC QoS

Scenarios

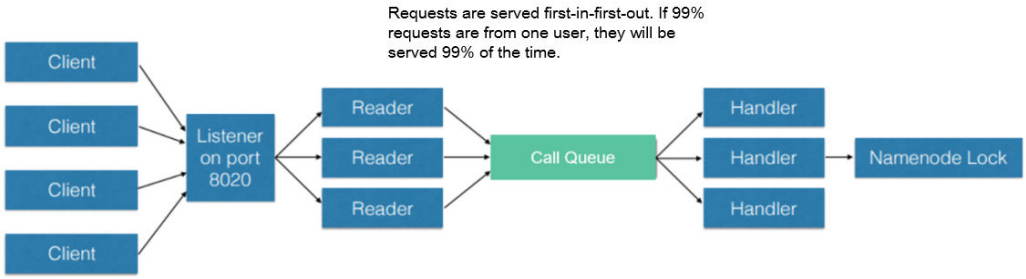
NOTE

This section applies to MRS 3.*x* or later.

Several finished Hadoop clusters are faulty because the NameNode is overloaded and unresponsive.

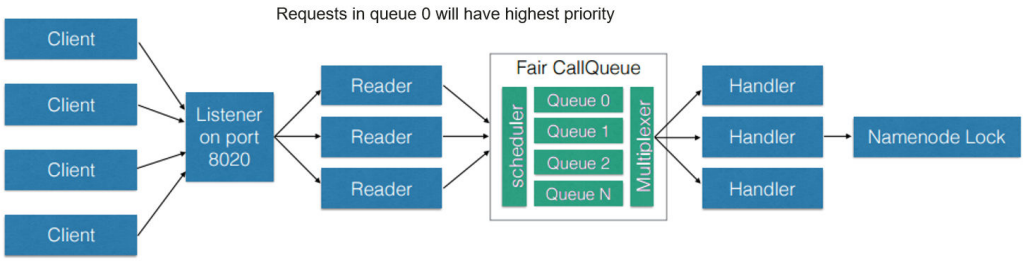
Such problem is caused by the initial design of Hadoop: In Hadoop, the NameNode functions as an independent part and in its namespace coordinates various HDFS operations, including obtaining the data block location, listing directories, and creating files. The NameNode receives HDFS operations, regards them as RPC calls, and places them in the FIFO call queue for read threads to process. Requests in FIFO call queue are served first-in first-out. However, users who perform more I/O operations are served more time than those performing fewer I/O operations. In this case, the FIFO is unfair and causes the delay.

Figure 12-21 NameNode request processing based on the FIFO call queue



The unfair problem and delaying mentioned before can be improved by replacing the FIFO queue with a new type of queue called FairCallQueue. In this way, FAIR queues assign incoming RPC calls to multiple queues based on the scale of the caller's call. The scheduling module tracks the latest calls and assigns a higher priority to users with a smaller number of calls.

Figure 12-22 NameNode request processing based on FAIRCallQueue



Configuration Description

- FairCallQueue ensures quality of service (QoS) by internally adjusting the order in which RPCs are invoked.

  This queue consists of the following parts:

a. DecayRpcScheduler: used to provide priority values from 0 to N (the value 0 indicates the highest priority).
b. Multi-level queues (located in the FairCallQueue): used to ensure that queues are invoked in order of priority.
c. Multi-channel converters (provided with Weighted Round Robin Multiplexer): used to provide logic control for queue selection.

After the FairCallQueue is configured, the control module determines the sub-queue to which the received invoking is allocated. The current scheduling module is DecayRpcScheduler, which only continuously tracks the priority numbers of various calls and periodically reduces these numbers.

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-210 FairCallQueue parameters

Parameter	Description	Default Value
ipc.*<port>*.callqueue.impl	Specifies the queue implementation class. You need to run the **org.apache.hadoop.ipc.FairCallQueue** command to enable the QoS feature.	java.util.concurrent.LinkedBlockingQueue

- RPC BackOff

  Backoff is one of the FairCallQueue functions. It requires the client to retry operations (such as creating, deleting, and opening a file) after a period of time. When the backoff occurs, the RCP server throws RetriableException. The FairCallQueue performs backoff in either of the following cases:

  – The queue is full, that is, there are many client calls in the queue.
  – The queue response time is longer than the threshold time (specified by the **ipc.<port>.decay-scheduler.backoff.responsetime.thresholds** parameter).

Table 12-211 RPC Backoff configuration

Parameter	Description	Default Value
ipc.*<port>*.backoff.enable	Specifies whether to enable the backoff. When the current application contains a large number of user callings, the RPC request is blocked if the connection limit of the operating system is not reached. Alternatively, when the RPC or NameNode is heavily loaded, some explicit exceptions can be thrown back to the client based on certain policies. The client can understand these exceptions and perform exponential rollback, which is another implementation of the RetryInvocationHandler class.	false
ipc.*<port>*.decay-scheduler.backoff.responsetime.enable	Indicate whether to enable the backoff based on the average queue response time.	false
ipc.*<port>*.decay-scheduler.backoff.responsetime.thresholds	Configure the response time threshold for each queue. The response time threshold must match the number of priorities (the value of **ipc.<port> .faircallqueue.priority-levels**). Unit: millisecond	10000,20000,30000,40000

NOTE

- **<port>** indicates the RPC port configured on the NameNode.
- The backoff function based on the response time takes effect only when **ipc.<port> .backoff.enable** is set to **true**.

12.9.23 Optimizing HDFS DataNode RPC QoS

Scenario

When the speed at which the client writes data to the HDFS is greater than the disk bandwidth of the DataNode, the disk bandwidth is fully occupied. As a result, the DataNode does not respond. The client can back off only by canceling or restoring the channel, which results in write failures and unnecessary channel recovery operations.

NOTE

This section applies to MRS 3.*x* or later.

Configuration

The new configuration parameter **dfs.pipeline.ecn** is introduced. When this configuration is enabled, the DataNode sends a signal from the write channel when the write channel is overloaded. The client may perform backoff based on the blocking signal to prevent the system from being overloaded. This configuration parameter is introduced to make the channel more stable and reduce unnecessary cancellation or recovery operations. After receiving the signal, the client backs off for a period of time (5,000 ms), and then adjusts the backoff time based on the related filter (the maximum backoff time is 50,000 ms).

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-212 DN ECN configuration

Parameter	Description	Default Value
dfs.pipeline.ecn	After configuration, the DataNode can send blocking notifications to the client.	false

12.9.24 Configuring Reserved Percentage of Disk Usage on DataNodes

Scenario

When the Yarn local directory and DataNode directory are on the same disk, the disk with larger capacity can run more tasks. Therefore, more intermediate data is stored in the Yarn local directory.

Currently, you can set **dfs.datanode.du.reserved** to configure the absolute value of the reserved disk space on DataNodes. A small value cannot meet the requirements of a disk with large capacity. However, configuring a large value for a disk with same capacity wastes a lot of disk space.

To avoid this problem, a new parameter **dfs.datanode.du.reserved.percentage** is introduced to configure the reserved percentage of the disk space.

NOTE

- If **dfs.datanode.du.reserved.percentage** and **dfs.datanode.du.reserved** are configured at the same time, the larger value of the reserved disk space calculated using the two parameters is used as the reserved space of the data nodes.
- You are advised to set **dfs.datanode.du.reserved** or **dfs.datanode.du.reserved.percentage** based on the actual disk space.

Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-213 Parameter description

Parameter	Description	Default Value
dfs.datanode.du.reserved.percentage	Indicates the percentage of the reserved disk space on DataNodes. The DataNode permanently reserves the disk space calculated using this percentage. The value is an integer ranging from 0 to 100.	10

12.9.25 Configuring HDFS NodeLabel

Scenario

You need to configure the nodes for storing HDFS file data blocks based on data features. You can configure a label expression to an HDFS directory or file and assign one or more labels to a DataNode so that file data blocks can be stored on specified DataNodes.

If the label-based data block placement policy is used for selecting DataNodes to store the specified files, the DataNode range is specified based on the label expression. Then proper nodes are selected from the specified range.

NOTE

This section applies to MRS 3.*x* or later.

After cross-AZ HA is enabled for a single cluster, the HDFS NodeLabel function cannot be configured.

- Scenario 1: DataNodes partitioning scenario

  Scenario description:

  When different application data is required to run on different nodes for separate management, label expressions can be used to achieve separation of different services, storing specified services on corresponding nodes.

By configuring the NodeLabel feature, you can perform the following operations:

- Store data in **/HBase** to DN1, DN2, DN3, and DN4.
- Store data in **/Spark** to DN5, DN6, DN7, and DN8.

Figure 12-23 DataNode partitioning scenario

NOTE

- Run the **hdfs nodelabel -setLabelExpression -expression 'LabelA[fallback=NONE]' -path /Hbase** command to set an expression for the **Hbase** directory. As shown in **Figure 12-23**, the data block replicas of files in the **/Hbase** directory are placed on the nodes labeled with the **LabelA**, that is, DN1, DN2, DN3, and DN4. Similarly, run the **hdfs nodelabel -setLabelExpression -expression 'LabelB[fallback=NONE]' -path /Spark** command to set an expression for the Spark directory. Data block replicas of files in the **/Spark** directory can be placed only on nodes labeled with **LabelB**, that is, DN5, DN6, DN7, and DN8.
- For details about how to set labels for a data node, see **Configuration Description**.
- If multiple racks are available in one cluster, it is recommended that DataNodes of these racks should be available under each label, to ensure reliability of data block placement.

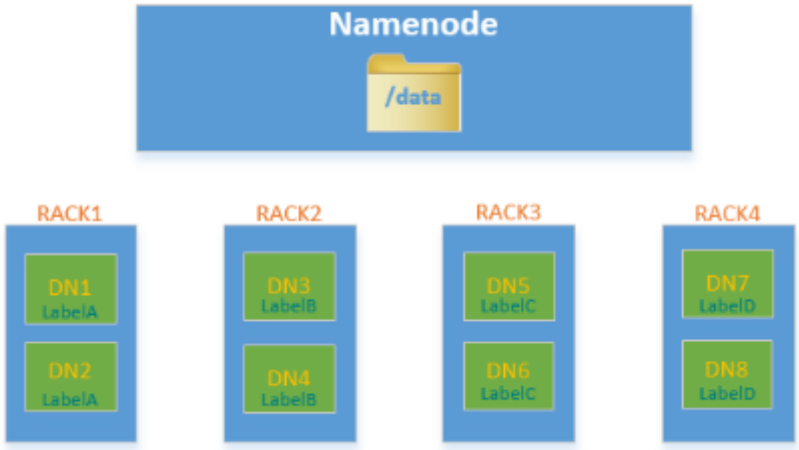
- Scenario 2: Specifying replica location when there are multiple racks

  Scenario description:

  In a heterogeneous cluster, customers need to allocate certain nodes with high availability to store important commercial data. Label expressions can be used to specify replica location so that the replica can be placed on a high reliable node.

  Data blocks in the **/data** directory have three replicas by default. In this case, at least one replica is stored on a node of RACK1 or RACK2 (nodes of RACK1 and RACK2 are high reliable), and the other two are stored separately on the nodes of RACK3 and RACK4.

Figure 12-24 Scenario example



NOTE

Run the **hdfs nodelabel -setLabelExpression -expression 'LabelA|| LabelB[fallback=NONE],LabelC,LabelD' -path /data** command to set an expression for the **/data** directory.

When data is to be written to the **/data** directory, at least one data block replica is stored on a node labeled with the LabelA or LabelB, and the other two data block replicas are stored separately on the nodes labeled with the LabelC and LabelD.

Configuration Description

- DataNode label configuration

  Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

  Table 12-214 Parameter description

Parameter	Description	Default Value
dfs.block.replicator.classname	Used to configure the DataNode policy of HDFS. To enable the NodeLabel function, set this parameter to **org.apache.hadoop.hdfs.server.blockmanagement.BlockPlacementPolicyWithNodeLabel**.	org.apache.hadoop.hdfs.server.blockmanagement.AvailableSpaceBlockPlacementPolicy

Parameter	Description	Default Value
host2tags	Used to configure a mapping between a DataNode host and a label. The host name can be configured with an IP address extension expression (for example, **192.168.1.[1-128]** or **192.168.[2-3].[1-128]**) or a regular expression (for example, **/datanode-[123]/** or **/datanode-\d{2}/**) starting and ending with a slash (/). The label configuration name cannot contain the following characters: = / \ **Note**: The IP address must be a service IP address.	-

NOTE

- The **host2tags** configuration item is described as follows:

  Assume there are 20 DataNodes which range from dn-1 to dn-20 in a cluster and the IP addresses of clusters range from 10.1.120.1 to 10.1.120.20. The value of **host2tags** can be represented in either of the following methods:

  Regular expression of the host name

  /dn-\d/ = label-1 indicates that the labels corresponding to dn-1 to dn-9 are label-1, that is, dn-1 = label-1, dn-2 = label-1, ..., dn-9 = label-1.

  /dn-((1[0-9]$)|(20$))/ = label-2 indicates that the labels corresponding to dn-10 to dn-20 are label-2, that is, dn-10 = label-2, dn-11 = label-2, ...dn-20 = label-2.

  IP address range expression

  10.1.120.[1-9] = label-1 indicates that the labels corresponding to 10.1.120.1 to 10.1.120.9 are label-1, that is, 10.1.120.1 = label-1, 10.1.120.2 = label-1, ..., and 10.1.120.9 = label-1.

  10.1.120.[10-20] = label-2 indicates that the labels corresponding to 10.1.120.10 to 10.1.120.20 are label-2, that is, 10.1.120.10 = label-2, 10.1.120.11 = label-2, ..., and 10.1.120.20 = label-2.

- Label-based data block placement policies are applicable to capacity expansion and reduction scenarios.

  A newly added DataNode will be assigned a label if the IP address of the DataNode is within the IP address range in the **host2tags** configuration item or the host name of the DataNode matches the host name regular expression in the **host2tags** configuration item.

  For example, the value of **host2tags** is **10.1.120.[1-9] = label-1**, but the current cluster has only three DataNodes: 10.1.120.1 to 10.1.120.3. If DataNode 10.1.120.4 is added for capacity expansion, the DataNode is labeled as label-1. If the 10.1.120.3 DataNode is deleted or out of the service, no data block will be allocated to the node.

- Set label expressions for directories or files.
  - On the HDFS parameter configuration page, configure **path2expression** to configure the mapping between HDFS directories and labels. If the configured HDFS directory does not exist, the configuration can succeed. When a directory with the same name as the HDFS directory is created manually, the configured label mapping relationship will be inherited by the directory within 30 minutes. After a labeled directory is deleted, a

new directory with the same name as the deleted one will inherit its mapping within 30 minutes.

- For details about configuring items using commands, see the **hdfs nodelabel -setLabelExpression** command.
- To set label expressions using the Java API, invoke the **setLabelExpression(String src, String labelExpression)** method using the instantiated object NodeLabelFileSystem. *src* indicates a directory or file path on HDFS, and **labelExpression** indicates the label expression.

- After the NodeLabel is enabled, you can run the **hdfs nodelabel -listNodeLabels** command to view the label information of each DataNode.

Block Replica Location Selection

Nodelabel supports different placement policies for replicas. The expression **label-1,label-2,label-3** indicates that three replicas are respectively placed in DataNodes containing label-1, label-2, and label-3. Different replica policies are separated by commas (,).

If you want to place two replicas in DataNode with label-1, set the expression as follows: **label-1[replica=2],label-2,label-3**. In this case, if the default number of replicas is 3, two nodes with label-1 and one node with label-2 are selected. If the default number of replicas is 4, two nodes with label-1, one node with label-2, and one node with label-3 are selected. Note that the number of replicas is the same as that of each replica policy from left to right. However, the number of replicas sometimes exceeds the expressions. If the default number of replicas is 5, the extra replica is placed on the last node, that is, the node labeled with label-3.

When the ACLs function is enabled and the user does not have the permission to access the labels used in the expression, the DataNode with the label is not selected for the replica.

Deletion of Redundant Block Replicas

If the number of block replicas exceeds the value of **dfs.replication** (number of file replicas specified by the user), HDFS will delete redundant block replicas to ensure cluster resource usage.

The deletion rules are as follows:

- Preferentially delete replicas that do not meet any expression.

  For example: The default number of file replicas is **3**.

  The label expression of **/test** is **LA[replica=1],LB[replica=1],LC[replica=1]**.

  The file replicas of **/test** are distributed on four nodes (D1 to D4), corresponding to labels (LA to LD).

  ```
  D1:LA
  D2:LB
  D3:LC
  D4:LD
  ```

  Then, block replicas on node D4 will be deleted.

- If all replicas meet the expressions, delete the redundant replicas which are beyond the number specified by the expression.

  For example: The default number of file replicas is **3**.

The label expression of **/test** is **LA[replica=1],LB[replica=1],LC[replica=1]**.

The file replicas of **/test** are distributed on the following four nodes, corresponding to the following labels.

```
D1:LA
D2:LA
D3:LB
D4:LC
```

Then, block replicas on node D1 or D2 will be deleted.

- If a file owner or group of a file owner cannot access a label, preferentially delete the replica from the DataNode mapped to the label.

Example of label-based block placement policy

Assume that there are six DataNodes, namely, dn-1, dn-2, dn-3, dn-4, dn-5, and dn-6 in a cluster and the corresponding IP address range is 10.1.120.[1-6]. Six directories must be configured with label expressions. The default number of block replicas is **3**.

- The following provides three expressions of the DataNode label in **host2labels** file. The three expressions have the same function.
  - Regular expression of the host name

    ```
    /dn-[1456]/ = label-1,label-2
    /dn-[26]/ = label-1,label-3
    /dn-[3456]/ = label-1,label-4
    /dn-5/ = label-5
    ```

  - IP address range expression

    ```
    10.1.120.[1-6] = label-1
    10.1.120.1 = label-2
    10.1.120.2 = label-3
    10.1.120.[3-6] = label-4
    10.1.120.[4-6] = label-2
    10.1.120.5 = label-5
    10.1.120.6 = label-3
    ```

  - Common host name expression

    ```
    /dn-1/ = label-1, label-2
    /dn-2/ = label-1, label-3
    /dn-3/ = label-1, label-4
    /dn-4/ = label-1, label-2, label-4
    /dn-5/ = label-1, label-2, label-4, label-5
    /dn-6/ = label-1, label-2, label-3, label-4
    ```

- The label expressions of the directories are set as follows:

  ```
  /dir1 = label-1
  /dir2 = label-1 && label-3
  /dir3 = label-2 || label-4[replica=2]
  /dir4 = (label-2 || label-3) && label-4
  /dir5 = !label-1
  /sdir2.txt = label-1 && label-3[replica=3,fallback=NONE]
  /dir6 = label-4[replica=2],label-2
  ```

  NOTE

  For details about the label expression configuration, see the **hdfs nodelabel -setLabelExpression** command.

  The file data block storage locations are as follows:

  - Data blocks of files in the **/dir1** directory can be stored on any of the following nodes: dn-1, dn-2, dn-3, dn-4, dn-5, and dn-6.
  - Data blocks of files in the **/dir2** directory can be stored on the dn-2 and dn-6 nodes. The default number of block replicas is **3**. The expression

matches only two DataNodes. The third replica will be stored on one of the remaining nodes in the cluster.

- Data blocks of files in the **/dir3** directory can be stored on any three of the following nodes: dn-1, dn-3, dn-4, dn-5, and dn-6.
- Data blocks of files in the **/dir4** directory can be stored on the dn-4, dn-5, and dn-6 nodes.
- Data blocks of files in the **/dir5** directory do not match any DataNode and will be stored on any three nodes in the cluster, which is the same as the default block selection policy.
- For the data blocks of the **/sdir2.txt** file, two replicas are stored on the dn-2 and dn-6 nodes. The left one is not stored in the node because **fallback=NONE** is enabled.
- Data blocks of the files in the **/dir6** directory are stored on the two nodes with label-4 selected from dn-3, dn-4, dn-5, and dn-6 and another node with label-2. If the specified number of file replicas in the **/dir6** directory is more than 3, the extra replicas will be stored on a node with label-2.

Restrictions

In configuration files, **key** and **value** are separated by equation signs (=), colons (:), and whitespace. Therefore, the host name of the **key** cannot contain these characters because these characters may be considered as separators.

12.9.26 Configuring HDFS Mover

Scenario

Mover is a new data migration tool whose working mode is similar to that of the HDFS Balancer. Mover can redistribute data in the cluster based on the configured data storage policy.

Use Mover to periodically check whether the specified HDFS file or directory in the HDFS file system meets the preset storage policy. If not, migrate data to make them meet the policy.

NOTE

This section applies to MRS 3.*x* or later.

Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-215 Parameter description

Parameter	Description	Default Value
dfs.mover.auto.enable	Specifies whether to enable the data replica migration function. This function supports multiple modes. The default value is **false**, indicating that this function is disabled.	false
dfs.mover.auto.cron.expression	Specifies the CRON expression for HDFS automatic data migration, and is used to control the start time of data migration. This parameter is valid only when **dfs.mover.auto.enable** is set to **true**. The default value is **0 * * * ***, indicating that the task is executed on the hour. For details about CRON expression, see **Table 12-216**.	0 * * * *
dfs.mover.auto.hdfsfiles_or_dirs	Specifies HDFS file and directory lists that implement automatic replica migration in specified clusters. Multiple values are separated by space. This parameter is valid only when **dfs.mover.auto.enable** is set to **true**.	-

Table 12-216 CRON expressions

Column	Description
1	Minute. The value ranges from 0 to 59.
2	Hour. The value ranges from 0 to 23.
3	Date. The value ranges from 1 to 31.
4	Month. The value ranges from 1 to 12.
5	Week. The value ranges from 0 to 6. **0** indicates Sunday.

Use Restrictions

Run the command on the HDFS client to enable the mover function. The command format is as follows:

hdfs mover -p *<Full path or directory path of an HDFS file >*

NOTE

Users running this command on the client must have the **supergroup** permission. You can use the system user **hdfs** of the HDFS service. Alternatively, you can create a user with the **supergroup** permission in the cluster and then run the command.

12.9.27 Using HDFS AZ Mover

Scenario

AZ Mover is a copy migration tool used to move copies to meet the new AZ policies set on the directory. It can be used to migrate copies from one AZ policy to another. AZ Mover instructs NameNode to move copies based on a new AZ policy. If the NameNode refuses to delete the old copies, the new policy may not be met. For example, the copies are marked as outdated.

Restrictions

- Changing the policy name to **LOCAL_AZ** is the same as that to **ONE_AZ** because the client location cannot be determined when the uploaded file is written.
- Mover cannot determine the AZ status. As a result, the copy may be moved to the abnormal AZ and depends on NameNode for further processing.
- Mover depends on whether the number of DataNodes in each AZ meets the minimum requirement. If the AZ Mover is executed in an AZ with a small number of DataNodes, the result may be different from the expected result.
- Mover only meets the AZ-level policies and does not guarantee to meet the basic block placement policy (BPP).
- Mover does not support the change of replication factors. If the number of copies in the new AZ is different from that in the old AZ, an exception occurs.

Procedure

Step 1 Run the following command to go to the client installation directory.

cd /opt/client

Step 2 Run the following command to configure environment variables:

source bigdata_env

Step 3 If the cluster is in security mode, the user must have the read permission on the source directory or file and the write permission on the destination directory, and run the following command to authenticate the user: In normal mode, skip user authentication.

kinit *Component service user*

Step 4 Create a directory and set an AZ policy.

Run the following command to create a directory.

hdfs dfs -mkdir <*path*>

Run the following command to set the AZ policy (**azexpression** indicates the AZ policy):

hdfs dfsadmin -setAZExpression *<path> <azexpression>*

Run the following command to view the AZ policy:

hdfs dfsadmin -getAZExpression *<path>*

Step 5 Upload files to the directory.

hdfs dfs -put <*localfile*> <*hdfs-path*>

Step 6 Delete the old policy from the directory and set a new policy.

Run the following command to clear the old policy:

hdfs dfsadmin -clearAZExpression <*path*>

Run the following command to configure a new policy:

hdfs dfsadmin -setAZExpression <*path*> <*azexpression*>

Step 7 Run the **azmover** command to make the copy distribution meet the new AZ policy.

hdfs azmover -p /targetDirecotry

----End

12.9.28 Configuring HDFS DiskBalancer

Scenario

DiskBalancer is an online disk balancer that balances disk data on running DataNodes based on various indicators. It works in the similar way of the HDFS Balancer. The difference is that HDFS Balancer balances data between DataNodes, while HDFS DiskBalancer balances data among disks on a single DataNode.

Data among disks may be unevenly distributed if a large number of files have been deleted from a cluster running for a long time, or disk capacity expansion is performed on a node in the cluster. Uneven data distribution may deteriorate the concurrent read/write performance of the HDFS, or cause service failure due to inappropriate HDFS write policies. In this case, the data density among disks on a node needs to be balanced to prevent heterogeneous small disks from becoming the performance bottleneck of the node.

NOTE

This section applies to MRS 3.*x* or later.

Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-217 Parameter description

Parameter	Description	Default Value
dfs.disk.balancer.auto.enabled	Indicates whether to enable the HDFS DiskBalancer function. The default value is **false**, indicating that this function is disabled.	false

Parameter	Description	Default Value
dfs.disk.balancer.auto.cron.expression	CRON expression of the HDFS disk balancing operation, which is used to control the start time of the balancing operation. This parameter is valid only when **dfs.disk.balancer.auto.enabled** is set to **true**. The default value is **0 1 * * 6**, indicating that tasks are executed at 01:00 every Saturday. For details about cron expression, see **Table 12-218**. The default value indicates that the DiskBalancer check is executed at 01:00 every Saturday.	0 1 * * 6
dfs.disk.balancer.max.disk.throughputInMBperSec	Specifies the maximum disk bandwidth that can be used for disk data balancing. The unit is MB/s, and the default value is **10**. Set this parameter based on the actual disk conditions of the cluster.	10
dfs.disk.balancer.max.disk.errors	Specifies the maximum number of errors that are allowed in a specified movement process. If the value exceeds this threshold, the movement fails.	5
dfs.disk.balancer.block.tolerance.percent	Specifies the difference threshold between the data storage capacity and perfect status of each disk during data balancing among disks. For example, the ideal data storage capacity of each disk is 1 TB, and this parameter is set to **10**. When the data storage capacity of the target disk reaches 900 GB, the storage status of the disk is considered as perfect. Value range: 1 to 100.	10
dfs.disk.balancer.plan.threshold.percent	Specifies the data density difference that is allowed between two disks during disk data balancing. If the absolute value of the data density difference between any two disks exceeds the threshold, data balancing is required. Value range: 1 to 100.	10
dfs.disk.balancer.top.nodes.number	Specifies the top *N* nodes whose disk data needs to be balanced in the cluster.	5

To use this function, set **dfs.disk.balancer.auto.enabled** to **true** and configure a proper CRON expression. Set other parameters based on the cluster status.

Table 12-218 CRON expressions

Column	Description
1	Minute. The value ranges from 0 to 59.
2	Hour. The value ranges from 0 to 23.
3	Date. The value ranges from 1 to 31.
4	Month. The value ranges from 1 to 12.
5	Week. The value ranges from 0 to 6. **0** indicates Sunday.

Use Restrictions

1. Data can only be moved between disks of the same type. For example, data can only be moved between SSDs or between DISKs.
2. Enabling this function occupies disk I/O resources and network bandwidth resources of involved nodes. Enable this function in off-peak hours.
3. The DataNodes specified by the **dfs.disk.balancer.top.nodes.number** parameter are frequently calculated. Therefore, set the parameter to a small value.
4. Commands for using the DiskBalancer function on the HDFS client are as follows:

   Table 12-219 DiskBalancer commands

Syntax	Description
hdfs diskbalancer -report -top <N>	Set *N* to an integer greater than 0. This command can be used to query the top *N* nodes that require disk data balancing in the cluster.
hdfs diskbalancer -plan <Hostname|IP Address>	This command can be used to generate a JSON file based on the DataNode. The file contains information about the source disk, target disk, and blocks to be moved. In addition, this command can be used to specify other parameters such as the network bandwidth.
hdfs diskbalancer -query <Hostname:$dfs.datanode.ipc.port>	The default port number of the cluster is 9867. This command is used to query the running status of the DiskBalancer task on the current node.

Syntax	Description
hdfs diskbalancer -execute <planfile>	In this command, **planfile** indicates the JSON file generated in the second command. Use the absolute path.
hdfs diskbalancer -cancel <planfile>	This command is used to cancel the running planfile. Use the absolute path.

NOTE

- Users running this command on the client must have the **supergroup** permission. You can use the system user **hdfs** of the HDFS service. Alternatively, you can create a user with the **supergroup** permission in the cluster and then run the command.
- Only formats and usage of commands are provided in **Table 12-219**. For more parameters to be configured for each command, run the **hdfs diskbalancer -help <command>** command to view detailed information.
- When you troubleshoot performance problems during the cluster O&M, check whether the HDFS disk balancing occurs in the event information of the cluster. If yes, check whether DiskBalancer is enabled in the cluster.
- After the automatic DiskBalancer function is enabled, the ongoing task stops only after the current data balancing is complete. The task cannot be canceled during the balancing.
- You can manually specify certain nodes for data balancing on the client.

12.9.29 Configuring the Observer NameNode to Process Read Requests

Scenario

In an HDFS cluster configured with HA, the active NameNode processes all client requests, and the standby NameNode reserves the latest metadata and block location information. However, in this architecture, the active NameNode is the bottleneck of client request processing. This bottleneck is more obvious in clusters with a large number of requests.

To address this issue, a new NameNode is introduced: an observer NameNode. Similar to the standby NameNode, the observer NameNode also reserves the latest metadata information and block location information. In addition, the observer NameNode can process read requests from clients in the same way as the active NameNode. In typical HDFS clusters with many read requests, the observer NameNode can be used to process read requests, reducing the active NameNode load and improving the cluster capability of processing requests.

NOTE

This section applies to MRS 3.*x* or later.

Impact on the System

- The active NameNode load can be reduced and the capability of HDFS cluster processing requests can be improved, which is especially obvious for large clusters.
- The client application configuration needs to be updated.

Prerequisites

- The HDFS cluster has been installed, the active and standby NameNodes are running properly, and the HDFS service is normal.
- The **${BIGDATA_DATA_HOME}/namenode** partition has been created on the node where the observer NameNode is to be installed.

Procedure

The following steps describe how to configure the observer NameNode of a hacluster and enable it to process read requests. If there are multiple pairs of NameServices in the cluster and they are all in use, perform the following steps to configure the observer NameNode for each pair.

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **NameService Management**.

Step 3 Click **Add** next to **hacluster**.

Step 4 On the **Add NameNode** page, set **NameNode type** to **Observer** and click **Next**.

Step 5 On the **Assign Role** page, select the planned host, add the observer NameNode, and click **Next**.

NOTE

A maximum of five observer NameNodes can be added to each pair of NameServices.

Step 6 On the configuration page, configure the storage directory and port number of the NameNode as planned and click **Next**.

Step 7 Confirm the information, click **Submit**, and wait until the installation of the observer NameNode is complete.

Step 8 Restart the upper-layer components that depend on HDFS, update the client application configuration, and restart the client application.

----End

12.9.30 Performing Concurrent Operations on HDFS Files

Scenario

Performing this operation can concurrently modify file and directory permissions and access control tools in a cluster.

NOTE

This section applies to MRS 3.*x* or later.

Impact on the System

Performing concurrent file modification operations in a cluster has adverse impacts on the cluster performance. Therefore, you are advised to do so when the cluster is idle.

Prerequisites

- The HDFS client or clients including HDFS has been installed. For example, the installation directory is **/opt/client**.
- Service component users are created by the administrator as required. In security mode, machine-machine users need to download the keytab file. A human-machine user needs to change the password upon the first login. (This operation is not required in normal mode.)

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, the user executing the DistCp command must belong to the **supergroup** group and run the following command to perform user authentication. In normal mode, user authentication is not required.

kinit *Component service user*

Step 5 Increase the JVM size of the client to prevent out of memory (OOM). (32 GB is recommended for 100 million files.)

NOTE

The HDFS client exits abnormally and the error message "java.lang.OutOfMemoryError" is displayed after the HDFS client command is executed.

This problem occurs because the memory required for running the HDFS client exceeds the preset upper limit (128 MB by default). You can change the memory upper limit of the client by modifying **CLIENT_GC_OPTS** in *<Client installation path>***/HDFS/component_env**. For example, if you want to set the upper limit to 1 GB, run the following command:

CLIENT_GC_OPTS="-Xmx1G"

After the modification, run the following command to make the modification take effect:

source <*Client installation path*>/**/bigdata_env**

Step 6 Run the concurrent commands shown in the following table.

Command	Description	Function
hdfs quickcmds [-t threadsNumber] [-p principal] [-k keytab] -setrep <rep> <path> ...	**threadsNumber** indicates the number of concurrent threads. The default value is the number of vCPUs of the local host. **principal** indicates the Kerberos user. **keytab** indicates the Keytab file. **rep** indicates the number of replicas. **path** indicates the HDFS directory.	Used to concurrently set the number of copies of all files in a directory.
hdfs quickcmds [-t threadsNumber] [-p principal] [-k keytab] -chown [owner][:[group]] <path> ...	**threadsNumber** indicates the number of concurrent threads. The default value is the number of vCPUs of the local host. **principal** indicates the Kerberos user. **keytab** indicates the Keytab file. **owner** indicates the owner. **group** indicates the group to which the user belongs. **path** indicates the HDFS directory.	Used to concurrently set the owner group of all files in the directory.
hdfs quickcmds [-t threadsNumber] [-p principal] [-k keytab] -chmod <mode> <path> ...	**threadsNumber** indicates the number of concurrent threads. The default value is the number of vCPUs of the local host. **principal** indicates the Kerberos user. **keytab** indicates the Keytab file. **mode** indicates the permission (for example, 754). **path** indicates the HDFS directory.	Used to concurrently set permissions for all files in a directory.
hdfs quickcmds [-t threadsNumber] [-p principal] [-k keytab] -setfacl [{-b|-k} {-m|-x <acl_spec>} <path> ...]|[--set <acl_spec> <path> ...]	**threadsNumber** indicates the number of concurrent threads. The default value is the number of vCPUs of the local host. **principal** indicates the Kerberos user. **keytab** indicates the Keytab file. **acl_spec** indicates the ACL list separated by commas (,). **path** indicates the HDFS directory.	Used to concurrently set ACL information for all files in a directory.

----End

12.9.31 Introduction to HDFS Logs

Log Description

Log path: The default path of HDFS logs is **/var/log/Bigdata/hdfs/***Role name*.

- NameNode: **/var/log/Bigdata/hdfs/nn** (run logs) and **/var/log/Bigdata/audit/hdfs/nn** (audit logs)
- DataNode: **/var/log/Bigdata/hdfs/dn** (run logs) and **/var/log/Bigdata/audit/hdfs/dn** (audit logs)
- ZKFC: **/var/log/Bigdata/hdfs/zkfc** (run logs) and **/var/log/Bigdata/audit/hdfs/zkfc** (audit logs)
- JournalNode: **/var/log/Bigdata/hdfs/jn** (run logs) and **/var/log/Bigdata/audit/hdfs/jn** (audit logs)
- Router: **/var/log/Bigdata/hdfs/router** (run logs) and **/var/log/Bigdata/audit/hdfs/router** (audit logs)
- HttpFS: **/var/log/Bigdata/hdfs/httpfs** (run logs) and **/var/log/Bigdata/audit/hdfs/httpfs** (audit logs)

Log archive rule: The automatic HDFS log compression function is enabled. By default, when the size of logs exceeds 100 MB, logs are automatically compressed into a log file named in the following format: *<Original log file name>-<yyyy-mm-dd_hh-mm-ss.[ID]>***.log.zip**. A maximum of 100 latest compressed files are reserved. The number of compressed files can be configured on Manager.

Table 12-220 HDFS log list

Type	Name	Description
Run log	hadoop-<SSH_USER>-<process_name>-<hostname>.log	HDFS system log, which records most of the logs generated when the HDFS system is running.
	hadoop-<SSH_USER>-<process_name>-<hostname>.out	Log that records the HDFS running environment information.
	hadoop.log	Log that records the operation of the Hadoop client.

Type	Name	Description
	hdfs-period-check.log	Log that records scripts that are executed periodically, including automatic balancing, data migration, and JournalNode data synchronization detection.
	<process_name>-<SSH_USER>-<DATE>-<PID>-gc.log	Garbage collection log file
	postinstallDetail.log	Work log before the HDFS service startup and after the installation.
	hdfs-service-check.log	Log that records whether the HDFS service starts successfully.
	hdfs-set-storage-policy.log	Log that records the HDFS data storage policies.
	cleanupDetail.log	Log that records the cleanup logs about the uninstallation of the HDFS service.
	prestartDetail.log	Log that records cluster operations before the HDFS service startup.
	hdfs-recover-fsimage.log	Recovery log of the NameNode metadata.
	datanode-disk-check.log	Log that records the disk status check during the cluster installation and use.
	hdfs-availability-check.log	Log that check whether the HDFS service is available.
	hdfs-backup-fsimage.log	Backup log of the NameNode metadata.
	startDetail.log	Detailed log that records the HDFS service startup.

Type	Name	Description
	hdfs-blockplacement.log	Log that records the placement policy of HDFS blocks.
	upgradeDetail.log	Upgrade logs.
	hdfs-clean-acls-java.log	Log that records the clearing of deleted roles' ACL information by HDFS.
	hdfs-haCheck.log	Run log that checks whether the NameNode in active or standby state has obtained scripts.
	<process_name>-jvmpause.log	Log that records JVM pauses during process running.
	hadoop-<SSH_USER>-balancer-<hostname>.log	Run log of HDFS automatic balancing.
	hadoop-<SSH_USER>-balancer-<hostname>.out	Log that records information of the environment where HDFS executes automatic balancing.
	hdfs-switch-namenode.log	Run log that records the HDFS active/standby switchover.
	hdfs-router-admin.log	Run log of the mount table management operation
Tomcat logs	hadoop-omm-host1.out, httpfs-catalina.<DATE>.log, httpfs-host-manager.<DATE>.log, httpfs-localhost.<DATE>.log, httpfs-manager.<DATE>.log, localhost_access_web_log.log	Tomcat run log
Audit log	hdfs-audit-<process_name>.log ranger-plugin-audit.log	Audit log that records the HDFS operations (such as creating, deleting, modifying and querying files).
	SecurityAuth.audit	HDFS security audit log.

Log Level

Table 12-221 lists the log levels supported by HDFS. The log levels include FATAL, ERROR, WARN, INFO, and DEBUG. Logs of which the levels are higher than or equal to the set level will be printed by programs. The higher the log level is set, the fewer the logs are recorded.

Table 12-221 Log levels

Level	Description
FATAL	Indicates the critical error information about system running.
ERROR	Indicates the error information about system running.
WARN	Indicates that the current event processing exists exceptions.
INFO	Indicates that the system and events are running properly.
DEBUG	Indicates the system and system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of HDFS by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 On the left menu bar, select the log menu of the target role.

Step 3 Select a desired log level.

Step 4 Save the configuration. In the displayed dialog box, click **OK** to make the configurations take effect.

NOTE

The configurations take effect immediately without restarting the service.

----End

Log Formats

The following table lists the HDFS log formats.

Table 12-222 Log formats

Type	Format	Example
Run log	*<yyyy-MM-dd HH:mm:ss,SSS>*|*<Log level>*|*<Name of the thread that generates the log>*|*<Message in the log>*|*<Location where the log event occurs>*	2015-01-26 18:43:42,840 | INFO | IPC Server handler 40 on 8020 | Rolling edit logs | org.apache.hadoop.hdfs.server.namenode.FSEditLog.rollEditLog(FSEditLog.java:1096)
Audit log	*<yyyy-MM-dd HH:mm:ss,SSS>*|*<Log level>*|*<Name of the thread that generates the log>*|*<Message in the log>*|*<Location where the log event occurs>*	2015-01-26 18:44:42,607 | INFO | IPC Server handler 32 on 8020 | allowed=true ugi=hbase (auth:SIMPLE) ip=/10.177.112.145 cmd=getfileinfo src=/hbase/WALs/hghoulaslx410,16020,1421743096083/hghoulaslx410%2C16020%2C1421743096083.1422268722795 dst=null perm=null | org.apache.hadoop.hdfs.server.namenode.FSNamesystem$DefaultAuditLogger.logAuditMessage(FSNamesystem.java:7950)

12.9.32 HDFS Performance Tuning

12.9.32.1 Improving Write Performance

Scenario

Improve the HDFS write performance by modifying the HDFS attributes.

NOTE

This section applies to MRS 3.*x* or later.

Procedure

Navigation path for setting parameters:

On FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Configurations** and select **All Configurations**. Enter a parameter name in the search box.

Table 12-223 Parameters for improving HDFS write performance

Parameter	Description	Default Value
dfs.datanode.drop.cache.behind.reads	Specifies whether to enable a DataNode to automatically clear all data in the cache after the data in the cache is transferred to the client. If it is set to **true**, the cached data is discarded. The parameter needs to be configured on the DataNode. You are advised to set it to **true** if data is repeatedly read only a few times, so that the cache can be used by other operations. You are advised to set it to **false** if data is repeatedly read many times to enhance the reading speed.	false
dfs.client-write-packet-size	Specifies the size of the client write packet. When the HDFS client writes data to the DataNode, the data will be accumulated until a packet is generated. Then, the packet is transmitted over the network. This parameter specifies the size (unit: byte) of the data packet to be transmitted, which can be specified by each job. In the 10-Gigabit network, you can increase the value of this parameter to enhance the transmission throughput.	262144

12.9.32.2 Improving Read Performance Using Client Metadata Cache

Scenario

Improve the HDFS read performance by using the client to cache the metadata for block locations.

NOTE

This function is recommended only for reading files that are not modified frequently. Because the data modification done on the server side by some other client is invisible to the cache client, which may cause the metadata obtained from the cache to be outdated.

This section applies to MRS 3.*x* or later.

Procedure

Navigation path for setting parameters:

On FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Configurations**, select **All Configurations**, and enter the parameter name in the search box.

Table 12-224 Parameter configuration

Parameter	Description	Default Value
dfs.client.metadata.cache.enabled	Enables or disables the client to cache the metadata for block locations. Set this parameter to **true** and use it along with the **dfs.client.metadata.cache.pattern** parameter to enable the cache.	false
dfs.client.metadata.cache.pattern	Indicates the regular expression pattern of the path of the file to be cached. Only the metadata for block locations of these files is cached until the metadata expires. This parameter is valid only when **dfs.client.metadata.cache.enabled** is set to **true**. Example: **/test.*** indicates that all files whose paths start with **/test** are read. **NOTE** • To ensure consistency, configure a specific mode to cache only files that are not frequently modified by other clients. • The regular expression pattern verifies only the path of the URI, but not the schema and authority in the case of the Fully Qualified path.	-
dfs.client.metadata.cache.expiry.sec	Indicates the duration for caching metadata. The cache entry becomes invalid after its caching time exceeds this duration. Even metadata that is frequently used during the caching process can become invalid. Time suffixes **s**/**m**/**h** can be used to indicate second, minute, and hour, respectively. **NOTE** If this parameter is set to **0s**, the cache function is disabled.	60s
dfs.client.metadata.cache.max.entries	Indicates the maximum number of non-expired data items that can be cached at a time.	65536

NOTE

Call *DFSClient#clearLocatedBlockCache()* to completely clear the client cache before it expires.

The sample usage is as follows:

```
FileSystem fs = FileSystem.get(conf);
DistributedFileSystem dfs = (DistributedFileSystem) fs;
DFSClient dfsClient = dfs.getClient();
dfsClient.clearLocatedBlockCache();
```

12.9.32.3 Improving the Connection Between the Client and NameNode Using Current Active Cache

Scenario

When HDFS is deployed in high availability (HA) mode with multiple NameNode instances, the HDFS client needs to connect to each NameNode in sequence to determine which is the active NameNode and use it for client operations.

Once the active NameNode is identified, its details can be cached and shared to all clients running on the client host. In this way, each new client first tries to load the details of the active Name Node from the cache and save the RPC call to the standby NameNode, which can help a lot in abnormal scenarios, for example, when the standby NameNode cannot be connected for a long time.

When a fault occurs and the other NameNode is switched to the active state, the cached details are updated to the information about the current active NameNode.

NOTE

This section applies to MRS 3.*x* or later.

Procedure

Navigation path for setting parameters:

On FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Configurations**, select **All Configurations**, and enter the parameter name in the search box.

Table 12-225 Configuration parameters

Parameter	Description	Default Value
dfs.client.failover.proxy.provider.[nameservice ID]	Client Failover proxy provider class which creates the NameNode proxy using the authenticated protocol. If this parameter is set to **org.apache.hadoop.hdfs.server.namenode.ha.BlackListingFailoverProxyProvider**, you can use the NameNode blacklist feature on the HDFS client. If this parameter is set to **org.apache.hadoop.hdfs.server.namenode.ha.ObserverReadProxyProvider**, you can configure the observer NameNode to process read requests.	org.apache.hadoop.hdfs.server.namenode.ha.AdaptiveFailoverProxyProvider
dfs.client.failover.activeinfo.share.flag	Specifies whether to enable the cache function and share the detailed information about the current active NameNode with other clients. Set it to **true** to enable the cache function.	false

Parameter	Description	Default Value
dfs.client.failover.activeinfo.share.path	Specifies the local directory for storing the shared files created by all clients in the host. If a cache area is to be shared by different users, the directory must have required permissions (for example, creating, reading, and writing cache files in the specified directory).	/tmp
dfs.client.failover.activeinfo.share.io.timeout.sec	(Optional) Used to control timeout. The cache file is locked when it is being read or written, and if the file cannot be locked within the specified time, the attempt to read or update the caches will be abandoned. The unit is second.	5

NOTE

The cache files created by the HDFS client are reused by other clients, and thus these files will not be deleted from the local system. If this function is disabled, you may need to manually clear the data.

12.9.33 FAQ

12.9.33.1 NameNode Startup Is Slow

Question

The NameNode startup is slow when it is restarted immediately after a large number of files (for example, 1 million files) are deleted.

Answer

It takes time for the DataNode to delete the corresponding blocks after files are deleted. When the NameNode is restarted immediately, it checks the block information reported by all DataNodes. If a deleted block is found, the NameNode generates the corresponding INFO log information, as shown below:

```
2015-06-10 19:25:50,215 | INFO  | IPC Server handler 36 on 25000 | BLOCK* processReport: blk_1075861877_2121067 on node 10.91.8.218:9866 size 10249 does not belong to any file | org.apache.hadoop.hdfs.server.blockmanagement.BlockManager.processReport(BlockManager.java:1854)
```

A log is generated for each deleted block. A file may contain one or more blocks. Therefore, after startup, the NameNode spends a large amount of time printing logs when a large number of files are deleted. As a result, the NameNode startup becomes slow.

To address this issue, the following operations can be performed to speed up the startup:

1. After a large number of files are deleted, wait until the DataNode deletes the corresponding blocks and then restart the NameNode.

You can run the ***hdfs dfsadmin -report*** command to check the disk space and check whether the files have been deleted.

2. If a large number of the preceding logs are generated, you can change the NameNode log level to **ERROR** so that the NameNode stops printing such logs.

   After the NameNode is restarted, change the log level back to **INFO**. You do not need to restart the service after changing the log level.

12.9.33.2 DataNode Is Normal but Cannot Report Data Blocks

Question

The DataNode is normal, but cannot report data blocks. As a result, the existing data blocks cannot be used.

Answer

This error may occur when the number of data blocks in a data directory exceeds four times the upper limit (4 x 1 MB). And the DataNode generates the following error logs:

```
2015-11-05 10:26:32,936 | ERROR | DataNode:[[[DISK]file:/srv/BigData/hadoop/data1/dn/]] heartbeating to
vm-210/10.91.8.210:8020 | Exception in BPOfferService for Block pool

```

The number of data blocks in the data directory is displayed as **Metric**. You can monitor its value through **http://<datanode-ip>:<http-port>/jmx**. If the value is greater than four times the upper limit (4 x 1 MB), you are advised to configure multiple drives and restart HDFS.

Recovery procedure:

1. Configure multiple data directories on the DataNode.

   For example, configure multiple directories on the DataNode where only the **/data1/datadir** directory is configured:

```
<property> <name>dfs.datanode.data.dir</name> <value>/data1/datadir</value> </property>
```

Configure as follows:

```
<property> <name>dfs.datanode.data.dir</name> <value>/data1/datadir/,/data2/datadir,/data3/
datadir</value> </property>
```

NOTE

You are advised to configure multiple data directories on multiple disks. Otherwise, performance may be affected.

2. Restart the HDFS.
3. Perform the following operation to move the data to the new data directory:

   mv */data1/datadir/current/finalized/subdir1 /data2/datadir/current/finalized/subdir1*

4. Restart the HDFS.

12.9.33.3 HDFS WebUI Cannot Properly Update Information About Damaged Data

Question

1. When errors occur in the **dfs.datanode.data.dir** directory of DataNode due to the permission or disk damage, HDFS WebUI does not display information about damaged data.
2. After errors are restored, HDFS WebUI does not timely remove related information about damaged data.

Answer

1. DataNode checks whether the disk is normal only when errors occur in file operations. Therefore, only when a data damage is detected and the error is reported to NameNode, NameNode displays information about the damaged data on HDFS WebUI.
2. After errors are fixed, you need to restart DataNode. During restarting DataNode, all data states are checked and damaged data information is uploaded to NameNode. Therefore, after errors are fixed, damaged data information is not displayed on the HDFS WebUI only by restarting DataNode.

12.9.33.4 Why Does the Distcp Command Fail in the Secure Cluster, Causing an Exception?

Question

Why distcp command fails in the secure cluster with the following error displayed?

Client side exception

```
Invalid arguments: Unexpected end of file from server
```

Server side exception

```
javax.net.ssl.SSLException: Unrecognized SSL message, plaintext connection?
```

Answer

The preceding error may occur if **webhdfs://** is used in the distcp command. The reason is that the big data cluster uses the HTTPS mechanism, that is, **dfs.http.policy** is set to **HTTPS_ONLY** in **core-site.xml** file. To avoid the error, replace **webhdfs://** with **swebhdfs://** in the file.

For example:

./hadoop distcp swebhdfs://IP:PORT/testfile hdfs://IP:PORT/testfile1

12.9.33.5 Why Does DataNode Fail to Start When the Number of Disks Specified by dfs.datanode.data.dir Equals dfs.datanode.failed.volumes.tolerated?

Question

If the number of disks specified by **dfs.datanode.data.dir** is equal to the value of **dfs.datanode.failed.volumes.tolerated**, DataNode startup will fail.

Answer

By default, the failure of a single disk will cause the HDFS DataNode process to shut down, which results in the NameNode scheduling additional replicas for each block that is present on the DataNode. This causes needless replications of blocks that reside on disks that have not failed.

To prevent this, you can configure DataNodes to tolerate the failure of dfs.data.dir directories; use the **dfs.datanode.failed.volumes.tolerated** parameter in **hdfs-site.xml.** For example, if the value for this parameter is 3, the DataNode will only shut down after four or more data directories have failed. This value is respected on DataNode startup.

When we are configuring tolerate volumes which should be always less than the configured volumes or else we can keep this as -1 which is equal to n-1 (where n is number of disks) then DataNode will not be shut down.

12.9.33.6 Why Does an Error Occur During DataNode Capacity Calculation When Multiple data.dir Are Configured in a Partition?

Question

DataNode capacity count incorrect if several data.dir configured in one disk partition.

Answer

Currently calculation will be done based on the disk like ***df*** command in linux. Ideally user should not configure multiple directories for same disk which will be huge impact on performance where all data will go to one disk.

Hence it is always better to configure like below:

For example:

if the machine is having disks like following:

```
host-4:~ # df -h
Filesystem      Size  Used  Avail  Use%  Mounted on
/dev/sda1       352G  11G    324G  4%    /
udev            190G  252K  190G  1%    /dev
tmpfs           190G  72K    190G  1%    /dev/shm
/dev/sdb1       2.7T  74G    2.5T  3%    /data1
/dev/sdc1       2.7T  75G    2.5T  3%    /data2
/dev/sdd1       2.7T  73G    2.5T  3%    /data
```

Suggested way of configuration:

```
<property>
<name>dfs.datanode.data.dir</name>
<value>/data1/datadir/,/data2/datadir,/data3/datadir</value>
</property>
```

Following is not recommended:

```
<property>
<name>dfs.datanode.data.dir</name>
<value>/data1/datadir1/,/data2/datadir1,/data3/datadir1,/data1/datadir2/data1/datadir3,/data2/datadir2,/
data2/datadir3,/data3/datadir2,/data3/datadir3</value>
</property>
```

12.9.33.7 Standby NameNode Fails to Be Restarted When the System Is Powered off During Metadata (Namespace) Storage

Question

When the standby NameNode is powered off during metadata (namespace) storage, it fails to be started and the following error information is displayed.

```
2015-12-04 11:49:12,121 | ERROR | main | Failed to load image from FS
ImageFile(file=/srv/BigData/namenode/current/fsimage_0000000000000096

eNode.java:1580)
at org.apache.hadoop.hdfs.server.namenode.NameNode.main(NameNode.java
:1654)
```

Answer

When the standby NameNode is powered off during metadata (namespace) storage, it fails to be started and the MD5 file is damaged. Remove the damaged fsimage and start the standby NameNode to rectify the fault. After the rectification, the standby NameNode loads the previous fsimage and reproduces all edits.

Recovery procedure:

1. Run the following command to remove the damaged fsimage:

   rm -rf ${BIGDATA_DATA_HOME}/namenode/current/fsimage_0000000000000096

2. Start the standby NameNode.

12.9.33.8 Why Data in the Buffer Is Lost If a Power Outage Occurs During Storage of Small Files

Question

Why data in the buffer is lost if a power outage occurs during storage of small files?

Answer

Because of a power outage, the blocks in the buffer are not written to the disk immediately after the write operation is completed. To enable synchronization of blocks to the disk, set **dfs.datanode.synconclose** to **true** in the **hdfs-site.xml** file.

By default, **dfs.datanode.synconclose** is set to **false**. This improves the performance but can cause a buffer data loss in the case of a power outage, and therefore, it is recommended that **dfs.datanode.synconclose** be set to **true** even if this may affect the performance. You can determine whether to enable the synchronization function based on your actual situation.

12.9.33.9 Why Does Array Border-crossing Occur During FileInputFormat Split?

Question

When HDFS calls the FileInputFormat getSplit method, the ArrayIndexOutOfBoundsException: 0 appears in the following log:

```
java.lang.ArrayIndexOutOfBoundsException: 0
at org.apache.hadoop.mapred.FileInputFormat.identifyHosts(FileInputFormat.java:708)
at org.apache.hadoop.mapred.FileInputFormat.getSplitHostsAndCachedHosts(FileInputFormat.java:675)
at org.apache.hadoop.mapred.FileInputFormat.getSplits(FileInputFormat.java:359)
at org.apache.spark.rdd.HadoopRDD.getPartitions(HadoopRDD.scala:210)
at org.apache.spark.rdd.RDD$$anonfun$partitions$2.apply(RDD.scala:239)
at org.apache.spark.rdd.RDD$$anonfun$partitions$2.apply(RDD.scala:237)
at scala.Option.getOrElse(Option.scala:120)
at org.apache.spark.rdd.RDD.partitions(RDD.scala:237)
at org.apache.spark.rdd.MapPartitionsRDD.getPartitions(MapPartitionsRDD.scala:35)
```

Answer

The elements of each block correspondent frame are as below: /default/rack0/:,/default/rack0/datanodeip:port.

The problem is due to a block damage or loss, making the block correspondent machine ip and port become null. Use **hdfs fsck** to check the file blocks health state when this problem occurs, and remove damaged block or restore the missing block to re-computing the task.

12.9.33.10 Why Is the Storage Type of File Copies DISK When the Tiered Storage Policy Is LAZY_PERSIST?

Question

When the storage policy of the file is set to **LAZY_PERSIST**, the storage type of the first replica should be **RAM_DISK**, and the storage type of other replicas should be **DISK**.

But why is the storage type of all copies shown as **DISK** actually?

Answer

When a user writes into a file whose storage policy is **LAZY_PERSIST**, three replicas are written one by one. The first replica is preferentially written into the

DataNode where the client is located. The storage type of all replicas is **DISK** in the following scenarios:

- If the DataNode where the client is located does not have the RAM disk, the first replica is written into the disk of the DataNode where the client is located, and other replicas are written into the disks of other nodes.
- If the DataNode where the client is located has the RAM disk, and the value of **dfs.datanode.max.locked.memory** is not specified or smaller than the value of **dfs.blocksize**, the first replica is written into the disk of the DataNode where the client is located, and other replicas are written into the disks of other nodes.

12.9.33.11 The HDFS Client Is Unresponsive When the NameNode Is Overloaded for a Long Time

Question

When the NameNode node is overloaded (100% of the CPU is occupied), the NameNode is unresponsive. The HDFS clients that are connected to the overloaded NameNode fail to run properly. However, the HDFS clients that are newly connected to the NameNode will be switched to a backup NameNode and run properly.

Answer

The default configuration must be used (as described in **Table 12-226**) when the error preceding described occurs: the **keep alive** mechanism is enabled for the RPC connection between the HDFS client and the NameNode. The **keep alive** mechanism will keep the HDFS client waiting for the response from server and prevent the connection from being out timed, causing the unresponsiveness of the HDFS client.

Perform the following operations to the unresponsive HDFS client:

- Leave the HDFS client waiting. Once the CPU usage of the node where NameNode locates drops, the NameNode will obtain CPU resources and the HDFS client will receive a response.
- If you do not want to leave the HDFS client running, restart the application where the HDFS client locates to reconnect the HDFS client to another idle NameNode.

Procedure:

Configure the following parameters in the **core-site.xml** file on the client.

Table 12-226 Parameter description

Parameter	Description	Default Value
ipc.client.ping	If the **ipc.client.ping** parameter is configured to **true**, the HDFS client will wait for the response from the server and periodically send the **ping** message to avoid disconnection caused by **tcp timeout**. If the **ipc.client.ping** parameter is configured to **false**, the HDFS client will set the value of **ipc.ping.interval** as the timeout time. If no response is received within that time, timeout occurs. To avoid the unresponsiveness of HDFS when the NameNode is overloaded for a long time, you are advised to set the parameter to **false**.	true
ipc.ping.interval	If the value of **ipc.client.ping** is **true**, **ipc.ping.interval** indicates the interval between sending the ping messages. If the value of **ipc.client.ping** is **false**, **ipc.ping.interval** indicates the timeout time for connection. To avoid the unresponsiveness of HDFS when the NameNode is overloaded for a long time, you are advised to set the parameter to a large value, for example **900000** (unit ms) to avoid timeout when the server is busy.	60000

12.9.33.12 Can I Delete or Modify the Data Storage Directory in DataNode?

Question

- In DataNode, the storage directory of data blocks is specified by **dfs.datanode.data.dir.** Can I modify **dfs.datanode.data.dir** to modify the data storage directory?
- Can I modify files under the data storage directory?

Answer

During the system installation, you need to configure the **dfs.datanode.data.dir** parameter to specify one or more root directories.

- During the system installation, you need to configure the dfs.datanode.data.dir parameter to specify one or more root directories.
- Exercise caution when modifying dfs.datanode.data.dir. You can configure this parameter to add a new data root directory.
- Do not modify or delete data blocks in the storage directory. Otherwise, the data blocks will lose.

NOTE

Similarly, do not delete the storage directory, or modify or delete data blocks under the directory using the following parameters:

- dfs.namenode.edits.dir
- dfs.namenode.name.dir
- dfs.journalnode.edits.dir

12.9.33.13 Blocks Miss on the NameNode UI After the Successful Rollback

Question

Why are some blocks missing on the NameNode UI after the rollback is successful?

Answer

This problem occurs because blocks with new IDs or genstamps may exist on the DataNode. The block files in the DataNode may have different generation flags and lengths from those in the rollback images of the NameNode. Therefore, the NameNode rejects these blocks in the DataNode and marks the files as damaged.

Scenarios:

1. Before an upgrade:

   Client A writes some data to file X. (Assume A bytes are written.)

2. During an upgrade:

   Client A still writes data to file X. (The data in the file is A + B bytes.)

3. After an upgrade:

   Client A completes the file writing. The final data is A + B bytes.

4. Rollback started:

   The status will be rolled back to the status before the upgrade. That is, file X in NameNode will have A bytes, but block files in DataNode will have A + B bytes.

Recovery procedure:

1. Obtain the list of damaged files from NameNode web UI or run the following command to obtain:

   hdfs fsck <filepath> -list-corruptfileblocks

2. Run the following command to delete unnecessary files:

   hdfs fsck <corrupt file path> - delete

   NOTE

   Deleting a file is a high-risk operation. Ensure that the files are no longer needed before performing this operation.

3. For the required files, run the **fsck** command to obtain the block list and block sequence.

- In the block sequence table provided, use the block ID to search for the data directory in the DataNode and download the corresponding block from the DataNode.
- Write all such block files in appending mode based on the sequence to construct the original file.

  Example:

  File 1--> blk_1, blk_2, blk_3

  Create a file by combining the contents of all three block files from the same sequence.
- Delete the old file from HDFS and rewrite the new file.

12.9.33.14 Why Is "java.net.SocketException: No buffer space available" Reported When Data Is Written to HDFS

Question

Why is an "java.net.SocketException: No buffer space available" exception reported when data is written to HDFS?

This problem occurs when files are written to the HDFS. Check the error logs of the client and DataNode.

The client logs are as follows:

Figure 12-25 Client logs

```
2017-07-05 21:58:06,459 INFO  [htable-pool3-t1] ipc.AbstractRpcClient: RPC Server Kerberos principal name for service=ClientService is hbase/hadoop.hadoop123.com@HADOOP12

Answer

The preceding problem may be caused by network memory exhaustion.

You can increase the threshold of the network device based on the actual scenario.

Example:

```
[root@xxxxx ~]# cat /proc/sys/net/ipv4/neigh/default/gc_thresh*
128
512
1024
[root@xxxxx ~]# echo 512 > /proc/sys/net/ipv4/neigh/default/gc_thresh1
[root@xxxxx ~]# echo 2048 > /proc/sys/net/ipv4/neigh/default/gc_thresh2
[root@xxxxx ~]# echo 4096 > /proc/sys/net/ipv4/neigh/default/gc_thresh3
[root@xxxxx ~]# cat /proc/sys/net/ipv4/neigh/default/gc_thresh*
512
2048
4096
```

You can also add the following parameters to the **/etc/sysctl.conf** file. The configuration takes effect even if the host is restarted.

```
net.ipv4.neigh.default.gc_thresh1 = 512
net.ipv4.neigh.default.gc_thresh2 = 2048
net.ipv4.neigh.default.gc_thresh3 = 4096
```

12.9.33.15 Why are There Two Standby NameNodes After the active NameNode Is Restarted?

Question

Why are there two standby NameNodes after the active NameNode is restarted?

When this problem occurs, check the ZooKeeper and ZooKeeper FC logs. You can find that the sessions used for the communication between the ZooKeeper server and client (ZKFC) are inconsistent. The session ID of the ZooKeeper server is **0x164cb2b3e4b36ae4**, and the session ID of the ZooKeeper FC is **0x144cb2b3e4b36ae4**. Such inconsistency means that the data interaction between the ZooKeeper server and ZKFC fails.

Content of the ZooKeeper log is as follows:

```
2015-04-15 21:24:54,257 | INFO | CommitProcessor:22 | Established session 0x164cb2b3e4b36ae4 with negotiated timeout 45000 for client /192.168.0.117:44586 | org.apache.zookeeper.server.ZooKeeperServer.finishSessionInit(ZooKeeperServer.java:623)
2015-04-15 21:24:54,261 | INFO | NIOServerCxn.Factory:192-168-0-114/192.168.0.114:2181 | Successfully authenticated client: authenticationID=hdfs/hadoop@<System domain name>; authorizationID=hdfs/hadoop@<System domain name>. | org.apache.zookeeper.server.auth.SaslServerCallbackHandler.handleAuthorizeCallback(SaslServerCallbackHandler.java:118)
2015-04-15 21:24:54,261 | INFO | NIOServerCxn.Factory:192-168-0-114/192.168.0.114:2181 | Setting authorizedID: hdfs/hadoop@<System domain name> | org.apache.zookeeper.server.auth.SaslServerCallbackHandler.handleAuthorizeCallback(SaslServerCallbackHandler.java:134)

2015-04-15 21:24:54,262 | INFO | ProcessThread(sid:22 cport:-1): | Got user-level KeeperException when processing sessionid:0x164cb2b3e4b36ae4 type:create cxid:0x3 zxid:0x20009fafc txntype:-1 reqpath:n/a Error Path:/hadoop-ha/hacluster/ActiveStandbyElectorLock Error:KeeperErrorCode = NodeExists for /hadoop-ha/hacluster/ActiveStandbyElectorLock | org.apache.zookeeper.server.PrepRequestProcessor.pRequest(PrepRequestProcessor.java:648)
```

Content of the ZKFC log is as follows:

```
2015-04-15 21:24:54,237 | INFO | main-SendThread(192-168-0-114:2181) | Socket connection established to 192-168-0-114/192.168.0.114:2181, initiating session | org.apache.zookeeper.ClientCnxn$SendThread.primeConnection(ClientCnxn.java:854)
2015-04-15 21:24:54,257 | INFO | main-SendThread(192-168-0-114:2181) | Session establishment complete on server 192-168-0-114/192.168.0.114:2181, sessionid = 0x144cb2b3e4b36ae4 , negotiated timeout = 45000 | org.apache.zookeeper.ClientCnxn$SendThread.onConnected(ClientCnxn.java:1259)
2015-04-15 21:24:54,260 | INFO | main-EventThread | EventThread shut down | org.apache.zookeeper.ClientCnxn$EventThread.run(ClientCnxn.java:512)
2015-04-15 21:24:54,262 | INFO | main-EventThread | Session connected. | org.apache.hadoop.ha.ActiveStandbyElector.processWatchEvent(ActiveStandbyElector.java:547)
2015-04-15 21:24:54,264 | INFO | main-EventThread | Successfully authenticated to ZooKeeper using SASL. | org.apache.hadoop.ha.ActiveStandbyElector.processWatchEvent(ActiveStandbyElector.java:573)
```

Answer

- Cause Analysis

  After the active NameNode restarts, the temporary node **/hadoop-ha/hacluster/ActiveStandbyElectorLock** created on ZooKeeper is deleted. After the standby NameNode receives that information that the **/hadoop-ha/hacluster/ActiveStandbyElectorLock** node is deleted, the standby NameNode creates the /**hadoop-ha/hacluster/ActiveStandbyElectorLock** node in ZooKeeper in order to switch to the active NameNode. However, when the standby NameNode connects with ZooKeeper through the client ZKFC, the session ID of ZKFC differs from that of ZooKeeper due to network issues, overload CPU, or overload clusters. In this case, the watcher of the standby NameNode fails to detect that the temporary node has been successfully created, and fails to consider the standby NameNode as the active NameNode. After the original active NameNode restarts, it detects that the **/hadoop-ha/hacluster/ActiveStandbyElectorLock** already exists and becomes the standby NameNode. Therefore, both NameNodes are standby NameNodes.

- Solution

  You are advised to restart two ZKFCs of HDFS on FusionInsight Manager.

12.9.33.16 When Does a Balance Process in HDFS, Shut Down and Fail to be Executed Again?

Question

After I start a Balance process in HDFS, the process is shut down abnormally. If I attempt to execute the Balance process again, it fails again.

Answer

After a Balance process is executed in HDFS, another Balance process can be executed only after the **/system/balancer.id** file is automatically released.

However, if a Balance process is shut down abnormally, the **/system/balancer.id** has not been released when the Balance is executed again, which triggers the **append /system/balancer.id** operation.

- If the time spent on releasing the **/system/balancer.id** file exceeds the soft-limit lease period 60 seconds, executing the Balance process again triggers the append operation, which preempts the lease. The last block is in construction or under recovery status, which triggers the block recovery operation. The **/system/balancer.id** file cannot be closed until the block recovery completes. Therefore, the append operation fails.

  After the **append /system/balancer.id** operation fails, the exception message **RecoveryInProgressException** is displayed.

  ```
  org.apache.hadoop.ipc.RemoteException(org.apache.hadoop.protocol.RecoveryInProgressException): Failed to APPEND_FILE /system/balancer.id for DFSClient because lease recovery is in progress. Try again later.
  ```

- If the time spent on releasing the **/system/balancer.id** file is within 60 seconds, the original client continues to own the lease and the exception AlreadyBeingCreatedException occurs and null is returned to the client. The following exception message is displayed on the client:

  ```
  java.io.IOException: Cannot create any NameNode Connectors.. Exiting...
  ```

Either of the following methods can be used to solve the problem:

- Execute the Balance process again after the hard-limit lease period expires for 1 hour, when the original client has released the lease.
- Delete the **/system/balancer.id** file before executing the Balance process again.

12.9.33.17 "This page can't be displayed" Is Displayed When Internet Explorer Fails to Access the Native HDFS UI

Question

Occasionally, nternet Explorer 9, Explorer 10, or Explorer 11 fails to access the native HDFS UI.

Symptom

Internet Explorer 9, Explorer 10, or Explorer 11 fails to access the native HDFS UI, as shown in the following figure.

Cause

Some Internet Explorer 9, Explorer 10, or Explorer 11versions fail to handle SSL handshake issues, causing access failure.

Solution

Refresh the page.

12.9.33.18 NameNode Fails to Be Restarted Due to EditLog Discontinuity

Question

If a JournalNode server is powered off, the data directory disk is fully occupied, and the network is abnormal, the EditLog sequence number on the JournalNode is inconsecutive. In this case, the NameNode restart may fail.

Symptom

The NameNode fails to be restarted. The following error information is reported in the NameNode run logs:

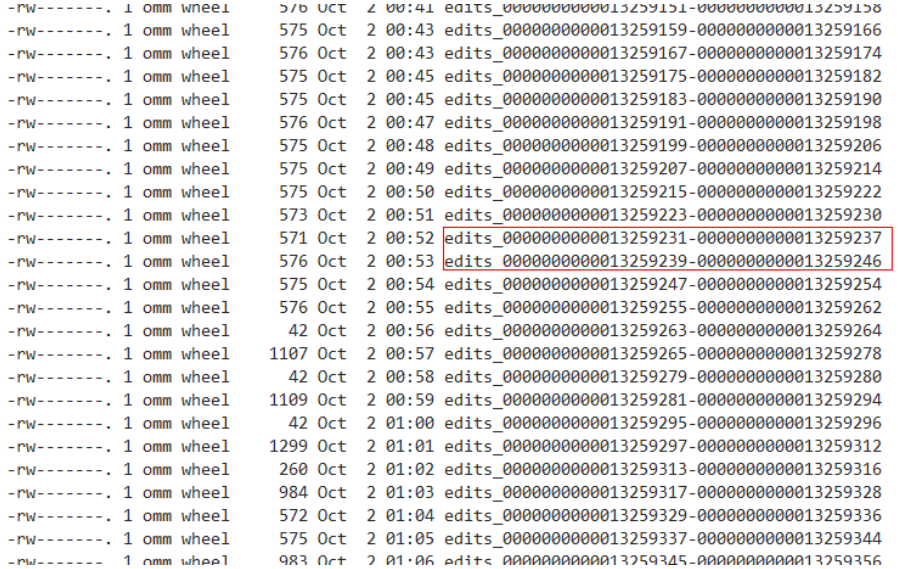
```
2019-11-08 16:30:28,399 | ERROR | main | Failed to start namenode. | NameNode.java:1732
java.io.IOException: There appears to be a gap in the edit log.  We expected txid 13698019, but got txid 13698088.
        at org.apache.hadoop.hdfs.server.namenode.MetaRecoveryContext.editLogLoaderPrompt(MetaRecoveryContext.java:94)
        at org.apache.hadoop.hdfs.server.namenode.FSEditLogLoader.loadEditRecords(FSEditLogLoader.java:278)
        at org.apache.hadoop.hdfs.server.namenode.FSEditLogLoader.loadFSEdits(FSEditLogLoader.java:188)
        at org.apache.hadoop.hdfs.server.namenode.FSImage.loadEdits(FSImage.java:924)
        at org.apache.hadoop.hdfs.server.namenode.FSImage.loadFSImage(FSImage.java:771)
        at org.apache.hadoop.hdfs.server.namenode.FSImage.recoverTransitionRead(FSImage.java:331)
        at org.apache.hadoop.hdfs.server.namenode.FSNamesystem.loadFSImage(FSNamesystem.java:1108)
        at org.apache.hadoop.hdfs.server.namenode.FSNamesystem.loadFromDisk(FSNamesystem.java:727)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.loadNamesystem(NameNode.java:638)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.initialize(NameNode.java:700)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.<init>(NameNode.java:943)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.<init>(NameNode.java:916)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.createNameNode(NameNode.java:1655)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.main(NameNode.java:1725)
```

Solution

1. Find the active NameNode before the restart, go to its data directory (you can obtain the directory, such as **/srv/BigData/namenode/current** by checking the configuration item **dfs.namenode.name.dir**), and obtain the sequence number of the latest FsImage file, as shown in the following figure:

```
-rw-------. 1 omm wheel     574 Oct  2 01:12 edits_0000000000013259401-00000000000
-rw-------. 1 omm wheel     575 Oct  2 01:13 edits_0000000000013259409-00000000000
-rw-------. 1 omm wheel      42 Oct  2 01:13 edits_0000000000013259417-00000000000
-rw-------. 1 omm wheel 1048576 Nov  8 16:01 edits_inprogress_0000000000013698088
-rw-------. 1 omm wheel  314803 Nov  8 15:53 fsimage_0000000000013698018
-rw-------. 1 omm wheel      62 Nov  8 15:53 fsimage_0000000000013698018.md5
-rw-------. 1 omm wheel  314803 Nov  8 15:56 fsimage_0000000000013698050
-rw-------. 1 omm wheel      62 Nov  8 15:56 fsimage_0000000000013698050.md5
-rw-------. 1 omm wheel  314803 Nov  8 15:59 fsimage_0000000000013698066
-rw-------. 1 omm wheel      62 Nov  8 15:59 fsimage_0000000000013698066.md5
-rw-------. 1 omm wheel       9 Oct  2 01:13 seen_txid
-rw-------. 1 omm wheel     187 Nov  8 15:59 VERSION
```

2. Check the data directory of each JournalNode (you can obtain the directory such as**/srv/BigData/journalnode/hacluster/current** by checking the value of the configuration item **dfs.journalnode.edits.dir**), and check whether the sequence number starting from that obtained in step 1 is consecutive in edits files. That is, you need to check whether the last sequence number of the previous edits file is consecutive with the first sequence number of the next edits file. (As shown in the following figure, edits_0000000000013259231-0000000000013259237 and edits_0000000000013259239-0000000000013259246 are not consecutive.)



3. If the edits files are not consecutive, check whether the edits files with the related sequence number exist in the data directories of other JournalNodes or NameNode. If the edits files can be found, copy a consecutive segment to the JournalNode.
4. In this way, all inconsecutive edits files are restored.
5. Restart the NameNode and check whether the restart is successful. If the fault persists, contact technical support.

12.10 Using Hive

12.10.1 Using Hive from Scratch

Hive is a data warehouse framework built on Hadoop. It maps structured data files to a database table and provides SQL-like functions to analyze and process data. It also allows you to quickly perform simple MapReduce statistics using SQL-like statements without the need of developing a specific MapReduce application. It is suitable for statistical analysis of data warehouses.

Background

Suppose a user develops an application to manage users who use service A in an enterprise. The procedure of operating service A on the Hive client is as follows:

Operations on common tables:

- Create the **user_info** table.
- Add users' educational backgrounds and professional titles to the table.
- Query user names and addresses by user ID.
- Delete the user information table after service A ends.

Table 12-227 User information

ID	Name	Gender	Age	Address
12005000201	A	Male	19	City A
12005000202	B	Female	23	City B
12005000203	C	Male	26	City C
12005000204	D	Male	18	City D
12005000205	E	Female	21	City E
12005000206	F	Male	32	City F
12005000207	G	Female	29	City G
12005000208	H	Female	30	City H
12005000209	I	Male	26	City I
12005000210	J	Female	25	City J

Procedure

Step 1 Download the client configuration file.

- For versions earlier than MRS 3.x, perform the following operations:
  a. Log in to MRS Manager. For details, see **Accessing Manager**. Then, choose **Services**.
  b. Click **Download Client**.
     Set **Client Type** to **Only configuration files**, **Download to** to **Server**, and click **OK** to generate the client configuration file. The generated file is saved in the **/tmp/MRS-client** directory on the active management node by default.
- For MRS 3.*x* or later, perform the following operations:
  a. Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**.
  b. Choose **Cluster** > *Name of the desired cluster* > **Dashboard** > **More** > **Download Client**.
  c. Download the cluster client.
     Set **Select Client Type** to **Configuration Files Only** , select a platform type, and click **OK** to generate the client configuration file which is then saved in the **/tmp/FusionInsight-Client/** directory on the active management node by default.

Step 2 Log in to the active management node of Manager.

- For versions earlier than MRS 3.x, perform the following operations:
  a. On the MRS console, click **Clusters**, choose **Active Clusters**, and click a cluster name. On the **Nodes** tab, view the node names. The node whose name contains **master1** is the Master1 node, and the node whose name contains **master2** is the Master2 node.

     The active and standby management nodes of MRS Manager are installed on Master nodes by default. Because Master1 and Master2 are switched over in active and standby mode, Master1 is not always the active management node of MRS Manager. Run a command in Master1 to check whether Master1 is active management node of MRS Manager. For details about the command, see **Step 2.d**.
  b. Log in to the Master1 node using the password as user **root**.
  c. Run the following commands to switch to user **omm**:

     sudo su - root

     su - omm
  d. Run the following command to check the active management node of MRS Manager:

     sh ${BIGDATA_HOME}/om-0.0.1/sbin/status-oms.sh

     In the command output, the node whose **HAActive** is **active** is the active management node, and the node whose **HAActive** is **standby** is the standby management node. In the following example, **mgtomsdat-sh-3-01-1** is the active management node, and **mgtomsdat-sh-3-01-2** is the standby management node.

```
Ha mode
double
NodeName            HostName                HAVersion         StartTime
HAActive            HAAllResOK          HARunPhase
192-168-0-30        mgtomsdat-sh-3-01-1     V100R001C01       2014-11-18 23:43:02
active              normal              Actived
192-168-0-24        mgtomsdat-sh-3-01-2     V100R001C01       2014-11-21 07:14:02
standby             normal              Deactived
```

  e. Log in to the active management node as user **root**, for example, node **192-168-0-30**.
- For MRS 3.*x* or later, perform the following operations:
  a. Log in to any node where Manager is deployed as user **root**.
  b. Run the following command to identify the active and standby nodes:

     sh ${BIGDATA_HOME}/om-server/om/sbin/status-oms.sh

     In the command output, the value of **HAActive** for the active management node is **active**, and that for the standby management node is **standby**. In the following example, **node-master1** is the active management node, and **node-master2** is the standby management node.

```
HAMode
double
NodeName            HostName        HAVersion         StartTime             HAActive
HAAllResOK          HARunPhase
192-168-0-30        node-master1    V100R001C01       2020-05-01 23:43:02   active
normal              Actived
192-168-0-24        node-master2    V100R001C01       2020-05-01 07:14:02
standby             normal          Deactived
```

c. Log in to the primary management node as user **root** and run the following command to switch to user **omm**:

sudo su - omm

Step 3 Run the following command to go to the client installation directory:

cd /opt/client

The cluster client has been installed in advance. The following client installation directory is used as an example. Change it based on the site requirements.

Step 4 Run the following command to update the client configuration for the active management node.

sh refreshConfig.sh /opt/client *Full path of the client configuration file package*

For example, run the following command:

sh refreshConfig.sh /opt/client /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Services_Client.tar

If the following information is displayed, the configurations have been updated successfully.

```
ReFresh components client config is complete.
Succeed to refresh components client config.
```

Step 5 Use the client on a Master node.

1. On the active management node, for example, **192-168-0-30**, run the following command to switch to the client directory, for example, **/opt/client**.

   cd /opt/client

2. Run the following command to configure environment variables:

   source bigdata_env

3. If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user:

   kinit *MRS cluster user*

   Example: user **kinit hiveuser**

   The current user must have the permission to create Hive tables.If Kerberos authentication is disabled, skip this step.

4. Run the client command of the Hive component directly.

   beeline

Step 6 Run the Hive client command to implement service A.

Operations on internal tables:

1. Create the **user_info** user information table according to **Table 12-227** and add data to it.

   create table user_info(id string,name string,gender string,age int,addr string);

   For MRS 1.*x*, MRS 3.*x*, or later, perform the following operations:

   insert into table user_info(id,name,gender,age,addr) values("12005000201","A","Male",19,"City A");

   For MRS 2.*x*, perform the following operations:

insert into table user_info values("12005000201","A","Male",19,"City A");

2. Add users' educational backgrounds and professional titles to the **user_info** table.

   For example, to add educational background and title information about user 12005000201, run the following command:

   alter table user_info add columns(education string,technical string);

3. Query user names and addresses by user ID.

   For example, to query the name and address of user 12005000201, run the following command:

   select name,addr from user_info where id='12005000201';

4. Delete the user information table.

   drop table user_info;

Operations on external partition tables:

Create an external partition table and import data.

1. Create a path for storing external table data.

   hdfs dfs -mkdir /hive/

   hdfs dfs -mkdir /hive/user_info

2. Create a table.

   create external table user_info(id string,name string,gender string,age int,addr string) partitioned by(year string) row format delimited fields terminated by ' ' lines terminated by '\n' stored as textfile location '/hive/user_info';

   NOTE

   fields terminated indicates delimiters, for example, spaces.

   lines terminated indicates line breaks, for example, **\n**.

   /hive/user_info indicates the path of the data file.

3. Import data.

   a. Execute the insert statement to insert data.

      insert into user_info partition(year="2018") values ("12005000201","A","Male",19,"City A");

   b. Run the **load data** command to import file data.

      i. Create a file based on the data in **Table 12-227**. For example, the file name is **txt.log**. Fields are separated by space, and the line feed characters are used as the line breaks.

      ii. Upload the file to HDFS.

      hdfs dfs -put txt.log /tmp

      iii. Load data to the table.

      load data inpath '/tmp/txt.log' into table user_info partition (year='2011');

4. Query the imported data.

   select * from user_info;

5. Delete the user information table.

   drop table user_info;

6. Run the following command to exit:

   !q

----End

12.10.2 Configuring Hive Parameters

Navigation Path

Go to the Hive configurations page by referring to **Modifying Cluster Service Configuration Parameters**.

Parameter Description

Table 12-228 Hive parameter description

Parameter	Description	Default Value
hive.auto.convert.join	Whether Hive converts common **join** to **mapjoin** based on the input file size. **NOTE** When Hive is used to query a join table, whatever the table size is (if the data in the join table is less than 24 MB, it is a small one), set this parameter to **false**. If this parameter is set to **true**, new **mapjoin** cannot be generated when you query a join table.	Possible values are as follows: • true • false The default value is **true**.
hive.default.fileformat	Indicates the default file format used by Hive.	Versions earlier than MRS 3.x: TextFile MRS 3.x or later: RCFile
hive.exec.reducers.max	Indicates the maximum number of reducers in a MapReduce job submitted by Hive.	999
hive.server2.thrift.max.worker.threads	Indicates the maximum number of threads that can be started in the HiveServer internal thread pool.	1,000
hive.server2.thrift.min.worker.threads	Indicates the number of threads started during initialization in the HiveServer internal thread pool.	5

Parameter	Description	Default Value
hive.hbase.delete.mode.enabled	Indicates whether to enable the function of deleting HBase records from Hive. If this function is enabled, you can use **remove table xx where xxx** to delete HBase records from Hive. **NOTE** This parameter applies to MRS 3.*x* or later.	true
hive.metastore.server.min.threads	Indicates the number of threads started by MetaStore for processing connections. If the number of threads is more than the set value, MetaStore always maintains a number of threads that is not lower than the set value, that is, the number of resident threads in the MetaStore thread pool is always higher than the set value.	200
hive.server2.enable.doAs	Indicates whether to simulate client users during sessions between HiveServer2 and other services (such as Yarn and HDFS). If you change the configuration item from **false** to **true**, users with only the column permission lose the permissions to access corresponding tables. **NOTE** This parameter applies to MRS 3.*x* or later.	true

12.10.3 Hive SQL

Hive SQL supports all features of Hive-3.1.0. For details, see **https://cwiki.apache.org/confluence/display/hive/languagemanual**.

Table 12-229 describes the extended Hive statements provided by .

Table 12-229 Extended Hive statements

Extended Syntax	Syntax Description	Syntax Example	Example Description
CREATE [TEMPORARY] [EXTERNAL] TABLE [IF NOT EXISTS] [db_name.]table_name (col_name data_type [COMMENT col_comment], ...) [ROW FORMAT row_format] [STORED AS file_format] | STORED BY 'storage.handler.class.name' [WITH SERDEPROPERTIES (...)] ..... [TBLPROPERTIES ("groupId"=" group1 ","locatorId"="locator1")] ...;	The statement is used to create a Hive table and specify locators on which table data files locate. For details, see **Using HDFS Colocation to Store Hive Tables**.	CREATE TABLE tab1 (id INT, name STRING) row format delimited fields terminated by '\t' stored as RCFILE TBLPROPERTIES(" groupId"=" group1 ","locatorId"="locator1");	The statement is used to create table **tab1** and specify locator1 on which the table data of **tab1** locates.

Extended Syntax	Syntax Description	Syntax Example	Example Description
CREATE [TEMPORARY] [EXTERNAL] TABLE [IF NOT EXISTS] [db_name.]table_name (col_name data_type [COMMENT col_comment], ...) [ROW FORMAT row_format] [STORED AS file_format] | STORED BY 'storage.handler.class.name' [WITH SERDEPROPERTIES (...)] ... [TBLPROPERTIES ('**column.encode.columns**'='col_name1,col_name2'| '**column.encode.indices**'='col_id1,col_id2', **'column.encode.classname'**='encode_classname')]...;	The statement is used to create a hive table and specify the table encryption column and encryption algorithm. For details, see **Using the Hive Column Encryption Function**.	create table encode_test(id INT, name STRING, phone STRING, address STRING) ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe' WITH SERDEPROPERTIES ('column.encode.indices'='2,3', 'column.encode.classname'='org.apache.hadoop.hive.serde2.SMS4Rewriter') STORED AS TEXTFILE;	The statement is used to create table **encode_test** and specify that column 2 and column 3 will be encrypted using the **org.apache.hadoop.hive.serde2.SMS4Rewriter** encryption algorithm class during data insertion.
REMOVE TABLE *hbase_tablename* [WHERE where_condition];	The statement is used to delete data that meets criteria from the Hive on HBase table. For details, see **Deleting Single-Row Records from Hive on HBase**.	remove table hbase_table1 where id = 1;	The statement is used to delete data that meets the criterion of "id = 1" from the table.

Extended Syntax	Syntax Description	Syntax Example	Example Description
CREATE [TEMPORARY] [EXTERNAL] TABLE [IF NOT EXISTS] [db_name.]table_name (col_name data_type [COMMENT col_comment], ...) [ROW FORMAT row_format] **STORED AS inputformat 'org.apache.hadoop.hive.contrib.fileformat.SpecifiedDelimiterInputFormat'** outputformat 'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat';	The statement is used to create a hive table and specify that the table supports customized row delimiters. For details, see **Customizing Row Separators**.	create table blu(time string, num string, msg string) row format delimited fields terminated by ',' **stored as inputformat 'org.apache.hadoop.hive.contrib.fileformat.SpecifiedDelimiterInputFormat'** outputformat 'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat';	The statement is used to create table **blu** and set **inputformat** to **SpecifiedDelimiterInputFormat** so that the query row delimiter can be specified during the query.

12.10.4 Permission Management

12.10.4.1 Hive Permission

Hive is a data warehouse framework built on Hadoop. It provides basic data analysis services using the Hive query language (HQL), a language like the structured query language (SQL).

MRS supports users, user groups, and roles. Permissions must be assigned to roles and then roles are bound to users or user groups. Users can obtain permissions only by binding a role or joining a group that is bound with a role. For details about Hive authorization, visit **https://cwiki.apache.org/confluence/display/Hive/LanguageManual+Authorization**.

NOTE

- Hive permissions in security mode need to be managed whereas those in normal mode do not.
- MRS 3.*x* or later supports Ranger. If the current component uses Ranger for permission control, you need to configure permission management policies based on Ranger. For details, see **Adding a Ranger Access Permission Policy for Hive**.

Hive Permission Model

To use the Hive component, users must have permissions on Hive databases and tables (including external tables and views). In MRS, the complete Hive permission model is composed of Hive metadata permission and HDFS file permission. The Hive permission model also includes the permission to use databases or tables.

- Hive metadata permission

  Similar to traditional relational databases, the Hive database of MRS supports the **CREATE** and **SELECT** permission, and the Hive tables and columns support the **SELECT**, **INSERT**, and **DELETE** permissions. Hive also supports the permissions of **OWNERSHIP** and **Hive Admin Privilege**.

  NOTE

  The **UPDATE** and **DELETE** operations on Hive tables and columns can be performed only when **ACID** is enabled. **ACID** cannot be enabled in the current version.

- Hive data file permission, also known as HDFS file permission

  Hive database and table files are stored in the HDFS. The created databases or tables are saved in the **/user/hive/warehouse** directory of the HDFS by default. The system automatically creates subdirectories named after database names and database table names. To access a database or a table, the corresponding file permissions (read, write, and execute) on the HDFS are required.

  NOTE

  MRS 3.*X* supports multiple Hive instances. In the multi-instance scenario, the directory is **/user/hiven** *n* (*n*=1–4)**/warehouse**.

To perform various operations on Hive databases or tables, you need to associate the metadata permission with the HDFS file permission. For example, to query Hive data tables, you need to associate the metadata permission **SELECT** and the HDFS file permissions **Read** and **Write**.

To use the role management function of Manager GUI to manage the permissions of Hive databases and tables, you only need to configure the metadata permission, and the system will automatically associate and configure the HDFS file permission. In this way, operations on the interface are simplified, and the efficiency is improved.

Hive Users

MRS provides users and roles to use Hive, such as creating tables, inserting data into tables, and querying tables. Hive defines the **USER** class, corresponding to user instances. Hive defines the **GROUP** class, corresponding to role instances.

You can use Manager to set permissions for Hive users. This method only supports permission setting in roles. A user or user group can obtain the permissions only after a role is bound to the user or user group. Hive users can be granted administrator permissions and permissions to access databases, tables, and columns.

Hive Usage Scenarios and Related Permissions

Creating a database with Hive requires users to join in the **hive** group, without granting a role. Users have all permissions on the databases or tables created by

themselves in Hive or HDFS. They can create tables, select, delete, insert, or update data, and grant permissions to other users to allow them to access the tables and corresponding HDFS directories and files.

A user can access the tables or database only with permissions. The permission required by users varies according to Hive usage scenarios.

Table 12-230 Hive usage scenarios

Typical Scenario	Permission
Using Hive tables, columns, or databases	Permissions required in different scenarios are as follows: ● To create tables, the **CREATE** permission is required. ● To query data, the **SELECT** permission is required. ● To insert data, the **INSERT** permission is required. ● To delete data, the **DELETE** permission is required.
Associating and using other components	In addition to Hive permissions, permissions of other components are required in some scenarios, for example: ● Yarn permissions are required when some HQL statements, such as **insert**, **count**, **distinct**, **group by**, **order by**, **sort by**, and **join**, are run. You are advised to grant Yarn permissions to the role of each Hive user. ● HBase permission is required when Hive over HBase is used, for example, querying HBase table data in Hive.

In some special Hive usage scenarios, you need to configure other types of permission.

Table 12-231 Hive authorization precautions

Scenario	Permission
Creating Hive databases, tables, and external tables, or adding partitions to created Hive tables or external tables when data files specified by Hive users are saved to other HDFS directories except **/user/hive/warehouse**	The directory must already exist, the Hive user must be the owner of the directory, and the Hive user must have the read, write, and execute permissions on the directory. The user must have the **read** and **write** permissions of all the upper-layer directories of the directory. After an administrator grants the Hive permission to the role, the HDFS permission is automatically granted.
Using **load** to load data from all the files or specified files in a specified directory to Hive tables as a Hive user	• The data source is a Linux local disk, the specified directory exists, and the system user **omm** has read and execute permission of the directory and all its upper-layer directories. The specified file exists, and user **omm** has read permission of the file and has the read and execute permission of all the upper-layer directories of the file. • The data source is HDFS, the specified directory exists, and the Hive user is the owner of the directory and has read, write, and execute permission on the directory and its subdirectories, and has read and write permission on all its upper-layer directories. The specified file exists, and the Hive user is the owner of the file and has read, write, and execute permission, and has read and execute permission on the file and all its upper-layer directories. **NOTE** When **load** is used to import data to a Linux local disk, files must be loaded to the HiveServer on which the command is run and the permission must be modified. You are advised to run the command on a client. The HiveSever to which the client is connected can be found. For example, if the Hive client displays **0: jdbc:hive2://10.172.0.43:21066/>**, the IP address of the connected HiveServer is 10.172.0.43.
Creating or deleting functions or modifying any database	The **Hive Admin Privilege** is required.

Scenario	Permission
Performing operations on all databases and tables in Hive	The user must be added to the **supergroup** user group and granted **Hive Admin Privilege**.

12.10.4.2 Creating a Hive Role

Scenario

This section describes how to create and configure a Hive role on Manager as the system administrator. The Hive role can be granted the permissions of the Hive administrator and the permissions to operate Hive table data.

Creating a database with Hive requires users to join in the **hive** group, without granting a role. Users have all permissions on the databases or tables created by themselves in Hive or HDFS. They can create tables, select, delete, insert, or update data, and grant permissions to other users to allow them to access the tables and corresponding HDFS directories and files. The created databases or tables are saved in the **/user/hive/warehouse** directory of the HDFS by default.

NOTE

- A Hive role can be created only in security mode.
- If the current component uses Ranger for permission control, you need to configure permission management policies based on Ranger. For details, see **Adding a Ranger Access Permission Policy for Hive** for MRS 3.*x* or later that supports Ranger.

Prerequisites

- The system administrator has understood the service requirements.
- Log in to FusionInsight Manager.
- The Hive client has been installed.

Procedure

For versions earlier than MRS 3.x, perform the following operations to create a Hive role:

Step 1 Log in to MRS Manager.

Step 2 Choose **System** > **Permission** > **Manage Role**.

Step 3 Click **Create Role**, and set **Role Name** and **Description**.

Step 4 Set permissions. For details, see **Table 12-232**.

- **Hive Admin Privilege**: Hive administrator permissions. If you want to use this permission, run the **set role admin** command to set the permission before running SQL statements.
- **Hive Read Write Privileges**: Hive data table management permission, which is the operation permission to set and manage the data of created tables.

Select the permissions of a database as required. To specify permissions on tables, click the database name and select the permissions of the tables.

NOTE

- Hive role management supports the administrator permission, and the permissions of accessing tables and views, without granting the database permission.
- The permissions of the Hive administrator do not include the permission to manage HDFS.
- If there are too many tables in the database or too many files in tables, the permission granting may last a while. For example, if a table contains 10,000 files, the permission granting lasts about 2 minutes.

Table 12-232 Setting a role

Scenario	Role Authorization
Setting the Hive administrator permission	In the **Permission** table, click **Hive** and select **Hive Admin Privilege**. **NOTE** After being bound to the Hive administrator role, perform the following operations during each maintenance operation: 1. Log in to the node where the client is installed. 2. Run the following command to configure environment variables: For example, if the Hive client installation directory is **/opt/hiveclient**, run **source /opt/hiveclient/bigdata_env**. 3. Run the following command to authenticate the user: **kinit** *Hive service user* 4. Run the following command to log in to the client tool: **beeline** 5. Run the following command to update the administrator permissions: **set role admin;**
Setting the permission to query a table of another user in the default database	1. In the **Permission** table, choose **Hive** > **Hive Read Write Privileges**. 2. In the **Permission** column of the specified table, select **SELECT**.
Setting the permission to query a table of another user in the default database	1. In the **Permission** table, choose **Hive** > **Hive Read Write Privileges**. 2. In the **Permission** column of the specified table, select **Insert**.

Scenario	Role Authorization
Setting the permission to import data to a table of another user in the default database	1. In the **Permission** table, choose **Hive** > **Hive Read Write Privileges**. 2. In the **Permission** column of the specified table, select **Delete** and **Insert**.
Setting the permission to submit HQL commands to Yarn for execution	The HQL commands used by some services are converted into MapReduce tasks and submitted to Yarn for execution. You need to set the Yarn permissions. For example, the HQL statements to be run use statements, such as **insert**, **count**, **distinct**, **group by**, **order by**, **sort by**, or **join**. 1. In the **Permission** table, choose **Yarn** > **Scheduler Queue** > **root**. 2. In the **Permission** column of the default queue, select **Submit**.

Step 5 Click **OK**, and return to the **Role** page.

Step 6 Choose **System** > **Manage User** > **Create User**.

Step 7 Enter the username, set **User Type** to **Human-machine**, set the user password, add a user group bound with the Hive administrator role, bind the new Hive role to the user group, and click **OK**.

Step 8 After the user is created, you can run the SQL statement using the user.

----End

For MRS 3.*x* or later, perform the following operations to create a Hive role:

Step 1 Log in to FusionInsight Manager. For details, see**Accessing FusionInsight Manager (MRS 3.x or Later)**

Step 2 Choose **System** > **Permission** > **Role**.

Step 3 Click **Create Role**, and set **Role Name** and **Description**.

Step 4 Set **Configure Resource Permission**. For details, see **Table 12-233**.

- Grant the read and execution permissions for the HDFS directory.
  - Click *Name of the desired cluster* and select **HDFS** for **Service Name**. On the displayed page, click **File System**, choose **hdfs://hacluster/** > **user**, locate the row where **hive** is located, and select **Read** and **Execute** in the **Permission** column.
  - Click *Name of the desired cluster* and select **HDFS** for **Service Name**. On the displayed page, click **File System**, choose **hdfs://hacluster/** > **user** > **hive**, locate the row where **warehouse** is located, and select **Read** and **Execute** in the **Permission** column.
  - Click *Name of the desired cluster* and select **HDFS** for **Service Name**. On the displayed page, click **File System**, choose **hdfs://hacluster/** > **tmp**,

locate the row where **hive-scratch** is located, and select **Read** and **Execute** in the **Permission** column.

- **Hive Admin Privilege**: Hive administrator permission.
- **Hive Read Write Privileges**: Hive data table management permission, which is the operation permission to set and manage the data of created tables.

NOTE

- In MRS 3.1.0, Hive role management supports the administrator permission, and the permissions of accessing tables and views, without granting the database permission.
- The permissions of the Hive administrator do not include the permission to manage HDFS.
- If there are too many tables in the database or too many files in tables, the permission granting may last a while. For example, if a table contains 10,000 files, the permission granting lasts about 2 minutes.

Table 12-233 Setting a role

Task	Role Authorization
Setting the Hive administrator permission	In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** and select **Hive Admin Privilege**. **NOTE** After being bound to the Hive administrator role, perform the following operations during each maintenance operation: 1. Log in to the node where the Hive client is installed as the client installation user. 2. Run the following command to configure environment variables: For example, if the Hive client installation directory is **/opt/hiveclient**, run **source /opt/hiveclient/bigdata_env**. 3. Run the following command to authenticate the user: **kinit** *Hive service user* 4. Run the following command to log in to the client tool: **beeline** 5. Run the following command to update the administrator permissions: **set role admin;**

Task	Role Authorization
Setting the permission to query a table of another user in the default database	1. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges**. 2. Click the name of the specified database in the database list. Tables in the database are displayed. 3. In the **Rights** column of the specified table, choose **Select**.
Setting the permission to query a table of another user in the default database	1. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges**. 2. Click the name of the specified database in the database list. Tables in the database are displayed. 3. In the **Permission** column of the specified table, select **INSERT**.
Setting the permission to import data to a table of another user in the default database	1. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges**. 2. Click the name of the specified database in the database list. Tables in the database are displayed. 3. In the **Permission** column of the specified indexes, select **DELETE** and **INSERT**.
Setting the permission to submit HQL commands to Yarn for execution	The HQL commands used by some services are converted into MapReduce tasks and submitted to Yarn for execution. You need to set the Yarn permissions. For example, the HQL statements to be run use statements, such as **insert**, **count**, **distinct**, **group by**, **order by**, **sort by**, or **join**. 1. In the **Permission** table, choose *Name of the desired cluster* > **Yarn** > **Scheduling Queue** > **root**. 2. In the **Permission** column of the **default** queue, select **Submit**.

Step 5 Click **OK**, and return to the **Role** page.

----End

12.10.4.3 Configuring Permissions for Hive Tables, Columns, or Databases

Scenario

You can configure related permissions if you need to access tables or databases created by other users. Hive supports column-based permission control. If a user needs to access some columns in tables created by other users, the user must be granted the permission for columns. The following describes how to grant table, column, and database permissions to users by using the role management function of MRS Manager.

NOTE

- You can configure permissions for Hive tables, columns, or databases only in security mode.
- MRS 3.x or later supports Ranger. If the current component uses Ranger for permission control, you need to configure permission management policies based on Ranger. For details, see **Adding a Ranger Access Permission Policy for Hive**.

Prerequisites

- You have obtained a user account with the administrator permissions, such as **admin**.
- You have created a role, for example, **hrole**, on Manager by referring to instructions in **Creating a Hive Role**. You do not need to set the Hive permission but need to set the permission to submit the HQL command to Yarn for execution.
- You have created two Hive human-machine users, such as **huser1** and **huser2**, on Manager and added them to the **hive** group. **huser2** has been bound to **hrole**. The **hdb** database has created by user **huser1** and the **htable** table has been created in the database.

Procedure

- Granting Table Permissions

  Users have complete permission on the tables created by themselves in Hive and the HDFS. To access the tables created by others, they need to be granted the permission. After the Hive metadata permission is granted, the HDFS permission is automatically granted. The procedure for granting a role the permission of querying, inserting, and deleting **htable** data is as follows:

  For versions earlier than MRS 3.x, perform the following operations to grant table permissions:

  a. On MRS Manager, choose **System** > **Permission** > **Manage Role**.

  b. Locate the row that contains **hrole**, and click **Modify**.

  c. Choose **Hive** > **Hive Read Write Privileges**.

  d. Click the name of the specified database **hdb** in the database list. Table **htable** in the database is displayed.

e. In the **Permission** column of the **htable** table, select **Select**, **Insert**, and **Delete**.

f. Click **OK**.

For MRS 3.*x* or later, perform the following operations to grant table permissions:

a. On FusionInsight Manager, choose **System** > **Permission** > **Role**.

b. Locate the row that contains **hrole**, and click **Modify**.

c. Choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges**.

d. Click the name of the specified database **hdb** in the database list. Table **htable** in the database is displayed.

e. In the **Permission** column of the **htable** table, select **SELECT**, **INSERT**, and **DELETE**.

f. Click **OK**.

NOTE

In role management, the procedure for granting a role the permission of querying, inserting, and deleting Hive external table data is the same. After the metadata permission is granted, the HDFS permission is automatically granted.

- Granting Column Permissions

  Users have all permissions for the tables created by themselves in Hive and HDFS. Users do not have the permission to access the tables created by others. If a user needs to access some columns in tables created by other users, the user must be granted the permission for columns. After the Hive metadata permission is granted, the HDFS permission is automatically granted. The procedure for granting a role the permission of querying and inserting data in **hcol** of **htable** is as follows:

  For versions earlier than MRS 3.x, perform the following operations to grant column permissions:

  a. On MRS Manager, choose **System** > **Permission** > **Manage Role**.

  b. Locate the row that contains **hrole**, and click **Modify**.

  c. Choose **Hive** > **Hive Read Write Privileges**.

  d. In the database list, click the specified database **hdb** to display the **htable** table in the database. Click the **htable** table to display the **hcol** column in the table.

  e. In the **Permission** column of the **hcol** column, select **Select** and **Insert**.

  f. Click **OK**.

  For MRS 3.*x* or later, perform the following operations:

  a. On FusionInsight Manager, choose **System** > **Permission** > **Role**.

  b. Locate the row that contains **hrole**, and click **Modify**.

  c. Choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges**.

  d. In the database list, click the specified database **hdb** to display the **htable** table in the database. Click the **htable** table to display the **hcol** column in the table.

e. In the **Permission** column of the **hcol** column, select **SELECT** and **INSERT**.

f. Click **OK**.

NOTE

In role management, after the metadata permission is granted, the HDFS permission is automatically granted. Therefore, after the column permission is granted, the HDFS ACL permission for all files of the table is automatically granted.

- Granting Database Permissions

  Users have complete permission on the databases created by themselves in Hive and the HDFS. To access the databases created by others, they need to be granted the permission. After the Hive metadata permission is granted, the HDFS permission is automatically granted. The procedure for granting a role the permission of querying data and creating tables in database **hdb** is as follows. Other types of database operation permission are not supported.

  For versions earlier than MRS 3.x, perform the following database authorization operations:

  a. On MRS Manager, choose **System** > **Permission** > **Manage Role**.

  b. Locate the row that contains **hrole**, and click **Modify**.

  c. Choose **Hive** > **Hive Read Write Privileges**.

  d. In the **Permission** column of the **hdb** database, select **Select** and **Create**.

  e. Click **OK**.

  For MRS 3.*x* or later, perform the following operations to grant database permissions:

  a. On FusionInsight Manager, choose **System** > **Permission** > **Role**.

  b. Locate the row that contains **hrole**, and click **Modify**.

  c. Choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges**.

  d. In the **Permission** column of the **hdb** database, select **SELECT** and **CREATE**.

  e. Click **OK**.

NOTE

- Any permission for a table in the database is automatically associated with the HDFS permission for the database directory to facilitate permission management. When any permission for a table is canceled, the system does not automatically cancel the HDFS permission for the database directory to ensure performance. In this case, users can only log in to the database and view table names.
- When the query permission on a database is added to or deleted from a role, the query permission on tables in the database is automatically added to or deleted from the role.

Concepts

Table 12-234 Scenarios of using Hive tables, columns, or databases

Scenario	Required Permission
DESCRIBE TABLE	SELECT

12.10.4.4 Configuring Permissions to Use Other Components for Hive

Scenario

Hive may need to be associated with other components. For example, Yarn permissions are required in the scenario of using HQL statements to trigger MapReduce jobs, and HBase permissions are required in the Hive over HBase scenario. The following describes the operations in the two scenarios.

NOTE

- In security mode, Yarn and HBase permission management is enabled by default. Therefore, Yarn and HBase permissions need to be configured by default.
- In common mode, Yarn and HBase permission management is disabled by default. That is, any user has permissions. Therefore, YARN and HBase permissions does not need to be configured by default. If a user enables the permission management by modifying the Yarn or HBase configurations, the Yarn and HBase permissions then need to be configured.
- MRS 3.*x* or later supports Ranger. If the current component uses Ranger for permission control, you need to configure permission management policies based on Ranger. For details, see **Adding a Ranger Access Permission Policy for Hive**.

Prerequisites

- The Hive client has been installed. For example, the installation directory is **/opt/client**.
- You have obtained a user account with the administrator permissions, such as **admin**.

Procedure

Association with Yarn in MRS Earlier than 3.x

Yarn permissions are required when HQL statements, such as **insert**, **count**, **distinct**, **group by**, **order by**, **sort by**, and **join**, are used to trigger MapReduce jobs. The following uses the procedure for assigning a role the permissions to run the **count** statements in the **thc** table as an example.

Step 1 Create a role on MRS Manager.

Step 2 In the **Permission** table, choose **Yarn** > **Scheduler Queue** > **root**.

Step 3 In the **Permission** column of the default queue, select **Submit** and click **OK**.

Step 4 In the **Permission** table, choose **Hive** > **Hive Read Write Privileges** > **default**, select **Select** for **thc**, and click **OK**.

----End

Association with Yarn in MRS 3.*x* or Later

Yarn permissions are required when HQL statements, such as **insert**, **count**, **distinct**, **group by**, **order by**, **sort by**, and **join**, are used to trigger MapReduce jobs. The following uses the procedure for assigning a role the permissions to run the **count** statements in the **thc** table as an example.

Step 1 Create a role on FusionInsight Manager.

Step 2 In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Yarn** > **Scheduler Queue** > **root**.

Step 3 In the **Permission** column of the **default** queue, select **Submit** and click **OK**.

Step 4 In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges** > **default**. Select **SELECT** for table **thc**, and click **OK**.

----End

Hive over HBase Authorization in MRS Earlier than 3.x

After the permissions are assigned, you can use HQL statements that are similar to SQL statements to access HBase tables from Hive. The following uses the procedure for assigning a user the rights to query HBase tables as an example.

Step 1 On the role management page of MRS Manager, create an HBase role, for example, **hive_hbase_create**, and grant the permission to create HBase tables.

In the **Permission** table, choose **HBase** > **HBase Scope** > **global**, select **create** of the namespace **default**, and click **OK**.

Step 2 On MRS Manager, create a human-machine user, for example, **hbase_creates_user**, add the user to the **hive** group, and bind the **hive_hbase_create** role to the user so that the user can create Hive and HBase tables.

Step 3 Log in to the node where the client is installed.

Step 4 Run the following command to configure environment variables:

source /opt/client/bigdata_env

Step 5 Run the following command to authenticate the user:

kinit hbase_creates_user

Step 6 Run the following command to go to the shell environment of the Hive client:

beeline

Step 7 Run the following command to create a table in Hive and HBase, for example, the **thh** table.

CREATE TABLE thh(id int, name string, country string) STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler' WITH SERDEPROPERTIES("hbase.columns.mapping" = "cf1:id,cf1:name,:key") TBLPROPERTIES ("hbase.table.name" = "thh");

The created Hive table and the HBase table are stored in the Hive database **default** and the HBase namespace **default**, respectively.

Step 8 On the role management page of MRS Manager, create a role, for example, **hive_hbase_select**, and assign the role the permission to query the Hive table **thh** and the HBase table **thh**.

1. In the **Permission** table, choose **HBase** > **HBase Scope** > **global** > **default**, select **Read** for the **thh** table, and click **OK** to grant the HBase role the permission to query the table.
2. Edit a role. In the **Permission** table, choose **HBase** > **HBase Scope** > **global** > **hbase**. Select **Execute** for **hbase:meta**, and click **OK**.
3. Edit a role. In the **Permission** table, choose **Hive** > **Hive Read Write Privileges** > **default**, select **Select** for **thh**, and click **OK**.

Step 9 On MRS Manager, create a human-machine user, for example, **hbase_select_user**, add the user to the **hive** group, and bind the **hive_hbase_select** role to the user so that the user can query Hive and HBase tables.

Step 10 Run the following command to configure environment variables:

source /opt/client/bigdata_env

Step 11 Run the following command to authenticate users:

kinit hbase_select_user

Step 12 Run the following command to go to the shell environment of the Hive client:

beeline

Step 13 Run the following command to use an HQL statement to query HBase table data:

select * from thh;

----End

Hive over HBase Authorization in MRS 3.*x* or Later

After the permissions are assigned, you can use HQL statements that are similar to SQL statements to access HBase tables from Hive. The following uses the procedure for assigning a user the rights to query HBase tables as an example.

Step 1 On the role management page of FusionInsight Manager, create an HBase role, for example, **hive_hbase_create**, and grant the permission to create HBase tables.

In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **HBase** > **HBase Scope** > **global**. Select **Create** of the namespace **default**, and click **OK**.

Step 2 On FusionInsight Manager, create a human-machine user, for example, **hbase_creates_user**, add the user to the **hive** group, and bind the **hive_hbase_create** role to the user so that the user can create Hive and HBase tables.

Step 3 If the current component uses Ranger for permission control, grant the create permission for **hive_hbase_create** or **hbase_creates_user**. For details, see **Adding a Ranger Access Permission Policy for Hive**.

Step 4 Log in to the node where the client is installed as the client installation user.

Step 5 Run the following command to configure environment variables:

source /opt/client/bigdata_env

Step 6 Run the following command to authenticate the user:

kinit hbase_creates_user

Step 7 Run the following command to go to the shell environment of the Hive client:

beeline

Step 8 Run the following command to create a table in Hive and HBase, for example, the **thh** table.

CREATE TABLE thh(id int, name string, country string) STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler' WITH SERDEPROPERTIES("hbase.columns.mapping" = "cf1:id,cf1:name,:key") TBLPROPERTIES ("hbase.table.name" = "thh");

The created Hive table and the HBase table are stored in the Hive database **default** and the HBase namespace **default**, respectively.

Step 9 On the role management page of FusionInsight Manager, create a role, for example, **hive_hbase_select**, and assign the role the permission to query the Hive table **thh** and the HBase table **thh**.

1. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **HBase** > **HBase Scope** > **global** > **default**. Select **read** of the **thh** table, and click **OK** to grant the table query permission to the HBase role.
2. Edit the role. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **HBase** > **HBase Scope** > **global** > **hbase**, select **Execute** for **hbase:meta**, and click **OK**.
3. Edit the role. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges** > **default**. Select **SELECT** for the **thh** table, and click **OK**.

Step 10 On FusionInsight Manager, create a human-machine user, for example, **hbase_select_user**, add the user to the **hive** group, and bind the **hive_hbase_select** role to the user so that the user can query Hive and HBase tables.

Step 11 Run the following command to configure environment variables:

source /opt/client/bigdata_env

Step 12 Run the following command to authenticate users:

kinit hbase_select_user

Step 13 Run the following command to go to the shell environment of the Hive client:

beeline

Step 14 Run the following command to use an HQL statement to query HBase table data:

select * from thh;

----End

12.10.5 Using a Hive Client

Scenario

This section guides users to use a Hive client in an O&M or service scenario.

Prerequisites

- The client has been installed. For example, the client is installed in the **/opt/hadoopclient** directory. The client directory in the following operations is only an example. Change it to the actual installation directory.
- Service component users are created by the administrator as required. In security mode, machine-machine users need to download the keytab file. A human-machine user must change the password upon the first login.

Using the Hive Client (Versions Earlier Than MRS 3.x)

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Log in to the Hive client based on the cluster authentication mode.

- In security mode, run the following command to complete user authentication and log in to the Hive client:

  kinit *Component service user*

  beeline

- In common mode, run the following command to log in to the Hive client. If no component service user is specified, the current OS user is used to log in to the Hive client.

  beeline -n *component service user*

  NOTE

  After a beeline connection is established, you can compile and submit HQL statements to execute related tasks. To run the Catalog client command, you need to run the **!q** command first to exit the beeline environment.

Step 5 Run the following command to execute the HCatalog client command:

hcat -e *"cmd"*

cmd must be a Hive DDL statement, for example, **hcat -e "show tables"**.

NOTE

- To use the HCatalog client, choose **More** > **Download Client** on the service page to download the clients of all services. This restriction does not apply to the beeline client.
- Due to permission model incompatibility, tables created using the HCatalog client cannot be accessed on the HiveServer client. However, the tables can be accessed on the WebHCat client.
- If you use the HCatalog client in Normal mode, the system performs DDL commands using the current user who has logged in to the operating system.
- Exit the beeline client by running the **!q** command instead of by pressing **Ctrl + c**. Otherwise, the temporary files generated by the connection cannot be deleted and a large number of junk files will be generated as a result.
- If multiple statements need to be entered during the use of beeline clients, separate the statements from each other using semicolons (**;**) and set the value of **entireLineAsCommand** to **false**.

  Setting method: If beeline has not been started, run the **beeline --entireLineAsCommand=false** command. If the beeline has been started, run the **!set entireLineAsCommand false** command.

  After the setting, if a statement contains semicolons (**;**) that do not indicate the end of the statement, escape characters must be added, for example, **select concat_ws('\;', collect_set(col1)) from tbl**.

----End

Using the Hive Client (MRS 3.x or Later)

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 MRS 3.*X* supports multiple Hive instances. If you use the client to connect to a specific Hive instance in a scenario when multiple Hive instances are installed, run the following command to load the environment variables of the instance. Otherwise, skip this step. For example, load the environment variables of the Hive2 instance.

source Hive2/component_env

Step 5 Log in to the Hive client based on the cluster authentication mode.

- In security mode, run the following command to complete user authentication and log in to the Hive client:

  kinit *Component service user*

  beeline

- In common mode, run the following command to log in to the Hive client. If no component service user is specified, the current OS user is used to log in to the Hive client.

  beeline -n *component service user*

Step 6 Run the following command to execute the HCatalog client command:

hcat -e *"cmd"*

cmd must be a Hive DDL statement, for example, **hcat -e "show tables"**.

NOTE

- To use the HCatalog client, choose **More** > **Download Client** on the service page to download the clients of all services. This restriction does not apply to the beeline client.
- Due to permission model incompatibility, tables created using the HCatalog client cannot be accessed on the HiveServer client. However, the tables can be accessed on the WebHCat client.
- If you use the HCatalog client in Normal mode, the system performs DDL commands using the current user who has logged in to the operating system.
- Exit the beeline client by running the **!q** command instead of by pressing **Ctrl + C**. Otherwise, the temporary files generated by the connection cannot be deleted and a large number of junk files will be generated as a result.
- If multiple statements need to be entered during the use of beeline clients, separate the statements from each other using semicolons (**;**) and set the value of **entireLineAsCommand** to **false**.

  Setting method: If beeline has not been started, run the **beeline --entireLineAsCommand=false** command. If the beeline has been started, run the **!set entireLineAsCommand false** command.

  After the setting, if a statement contains semicolons (**;**) that do not indicate the end of the statement, escape characters must be added, for example, **select concat_ws('\;', collect_set(col1)) from tbl**.

----End

Common Hive Client Commands

The following table lists common Hive Beeline commands.

For more commands, see **https://cwiki.apache.org/confluence/display/Hive/HiveServer2+Clients#HiveServer2Clients-BeelineCommands**.

Table 12-235 Common Hive Beeline commands

Command	Description
set <key>=<value>	Sets the value of a specific configuration variable (key). **NOTE** If the variable name is incorrectly spelled, the Beeline does not display an error.
set	Prints the list of configuration variables overwritten by users or Hive.
set -v	Prints all configuration variables of Hadoop and Hive.
add FILE[S] <filepath> <filepath>*add JAR[S] <filepath> <filepath>*add ARCHIVE[S] <filepath> <filepath>*	Adds one or more files, JAR files, or ARCHIVE files to the resource list of the distributed cache.

Command	Description
add FILE[S] <ivyurl> <ivyurl>* add JAR[S] <ivyurl> <ivyurl>* add ARCHIVE[S] <ivyurl> <ivyurl>*	Adds one or more files, JAR files, or ARCHIVE files to the resource list of the distributed cache using the lvy URL in the **ivy://goup:module:version?query_string** format.
list FILE[S]list JAR[S]list ARCHIVE[S]	Lists the resources that have been added to the distributed cache.
list FILE[S] <filepath>*list JAR[S] <filepath>*list ARCHIVE[S] <filepath>*	Checks whether given resources have been added to the distributed cache.
delete FILE[S] <filepath>*delete JAR[S] <filepath>*delete ARCHIVE[S] <filepath>*	Deletes resources from the distributed cache.
delete FILE[S] <ivyurl> <ivyurl>* delete JAR[S] <ivyurl> <ivyurl>* delete ARCHIVE[S] <ivyurl> <ivyurl>*	Delete the resource added using **<ivyurl>** from the distributed cache.
reload	Enable HiveServer2 to discover the change of the JAR file **hive.reloadable.aux.jars.path** in the specified path. (You do not need to restart HiveServer2.) Change actions include adding, deleting, or updating JAR files.
dfs <dfs command>	Runs the **dfs** command.
<query string>	Executes the Hive query and prints the result to the standard output.

12.10.6 Using HDFS Colocation to Store Hive Tables

Scenario

HDFS Colocation is the data location control function provided by HDFS. The HDFS Colocation API stores associated data or data on which associated operations are performed on the same storage node. Hive supports the HDFS Colocation function. When Hive tables are created, after the locator information is set for table files, data files of related tables are stored on the same storage node when data is inserted into tables using the insert statement (other data import modes are not supported). This ensures convenient and efficient data computing among associated tables. The supported table formats are only TextFile and RCFile.

NOTE

This section applies to MRS 3.*x* or later.

Procedure

Step 1 Log in to the node where the client is installed as a client installation user.

Step 2 Run the following command to switch to the client installation directory, for example, **opt/client**:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, run the following command to authenticate the user:

kinit *MRS username*

Step 5 Create the *groupid* through the HDFS API.

hdfs colocationadmin -createGroup -groupId *<groupid>* -locatorIds *<locatorid1>*,*<locatorid2>*,*<locatorid3>*

NOTE

In the preceding command, *<groupid>* indicates the name of the created group. The group created in this example contains three locators. You can define the number of locators as required.

For details about group ID creation and HDFS Colocation, see HDFS description.

Step 6 Run the following command to log in to the Hive client:

beeline

Step 7 Enable Hive to use colocation.

Assume that **table_name1** and **table_name2** are associated with each other. Run the following statements to create them:

CREATE TABLE *<[db_name.]table_name1>[(col_name data_type , ...)]* [ROW FORMAT *<row_format>*] [STORED AS *<file_format>*] TBLPROPERTIES("groupId"=" *<group>* ","locatorId"="*<locator1>*");

CREATE TABLE *<[db_name.]table_name2> [(col_name data_type , ...)]* [ROW FORMAT *<row_format>*] [STORED AS *<file_format>*] TBLPROPERTIES("groupId"=" *<group>* ","locatorId"="*<locator1>*");

After data is inserted into **table_name1** and **table_name2** using the insert statement, data files of **table_name1** and **table_name2** are distributed to the same storage position in the HDFS, facilitating associated operations among the two tables.

----End

12.10.7 Using the Hive Column Encryption Function

Scenario

Hive supports encryption of one or multiple columns in a table. When creating a Hive table, you can specify the column to be encrypted and encryption algorithm. When data is inserted into the table using the insert statement, the related columns are encrypted. Column encryption can be performed in HDFS tables of only the TextFile and SequenceFile file formats. The Hive column encryption does not support views and the Hive over HBase scenario.

Hive supports two column encryption algorithms, which can be specified during table creation:

- AES (the encryption class is org.apache.hadoop.hive.serde2.AESRewriter)
- SMS4 (the encryption class is org.apache.hadoop.hive.serde2.SMS4Rewriter)

NOTE

- In national cryptographic cluster scenarios, Hive column encryption supports only table creation using the SMS4 algorithm.
- When you import data from a common Hive table into a Hive column encryption table, you are advised to delete the original data from the common Hive table as long as doing this does not affect other services. Retaining an unencrypted table poses security risks.

Procedure

Step 1 Specify the column to be encrypted and encryption algorithm when creating a table.

create table*<[db_name.]table_name> (<col_name1> <data_type> ,<col_name2> <data_type>,<col_name3> <data_type>,<col_name4> <data_type>)* ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe' WITH SERDEPROPERTIES ('column.encode.columns'='*<col_name2>,<col_name3>*', 'column.encode.classname'='org.apache.hadoop.hive.serde2.AESRewriter')STORED AS TEXTFILE;

Alternatively, use the following statement:

create table *<[db_name.]table_name> (<col_name1> <data_type> ,<col_name2> <data_type>,<col_name3> <data_type>,<col_name4> <data_type>)* ROW FORMAT SERDE 'org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe' WITH SERDEPROPERTIES ('column.encode.indices'='1,2', 'column.encode.classname'='org.apache.hadoop.hive.serde2.SMS4Rewriter') STORED AS TEXTFILE;

NOTE

- The numbers used to specify encryption columns start from 0. 0 indicates column 1, 1 indicates column 2, and so on.
- When creating a table with encrypted columns, ensure that the directory where the table resides is empty.

Step 2 Insert data into the table using the insert statement.

Assume that the test table exists and contains data.

insert into table *<table_name>* select *<col_list>* from test;

----End

12.10.8 Customizing Row Separators

Scenario

In most cases, a carriage return character is used as the row delimiter in Hive tables stored in text files, that is, the carriage return character is used as the terminator of a row during queries. However, some data files are delimited by special characters, and not a carriage return character.

MRS Hive allows you to use different characters or character combinations to delimit rows of Hive text data. When creating a table, set **inputformat** to **SpecifiedDelimiterInputFormat**, and set the following parameter before search each time. Then the table data is queried by the specified delimiter.

set hive.textinput.record.delimiter='';

NOTE

- The Hue component of the current version does not support the configuration of multiple separators when files are imported to a Hive table.
- This section applies to MRS 3.*x* or later.

Procedure

Step 1 Specify **inputFormat** and **outputFormat** when creating a table.

CREATE [TEMPORARY] [EXTERNAL] TABLE [IF NOT EXISTS] *[db_name.]table_name* **[(***col_name data_type* **[COMMENT** *col_comment***], ...)] [ROW FORMAT** *row_format***] STORED AS inputformat 'org.apache.hadoop.hive.contrib.fileformat.SpecifiedDelimiterInputFormat' outputformat 'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'**

Step 2 Specify the delimiter before search.

set hive.textinput.record.delimiter='!@!'

Hive will use '!@!' as the row delimiter.

----End

12.10.9 Configuring Hive on HBase in Across Clusters with Mutual Trust Enabled

For mutually trusted Hive and HBase clusters with Kerberos authentication enabled, you can access the HBase cluster and synchronize its key configurations to HiveServer of the Hive cluster.

Prerequisites

The mutual trust relationship has been configured between the two security clusters with Kerberos authentication enabled.

Procedure for Configuring Hive on HBase Across Clusters

Step 1 Download the HBase configuration file and decompress it.

1. Log in to FusionInsight Manager of the target HBase cluster and choose **Cluster** > **Services** > **HBase**.
2. Choose **More** > **Download Client**.
3. Download the HBase configuration file and choose **Configuration Files only** for **Select Client Type**.

Step 2 Log in to FusionInsight Manager of the source Hive cluster.

Step 3 Choose **Cluster** > **Services** > **Hive** and click the **Configurations** tab and then **All Configurations**. On the displayed page, add the following parameters to the **hive-site.xml** configuration file of the HiveServer role.

Search for the following parameters in the **hbase-site.xml** configuration file of the downloaded HBase client and add them to HiveServer:

- hbase.security.authentication
- hbase.security.authorization
- hbase.zookeeper.property.clientPort
- hbase.zookeeper.quorum (The domain name needs to be converted into an IP address.)
- hbase.regionserver.kerberos.principal
- hbase.master.kerberos.principal

Step 4 Save the configurations and restart Hive.

----End

12.10.10 Deleting Single-Row Records from Hive on HBase

Scenario

Due to the limitations of underlying storage systems, Hive does not support the ability to delete a single piece of table data. In Hive on HBase, MRS Hive supports the ability to delete a single piece of HBase table data. Using a specific syntax, Hive can delete one or more pieces of data from an HBase table.

Table 12-236 Permissions required for deleting single-row records from the Hive on HBase table

Cluster Authentication Mode	Required Permission
Security mode	SELECT, INSERT, and DELETE
Common mode	None

Procedure

Step 1 To delete some data from an HBase table, run the following HQL statement:

remove table *<table_name>* where *<expression>*;

In the preceding information, *<expression>* specifies the filter condition of the data to be deleted. *<table_name>* indicates the Hive on HBase table from which data is to be deleted.

----End

12.10.11 Configuring HTTPS/HTTP-based REST APIs

Scenario

WebHCat provides external REST APIs for Hive. By default, the open-source community version uses the HTTP protocol.

MRS Hive supports the HTTPS protocol that is more secure, and enables switchover between the HTTP protocol and the HTTPS protocol.

NOTE

The security mode supports HTTPS and HTTP, and the common mode supports only HTTP.

Procedure

Step 1 The Hive service configuration page is displayed.

- For versions earlier than MRS 3.x, click the cluster name. On the cluster details page that is displayed, choose **Components** > **Hive** > **Service Configuration**, and select **All** from the **Basic** drop-down list.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. And choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 2 Modify the Hive configuration.

- For versions earlier than MRS 3.x: Enter the parameter name in the search box, search for **templeton.protocol.type**, change the parameter value to **HTTPS** or **HTTP**, and restart the Hive service to use the corresponding protocol.
- For MRS 3.*x* or earlier: Choose **WebHCat** > **Security**. On the page that is displayed, select **HTTPS** or **HTTP**. After the modification, restart the Hive service to use the corresponding protocol.

----End

12.10.12 Enabling or Disabling the Transform Function

Scenario

The Transform function is not allowed by Hive of the open source version.

MRS Hive supports the configuration of the Transform function. The function is disabled by default, which is the same as that of the open-source community version.

Users can modify configurations of the Transform function to enable the function. However, security risks exist when the Transform function is enabled.

NOTE

The Transform function can be disabled only in security mode.

Procedure

Step 1 The Hive service configuration page is displayed.

- For versions earlier than MRS 3.x, click the cluster name. On the cluster details page that is displayed, choose **Components** > **Hive** > **Service Configuration**, and select **All** from the **Basic** drop-down list.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. And choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 2 Enter the parameter name in the search box, search for **hive.security.transform.disallow**, change the parameter value to **true** or **false**, and restart all HiveServer instances.

NOTE

- If this parameter is set to **true**, the Transform function is disabled, which is the same as that in the open-source community version.
- If this parameter is set to **false**, the Transform function is enabled, which poses security risks.

----End

12.10.13 Access Control of a Dynamic Table View on Hive

Scenario

This section describes how to create a view on Hive when MRS is configured in security mode, authorize access permissions to different users, and specify that different users access different data.

In the view, Hive can obtain the built-in function **current_user()** of the users who submit tasks on the client and filter the users. This way, authorized users can only access specific data in the view.

NOTE

In normal mode, the **current_user()** function cannot distinguish users who submit tasks on the client. Therefore, the access control function takes effect only for Hive in security mode.

If the **current_user()** function is used in the actual service logic, the possible risks must be fully evaluated during the conversion between the security mode and normal mode.

Operation Example

- If the current_user function is not used, different views need to be created for different users to access different data.
  - Authorize the view **v1** permission to user **hiveuser1**. The user **hiveuser1** can access data with **type** set to **hiveuser1** in **table1**.

    create view v1 as select * from table1 where type='hiveuser1'
  - Authorize the view **v2** permission to user **hiveuser2**. The user **hiveuser2** can access data with **type** set to **hiveuser2** in **table1**.

    create view v2 as select * from table1 where type='hiveuser2'
- If the current_user function is used, only one view needs to be created.

  Authorize the view **v** permission to users **hiveuser1** and **hiveuser2**. When user **hiveuser1** queries view **v**, the current_user() function is automatically converted to **hiveuser1**. When user **hiveuser2** queries view **v**, the **current_user()** function is automatically converted to **hiveuser2**.

  create view v as select * from table1 where type=current_user()

12.10.14 Specifying Whether the ADMIN Permissions Is Required for Creating Temporary Functions

Scenario

You must have **ADMIN** permission when creating temporary functions on Hive of the open source community version.

MRS Hive supports the configuration of the function for creating temporary functions with **ADMIN** permission. The function is disabled by default, which is the same as that of the open-source community version.

You can modify configurations of this function. After the function is enabled, you can create temporary functions without **ADMIN** permission. If this parameter is set to **false**, security risks exist.

NOTE

The security mode supports the configuration of whether the ADMIN permission is required for creating temporary functions, but the common mode does not support this function.

Procedure

Step 1 The Hive service configuration page is displayed.

- For versions earlier than MRS 3.x, click the cluster name. On the cluster details page that is displayed, choose **Components** > **Hive** > **Service Configuration**, and select **All** from the **Basic** drop-down list.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. And choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 2 Enter the parameter name in the search box, search for **hive.security.temporary.function.need.admin**, change the parameter value to **true** or **false**, and restart all HiveServer instances.

NOTE

- If this parameter is set to **true**, the ADMIN permission is required for creating temporary functions, which is the same as that in the open source community.
- If this parameter is set to **false**, the ADMIN permission is not required for creating temporary functions.

----End

12.10.15 Using Hive to Read Data in a Relational Database

Scenario

Hive allows users to create external tables to associate with other relational databases. External tables read data from associated relational databases and support Join operations with other tables in Hive.

Currently, the following relational databases can use Hive to read data:

- DB2
- Oracle

NOTE

This section applies to MRS 3.*x* or later.

Prerequisites

The Hive client has been installed.

Procedure

Step 1 Log in to the node where the Hive client is installed as the Hive client installation user .

Step 2 Run the following command to go to the client installation directory:

cd *Client installation directory*

For example, if the client installation directory is **/opt/client**, run the following command:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Check whether the cluster authentication mode is Security.

- If yes, run the following command to authenticate the user:

  kinit *Hive service user*

- If no, go to **Step 5**.

Step 5 Run the following command to upload the driver JAR package of the relational database to be associated to an HDFS directory.

hdfs dfs -put *directory where the JAR package is located HDFS directory to which the JAR is uploaded*

For example, to upload the Oracle driver JAR package in **/opt** to the **/tmp** directory in HDFS, run the following command:

hdfs dfs -put /opt/ojdbc6.jar /tmp

Step 6 Create an external table on the Hive client to associate with the relational database, as shown in the following example.

NOTE

If the security mode is used, the user who creates the table must have the **ADMIN** permission. The **ADD JAR** path is subject to the actual path.

```
-- Example of associating with an Oracle Linux 6 database
-- In security mode, set the admin permission.
set role admin;
-- Upload the driver JAR package of the relational database to be associated. The driver JAR packages vary according to databases.
ADD JAR hdfs:///tmp/ojdbc6.jar;

CREATE EXTERNAL TABLE ora_test
-- The Hive table must have one more column than the database return result. This column is used for paging query.
(id STRING,rownum string)
STORED BY 'com.qubitproducts.hive.storage.jdbc.JdbcStorageHandler'
TBLPROPERTIES (
-- Relational database table type
"qubit.sql.database.type" = "ORACLE",
-- Connect to the URL of the relational database through JDBC. (The URL formats vary according to databases.)
"qubit.sql.jdbc.url" = "jdbc:oracle:thin:@//10.163.0.1:1521/mydb",
-- Relational database driver class type
"qubit.sql.jdbc.driver" = "oracle.jdbc.OracleDriver",
-- SQL statement queried in the relational database. The result is returned to the Hive table.
"qubit.sql.query" = "select name from aaa",
-- (Optional) Match the Hive table columns to the relational database table columns.
"qubit.sql.column.mapping" = "id=name",
-- Relational database user
"qubit.sql.dbcp.username" = "test",
-- Relational database password
"qubit.sql.dbcp.password" = "xxx");
```

----End

12.10.16 Supporting Traditional Relational Database Syntax in Hive

Overview

Hive supports the following types of traditional relational database syntax:

- Grouping
- EXCEPT and INTERSECT

Grouping

Syntax description:

- Grouping takes effect only when the Group by statement contains ROLLUP or CUBE.
- The result set generated by CUBE contains all the combinations of values in the selected columns.
- The result set generated by ROLLUP contains the combinations of a certain layer structure in the selected columns.
- Grouping: If a row is added by using the CUBE or ROLLUP operator, the output value of the added row is 1. If the row is not added by using the CUBE or ROLLUP operator, the output value of the added row is 0.

For example, the **table_test** table exists in Hive and the table structure is as follows:

```
+----------------+-------------------+--+
| table_test.id  | table_test.value  |
+----------------+-------------------+--+
| 1              | 10                |
| 1              | 15                |
| 2              | 20                |
| 2              | 5                 |
| 2              | 13                |
+----------------+-------------------+--+
```

Run the following statement:

select id,grouping(id),sum(value) from table_test group by id with rollup;

The result is as follows:

```
+-------+-----------------+------+--+
|  id   | groupingresult  | sum  |
+-------+-----------------+------+--+
| 1     | 0               | 25   |
| NULL  | 1               | 63   |
| 2     | 0               | 38   |
+-------+-----------------+------+--+
```

EXCEPT and INTERSECT

Syntax description:

- EXCEPT returns the difference of two result sets (that is, non-duplicated values return only one query).

- INTERSECT returns the intersection of two result sets (that is, non-duplicated values return by both queries).

For example, two tables **test_table1** and **test_table2** exist in Hive.

The table structure of **test_table1** is as follows:

```
+-----------------+--+
| test_table1.id  |
+-----------------+--+
| 1               |
| 2               |
| 3               |
| 4               |
+-----------------+--+
```

The table structure of **test_table2** is as follows:

```
+-----------------+--+
| test_table2.id  |
+-----------------+--+
| 2               |
| 3               |
| 4               |
| 5               |
+-----------------+--+
```

- Run the following EXCEPT statement:

  select id from test_table1 except select id from test_table2;

  The result is as follows:

  ```
  +--------------+--+
  | _alias_0.id  |
  +--------------+--+
  | 1            |
  +--------------+--+
  ```

- Run the following INTERSECT statement:

  select id from test_table1 intersect select id from test_table2;

  The result is as follows:

  ```
  +--------------+--+
  | _alias_0.id  |
  +--------------+--+
  | 2            |
  | 3            |
  | 4            |
  +--------------+--+
  ```

12.10.17 Creating User-Defined Hive Functions

When built-in functions of Hive cannot meet requirements, you can compile user-defined functions (UDFs) and use them for query.

According to implementation methods, UDFs are classified as follows:

- Common UDFs: used to perform operations on a single data row and export a single data row.
- User-defined aggregating functions (UDAFs): used to input multiple data rows and export a single data row.
- User-defined table-generating functions (UDTFs): used to perform operations on a single data row and export multiple data rows.

According to use methods, UDFs are classified as follows:

- Temporary functions: used only in the current session and must be recreated after a session restarts.
- Permanent functions: used in multiple sessions. You do not need to create them every time a session restarts.

NOTE

You need to properly control the memory and thread usage of variables in UDFs. Improper control may cause memory overflow or high CPU usage.

The following uses AddDoublesUDF as an example to describe how to compile and use UDFs.

Function

AddDoublesUDF is used to add two or more floating point numbers. In this example, you can learn how to write and use UDFs.

NOTE

- A common UDF must be inherited from **org.apache.hadoop.hive.ql.exec.UDF**.
- A common UDF must implement at least one **evaluate()**. The evaluate function supports overloading.
- To develop a customized function, you need to add the **hive-exec-3.1.0.jar** dependency package to the project. The package can be obtained from the Hive installation directory.

Sample Code

The following is a UDF code example:

xxx indicates the name of the organization that develops the program.

```
package com.xxx.bigdata.hive.example.udf;
import org.apache.hadoop.hive.ql.exec.UDF;

public class AddDoublesUDF extends UDF {
 public Double evaluate(Double... a) {
    Double total = 0.0;
    // Processing logic
    for (int i = 0; i < a.length; i++)
      if (a[i] != null)
        total += a[i];
    return total;
  }
}
```

How to Use

Step 1 Packing programs as **AddDoublesUDF.jar** on the client node, and upload the package to a specified directory in HDFS, for example, **/user/hive_examples_jars**.

Both the user who creates the function and the user who uses the function must have the read permission on the file.

The following are example statements:

hdfs dfs -put ./hive_examples_jars /user/hive_examples_jars

hdfs dfs -chmod 777 /user/hive_examples_jars

Step 2 Check the cluster authentication mode.

- In security mode, log in to the beeline client as a user with the Hive management permission and run the following commands:

  kinit *Hive service user*

  beeline

  set role admin;

- In common mode, run the following command:

  beeline -n *Hive service user*

Step 3 Define the function in HiveServer. Run the following SQL statement to create a permanent function:

CREATE FUNCTION *addDoubles* **AS 'com.***xxx***.bigdata.hive.example.udf.AddDoublesUDF' using jar 'hdfs://hacluster/user/hive_examples_jars/AddDoublesUDF.jar';**

addDoubles indicates the function alias that is used for SELECT query. *xxx* indicates the name of the organization that develops the program.

Run the following statement to create a temporary function:

CREATE TEMPORARY FUNCTION addDoubles AS 'com.*xxx***.bigdata.hive.example.udf.AddDoublesUDF' using jar 'hdfs://hacluster/user/hive_examples_jars/AddDoublesUDF.jar';**

- *addDoubles* indicates the function alias that is used for SELECT query.
- **TEMPORARY** indicates that the function is used only in the current session with the HiveServer.

Step 4 Run the following SQL statement to use the function on the HiveServer:

SELECT addDoubles(1,2,3);

NOTE

If an [Error 10011] error is displayed when you log in to the client again, run the **reload function;** command and then use this function.

Step 5 Run the following SQL statement to delete the function from the HiveServer:

DROP FUNCTION addDoubles;

----End

Extended Applications

None

12.10.18 Enhancing beeline Reliability

Scenario

- When the beeline client is disconnected due to network exceptions during the execution of a batch processing task, tasks submitted before beeline is disconnected can be properly executed in Hive. When you start the batch

processing task again, the submitted tasks are not executed and tasks that are not executed are executed in sequence.

- When the HiveServer service breaks down due to some reasons during the execution of a batch processing task, Hive enables that the tasks that have been successfully executed are not executed again when the same batch processing task is started again. The execution starts from the task that has not been executed from the time when HiveServer2 breaks down.

NOTE

This section applies to MRS 3.*x* or later.

Example

1. Beeline is reconnected after being disconnection.

   Example:

   beeline -e "${*SQL*}" --hivevar batchid=*xxxxx*

2. Beeline kills the running tasks.

   Example:

   beeline -e "" --hivevar batchid=*xxxxx* --hivevar kill=true

3. Log in to the beeline client and start the mechanism of reconnection after disconnection.

   Log in to the beeline client and run the **set hivevar:batchid=***xxxx* command.

NOTE

Instructions:

- *xxxx* indicates the batch ID of tasks submitted in the same batch using the beeline client. Batch IDs can be used to identify the task submission batch. If the batch ID is not contained when a task is submitted, this feature is not enabled. The value of *xxxx* is specified during task execution. In the following example, the value of *xxxx* is **012345678901**.

  beeline -f hdfs://hacluster/user/hive/table.sql --hivevar batchid=012345678901
- If the running SQL script depends on the data timeliness, you are advised not to enable the breakpoint reconnection mechanism. You can use a new batch ID to submit tasks. During reexecution of the scripts, some SQL statements have been executed and are not executed again. As a result, expired data is obtained.
- If some built-in time functions are used in the SQL script, it is recommended that you do not enable the breakpoint reconnection mechanism or the use of a new batch ID for each execution. The reason is the same as above.
- A SQL script contains one or more subtasks. If the logic for deleting and creating temporary tables exist in the SQL script, it is recommended that the logic for deleting temporary tables be placed at the end of the script. If the subtasks executed after the temporary table deletion task fail to be executed and the temporary table is used in the subtasks before the temporary table deletion task, when the SQL script is executed using the same batch ID for the next time, the compilation of the subtasks (excluding the task for creating the temporary table because the creation has been completed and is not executed again, and only compilation is allowed) executed before the temporary table deletion task fails because the temporary has been deleted. In this case, you are advised to use a new batch ID to execute the script.

Parameter description:

- **zk.cleanup.finished.job.interval**: indicates the interval for executing the cleanup task. The default interval is 60 seconds.
- **zk.cleanup.finished.job.outdated.threshold**: indicates the threshold of the node validity period. A node is generated for tasks in the same batch. The threshold is calculated from the end time of the execution of the current batch task. If the time exceeds 60 minutes, the node is deleted.
- **batch.job.max.retry.count**: indicates the maximum number of retry times of a batch task. If the number of retry times of a batch task exceeds the value of this parameter, the task execution record is deleted. The task will be executed from the first task when the task is started next time. The default value is **10**.
- **beeline.reconnect.zk.path**: indicates the root node for storing task execution progress. The default value for the Hive service is **/beeline**.

12.10.19 Viewing Table Structures Using the show create Statement as Users with the select Permission

Scenario

This function is applicable to Hive and Spark2x in MRS 3.x and later.

With this function enabled, if the select permission is granted to a user during Hive table creation, the user can run the **show create table** command to view the table structure.

Procedure

Step 1 The Hive service configuration page is displayed.

- For versions earlier than MRS 3.x, click the cluster name. On the cluster details page that is displayed, choose **Components** > **Hive** > **Service Configuration**, and select **All** from the **Basic** drop-down list.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. And choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 2 Choose **HiveServer(Role)** > **Customization**, add a customized parameter to the **hive-site.xml** parameter file, set **Name** to **hive.allow.show.create.table.in.select.nogrant**, and set **Value** to **true**. Restart all Hive instances after the modification.

Step 3 Determine whether to enable this function on the Spark/Spark2x client.

- If yes, download and install the Spark/Spark2x client again.
- If no, no further action is required.

----End

12.10.20 Writing a Directory into Hive with the Old Data Removed to the Recycle Bin

Scenario

This function applies to Hive.

After this function is enabled, run the following command to write a directory into Hive: **insert overwrite directory "***/path1***" ...**. After the operation is successfully performed, the old data is removed to the recycle bin, and the directory cannot be an existing database path in the Hive metastore.

Step 1 The Hive service configuration page is displayed.

- For versions earlier than MRS 3.x, click the cluster name. On the cluster details page that is displayed, choose **Components** > **Hive** > **Service Configuration**, and select **All** from the **Basic** drop-down list.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. And choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 2 Choose **HiveServer(Role)** > **Customization**, add a customized parameter to the **hive-site.xml** parameter file, set **Name** to **hive.overwrite.directory.move.trash**, and set **Value** to **true**. Restart all Hive instances after the modification.

----End

12.10.21 Inserting Data to a Directory That Does Not Exist

Scenario

This function applies to Hive.

With this function enabled, run the **insert overwrite directory** */path1/path2/path3*... command to write a subdirectory. The permission of the */path1/path2* directory is 700, and the owner is the current user. If the */path3* directory does not exist, it is automatically created and data is written successfully.

This function is supported when **hive.server2.enable.doAs** is set to **true** in earlier versions. This version supports the function when **hive.server2.enable.doAs** is set to **false**.

NOTE

The parameter adjustment of this function is the same as that of the custom parameters added in **Writing a Directory into Hive with the Old Data Removed to the Recycle Bin**.

Procedure

Step 1 The Hive service configuration page is displayed.

- For versions earlier than MRS 3.x, click the cluster name. On the cluster details page that is displayed, choose **Components** > **Hive** > **Service Configuration**, and select **All** from the **Basic** drop-down list.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. And choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 2 Choose **HiveServer(Role)** > **Customization**, add a customized parameter to the **hive-site.xml** parameter file, set **Name** to **hive.overwrite.directory.move.trash**, and set **Value** to **true**. Restart all Hive instances after the modification.

----End

12.10.22 Creating Databases and Creating Tables in the Default Database Only as the Hive Administrator

Scenario

This function is applicable to Hive and Spark2x for MRS 3.*x* or later, or Hive and Spark for versions earlier than MRS 3.x.

After this function is enabled, only the Hive administrator can create databases and tables in the default database. Other users can use the databases only after being authorized by the Hive administrator.

NOTE

- After this function is enabled, common users are not allowed to create a database or create a table in the default database. Based on the actual application scenario, determine whether to enable this function.
- Permissions of common users are restricted. In the scenario where common users have been used to perform operations, such as database creation, table script migration, and metadata recreation in an earlier version of database, the users can perform such operations on the database in the condition that this function is disabled temporarily after the database is migrated or after the cluster is upgraded.

Procedure

Step 1 The Hive service configuration page is displayed.

- For versions earlier than MRS 3.x, click the cluster name. On the cluster details page that is displayed, choose **Components** > **Hive** > **Service Configuration**, and select **All** from the **Basic** drop-down list.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. And choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 2 Choose **HiveServer(Role)** > **Customization**, add a customized parameter to the **hive-site.xml** parameter file, set **Name** to **hive.allow.only.admin.create**, and set **Value** to **true**. Restart all Hive instances after the modification.

Step 3 Determine whether to enable this function on the Spark/Spark2x client.

- If yes, go to **Step 4**.
- If no, no further action is required.

Step 4 Choose **SparkResource2x** > **Customization**, add a customized parameter to the **hive-site.xml** parameter file, set **Name** to **hive.allow.only.admin.create**, and set **Value** to **true**. Then, choose **JDBCServer2x** > **Customization** and repeat the preceding operations to add the customized parameter. Restart all Spark2x instances after the modification.

Step 5 Download and install the Spark/Spark2x client again.

----End

12.10.23 Disabling of Specifying the location Keyword When Creating an Internal Hive Table

Scenario

This function is applicable to Hive and Spark2x for MRS 3.*x* or later, or Hive and Spark for versions earlier than MRS 3.x.

After this function is enabled, the **location** keyword cannot be specified when a Hive internal table is created. Specifically, after a table is created, the table path following the location keyword is created in the default **\warehouse** directory and cannot be specified to another directory. If the location is specified when the internal table is created, the creation fails.

NOTE

After this function is enabled, the location keyword cannot be specified during the creation of a Hive internal table. The table creation statement is restricted. If a table that has been created in the database is not stored in the default directory **/warehouse**, the **location** keyword can still be specified when the database creation, table script migration, or metadata recreation operation is performed by disabling this function temporarily.

Procedure

Step 1 The Hive service configuration page is displayed.

- For versions earlier than MRS 3.x, click the cluster name. On the cluster details page that is displayed, choose **Components** > **Hive** > **Service Configuration**, and select **All** from the **Basic** drop-down list.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. And choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 2 Choose **HiveServer(Role)** > **Customization**, add a customized parameter to the **hive-site.xml** parameter file, set **Name** to **hive.internaltable.notallowlocation**, and set **Value** to **true**. Restart all Hive instances after the modification.

Step 3 Determine whether to enable this function on the Spark/Spark2x client.

- If yes, download and install the Spark/Spark2x client again.
- If no, no further action is required.

----End

12.10.24 Enabling the Function of Creating a Foreign Table in a Directory That Can Only Be Read

Scenario

This function is applicable to Hive and Spark2x for MRS 3.*x* or later, or Hive and Spark for versions earlier than MRS 3.x.

After this function is enabled, the user or user group that has the read and execute permissions on a directory can create foreign tables in the directory without checking whether the current user is the owner of the directory. In addition, the directory of a foreign table cannot be stored in the default directory **\warehouse**. In addition, do not change the permission of the directory during foreign table authorization.

NOTE

After this function is enabled, the function of the foreign table changes greatly. Based on the actual application scenario, determine whether to enable this function.

Procedure

Step 1 The Hive service configuration page is displayed.

- For versions earlier than MRS 3.x, click the cluster name. On the cluster details page that is displayed, choose **Components** > **Hive** > **Service Configuration**, and select **All** from the **Basic** drop-down list.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. And choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 2 Choose **HiveServer(Role)** > **Customization**, add a customized parameter to the **hive-site.xml** parameter file, set **Name** to **hive.restrict.create.grant.external.table**, and set **Value** to **true**.

Step 3 Choose **MetaStore(Role)** > **Customization**, add a customized parameter to the **hivemetastore-site.xml** parameter file, set **Name** to **hive.restrict.create.grant.external.table**, and set **Value** to **true**. Restart all Hive instances after the modification.

Step 4 Determine whether to enable this function on the Spark/Spark2x client.

- If yes, download and install the Spark/Spark2x client again.
- If no, no further action is required.

----End

12.10.25 Authorizing Over 32 Roles in Hive

Scenario

This function applies to Hive.

The number of OS user groups is limited, and the number of roles that can be created in Hive cannot exceed 32. After this function is enabled, more than 32 roles can be created in Hive.

NOTE

- After this function is enabled and the table or database is authorized, roles that have the same permission on the table or database will be combined using vertical bars (|). When the ACL permission is queried, the combined result is displayed, which is different from that before the function is enabled. This operation is irreversible. Determine whether to make adjustment based on the actual application scenario.
- MRS 3.*x* and later versions support Ranger. If the current component uses Ranger for permission control, you need to configure related policies based on Ranger for permission management. For details, see **Adding a Ranger Access Permission Policy for Hive**.
- After this function is enabled, a maximum of 512 roles (including **owner**) are supported by default. The number is controlled by the user-defined parameter **hive.supports.roles.max** of MetaStore. You can change the value based on the actual application scenario.

Procedure

Step 1 The Hive service configuration page is displayed.

- For versions earlier than MRS 3.x, click the cluster name. On the cluster details page that is displayed, choose **Components** > **Hive** > **Service Configuration**, and select **All** from the **Basic** drop-down list.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. And choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 2 Choose **MetaStore(Role)** > **Customization**, add a customized parameter to the **hivemetastore-site.xml** parameter file, set **Name** to **hive.supports.over.32.roles**, and set **Value** to **true**. Restart all Hive instances after the modification.

Step 3 Choose **HiveServer(Role)** > **Customization**, add a customized parameter to the **hive-site.xml** parameter file, set **Name** to **hive.supports.over.32.roles**, and set **Value** to **true**. Restart all Hive instances after the modification.

----End

12.10.26 Restricting the Maximum Number of Maps for Hive Tasks

Scenario

- This function applies to Hive.
- This function is used to limit the maximum number of maps for Hive tasks on the server to avoid performance deterioration caused by overload of the HiveSever service.

Procedure

Step 1 The Hive service configuration page is displayed.

- For versions earlier than MRS 3.x, click the cluster name. On the cluster details page that is displayed, choose **Components** > **Hive** > **Service Configuration**, and select **All** from the **Basic** drop-down list.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. And choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 2 Choose **MetaStore(Role)** > **Customization**, add a customized parameter to the **hivemetastore-site.xml** parameter file, set **Name** to **hive.mapreduce.per.task.max.splits**, and set the parameter to a large value. Restart all Hive instances after the modification.

----End

12.10.27 HiveServer Lease Isolation

Scenario

- This function applies to Hive.
- This function can be enabled to specify specific users to access HiveServer services on specific nodes, achieving HiveServer resource isolation.

NOTE

This section applies to MRS 3.*x* or later.

Procedure

This section describes how to set lease isolation for user **hiveuser** for existing HiveServer instances.

Step 1 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **HiveServer**.

Step 3 In the HiveServer list, select the HiveServer for which lease isolation is configured and choose **HiveServer** > **Instance Configurations** > **All Configurations**.

Step 4 In the upper right corner of the **All Configurations** page, search for **hive.server2.zookeeper.namespace** and specify its value, for example, **hiveserver2_zk**.

Step 5 Click **Save**. In the dialog box that is displayed, click **OK**.

Step 6 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive**, choose **More** > **Restart Service**, and enter the password to restart the service.

Step 7 Run the **beeline -u** command to log in to the client and run the following command:

beeline -u "jdbc:hive2:// *10.5.159.13* **:2181/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=** *hiveserver2_zk* **;sasl.qop=auth-conf;auth=KERBEROS;principal=hive/hadoop.** *<System domain name>* **@** *<System domain name>* **"**

In the command, **10.5.159.13** is replaced with the IP address of any ZooKeeper instance, which can be viewed through **Cluster** > *Name of the desired cluster* > **Services** > **ZooKeeper** > **Instance**.

hiveserver2_zk following **zooKeeperNamespace=** is set to the value of **hive.server2.zookeeper.namespace** in **Step 4**.

As a result, only the HiveServer whose lease isolation is configured can be logged in.

NOTE

- After this function is enabled, you must run the preceding command during login to access the HiveServer for which lease isolation is configured. If you run the **beeline** command to log in to the client, only the HiveServer that is not isolated by the lease is accessed.
- You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and view the value of **Local Domain**, which is the current system domain name. **hive/hadoop.**<*system domain name*> is the username. All letters in the system domain name contained in the username are lowercase letters.

----End

12.10.28 Hive Supporting Transactions

Scenario

Hive supports transactions at the table and partition levels. When the transaction mode is enabled, transaction tables can be incrementally updated, deleted, and read, implementing atomicity, isolation, consistency, and durability of operations on transaction tables.

NOTE

This section applies to MRS 3.*x* or later.

Introduction to Transaction Features

A transaction is a group of unitized operations. These operations are either executed together or not executed together. A transaction is an inseparable unit of work. The four basic elements of a transaction are usually called ACID features, which are as follows:

- Atomicity: A transaction is an inseparable unit of work. All operations in a transaction occur or do not occur together.
- Consistency: The database integrity constraints are not damaged before and after a transaction starts.
- Isolation: When multiple transactions are concurrently accessed, the transactions are isolated from each other. A transaction does not affect the running of other transactions. The impacts between transactions are as follows: dirty read, non-repeatable read, phantom read, and lost update.
- Durability: After a transaction is complete, changes made by the transaction lock to the database are permanently stored in the database.

Characteristics of transaction execution:

- A statement can be written to multiple partitions or tables. If the operation fails, the user cannot see partial write or insert. Even if data is frequently changed, operations can still be quickly performed.
- Hive can automatically compress ACID transaction files without affecting concurrent queries. When querying many small partition files, automatic compression can improve query performance and metadata occupation.
- Read semantics include snapshot isolation. When the read operation starts, the Hive data warehouse is logically locked. The read operation is not affected by any changes that occur during the operation.

Lock Mechanism

Transactions implement the ACID feature through the following two aspects:

- Write-ahead logging ensures atomicity and durability.
- Locking ensures isolation.

Operation	Type of Held Locks
Insert overwrite	If **hive.txn.xlock.iow** is set to **true**, the exclusive lock is held. If **hive.txn.xlock.iow** is set to **false**, the semi-shared lock is held.
Insert	Shared lock. When performing this operation, you can perform read and write operations on the current table or partition.
Update/delete	Semi-shared lock. When this operation is performed, an operation of holding a shared lock can be performed, but an operation of holding an exclusive lock or a semi-shared lock cannot be performed.

Operation	Type of Held Locks
Drop	Exclusive lock. You cannot perform any other operations on the current table or partition when performing this operation.

NOTE

If a conflict caused by the lock mechanism exists in the write operation, the operation that preferentially holds the lock succeeds, and other operations fail.

Procedure

Starting a Transaction

Step 1 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations** > **MetaStore(Role)** > **Transaction**.

Step 2 Set **metastore.compactor.initiator.on** to **true**.

Step 3 Set **metastore.compactor.worker.threads** to a positive integer.

NOTE

metastore.compactor.worker.threads: Specifies the number of working threads for running the compression program on MetaStore. Set this parameter based on the actual requirements. If the value is too small, the transaction compression task is executed slowly. If the value is too large, the MetaStore execution performance deteriorates.

Step 4 Log in to the Hive client and run the following command to enable the following parameters. For details, see **Using a Hive Client**.

set hive.support.concurrency=true;

set hive.exec.dynamic.partition.mode=nonstrict;

set hive.txn.manager=org.apache.hadoop.hive.ql.lockmgr.DbTxnManager;

Create a transaction table.

Step 5 Run the following command to create a transaction table:

CREATE TABLE [IF NOT EXISTS] *[db_name.]table_name* **(***col_name data_type [COMMENT col_comment], ...***) [ROW FORMAT row_format] STORED AS orc ..... TBLPROPERTIES ('transactional'='true'[,'groupId'='group1' ...]);**

For example:

CREATE TABLE acidTbl (a int, b int) STORED AS ORC TBLPROPERTIES ('transactional'='true');

NOTE

- Currently, the transactions support only the ORC format.
- External tables are not supported.
- Sorted tables are not supported.
- To create a transaction table, you must add the table attribute **transactional'='true'**.
- The transaction table can be read and written only in transaction mode.

Use the transaction table.

Step 6 Run commands to use the transaction table. The following uses the **acidTbl** table as an example:

- Insert data into an existing transaction table:

  INSERT INTO acidTbl VALUES(1,1);

- Update an existing transaction table:

  UPDATE acidTbl SET b = 10 where a = 1;

  The content of **acidTbl** is changed to:

  ```
  +------------+------------+
  | acidtbl.a  | acidtbl.b  |
  +------------+------------+
  | 1          | 10         |
  +------------+------------+
  1 row selected (0.775 seconds)
  ```

- Merge the old and new transaction tables:

  The **acidTbl_update** table contains the following data:

  ```
  +--------------------+--------------------+
  | acidtbl_update.a   | acidtbl_update.b   |
  +--------------------+--------------------+
  | 1                  | 20                 |
  | 2                  | 10                 |
  +--------------------+--------------------+
  2 rows selected (0.537 seconds)
  ```

  MERGE INTO acidTbl AS a

  USING acidTbl_update AS b ON a.a = b.a

  WHEN MATCHED THEN UPDATE SET b = b. b

  WHEN NOT MATCHED THEN INSERT VALUES (b.a, b.b);

  The content of **acidTbl** is changed to:

  ```
  +------------+------------+
  | acidtbl.a  | acidtbl.b  |
  +------------+------------+
  | 1          | 20         |
  | 2          | 10         |
  +------------+------------+
  2 rows selected (0.666 seconds)
  ```

  NOTE

  If "Error evaluating cardinality_violation" is displayed when you run the **merge** command, check whether duplicate connection keys exist or run the **set hive.merge.cardinality.check=false** command to avoid this exception.

- Delete records from the transaction table.

  DELETE FROM acidTbl where a = 2;

  ```
  +------------+------------+
  | acidtbl.a  | acidtbl.b  |
  +------------+------------+
  | 1          | 20         |
  +------------+------------+
  1 row selected (1.253 seconds)
  ```

Checking the Transaction Execution Status

Step 7 Run the following command to check the transaction execution status:

- Check the lock:

  show locks;

- Check the compression task:

  show compactions;

- Check the task execution status:

  show transactions;

- Interrupt a transaction:

  abort transactions *TransactionId*;

  TransactionId is the value in the **Transaction ID** column in the command output of **Check the task execution status**.

----End

Configuring the Compression Function

HDFS does not support in-place file changing. For the new content, HDFS does not provide read consistency either. To provide these features on HDFS, we follow the standard approach used in other data warehouse tools: table or partition data is stored in a set of base files, and new, updated, as well as deleted records are stored in incremental files. Each transaction creates a new set of incremental files to change the table or partition. When read, the base files and the incremental files are merged and the changes of the update or deletion are applied.

Writing a transaction table generates some small files in HDFS. Hive provides major and minor compression policies for combining these small files.

Procedure of Automatic Compression

Step 1 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations** > **MetaStore(Role)** > **Transaction**.

Step 2 Set the following parameters as required:

Table 12-237 Parameter description

Parameter	Description
hive.compactor.check.interval	Interval of executing compression threads. Unit: second. Default value: **300**
hive.compactor.cleaner.run.interval	Interval of executing cleaning threads. Unit: millisecond. Default value: **5,000**.
hive.compactor.delta.num.threshold	Threshold of the number of incremental files that trigger minor compression. Default value: **10**

Parameter	Description
hive.compactor.delta.pct.threshold	Ratio threshold of the total size of incremental files (delta) that trigger Major compression to the size of base files. The value **0.1** indicates that Major compression is triggered when the ratio of the total size of delta files to the size of base files is 10%. Default value: **0.1**
hive.compactor.max.num.delta	Maximum number of incremental files that the compressor will attempt to process in a single job. Default value: **500**
metastore.compactor.initiator.on	Indicates whether to run the startup program thread and cleanup program thread on the MetaStore instance. The value must be **true**. Default value: **false**.
metastore.compactor.worker.threads	Number of compression program work threads running on MetaStore. If this parameter is set to **0**, no compression is performed. To use a transaction, you must set this parameter to a positive number on one or more instances of the MetaStore service. Unit: second Default value: **0**

Step 3 Log in to the Hive client and perform compression. For details, see **Using a Hive Client**.

```
CREATE TABLE table_name (
 id int, name string
)
CLUSTERED BY (id) INTO 2 BUCKETS STORED AS ORC
TBLPROPERTIES ("transactional"="true",
  "compactor.mapreduce.map.memory.mb"="2048",                    -- Specify the properties of a compression map job.
  "compactorthreshold.hive.compactor.delta.num.threshold"="4", -- If there are more than four incremental directories, slight compression is triggered.
  "compactorthreshold.hive.compactor.delta.pct.threshold"="0.5" -- If the ratio of the incremental file size to the basic file size is greater than 50%, deep compression is triggered.
);
```

or

```
ALTER TABLE table_name COMPACT 'minor' WITH OVERWRITE TBLPROPERTIES
("compactor.mapreduce.map.memory.mb"="3072"); -- Specify the properties of a compression map job.
ALTER TABLE table_name COMPACT 'major' WITH OVERWRITE TBLPROPERTIES
("tblprops.orc.compress.size"="8192");        -- Modify any other Hive table attributes.
```

NOTE

After compression, small files are not deleted immediately. After the cleaner thread performs cleaning, the files are deleted in batches.

----End

12.10.29 Switching the Hive Execution Engine to Tez

Scenario

Hive can use the Tez engine to process data computing tasks. Before executing a task, you can manually switch the execution engine to Tez.

Prerequisites

The TimelineServer role of the Yarn service has been installed in the cluster and is running properly.

Switching the Execution Engine on the Client to Tez

Step 1 Install and log in to the Hive client. For details, see **Using a Hive Client**.

Step 2 Run the following commands to switch the engine and enable the **yarn.timeline-service.enabled** parameter:

set hive.execution.engine=tez;

set yarn.timeline-service.enabled=true;

NOTE

- After **yarn.timeline-service.enabled** is enabled, you can view the details about the tasks executed by the Tez engine on TezUI. After this function is enabled, task information will be reported to TimelineServer. If the TimelineServer instance is faulty, the task will fail.
- Tez uses the ApplicationMaster buffer pool. Therefore, **yarn.timeline-service.enabled** must be enabled before Tez tasks are submitted. Otherwise, this parameter cannot take effect and you need to log in to the client again to configure it.
- When the execution engine needs to be switched to another engine, you need to run the **set yarn.timeline-service.enabled=false** command on the client to disable the **yarn.timeline-service.enabled** parameter.
- To specify a Yarn running queue, run the **set tez.queue.name=default** command on the client.

Step 3 Submit and execute the Tez tasks.

Step 4 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the desired cluster* > **Services** > **Tez** > **TezUI***(host name)* to view the task execution status on the TezUI page.

For versions earlier than MRS 3.x, log in to MRS Manager, choose **Services**, and click **Tez**. On the displayed page, click the link next to **Tez WebUI** to view the task execution status on the TezUI page.

----End

Switching the Default Execution Engine of Hive to Tez

Step 1 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations** > **HiveServer(Role)**, and search for **hive.execution.engine**.

For versions earlier than MRS 3.x, log in to MRS Manager, choose **Services**, and click **Hive**. On the displayed page, click the **Service Configuration** tab, select **All** from the **Type** drop-down list. On the navigation pane on the left, choose **HiveServer** and search for **hive.execution.engine**.

Step 2 Set **hive.execution.engine** to **tez**.

Step 3 Choose **Hive(Service)** > **Customization** and search for **yarn.site.customized.configs**.

Step 4 Add custom parameter **yarn.timeline-service.enabled** to **yarn.site.customized.configs** and set it to **true**.

NOTE

- After **yarn.timeline-service.enabled** is enabled, you can view the details about the tasks executed by the Tez engine on TezUI. After this function is enabled, task information will be reported to TimelineServer. If the TimelineServer instance is faulty, the task will fail.
- Tez uses the ApplicationMaster buffer pool. Therefore, **yarn.timeline-service.enabled** must be enabled before Tez tasks are submitted. Otherwise, this parameter cannot take effect and you need to log in to the client again to configure it.
- When the execution engine needs to be switched to another one, you need to set the value of parameter **yarn.timeline-service.enabled** to **false**.

Step 5 Click **Save**. In the displayed confirmation dialog box, click **OK**.

For versions earlier than MRS 3.x, click **Save Configuration** and click **Yes** in the displayed dialog box.

Step 6 Choose **Dashboard** > **More** > **Restart Service** to restart the Hive service. Enter the password to restart the service.

For versions earlier than MRS 3.x, Click the **Service Status** tab and choose **More** > **Restart Service** to restart the Hive service.

Step 7 Install and log in to the Hive client. For details, see **Using a Hive Client**.

Step 8 Submit and execute the Tez tasks.

Step 9 Log in to FusionInsight Manager and choose **Cluster** > *Name of the desired cluster* > **Services** > **Tez** > **TezUI***(host name)*. On the displayed TezUI page, view the task execution status.

For versions earlier than MRS 3.x, log in to MRS Manager, choose **Services**, and click **Tez**. On the displayed page, click the link next to **Tez WebUI** to view the task execution status on the TezUI page.

----End

12.10.30 Hive Materialized View

Introduction

A Hive materialized view is a special table obtained based on the query results of Hive internal tables. A materialized view can be considered as an intermediate table that stores actual data and occupies physical space. The tables on which a materialized view depends are called the base tables of the materialized view.

Materialized views are used to pre-compute and save the results of time-consuming operations such as table joining or aggregation. When executing a query, you can rewrite the query statement based on the base tables to the query statement based on materialized views. In this way, you do not need to perform time-consuming operations such as join and group by, thereby quickly obtaining the query result.

NOTE

- A materialized view is a special table that stores actual data and occupies physical space.
- Before deleting a base table, you must delete the materialized view created based on the base table.
- The materialized view creation statement is atomic, which means that other users cannot see the materialized view until all query results are populated.
- A materialized view cannot be created based on the query results of another materialized view.
- A materialized view cannot be created based on the results of a tableless query.
- You cannot insert, update, delete, load, or merge materialized views.
- You can perform complex query operations on materialized views, because they are special tables in nature.
- When the data of a base table is updated, you need to manually update the materialized view. Otherwise, the materialized view will retain the old data. That is, the materialized view expires.
- You can use the describe syntax to check whether the materialized view created based on ACID tables has expired.
- The describe statement cannot be used to check whether a materialized view created based on non-ACID tables has expired.
- A materialized view can store only ORC files. You can use TBLPROPERTIES ('transactional'='true') to create a transactional Hive internal table.

Creating a Materialized View

Syntax

```
CREATE MATERIALIZED VIEW [IF NOT EXISTS] [db_name.]materialized_view_name
  [COMMENT materialized_view_comment]
  DISABLE REWRITE
    [ROW FORMAT row_format]
    [STORED AS file_format]
      | STORED BY 'storage.handler.class.name' [WITH SERDEPROPERTIES (...)]
  ]
  [LOCATION hdfs_path]
  [TBLPROPERTIES (property_name=property_value, ...)]
AS
<query>;
```

NOTE

- Currently, the following materialized view file formats are supported: PARQUET, TextFile, SequenceFile, RCfile, and ORC. If **STORED AS** is not specified in the creation statement, the default file format is ORC.
- Names of materialized views must be unique in the same database. Otherwise, you cannot create a new materialized view, and data files of the original materialized view will be overwritten by the data files queried based on the base table in the new one. As a result, data may be tampered with. (After being tampered with, the materialized view can be restored by re-creating the materialized view.).

Cases

Step 1 Log in to the Hive client and run the following command to enable the following parameters. For details, see **Using a Hive Client**.

set hive.support.concurrency=true;

set hive.exec.dynamic.partition.mode=nonstrict;

set hive.txn.manager=org.apache.hadoop.hive.ql.lockmgr.DbTxnManager;

Step 2 Create a base table and insert data.

```
create table tb_emp(
empno int,ename string,job string,mgr int,hiredate TIMESTAMP,sal float,comm float,deptno int
)stored as orc
tblproperties('transactional'='true');

insert into tb_emp values(7369, 'SMITH', 'CLERK',7902, '1980-12-17 08:30:09',800.00,NULL,20),
(7499, 'ALLEN', 'SALESMAN',7698, '1981-02-20 17:12:00',1600.00,300.00,30),
(7521, 'WARD', 'SALESMAN',7698, '1981-02-22 09:05:34',1250.00,500.00,30),
(7566, 'JONES', 'MANAGER', 7839, '1981-04-02 10:14:13',2975.00,NULL,20),
(7654, 'MARTIN', 'SALESMAN',7698, '1981-09-28 08:36:17',1250.00,1400.00,30),
(7698, 'BLAKE', 'MANAGER',7839, '1981-05-01 11:12:55',2850.00,NULL,30),
(7782, 'CLARK', 'MANAGER',7839, '1981-06-09 15:45:28',2450.00,NULL,10),
(7788, 'SCOTT', 'ANALYST',7566, '1987-04-19 14:05:34',3000.00,NULL,20),
(7839, 'KING', 'PRESIDENT',NULL, '1981-11-17 10:18:25',5000.00,NULL,10),
(7844, 'TURNER', 'SALESMAN',7698, '1981-09-08 09:05:34',1500.00,0.00,30),
(7876, 'ADAMS', 'CLERK',7788, '1987-05-23 15:07:44',1100.00,NULL,20),
(7900, 'JAMES', 'CLERK',7698, '1981-12-03 16:23:56',950.00,NULL,30),
(7902, 'FORD', 'ANALYST',7566, '1981-12-03 08:48:17',3000.00,NULL,20),
(7934, 'MILLER', 'CLERK',7782, '1982-01-23 11:45:29',1300.00,NULL,10);
```

Step 3 Create a materialized view based on the results of the **tb_emp** query.

```
create materialized view group_mv disable rewrite
row format serde 'org.apache.hadoop.hive.serde2.JsonSerDe'
stored as textfile
tblproperties('mv_content'='Total compensation of each department')
as select deptno,sum(sal) sum_sal from tb_emp group by deptno;
```

----End

Applying a Materialized View

Rewrite the query statement based on base tables to the query statement based on materialized views to improve the query efficiency.

Cases

Execute the following query statement:

select deptno,sum(sal) from tb_emp group by deptno having sum(sal)>10000;

Based on the created materialized view, rewrite the query statement:

select deptno, sum_sal from group_mv where sum_sal>10000;

Checking a Materialized View

Syntax

SHOW MATERIALIZED VIEWS [IN database_name]
['identifier_with_wildcards'];

DESCRIBE [EXTENDED | FORMATTED] [db_name.]materialized_view_name;

Cases

show materialized views;

describe formatted group_mv;

Deleting a Materialized View

Syntax

DROP MATERIALIZED VIEW [db_name.]materialized_view_name;

Cases

drop materialized view group_mv;

Rebuilding a Materialized View

When a materialized view is created, the base table data is filled in the materialized view. However, the data that is added, deleted, or modified in the base table is not automatically synchronized to the materialized view. Therefore, you need to manually rebuild the view after updating the data.

Syntax

ALTER MATERIALIZED VIEW [db_name.]materialized_view_name REBUILD;

Cases

alter materialized view group_mv rebuild;

NOTE

When the base table data is updated but the materialized view data is not updated, the materialized view is in the expired state by default.

The describe statement can be used to check whether a materialized view created based on transaction tables has expired. If the value of **Outdated for Rewriting** is **Yes**, the license has expired. If the value of **Outdated for Rewriting** is **No**, the license has not expired.

12.10.31 Hive Log Overview

Log Description

Log path: The default save path of Hive logs is **/var/log/Bigdata/hive/***role name*, the default save path of Hive1 logs is **/var/log/Bigdata/hive1/***role name*, and the others follow the same rule.

- HiveServer: **/var/log/Bigdata/hive/hiveserver** (run log) and **var/log/Bigdata/audit/hive/hiveserver** (audit log)
- MetaStore: **/var/log/Bigdata/hive/metastore** (run log) and **/var/log/Bigdata/audit/hive/metastore** (audit log)
- WebHCat: **/var/log/Bigdata/hive/webhcat** (run log) and **/var/log/Bigdata/audit/hive/webhcat** (audit log)

Log archive rule: The automatic compression and archiving function of Hive is enabled. By default, when the size of a log file exceeds 20 MB (which is adjustable), the log file is automatically compressed. The naming rule of a compressed log file is as follows: <*Original log name*>-<*yyyy-mm-dd_hh-mm-ss*>.[*ID*].**log.zip** A maximum of 20 latest compressed files are reserved. The number of compressed files and compression threshold can be configured.

Table 12-238 Hive log list

Log Type	Log File Name	Description
Run log	/hiveserver/hiveserver.out	Log file that records HiveServer running environment information.
	/hiveserver/hive.log	Run log file of the HiveServer process.
	/hiveserver/hive-omm-*<Date>*-*<PID>*-gc.log.*<No.>*	GC log file of the HiveServer process.
	/hiveserver/prestartDetail.log	Work log file before the HiveServer startup.
	/hiveserver/check-serviceDetail.log	Log file that records whether the Hive service starts successfully
	/hiveserver/cleanupDetail.log	Cleanup log file about the HiveServer uninstallation
	/hiveserver/startDetail.log	Startup log file of the HiveServer process.
	/hiveserver/stopDetail.log	Shutdown log file of the HiveServer process.
	/hiveserver/localtasklog/omm_*<Date>*_*<Task ID>*.log	Run log file of the local Hive task.
	/hiveserver/localtasklog/omm_*<Date>*_*<Task ID>*-gc.log.*<No.>*	GC log file of the local Hive task.
	/metastore/metastore.log	Run log file of the MetaStore process.
	/metastore/hive-omm-*<Date>*-*<PID>*-gc.log.*<No.>*	GC log file of the MetaStore process.
	/metastore/postinstallDetail.log	Work log file after the MetaStore installation.
	/metastore/prestartDetail.log	Work log file before the MetaStore startup
	/metastore/cleanupDetail.log	Cleanup log file of the MetaStore uninstallation
	/metastore/startDetail.log	Startup log file of the MetaStore process.

Log Type	Log File Name	Description
	/metastore/stopDetail.log	Shutdown log file of the MetaStore process.
	/metastore/metastore.out	Log file that records MetaStore running environment information.
	/webhcat/webhcat-console.out	Log file that records the normal start and stop of the WebHCat process.
	/webhcat/webhcat-console-error.out	Log file that records the start and stop exceptions of the WebHCat process.
	/webhcat/prestartDetail.log	Work log file before the WebHCat startup.
	/webhcat/cleanupDetail.log	Cleanup logs generated during WebHCat uninstallation or before WebHCat installation
	/webhcat/hive-omm-<*Date*>-<PID>-gc.log.<*No.*>	GC log file of the WebHCat process.
	/webhcat/webhcat.log	Run log file of the WebHCat process
Audit log	hive-audit.log hive-rangeraudit.log	HiveServer audit log file
	metastore-audit.log	MetaStore audit log file.
	webhcat-audit.log	WebHCat audit log file.
	jetty-<Date>.request.log	Request logs of the jetty service.

Log Levels

Table 12-239 describes the log levels supported by Hive.

Levels of run logs are ERROR, WARN, INFO, and DEBUG from the highest to the lowest priority. Run logs of equal or higher levels are recorded. The higher the specified log level, the fewer the logs recorded.

Table 12-239 Log levels

Level	Description
ERROR	Logs of this level record error information about system running.
WARN	Logs of this level record exception information about the current event processing.
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record the system information and system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of the Yarn service by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 On the menu bar on the left, select the log menu of the target role.

Step 3 Select a desired log level and save the configuration.

NOTE

The Hive log level takes effect immediately after being configured. You do not need to restart the service.

----End

Log Formats

The following table lists the Hive log formats:

Table 12-240 Log formats

Log Type	Format	Example
Run log	<yyyy-MM-dd HH:mm:ss,SSS>| <LogLevel>|<Thread that generates the log>| <Message in the log>| <Location of the log event>	2014-11-05 09:45:01,242 | INFO | main | Starting hive metastore on port 21088 | org.apache.hadoop.hive.metastore.HiveMetaStore.main(HiveMetaStore.java:5198)

Log Type	Format	Example
Audit log	<yyyy-MM-dd HH:mm:ss,SSS>| <LogLevel>|<Thread that generates the log>|<User Name><User IP><Time><Operation><Resource><Result><Detail >|< Location of the log event >	2018-12-24 12:16:25,319 | INFO | HiveServer2-Handler-Pool: Thread-185 | UserName=hive UserIP=10.153.2.204 Time=2018/12/24 12:16:25 Operation=CloseSession Result=SUCCESS Detail= | org.apache.hive.service.cli.thrift.ThriftCLIService.logAuditEvent(ThriftCLIService.java:434)

12.10.32 Hive Performance Tuning

12.10.32.1 Creating Table Partitions

Scenario

During the Select query, Hive generally scans the entire table, which is time-consuming. To improve query efficiency, create table partitions based on service requirements and query dimensions.

Procedure

Step 1 For versions earlier than MRS 3.x:

Log in to the MRS console. In the left navigation pane, choose **Clusters** > **Active Clusters**, and click a cluster name. Choose **Nodes** > **Node**. The ECS page is displayed. Click **Remote Login** to log in to the Hive node.

For MRS 3.*x* or later:

Log in to the node where the Hive client has been installed as user **root**.

Step 2 Run the following command to go to the client installation directory, for example, **/opt/client**.

cd /opt/client

Step 3 Run the **source bigdata_env** command to configure environment variables for the client.

Step 4 Run the following command on the client for login:

kinit *Username*

Step 5 Run the following command to log in to the client tool:

beeline

Step 6 Select the static or dynamic partition.

- Static partition:

  Manually enter a partition name, and use the keyword **PARTITIONED BY** to specify partition column name and data type when creating a table. During application development, use the **ALTER TABLE ADD PARTITION** statement to add a partition and use the **LOAD DATA INTO PARTITION** statement to load data to the partition, which supports only static partitions.

- Dynamic partition: Use a query command to insert results to a partition of a table. The partition can be a dynamic partition.

  The dynamic partition can be enabled on the client tool by running the following command:

  set hive.exec.dynamic.partition=true;

  The default mode of the dynamic partition is strict. That is, at least a column must be specified as a static partition, under which dynamic sub-partitions can be created. You can run the following command to enable a completely dynamic partition:

  set hive.exec.dynamic.partition.mode=nonstrict;

NOTE

- The dynamic partition may cause a DML statement to create a large number of partitions and new mapping folders, which deteriorates system performance.
- If there are a large number of files, it takes a long time to run a SQL statement. You can run the **set mapreduce.input.fileinputformat.list-status.num-threads = 100;** statement before running a SQL statement to shorten the time. The parameter **mapreduce.input.fileinputformat.list-status.num-threads** can be set only after being added to the Hive whitelist.

----End

12.10.32.2 Optimizing Join

Scenario

When the Join statement is used, the command execution speed and query speed may be slow in case of large data volume. To resolve this problem, you can optimize Join.

Join optimization can be classified into the following modes:

- Map Join
- Sort Merge Bucket Map Join
- Optimizing Join Sequences

Map Join

Hive Map Join applies to small tables (the table size is less than 25 MB) that can be stored in the memory. The table size can be defined using **hive.mapjoin.smalltable.filesize**, and the default table size is 25 MB.

Map Join has two methods:

- Use /*+ MAPJOIN(join_table) */.

- Set the following parameter before running the statement. The default value is true in the current version.

  set hive.auto.convert.join=true;

There is no Reduce task when Map Join is used. Instead, a MapReduce Local Task is created before the Map job. The task uses TableScan to read small table data to the local computer, saves and writes the data in HashTable mode to a hard disk on the local computer, upload the data to DFS, and saves the data in distributed cache. The small table data that the map task reads from the local disk or distributed cache is the output together with the large table join result.

When using Map Join, make sure that the size of small tables cannot be too large. If small tables use up memory, the system performance will deteriorate and even memory leakage occurs.

Sort Merge Bucket Map Join

The following conditions must be met before using Sort Merge Bucket Map Join:

- The two Join tables are large and cannot be stored in the memory.
- The two tables are bucketed (clustered by (column)) and sorted (sorted by(column)) according to the join key, and the buckets counts of the two tables are in integral multiple relationship.

Set the following parameters to enable Sort Merge Bucket Map Join:

set hive.optimize.bucketmapjoin=true;

set hive.optimize.bucketmapjoin.sortedmerge=true;

This type of Map Join does not have Reduce tasks too. A MapReduce Local Task is started before the Map job to read small table data by bucket to the local computer. The local computer saves the HashTable backup of multiple buckets and writes the backup into HDFS. The backup is also saved in the distributed cache. The small table data that the map task reads from the local disk or distributed cache by bucket is the output after mapping with the large table.

Optimizing Join Sequences

If the Join operation is to be performed on three or more tables and different Join sequences are used, the execution time will be greatly different. Using an appropriate Join sequence can shorten the time for task execution.

Rules of a Join sequence:

- A table with small data volume or a combination with fewer results generated after a Join operation is executed first.
- A table with large data volume or a combination with more results generated after a Join operation is executed later.

For example, the **customer** table has the largest data volume, and fewer results will be generated if a Join operation is performed on the **orders** and **lineitem** tables first.

The original Join statement is as follows.

```
select
  l_orderkey,
```

```
  sum(l_extendedprice * (1 - l_discount)) as revenue,
  o_orderdate,
  o_shippriority
from
  customer,
  orders,
  lineitem
where
  c_mktsegment = 'BUILDING'
  and c_custkey = o_custkey
  and l_orderkey = o_orderkey
  and o_orderdate < '1995-03-22'
  and l_shipdate > '1995-03-22'
limit 10;
```

After the sequence is optimized, the Join statements are as follows:

```
select
  l_orderkey,
  sum(l_extendedprice * (1 - l_discount)) as revenue,
  o_orderdate,
  o_shippriority
from
  orders,
  lineitem,
  customer
where
  c_mktsegment = 'BUILDING'
  and c_custkey = o_custkey
  and l_orderkey = o_orderkey
  and o_orderdate < '1995-03-22'
  and l_shipdate > '1995-03-22'
limit 10;
```

Precautions

Join Data Skew Problem

Data skew refers to the symptom that the task progress is 99% for a long time.

Data skew often exists because the data volume of a few Reduce tasks is much larger than that of others. Most Reduce tasks are complete while a few Reduce tasks are not complete.

To resolve the data skew problem, set **hive.optimize.skewjoin=true** and adjust the value of **hive.skewjoin.key**. **hive.skewjoin.key** specifies the maximum number of keys received by a Reduce task. If the number reaches the maximum, the keys are atomically distributed to other Reduce tasks.

12.10.32.3 Optimizing Group By

Scenario

Optimize the Group by statement to accelerate the command execution and query speed.

During the Group by operation, Map performs grouping and distributes the groups to Reduce; Reduce then performs grouping again. Group by optimization can be performed by enabling Map aggregation to reduce Map output data volume.

Procedure

On a Hive client, set the following parameter:

```
set hive.map.aggr=true
```

Precautions

Group By Data Skew

Group by have data skew problems. When hive.groupby.skewindata is set to true, the created query plan has two MapReduce jobs. The Map output result of the first job is randomly distributed to Reduce tasks, and each Reduce task performs aggregation operations and generates output result. Such processing may distribute the same Group By Key to different Reduce tasks for load balancing purpose. According to the preprocessing result, the second Job distributes Group By Key to Reduce to complete the final aggregation operation.

Count Distinct Aggregation Problem

When the aggregation function count distinct is used in deduplication counting, serious Reduce data skew occurs if the processed value is empty. The empty value can be processed independently. If count distinct is used, exclude the empty value using the where statement and increase the last count distinct result by 1. If there are other computing operations, process the empty value independently and then combine the value with other computing results.

12.10.32.4 Optimizing Data Storage

Scenario

ORC is an efficient column storage format and has higher compression ratio and reading efficiency than other file formats.

You are advised to use **ORC** as the default Hive table storage format.

Prerequisites

You have logged in to the Hive client. For details, see **Using a Hive Client**.

Procedure

- Recommended: **SNAPPY** compression, which applies to scenarios with even compression ratio and reading efficiency requirements.

  Create table *xx (col_name data_type)* stored as orc tblproperties ("orc.compress"="SNAPPY");

- Available: **ZLIB** compression, which applies to scenarios with high compression ratio requirements.

  Create table *xx (col_name data_type)* stored as orc tblproperties ("orc.compress"="ZLIB");

NOTE

xx indicates the specific Hive table name.

12.10.32.5 Optimizing SQL Statements

Scenario

When SQL statements are executed on Hive, if the **(a&b) or (a&c)** logic exists in the statements, you are advised to change the logic to **a & (b or c)**.

Example

If condition a is **p_partkey = l_partkey**, the statements before optimization are as follows:

```
select
	sum(l_extendedprice* (1 - l_discount)) as revenue
from
	lineitem,
	part
where
	(
		p_partkey = l_partkey
		and p_brand = 'Brand#32'
		and p_container in ('SM CASE', 'SM BOX', 'SM PACK', 'SM PKG')
		and l_quantity >= 7 and l_quantity <= 7 + 10
		and p_size between 1 and 5
		and l_shipmode in ('AIR', 'AIR REG')
		and l_shipinstruct = 'DELIVER IN PERSON'
	)
	or
	(	p_partkey = l_partkey
		and p_brand = 'Brand#35'
		and p_container in ('MED BAG', 'MED BOX', 'MED PKG', 'MED PACK')
		and l_quantity >= 15 and l_quantity <= 15 + 10
		and p_size between 1 and 10
		and l_shipmode in ('AIR', 'AIR REG')
		and l_shipinstruct = 'DELIVER IN PERSON'
	)
	or
	(	p_partkey = l_partkey
		and p_brand = 'Brand#24'
		and p_container in ('LG CASE', 'LG BOX', 'LG PACK', 'LG PKG')
		and l_quantity >= 26 and l_quantity <= 26 + 10
		and p_size between 1 and 15
		and l_shipmode in ('AIR', 'AIR REG')
		and l_shipinstruct = 'DELIVER IN PERSON'
	)
```

The statements after optimization are as follows:

```
select
	sum(l_extendedprice* (1 - l_discount)) as revenue
from
	lineitem,
	part
where	p_partkey = l_partkey and
	((
		p_brand = 'Brand#32'
		and p_container in ('SM CASE', 'SM BOX', 'SM PACK', 'SM PKG')
		and l_quantity >= 7 and l_quantity <= 7 + 10
		and p_size between 1 and 5
		and l_shipmode in ('AIR', 'AIR REG')
		and l_shipinstruct = 'DELIVER IN PERSON'
	)
	or
	(
		p_brand = 'Brand#35'
		and p_container in ('MED BAG', 'MED BOX', 'MED PKG', 'MED PACK')
```

```
        and l_quantity >= 15 and l_quantity <= 15 + 10
        and p_size between 1 and 10
        and l_shipmode in ('AIR', 'AIR REG')
        and l_shipinstruct = 'DELIVER IN PERSON'
)
or
(
        p_brand = 'Brand#24'
        and p_container in ('LG CASE', 'LG BOX', 'LG PACK', 'LG PKG')
        and l_quantity >= 26 and l_quantity <= 26 + 10
        and p_size between 1 and 15
        and l_shipmode in ('AIR', 'AIR REG')
        and l_shipinstruct = 'DELIVER IN PERSON'
))
```

12.10.32.6 Optimizing the Query Function Using Hive CBO

Scenario

When joining multiple tables in Hive, Hive supports Cost-Based Optimization (CBO). The system automatically selects the optimal plan based on the table statistics, such as the data volume and number of files, to improve the efficiency of joining multiple tables. Hive needs to collect table statistics before CBO optimization.

NOTE

- The CBO optimizes the joining sequence based on statistics and search criteria. However, the joining sequence may fail to be optimized in some special scenarios, such as data skew occurs and query condition values are not in the table.
- When column statistics collection is enabled, Reduce operations must be performed for aggregation. For insert tasks without the Reduce phase, Reduce operations will be performed to collect statistics.
- This section applies to MRS 3.*x* or later.

Prerequisites

You have logged in to the Hive client. For details, see **Using a Hive Client**.

Procedure

Step 1 On the Manager UI, search for the **hive.cbo.enable** parameter in the service configuration of the Hive component, and select **true** to enable the function permanently.

Step 2 Collect statistics about the existing data in Hive tables manually.

Run the following command to manually collect statistics: Statistics about only one table can be collected. If statistics about multiple tables need to be collected, the command needs to be executed repeatedly.

ANALYZE TABLE [db_name.]tablename [PARTITION(partcol1[=val1], partcol2[=val2], ...)]

COMPUTE STATISTICS

[FOR COLUMNS]

[NOSCAN];

NOTE

- When **FOR COLUMNS** is specified, column-level statistics are collected.
- When NOSCAN is specified, statistics about the file size and number of files will be collected, but specific files will not be scanned.

For example:

analyze table table_name compute statistics;

analyze table table_name compute statistics for columns;

Step 3 Configure the automatic statistics collection function of Hive. After the function is enabled, new statistics will be collected only when you insert data by running the **insert overwrite/into** command.

- Run the following commands on the Hive client to enable the statistics collection function temporarily:

  set hive.stats.autogather = true; enables the automatic collection of table/partition-level statistics.

  set hive.stats.column.autogather = true; enables the automatic collection of column-level statistics.

  NOTE

  - The column-level statistics collection does not support complex data types, such as Map and Struct.
  - The automatic table-level statistics collection does not support Hive on HBase tables.

- On the Manager UI, search for the **hive.stats.autogather** and **hive.stats.column.autogather** parameters in the service configuration of Hive, and select **true** to enable the collection function permanently.

Step 4 Run the following command to view statistics:

DESCRIBE FORMATTED table_name[.column_name] PARTITION partition_spec;

For example:

desc formatted table_name;

desc formatted table_name id;

desc formatted table_name partition(time='2016-05-27');

NOTE

Partition tables only support partition-level statistics collection, so you must specify partitions to query statistics for partition tables.

----End

12.10.33 Common Issues About Hive

12.10.33.1 How Do I Delete UDFs on Multiple HiveServers at the Same Time?

Question

How can I delete permanent user-defined functions (UDFs) on multiple HiveServers at the same time?

Answer

Multiple HiveServers share one MetaStore database. Therefore, there is a delay in the data synchronization between the MetaStore database and the HiveServer memory. If a permanent UDF is deleted from one HiveServer, the operation result cannot be synchronized to the other HiveServers promptly.

In this case, you need to log in to the Hive client to connect to each HiveServer and delete permanent UDFs on the HiveServers one by one. The operations are as follows:

Step 1 Log in to the node where the Hive client is installed as the Hive client installation user.

Step 2 Run the following command to go to the client installation directory:

cd *Client installation directory*

For example, if the client installation directory is **/opt/client**, run the following command:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the following command to authenticate the user:

kinit *Hive service user*

NOTE

The login user must have the Hive admin rights.

Step 5 Run the following command to connect to the specified HiveServer:

beeline -u "jdbc:hive2:// *10.39.151.74*:*21066*/**default;sasl.qop=auth-conf;auth=KERBEROS;principal=***hive/hadoop.<system domain name>@<system domain name>*"

NOTE

- *10.39.151.74* is the IP address of the node where the HiveServer is located.
- *21066* is the port number of the HiveServer. The HiveServer port number ranges from 21066 to 21070 by default. Use the actual port number.
- *hive* is the username. For example, if the Hive1 instance is used, the username is **hive1**.
- You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and view the value of **Local Domain**, which is the current system domain name.
- **hive/hadoop.*<system domain name>*** is the username. All letters in the system domain name contained in the username are lowercase letters.

Step 6 Run the following command to enable the Hive admin rights:

set role admin;

Step 7 Run the following command to delete the permanent UDF:

drop function *function_name*;

NOTE

- *function_name* indicates the name of the permanent function.
- If the permanent UDF is created in Spark, the permanent UDF needs to be deleted from Spark and then from HiveServer by running the preceding command.

Step 8 Check whether the permanent UDFs are deleted from all HiveServers.

- If yes, no further action is required.
- If no, go to **Step 5**.

----End

12.10.33.2 Why Cannot the DROP operation Be Performed on a Backed-up Hive Table?

Question

Why cannot the **DROP** operation be performed for a backed up Hive table?

Answer

Snapshots have been created for an HDFS directory mapping to the backed up Hive table, so the HDFS directory cannot be deleted. As a result, the Hive table cannot be deleted.

When a Hive table is being backed up, snapshots are created for the HDFS directory mapping to the table. The snapshot mechanism of HDFS has the following limitation: If snapshots have been created for an HDFS directory, the directory cannot be deleted or renamed unless the snapshots are deleted. When the **DROP** operation is performed for a Hive table (except the EXTERNAL table), the system attempts to delete the HDFS directory mapping to the table. If the directory fails to be deleted, the system displays a message indicating that the table fails to be deleted.

If you need to delete this table, manually delete all backup tasks related to this table.

12.10.33.3 How to Perform Operations on Local Files with Hive User-Defined Functions

Question

How to perform operations on local files (such as reading the content of a file) with Hive user-defined functions?

Answer

By default, you can perform operations on local files with their relative paths in UDF. The following are sample codes:

```
public String evaluate(String text) {
  // some logic
  File file = new File("foo.txt");
  // some logic
  // do return here
}
```

In Hive, upload the file **foo.txt** used in UDF to HDFS, such as **hdfs://hacluster/tmp/foo.txt**. You can perform operations on the **foo.txt** file by creating UDF with the following sentences:

create function testFunc as 'some.class' using jar 'hdfs://hacluster/somejar.jar', file 'hdfs://hacluster/tmp/foo.txt';

In abnormal cases, if the value of **hive.fetch.task.conversion** is **more**, you can perform operations on local files in UDF by using absolute path instead of relative path. In addition, you must ensure that the file exists on all HiveServer nodes and NodeManager nodes and **omm** user have corresponding operation rights.

12.10.33.4 How Do I Forcibly Stop MapReduce Jobs Executed by Hive?

Question

How do I stop a MapReduce task manually if the task is suspended for a long time?

Answer

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Yarn**.

Step 3 On the left pane, click **ResourceManager(Host name, Active)**, and log in to Yarn.

Step 4 Click the button corresponding to the task ID. On the task page that is displayed, click **Kill Application** in the upper left corner and click **OK** in the displayed dialog box to stop the task.

----End

12.10.33.5 How Do I Monitor the Hive Table Size?

Question

How do I monitor the Hive table size?

Answer

The HDFS refined monitoring function allows you to monitor the size of a specified table directory.

Prerequisites

- The Hive and HDFS components are running properly.
- The HDFS refined monitoring function is normal.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Resource**.

Step 3 Click the first icon in the upper left corner of **Resource Usage (by Directory)**, as shown in the following figure.

Step 4 In the displayed sub page for configuring space monitoring, click **Add**.

Step 5 In the displayed **Add a Monitoring Directory** dialog box, set **Name** to the name or the user-defined alias of the table to be monitored and **Path** to the path of the monitored table. Click **OK**. In the monitoring result, the horizontal coordinate indicates the time, and the vertical coordinate indicates the size of the monitored directory.

----End

12.10.33.6 How Do I Prevent Key Directories from Data Loss Caused by Misoperations of the insert overwrite Statement?

Question

How do I prevent key directories from data loss caused by misoperations of the **insert overwrite** statement?

Answer

During monitoring of key Hive databases, tables, or directories, to prevent data loss caused by misoperations of the **insert overwrite** statement, configure **hive.local.dir.confblacklist** in Hive to protect directories.

This configuration item has been configured for directories such as **/opt/** and **/user/hive/warehouse** by default.

Prerequisites

The Hive and HDFS components are running properly.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**, and search for the **hive.local.dir.confblacklist** configuration item.

Step 3 Add paths of databases, tables, or directories to be protected in the parameter value.

Step 4 Click **Save** to save the settings.

----End

12.10.33.7 Why Is Hive on Spark Task Freezing When HBase Is Not Installed?

Scenario

This function applies to Hive.

Perform the following operations to configure parameters. When Hive on Spark tasks are executed in the environment where the HBase is not installed, freezing of tasks can be prevented.

NOTE

The Spark kernel version of Hive on Spark tasks has been upgraded to Spark2x. Hive on Spark tasks can be executed is Spark2x is not installed. If HBase is not installed, when Spark tasks are executed, the system attempts to connect to the ZooKeeper to access HBase until timeout occurs by default. As a result, task freezing occurs.

If HBase is not installed, perform the following operations to execute Hive on Spark tasks. If HBase is upgraded from an earlier version, you do not need to configure parameters after the upgrade.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Configurations** > **All Configurations**.

Step 3 Choose **HiveServer(Role)** > **Customization**. Add a customized parameter to the **spark-defaults.conf** parameter file. Set **Name** to **spark.security.credentials.hbase.enabled**, and set **Value** to **false**.

Step 4 Click **Save**. In the dialog box that is displayed, click **OK**.

Step 5 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Hive** > **Instance**, select all Hive instances, choose **More** > **Restart Instance**, enter the password, and click **OK**.

----End

12.10.33.8 Error Reported When the WHERE Condition Is Used to Query Tables with Excessive Partitions in FusionInsight Hive

Question

When a table with more than 32,000 partitions is created in Hive, an exception occurs during the query with the WHERE partition. In addition, the exception information printed in **metastore.log** contains the following information:

```
Caused by: java.io.IOException: Tried to send an out-of-range integer as a 2-byte value: 32970
    at org.postgresql.core.PGStream.SendInteger2(PGStream.java:199)
    at org.postgresql.core.v3.QueryExecutorImpl.sendParse(QueryExecutorImpl.java:1330)
    at org.postgresql.core.v3.QueryExecutorImpl.sendOneQuery(QueryExecutorImpl.java:1601)
    at org.postgresql.core.v3.QueryExecutorImpl.sendParse(QueryExecutorImpl.java:1191)
    at org.postgresql.core.v3.QueryExecutorImpl.execute(QueryExecutorImpl.java:346)
```

Answer

During a query with partition conditions, HiveServer optimizes the partitions to avoid full table scanning. All partitions whose metadata meets the conditions need to be queried. However, the **sendOneQuery** interface provided by GaussDB limits the parameter value to **32767** in the **sendParse** method. If the number of partition conditions exceeds **32767**, an exception occurs.

12.10.33.9 Why Cannot I Connect to HiveServer When I Use IBM JDK to Access the Beeline Client?

Scenario

When users check the JDK version used by the client, if the JDK version is IBM JDK, the Beeline client needs to be reconstructed. Otherwise, the client will fail to connect to HiveServer.

Procedure

Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **User**. In the **Operation** column of the target user, choose **More** > **Download Authentication Credential**, select the cluster information, and click **OK** to download the keytab file.

Step 2 Decompress the keytab file and use WinSCP to upload the decompressed **user.keytab** file to the Hive client installation directory on the node to be operated, for example, **/opt/client**.

Step 3 Run the following command to open the **Hive/component_env** configuration file in the Hive client directory:

vi *Hive client installation directory*/**Hive/component_env**

Add the following content to the end of the line where **export CLIENT_HIVE_URI** is located:

```
\; user.principal=Username @HADOOP.COM\;user.keytab=user.keytab file path/user.keytab
```

----End

12.10.33.10 Description of Hive Table Location (Either Be an OBS or HDFS Path)

Question

Can Hive tables be stored in OBS or HDFS?

Answer

1. The location of a common Hive table stored on OBS can be set to an HDFS path.
2. In the same Hive service, you can create tables stored in OBS and HDFS, respectively.
3. For a Hive partitioned table stored on OBS, the location of the partition cannot be set to an HDFS path. (For a partitioned table stored on HDFS, the location of the partition cannot be changed to OBS.)

12.10.33.11 Why Cannot Data Be Queried After the MapReduce Engine Is Switched After the Tez Engine Is Used to Execute Union-related Statements?

Question

Hive uses the Tez engine to execute union-related statements to write data. After Hive is switched to the MapReduce engine for query, no data is found.

Answer

When Hive uses the Tez engine to execute the union-related statement, the generated output file is stored in the **HIVE_UNION_SUBDIR** directory. After Hive is switched back to the MapReduce engine, files in the directory are not read by default. Therefore, data in the **HIVE_UNION_SUBDIR** directory is not read.

In this case, you can set **mapreduce.input.fileinputformat.input.dir.recursive** to **true** to enable union optimization and determine whether to read data in the directory.

12.10.33.12 Why Does Hive Not Support Concurrent Data Writing to the Same Table or Partition?

Question

Why Does Data Inconsistency Occur When Data Is Concurrently Written to a Hive Table Through an API?

Answer

Hive does not support concurrent data insertion for the same table or partition. As a result, multiple tasks perform operations on the same temporary data directory, and one task moves the data of another task, causing task data exception. The service logic is modified so that data is inserted to the same table or partition in single thread mode.

12.10.33.13 Why Does Hive Not Support Vectorized Query?

Question

When the vectorized parameter **hive.vectorized.execution.enabled** is set to **true**, why do some null pointers or type conversion exceptions occur occasionally when Hive on Tez/MapReduce/Spark is executed?

Answer

Currently, Hive does not support vectorized execution. Many community issues are introduced during vectorized execution and are not resolved stably. The default value of **hive.vectorized.execution.enabled** is **false**. You are advised not to set this parameter to **true**.

12.10.33.14 Why Does Metadata Still Exist When the HDFS Data Directory of the Hive Table Is Deleted by Mistake?

Question

The HDFS data directory of the Hive table is deleted by mistake, but the metadata still exists. As a result, an error is reported during task execution.

Answer

This is a exception caused by misoperation. You need to manually delete the metadata of the corresponding table and try again.

Example:

Run the following command to go to the console:

source ${BIGDATA_HOME}/FusionInsight_BASE_8.1.0.1/install/FusionInsight-dbservice-2.7.0/.dbservice_profile

gsql -p 20051 -U hive -d hivemeta -W HiveUser@

Run the **delete from tbls where tbl_id='xxx';** command.

12.10.33.15 How Do I Disable the Logging Function of Hive?

Question

How do I disable the logging function of Hive?

Answer

Step 1 Log in to the node where the client is installed as user **root**.

Step 2 Run the following command to switch to the client installation directory, for example, **/opt/Bigdata/client**:

cd /opt/Bigdata/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Log in to the Hive client based on the cluster authentication mode.

- In security mode, run the following command to complete user authentication and log in to the Hive client:

  kinit *Component service user*

  beeline

- In normal mode, run the following command to log in to the Hive client:
  - Run the following command to log in to the Hive client as the component service user:

    beeline -n *component service user*

  - If no component service user is specified, the current OS user is used to log in to the Hive client.

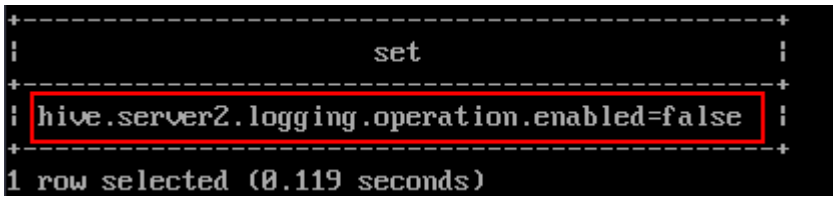
    beeline

Step 5 Run the following command to disable the logging function:

set hive.server2.logging.operation.enabled=false;

Step 6 Run the following command to check whether the logging function is disabled. If the following information is displayed, the logging function is disabled successfully.

set hive.server2.logging.operation.enabled;



----End

12.10.33.16 Why Hive Tables in the OBS Directory Fail to Be Deleted?

Question

In the scenario where the fine-grained permission is configured for multiple MRS users to access OBS, after the permission for deleting Hive tables in the OBS directory is added to the custom configuration of Hive, tables are deleted on the Hive client but still exist in the OBS directory.

Answer

You do not have the permission to delete directories on OBS. As a result, Hive tables cannot be deleted. In this case, modify the custom IAM policy of the agency and configure Hive with the permission for deleting tables in the OBS directory.

12.10.33.17 Hive Configuration Problems

- The error message "java.lang.OutOfMemoryError: Java heap space." is displayed during Hive SQL execution.

  Solution:

  - For MapReduce tasks, increase the values of the following parameters:

    set mapreduce.map.memory.mb=8192;

    set mapreduce.map.java.opts=-Xmx6554M;

    set mapreduce.reduce.memory.mb=8192;

    set mapreduce.reduce.java.opts=-Xmx6554M;
  - For Tez tasks, increase the value of the following parameter:

    set hive.tez.container.size=8192;
- After a column name is changed to a new one using the Hive SQL **as** statement, the error message "Invalid table alias or column reference 'xxx'." is displayed when the original column name is used for compilation.

  Solution: Run the **set hive.cbo.enable=true;** statement.
- The error message "Unsupported SubQuery Expression 'xxx': Only SubQuery expressions that are top level conjuncts are allowed." is displayed during Hive SQL subquery compilation.

  Solution: Run the **set hive.cbo.enable=true;** statement.
- The error message "CalciteSubquerySemanticException [Error 10249]: Unsupported SubQuery Expression Currently SubQuery expressions are only allowed as Where and Having Clause predicates." is displayed during Hive SQL subquery compilation.

  Solution: Run the **set hive.cbo.enable=true;** statement.
- The error message "Error running query: java.lang.AssertionError: Cannot add expression of different type to set." is displayed during Hive SQL compilation.

  Solution: Run the **set hive.cbo.enable=false;** statement.
- The error message "java.lang.NullPointerException at org.apache.hadoop.hive.ql.udf.generic.GenericUDAFComputeStats $GenericUDAFNumericStatsEvaluator.init." is displayed during Hive SQL execution.

  Solution: Run the **set hive.map.aggr=false;** statement.
- When **hive.auto.convert.join** is set to **true** (enabled by default) and **hive.optimize.skewjoin** is set to **true**, the error message "ClassCastException org.apache.hadoop.hive.ql.plan.ConditionalWork cannot be cast to org.apache.hadoop.hive.ql.plan.MapredWork" is displayed.

  Solution: Run the **set hive.optimize.skewjoin=false;** statement.
- When **hive.auto.convert.join** is set to **true** (enabled by default), **hive.optimize.skewjoin** is set to **true**, and **hive.exec.parallel** is set to **true**, the error message "java.io.FileNotFoundException: File does not exist:xxx/reduce.xml" is displayed.

  Solution:

  - Method 1: Switch the execution engine to Tez. For details, see **Switching the Hive Execution Engine to Tez**.
  - Method 2: Run the **set hive.exec.parallel=false;** statement.

  - Method 3: Run the **set hive.auto.convert.join=false;** statement.
- Eerror message "NullPointerException at org.apache.hadoop.hive.ql.exec.CommonMergeJoinOperator.mergeJoinComputeKeys" is displayed when Hive on Tez executes bucket map join.

  Solution: Run the **set tez.am.container.reuse.enabled=false;** statement.

12.11 Using Hue (Versions Earlier Than MRS 3.x)

12.11.1 Using Hue from Scratch

Hue provides the file browser function using a graphical user interface (GUI) so that you can view files and directories on Hive.

Prerequisites

You have installed Hive and Hue, and the Kerberos authentication cluster in the running state.

Procedure

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 Open the Hue web UI and choose **Query Editors** > **Hive**.

Step 3 In **Databases**, select a Hive database, the default database is **default**.

The system displays all available tables. You can enter a keyword of the table name to search for the desired table.

Step 4 Click the desired table name. All columns in the table are displayed.

Step 5 Enter the HiveQL statements in the area for editing.

create table hue_table(id int,name string,company string) row format delimited fields terminated by ',' stored as textfile;

Click  and select **Explain**. The editor checks the syntax and execution plan of the entered HiveQL statements. If the statements have syntax errors, the editor reports **Error while compiling statement**.

Step 6 Click , and select the engine for executing the HiveQL statements.

Step 7 Click  to execute the HiveQL statements.

Step 8 In the command text box, enter **show tables;** and click  . Check whether the **hue-table** table created in **Step 5** exists in the result.

----End

12.11.2 Accessing the Hue Web UI

Scenario

After Hue is installed in an MRS cluster, users can use Hadoop and Hive on the Hue web UI.

This section describes how to open the Hue web UI on the MRS cluster.

NOTE

To access the Hue web UI, you are advised to use a browser that is compatible with the Hue WebUI, for example, Google Chrome 50. The Internet Explorer may be incompatible with the Hue web UI.

Impact on the System

Site trust must be added to the browser when you access Manager and Hue web UI for the first time. Otherwise, the Hue web UI cannot be accessed.

Prerequisites

When Kerberos authentication is enabled, the MRS cluster administrator has assigned the permission for using Hive to the user. For details, see "MRS Manager Operation Guide" > "Permission Management" > "Creating a User" in *MapReduce Service User Guide*. For example, create a human-machine user named **hueuser**, add the user to user groups **hive** (the primary group), **hadoop**, and **supergroup**, and role **System_administrator**.

This user is used to log in to the Hue WebUI.

Procedure

Step 1 Log in to the service page, click the cluster name to go to the cluster details page, and choose **Components**.

NOTE

If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Step 2 Select **Hue**. On the right side of **Hue WebUI**, click the link to log in to the Hue web UI as user **hueuser**.

Hue WebUI provides the following functions:

- If Hive is installed in the MRS cluster, you can use **Query Editors** to execute query statements of Hive. Hive has been installed in the MRS cluster.
- If Hive is installed in the MRS cluster, you can use **Data Browsers** to manage Hive tables.
- If HDFS is installed in the MRS cluster, you can use  to view directories and files in HDFS.
- If Yarn is installed in the MRS cluster, you can use  to view all jobs in the MRS cluster.

NOTE

- When you log in to the Hue web UI as user **hueuser** for the first time, you need to change the password.
- After obtaining the URL for accessing the Hue web UI, you can give the URL to other users who cannot access MRS Manager for accessing the Hue web UI.
- If you perform operations on the Hue WebUI only but not on Manager, you must enter the password of the current login user when accessing Manager again.

----End

12.11.3 Hue Common Parameters

Navigation Path

For details about how to set parameters, see **Modifying Cluster Service Configuration Parameters**.

Parameters

Table 12-241 Hue common parameters

Parameter	Description	Default Value	Value Range
HANDLER_ACCESSLOG_LEVEL	Hue access log level	DEBUG	• ERROR • WARN • INFO • DEBUG
HANDLER_AUDITSLOG_LEVEL	Hue audit log level	DEBUG	• ERROR • WARN • INFO • DEBUG
HANDLER_ERRORLOG_LEVEL	Hue error log level	ERROR	• ERROR • WARN • INFO • DEBUG
HANDLER_LOGFILE_LEVEL	Hue run log level	INFO	• ERROR • WARN • INFO • DEBUG
HANDLER_LOGFILE_MAXBACKUPINDEX	Maximum number of Hue log files.	20	1 to 999
HANDLER_LOGFILE_SIZE	Maximum size of a Hue log file.	5 MB	-

12.11.4 Using HiveQL Editor on the Hue Web UI

Scenario

Users can use the Hue web UI to execute HiveQL statements in a cluster.

Accessing Query Editors

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 Choose **Query Editors** > **Hive**. The **Hive** page is displayed.

Hive supports the following functions:

- Executes and manages HiveQL statements.
- View the HiveQL statements saved by the current user in **Saved Queries**.
- Query HiveQL statements executed by the current user in **Query History**.
- Click  to display all databases included in **Databases** of Hive.

----End

Executing HiveQL Statements

Step 1 Choose **Query Editors > Hive**. The **Hive** page is displayed.

Step 2 Click  and select a database from **Databases**. The default database is **default**.

The system displays all available tables in the database. You can enter a keyword of the table name to search for the desired table.

Step 3 Click the desired table name. All columns in the table are displayed.

Move the cursor to the row of the table and click  . Column details are displayed.

Step 4 Enter the query statements in the area for editing HiveQL statements.

Click  and select **Explain**. The editor checks the syntax and execution plan of the entered statements. If the statements have syntax errors, the editor reports **Error while compiling statement**.

Step 5 Click and select the engine for executing the HiveQL statements.

- **mr**: MapReduce computing framework
- **spark**: Spark computing framework
- **tez**: Tez computing framework

  NOTE

  Tez is applicable to MRS 1.9.*x* and later versions.

Step 6 Click  to execute the HiveQL statements.

NOTE

- If you want to use the entered HiveQL statements again, click to save them.
- To format HiveQL statements, click and select **Format**.
- To delete an entered HiveQL statement, click and select **Clear**.
- Clear the entered statement and execute a new statement. Click and select **New query**.
- Viewing history:

  Click **Query History** to view the HiveQL running status. You can view the history of all the statements or only the saved statements. If many historical records exist, you can enter keywords in the text box to search for desired records.
- Advanced query configuration:

  Click in the upper right corner to configure information such as files, functions, and settings.
- Viewing the information of shortcut keys:

  Click in the upper right corner to view all shortcut keys.

----End

Viewing Execution Results

Step 1 In the **Hive** execution area, **Query History** is displayed by default.

Step 2 Click **Results** to view the execution result of the executed statement.

----End

Managing Query Statements

Step 1 Choose **Query Editors > Hive**. The **Hive** page is displayed.

Step 2 Click **Saved Queries**.

Click a saved statement. The system automatically adds the statement to the editing area.

----End

Modifying Query Editors Settings

Step 1 On the **Hive** tab page, click .

Step 2 Click on the right of **Files** and click to specify the directory for storing the file.

You can click to add a file resource.

Step 3 Click on the right of **Functions** and enter the names of user-defined function and function class.

You can click  to add a customized function.

Step 4 Click  on the right of **Settings**, enter the Hive parameter name in the **Key**, and value in **Value**. The current Hive session connects to Hive based on the customized configuration.

You can click  to add a parameter.

----End

12.11.5 Using the Metadata Browser on the Hue Web UI

Scenario

Users can use the Hue web UI to manage Hive metadata in an MRS cluster.

Using Metastore Manager

Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Choose **Data Browsers** > **Metastore Tables**, and access **Metastore Manager**.

- Viewing metadata of Hive tables

  In the left navigation pane, move the cursor to a table and click  on the right. The metadata of the Hive table is displayed.

- Managing metadata of Hive tables

  On the metadata page of a Hive table, you can click  in the upper right corner to import data, click  to browse data, and click  to view the location of the table file.

  ⚠ CAUTION

  The Hue page is used to view and analyze data such as files and tables. Do not perform high-risk management operations such as deleting objects on the page. If an operation is required, you are advised to perform the operation on each component after confirming that the operation has no impact on services. For example, you can use the HDFS client to perform operations on HDFS files and use the Hive client to perform operations on Hive tables.

- Managing Hive metadata tables

  Click  in the upper right corner to create a table in the database based on the uploaded files. Or click  in the upper right corner to manually create a table.

Accessing Metastore Manager

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 Choose **Data Browsers** > **Metastore Tables**, and access **Metastore Manager**.

Metastore Manager supports the following functions:

- Creating a Hive table from a file
- Manually creating a Hive table
- Viewing Hive table metadata

----End

Creating a Hive table from a File

Step 1 Access **Metastore Manager** and select a database in **Databases**.

The default database is **default**.

Step 2 Click  . The **Create a new table from a file** page is displayed.

Step 3 Select a file.

1. In **Table Name**, enter a Hive table name.

   A Hive table name contains no more than 128 characters, including letters, numbers, or underscores (_), and must start with a letter or number.
2. In **Description**, enter description about the Hive table as required.
3. In **Input File or Location**, click and select a Hive table file from HDFS. The file is used to store new data of the Hive table.

   If the file is not stored in HDFS, click **Upload a file** to upload the file from the local directory to HDFS. Multiple files can be simultaneously uploaded. The files cannot be empty.
4. If you need to import the data in the file to the Hive table, select **Import data** as **Load method**. By default, **Import data** is selected.

   If you select **Create External Table**, a Hive external table is created.

   NOTE

   If you select **Create External Table**, set **Input File or Location** to a path.

   If you select **Leave Empty**, an empty Hive table is created.
5. Click **Next**.

Step 4 Set a delimiter.

1. In **Delimiter**, select one.

   If your desired delimiter is not in the list, select **Other..** and enter a delimiter.
2. Click **Preview** to preview data processing.
3. Click **Next**.

Step 5 Define a column.

1. If you click on the right side of **Use first row as column names**, the first row of data in the file is used as a column name. If you do not click it, the first row of data is not used as the column name.
2. In **Column name**, set a name for each column.

   A Hive table name contains no more than 128 characters, including letters, numbers, or underscores (_), and must start with a letter or number.

   NOTE

   You can rename columns in batches by clicking on the right side of **Bulk edit column names**. Enter all column names and separate them by commas (,).
3. In **Column Type**, select a type for each column.

Step 6 Click **Create Table** to create the table. Wait for Hue to display information about the Hive table.

----End

Manually Creating a Hive Table

Step 1 Access **Metastore Manager** and select a database in **Databases**.

The default database is **default**.

Step 2 Click . The **Create a new table manually** page is displayed.

Step 3 Set a table name.

1. In **Table Name**, enter a Hive table name.

   A Hive table name contains no more than 128 characters, including letters, numbers, or underscores (_), and must start with a letter or number.
2. In **Description**, enter description about the Hive table as required.
3. Click **Next**.

Step 4 Select a data storage format.

- If data needs to be separated by delimiters, select **Delimited** and perform **Step 5**.
- If data needs to be stored in serialization format, select **SerDe** and perform **Step 6**.

Step 5 Set a delimiter.

1. In **Field terminator**, set a column delimiter.

   If your desired delimiter is not in the list, select **Other..** and enter a delimiter.
2. In **Collection terminator**, set a delimiter to separate the data set of columns of the **array** type in Hive. For example, the type of a column is array. A value needs to store **employee** and **manager**. The user specifies a colon (**:**) as the delimiter. Therefore, the final value is **employee:manager**.
3. In **Map key terminator**, set a delimiter to separate the data set of columns of the **map** type in Hive. For example, the type of a column is map. A value needs to store **home** of **aaa** and **company** of **bbb**. The user defines **|** as the delimiter. Therefore, the final value is **home|aaa:company|bbb**.

4. Click **Next** and perform **Step 7**.

Step 6 Set serialization properties.

1. In **SerDe Name**, enter the class name of the serialization format: **org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe**

   Users can expand Hive to support more customized serialization classes.
2. In **Serde properties**, enter the value of the serialization format: **"field.delim"="," "colelction.delim"=":" "mapkey.delim"="|"**
3. Click **Next** and perform **Step 7**.

Step 7 Select a data table format and click **Next**.

- **TextFile**: indicates that data is stored in text files.
- **SequenceFile**: indicates that data is stored in binary files.
- **InputFormat**: indicates that data in files is used in the customized input and output formats.

  Users can expand Hive to support more customized formatting classes.

  a. In **InputFormat Class**, enter the class used by input data: **org.apache.hadoop.hive.ql.io.RCFileInputFormat**

  b. In **OutputFormat Class**, enter the class used by output data: **org.apache.hadoop.hive.ql.io.RCFileOutputFormat**

Step 8 Select a file storage location and click **Next**.

Use default location is selected by default. If you want to customize a storage location, deselect the default value and specify a file storage location in **External location** by clicking .

Step 9 Set columns of the Hive table.

1. In **Column name**, set a column name.

   A Hive table name contains no more than 128 characters, including letters, numbers, or underscores (_), and must start with a letter or number.
2. In **Column type**, select a type for each column.

   Click **Add a column** to add a new column.
3. Click **Add a partition** to add a new partition for the Hive table to improve the query efficiency.

Step 10 Click **Create Table** to create a new table. Wait for Hue to display information about the Hive table.

----End

Managing the Hive Table

Step 1 Access **Metastore Manager** and select a database in **Databases**. All tables in the database are displayed on the page.

The default database is **default**.

Step 2 Click a table name in the database to view table details.

The following operations are supported: importing data, browsing data,, or viewing file storage location. When viewing all tables in the database, you can

select tables and perform the following operations such as viewing tables and browsing data.

CAUTION

The Hue page is used to view and analyze data such as files and tables. Do not perform high-risk management operations such as deleting objects on the page. If an operation is required, you are advised to perform the operation on each component after confirming that the operation has no impact on services. For example, you can use the HDFS client to perform operations on HDFS files and use the Hive client to perform operations on Hive tables.

----End

12.11.6 Using File Browser on the Hue Web UI

Scenario

Users can use the Hue web UI to manage files in HDFS in a cluster.

CAUTION

The Hue page is used to view and analyze data such as files and tables. Do not perform high-risk management operations such as deleting objects on the page. If an operation is required, you are advised to perform the operation on each component after confirming that the operation has no impact on services. For example, you can use the HDFS client to perform operations on HDFS files and use the Hive client to perform operations on Hive tables.

File Browser (File Browser)

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 Click  . The **File Browser** page is displayed.

You can view the home directory of the current login user.

On the **File Browser** page, the following information about subdirectories for files in the directory is displayed.

Table 12-242 HDFS file attributes

Attribute	Description
Name	Name of a directory or file
Size	File size
User	Owner of a directory or file
Group	Group of a directory or file

Attribute	Description
Permissions	Permission of a directory or file
Date	Time when a directory or file is created

Step 3 In the search box, enter a keyword. The system automatically searches directories or files in the current directory.

Step 4 Clear the search criteria. The system displays all directories or files.

----End

Performing Actions

Step 1 Click  and select one or more directories or files.

Step 2 Click **Actions**. On the menu that is displayed, select an operation.

- **Rename**: renames a directory or file.
- **Move**: moves a file. In **Move to**, select a new directory and click **Move**.
- **Copy**: copies the selected files or directories.
- **Change permissions**: changes permission to access the selected directory or file.
  - You can grant the owner, the group, or other users with the **Read**, **Write**, and **Execute** permissions.
  - **Sticky**: indicates that only HDFS administrators, directory owners, and file owners can move files in the directory.
  - **Recursive**: indicates that permission is granted to subdirectories recursively.
- **Storage policies**: indicates the policies for storing files or directories in HDFS.
- **Summary**: indicates that you can view HDFS storage information about the selected file or directory.

----End

Accessing Other Directories

Step 1 Click the directory name, type a full path you want to access, for example, **/mr-history/tmp**, and press **Enter**.

The current user must have permission to access other directories.

Step 2 Click **Home** to go to the home directory.

Step 3 Click **History**. The history records of directory access are displayed and the directories can be accessed again.

Step 4 Click **Trash** to access the recycle bin of the current directory.

Click **Empty Trash** to clean up the recycle bin.

----End

Uploading User Files

Step 1 Click  and click **Upload**.

Step 2 Select an operation.

- **Files**: uploads user files to the current user.
- **Zip/Tgz/Bz2 file**: uploads a compressed file. In the dialog box that is displayed, click **Select ZIP, TGZ or BZ2 files** to select the compressed file to be uploaded. The system automatically decompresses the file in HDFS. Compressed files in **ZIP**, **TGZ**, and **BZ2** formats are supported.

----End

Creating a New File or Directory

Step 1 Click  and click **New**.

Step 2 Select an operation.

- **File**: creates a file. Enter a file name and click **Create**.
- **Directory**: creates a directory. Enter a directory name and click **Create**.

----End

Storage Policy Definition and Usage

NOTE

If the value of Hue parameter **fs_defaultFS** is set to **viewfs://ClusterX**, the big data storage policy cannot be enabled.

Step 1 Log in to MRS Manager.

Step 2 On MRS Manager, choose **System** > **Permission > Manage Role** > **Create Role**.

1. Set **Role Name**.
2. Choose **Configure Resource Permission > Hue**, select **Storage Policy Admin**, and click **OK** to grant the storage policy administrator permission to the role.

Step 3 Choose **System** > **Permission** > **Manage User Group** > **Create User Group**, set **Group Name**, and click **Select and Add Role** next to **Role**. On the displayed page, select the created role and click **OK** to add the role to the group.

Step 4 Choose **System** > **Permission** > **Manage User** > **Create User**.

1. Specify the **Username** of a user who can log in to the Hue web UI and has the **Storage Policy Admin** permission.
2. Set **User Type** to **Human-machine**.
3. Set **Password** and **Confirm Password** for logging in to the Hue web UI.
4. Click **Select and Join User Group** next to **User Group**. On the page that is displayed, select the created user group, **supergroup**, **hadoop**, and **hive**, and click **OK**.
5. Set **Primary Group** to **hive**.

6. Click **Select and Add Role** on the right of **Assign Rights by Role**. On the Select snf page that is displayed, select the newly created role and the **System_administrator** role, and click **OK**.
7. Click **OK**. The user is added successfully.

Step 5 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 6 Click  in the upper right corner.

Step 7 Select the check box of the directory and click **Action** on the upper part of the page. Then select **Storage policies**.

Step 8 In the dialog box that is displayed, set a new storage policy and click **OK**.

----End

12.11.7 Using Job Browser on the Hue Web UI

Scenario

You can use the Hue web UI to query all jobs in the cluster.

Accessing Job Browser

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 Click **Job Browser**.

View the jobs in the cluster.

NOTE

The number on **Job Browser** indicates the total number of jobs in the cluster.

Job Browser displays the following job information.

Table 12-243 MRS job attributes

Attribute	Description
Logs	Log information. If a job has logs, is displayed.
ID	Job ID, which is generated by the system automatically.
Name	Job name
Application Type	Job type
Status	Job status. Possible values are **RUNNING**, **SUCCEEDED**, **FAILED**, and **KILLED**.
User	User who starts the job
Maps	Map progress
Reduces	Reduce progress

Attribute	Description
Queue	Yarn queue used for job running
Priority	Job running priority
Duration	Job running duration
Submitted	Time when the job is submitted to the MRS cluster

NOTE

If the MRS cluster has Spark, the **Spark-JDBCServer** job is started by default to execute tasks.

----End

Searching for Jobs

Step 1 Enter keywords in **Username** or **Text** on the **Job Browser** page to search for the desired jobs.

Step 2 Clear the search criteria. The system displays all jobs.

----End

Querying Job Details

Step 1 In the job list on the **Job Browser** page, click the row that contains the desired job to view details.

Step 2 On the **Metadata** tab page, you can view the metadata of the job.

NOTE

You can click to open job running logs.

----End

12.12 Using Hue (MRS 3.*x* or Later)

12.12.1 Using Hue from Scratch

Hue aggregates interfaces which interact with most Apache Hadoop components and enables you to use Hadoop components with ease on a web UI. You can operate components such as HDFS, Hive, HBase, Yarn, MapReduce, Oozie, and Spark SQL on the Hue web UI.

Prerequisites

You have installed Hue, and the Kerberos authentication cluster is in the running state.

Procedure

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 In the navigation tree on the left, click the editor icon  and choose **Hive**.

Step 3 Select a Hive database from the **Database** drop-down list box. The default database is **default**.

The system displays all available tables. You can enter a keyword of the table name to search for the desired table.

Step 4 Click the desired table name. All columns in the table are displayed.

Step 5 Enter the HiveQL statements in the area for editing.

create table hue_table(id int,name string,company string) row format delimited fields terminated by ',' stored as textfile;

Step 6 Click  to execute the HiveQL statements.

Step 7 In the command text box, enter **show tables;** and click  . Check whether the **hue_table** table created in **Step 5** exists in the **Result**.

----End

12.12.2 Accessing the Hue Web UI

Scenario

After Hue is installed in an MRS cluster, users can use Hadoop-related components on the Hue web UI.

This section describes how to open the Hue web UI on the MRS cluster.

NOTE

To access the Hue web UI, you are advised to use a browser that is compatible with the Hue WebUI, for example, Google Chrome 50. The Internet Explorer may be incompatible with the Hue web UI.

Impact on the System

Site trust must be added to the browser when you access Manager and Hue web UI for the first time. Otherwise, the Hue web UI cannot be accessed.

Prerequisites

When Kerberos authentication is enabled, the MRS cluster administrator has assigned the permission for using Hive to the user. For details, see . For example, create a human-machine user named **hueuser**, add the user to user groups **hive** (the primary group), **hadoop**, **supergroup**, and **System_administrator**, and assign the **System_administrator** role.

This user is used to log in to Manager.

Procedure

Step 1 Log in to the service page.

For versions earlier than MRS 3.*x*, click the cluster name on the MRS console and choose **Components** > **Hue**.

For MRS 3.*x* or later, log in to FusionInsight Manager (for details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**) and choose **Cluster** > **Services** > **Hue**.

Step 2 On the right of **Hue WebUI**, click the link to open the Hue web UI.

Hue WebUI provides the following functions:

- Click  to execute query statements of Hive and SparkSQL as well as Notebook code. Make sure that Hive and Spark2x have been installed in the MRS cluster before this operation.
- Click  to submit workflow tasks, scheduled tasks, and bundle tasks.
- Click  to view, import, and export tasks on the Hue web UI, such as workflow tasks, scheduled tasks, and bundle tasks.
- Click  to manage metadata in Hive and SparkSQL. Make sure that Hive and Spark2x have been installed in the MRS cluster before this operation.
- Click  to view the directories and files in HDFS. Make sure that HDFS has been installed in the MRS cluster before this operation.
- Click  to view all jobs in the MRS cluster. Make sure that Yarn has been installed in the MRS cluster before this operation.
- Use  to create or query HBase tables. Make sure that the HBase component has been installed in the MRS cluster and the Thrift1Server instance has been added before this operation.
- Use  to import data that is in the CSV or TXT format.

NOTE

- When you log in to the Hue web UI as user **hueuser** for the first time, you need to change the password.
- After obtaining the URL for accessing the Hue web UI, you can give the URL to other users who cannot access MRS Manager for accessing the Hue web UI.
- If you perform operations on the Hue WebUI only but not on Manager, you must enter the password of the current login user when accessing Manager again.

----End

12.12.3 Hue Common Parameters

Page Access

Go to the **All Configurations** page of the Hue service by referring to **Modifying Cluster Service Configuration Parameters**.

Parameter Description

For details about Hue common parameters, see **Table 12-244**.

Table 12-244 Hue common parameters

Configuration	Description	Default Value	Value Range
HANDLER_ACCESSLOG_LEVEL	Hue access log level.	DEBUG	• ERROR • WARN • INFO • DEBUG
HANDLER_AUDITSLOG_LEVEL	Hue audit log level.	DEBUG	• ERROR • WARN • INFO • DEBUG
HANDLER_ERRORLOG_LEVEL	Hue error log level.	ERROR	• ERROR • WARN • INFO • DEBUG
HANDLER_LOGFILE_LEVEL	Hue run log level.	INFO	• ERROR • WARN • INFO • DEBUG
HANDLER_LOGFILE_MAXBACKUPINDEX	Maximum number of Hue log files.	20	1 to 999
HANDLER_LOGFILE_SIZE	Maximum size of a Hue log file.	5 MB	-

12.12.4 Using HiveQL Editor on the Hue Web UI

Scenario

Users can use the Hue web UI to execute HiveQL statements in an MRS cluster.

Access Editor

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 In the navigation tree on the left, click  and choose **Hive**. The **Hive** page is displayed.

Hive supports the following functions:

- Executes and manages HiveQL statements.
- Views the HiveQL statements saved by the current user in **Saved Queries**.
- Queries HiveQL statements executed by the current user in **Query History**.

----End

Executing HiveQL Statements

Step 1 Select a Hive database from the **Database** drop-down list box. The default database is **default**.

The system displays all available tables. You can enter a keyword of the table name to search for the desired table.

Step 2 Click the desired table name. All columns in the table are displayed.

Move the cursor to the row where the table or column is located and click . Column details are displayed.

Step 3 Enter the query statements in the area for editing HiveQL statements.

Step 4 Click to execute the HiveQL statements.

NOTE

- If you want to use the entered HiveQL statements again, click to save them.
- Advanced query configuration:

  Click in the upper right corner to configure information such as files, functions, and settings.
- Viewing the information of shortcut keys:

  Click in the upper right corner to view the syntax and keyboard shortcut information.
- To delete an entered HiveQL statement, click the triangle next to and select **Clear**.
- Viewing history:

  Click **Query History** to view the HiveQL running status. You can view the history of all the statements or only the saved statements. If many historical records exist, you can enter keywords in the text box to search for desired records.

----End

Viewing Execution Results

Step 1 View the execution results below the execution area on **Hive**. The **Query History** tab page is displayed by default.

Step 2 Click a result to view the execution result of the executed statement.

----End

Managing Query Statements

Step 1 Click **Saved Queries**.

Step 2 Click a saved statement. The system automatically adds the statement to the editing area.

----End

Modifying the Session Configuration of the Hue Editor

Step 1 On the editor page, click .

Step 2 Click on the right of **Files**, and then click to select files.

You can click next to **Files** to add a file resource.

Step 3 In the **Functions** area, enter a user-defined name and the class name of the function.

You can click next to **Functions** to add a customized function.

Step 4 In the **Settings** area, enter the Hive parameter name in the **Key**, and value in **Value**. The current Hive session connects to Hive based on the customized configuration.

You can click to add a parameter.

----End

12.12.5 Using the SparkSql Editor on the Hue Web UI

Scenario

You can use Hue to execute SparkSql statements in a cluster on a graphical user interface (GUI).

Configuring Spark2x

Before using the SparkSql editor, you need to modify the Spark2x configuration.

Step 1 Go to the Spark2x configuration page. For details, see **Modifying Cluster Service Configuration Parameters**.

Step 2 Set the Spark2x multi-instance mode. Search for and modify the following parameters of the Spark2x service:

Parameter	Value
spark.thriftserver.proxy.enabled	false
spark.scheduler.allocation.file	#{conf_dir}/fairscheduler.xml

Step 3 Go to the JDBCServer2x customization page and add the following customized items to the **spark.core-site.customized.configs** parameter:

Set **hadoop.proxyuser.hue.groups** to *.

Set **hadoop.proxyuser.hue.hosts** to *.

Step 4 Save the configuration and restart the meta and Spark2x services.

----End

Accessing the Editor

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 In the navigation tree on the left, click  and choose **SparkSql**. The **SparkSql** page is displayed.

SparkSql supports the following functions:

- Executes and manages SparkSql statements.
- Views the SparkSql statements saved by the current user in **Saved Queries**.
- Queries SparkSql statements executed by the current user in **Query History**.

----End

Executing SparkSql Statements

Step 1 Select a SparkSql database from the **Database** drop-down list box. The default database is **default**.

The system displays all available tables. You can enter a keyword of the table name to search for the desired table.

Step 2 Click the desired table name. All columns in the table are displayed.

Move the cursor to the row of the table and click  . Column details are displayed.

Step 3 In the SparkSql statement editing area, enter the query statement.

Click the triangle next to  and select **Explain**. The editor checks the syntax and execution plan of the entered statements. If the statements have syntax errors, the editor reports **Error while compiling statement**.

Step 4 Click  to execute the SparkSql statement.

NOTE

- If you want to use the entered SparkSql statements again, click to save them.
- Advanced query configuration:

  Click in the upper right corner to configure information such as files, functions, and settings.
- Viewing the information of shortcut keys:

  Click in the upper right corner to view the syntax and keyboard shortcut information.
- To format the SparkSql statement, click the triangle next to and select **Format**.
- To delete an entered SparkSql statement, click the triangle next to and select **Clear**.
- Viewing historical records:

  Click **Query History** to view the SparkSql running status. You can view the history of all the statements or only the saved statements. If many historical records exist, you can enter keywords in the text box to search for desired records.

----End

Viewing Execution Results

Step 1 View the execution results below the execution area on **SparkSql**. The **Query History** tab page is displayed by default.

Step 2 Click a result to view the execution result of the executed statement.

----End

Managing Query Statements

Step 1 Click **Saved Queries**.

Step 2 Click a saved statement. The system automatically adds the statement to the editing area.

----End

12.12.6 Using the Metadata Browser on the Hue Web UI

Scenario

Users can use the Hue web UI to manage Hive metadata in an MRS cluster.

Using Metadata Manager

Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

- Viewing metadata of Hive tables

  Click in the navigation tree on the left and click a table name. The metadata of the Hive table is displayed.

- Managing metadata of Hive tables

  On the metadata information page of a Hive table:

  - Click **Import** in the upper right corner to import data.
  - Click **Overview** to view the location of the table file in the **PROPERTIES** field.

    View the field information of each column in a Hive table and manually add description information. Note that the added description information is not the field comments in the Hive table.
  - Click **Sample** to browse data.
- Managing Hive metadata tables

  Click ➕ in the left list to create a table based on the uploaded file in the database. You can also manually create a table.

CAUTION

The Hue page is used to view and analyze data such as files and tables. Do not perform high-risk management operations such as deleting objects on the page. If an operation is required, you are advised to perform the operation on each component after confirming that the operation has no impact on services. For example, you can use the HDFS client to perform operations on HDFS files and use the Hive client to perform operations on Hive tables.

12.12.7 Using File Browser on the Hue Web UI

Scenario

Users can use the Hue web UI to manage files in HDFS.

CAUTION

The Hue page is used to view and analyze data such as files and tables. Do not perform high-risk management operations such as deleting objects on the page. If an operation is required, you are advised to perform the operation on each component after confirming that the operation has no impact on services. For example, you can use the HDFS client to perform operations on HDFS files and use the Hive client to perform operations on Hive tables.

Accessing File Browser

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 In the left navigation pane, click  . The **File Browser** page is displayed.

By default, the homepage of **File Browser** is the home directory of the current login user. On the displayed page, the following information about subdirectories for files in the directory is displayed:

Table 12-245 HDFS file attributes

Attribute	Description
Name	Name of a directory or file
Size	File size
User	Owner of a directory or file
Group	Group of a directory or file
Permission	Permission of a directory or file
Date	Time when a directory or file is created

Step 3 In the search box, enter a keyword. The system automatically searches directories or files in the current directory.

Step 4 Clear the search criteria. The system displays all directories or files.

----End

Performing Actions

Step 1 On the **File Browser** page, select one or more directories or files.

Step 2 Click **Actions**. On the menu that is displayed, select an operation.

- **Rename**: renames a directory or file.
- **Move**: moves a file. In **Move to**, select a new directory and click **Move**.
- **Copy**: copies the selected files or directories.
- **Change permissions**: changes permission to access the selected directory or file.
  - You can grant the owner, the group, or other users with the **Read**, **Write**, and **Execute** permissions.
  - **Sticky**: indicates that only HDFS administrators, directory owners, and file owners can move files in the directory.
  - **Recursive**: indicates that permission is granted to subdirectories recursively.
- **Storage policies**: indicates the policies for storing files or directories in HDFS.
- **Summary**: indicates that the HDFS storage information about the selected file or directory can be viewed.

----End

Uploading User Files

Step 1 On the **File Browser** page, click **Upload**.

Step 2 In the displayed dialog box for uploading files, click **Select files** or drag the file to the dialog box.

----End

Creating a New File or Directory

Step 1 On the **File Browser** page, click **New**.

Step 2 Select an operation.

- **File**: creates a file. Enter a file name and click **Create**.
- **Directory**: creates a directory. Enter a directory name and click **Create**.

----End

Storage Policy Definition and Usage

NOTE

If the value of Hue parameter **fs_defaultFS** is set to **viewfs://ClusterX**, the big data storage policy cannot be enabled.

Step 1 Log in to FusionInsight Manager.

Step 2 On FusionInsight Manager, choose **System** > **Permission** > **Manage Role** > **Create Role**.

1. Set **Role Name**.
2. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > **Hue**, select **Storage Policy Admin**, and click **OK**. Then, grant the permission to the role.

Step 3 Choose **System** > **Permission** > **User Group** > **Create User Group**. Set **Group Name** and click **Select and Add Role** next to **Role**. On the displayed page, select the role created in **Step 2** and click **OK** to add the role to the group.

Step 4 Choose **System** > **Permission** > **User** > **Create**.

1. **Username**: Enter the name of the user to be added.
2. Set **User Type** to **Human-machine**.
3. Set **Password** and **Confirm Password** for logging in to the Hue web UI.
4. Click **Add** next to **User Group**. On the page that is displayed, select the user group created in **Step 3**, **supergroup**, **hadoop**, and **hive**, and click **OK**.
5. Set **Primary Group** to **hive**.
6. Click **Add** on the right of **Role**. On the page that is displayed, select the role created in **Step 2** and **System_administrator** role, and click **OK**.
7. Click **OK**. The user is added successfully.

Step 5 Access the Hue web UI as the created user. For details, see **Accessing the Hue Web UI**.

Step 6 In the left navigation tree, click  . The **File Browser** page is displayed.

Step 7 Select the check box of the directory and click **Actions** on the top of the page. Choose **Storage policies**.

Step 8 In the dialog box that is displayed, set a new storage policy and click **OK**.

----End

12.12.8 Using Job Browser on the Hue Web UI

Scenario

Users can use the Hue web UI to query all jobs in an MRS cluster.

Accessing Job Browser

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 Click  .

View the jobs in the current cluster.

NOTE

The number on **Job Browser** indicates the total number of jobs in the cluster.

Job Browser displays the following job information:

Table 12-246 MRS job attributes

Attribute	Description
Name	Job name
User	User who starts a job
Type	Job type
Status	Job status, including **Succeeded**, **Running**, and **Failed**.
Progress	Job running progress
Group	Group to which a job belongs
Start	Start time of a job
Duration	Job running duration
Id	Job ID, which is generated by the system automatically.

NOTE

If the MRS cluster has Spark, the **Spark-JDBCServer** job is started by default to execute tasks.

----End

Searching for Jobs

Step 1 In the search box of **Job Browser**, enter the specified character. The system automatically searches for all jobs that contain the keyword by ID, name, or user.

Step 2 Clear the search criteria. The system displays all jobs.

----End

Querying Job Details

Step 1 In the job list on the **Job Browser** page, click the row that contains the desired job to view details.

Step 2 On the **Metadata** tab page, you can view the metadata of the job.

NOTE

You can click **Log** to open the job running log.

----End

12.12.9 Using HBase on the Hue Web UI

Scenario

You can use Hue to create or query HBase tables in a cluster and run tasks on the Hue web UI.

Make sure that the HBase component has been installed in the MRS cluster and the Thrift1Server instance has been added before this operation.

Accessing Job Browser

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 Click HBase  . The **HBase Browser** page is displayed.

----End

Creating an HBase Table

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 Click HBase  . The **HBase Browser** page is displayed.

Step 3 Click **New Table** on the right, enter the table name and column family parameters, and click **Submit**.

----End

Querying Data in an HBase Table

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 Click HBase  . The **HBase Browser** page is displayed.

Step 3 Click the HBase table to be queried. Then, click the key value next to search box in the upper part, and query the HBase table.

----End

12.12.10 Typical Scenarios

12.12.10.1 HDFS on Hue

Hue provides the file browser function for users to use HDFS in GUI mode.

CAUTION

The Hue page is used to view and analyze data such as files and tables. Do not perform high-risk management operations such as deleting objects on the page. If an operation is required, you are advised to perform the operation on each component after confirming that the operation has no impact on services. For example, you can use the HDFS client to perform operations on HDFS files and use the Hive client to perform operations on Hive tables.

How to Use File Browser

Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Click  . The **File Browser** page is displayed. You can perform the following operations:

- Viewing files or directories

  By default, the directory and files in the directory of the login user are displayed. You can view **Name**, **Size**, **User**, **Group**,**Permission**, and **Date**.

  Click a file name to view the text information or binary data in the text file. The file content can be edited.

  If there are a large number of files and directories, you can enter keywords in the search text box to search for specific files or directories.

- Creating files or directories

  Click **New** in the upper right corner. Choose **File** to create the file. Choose **Directory** to create a directory.

- Managing files or directories

  Select the check box of a file or director, and click **Actions**. In the displayed menu, choose **Rename**, **Move**, **Copy**, and **Change permissions** to rename, move, copy, or change the file or directory permissions.

- Uploading files

  Click **Upload** in the upper right corner and click **Select files** or drag the file to the window.

How to Use Storage Policies

NOTE

If the value of Hue parameter **fs_defaultFS** is set to **viewfs://ClusterX**, the big data storage policy cannot be enabled.

Storage policies on the Hue web UI are classified into the following two types:

- Static Storage Policies

  Current storage policy

  According to the access frequency and importance of documents in HDFS, specify a storage policy for an HDFS directory, such as ONE_SSD or ALL_SSD. The files in this directory can be migrated to the storage media.

- Dynamic Storage Policies

  Set rules for an HDFS directory. The system can automatically change the storage policy, the number of file copies, migrate the file directory..

  Before configuring a dynamic storage policy on the Hue WebUI, you must set the CRON expressions for cold and hot data migration and start automatic cold and hot data migration on Manager.

  Operations:

  Change the value of **dfs.auto.data.mover.cron.expression** for NameNode of the HDFS service. For details, see **Modifying Cluster Service Configuration Parameters**.

  NOTE

  - **dfs.auto.data.mover.cron.expression** indicates the CRON expression for checking whether HDFS data meets the dynamic storage policy rule. It is used to control the start time of data migration. The default value is **0 * * * ***, indicating that the detection is performed on the hour. When the dynamic storage policy rule is met, cold and hot data migration tasks are executed on the hour.
  - The default value of **dfs.auto.data.mover.enable** is **false**. This parameter value is valid only when **dfs.auto.data.mover.enable** is set to **true**.

  Table 12-247 describes the expression for modifying this parameter. ***** indicates consecutive time segments.

  Table 12-247 Parameters in the execution expression

Column	Description
1	Minute. The value ranges from 0 to 59.
2	Hour. The value ranges from 0 to 23.
3	Date. The value ranges from 1 to 31.
4	Month. The value ranges from 1 to 12.
5	Week. The value ranges from 0 to 6. **0** indicates Sunday.

To set storage policies on the web UI, perform the following operations:

Step 1 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**.

Step 2 On FusionInsight Manager, choose **System** > **Permission > Role** > **Create Role**.

1. Set **Role Name**.
2. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > **Hue**, select **Storage Policy Admin**, and click **OK**. Then, grant the permission to the role.

Step 3 Choose **System** > **Permission** > **User Group** > **Create User Group**. Set **Group Name**, and click **Add** next to **Role**. On the displayed page, select the created role, click **OK** to add the role to the group, and click **OK**.

Step 4 Choose **System** > **Permission** > **User** > **Create**.

1. **Username**: Enter the name of the user to be added.
2. Set **User Type** to **Human-machine**.
3. Set **Password** and **Confirm Password** for logging in to the Hue web UI.
4. Click **Add** next to **User Group**. On the page that is displayed, select the created user group in **Step 3**, **supergroup**, **hadoop**, and **hive**, and click **OK**.
5. Set **Primary Group** to **hive**.
6. Click **Add** next to **Role**. On the page that is displayed, select the created role in **Step 2** and the **System_administrator** role, and click **OK**.
7. Click **OK**. The user is added successfully.

Step 5 Access the Hue web UI as the created user. For details, see **Accessing the Hue Web UI**.

Step 6 In the left navigation pane, click  . The **File Browser** page is displayed.

Step 7 Select the check box of a directory and choose **Action** on the top of the page. Choose **Storage policies**.

Step 8 In the dialog box that is displayed, set a new storage policy and click **OK**.

- On the **Static Storage Policy** page, you can set a static storage policy and click **Save**.
- On the **Dynamic Storage Policy** page, you can create, delete, or modify a dynamic storage policy. **Table 12-248** describes the parameters.

Table 12-248 Parameters of the dynamic storage policy

Category	Parameter	Description
Rule	Last Access to File	Indicates the time when the file is last accessed.
	Last File Modification	Indicates the time when the file is last modified.
Operation	Change Number of Copies	Indicates the number of file copies.

Category	Parameter	Description
	Modify Storage Policy	Indicates that you can modify storage policies to the following: HOT, WARM, COLD, ONE_SSD, and ALL_SSD.
	Move to Directory	Indicates that you can move the file to another directory.

NOTE

- You need to consider whether the rules conflict with each other and whether the rules damage the system when setting rules.
- When a directory is configured with multiple rules and operations, the rule that is triggered first is located at the bottom of the rule/operation list, and the rules that are triggered later are placed from bottom to top to prevent repeated operations.
- The system checks whether the files under the directory specified by the dynamic storage policy meet the rules on an hourly basis. If the files meet the rules, the execution is triggered. Execution logs are recorded in the **/var/log/Bigdata/hdfs/nn/hadoop.log** directory of the active NameNode.

----End

Typical Scenarios

On the Hue page, view and edit HDFS files in text or binary mode as follows:

Viewing a File

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 In the left navigation pane, click  . The **File Browser** page is displayed.

Step 3 Click the name of the file to be viewed.

Step 4 Click **View as binary** to switch from the text mode to the binary mode. Click **View as file** to switch from the binary mode to the text mode.

Editing a file

Step 5 Click **Edit File**. The file content can be edited.

Step 6 Click **Save** or **Save As** to save the file.

----End

12.12.10.2 Configuring HDFS Cold and Hot Data Migration

Scenario

The hot and cold data migration tool migrates HDFS files based on the configured policy. A policy is a set of conditional or non-conditional rules. If a file matches the rule set, the tool performs a group of operations for the file.

The hot and cold data migration tool supports the following rules and operations:

- Migration rules:
  - Data is migrated based on the latest access time of the file.
  - Data is migrated based on the file modification time.
  - Data is migrated without conditions.

  Table 12-249 Rule condition tags

Condition Tag	Description
<age operator="lt">	Defines the conditions for changing the age or modification time.
<atime operator="gt">	Defines the condition for accessing time.

  NOTE

  For a manual migration rule, no condition is required.

- Operations:
  - Set the storage policy to a given data tier.
  - Migrate files to another folder.
  - Configure the number of copies for a file.
  - Delete a file.
  - Set a node label.

  Table 12-250 Behavior types:

Behavior Type	Description	Required Parameters
MARK	Determines the data access frequency and set a data storage policy.	<param> <name>targettier</name> <value>STORAGE_POLICY</value> <param>

Behavior Type	Description	Required Parameters
MOVE	Sets the data storage policy or NodeLabel and invokes the HDFS Mover tool.	<param> <name>targettier</name> <value>STORAGE_POLICY</value> <param> <param> <name>targetnodelabels</name> <value>SOME_EXPRESSION</value> <param> **NOTE** You can set either or both of the parameters.
SET_REPL	Configures the number of copies for a file.	<param> <name>replcount</name> <value>INTEGER</value> <param>
MOVE_TO_FOLDER	Moves the file to the target folder. If **overwrite** is set to **true**, the target path will be overwritten.	<param> <name>target</name> <value>PATH</value> <param> <param> <name>overwrite</name> <value>true/false</value> <param> **NOTE** **overwrite** is an optional parameter. If this parameter is not set, the default value **false** is used.
DELETE	Delete a file.	N/A

Configuration Description

You must periodically invoke the migration tool and perform the following operations in the **hdfs-site.xml** file on the client:

Table 12-251 Parameter description

Parameter	Description	Default Value
dfs.auto-data-movement.policy.class	Specifies the default data migration policy. **NOTE** Currently, only **DefaultDataMovementPolicy** is supported.	com.xxx.hadoop.hdfs.datamovement.policy.DefaultDataMovementPolicy
dfs.auto.data.mover.id	Specifies the output file name of the hot and cold data migration policy.	Current system time (ms)
dfs.auto.data.mover.output.dir	Specifies the name of the HDFS directory to which cold and hot data is migrated. The migration tool writes the behavior status file here.	/system/datamovement

DefaultDataMovementPolicy has the configuration file **default-datamovement-policy.xml**. Users need to define all rules based on the age or access time and operations performed in this file. This file must be stored in **classpath** of the client.

The following is an example of the **default-datamovement-policy.xml** file:

```
<policies>
  <policy>
    <fileset>
      <file>
        <name>/opt/data/1.txt</name>
      </file>
      <file>
        <name>/opt/data/*/subpath/</name>
        <excludes>
          <name>/opt/data/some/subpath/sub1</name>
        </excludes>
      </file>
    </fileset>
    <rules>
      <rule>
        <age>2w</age>
        <action>
          <type>MOVE</type>
          <params>
            <param>
              <name>targettier</name>
              <value>HOT</value>
            </param>
          </params>
        </action>
      </rule>
    </rules>
  </policy>
</policies>
```

NOTE

Other attributes can be added to the tags used in policies, rules, and behavior operations. For example, **name** can be used to manage the mapping between the user UI (for example, Hue UI) and tool input XML.

Example: **<policy name="Manage_File1">**

The tags are described as follows:

Table 12-252 Description of configuring tags

Tag	Description	Reusable or Not
<policy>	Define a single policy. • **idempotent**: specifies whether to check the next rule if the current rule is met when multiple rules exist in the policy. Example: **<policy name ="policy2" idempotent ="true">** The default value is **true**, indicating that the rule and action are idempotent and you can continue to check the next rule. If the value is **false**, the evaluation stops at the current rule. • **hours_allowed**: indicates whether to execute policy evaluation based on the system time. The value of **hours_allowed** is a number separated by commas (,). The value ranges from 0 to 23, indicating the system time. Example: **<policy name ="policy1" hours_allowed ="2-6,13-14">** If the current system time is within the configured range, continue the evaluation. Otherwise, the evaluation will be skipped. **NOTE** In the input XML, only one policy is supported per file. Therefore, all rules in the file must be covered by a policy tag.	Yes
<fileset>	Define a group of files or folders for each policy.	No (in the **policy** tag)
<file>	One or more **<name>** tags are configured for the definition file and/or folder in the **<file>** tag. The file or folder name supports POSIX globs.	Yes (in the **fileset** tag)
<excludes>	Define this tag in the **<file>** tag. This tag can contain multiple **<name>** tags. In the file or folder range configured in the **<file>** tag, the files or folders contained in the **<name>** tag will be excluded. The file or folder name supports POSIX globs.	No (in the **fileset** tag)

Tag	Description	Reusable or Not
<rules>	Specifies multiple rules defined for a policy.	No (in the **policy** tag)
<rule>	Specifies a single rule to be defined.	Yes (in the **rules** tag)
<age>or<atime>	Defines the age/accesstime of the file defined in **<fileset>**. The policy matches the age. The value of **age** can be in the *[num]y[num]m[num]w[num]d[num]h* format. In the command, *num* indicates a number. The meanings of the letters are as follows: * *y*: year (365 days in a year) * *m*: month (30 days in a month) * *w*: week (7 days in a week) * *d*: day * *h*: hour You can use the year, month, week, day, or hour independently, or you can combine them. For example, **1y2d** indicates one year and two days or 367 days. If there is no unit (that is, the number is not followed by any letter), the default unit is day. **NOTE** You can configure **gt** (greater) and **lt** (less) in the **<age>** and **<atime>** tags. The default operator is **gt**. Example: **<age operator="lt">**	No (in the **rule** tag)
<action>	If the rule is matched, this tag defines the action to be executed.	No (in the **rule** tag)
<type>	Defines the action type. Currently, the supported action types are MOVE and MARK.	No (in the **action** tag)
<**params**>	Defines parameters related to each action.	No (in the **action** tag)

Tag	Description	Reusable or Not
<param>	Defines a name-value format parameter that uses the **<name>** and **<value>** tags. For MARK and MOVE, only the **targettier** parameter is supported. This parameter specifies the data storage policy if the age rule is met. If multiple parameters have the same name, the first parameter value is used. For marks, the supported **targettier** values are **ALL_SSD**, **ONE_SSD**, **HOT**, **WARM**, and **COLD**. For MOVE, the supported **targettier** values are **ALL_SSD**, **ONE_SSD**, **HOT**, **WARM**, and **COLD**.	Yes (in the **params** tag)

For files or folders under the **<file>** tag, the **FileSystem#globStatus** API is used. For other files or folders, the **GlobPattern** class (used by GlobFilter) is used. For details, see the description of supported APIs. For example, for globStatus, **/opt/hadoop/*** will match everything in the **/opt/hadoop** folder. **/opt/*/hadoop** matches all hadoop folders in the subdirectories of the**/opt** directory.

For globStatus, the glob mode of each path component is matched. For other components, the glob mode is directly matched.

https://hadoop.apache.org/docs/r3.1.1/api/org/apache/hadoop/fs/FileSystem.html#globStatus(org.apache.hadoop.fs.Path)

Glob	Name	Matches
*	*asterisk*	Matches zero or more characters
?	*question mark*	Matches a single character
[ab]	*character class*	Matches a single character in the set {a, b}
[^ab]	*negated character class*	Matches a single character that is not in the set {a, b}
[a-b]	*character range*	Matches a single character in the (closed) range [a, b], where a is lexicographically less than or equal to b
[^a-b]	*negated character range*	Matches a single character that is not in the (closed) range [a, b], where a is lexicographically less than or equal to b
{a,b}	*alternation*	Matches either expression a or b
\c	*escaped character*	Matches character c when it is a metacharacter

Behavior Operation Example

- MARK

```
<action>
  <type>MARK</type>
  <params>
    <param>
      <name>targettier</name>
      <value>HOT</value>
    </param>
  </params>
</action>
```

- MOVE

```
<action>
 <type>MOVE</type>
 <params>
  <param>
   <name>targettier</name>
   <value>HOT</value>
  </param>
  <param>
   <name>targetnodelabels</name>
   <value>SOME_EXPRESSION</value>
  </param>
 </params>
</action>
```

- SET_REPL

```
<action>
 <type>SET_REPL</type>
 <params>
  <param>
   <name>replcount</name>
   <value>5</value>
  </param>
 </params>
</action>
```

- MOVE_TO_FOLDER

```
<action>
 <type>MOVE_TO_FOLDER</type>
 <params>
  <param>
   <name>target</name>
   <value>path</value>
  </param>
  <param>
   <name>overwrite</name>
   <value>true</value>
  </param>

 </params>
</action>
```

NOTE

The **MOVE_TO_FOLDER** operation only changes the file path to the target folder and does not change the block location. If you want to move a block, you need to configure an independent move policy.

- DELETE

```
<action>
 <type>DELETE</type>
</action>
```

NOTE

- When writing an XML file, pay attention to the configuration and sequence of behavior operations. The hot and cold data migration tool executes the rules in the sequence specified in the input XML file.
- If you want to run only one rule based on **atime/age**, sort the rules in descending order of time and set the idempotent attribute to false.
- If the delete operation is configured for a file set, other rules cannot be configured after the delete operation is performed.
- The **-fs** option can be used to specify the default file system address of the client.

Audit Logs

The cold and hot data migration tool supports audit logs of the following operations:

- Tool startup status
- Behavior type, parameter details, and status
- Tool completion status

To enable the audit log tool, add the following attributes to the **<HADOOP_CONF_DIR>/log4j.property** file:

```
autodatatool.logger=INFO, ADMTRFA
autodatatool.log.file=HDFSAutoDataMovementTool.audit
log4j.logger.com.xxx.hadoop.hdfs.datamovement.HDFSAutoDataMovementTool.audit=${autodatatool.logger}
log4j.additivity.com.xxx.hadoop.hdfs.datamovement.HDFSAutoDataMovementTool-audit=false
log4j.appender.ADMTRFA=org.apache.log4j.RollingFileAppender
log4j.appender.ADMTRFA.File=${hadoop.log.dir}/${autodatatool.log.file}
log4j.appender.ADMTRFA.layout=org.apache.log4j.PatternLayout
log4j.appender.ADMTRFA.layout.ConversionPattern=%d{ISO8601} %p %c: %m%n
log4j.appender.ADMTRFA.MaxBackupIndex=10
log4j.appender.ADMTRFA.MaxFileSize=64MB
```

NOTE

For details, see the **<HADOOP_CONF_DIR>/log4j_autodata_movment_template.properties** file.

12.12.10.3 Hive on Hue

Hue provides the Hive GUI management function so that users can query Hive data in GUI mode.

How to Use Query Editor

Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

In the navigation tree on the left, click  and choose **Hive**. The **Hive** page is displayed.

- Running Hive HQL statements

  Select the target database on the left. You can also click  in the upper right corner and enter the target database name to search for the target database.

  Enter a Hive HQL statement in the text box and click  or press **Ctrl+Enter** to run the HQL statement. The execution result is displayed on the **Result** tab page.

- Analyzing Hive HQL statements

  Select the target database on the left, enter the Hive HQL statement in the text box, and click  to compile the HQL statement and check whether the statement is correct. The execution result is displayed under the text editing box.

- Saving HQL statements

Enter the Hive HQL statement in the text box, click in the upper right corner, and enter the name and description. You can view the saved statements on the **Saved Queries** tab page.

- Viewing historical records

  Click **Query History** to view the HQL running status. You can view the history of all the statements or only the saved statements. If many historical records exist, you can enter keywords in the text box to search for desired records.

- Configuring advanced query

  Click in the upper right corner to configure the file, function, and settings.

- Viewing the information of shortcut keys

  Click in the upper right corner to view information about all shortcut keys.

How to Use Metadata Browser

Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

- Viewing metadata of Hive tables

  Click in the navigation tree on the left and click a table name. The metadata of the Hive table is displayed.

- Managing metadata of Hive tables

  On the metadata information page of a Hive table:

  - Click **Import** in the upper right corner to import data.
  - Click **Overview** to view the location of the table file in the **PROPERTIES** field.

    View the field information of each column in a Hive table and manually add description information. Note that the added description information is not the field comments in the Hive table.
  - Click **Sample** to browse data.

- Managing Hive metadata tables

  Click in the left list to create a table based on the uploaded file in the database. You can also manually create a table.

CAUTION

The Hue page is used to view and analyze data such as files and tables. Do not perform high-risk management operations such as deleting objects on the page. If an operation is required, you are advised to perform the operation on each component after confirming that the operation has no impact on services. For example, you can use the HDFS client to perform operations on HDFS files and use the Hive client to perform operations on Hive tables.

Typical Scenarios

On the Hue page, create a Hive table as follows:

Step 1 Click  at the upper left corner of Hue web UI and select the Hive instance to be operated to enter the Hive command execution page.

Step 2 Enter an HQL statement in the command input box, for example:

create table hue_table(id int,name string,company string) row format delimited fields terminated by ',' stored as textfile;

Click  to execute the HQL statements.

Step 3 Enter the following command in the command input box:

show tables;

Click  to view the created table **hue_table** in **Result**.

----End

12.12.10.4 Oozie on Hue

Hue provides the Oozie job manager function, in this case, you can use Oozie in GUI mode.

CAUTION

The Hue page is used to view and analyze data such as files and tables. Do not perform high-risk management operations such as deleting objects on the page. If an operation is required, you are advised to perform the operation on each component after confirming that the operation has no impact on services. For example, you can use the HDFS client to perform operations on HDFS files and use the Hive client to perform operations on Hive tables.

How to Use Oozie Job Designer

Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

In the navigation tree on the left, click  and choose **Workflow**.

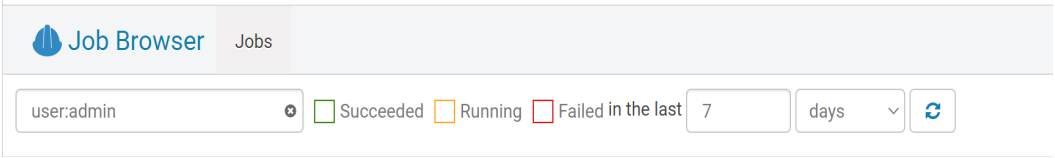
The job designer allows users to create MapReduce, Java, Streaming, Fs, SSH, Shell and DistCp jobs.

How to Use Dashboard

Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Click **Jobs** in the upper right corner. The **Job Browser** page is displayed.

View the running status of the Workflow, Coordinator, and Bundles jobs.



How to Use Editor

Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

In the navigation tree on the left, click  and choose **Workflow**.

Workflows, Schedule, and Bundle tasks can be created. Existing applications can be submitted for running, shared, copied, and exported.

- Each Workflow can contain one or more jobs to form a complete workflow for a specified service.

  When creating a Workflow, you can design jobs in the Hue editor and add the jobs to the Workflow.
- Each Schedule can define a time trigger to periodically execute a specified Workflow. One time trigger cannot execute multiple Workflows.
- Each Bundles can define a set to execute multiple Schedules so that different Workflows can be executed in batches.

12.12.11 Hue Log Overview

Log Description

Log paths: The default paths of Hue logs are **/var/log/Bigdata/hue** (for storing run logs) and **/var/log/Bigdata/audit/hue** (for storing audit logs).

Log archive rules: The automatic compression and archiving function of the Hue logs is enabled. By default, when the size of a log file (**access.log**, **error.log**, **runcpserver.log**, or **hue-audits.log**) exceeds 5 MB, logs are automatically compressed. A maximum of 20 latest compressed files are reserved. The number of compressed files and compression threshold can be configured.

Table 12-253 Hue log list

Type	Log File Name	Description
Run log	access.log	Access log file
	error.log	Error log file
	gsdb_check.log	Log file of the GaussDB check information
	kt_renewer.log	Log file of Kerberos authentication
	kt_renewer.out.log	Log file of the abnormal Kerberos authentication logs
	runcpserver.log	Log file of operation records
	runcpserver.out.log	Log file of process running exceptions
	supervisor.log	Log file of process startup

Type	Log File Name	Description
	supervisor.out.log	Log file of process startup exceptions
	dbDetail.log	Log file of database initialization
	initSecurityDetail.log	Download initialization log file of the Keytab file
	postinstallDetail.log	Work log file generated after the Hue service is installed
	prestartDetail.log	Prestart log file
	statusDetail.log	Log file of the Hue health status
	startDetail.log	Startup log
	get-hue-ha.log	Log file of the Hue HA status
	hue-ha-status.log	Log file of the Hue HA status monitoring
	get-hue-health.log	Log file of the Hue health status
	hue-health-check.log	Log file of the Hue health check
	hue-refresh-config.log	Log file of the Hue configuration update
	hue-script-log.log	Log file of the Hue operations on the Manager console
	hue-service-check.log	Log file of the Hue service status monitoring
	db_pwd.log	Log that records the changes of the password for Hue to connect to the DBService database
	modifyDBPwd_*Date*.log	-
	watch_config_update.log	Parameter update log file
Audit log	hue-audits.log	Audit log file

Log Level

Table 12-254 describes the log levels supported by Hue.

Levels of logs are ERROR, WARN, INFO, and DEBUG from the highest to the lowest priority. Run logs of equal or higher levels are recorded. The higher the specified log level, the fewer the logs recorded.

Table 12-254 Log levels

Level	Description
ERROR	Logs of this level record error information about system running.
WARN	Logs of this level record exception information about the current event processing.
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record the system information and system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of the Hue service by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 In the navigation tree on the left, select **Log** corresponding to the role to be modified.

Step 3 Select the log level to be changed on the right.

Step 4 Save the configuration. In the displayed dialog box, click **OK** to make the configurations take effect.

Step 5 Restart the service or instance whose configuration has expired for the configuration to take effect.

----End

Log Format

The following table lists the Hue log formats:

Table 12-255 Log formats

Type	Format	Example
Run log	*<dd-MM-yy HH:mm:ss,SSS><Location where the log event occurs><Log level><Message in the log>*	[03/Nov/2014 11:57:19] middleware | INFO | Unloading MimeTypeJSFileFixStrea-mingMiddleware.

Type	Format	Example
	<Log level><Time format><yyyy-MM-dd HH:mm:ss,SSS><Location where the log event occurs><Message in the log>	INFO : CST 2014-11-06 11:22:52 hue-ha-status.sh : update 4 <= 15:myHostName=10.0.0.250 ACTIVE=10.0.0.250
Audit log	*<UserName><yyyy-MM-dd HH:mm:ss,SSS>< Audit operation description> <Resource parameter> <URL> <Whether to allow> <Audit operation> <IP address>*	{"username": "admin", "eventTime": "2014-11-06 10:28:34", "operationText": "Successful login for user: admin", "service": "accounts", "url": "/accounts/login/", "allowed": true, "operation": "USER_LOGIN", "ipAddress": "10.0.0.250"}

12.12.12 Common Issues About Hue

12.12.12.1 How Do I Solve the Problem that HQL Fails to Be Executed in Hue Using Internet Explorer?

Question

What do I do if all HQL statements fail to be executed when I use Internet Explorer to access Hive Editor in Hue and the message "There was an error with your query" is displayed?

Answer

Internet Explorer does not support processing of AJAX POST requests containing form data in 307 redirection. You are advised to use a compatible browser, for example, Google Chrome.

12.12.12.2 Why Does the use database Statement Become Invalid When Hive Is Used?

Question

When Hive is used, the **use database** statement is entered in the text box to switch the database, and other statements are also entered, why does the database fail to be switched?

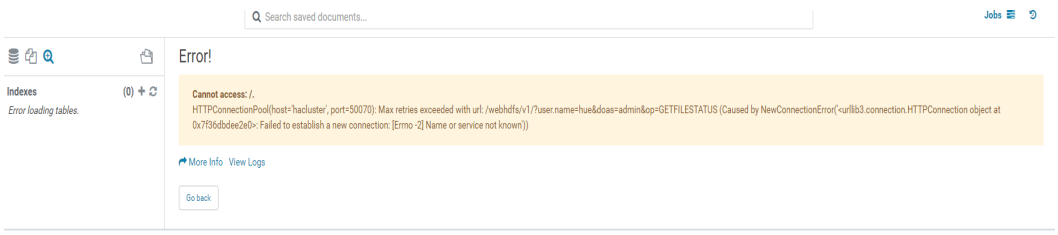
Answer

Using Hive on Hue is different from using Hive on the Hive client. There is an option to select a database on the Hue interface, and the database where the current SQL is executed is the one that is displayed on the interface. You are advised to use functions on the Hue interface instead of using statements to perform session-level and one-off operations, for example, setting parameters. If you must enter specific statements to perform an operation, ensure that all statements you enter are in one text box.

12.12.12.3 What Can I Do If HDFS Files Fail to Be Accessed Using Hue WebUI?

Question

What can I do if an error message shown in the following figure is displayed, indicating that the HDFS file cannot be accessed when I use Hue web UI to access the HDFS file?



Answer

1. Check whether the user who logs in to the Hue web UI has the permissions of the **hadoop** user group.
2. Check whether the HttpFS instance has been installed for the HDFS service and is running properly. If the HttpFS instance is not installed, manually install and restart the Hue service.

12.12.12.4 What Can I Do If a Large File Fails to Be Uploaded on the Hue Page?

Question

What can I do when a large file fails to be uploaded on the Hue page?

Answer

1. You are advised to run commands on the client to upload large files instead of using the Hue file browser.
2. If you must use Hue to upload the file, perform the following steps to modify Httpd parameters:
   a. Log in to the active management node as user **omm**.
   b. Run the following command to edit the **httpd.conf** file:
      vi $BIGDATA_HOME/om-server/Apache-httpd-*/conf/httpd.conf

c. Search for **21201** and add **RequestReadTimeout handshake=0 header=0 body=0** to the **</VirtualHost>** configuration, as shown in the following:

```
...
<VirtualHost *:21201>
   ServerName https://10.112.16.93:21201
   AllowEncodedSlashes On
   SSLProxyEngine On
   ProxyRequests Off
   TraceEnable off
   ProxyTimeout  1200
   RewriteEngine on
   RewriteMap proxylist dbm:${BIGDATA_ROOT_HOME}/om-server_*/Apache-httpd-*/conf/
proxylist.dbm

   RewriteRule ^(\/.*)$  ${proxylist:/Hue/Hue/21201}$1 [E=TARGET_PATH:$1,L,P]

   Header edit Location ^(?!https://10.112.16.93:20009|https://
10.112.16.93:21201)http[s]?://[^/]*(.*)$  https://10.112.16.93:21201$1

   ProxyPassReverseCookiePath / / interpolate

   SSLEngine On
   SSLProxyProtocol  All +TLSv1.2 -SSLv2 -SSLv3 -TLSv1 -TLSv1.1
   SSLProtocol ALL +TLSv1.2 -SSLv2 -SSLv3 -TLSv1 -TLSv1.1
   SSLCipherSuite ECDHE-RSA-AES256-GCM-SHA384:ECDHE-ECDSA-AES256-GCM-
SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-ECDSA-AES128-GCM-SHA256:DHE-DSS-
AES256-GCM-SHA384:DHE-RSA-AES256-GCM-SHA384:DHE-DSS-AES128-GCM-SHA256:DHE-
RSA-AES128-GCM-SHA256
   SSLProxyCheckPeerName off
   SSLProxyCheckPeerCN off
   SSLCertificateFile "${BIGDATA_ROOT_HOME}/om-server_*/Apache-httpd-*/conf/security/
proxy_ssl.cert"
   SSLCertificateKeyFile "${BIGDATA_ROOT_HOME}/om-server_*/Apache-httpd-*/conf/security/
server.key"
   SSLProxyCACertificateFile ${BIGDATA_ROOT_HOME}/om-server_*/apache-tomcat-*/conf/
security/tomcat.crt
   SSLCertificateChainFile "${BIGDATA_ROOT_HOME}/om-server_*/Apache-httpd-2.4.39/conf/
security/proxy_chain.cert"
   RequestReadTimeout handshake=0 header=0 body=0
</VirtualHost>
...
```

d. Run the **ps -ef|grep httpd|grep -v grep|xargs kill -9** command to restart **httpd**.

12.12.12.5 Why Is the Hue Native Page Cannot Be Properly Displayed If the Hive Service Is Not Installed in a Cluster?

Question

Why is the native Hue page blank if the Hive service is not installed in a cluster?

Answer

In MRS 3.x, Hue depends on Hive. If this problem occurs, check whether the Hive component is installed in the current cluster. If not, install it.

12.13 Using Impala

12.13.1 Using Impala from Scratch

Impala is a massively parallel processing (MPP) SQL query engine for processing vast amounts of data stored in Hadoop clusters. It is an open source software written in C++ and Java. It provides high performance and low latency compared with other SQL engines for Hadoop.

Background

Suppose a user develops an application to manage users who use service A in an enterprise. The procedure of operating service A on the Impala client is as follows:

Operations on common tables:

- Create the **user_info** table.
- Add users' educational backgrounds and titles to the table.
- Query user names and addresses by user ID.
- Delete the user information table after service A ends.

Table 12-256 User information

No.	Name	Gender	Age	Address
12005000201	A	Male	19	City A
12005000202	B	Female	23	City B
12005000203	C	Male	26	City C
12005000204	D	Male	18	City D
12005000205	E	Female	21	City E
12005000206	F	Male	32	City F
12005000207	G	Female	29	City G
12005000208	H	Female	30	City H
12005000209	I	Male	26	City I
12005000210	J	Female	25	City J

Prerequisites

The client has been installed. For example, the client is installed in the **/opt/hadoopclient** directory. The client directory in the following operations is only an example. Change it to the actual installation directory.

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the Impala client command to implement service A.

Run the client command of the Impala component directly.

impala-shell

NOTE

By default, **impala-shell** attempts to connect to the Impala daemon on port 21000 of **localhost**. To connect to another host, use the **-i < host:port >** option, for example, **impala-shell -i** *xxx.xxx.xxx.xxx***:21000**. To automatically connect to a specific Impala database, use the **-d <database>** option. For example, if all your Kudu tables are in the **impala_kudu** database, **-d impala_kudu** can use this database. To exit the Impala Shell, run the **quit** command.

Operations on internal tables:

1. Create the **user_info** user information table according to **Table 12-256** and add data to it.
   ```
   create table user_info(id string,name string,gender string,age int,addr string);
   insert into table user_info(id,name,gender,age,addr) values("12005000201", "A", "Male", 19, "City A");
   ```
   ... (Other statements are the same.)
2. Add users' educational backgrounds and titles to the **user_info** table.

   For example, to add educational background and title information about user 12005000201, run the following commands.
   ```
   alter table user_info add columns(education string,technical string);
   ```
3. Query user names and addresses by user ID.

   For example, to query the name and address of user 12005000201, run the following command:
   ```
   select name,addr from user_info where id='12005000201';
   ```
4. Delete the user information table:
   ```
   drop table user_info;
   ```

Operations on external partition tables:

Create an external partition table and import data.

1. Create a path for storing external table data.
   - Security mode (Kerberos authentication is enabled for clusters)

     cd /opt/hadoopclient

     source bigdata_env

     kinit *hive*

     NOTE

     The user must have the hive administrator permissions.

     impala-shell

     hdfs dfs -mkdir /hive

     hdfs dfs -mkdir /hive/user_info

- Normal mode (Kerberos authentication is disabled for clusters)

  su - omm

  cd /opt/hadoopclient

  source bigdata_env

  impala-shell

  hdfs dfs -mkdir /hive

  hdfs dfs -mkdir /hive/user_info

2. Create a table.

```
create external table user_info(id string,name string,gender string,age int,addr string) partitioned by(year string) row format delimited fields terminated by ' ' lines terminated by '\n' stored as textfile location '/hive/user_info';
```

   NOTE

   fields terminated indicates delimiters, for example, spaces.

   lines terminated indicates line breaks, for example, **\n**.

   /hive/user_info indicates the path of the data file.

3. Import data.

   a. Execute the **insert** statement to insert data.

```
insert into user_info partition(year="2018") values ("12005000201", "A", "Male", 19, "City A");
```

   b. Run the **load data** command to import file data.

      i. Create a file based on the data in **Table 12-256**. For example, the file name is **txt.log**. Fields are separated by space, and the line feed characters are used as the line breaks.

      ii. Upload the file to HDFS.

      hdfs dfs -put txt.log /tmp

      iii. Load data to the table.

      load data inpath '/tmp/txt.log' into table user_info partition (year='2018');

4. Query the imported data:

```
select * from user_info;
```

5. Delete the user information table:

```
drop table user_info;
```

----End

12.13.2 Accessing the Impala Web UI

You can view Impala job information on the Impala web UI. Impala web UIs are classified into the following types based on instances:

- **StateStore WebUI**: used to manage nodes.
- **Catalog WebUI**: used to view metadata.
- **Impalad WebUI**: used to view details about each SQL statement.

Prerequisites

Impala has been installed in a cluster.

Accessing the StateStore Web UI

Step 1 Access Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**.

Step 2 Choose **Services** > **Impala**.

Step 3 In **StateStore WebUI** of **Impala Summary**, click **StateStore(Statestore)**. The StateStore web UI is displayed.

----End

Accessing the Catalog Web UI

Step 1 Access Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**.

Step 2 Choose **Services** > **Impala**.

Step 3 In **Catalog WebUI** of **Impala Summary**, click **Catalog(Catalog)**. The Catalog web UI is displayed.

----End

Accessing the Impalad Web UI

Step 1 Access Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**.

Step 2 Choose **Services** > **Impala** > **Instance**.

Step 3 Move the cursor to the Impalad instance in the **Role** column. The following link is displayed in the lower left corner of the page. Obtain the value after **null**, for example, **82** in this example.

https://*EIP*:9022/mrsmanager/index.jsp?locale=zh-cn#/app/services/Impala/Impalad/null/82/*EIP*/STARTED/status/detail

In the preceding command, **82** is an example. Change it based on the site requirements.

Step 4 For details, see **Accessing the StateStore Web UI**.

Step 5 Change **StateStore/*xx*** in the URL of the StateStore web UI to **Impalad/*xx*** and access the new URL, where *xx* is the value obtained in **Step 3**.

----End

12.13.3 Using Impala to Operate Kudu

You can use the SQL statements of Impala to insert, query, update, and delete data in Kudu as an alternative to using Kudu APIs to build custom Kudu applications.

Prerequisite

A complete cluster client has been installed. For example, the installation directory is **/opt/Bigdata/client**. The client directory in the following operations is only an example. Replace it with the actual installation directory.

Impala on Kudu

Step 1 Log in to the node where the client is installed.

Step 2 Run the following command to initialize environment variables:

source /opt/Bigdata/client/bigdata_env

Step 3 If Kerberos authentication is enabled for the cluster, perform the following operation to authenticate the user. If Kerberos authentication is not enabled for the cluster, skip this step.

kinit *Service user*

Step 4 Run the following command to log in to the Impala client:

impala-shell

NOTE

By default, **impala-shell** attempts to connect to the Impala daemon on port 21000 of **localhost**. To connect to another host, use the **-i <host:port>** option. To automatically connect to a specific Impala database, use the **-d <database>** option. For example, if all your Kudu tables are in the **impala_kudu** database, **-d impala_kudu** can use this database. To exit the Impala shell, run the **quit** command.

Step 5 Run the following commands to create an Impala table and import the prepared data, for example, data in the **/tmp/data10** directory:

create table dataorigin (name string,age string,pt string, date_p date) row format delimited fields terminated by ',' stored as textfile;

load data inpath '/tmp/data10' overwrite into table dataorigin;

Step 6 Run the following command to create a Kudu table. In the command, **kudu.master_addresses** indicates the IP address of the KuduMaster instance. Set it to the actual IP address.

create table dataorigin2 (name string,age string,pt string, date_p date, primary key(name)) stored as kudu TBLPROPERTIES('kudu.master_addresses'='192.168.190.164:7051,192.168.204.178:7051,192.168.244.63:7051');

Step 7 Perform the following operations on the Kudu table.

1. Insert data.

   insert into dataorigin2 select * from dataorigin;

2. Update data.

   UPDATE dataorigin2 SET date_p="2021-03-31" where age="73";

3. Upsert rows.

   UPSERT INTO dataorigin2 VALUES ("spjted","75","28","2021-03-32");

   UPSERT INTO dataorigin2 VALUES ("kwhakb","92","29","2021-03-33");

UPSERT INTO dataorigin2 VALUES ("oftrkf","13","30","2021-03-34");
UPSERT INTO dataorigin2 VALUES ("kiewti","36","31","2021-03-35");
UPSERT INTO dataorigin2 VALUES ("rknmql","98","32","2021-03-36");
UPSERT INTO dataorigin2 VALUES ("fwcoij","52","33","2021-03-37");
UPSERT INTO dataorigin2 VALUES ("pgvpdo","37","34","2021-03-35");

4. Delete a row.
   DELETE FROM dataorigin2 WHERE date_p="2021-03-31";

----End

12.13.4 Interconnecting Impala with External LDAP

This section applies to MRS 3.1.0 or later.

Step 1 Log in to Manager.

Step 2 On Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **Impala** > **Configurations** > **All Configurations** > **Impalad(Role)** > **LDAP**.

Step 3 Set the following parameters.

Table 12-257 Parameter configuration

Parameter	Description	Remarks
--enable_ldap_auth	Whether to enable LDAP authentication	Value: **true** or **false**
--ldap_bind_pattern	LDAP user DN pattern	Example: **cn=#UID,ou=People,dc=xxx,dc=com** or **cn=%s,ou=People,dc=xxx,dc=com**

Parameter	Description	Remarks
--ldap_passwords_in_clear_ok	Whether the LDPA password is sent in plaintext	If this parameter is set to **true**, the LDAP password can be sent in plaintext. Value: **true** or **false** **NOTE** If **--enable_ldap_auth** is set to **true**, the LDAP TLS protocol is disabled by default during authentication. Therefore, you need to set **--ldap_passwords_in_clear_ok** to **true**. Otherwise, the Impalad role will fail to be started. To enable the Ldap TLS protocol, set **--ldap_tls** to **true** in the customized configuration of the Impalad role. After the configuration, the password can be sent in ciphertext.
--ldap_uri-ip	LDAP IP address	-
--ldap_uri-port	LDAP port number	Default value: **389**

Step 4 After the modification, click **Save** in the upper left corner. In the displayed dialog box, click **OK**.

Step 5 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Impala** > **Instance**. On the displayed page, select the instances whose **Configuration Status** is **Expired**, choose **More** > **Restart Instance**, and restart the instance.

----End

12.14 Using Kafka

12.14.1 Using Kafka from Scratch

Scenario

You can create, query, and delete topics on a cluster client.

Prerequisites

The client has been installed. For example, the client is installed in the **/opt/hadoopclient** directory. The client directory in the following operations is only an example. Change it to the actual installation directory.

Using the Kafka Client (Versions Earlier Than MRS 3.x)

Step 1 Access the ZooKeeper instance page.

Click the cluster name to go to the cluster details page and choose **Components** > **ZooKeeper** > **Instances**.

NOTE

If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Step 2 View the IP addresses of the ZooKeeper role instance.

Record any IP address of the ZooKeeper instance.

Step 3 Log in to the node where the client is installed.

Step 4 Run the following command to switch to the client directory, for example, **/opt/hadoopclient/Kafka/kafka/bin**.

cd /opt/hadoopclient/Kafka/kafka/bin

Step 5 Run the following command to configure environment variables:

source /opt/hadoopclient/bigdata_env

Step 6 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. If Kerberos authentication is disabled for the current cluster, skip this step.

kinit *Kafka user*

Step 7 Create a topic.

sh kafka-topics.sh --create --topic *Topic name* **--partitions** *Number of partitions occupied by the topic* **--replication-factor** *Number of replicas of the topic* **--zookeeper** *IP address of the node where the ZooKeeper instance resides:clientPort*/**kafka**

Step 8 Run the following command to view the topic information in the cluster:

sh kafka-topics.sh --list --zookeeper *IP address of the node where the ZooKeeper instance resides:clientPort*/**kafka**

Step 9 Delete the topic created in **Step 7**.

sh kafka-topics.sh --delete --topic *Topic name* **--zookeeper** *IP address of the node where the ZooKeeper instance resides*:*clientPort*/**kafka**

Type **y** and press **Enter**.

----End

Using the Kafka Client (MRS 3.x or Later)

Step 1 Access the ZooKeeper instance page.

Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the desired cluster* > **Services** > **ZooKeeper** > **Instance**.

Step 2 View the IP addresses of the ZooKeeper role instance.

Record any IP address of the ZooKeeper instance.

Step 3 Log in to the node where the client is installed.

Step 4 Run the following command to switch to the client directory, for example, **/opt/hadoopclient/Kafka/kafka/bin**.

cd /opt/hadoopclient/Kafka/kafka/bin

Step 5 Run the following command to configure environment variables:

source /opt/hadoopclient/bigdata_env

Step 6 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. If Kerberos authentication is disabled for the current cluster, skip this step.

kinit *Kafka user*

Step 7 Log in to FusionInsight Manager, choose **Cluster** > **Name of the desired cluster** > **Services** > **ZooKeeper**, and click the **Configurations** tab and then **All Configurations**. On the displayed page, search for the **clientPort** parameter and record its value.

Step 8 Create a topic.

sh kafka-topics.sh --create --topic *Topic name* **--partitions** *Number of partitions occupied by the topic* **--replication-factor** *Number of replicas of the topic* **--zookeeper** *IP address of the node where the ZooKeeper instance resides:clientPort***/kafka**

Step 9 Run the following command to view the topic information in the cluster:

sh kafka-topics.sh --list --zookeeper *IP address of the node where the ZooKeeper instance resides:clientPort***/kafka**

Step 10 Delete the topic created in **Step 8**.

sh kafka-topics.sh --delete --topic *Topic name* **--zookeeper** *IP address of the node where the ZooKeeper instance resides*:*clientPort***/kafka**

----End

12.14.2 Managing Kafka Topics

Scenario

You can manage Kafka topics on a cluster client based on service requirements. Management permission is required for clusters with Kerberos authentication enabled.

Prerequisites

You have installed the Kafka client.

Procedure

Step 1 Access the ZooKeeper instance page.

- For versions earlier than MRS 3.x, click the cluster name to go to the cluster details page and choose **Components** > **ZooKeeper** > **Instances**.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the desired cluster* > **Services** > **ZooKeeper** > **Instance**.

Step 2 View the IP addresses of the ZooKeeper role instance.

Record any IP address of the ZooKeeper instance.

Step 3 Prepare the client based on service requirements. Log in to the node where the client is installed.

Log in to the node where the client is installed. For details, see **Using an MRS Client**.

Step 4 Run the following command to switch to the client directory, for example, /**opt/client/Kafka/kafka/bin**.

cd /opt/client/Kafka/kafka/bin

Step 5 Run the following command to configure environment variables:

source /opt/client/bigdata_env

Step 6 Run the following command to perform user authentication (skip this step in normal mode):

kinit *Component service user*

Step 7 For versions earlier than MRS 3.x, run the following commands to manage Kafka topics:

- Creating a topic

  sh kafka-topics.sh --create --topic *Topic name* **--partitions** *Number of partitions occupied by the topic* **--replication-factor** *Number of replicas of the topic* **--zookeeper** *IP address of the node where the ZooKeeper instance resides:clientPort*/**kafka**

- Deleting a topic

  sh kafka-topics.sh --delete --topic *Topic name* **--zookeeper** *IP address of the node where the ZooKeeper instance resides*:*clientPort*/**kafka**

NOTE

- The number of topic partitions or topic backup replicas cannot exceed the number of Kafka instances.
- By default, the value of **clientPort** of ZooKeeper is **2181**.
- There are three ZooKeeper instances. Use the IP address of any one.
- For details about managing messages in Kafka topics, see **Managing Messages in Kafka Topics**.

Step 8 MRS 3.*x* and later versions: Use **kafka-topics.sh** to manage Kafka topics.

- Creating a topic:

  By default, partitions of a topic are distributed based on the number of partitions on the node and disk. To distribute partitions based on the disk capacity, set **log.partition.strategy** to **capacity** for the Kafka service.

  When a topic is created in Kafka, partitions and copies can be generated based on the combination of rack awareness and cross-AZ feature. The **--zookeeper** and **--bootstrap-server** modes are supported.

  – Disable the rack policy and cross-AZ feature (default policy).

    Copies of topics created based on this policy are randomly allocated to any node in the cluster.

    ./kafka-topics.sh --create --topic *topic name* **--partitions** *number of partitions occupied by the topic***--replication-factor** *number of replicas of the topic***--zookeeper** *IP address of any ZooKeeper node:clientPort***/kafka**

    ./kafka-topics.sh --create --topic *topic name* **--partitions** *number of partitions occupied by the topic***--replication-factor** *number of replicas of the topic* **--bootstrap-server** *IP address of the Kafkacluster:21007* **--command-config ../config/client.properties**

    If you use **--bootstrap-server** to create a topic, set **rack.aware.enable** and **az.aware.enable** to **false**.

  – Enable the rack policy and disable the cross-AZ feature.

    The leader of each partition of the topic created based on this policy is randomly allocated on the cluster node. However, different replicas of the same partition are allocated to different racks. Therefore, when this policy is used, ensure that the number of nodes in each rack is the same, otherwise, the load of nodes in the rack with fewer nodes is much higher than the average load of the cluster.

    ./kafka-topics.sh --create --topic *topic name* **--partitions** *number of partitions occupied by the topic***--replication-factor** *number of replicas of the topic* **--zookeeper** *IP address of any ZooKeeper node:clientPort***/kafka --enable-rack-aware**

    ./kafka-topics.sh --create --topic *topic name* **--partitions** *number of partitions occupied by the topic***--replication-factor** *number of replicas of the topic* **--bootstrap-server** *IP address of the Kafkacluster:21007* **--command-config ../config/client.properties**

    If you use **--bootstrap-server** to create a topic, set **rack.aware.enable** to **true** and **az.aware.enable** to **false**.

  – Disable the rack policy and enable the cross-AZ feature.

    The leader of each partition of the topic created based on this policy is randomly allocated on the cluster node. However, different replicas of the

same partition are allocated to different AZs. Therefore, when this policy is used, ensure that the number of nodes in each AZ is the same, otherwise, the load of nodes in the AZ with fewer nodes is much higher than the average load of the cluster.

./kafka-topics.sh --create --topic *topic name* **--partitions** *number of partitions occupied by the topic***--replication-factor** *number of replicas of the topic* **--zookeeper** *IP address of any ZooKeeper node:clientPort***/kafka --enable-az-aware**

./kafka-topics.sh --create --topic *topic name* **--partitions** *number of partitions occupied by the topic***--replication-factor** *number of replicas of the topic* **--bootstrap-server** *IP address of the Kafkacluster:21007* **--command-config ../config/client.properties**

If you use **--bootstrap-server** to create a topic, set **rack.aware.enable** to **false** and **az.aware.enable** to **true**.

- Enable the rack policy and cross-AZ feature.

  The leader of each partition of the topic created based on this policy is randomly allocated on the cluster node. However, different replicas of the same partition are allocated to different racks in different AZs. This policy ensures that the number of nodes on each rack in each AZ is the same, otherwise, the load in the cluster is unbalanced.

  ./kafka-topics.sh --create --topic *topic name* **--partitions** *number of partitions occupied by the topic* **--replication-factor** *number of replicas of the topic* **--zookeeper** *IP address of any ZooKeeper node:clientPort***/kafka --enable-rack-aware --enable-az-aware**

  ./kafka-topics.sh --create --topic *topic name* **--partitions** *number of partitions occupied by the topic***--replication-factor** *number of replicas of the topic* **--bootstrap-server** *IP address of the Kafkacluster:21007* **--command-config ../config/client.properties**

  If you use **--bootstrap-server** to create a topic, set **rack.aware.enable** and **az.aware.enable** to **true**.

  NOTE

  - Kafka supports topic creation in either of the following modes:
    - In **--zookeeper** mode, the client generates a copy allocation scheme. The community supports this mode from the beginning. To reduce the dependency on the ZooKeeper component, the community will delete the support for this mode in later versions. When creating a topic in this mode, you can select a copy allocation policy by combining the **--enable-rack-aware** and **--enable-az-aware** options. Note: The **--enable-az-aware** option can be used only when the cross-AZ feature is enabled on the server, that is, **az.aware.enable** is set to **true**. Otherwise, the execution fails.
    - In **--bootstrap-server** mode, the server generates a copy allocation solution. In later versions, the community supports only this mode for topic management. When a topic is created in this mode, the **--enable-rack-aware** and **--enable-az-aware** options cannot be used to control the copy allocation policy. The **rack.aware.enable** and **az.aware.enable** parameters can be used together to control the copy allocation policy. Note that the **az.aware.enable** parameter cannot be modified; if the cross-AZ feature is enabled during cluster creation, this parameter is automatically set to **true**; the **rack.aware.enable** parameter can be customized.

- List of topics:
  - **./kafka-topics.sh --list --zookeeper** *service IP address of any ZooKeeper node:clientPort*/**kafka**
  - **./kafka-topics.sh --list --bootstrap-server** *IP address of the Kafkacluster:21007* **--command-config ../config/client.properties**
- Viewing the topic:
  - **./kafka-topics.sh --describe --zookeeper** *service IP address of any ZooKeeper node:clientPort*/**kafka** --**topic** *topic name*
  - **./kafka-topics.sh --describe --bootstrap-server** *IP address of the Kafkacluster:21007* **--command-config ../config/client.properties --topic** *topic name*
- Modifying a topic:
  - **./kafka-topics.sh --alter --topic** *topic name*--**config** *configuration item=configuration value* **--zookeeper** *service IP address of any ZooKeeper node:clientPort*/**kafka**
- Expanding partitions:
  - **./kafka-topics.sh --alter --topic** *topic name* **--zookeeper** *service IP address of any ZooKeeper node:clientPort*/**kafka --command-config Kafka/kafka/config/client.properties --partitions** *number of partitions after the expansion*
  - **./kafka-topics.sh --alter --topic** *topic name* **--bootstrap-server** *IP address of the Kafka cluster:21007* **--command-config Kafka/kafka/config/client.properties --partitions** *number of partitions after the expansion*
- Deleting a topic
  - **./kafka-topics.sh --delete --topic** *topic name* **--zookeeper** *Service IP address of any ZooKeeper node:clientPort*/**kafka**
  - **./kafka-topics.sh --delete --topic** *topic name*--**bootstrap-server** *IP address of the Kafka cluster:21007* **--command-config ../config/client.properties**

----End

12.14.3 Querying Kafka Topics

Scenario

You can query existing Kafka topics on MRS.

Procedure

Step 1 Go to the Kafka service page.

- For versions earlier than MRS 3.x, click the cluster name to go to the cluster details page and choose **Components** > **Kafka**.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the desired cluster* > **Services** > **Kafka**.

Step 2 Click **KafkaTopicMonitor**.

All topics are displayed in the list by default. You can view the number of partitions and replicas of the topics.

Step 3 Click the desired topic in the list to view its details.

----End

12.14.4 Managing Kafka User Permissions

Scenario

For clusters with Kerberos authentication enabled, using Kafka requires relevant permissions. MRS clusters can grant the use permission of Kafka to different users.

Table 12-258 lists the default Kafka user groups.

NOTE

In MRS 3.*x* or later, Kafka supports two types of authentication plug-ins: Kafka open source authentication plug-in and Ranger authentication plug-in.

This section describes the user permission management based on the Kafka open source authentication plug-in. For details about how to use the Ranger authentication plug-in, see **Adding a Ranger Access Permission Policy for Kafka**.

Table 12-258 Default Kafka user groups

User Group	Description
kafkaadmin	Kafka administrator group. Users in this group have the permissions to create, delete, read, and write all topics, and authorize other users.
kafkasuperuser	Kafka super user group. Users in this group have the permissions to read and write all topics.
kafka	Kafka common user group. Users in this group can access a topic only when they are granted with the read and write permissions of the topic by a user in the **kafkaadmin** group.

Prerequisites

- You have installed the Kafka client.
- A user in the **kafkaadmin** group, for example **admin**, has been prepared.

Procedure

Step 1 Access the ZooKeeper instance page.

- For versions earlier than MRS 3.x, click the cluster name to go to the cluster details page and choose **Components** > **ZooKeeper** > **Instances**.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the desired cluster* > **Services** > **ZooKeeper** > **Instance**.

Step 2 View the IP addresses of the ZooKeeper role instance.

Record the IP address of any ZooKeeper instance.

Step 3 Prepare the client based on service requirements. Log in to the node where the client is installed.

Log in to the node where the client is installed. For details, see **Using an MRS Client**.

Step 4 Run the following command to switch to the client directory, for example, **/opt/client/Kafka/kafka/bin**.

cd /opt/client/Kafka/kafka/bin

Step 5 Run the following command to configure environment variables:

source /opt/client/bigdata_env

Step 6 Run the following command to authenticate the user(skip this step in normal mode):

kinit *Component service user*

Step 7 Versions earlier than MRS 3.x: Select the scenario required by the service and manage Kafka user permissions.

- Querying the permission list of a topic

  sh kafka-acls.sh --authorizer-properties zookeeper.connect=*IP address of the node where the ZooKeeper instance resides*:2181/kafka --list --topic *Topic name*

- Adding producer permission to a user

  sh kafka-acls.sh --authorizer-properties zookeeper.connect=*IP address of the node where the ZooKeeper instance resides*:2181/kafka --add --allow-principal User:*Username* --producer --topic *Topic name*

- Removing producer permission of a user

  sh kafka-acls.sh --authorizer-properties zookeeper.connect=*IP address of the node where the ZooKeeper instance resides*:2181/kafka --remove --allow-principal User:*Username* --producer --topic *Topic name*

- Adding consumer permission to a user

  sh kafka-acls.sh --authorizer-properties zookeeper.connect=*IP address of the node where the ZooKeeper instance resides*:2181/kafka --add --allow-principal User:*Username* --consumer --topic *Topic name* --group *Consumer group name*

- Removing consumer permission of a user

  sh kafka-acls.sh --authorizer-properties zookeeper.connect=*IP address of the node where the ZooKeeper instance resides*:2181/kafka --remove --allow-principal User:*Username* --consumer --topic *Topic name* --group *Consumer group name*

  NOTE

  You need to enter **y** twice to confirm the removal of permission.

Step 8 MRS 3.*x* and later versions: The following table lists the common commands used for user authorization when **kafka-acl.sh** is used.

- View the permission control list of a topic:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=*<Service IP address of any ZooKeeper node:21812181/kafka >* **--list --topic** *<Topic name>*

  ./kafka-acls.sh --bootstrap-server <*IP address of the Kafkacluster:21007*> **--command-config ../config/client.properties --list --topic** <*topic name*>

- Add the Producer permission for a user:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=*<Service IP address of any ZooKeeper node:21812181/kafka >* **--add --allow-principal User:***<User name>* **--producer --topic** *<Topic name>*

  ./kafka-acls.sh --bootstrap-server <*IP address of the Kafkacluster:21007*> **--command-config ../config/client.properties --add --allow-principal User:***<username>* **--producer --topic** <*topic name*>

- Assign the Producer permission to a user in batches.

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=*<Service IP address of any ZooKeeper node:21812181/kafka >* **--add --allow-principal User:***<User name>* **--producer --topic** *<Topic name>* **--resource-pattern-type prefixed**

  ./kafka-acls.sh --bootstrap-server <*IP address of the Kafkacluster:21007*> **--command-config ../config/client.properties --add --allow-principal User:***<username>* **--producer --topic** *<topic name>***--resource-pattern-type prefixed**

- Remove the Producer permission from a user:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=*<Service IP address of any ZooKeeper node:21812181/kafka >* **--remove --allow-principal User:***<User name>* **--producer --topic** *<Topic name>*

  ./kafka-acls.sh --bootstrap-server <*IP address of the Kafkacluster:21007*> **--command-config ../config/client.properties --remove --allow-principal User:***<username>* **--producer --topic** <*topic name*>

- Delete the Producer permission of a user in batches:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=*<Service IP address of any ZooKeeper node:21812181/kafka >* **--remove --allow-principal User:***<User name>* **--producer --topic** *<Topic name>* **--resource-pattern-type prefixed**

  ./kafka-acls.sh --bootstrap-server <*IP address of the Kafkacluster:21007*> **--command-config ../config/client.properties --remove --allow-principal User:***<username>* **--producer --topic** *<topic name>***--resource-pattern-type prefixed**

- Add the Consumer permission for a user:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=*<Service IP address of any ZooKeeper node:21812181/kafka >* **--add --allow-principal User:***<User name>* **--consumer --topic** *<Topic name>* **--group** *<Consumer group name>*

  ./kafka-acls.sh --bootstrap-server *<IP address of the Kafkacluster:21007>* **--command-config ../config/client.properties --add --allow-principal User:***<username>* **--consumer --topic** *<topicname>* **--group** *<consumer group name>*

- Add consumer permissions to a user in batches:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=*<Service IP address of any ZooKeeper node:21812181/kafka >* **--add --allow-principal User:***<User name>* **--consumer --topic** *<Topic name>* **--group** *<Consumer group name>* **--resource-pattern-type prefixed**

  ./kafka-acls.sh --bootstrap-server *<IP address of the Kafkacluster:21007>* **--command-config ../config/client.properties --add --allow-principal User:***<username>* **--consumer --topic** *<topicname>* **--group** *<consumer group name>* **--resource-pattern-type prefixed**

- Remove the consumer permission from a user:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=*<Service IP address of any ZooKeeper nodeIP:21812181/kafka >* **--remove --allow-principal User:***<User name>* **--consumer --topic** *<Topic name>* **--group** *<Consumer group name>*

  ./kafka-acls.sh --bootstrap-server *<IP address of the Kafkacluster:21007>* **--command-config ../config/client.properties --remove --allow-principal User:***<username>* ***--consumer --topic*** *<topic name>* **--group** *<consumer group name>*

- Delete the consumer permission of a user in batches:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=*Service IP address of any ZooKeeper node:21812181/kafka >* **--remove --allow-principal User:***<User name>* **--consumer --topic** *<Topic name>* **--group** *<Consumer group name>* **--resource-pattern-type prefixed**

  ./kafka-acls.sh --bootstrap-server *<IP address of the Kafkacluster:21007>* **--command-config ../config/client.properties --remove --allow-principal User:***<username>* **--consumer --topic** *<topicname>* **--group** *<consumer group name>* **--resource-pattern-type prefixed**

----End

12.14.5 Managing Messages in Kafka Topics

Scenario

You can produce or consume messages in Kafka topics using the MRS cluster client. For clusters with Kerberos authentication enabled, you must have the permission to perform these operations.

Prerequisites

You have installed the Kafka client.

Procedure

Step 1 Go to the Kafka service page.

- For versions earlier than MRS 3.x, click the cluster name to go to the cluster details page and choose **Components** > **Kafka**.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager and choose **Cluster** > *Name of the desired cluster* > **Services** > **Kafka**.

Step 2 Click **instance**. Query the IP addresses of the Kafka instances.

Record the IP address of any Kafka instance.

Step 3 Prepare the client based on service requirements. Log in to the node where the client is installed.

Log in to the node where the client is installed. For details, see **Using an MRS Client**.

Step 4 Run the following command to switch to the client directory, for example, /**opt/client/Kafka/kafka/bin**.

cd /opt/client/Kafka/kafka/bin

Step 5 Run the following command to configure environment variables:

source /opt/client/bigdata_env

Step 6 For clusters with Kerberos authentication enabled, run the following command to authenticate the user. For clusters with Kerberos authentication disabled, skip this step.

kinit *Kafka user*

Example:

kinit admin

Step 7 Manage messages in Kafka topics using the following commands:

- Producing messages

  sh kafka-console-producer.sh --broker-list *IP address of the node where the Kafka instance resides*:**9092 --topic** *Topic name* **--producer.config /opt/client/Kafka/kafka/config/producer.properties**

  You can input specified information as the messages produced by the producer and then press **Enter** to send the messages. To end message producing, press **Ctrl + C** to exit.

- Consuming messages

  sh kafka-console-consumer.sh --topic *Topic name* **--bootstrap-server** *IP address of the node where the Kafka instance resides*:**9092 --consumer.config /opt/client/Kafka/kafka/config/consumer.properties**

In the configuration file, **group.id** (indicating the consumer group) is set to **example-group1** by default. Users can change the value as required. The value takes effect each time consumption occurs.

By default, the system reads unprocessed messages in the current consumer group when the command is executed. If a new consumer group is specified in the configuration file and the **--from-beginning** parameter is added to the command, the system reads all messages that have not been automatically deleted in Kafka.

NOTE

----End

12.14.6 Synchronizing Binlog-based MySQL Data to the MRS Cluster

This section describes how to use the Maxwell data synchronization tool to migrate offline binlog-based data to an MRS Kafka cluster.

Maxwell is an open source application that reads MySQL binlogs, converts operations, such as addition, deletion, and modification, into a JSON format, and sends them to an output end, such as a console, a file, and Kafka. For details about Maxwell, visit **https://maxwells-daemon.io**. Maxwell can be deployed on a MySQL server or on other servers that can communicate with MySQL.

Maxwell runs on a Linux server, including EulerOS, Ubuntu, Debian, CentOS, and OpenSUSE. Java 1.8+ must be supported.

The following provides details about data synchronization.

1. **Configuring MySQL**
2. **Installing Maxwell**
3. **Configuring Maxwell**
4. **Starting Maxwell**
5. **Verifying Maxwell**
6. **Stopping Maxwell**
7. **Format of the Maxwell Generated Data and Description of Common Fields**

Configuring MySQL

Step 1 Start the binlog, open the **my.cnf** file in MySQL, and check whether **server_id**, **log-bin**, and **binlog_format** are configured in the **[mysqld]** block. If they are not configured, run the following command to add configuration items and restart MySQL. If they are configured, skip this step.

```
$ vi my.cnf

[mysqld]
server_id=1
log-bin=master
binlog_format=row
```

Step 2 Maxwell needs to connect to MySQL, create a database named **maxwell** for storing metadata, and access the database to be synchronized. Therefore, you are

advised to create a MySQL user for Maxwell to use. Log in to MySQL as user **root** and run the following commands to create a user named **maxwell** (*XXXXXX* indicates the password and needs to be replaced with actual one).

- If Maxwell is deployed on a non-MySQL server, the created user **maxwell** must have a permission to remotely log in to the database. In this case, run the following command to create the user:

  mysql> GRANT ALL on maxwell.* to 'maxwell'@'%' identified by 'XXXXXX';

  mysql> GRANT SELECT, REPLICATION CLIENT, REPLICATION SLAVE on *.* to 'maxwell'@'%';

- If Maxwell is deployed on the MySQL server, the created user **maxwell** can be configured to log in to the database only on the local host. In this case, run the following command:

  mysql> GRANT SELECT, REPLICATION CLIENT, REPLICATION SLAVE on *.* to 'maxwell'@'localhost' identified by 'XXXXXX';

  mysql> GRANT ALL on maxwell.* to 'maxwell'@'localhost';

----End

Installing Maxwell

Step 1 Download the installation package at **https://github.com/zendesk/maxwell/releases** and select the **maxwell-XXX.tar.gz** binary file for download. In the file name, **XXX** indicates a version number.

Step 2 Upload the **tar.gz** package to any directory (the **/opt** directory of the Master node used as an example here).

Step 3 Log in to the server where Maxwell is deployed and run the following command to go to the directory where the **tar.gz** package is stored.

cd /opt

Step 4 Run the following commands to decompress the **maxwell-XXX.tar.gz** package and go to the **maxwell-XXX** directory:

tar -zxvf maxwell-XXX.tar.gz

cd maxwell-XXX

----End

Configuring Maxwell

If the **conf** directory exists in the **maxwell-XXX** folder, configure the **config.properties** file. For details about the configuration items, see **Table 12-259**. If the **conf** directory does not exist, change **config.properties.example** in the **maxwell-XXX** folder to **config.properties**.

Table 12-259 Maxwell configuration item description

Parameter	Mandatory	Description	Default Value
user	Yes	Name of the user for connecting to MySQL, that is, the user created in **Step 2**.	-
password	Yes	Password for connecting to MySQL	-
host	No	MySQL address	localhost
port	No	MySQL port	3306
log_level	No	Log print level. The options are as follows: • debug • info • warn • error	info
output_ddl	No	Whether to send a DDL (modified based on definitions of the database and data table) event • **true**: Send DDL events. • **false**: Do not send DDL events.	false
producer	Yes	Producer type. Set this parameter to **kafka**. • **stdout**: Log the generated events. • **kafka**: Send the generated events to Kafka.	stdout
producer_partition_by	No	Partition policy used to ensure that data of the same type is written to the same partition of Kafka. • **database**: Events of the same database are written to the same partition of Kafka. • **table**: Events of the same table are written to the same partition of Kafka.	databa
ignore_producer_error	No	Specifies whether to ignore the error that the producer fails to send data. • **true**: The error information is logged and the error data is skipped. The program continues to run. • **false**: The error information is logged and the program is terminated.	true
metrics_slf4j_interval	No	Interval for outputting statistics on data successfully uploaded or failed to be uploaded to Kafka in logs. The unit is second.	60

Parameter	Mandatory	Description	Default Value
kafka.bootstrap.servers	Yes	Address of the Kafka proxy node. The value is in the format of **HOST:PORT[,HOST:PORT]**.	-
kafka_topic	No	Name of the topic that is written to Kafka	maxwell
dead_letter_topic	No	Kafka topic used to record the primary key of the error log record when an error occurs when the record is sent	-
kafka_version	No	Kafka producer version used by Maxwell, which cannot be configured in the **config.properties** file. You need to use the **--kafka_version xxx** parameter to import the version number when starting the command.	-
kafka_partition_hash	No	Kafka topic partitioning algorithm. The value can be **default** or **murmur3**.	default
kafka_key_format	No	Key generation method of the Kafka record. The value can be **array** or **Hash**.	Hash
ddl_kafka_topic	No	Topic that is written to the DDL operation when **output_ddl** is set to **true**	{kafka_topic}
filter	No	Used to filter databases or tables. ● If only the **mydatabase** database needs to be collected, set this parameter to the following: exclude: *.*,include: mydatabase.* ● If only the **mydatabase.mytable** table needs to be collected, set this parameter to the following: exclude: *.*,include: mydatabase.mytable ● If only the **mytable**, **mydate_123**, and **mydate_456** tables in the **mydatabase** database need to be collected, set this parameter to the following: exclude: *.*,include: mydatabase.mytable,include: mydatabase./mydate_\\d*/	-

Starting Maxwell

Step 1 Log in to the server where Maxwell is deployed.

Step 2 Run the following command to go to the Maxwell installation directory:

cd /opt/maxwell-1.21.0/

NOTE

For the first time to use Maxwell, you are advised to change **log_level** in **conf/config.properties** to **debug** (debug level) so that you can check whether data can be obtained from MySQL and sent to Kafka after startup. After the entire process is debugged, change **log_level** to **info**, and then restart Maxwell for the modification to take effect.

```
# log level [debug | info | warn | error]
log_level=debug
```

Step 3 Run the following commands to start Maxwell:

source /opt/client/bigdata_env

bin/Maxwell

**bin/maxwell --user='maxwell' --password='XXXXXX' --host='127.0.0.1' **

--producer=kafka --kafka.bootstrap.servers=kafkahost:9092 --kafka_topic=Maxwell

In the preceding commands, **user**, **password**, and **host** indicate the username, password, and IP address of MySQL, respectively. You can configure the three parameters by modifying configurations of the configuration items or using the preceding commands. **kafkahost** indicates the IP address of the Core node in the streaming cluster.

If information similar to the following appears, Maxwell has started successfully:

```
Success to start Maxwell [78092].
```

----End

Verifying Maxwell

Step 1 Log in to the server where Maxwell is deployed.

Step 2 View the logs. If the log file does not contain an ERROR log and the following information is displayed, the connection between Maxwell and MySQL is normal:

```
BinlogConnectorLifecycleListener - Binlog connected.
```

Step 3 Log in to the MySQL database and update, create, or delete test data. The following provides operation statement examples for your reference.

```
--Creating a database
create database test;
--Creating a table
create table test.e (
  id int(10) not null primary key auto_increment,
  m double,
  c timestamp(6),
  comment varchar(255) charset 'latin1'
);
-- Adding a record
insert into test.e set m = 4.2341, c = now(3), comment = 'I am a creature of light.';
--Updating a record
update test.e set m = 5.444, c = now(3) where id = 1;
--Deleting a record
delete from test.e where id = 1;
--Modifying a table
alter table test.e add column torvalds bigint unsigned after m;
--Deleting a table
drop table test.e;
-- Deleting a database
drop database test;
```

Step 4 Check the Maxwell logs. If no WARN/ERROR is displayed, Maxwell is installed and configured properly.

To check whether the data is successfully uploaded, set **log_level** in the **config.properties** file to **debug**. When the data is successfully uploaded, the following JSON data is printed immediately. For details about the fields, see **Format of the Maxwell Generated Data and Description of Common Fields**.

```
{"database":"test","table":"e","type":"insert","ts":1541150929,"xid":60556,"commit":true,"data":
{"id":1,"m":4.2341,"c":"2018-11-02 09:28:49.297000","comment":"I am a creature of light."}}
.....
```

NOTE

After the entire process is debugged, you can change the value of **log_level** in the **config.properties** file to **info** to reduce the number of logs to be printed and restart Maxwell for the modification to take effect.

```
# log level [debug | info | warn | error]
log_level=info
```

----End

Stopping Maxwell

Step 1 Log in to the server where Maxwell is deployed.

Step 2 Run the command to obtain the Maxwell process ID (PID). The second field in the command output is PID.

ps -ef | grep Maxwell | grep -v grep

Step 3 Run the following command to forcibly stop the Maxwell process:

kill -9 PID

----End

Format of the Maxwell Generated Data and Description of Common Fields

The data generated by Maxwell is in JSON format. The common fields are described as follows:

- **type**: operation type. The options are **database-create**, **database-drop**, **table-create**, **table-drop**, **table-alter**, **insert**, **update**, and **delete**.
- **database**: name of the database to be operated
- **ts**: operation time, which is a 13-digit timestamp
- **table**: name of the table to be operated
- **data**: content after data is added, deleted, or modified
- **old**: content before data is modified or schema definition before a table is modified
- **sql**: SQL statement for DDL operations
- **def**: schema definition for table creation and modification
- **xid**: unique ID of an object
- **commit**: check whether such operations as data addition, deletion, and modification have been submitted.

12.14.7 Creating a Kafka Role

Scenario

This section describes how to create and configure a Kafka role.

This section applies to MRS 3.x or later.

NOTE

Users can create Kafka roles only in security mode.

If the current component uses Ranger for permission control, you need to configure permission management policies based on Ranger. For details, see **Adding a Ranger Access Permission Policy for Kafka**.

Prerequisites

The system administrator has understood the service requirements.

Procedure

Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **Role**.

Step 2 On the displayed page, click **Create Role** and enter a **Role Name** and **Description**.

Step 3 On the **Configure Resource Permission** page, choose *Name of the desired cluster* > **Kafka**.

Step 4 Select permissions based on service requirements. For details about configuration items, see **Table 12-260**.

Table 12-260 Description

Scenario	Role Authorization
Setting the Kafka administrator permissions	In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Kafka** > **Kafka Manager Privileges**. **NOTE** This permission allows you to create and delete topics, but does not allow you to produce or consume any topics.
Setting the production permission of a user on a topic	1. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Kafka** > **Kafka Topic Producer And Consumer Privileges**. 2. In the **Permission** column of the specified topic, select **Kafka Producer Permission**.

Scenario	Role Authorization
Setting the consumption permission of a user on a topic	1. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Kafka** > **Kafka Topic Producer And Consumer Privileges**. 2. In the **Permission** column of the specified topic, select **Kafka Consumer Privileges**.

Step 5 Click **OK**, and return to the **Role** page.

----End

12.14.8 Kafka Common Parameters

This section applies to MRS 3.x or later.

Navigation path for setting parameters:

For details about how to set parameters, see **Modifying Cluster Service Configuration Parameters**.

Common Parameters

Table 12-261 Parameter description

Parameter	Description	Default Value
log.dirs	List of Kafka data storage directories. Use commas (,) to separate multiple directories.	%{@auto.detect.datapart.bk.log.logs}
KAFKA_HEAP_OPTS	Specifies the JVM option used for Kafka to start broker. It is recommended that you set this parameter based on service requirements.	-Xmx6G -Xms6G
auto.create.topics.enable	Indicates whether a topic is automatically created. If this parameter is set to **false**, you need to run a command to create a topic before sending a message.	true
default.replication.factor	Default number of replicas of a topic is automatically created.	2

Parameter	Description	Default Value
monitor.preInitDelay	Delay of the first health check after the server is started. If the startup takes a long time, increase the value of the parameter. Unit: millisecond	600,000

Timeout Parameters

Table 12-262 Broker-related timeout parameters

Parameter	Description	Default Value	Impact
controller.socket.timeout.ms	Specifies the timeout for connecting controller to broker. Unit: millisecond	30,000	Generally, retain the default value of this parameter.
group.max.session.timeout.ms	Specifies the maximum session timeout during the consumer registration. Unit: millisecond	1800000	The configured value must be less than the value of this parameter.
group.min.session.timeout.ms	Specifies the minimum session timeout during the consumer registration. Unit: millisecond	6,000	The configured value must be greater than the value of this parameter.
offsets.commit.timeout.ms	Specifies the timeout for the Offset to submit requests. Unit: millisecond	5,000	This parameter specifies the maximum delay for processing an Offset request.
replica.socket.timeout.ms	Specifies the timeout of the request for synchronizing replica data. Its value must be greater than or equal to that of the **replica.fetch.wait.max.ms** parameter. Unit: millisecond	30,000	Specifies the maximum timeout for establishing a channel before the synchronization thread sends a synchronization request. The value must be greater than that of the **replica.fetch.wait.max.ms** parameter.

Parameter	Description	Default Value	Impact
request.timeout.ms	Specifies the timeout for waiting for a response after the client sends a connection request. If no response is received within the timeout, the client resends the request. A request failure is returned after the maximum retry times is reached. Unit: millisecond	30,000	This parameter is configured when the networkclient connection is transferred in the controller and replica threads on the broker node.
transaction.max.timeout.ms	Specifies the maximum timeout allowed by the transaction. If the client request time exceeds the value of this parameter, broker returns an error in InitProducerIdRequest. This prevents a long client request timeout, ensuring that consumer can receive topics. Unit: millisecond	900,000	Specifies the maximum timeout for transactions.
user.group.cache.timeout.sec	Specifies the time when the user group information is stored in the cache. Unit: second	300	Specifies the time for caching the mapping between users and user groups. If time exceeds the threshold, the system automatically runs the **id -Gn** command to query the user information. During this period, the mapping in the cache is used.
zookeeper.connection.timeout.ms	Specifies the timeout for connecting to ZooKeeper. Unit: millisecond	45,000	This parameter specifies the duration for connecting the ZooKeeper and zkclient for the first time. If the duration exceeds the value of this parameter, the zkclient automatically disconnects the connection.

Parameter	Description	Default Value	Impact
zookeeper.session.timeout.ms	Specifies the ZooKeeper session timeout duration. During this period, ZooKeeper disconnects the connection if broker does not report its heartbeats to ZooKeeper. Unit: millisecond	45,000	ZooKeeper session timeout has the following functions: 1) Based on value of this parameter and the number of ZooKeeper URLs in ZKURL, if the connection duration exceeds the node timeout value (sessionTimeout/ Number of transferred ZooKeeper URLs), the connection fails and the system attempts to connect to the next node. 2) After the connection is established, a session (for example, the temporary BrokerId node registered on the ZooKeeper) is cleared by the ZooKeeper a session timeout later if the broker is stopped.

Table 12-263 Producer-related timeout parameters

Parameter	Description	Default Value	Impact
request.timeout.ms	Specifies the timeout of a message request.	30,000	If a network fault occurs, increase the value of this parameter. If the value is too small, the Batch Expire occurs.

Table 12-264 Consumer-related timeout parameters

Parameter	Description	Default Value	Impact
connections.max.idle.ms	Specifies the maximum retention period for idle connections.	600,000	If the idle connection time is greater than this parameter value, this connection is disconnected. If necessary, a new connection is created.
request.timeout.ms	Specifies the timeout for consumer requests.	30,000	If the request times out, the request will fail and be sent again.

12.14.9 Safety Instructions on Using Kafka

This section applies to MRS 3.*x* or later.

Brief Introduction to Kafka APIs

- Producer API

  Indicates the API defined in **org.apache.kafka.clients.producer.KafkaProducer**. When **kafka-console-producer.sh** is used, the API is used by default.

- Consumer API

  Indicates the API defined in **org.apache.kafka.clients.consumer.KafkaConsumer**. When **kafka-console-consumer.sh** is used, the API is used by default.

NOTE

In MRS 3.*x* or later, Kafka no longer support old Producer or Consumer APIs.

Protocol Description for Accessing Kafka

The protocols used to access Kafka are as follows: PLAINTEXT, SSL, SASL_PLAINTEXT, and SASL_SSL.

When Kafka service is started, the listeners using the PLAINTEXT and SASL_PLAINTEXT protocols are started. You can set **ssl.mode.enable** to **true** in Kafka service configuration to start listeners using SSL and SASL_SSL protocols. The following table describes the four protocols:

Protocol	Description	Default Port
PLAINTEXT	Supports plaintext access without authentication.	9092

Protocol	Description	Default Port
SASL_PLAINTEXT	Supports plaintext access with Kerberos authentication.	21007
SSL	Supports SSL-encrypted access without authentication.	9093
SASL_SSL	Supports SSL-encrypted access with Kerberos authentication.	21009

ACL Settings for a Topic

To view and set topic permission information, run the **kafka-acls.sh** script on the Linux client. For details, see **Managing Kafka User Permissions**.

Use of Kafka APIs in Different Scenarios

- Scenario 1: accessing the topic with an ACL

Used API	User Group	Client Parameter	Server Parameter	Accessed Port
API	Users need to meet one of the following conditions: • In the administrator group • In the **kafkaadmin** group • In the **kafkasuperuser** group • In the **kafka** group and be authorized	security.inter.broker.protocol=SASL_PLAINTEXT sasl.kerberos.service.name = kafka	-	sasl.port (The default number is 21007.)
		security.protocol=SASL_SSL sasl.kerberos.service.name = kafka	Set **ssl.mode.enable** to **true**.	sasl-ssl.port (The default number is 21009.)

- Scenario 2: accessing the topic without an ACL

Used API	User Group	Client Parameter	Server Parameter	Accessed Port
API	Users need to meet one of the following conditions: • In the administrator group • In the **kafkaadmin** group • In the **kafkasuperuser** group	security.protocol=SASL_PLAINTEXT sasl.kerberos.service.name = kafka	-	sasl.port (The default number is 21007.)
	Users are in the **kafka** group.		Set **allow.everyone.if.no.acl.found** to **true**. **NOTE** In normal mode, the server parameter **allow.everyone.if.no.acl.found** does not need to be modified.	sasl.port (The default number is 21007.)
	Users need to meet one of the following conditions: • In the administrator group • In the **kafkaadmin** group • In the **kafkasuperuser** group	security.protocol=SASL_SSL sasl.kerberos.service.name = kafka	Set **ssl.mode.enable** to **true**.	sasl-ssl.port (The default number is 21009.)

Used API	User Group	Client Parameter	Server Parameter	Accessed Port
	Users are in the **kafka** group.		1. Set **allow.everyone.if.no.acl.found** to **true**. 2. Set **ssl.mode.enable** to **true**.	sasl-ssl.port (The default number is 21009.)
	-	security.protocol=PLAINTEXT	Set **allow.everyone.if.no.acl.found** to **true**.	port (The default number is 9092.)
	-	security.protocol=SSL	1. Set **allow.everyone.if.no.acl.found** to **true**. 2. Set **ssl.mode.enable** to **true**.	ssl.port (The default number is 9063.)

12.14.10 Kafka Specifications

This section applies to MRS 3.x or later.

Upper Limit of Topics

The maximum number of topics depends on the number of file handles (mainly used by data and index files on site) opened in the process.

1. Run the **ulimit -n** command to view the maximum number of file handles that can be opened in the process.
2. Run the **lsof -p** *<Kafka PID>* command to view the file handles (which may keep increasing) that are opened in the Kafka process on the current single node.
3. Determine whether the maximum number of file handles will be reached and whether the running of Kafka is affected after required topics are created, and estimate the maximum size of data that each partition folder can store and the number of data (*.log file, whose default size is 1 GB and can be adjusted by modifying **log.segment.bytes**) and index (*.index file, whose default size is 10 MB and can be adjusted by modifying **log.index.size.max.bytes**) files that will be produced after required topics are created.

Number of Concurrent Consumers

In an application, it is recommended that the number of concurrent consumers in a group be the same as the number of partitions in a topic, ensuring that a consumer consumes data in only a specified partition. If the number of concurrent consumers is more than the number of partitions, the redundant consumers have no data to consume.

Relationship Between Topic and Partition

- If *K* Kafka nodes are deployed in the cluster, each node is configured with *N* disks, the size of each disk is *M*, the cluster contains *n* topics (named as T1, T2, ..., Tn), the data input traffic per second of the *m* topic is *X* (Tm) MB/s, the number of configured replicas is *R* (Tm), and the configured data retention time is *Y* (Tm) hour, the following requirement must be met:

$$M \times N \times K > \sum_{i=T1}^{Tn} (X(i)R(i)Y(i) \times 3600)$$

- If the size of a disk is *M*, the disk has *n* partitions (named as P0, P1, ..., Pn), the data write traffic per second of the *m* partition is *Q* (Pm) MB/s (calculation method: data traffic of the topic to which the *m* partition belongs divided by the number of partitions), and the data retention time is *T* (Pm) hours, the following requirement must be met for the disk:

$$M > \sum_{i=P0}^{Pn} (Q(i)T(i) \times 3600)$$

- Based on the throughput, if the throughput that can be reached by the producer is *P*, the throughput that can be reached by the consumer is *C*, and the expected throughput of Kafka is *T*, it is recommended that the number of partitions of the topic be set to Max(T/P, T/C).

NOTE

- In a Kafka cluster, more partitions mean higher throughput. However, too many partitions also pose potential impacts, such as a file handle increase, unavailability increase (for example, if a node is faulty, the time window becomes large after the leader is reselected in some partitions), and end-to-end latency increase.
- Suggestion: The disk usage of a partition is smaller than or equal to 100 GB; the number of partitions on a node is smaller than or equal to 3,000; the number of partitions in the entire cluster is smaller than or equal to 10,000.

12.14.11 Using the Kafka Client

Scenario

This section guides users to use a Kafka client in an O&M or service scenario.

This section applies to MRS 3.x or later.

Prerequisites

- The client has been installed. For example, the installation directory is **/opt/client**.

- Service component users are created by the administrator as required. Machine-machine users need to download the keytab file. A human-machine user must change the password upon the first login. (Not involved in normal mode)
- After changing the domain name of a cluster, redownload the client to ensure that the **kerberos.domain.name** value in the configuration file of the client is set to the correct server domain name.

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the following command to perform user authentication (skip this step in normal mode):

kinit *Component service user*

Step 5 Run the following command to switch to the Kafka client installation directory:

cd Kafka/kafka/bin

Step 6 Run the following command to use the client tool to view and use the help information:

- **./kafka-console-consumer.sh**: Kafka message reading tool
- **./kafka-console-producer.sh**: Kafka message publishing tool
- **./kafka-topics.sh**: Kafka topic management tool

----End

12.14.12 Configuring Kafka HA and High Reliability Parameters

Scenario

For the Kafka message transmission assurance mechanism, different parameters are available for meeting different performance and reliability requirements. This section describes how to configure Kafka high availability (HA) and high reliability parameters.

This section applies to MRS 3.x or later.

Impact on the System

- Impact of HA and high performance configurations:

NOTICE

After HA and high performance are configured, the data reliability decreases. Specifically, data may be lost of disks or nodes are faulty.

- Impact of high reliability configurations:
  - Deteriorated performance

    If **ack** is set to **–1**, data written is considered as successful only when data is written to multiple replicas. As a result, the delay of a single message increases and the client processing capability decreases. The impact is subject to the actual test data.
  - Reduced availability

    A replica that is not in the ISR list cannot be elected as a leader. If the leader goes offline and other replicas are not in the ISR list, the partition remains unavailable until the leader node recovers. When the node where a replica of a partition is located is faulty, the minimum number of successful replicas cannot be met. As a result, service writing fails.
- If parameters are at the service level, Kafka needs to be restarted. You are advised to modify the service-level configuration in the change window.

Parameter Description

- If services require high availability and high performance,

  set the parameters listed in **Table 12-265** on the server. For details about the parameter configuration entry, see **Modifying Cluster Service Configuration Parameters**.

  Table 12-265 Server HA and high performance parameters

Parameter	Default Value	Description
unclean.leader.election.enable	true	Specifies whether a replica that is not in the ISR can be selected as the leader. If this parameter is set to **true**, data may be lost.
auto.leader.rebalance.enable	true	Specifies whether the leader automated balancing function is used. If this parameter is set to **true**, the controller periodically balances the leader of each partition on all nodes and assigns the leader to a replica with a higher priority.
min.insync.replicas	1	Specifies the minimum number of replicas to which data is written when **acks** is set to **-1** for the Producer.

Set the parameters listed in **Table 12-266** in the client configuration file **producer.properties**. The path for storing **producer.properties** is /**opt/client/Kafka/kafka/config/producer.properties**, where **/opt/client** indicates the installation directory of the Kafka client.

Table 12-266 Client HA and high performance parameters

Parameter	Default Value	Description
acks	1	The leader needs to check whether the message has been received and determine whether the required operation has been processed. This parameter affects message reliability and performance. ● If this parameter is set to **0**, the producer does not wait for any response from the server, and the message is considered successful. ● If this parameter is set to **1**, when the leader of the replica verifies that data has been written into the cluster, the leader returns a response without waiting for data to be written to all replicas. In this case, if the leader is abnormal when the leader makes the confirmation but replica synchronization is not complete, data will be lost. ● If this parameter is set to **-1**, the message is considered to be successfully received only when all synchronized replicas are confirmed. If the **min.insync.replicas**

Parameter	Default Value	Description
		parameter is also configured, data can be written into multiple replicas. In this case, records will not be lost as long as one replica remains active.

- To ensure high data reliability for services,

  set the parameters listed in **Table 12-267** on the server. For details about the parameter configuration entry, see **Modifying Cluster Service Configuration Parameters**.

  Table 12-267 Server HA parameters

Parameter	Recommended Value	Description
unclean.leader.election.enable	false	A replica that is not in the ISR list cannot be elected as a leader.
min.insync.replicas	2	Specifies the minimum number of replicas to which data is written when **acks** is set to **-1** for the Producer. Ensure that the value of **min.insync.replicas** is equal to or less than that of **replication.factor**.

Set the parameters listed in **Table 12-268** in the client configuration file **producer.properties**. The path for storing **producer.properties** is **/opt/client/Kafka/kafka/config/producer.properties**, where **/opt/client** indicates the installation directory of the Kafka client.

Table 12-268 Server HA parameters

Parameter	Recommended Value	Description
acks	-1	The leader needs to check whether the message has been received and determine whether the required operation has been processed. If this parameter is set to **-1**, the message is considered to be successfully received only when all replicas in the ISR list have confirmed to receive the message. This parameter is used along with **min.insync.replicas** to ensure that multiple copies are successfully written. As long as one copy is active, the record will not be lost. If this parameter is set to **-1**, the production performance deteriorates. Therefore, you need to set this parameter based on the actual situation.

Configuration Suggestions

Configure parameters based on requirements on reliability and performance in the following service scenarios:

- For valued data, you are advised to configure RAID1 or RAID5 for Kafka data directory disks to improve data reliability when a single disk is faulty.
- For parameters that can be modified at the topic level, the service level configurations are used by default.

  These parameters can be separately configured based on topic reliability requirements. For example, log in to the Kafka client as user **root**, and run the following command to configure the reliability parameter with topic named test in the client installation directory:

  cd Kafka/kafka/bin

  kafka-topics.sh --zookeeper 192.168.1.205:2181/kafka --alter --topic test --config unclean.leader.election.enable=false --config min.insync.replicas=2

192.168.1.205 indicates the ZooKeeper service IP address.

- If parameters are at the service level, Kafka needs to be restarted. You are advised to modify the service-level configuration in the change window.

12.14.13 Changing the Broker Storage Directory

Scenario

This section applies to MRS 3.x or later.

When a broker storage directory is added, the system administrator needs to change the broker storage directory on FusionInsight Manager, to ensure that the Kafka can work properly. The new topic partition will be generated in the directory that has fewest partitions. Changing the ZooKeeper storage directory includes the following scenarios:

NOTE

Because Kafka does not detect disk capacity, ensure that the disk quantity and capacity configured for each Broker instance are the same.

- Change the storage directory of the Broker role. In this way, the storage directories of all Broker instances are changed.
- Change the storage directory of a single Broker instance. In this way, only the storage directory of this Broker instance is changed, and the storage directories of other Broker instances remain the same.

Impact on the System

- Changing the Broker role storage directory requires the restart of services. The services cannot be accessed during the restart.
- The storage directory of a single Broker instance can be changed only after the instance is restarted. The instance cannot provide services during the restart.
- The directory for storing service parameter configurations must also be updated.

Prerequisites

- New disks have been prepared and installed on each data node, and the disks are formatted.
- The Kafka client has been installed.
- When you change the storage directory of a single Broker instance, the number of active Broker instances must be greater than the number of backups specified during topic creation.

Procedure

Changing the storage directory of the Kafka role

Step 1 Log in as user **root** to each node on which the Kafka service is installed, and perform the following operations:

1. Create a target directory.

   For example, to create the target directory **${BIGDATA_DATA_HOME}/kafka/data2**, run the following command:

   mkdir ${BIGDATA_DATA_HOME}/kafka/data2

2. Mount the directory to the new disk. For example, mount **${BIGDATA_DATA_HOME}/kafka/data2** to the new disk.
3. Modify permissions on the new directory.

   For example, to modify permissions on the **${BIGDATA_DATA_HOME}/kafka/data2** directory, run the following commands:

   chmod 700 ${BIGDATA_DATA_HOME}/kafka/data2 -R and **chown omm:wheel ${BIGDATA_DATA_HOME}/kafka/data2 -R**

Step 2 Log in to FusionInsight Manager for clusters of MRS 3.*x* or later and choose **Cluster** > **Services** > **Kafka** > **Configurations**.

Step 3 Add a new directory to the end of the default value of **log.dirs**.

Enter **log.dirs** in the search box and add the new directory to the end of the default value of the **log.dirs** configuration item. Use commas (,) to separate multiple directories. For example:

${BIGDATA_DATA_HOME}/kafka/data1/kafka-logs,${BIGDATA_DATA_HOME}/kafka/data2/kafka-logs

Step 4 Click **Save**, and then click **OK**. When **Operation succeeded** is displayed, click **Finish**.

Step 5 Choose **Cluster** > **Services** > **Kafka**. In the upper right corner, choose **More** > **Restart Service** to restart the Kafka service.

Changing the storage directory of a single Kafka instance

Step 6 Log in to the Broker node as user **root** and perform the following operations:

1. Create a target directory.

   For example, to create the target directory **${BIGDATA_DATA_HOME}/kafka/data2**, run the following command:

   mkdir ${BIGDATA_DATA_HOME}/kafka/data2

2. Mount the directory to the new disk. For example, mount **${BIGDATA_DATA_HOME}/kafka/data2** to the new disk.
3. Modify permissions on the new directory.

   For example, to modify permissions on the **${BIGDATA_DATA_HOME}/kafka/data2** directory, run the following commands:

   chmod 700 ${BIGDATA_DATA_HOME}/kafka/data2 -R and **chown omm:wheel ${BIGDATA_DATA_HOME}/kafka/data2 -R**

Step 7 Log in to FusionInsight Manager for MRS 3.*x* or later, and choose **Cluster** > **Services** > **Kafka** > **Instance**.

Step 8 Click the specified broker instance and switch to **Instance Configurations**.

Enter **log.dirs** in the search box and add the new directory to the end of the default value of the **log.dirs** configuration item. Use commas (,) to separate

multiple directories, for example, **${BIGDATA_DATA_HOME}/kafka/data1/kafka-logs,${BIGDATA_DATA_HOME}/kafka/data2/kafka-logs**.

Step 9 Click **Save**, and then click **OK**. A message is displayed, indicating that the operation is successful. Click **Finish**.

Step 10 On the Broker instance page, choose **More** > **Restart Instance** to restart the Broker instance.

----End

12.14.14 Checking the Consumption Status of Consumer Group

Scenario

This section describes how to view the current expenditure on the client based on service requirements.

This section applies to MRS 3.*x* or later.

Prerequisites

- The system administrator has understood service requirements and prepared a system user.
- The Kafka client has been installed.

Procedure

Step 1 Log in as a client installation user to the node on which the Kafka client is installed.

Step 2 Switch to the Kafka client installation directory, for example, **/opt/kafkaclient**.

cd /opt/kafkaclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the following command to perform user authentication (skip this step in normal mode):

kinit *Component service user*

Step 5 Run the following command to switch to the Kafka client installation directory:

cd Kafka/kafka/bin

Step 6 Run the **kafka-consumer-groups.sh** command to check the current consumption status.

- Check the Consumer Group list on Kafka saved by Offset:

  ./kafka-consumer-groups.sh --list --bootstrap-server <*Service IP address of any broker node:21007*> **--command-config ../config/consumer.properties**

  eg:./kafka-consumer-groups.sh --bootstrap-server 192.168.1.1:21007 --list --command-config ../config/consumer.properties

- Check the consumption status of Consumer Group on Kafka saved by Offset:

  ./kafka-consumer-groups.sh --describe --bootstrap-server <*Service IP address of any broker node:21007*> *--group Consumer group name* **--command-config ../config/consumer.properties**

  eg:./kafka-consumer-groups.sh --describe --bootstrap-server 192.168.1.1:21007 --group example-group --command-config ../config/consumer.properties

NOTICE

1. Ensure that the current consumer is online and consumes data.
2. Configure the **group.id** in the **consumer.properties** configuration file and **--group** in the command to the group to be queried.
3. The Kafka cluster's IP port number is 21007 in security mode and 9092 in normal mode.

----End

12.14.15 Kafka Balancing Tool Instructions

Scenario

This section describes how to use the Kafka balancing tool on a client to balance the load of the Kafka cluster based on service requirements in scenarios such as node decommissioning, node recommissioning, and load balancing.

This section applies to MRS 3.*x* or later. For versions earlier than MRS 3.*x*, see **Balancing Data After Kafka Node Scale-Out**.

Prerequisites

- The system administrator has understood service requirements and prepared a Kafka administrator (belonging to the **kafkaadmin** group. It is not required for the normal mode.).
- The Kafka client has been installed.

Procedure

Step 1 Log in as a client installation user to the node on which the Kafka client is installed.

Step 2 Switch to the Kafka client installation directory, for example, **/opt/kafkaclient**.

cd /opt/kafkaclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the following command to authenticate the user (skip this step in normal mode):

kinit *Component service user*

Step 5 Run the following command to switch to the Kafka client installation directory:

cd Kafka/kafka

Step 6 Run the **kafka-balancer.sh** command to balance user cluster. The commonly used commands are:

- Run the **--run** command to perform cluster balancing:

  ./bin/kafka-balancer.sh --run --zookeeper *<ZooKeeper service IP address of any ZooKeeper node:zkPort/**kafka**>* **--bootstrap-server** *<Kafka cluster IP: port>* **--throttle 10000000 --consumer-config config/consumer.properties --enable-az-aware --show-details**

  This command consists of generation and execution of the balancing solution. **--show-details** is optional, indicating whether to print the solution details. **--throttle** indicates the bandwidth limit during the execution of the balancing solution. The unit is bytes per second (bytes/sec). **--enable-az-aware** indicates that the cross-AZ feature is enabled when the balancing solution is generated. When this parameter is used, ensure that the cross-AZ feature has been enabled for the cluster.

- Run the **--run** command to decommission a node:

  ./bin/kafka-balancer.sh --run --zookeeper *<Service IP address of any ZooKeeper node:zkPort/**kafka**>* **--bootstrap-server** *<Kafka cluster IP address: port>* **--throttle 10000000 --consumer-config config/consumer.properties --remove-brokers** *<BrokerId list>* **--enable-az-aware --force**

  In the command, **--remove-brokers** indicates the list of broker IDs to be deleted. Multiple broker IDs are separated by commas (,). **--force** is optional, indicating that the disk usage alarm is ignored and the migration solution is forcibly generated. **-enable-az-aware** is optional, indicating that the cross-AZ feature is enabled when the balancing solution is generated. When this parameter is used, ensure that the cross-AZ feature has been enabled for the cluster.

- Run the following command to view the execution status:

  ./bin/kafka-balancer.sh --status --zookeeper *<Service IP address of any ZooKeeper node:zkPort/**kafka**>*

- Run the following command to generate a balancing solution:

  ./bin/kafka-balancer.sh --generate --zookeeper *<Service IP address of any ZooKeeper node:zkPort/**kafka**>* **--bootstrap-server** *<Kafka cluster IP address:port>* **--consumer-config config/consumer.properties --enable-az-aware**

  This command is used to generate a migration solution based on the current cluster status and print the solution to the console. **--enable-az-aware** is optional, indicating that the cross-AZ feature is enabled when a migration solution is generated. If this parameter is used, ensure that the cross-AZ feature has been enabled for the cluster.

- Clearing the intermediate status

  ./bin/kafka-balancer.sh --clean --zookeeper *<Service IP address of any ZooKeeper node:zkPort/**kafka**>*

  This command is used to clear the intermediate status information on the ZooKeeper when the migration is not complete.

NOTICE

The port number of the Kafka cluster's IP address is 21007 in security mode and 9092 in normal mode.

----End

Troubleshooting

During partition migration using the Kafka balancing tool, if the execution progress of the balancing tool is blocked due to a Broker fault in the cluster, you need to manually rectify the fault. The scenarios are as follows:

- The Broker is faulty because the disk usage reaches 100%.
  a. Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **Kafka** > **Instance**, stop the Broker instance in the **Restoring** state, and record the management IP address of the node where the instance resides and the corresponding **broker.id**. You can click the role name to view the value, on the **Instance Configurations** page, select **All Configurations** and search for the **broker.id** parameter.
  b. Log in to the recorded management IP address as user **root**, and run the **df -lh** command to view the mounted directory whose disk usage is 100%, for example, **${BIGDATA_DATA_HOME}/kafka/data1**.
  c. Go to the directory, run the **du -sh *** command to view the size of each file in the directory, Check whether files other than files in the **kafka-logs** directory exist, and determine whether these files can be deleted or migrated.
     - If yes, delete or migrate the related data and go to **8**.
     - If no, go to **4**.
  d. Go to the **kafka-logs** directory, run the **du -sh *** command, select a partition folder to be moved. The naming rule is **Topic name-Partition ID**. Record the topic and partition.
  e. Modify the **recovery-point-offset-checkpoint** and **replication-offset-checkpoint** files in the **kafka-logs** directory in the same way.
     i. Decrease the number in the second line in the file. (To remove multiple directories, the number deducted is equal to the number of files to be removed.
     ii. Delete the line of the to-be-removed partition. (The line structure is "*Topic name Partition ID Offset*". Save the data before deletion. Subsequently, the content must be added to the file of the same name in the destination directory.)
  f. Modify the **recovery-point-offset-checkpoint** and **replication-offset-checkpoint** files in the destination data directory (for example, **${BIGDATA_DATA_HOME}/kafka/data2/kafka-logs**) in the same way.
     - Increase the number in the second line in the file. (To move multiple directories, the number added is equal to the number of files to be moved.

- Add the to-be moved partition to the end of the file. (The line structure is "*Topic name Partition ID Offset*". You can copy the line data saved in **5**.)

g. Move the partition to the destination directory. After the partition is moved, run the **chown omm:wheel -R** *Partition directory* command to modify the directory owner group for the partition.

h. Log in to FusionInsight Manager and choose **Cluster** > *Name of the desired cluster* > **Services** > **Kafka** > **Instance** to start the stopped Broker instance.

i. Wait for 5 to 10 minutes and check whether the health status of the Broker instance is **Good**.

- If yes, resolve the disk capacity insufficiency problem according to the handling method of "ALM-38001 Insufficient Kafka Disk Capacity" after the alarm is cleared.
- If no, contact O&M support.

After the faulty Broker is recovered, the blocked balancing task continues. You can run the **--status** command to view the task execution progress.

- The Broker fault occurs because of other causes, the fault scenario is clear, and the fault can be rectified within a short period of time.

a. Restore the faulty Broker according to the root cause.

b. After the faulty Broker is recovered, the blocked balancing task continues. You can run the **--status** command to view the task execution progress.

- The Broker fault occurs because of other causes, the fault scenario is complex, and the fault cannot be rectified within a short period of time.

a. Run the **kinit** *Kafka administrator account* command (skip this step in normal mode).

b. Run the **zkCli.sh -server <***ZooKeeper cluster service IP address:zkPort***/kafka>** command to log in to ZooKeeper Shell.

c. Run the **addauth krbgroup** command (skip this step in normal mode).

d. Delete the **/admin/reassign_partitions** and **/controller** directories.

e. Perform the preceding steps to forcibly stop the migration. After the cluster recovers, run the **kafka-reassign-partitions.sh** command to delete redundant copies generated during the intermediate process.

12.14.16 Balancing Data After Kafka Node Scale-Out

Scenario

This section describes how to use the Kafka balancing tool on the client to balance the load of the Kafka cluster after Kafka nodes are scaled out.

This section applies to versions earlier than MRS 3.*x*. For MRS 3.*x* or later, see **Kafka Balancing Tool Instructions**.

Prerequisites

- The system administrator has understood service requirements and prepared a Kafka administrator (belonging to the **kafkaadmin** group and not required for the normal mode).
- The Kafka client has been installed, for example, in the **/opt/kafkaclient** directory.
- Two topics named **test_2** and **test_3** has been created by referring to **Step 7**. The **move-kafka-topic.json** file has been created in the **/opt/kafkaclient/Kafka/kafka** directory. The topic format is as follows:

```
{
"topics":
[{"topic":"test_2"},{"topic":"test_3"}],
"version":1
}
```

Procedure

Step 1 Log in to the node where the Kafka client is installed as the client installation user.

Step 2 Run the following command to switch to the client installation directory:

cd /opt/kafkaclient

Step 3 Run the following command to set environment variables:

source bigdata_env

Step 4 Run the following command to perform user authentication (skip this step if the cluster is in normal mode):

kinit *Component service user*

Step 5 Run the following command to go to the **bin** directory of the Kafka client:

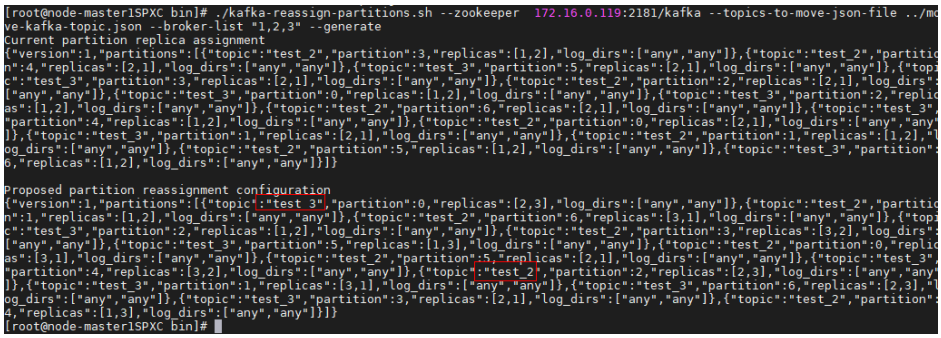
cd Kafka/kafka/bin

Step 6 Run the following command to generate an execution plan:

./kafka-reassign-partitions.sh --zookeeper *172.16.0.119:***2181/kafka --topics-to-move-json-file ../move-kafka-topic.json --broker-list "***1,2,3***" --generate**

NOTE

- **172.16.0.119**: service IP address of the ZooKeeper instance
- **--broker-list "1,2,3"**: list of broker instances. **1,2,3** indicates all broker IDs after a scale-out.



Step 7 Run the **vim ../reassignment.json** command to create the **reassignment.json** file and save it to the **/opt/kafkaclient/Kafka/kafka** directory.

Copy the content under **Proposed partition reassignment configuration** generated in **Step 6** to the **reassignment.json** file, as shown in the follows:

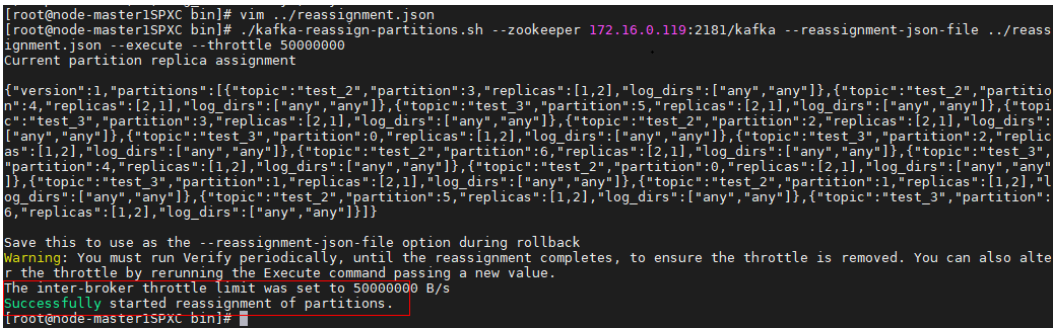
```
{"version":1,"partitions":[{"topic":"test","partition":4,"replicas":[1,2],"log_dirs":["any","any"]},
{"topic":"test","partition":1,"replicas":[1,3],"log_dirs":["any","any"]},{"topic":"test","partition":3,"replicas":
[3,1],"log_dirs":["any","any"]},{"topic":"test","partition":0,"replicas":[3,2],"log_dirs":["any","any"]},
{"topic":"test","partition":2,"replicas":[2,1],"log_dirs":["any","any"]}]}
```

Step 8 Run the following command to redistribute partitions:

./kafka-reassign-partitions.sh --zookeeper *172.16.0.119:***2181/kafka --reassignment-json-file ../reassignment.json --execute --throttle** *50000000*

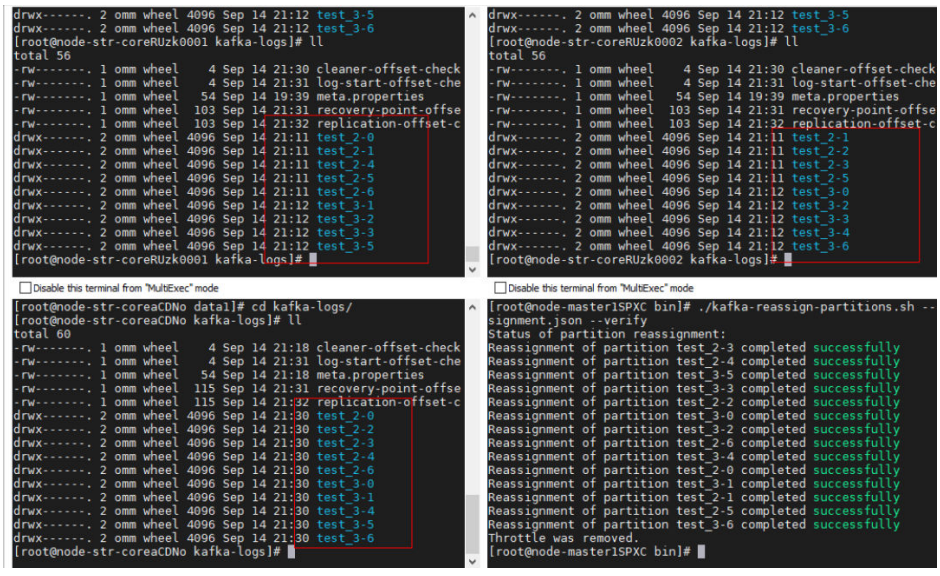
NOTE

--throttle 50000000: The maximum bandwidth is 50 MB/s. You can change the bandwidth based on the data volume and the customer's requirements on the balancing time. If the data volume is 5 TB, the bandwidth is 50 MB/s and the data balancing takes about 8 hours.



Step 9 Run the following command to check the data migration status:

./kafka-reassign-partitions.sh --zookeeper *172.16.0.119:***2181/kafka --reassignment-json-file ../reassignment.json --verify**



----End

12.14.17 Kafka Token Authentication Mechanism Tool Usage

Scenario

Operations need to be performed on tokens when the token authentication mechanism is used.

This section applies to security clusters of MRS 3.*x* or later.

Prerequisites

- The system administrator has understood service requirements and prepared a system user.
- The Kafka client has been installed.

Procedure

Step 1 Log in as a client installation user to the node on which the Kafka client is installed.

Step 2 Switch to the Kafka client installation directory, for example, **/opt/kafkaclient**.

cd /opt/kafkaclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the following command to perform user authentication:

kinit *Component service user*

Step 5 Run the following command to switch to the Kafka client installation directory:

cd Kafka/kafka/bin

Step 6 Use **kafka-delegation-tokens.sh** to perform operations on tokens.

- Generate a token for a user.

  ./kafka-delegation-tokens.sh --create --bootstrap-server <*IP1:PORT, IP2:PORT,...***> --max-life-time-period <***Long: max life period in milliseconds***> --command-config <***config file***> --renewer-principal User:<***user name***>**

  Example: **./kafka-delegation-tokens.sh --create --bootstrap-server 192.168.1.1:21007,192.168.1.2:21007,192.168.1.3:21007 --command-config ../config/producer.properties --max-life-time-period -1 --renewer-principal User:username**

- List information about all tokens of a specified user.

  ./kafka-delegation-tokens.sh --describe --bootstrap-server <*IP1:PORT, IP2:PORT,...***> --command-config <***config file***> --owner-principal User:<***user name***>**

  Example: **./kafka-delegation-tokens.sh --describe --bootstrap-server 192.168.1.1:21007,192.168.1.2:21007,192.168.1.3:21007 --command-config ../config/producer.properties --owner-principal User:username**

- Update the token validity period.

./kafka-delegation-tokens.sh --renew --bootstrap-server <*IP1:PORT, IP2:PORT,...***> --renew-time-period <***Long: renew time period in milliseconds***> --command-config <***config file***> --hmac <***String: HMAC of the delegation token***>**

Example: **./kafka-delegation-tokens.sh --renew --bootstrap-server 192.168.1.1:21007,192.168.1.2:21007,192.168.1.3:21007 --renew-time-period -1 --command-config ../config/producer.properties --hmac ABCDEFG**

- Destroy a token.

  ./kafka-delegation-tokens.sh --expire --bootstrap-server <*IP1:PORT, IP2:PORT,...***> --expiry-time-period <***Long: expiry time period in milliseconds***> --command-config <***config file***> --hmac <***String: HMAC of the delegation token***>**

  Example: **./kafka-delegation-tokens.sh --expire --bootstrap-server 192.168.1.1:21007,192.168.1.2:21007,192.168.1.3:21007 --expiry-time-period -1 --command-config ../config/producer.properties --hmac ABCDEFG**

----End

12.14.18 Introduction to Kafka Logs

This section applies to MRS 3.*x* or later.

Log Description

Log paths: The default storage path of Kafka logs is **/var/log/Bigdata/kafka**. The default storage path of audit logs is **/var/log/Bigdata/audit/kafka**.

- Broker: **/var/log/Bigdata/kafka/broker** (run logs)

Log archive rule: The automatic Kafka log compression function is enabled. By default, when the size of logs exceeds 30 MB, logs are automatically compressed into a log file named in the following format: *<Original log file name>-<yyyy-mm-dd_hh-mm-ss>.[ID]*.**log.zip**. A maximum of 20 latest compressed files are retained by default. You can configure the number of compressed files and the compression threshold.

Table 12-269 Broker log list

Type	Log File Name	Description
Run log	server.log	Server run log of the broker process
	controller.log	Controller run log of the broker process
	kafka-request.log	Request run log of the broker process
	log-cleaner.log	Cleaner run log of the broker process

Type	Log File Name	Description
	state-change.log	State-change run log of the broker process
	kafkaServer-<SSH_USER>-<DATE>-<PID>-gc.log	GC log of the broker process
	postinstall.log	Work log after broker installation
	prestart.log	Work log before broker startup
	checkService.log	Log that records whether broker starts successfully
	start.log	Startup log of the broker process
	stop.log	Stop log of the broker process
	checkavailable.log	Log that records the health check details of the Kafka service
	checkInstanceHealth.log	Log that records the health check details of broker instances
	kafka-authorizer.log	Broker authorization log
	kafka-root.log	Broker basic log
	cleanup.log	Cleanup log of broker uninstallation
	metadata-backup-recovery.log	Broker backup and recovery log
	ranger-kafka-plugin-enable.log	Log that records the Ranger plug-ins enabled by brokers
	server.out	Broker JVM log
	audit.log	Authentication log of the Ranger authentication plug-in. This log is archived in the **/var/log/Bigdata/audit/kafka** directory.

Log Level

Table 12-270 describes the log levels supported by Kafka.

Levels of run logs are ERROR, WARN, INFO, and DEBUG from the highest to the lowest priority. Run logs of equal or higher levels are recorded. The higher the specified log level, the fewer the logs recorded.

Table 12-270 Log levels

Level	Description
ERROR	Logs of this level record error information about system running.
WARN	Logs of this level record exception information about the current event processing.
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record the system information and system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page. See **Modifying Cluster Service Configuration Parameters**.

Step 2 On the menu bar on the left, select the log menu of the target role.

Step 3 Select a desired log level.

Step 4 Save the configuration. In the displayed dialog box, click **OK** to make the configurations take effect.

----End

Log Format

The following table describes the Kafka log format.

Table 12-271 Log formats

Type	Format	Example
Run log	<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|<Thread that generates the log>| <Message in the log>| <Full name of the log event invocation class>(<Log file>:<Row>)	2015-08-08 11:09:53,483 | INFO | [main] | Loading logs. | kafka.log.LogManager (Logging.scala:68)

Type	Format	Example
	<yyyy-MM-dd HH:mm:ss><HostName> <Component name><logLevel><Message>	2015-08-08 11:09:51 10-165-0-83 Kafka INFO Running kafka-start.sh.

12.14.19 Performance Tuning

12.14.19.1 Kafka Performance Tuning

Scenario

You can modify Kafka server parameters to improve Kafka processing capabilities in specific service scenarios.

Parameter Tuning

Modify the service configuration parameters. For details, see **Modifying Cluster Service Configuration Parameters**. For details about the tuning parameters, see **Table 12-272**.

Table 12-272 Tuning parameters

Parameter	Default Value	Scenario
num.recovery.threads.per.data.dir	10	During the Kafka startup process, if a large volume of data exists, you can increase the value of this parameter to accelerate the startup.
background.threads	10	Specifies the number of threads processed by a broker background task. If a large volume of data exists, you can increase the value of this parameter to improve broker processing capabilities.
num.replica.fetchers	1	Specifies the number of threads used when a replica requests to the Leader for data synchronization. If the value of this parameter is increased, the replica I/O concurrency increases.

Parameter	Default Value	Scenario
num.io.threads	8	Specifies the number of threads used by the broker to process disk I/O. It is recommended that the number of threads be greater than or equal to the number of disks.
KAFKA_HEAP_OPTS	-Xmx6G -Xms6G	Specifies the Kafka JVM heap memory setting. If the data volume on the broker is large, adjust the heap memory size.

12.14.20 Kafka Feature Description

Kafka Idempotent Feature

Feature description: The function of creating idempotent producers is introduced in Kafka 0.11.0.0. After this function is enabled, producers are automatically upgraded to idempotent producers. When producers send messages with the same field values, brokers automatically detect whether the messages are duplicate to avoid duplicate data. Note that this feature can only ensure idempotence in a single partition. That is, an idempotent producer can ensure that no duplicate messages exist in a partition of a topic. Only idempotence on a single session can be implemented. The session refers to the running of the producer process. That is, idempotence cannot be ensured after the producer process is restarted.

Method for enabling this feature:

1. Add **props.put("enable.idempotence", true)** to the secondary development code.
2. Add **enable.idempotence = true** to the client configuration file.

Kafka Transaction Feature

Feature description: Kafka 0.11 introduces the transaction feature. The Kafka transaction feature indicates that a series of producer message production and consumer offset submission operations are in the same transaction, or are regarded as an atomic operation. Message production and offset submission succeed or fail at the same time. This feature provides transactions at the Read Committed isolation level to ensure that multiple messages are written to the target partition atomically and that the consumer can view only the transaction messages that are successfully submitted. The transaction feature of Kafka is used in the following scenarios:

1. Multiple pieces of data sent by a producer can be encapsulated in a transaction to form an atomic operation. All messages are successfully sent or fail to be sent.
2. read-process-write mode: Message consumption and production are encapsulated in a transaction to form an atomic operation. In a streaming

application, a service usually needs to receive messages from the upstream system, process the messages, and then send the processed messages to the downstream system. This corresponds to message consumption and production.

Example of secondary development code:

```
// Initialize the configuration and enable the transaction feature.
Properties props = new Properties();
props.put("enable.idempotence", true);
props.put("transactional.id", "transaction1");
...

KafkaProducer producer = new KafkaProducer<String, String>(props);

// init transaction
producer.initTransactions();
try {
    // Start a transaction.
    producer.beginTransaction();
    producer.send(record1);
    producer.send(record2);
    // Stop a transaction.
    producer.commitTransaction();
} catch (KafkaException e) {
    // Abort a transaction.
    producer.abortTransaction();
}
```

Nearby Consumption

Feature description: In versions earlier than Kafka 2.4.0, the production and consumption of the client are leader copies oriented to each partition. Follower copies are used only for data redundancy and do not provide services for external systems. As a result, the leader copy has high pressure. In addition, in cross-DC and cross-rack consumption scenarios, a large volume of data is transmitted between DCs and between racks. In Kafka 2.4.0 and later versions, the Kafka kernel can consume data from follower replicas, which greatly reduces the data transmission volume and reduces the network bandwidth pressure in cross-DC and cross-rack scenarios. The community opens the ReplicaSelector API to support this feature. By default, MRS Kafka provides two methods to use this API.

1. **RackAwareReplicaSelector**: indicates that replicas in the same rack are preferentially consumed (nearby consumption in a rack).
2. **AzAwareReplicaSelector**: indicates that copies from nodes in the same AZ are preferentially consumed (nearby consumption in an AZ).

The following uses **RackAwareReplicaSelector** as an example to describe how to consume the closest replica.

```
public class RackAwareReplicaSelector implements ReplicaSelector {

  @Override
  public Optional<ReplicaView> select(TopicPartition topicPartition,
                                      ClientMetadata clientMetadata,
                                      PartitionView partitionView) {
    if (clientMetadata.rackId() != null && !clientMetadata.rackId().isEmpty()) {
      Set<ReplicaView> sameRackReplicas = partitionView.replicas().stream()
              // Filter the replicas that are in the same rack as the client.
              .filter(replicaInfo -> clientMetadata.rackId().equals(replicaInfo.endpoint().rack()))
              .collect(Collectors.toSet());
      if (sameRackReplicas.isEmpty()) {
        // If no replicas are in the same rack as the client, the leader replica is returned.
        return Optional.of(partitionView.leader());
```

```
            } else {
                // It shows that a replica that is in the same rack as the client exists.
                if (sameRackReplicas.contains(partitionView.leader())) {
                    // If the client and the leader replica are in the same rack, the leader replica returns first.
                    return Optional.of(partitionView.leader());
                } else {
                    // Otherwise, the latest replica synchronized with the leader is returned.
                    return sameRackReplicas.stream().max(ReplicaView.comparator());
                }
            }
        } else {
            // If the rack information is not contained in the client request, the leader replica is returned first.
            return Optional.of(partitionView.leader());
        }
    }
}
```

Method for enabling this feature:

1. Server: Update the **replica.selector.class** configuration item based on different features.
   - To enable "nearby consumption in a rack", set this parameter to **org.apache.kafka.common.replica.RackAwareReplicaSelector**.
   - To enable "nearby consumption in an AZ", set this parameter to **org.apache.kafka.common.replica.AzAwareReplicaSelector**.
2. Client: Add the **client.rack** configuration item to the **consumer.properties** file in the *{Client installation directory}***/Kafka/kafka/config** directory.
   - If the "nearby consumption in a rack" is enabled on the server, add the information about the rack where the client is located, for example, **client.rack = /default0/rack1**.
   - If the "nearby consumption in an AZ" is enabled on the server, add the information about the rack where the client is located, for example, **client.rack = /AZ1/rack1**.

Ranger Unified Authentication

Feature description: In versions earlier than Kafka 2.4.0, Kafka supports only the SimpleAclAuthorizer authentication plugin provided by the community. In Kafka 2.4.0 and later versions, MRS Kafka supports both the Ranger authentication plugin and the authentication plugin provided by the community. Ranger authentication is used by default. Based on the Ranger authentication plugin, fine-grained Kafka ACL management can be performed.

NOTE

If the Ranger authentication plugin is used on the server and **allow.everyone.if.no.acl.found** is set to **true**, all actions are allowed when a non-secure port is used for access. You are advised to disable **allow.everyone.if.no.acl.found** for security clusters that use the Ranger authentication plugin.

12.14.21 Migrating Data Between Kafka Nodes

Scenario

This section describes how to use Kafka client commands to migrate partition data between disks on a node without stopping the Kafka service.

Prerequisites

- The system administrator has understood service requirements and prepared a Kafka user (belonging to the **kafkaadmin** group and not required for the normal mode).
- The Kafka client has been installed.
- The Kafka instance status and disk status are normal.
- Based on the current disk space usage of the partition to be migrated, ensure that the disk space will be sufficient after the migration.

Procedure

Step 1 Log in as a client installation user to the node on which the Kafka client is installed.

Step 2 Run the following command to switch to the Kafka client installation directory, for example, **/opt/kafkaclient**:

cd /opt/kafkaclient

Step 3 Run the following command to set environment variables:

source bigdata_env

Step 4 Run the following command to authenticate the user (skip this step in normal mode):

kinit *Component service user*

Step 5 Run the following command to switch to the Kafka client directory:

cd Kafka/kafka/bin

Step 6 Run the following command to view the topic details of the partition to be migrated:

Security mode:

./kafka-topics.sh --describe --bootstrap-server *IP address of the Kafkacluster:21007* **--command-config ../config/client.properties --topic** *topic name*

Normal mode:

./kafka-topics.sh --describe --bootstrap-server *IP address of the Kafka cluster:21005* **--command-config ../config/client.properties --topic** *Topic name*

Step 7 Run the following command to query the mapping between **Broker_ID** and the IP address:

./kafka-broker-info.sh --zookeeper *IP address of the ZooKeeper quorumpeer instance*:*ZooKeeper port number*/**kafka**

```
Broker_ID     IP_Address
--------------------------
4             192.168.0.100
5             192.168.0.101
6             192.168.0.102
```

NOTE

- IP address of the ZooKeeper quorumpeer instance

  To obtain IP addresses of all ZooKeeper quorumpeer instances, log in to FusionInsight Manager and choose **Cluster** > **Services** > **ZooKeeper**. On the displayed page, click **Instance** and view the IP addresses of all the hosts where the quorumpeer instances locate.

- Port number of the ZooKeeper client

  Log in to FusionInsight Manager and choose **Cluster** > **Service** > **ZooKeeper**. On the displayed page, click **Configurations** and check the value of **clientPort**. The default value is **24002**.

Step 8 Obtain the partition distribution and node information from the command output in **Step 6** and **Step 7**, and create the JSON file for reallocation in the current directory.

To migrate data in the partition whose **Broker_ID** is **6** to the **/srv/BigData/hadoop/data1/kafka-logs** directory, the required JSON configuration file is as follows:

```
{"partitions":[{"topic": "testws","partition": 2,"replicas": [6,5],"log_dirs": ["/srv/BigData/hadoop/data1/kafka-logs","any"]}],"version":1}
```

NOTE

- **topic** indicates the topic name, for example, **testws**.
- **partition** indicates the topic partition.
- The number in **replicas** corresponds to **Broker_ID**.
- **log_dirs** indicates the path of the disk to be migrated. In this example, **log_dirs** of the node whose **Broker_ID** is **5** is set to **any**, and that of the node whose **Broker_ID** is **6** is set to **/srv/BigData/hadoop/data1/kafka-logs.** Note that the path must correspond to the node.

Step 9 Run the following command to perform reallocation:

Security mode:

./kafka-reassign-partitions.sh --bootstrap-server *Service IP address of Broker*:**21007 --command-config ../config/client.properties --zookeeper** *{zk_host}:{port}*/**kafka --reassignment-json-file** *Path of the JSON file compiled in* ***Step 8*** **--execute**

Normal mode:

./kafka-reassign-partitions.sh --bootstrap-server *Service IP address of Broker*:**21005 --command-config ../config/client.properties --zookeeper** *{zk_host}:{port}*/**kafka --reassignment-json-file** *Path of the JSON file compiled in* ***Step 8*** **--execute**

If message "Successfully started reassignment of partitions" is displayed, the execution is successful.

----End

12.14.22 Common Issues About Kafka

12.14.22.1 How Do I Solve the Problem that Kafka Topics Cannot Be Deleted?

Question

How do I delete a Kafka topic if it fails to be deleted?

Answer

- Possible cause 1: The **delete.topic.enable** configuration item is not set to **true**. The deletion can be performed only when the configuration item is set to **true**.
- Possible cause 2: The **auto.create.topics.enable** configuration parameter is set to **true**, which is used by other applications and is always running in the background.

Solution:

- For cause 1: Set **delete.topic.enable** to **true** on the configuration page.
- For cause 2: Stop the application that uses the topic in the background, or set **auto.create.topics.enable** to **false** (restart the Kafka service), and then delete the topic.

12.15 Using KafkaManager

12.15.1 Introduction to KafkaManager

KafkaManager is a tool for managing Apache Kafka and provides GUI-based metric monitoring and management of Kafka clusters.

KafkaManager supports the following functions:

- Manage multiple Kafka clusters.
- Check cluster status (topics, consumers, offsets, partitions, replicas, and nodes)
- Run preferred replica election.
- Generate partition assignments with option to select brokers to use.
- Run reassignment of partitions (based on generated assignments).
- Create a topic with optional topic configurations (Multiple Kafka cluster versions are supported).
- Delete a topic (only supported on 0.8.2+ and **delete.topic.enable = true** is set in broker configuration).

- Batch generate partition assignments for multiple topics with option to select brokers to use.
- Batch run reassignment of partitions for multiple topics.
- Add partitions to an existing topic.
- Update configurations for an existing topic.
- Optionally enable JMX polling for broker-level and topic-level metrics.
- Optionally filter out consumers that do not have ids/owner/&offsets/ directories in ZooKeeper.

12.15.2 Accessing the KafkaManager Web UI

You can monitor and manage Kafka clusters on the graphical KafkaManager web UI.

Prerequisites

- KafkaManager has been installed in a cluster.
- The password of user **admin** has been obtained. The password of user **admin** is specified by the user during MRS cluster creation.

Accessing the KafkaManager Web UI

Step 1 In the **KafkaManager Summary** area, click any UI link in **KafkaManager WebUI** to access the KafkaManager web UI.

You can view the following information on the KafkaManager web UI.

- Kafka cluster list
- Broker node list and metric monitoring information of Kafka clusters
- Kafka cluster replica monitoring information
- Kafka cluster consumer monitoring information

NOTE

You can click the KafkaManager logo in the upper left corner on any sub-page of KafkaManager to return to the homepage of the KafkaManager web UI, where a cluster list is displayed.

----End

12.15.3 Managing Kafka Clusters

Kafka cluster management includes the following operations:

- **Adding a Cluster on the KafkaManager Web UI**
- **Updating Cluster Parameters**
- **Deleting a Cluster on the KafkaManager Web UI**

Adding a Cluster on the KafkaManager Web UI

After a Kafka cluster is created for the first time, a default Kafka cluster named **my-cluster** is created on the KafkaManager web UI. You can also add Kafka

clusters that have been created on the MRS management console on the KafkaManager web UI to manage multiple Kafka clusters.

Step 1 Log in to the KafkaManager web UI.

Step 2 In the upper part of the page, choose **Cluster** > **Add Cluster**.

Step 3 Set the cluster parameters. For the following parameters, refer to their example values. Retain the default values for other parameters.

Table 12-273 Cluster parameters to be modified

Parameter	Example Value	Description
Cluster Name	mrs-demo	Name of the cluster to be added on the KafkaManager web UI
Cluster Zookeeper Hosts	zk1_ip:zk1_port, zk2_ip:zk2_port/kafka	ZooKeeper address of the cluster to be added
Kafka Version	1.1.0	Kafka version of the cluster to be added. The default value is **1.1.0**.
Enable JMX Polling (Set JMX_PORT env variable before starting kafka server)	Selected	-
Poll consumer information (Not recommended for large # of consumers)	Selected	-
Enable Active OffsetCache (Not recommended for large # of consumers)	Selected	-
Display Broker and Topic Size (only works after applying this patch)	Selected	-
Security Protocol	PLAINTEXT	• For a Kafka cluster with Kerberos authentication enabled, select **SASL_PLAINTEXT**. • For a Kafka cluster with Kerberos authentication disabled, select **PLAINTEXT**.

Step 4 Click **Save**.

----End

Updating Cluster Parameters

Step 1 Log in to the KafkaManager web UI.

Step 2 Click **Modify** in the **Operations** column of the cluster.

Step 3 Go to the cluster configuration page and modify cluster parameters.

----End

Deleting a Cluster on the KafkaManager Web UI

Step 1 Log in to the KafkaManager web UI.

Step 2 Click **Disable** in the **Operations** column of the cluster.

Step 3 When **Delete** or **Enable** is displayed in the **Operations** column on the cluster list page, click **Delete** to delete the cluster. You can also click **Enable** to enable the cluster.

----End

12.15.4 Kafka Cluster Monitoring Management

The Kafka cluster monitoring management includes the following operations:

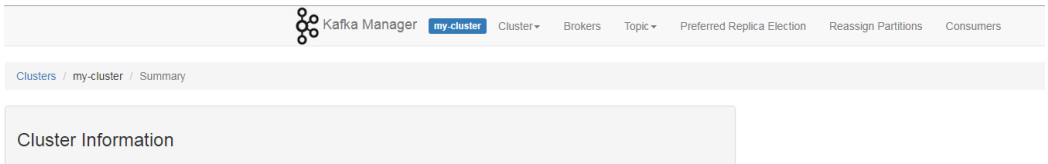
- **Viewing Broker Information**
- **Viewing Topic Information**
- **Viewing Consumers Information**
- **Modifying the Partition of a Topic Through KafkaManager**

Viewing Broker Information

Step 1 Log in to the KafkaManager web UI.

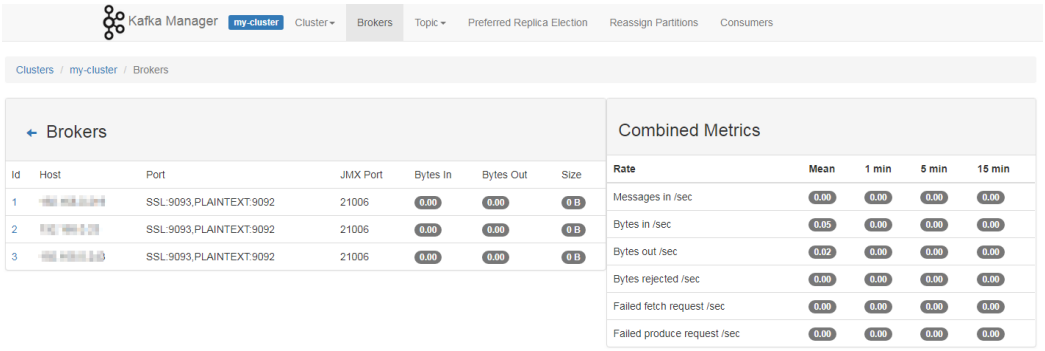
Step 2 On the cluster list page, click a cluster name to access the Summary page of the cluster.

Figure 12-26 Summary page of a cluster



Step 3 Click **Brokers** to access the Broker monitoring page. The page displays the Broker list and I/O statistics of the Broker nodes.

Figure 12-27 Broker monitoring page



----End

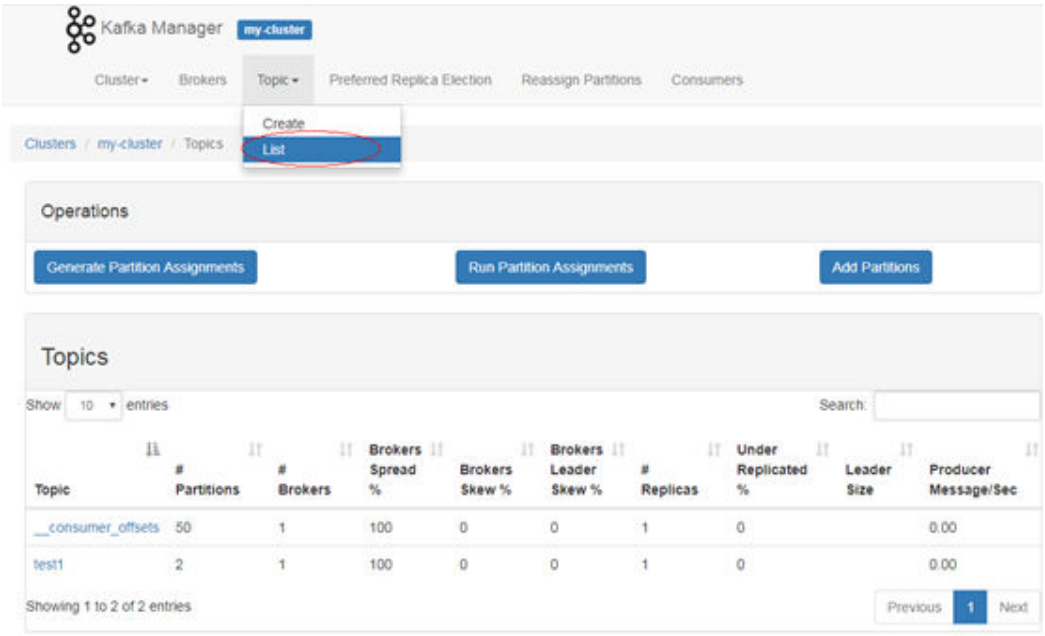
Viewing Topic Information

Step 1 Log in to the KafkaManager web UI.

Step 2 On the cluster list page, click a cluster name to access the **Summary** page of the cluster.

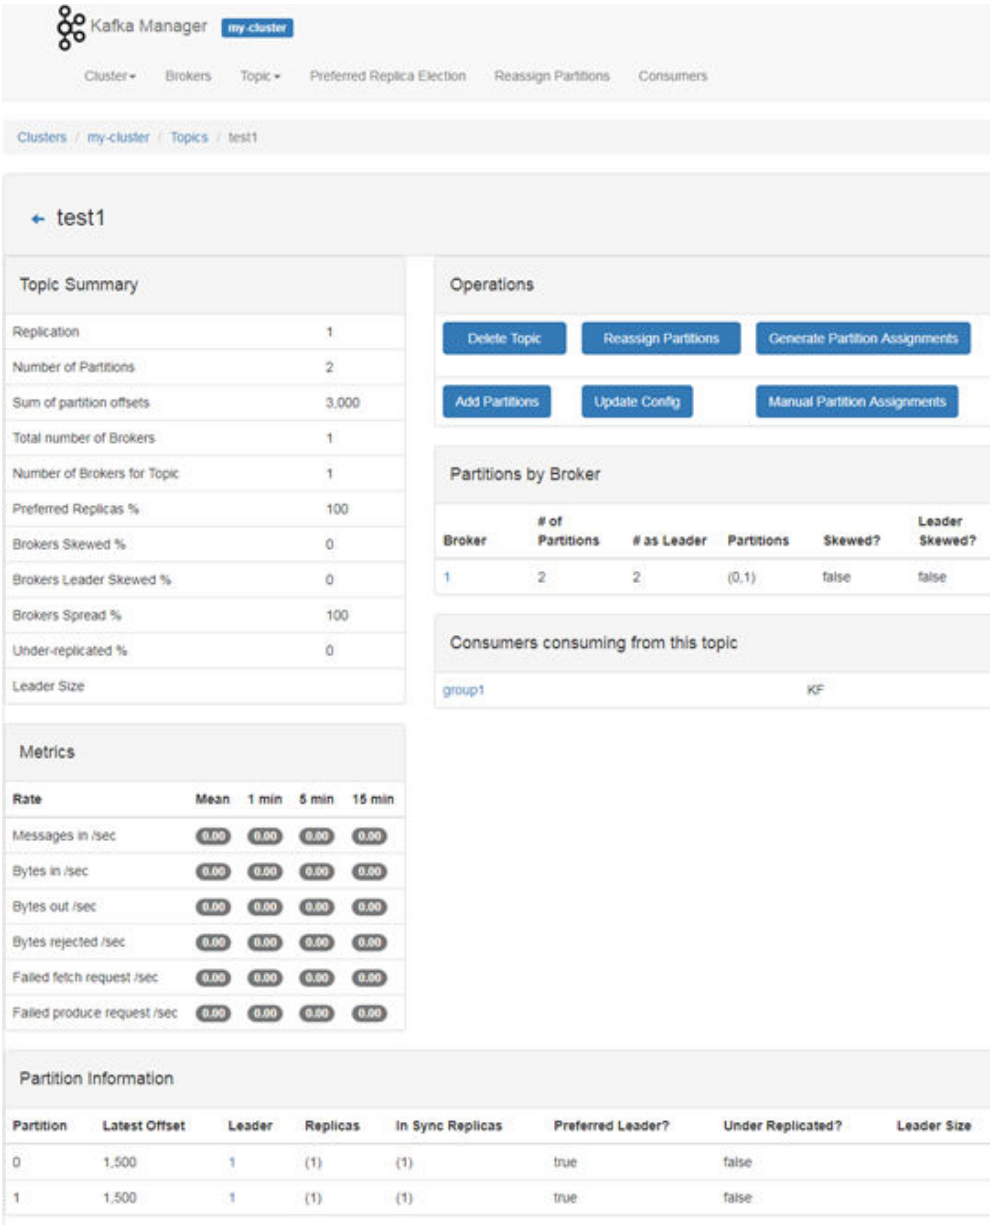
Step 3 Choose **Topic** > **List** to view the topic list of the current cluster and information about each topic.

Figure 12-28 Topic list



Step 4 Click a topic name to view details about the topic.

Figure 12-29 Topic details



----End

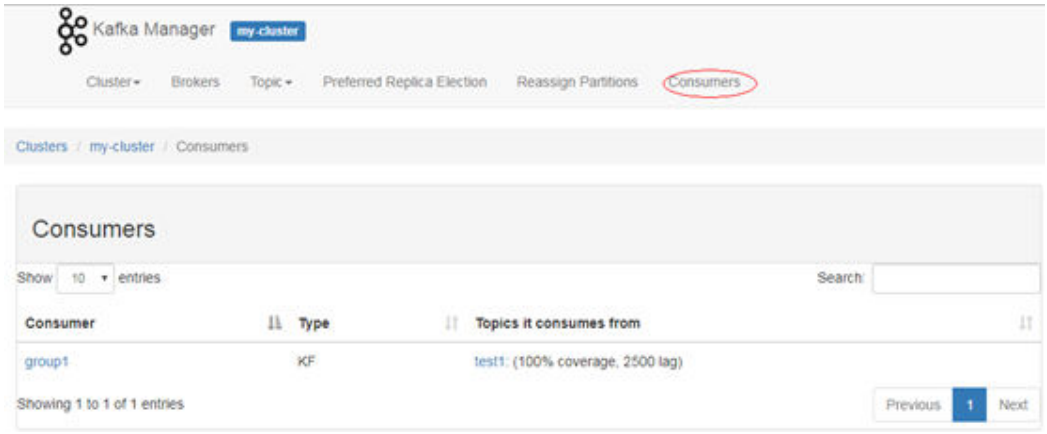
Viewing Consumers Information

Step 1 Log in to the KafkaManager web UI.

Step 2 On the cluster list page, click a cluster name to access the **Summary** page of the cluster.

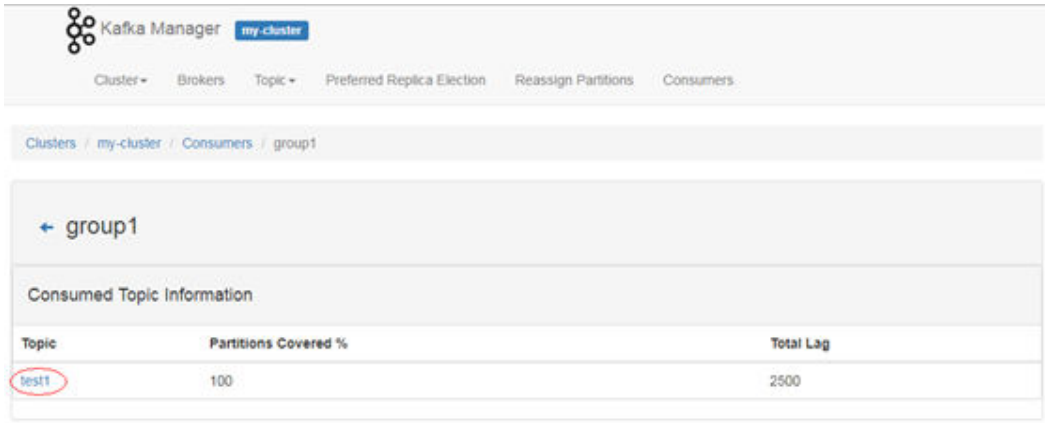
Step 3 Click **Consumers** to view the consumers of the current cluster and each consumer's consumption information.

Figure 12-30 Consumers



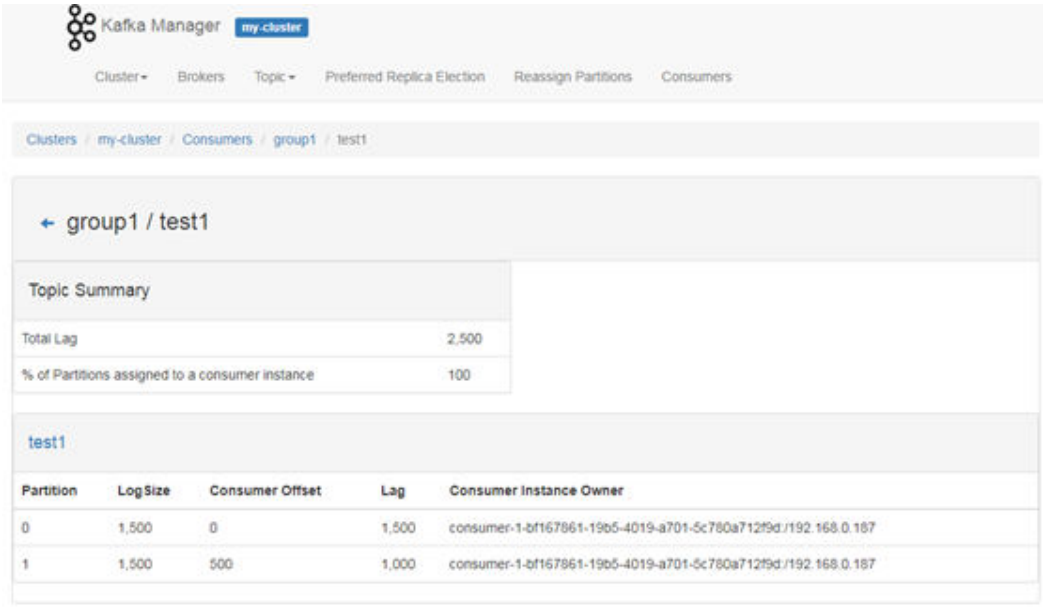
Step 4 Click a consumer name to view the list of the consumed topics.

Figure 12-31 List of topics consumed by the consumer



Step 5 Click a topic name in the topic list of the consumer to view consumption information about the topic.

Figure 12-32 Topic consumption details



----End

Modifying the Partition of a Topic Through KafkaManager

Step 1 Log in to the KafkaManager web UI.

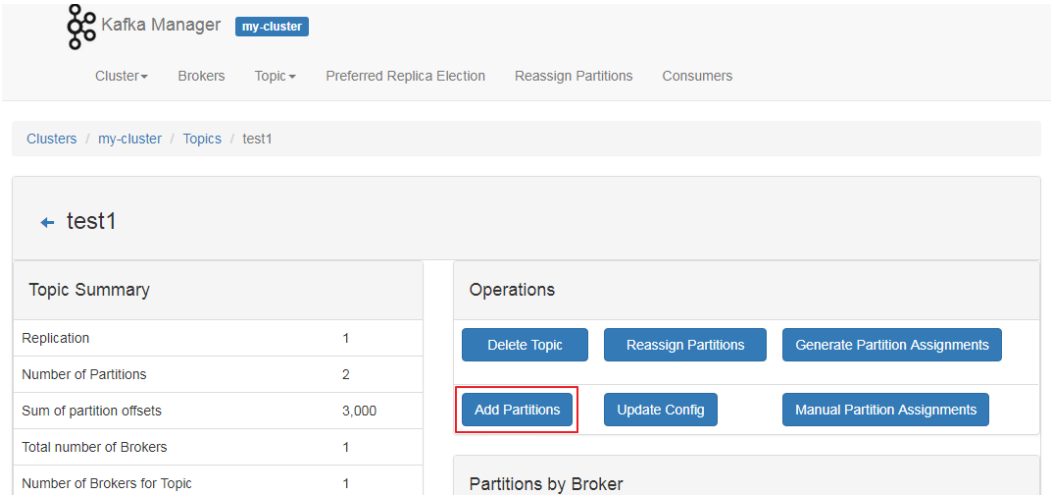
Step 2 On the cluster list page, click a cluster name to access the **Summary** page of the cluster.

Step 3 Choose **Topic** > **List** to access the topic list page of the current cluster.

Step 4 Click a topic name to access the **Topic Summary** page.

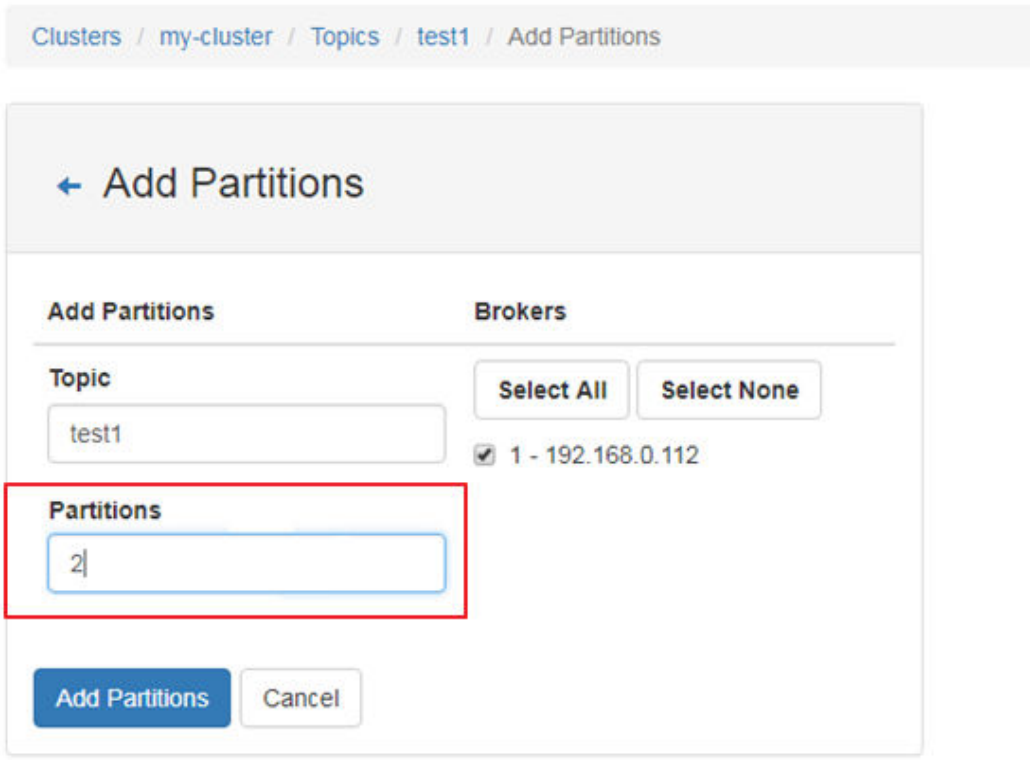
Step 5 Click **Add Partitions**. The page for adding partitions is displayed.

Figure 12-33 Adding partitions



Step 6 Confirm the topic name and modify the value of the **Partitions** parameter and click **Add Partitions** to add partitions.

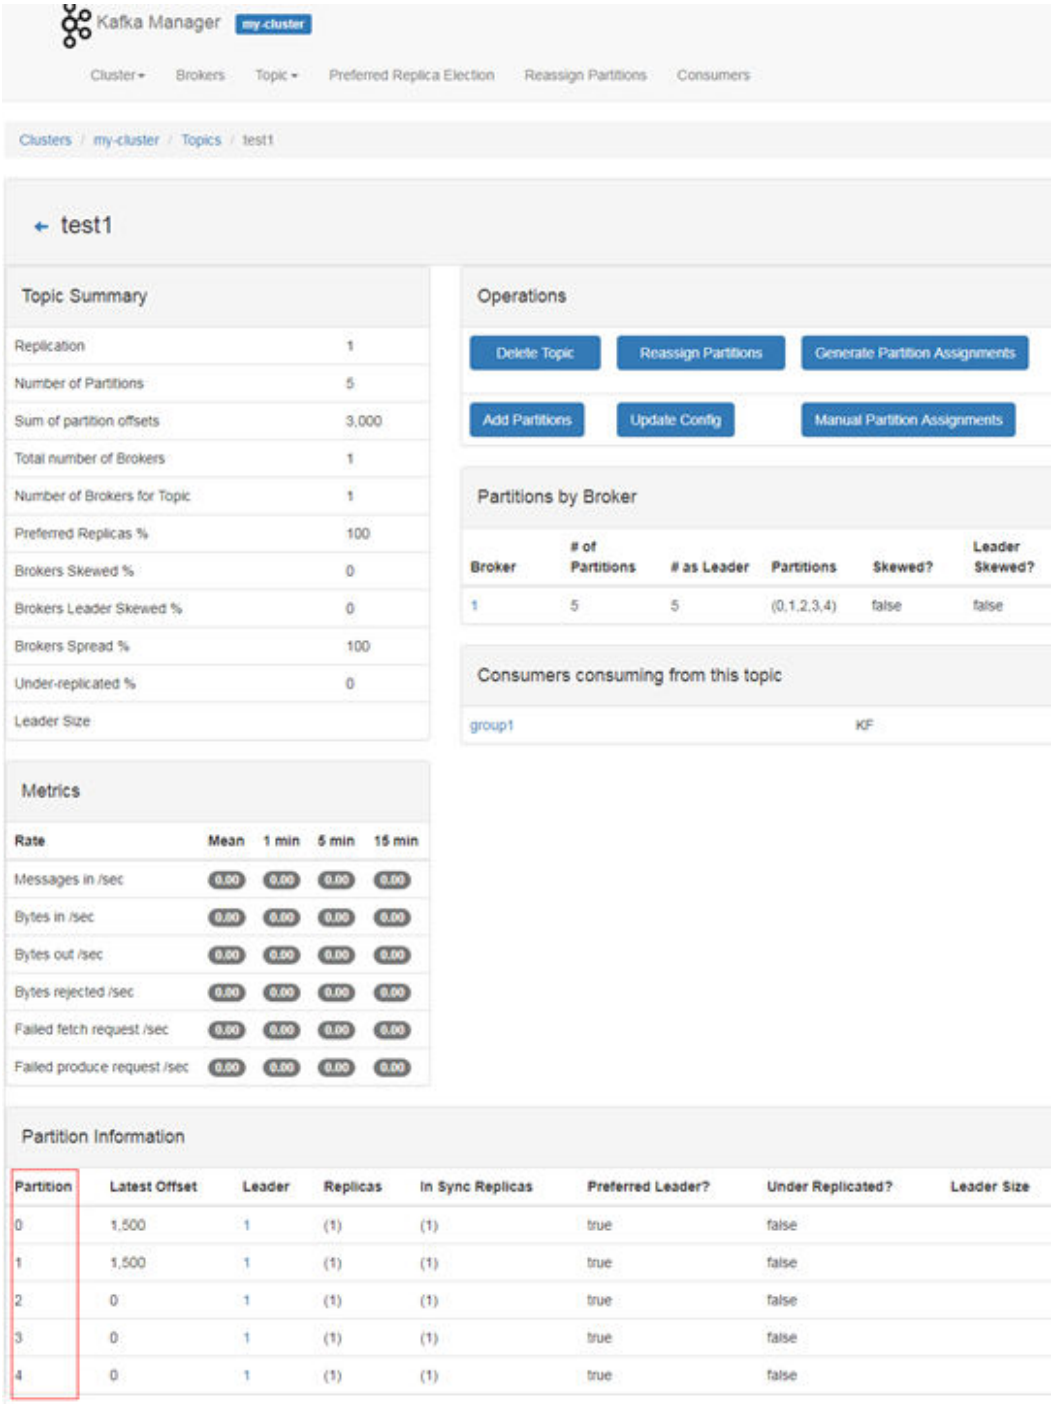
Figure 12-34 Modifying the number of partitions



Step 7 After the partitions are added successfully, click **Go to topic view** to return to the **Topic Summary** page.

Step 8 Check the number of partitions in **Partition Information** in the lower part of the **Topic Summary** page.

Figure 12-35 Partition Information



Step 9 (Optional) If you are not satisfied with the assigned partitions, you can use the partition reassignment function to automatically reassign partitions.

1. On the **Topic Summary** page, click **Generate Partition Assignments**.
2. Select the broker instance and click **Generate Partition Assignments** to generate a partition.
3. After partition generation, click **Go to topic view** to return to the **Topic Summary** page.

4. On the **Topic Summary** page, click **Reassign Partitions** to automatically assign partitions to the broker instance of the cluster.
5. Click **Go to reassign partitions** to view details about the reassigned partitions.

Step 10 (Optional) If you are not satisfied with the automatically assigned partitions, you can manually assign the partitions.

1. On the **Topic Summary** page, click **Manual Partition Assignments** to access the page for manually assign partitions.
2. Manually assign a broker ID to each partition replica, and click **Save Partition Assignment** to save the changes.
3. Click **Go to topic view** to return to the **Topic Summary** page and view the partition details.

----End

12.16 Using Kudu

12.16.1 Using Kudu from Scratch

Kudu is a columnar storage manager developed for the Apache Hadoop platform. Kudu shares the common technical properties of Hadoop ecosystem applications. It is horizontally scalable and supports highly available operations.

Prerequisites

The cluster client has been installed. For example, the client is installed in the **/opt/hadoopclient** directory. The client directory in the following operations is only an example. Change it to the actual installation directory.

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the Kudu command line tool.

Run the command line tool of the Kudu component to view help information.

kudu -h

The command output is as follows:

```
Usage: kudu <command> [<args>]

<command> can be one of the following:
     cluster   Operate on a Kudu cluster
    diagnose   Diagnostic tools for Kudu servers and clusters
```

```
          fs   Operate on a local Kudu filesystem
         hms   Operate on remote Hive Metastores
local_replica   Operate on local tablet replicas via the local filesystem
      master   Operate on a Kudu Master
         pbc   Operate on PBC (protobuf container) files
        perf   Measure the performance of a Kudu cluster
remote_replica   Operate on remote tablet replicas on a Kudu Tablet Server
       table   Operate on Kudu tables
      tablet   Operate on remote Kudu tablets
        test   Various test actions
     tserver   Operate on a Kudu Tablet Server
         wal   Operate on WAL (write-ahead log) files
```

NOTE

The Kudu command line tool does not support DDL and DML operations, but provides the refined query function for the **cluster**, **master**, **tserver**, **fs**, and **table** parameters.

Common operations:

- Check the tables in the current cluster.

  kudu table list *KuduMaster instance IP1:7051, KuduMaster instance IP2:7051, KuduMaster instance IP3:7051*

- Query the configurations of the KuduMaster instance of the Kudu service.

  kudu master get_flags *KuduMaster instance IP:7051*

- Query the schema of a table.

  kudu table describe *KuduMaster instance IP1:7051, KuduMaster instance IP2:7051, KuduMaster instance IP3:7051 Table name*

- Delete a table.

  kudu table delete *KuduMaster instance IP1:7051, KuduMaster instance IP2:7051, KuduMaster instance IP3:7051 Table name*

  NOTE

  To obtain the IP address of the KuduMaster instance, choose **Components** > **Kudu** > **Instances** on the cluster details page.

----End

12.16.2 Accessing the Kudu Web UI

You can view Kudu job information on the Kudu web UI.

Prerequisites

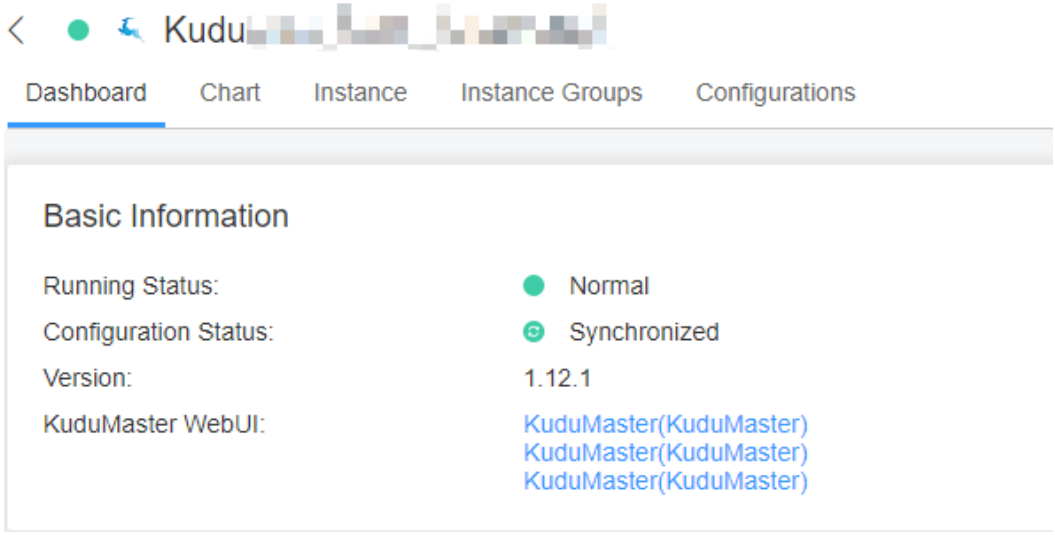
Kudu has been installed in a cluster.

Accessing KuduMaster WebUI (MRS 3.x or Later)

Step 1 Log in to Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**.

Step 2 Choose **Cluster** > **Services**> **Spark**.

Step 3 In the **Dashboard** page of Kudu, click **KuduMaster(KuduMaster)** on the right side of **KuduMaster WebUI**. The KuduMaster web UI is displayed.



----End

Accessing KuduMaster WebUI (Versions Earlier Than MRS 3.*x*)

Step 1 Access Manager. For details, see **Accessing MRS Manager (Versions Earlier Than MRS 3.x)**.

Step 2 choose **Services** > **Kudu**.

Step 3 In **KuduMaster WebUI** of **Kudu Summary**, click **KuduMaster(KuduMaster)**. The KuduMaster web UI is displayed.

----End

12.17 Using Loader

12.17.1 Using Loader from Scratch

You can use Loader to import data from the SFTP server to HDFS.

This section applies to versions earlier than MRS 3.x.

Prerequisites

- You have prepared service data.
- You have created an analysis cluster.

Procedure

Step 1 Access the Loader page.

1. Go to the cluster details page and choose **Services**.
2. Choose **Hue**. In **Hue Web UI** of **Hue Summary**, click **Hue (Active)**. The Hue web UI is displayed.
3. Choose **Data Browsers** > **Sqoop**.

The job management tab page is displayed by default on the Loader page.

Step 2 On the Loader page, click **Manage links**.

Step 3 Click **New link** and create **sftp-connector**. For details, see **File Server Link**.

Step 4 Click **New link**, enter the link name, select **hdfs-connector**, and create **hdfs-connector**.

Step 5 On the Loader page, click **Manage jobs**.

Step 6 Click **New Job**.

Step 7 In **Connection**, set parameters.

1. In **Name**, enter a job name.
2. Select the source link created in **Step 3** and the target link created in **Step 4**.

Step 8 In **From**, configure the job of the source link.

For details, see **ftp-connector or sftp-connector**.

Step 9 In **To**, configure the job of the target link.

For details, see **hdfs-connector**.

Step 10 In **Task Config**, set job running parameters.

Table 12-274 Loader job running properties

Parameter	Description
Extractors	Number of Map tasks
Loaders	Number of Reduce tasks This parameter is displayed only when the destination field is HBase or Hive.
Max. Error Records in a Single Shard	Error record threshold. If the number of error records of a single Map task exceeds the threshold, the task automatically stops and the obtained data is not returned. **NOTE** Data is read and written in batches for **MYSQL** and **MPPDB** of **generic-jdbc-connector** by default. Errors are recorded once at most for each batch of data.
Dirty Data Directory	Directory for saving dirty data. If you leave this parameter blank, dirty data will not be saved.

Step 11 Click **Save**.

----End

12.17.2 How to Use Loader

This section applies to versions earlier than MRS 3.x.

Process

The process for migrating user data with Loader is as follows:

1. Access the Loader page of the Hue web UI.
2. Manage Loader links.
3. Create a job and select a data source link and a link for saving data.
4. Run the job to complete data migration.

Loader Page

The Loader page is a graphical data migration management tool based on the open source Sqoop web UI and is hosted on the Hue web UI. Perform the following operations to access the Loader page:

1. Access the Hue web UI. For details, see **Accessing the Hue Web UI**.
2. Choose **Data Browsers** > **Sqoop**.

   The job management tab page is displayed by default on the Loader page.

Loader Links

Loader links save data location information. Loader uses links to access data or save data to the specified location. Perform the following operations to access the Loader link management page:

1. Access the Loader page.
2. Click **Manage links**.

   The Loader link management page is displayed.

   Click **Manage jobs** to return to the job management page.
3. Click **New link** to go to the configuration page and set parameters to create a Loader link.

Loader Jobs

Loader jobs are used to manage data migration tasks. Each job consists of a source data link and a destination data link. A job reads data from the source link and saves data to the destination link to complete a data migration task.

12.17.3 Loader Link Configuration

This section applies to versions earlier than MRS 3.x.

Overview

Loader supports the following links. This section describes configurations of each link.

- obs-connector
- generic-jdbc-connector
- ftp-connector or sftp-connector

- hbase-connector, hdfs-connector, or hive-connector

OBS Link

An OBS link is a data exchange channel between Loader and OBS. **Table 12-275** describes the configuration parameters.

Table 12-275 obs-connector configuration

Parameter	Description
Name	Name of a Loader connection
OBS Server	Enter an OBS endpoint. The common format is **OBS.*Region.DomainName***. Run the following command to query the endpoints of OBS: **cat /opt/Bigdata/apache-tomcat-7.0.78/webapps/web/WEB-INF/classes/cloud-obs.properties**
Port	Specifies the port for accessing OBS data. The default value is **443**.
Access Key	AK for a user to access OBS
Security Key	SK corresponding to AK

Relational Database Link

A relational database link is a data exchange channel between Loader and a relational database. **Table 12-276** describes the configuration parameters.

NOTE

Some parameters are hidden by default. They appear only after you click **Show Senior Parameter**.

Table 12-276 generic-jdbc-connector configuration

Parameter	Description
Name	Name of a Loader link
Database Type	Data types supported by Loader links: **ORACLE**, **MYSQL**, and **MPPDB**
Host	Database access address, which can be an IP address or domain name.
Port	Port for accessing the database
Database	Name of the database saving data
Username	Username for accessing the database

Parameter	Description
Password	Password of the user Use the actual password.

Table 12-277 Senior parameter configuration

Parameter	Description
Fetch Size	A maximum volume of data obtained during each database access
Connection Properties	Drive properties exclusive to the database link supported by databases of different types, for example, **autoReconnect** of MYSQL. If you want to define the drive properties, click **Add**.
Identifier Enclose	Delimiter for reserving keywords in the database SQL. Delimiters defined in different databases vary.

File Server Link

File server links include FTP and SFTP links and serve as a data exchange channel between Loader and a file server. **Table 12-278** describes the configuration parameters.

Table 12-278 ftp-connector or **sftp-connector** configuration

Parameter	Description
Name	Name of a Loader link
Hostname/IP	Enter the file server access address, which can be a host name or IP address.
Port	Port for accessing the file server. • Use port **21** for FTP. • Use port **22** for SFTP.
Username	Username for logging in to the file server
Password	Password of the user

MRS Cluster Link

MRS cluster links include HBase, HDFS, and Hive links and serve as a data exchange channel between Loader and HBase, HDFS, or Hive.

When configuring an MRS cluster link, set the name, select a connector, for example, **hbase-connector**, **hdfs-connector**, or **hive-connector**, and save the settings.

12.17.4 Managing Loader Links (Versions Earlier Than MRS 3.x)

Scenario

You can create, view, edit, and delete links on the Loader page.

This section applies to versions earlier than MRS 3.x.

Prerequisites

You have accessed the Loader page. For details, see **Loader Page**.

Creating a Link

Step 1 On the Loader page, click **Manage links**.

Step 2 Click **New link** and configure link parameters.

For details about the parameters, see **Loader Link Configuration**.

Step 3 Click **Save**.

If link configurations, for example, IP address, port, and access user information, are incorrect, the link will fail to be verified and saved. In addition, VPC configurations may affect the network connectivity.

NOTE

You can click **Test** to immediately check whether the link is available.

----End

Viewing a Link

Step 1 On the Loader page, click **Manage links**.

- If Kerberos authentication is enabled for the cluster, all links created by the current user are displayed by default and other users' links cannot be displayed.
- If Kerberos authentication is disabled for the cluster, all Loader links of the cluster are displayed.

Step 2 In **Sqoop Links**, enter a link name to filter the link.

----End

Editing a Link

Step 1 On the Loader page, click **Manage links**.

Step 2 Click the link name to go to the edit page.

Step 3 Modify the link configuration parameters based on service requirements.

Step 4 Click **Test**.

If the test is successful, go to **Step 5**. If a message displays indicating that OBS server cannot be connected, repeat **Step 3**.

Step 5 Click **Save**.

If a Loader job has integrated into a Loader link, editing the link parameters may affect Loader running.

----End

Deleting a Link

Step 1 On the Loader page, click **Manage links**.

Step 2 Locate the row that contains the target link, and click **Delete**.

Step 3 In the dialog box, click **Yes, delete it**.

If a Loader job has integrated a Loader link, the link cannot be deleted.

----End

12.17.5 Source Link Configurations of Loader Jobs

Overview

When Loader jobs obtain data from different data sources, a link corresponding to a data source type needs to be selected and the link properties need to be configured.

This section applies to versions earlier than MRS 3.x.

obs-connector

Table 12-279 Data source link properties of **obs-connector**

Parameter	Description
Bucket Name	OBS file system for storing source data.
Source Directory/ File	Actual storage form of source data. It can be either all data files in a directory or a single data file contained in the file system.
File Format	Loader supports the following file formats of data stored in OBS: • **CSV_FILE**: Specifies a text file. When the destination link is a database link, only the text file is supported. • **BINARY_FILE**: Specifies binary files excluding text files.
Line Separator	Identifier of each line end of source data
Field Separator	Identifier of each field end of source data

Parameter	Description
Encoding Type	Text encoding type of source data. It takes effect on text files only.
File Split Type	The following types are supported: ● **File**: The number of files is assigned to a map task by the total number of files. The calculation formula is **Total number of files/Extractors**. ● **Size**: A file size is assigned to a map task by the total file size. The calculation formula is **Total file size/ Extractors**.

generic-jdbc-connector

Table 12-280 Data source link properties of **generic-jdbc-connector**

Parameter	Description
Schema/ Tablespace	Name of the database storing source data. You can query and select it on the interface.
Table Name	Data table storing the source data. You can query and select it on the interface.
Partition Column	If multiple columns need to be read, use this column to split the result and obtain data.
Where Clause	Query statement used when accessing the database

ftp-connector or sftp-connector

Table 12-281 Data source link properties of **ftp-connector** or **sftp-connector**

Parameter	Description
Source Directory/ File	Actual storage form of source data. It can be either all data files in a directory or single data file contained in the file server.
File Format	Loader supports the following file formats of data stored in the file server: ● **CSV_FILE**: Specifies a text file. When the destination link is a database link, only the text file is supported. ● **BINARY_FILE**: Specifies binary files excluding text files.

Parameter	Description
Line Separator	Identifier of each line end of source data **NOTE** If FTP or SFTP serves as a source link and **File Format** is set to **BINARY_FILE**, the value of **Line Separator** in the advanced properties is invalid.
Field Separator	Identifier of each field end of source data **NOTE** If FTP or SFTP serves as a source link and **File Format** is set to **BINARY_FILE**, the value of **Field Separator** in the advanced properties is invalid.
Encoding Type	Text encoding type of source data. It takes effect on text files only.
File Split Type	The following types are supported: ● **File**: The number of files is assigned to a map task by the total number of files. The calculation formula is **Total number of files/Extractors**. ● **Size**: A file size is assigned to a map task by the total file size. The calculation formula is **Total file size/ Extractors**.

hbase-connector

Table 12-282 Data source link properties of **hbase-connector**

Parameter	Description
Table Name	HBase table storing source data

hdfs-connector

Table 12-283 Data source link properties of **hdfs-connector**

Parameter	Description
Source Directory/ File	Actual storage form of source data. It can be either all data files in a directory or single data file contained in HDFS.
File Format	Loader supports the following file formats of data stored in HDFS: ● **CSV_FILE**: Specifies a text file. When the destination link is a database link, only the text file is supported. ● **BINARY_FILE**: Specifies binary files excluding text files.

Parameter	Description
Line Separator	Identifier of each line end of source data **NOTE** If HDFS serves as a source link and **File Format** is set to **BINARY_FILE**, the value of **Line Separator** in the advanced properties is invalid.
Field Separator	Identifier of each field end of source data **NOTE** If HDFS serves as a source link and **File Format** is set to **BINARY_FILE**, the value of **Field Separator** in the advanced properties is invalid.
File Split Type	The following types are supported: • **File**: The number of files is assigned to a map task by the total number of files. The calculation formula is **Total number of files/Extractors**. • **Size**: A file size is assigned to a map task by the total file size. The calculation formula is **Total file size/ Extractors**.

hive-connector

Table 12-284 Data source link properties of **hive-connector**

Parameter	Description
Database Name	Name of the Hive database storing the data source. You can query and select it on the interface.
Table	Name of the Hive table storing the data source. You can query and select it on the interface.

12.17.6 Destination Link Configurations of Loader Jobs

Overview

When Loader jobs save data to different storage locations, a destination link needs to be selected and the link properties need to be configured.

obs-connector

Table 12-285 Destination link properties of **obs-connector**

Parameter	Description
Bucket Name	OBS file system for storing final data.

Parameter	Description
Output Directory	Directory for storing final data in the file system. A directory must be specified.
File Format	Loader supports the following file formats of data stored in OBS: • **CSV_FILE**: Specifies a text file. When the destination link is a database link, only the text file is supported. • **BINARY_FILE**: Specifies binary files excluding text files.
Line Separator	Identifier of each line end of final data
Field Separator	Identifier of each field end of final data
Encoding Type	Text encoding type of final data. It takes effect on text files only.

generic-jdbc-connector

Table 12-286 Destination link properties of **generic-jdbc-connector**

Parameter	Description
Schema Name	Name of the database storing final data
Table	Name of the table saving final data

ftp-connector or sftp-connector

Table 12-287 Destination link properties of **ftp-connector** or **sftp-connector**

Parameter	Description
Output Directory	Directory for storing final data in the file server. A directory must be specified.
File Format	Loader supports the following file formats of data stored in the file server: • **CSV_FILE**: Specifies a text file. When the destination link is a database link, only the text file is supported. • **BINARY_FILE**: Specifies binary files excluding text files.
Line Separator	Identifier of each line end of final data **NOTE** If FTP or SFTP serves as a destination link and **File Format** is set to **BINARY_FILE**, the value of **Line Separator** in the advanced properties is invalid.

Parameter	Description
Field Separator	Identifier of each field end of final data **NOTE** If FTP or SFTP serves as a destination link and **File Format** is set to **BINARY_FILE**, the value of **Field Separator** in the advanced properties is invalid.
Encoding Type	Text encoding type of final data. It takes effect on text files only.

hbase-connector

Table 12-288 Destination link properties of **hbase-connector**

Parameter	Description
Table Name	Name of the HBase table saving final data. You can query and select it on the interface.
Method	Data can be imported to an HBase table using either **BULKLOAD** or **PUTLIST**.
Clear Data Before Import	Whether to clear data in the destination HBase table. Options are as follows: ● **True**: Clean up data in the table. ● **False**: Do not clean up data in the table. If you select **False**, an error is reported during job running if data exists in the table.

hdfs-connector

Table 12-289 Destination link properties of **hdfs-connector**

Parameter	Description
Output Directory	Directory for storing final data in HDFS. A directory must be specified.
File Format	Loader supports the following file formats of data stored in HDFS: ● **CSV_FILE**: Specifies a text file. When the destination link is a database link, only the text file is supported. ● **BINARY_FILE**: Specifies binary files excluding text files.
Compression Codec	Compression mode used when a file is saved to HDFS. The following modes are supported: **NONE**, **DEFLATE**, **GZIP**, **BZIP2**, **LZ4**, and **SNAPPY**.

Parameter	Description
Overwrite	How to process files in the output directory when files are imported to HDFS. Options are as follows: • **True**: Clean up files in the directory and import new files by default. • **False**: Do not clean up files. If files exist in the output directory, job running fails.
Line Separator	Identifier of each line end of final data **NOTE** If HDFS serves as a destination link and **File Format** is set to **BINARY_FILE**, the value of **Line Separator** in the advanced properties is invalid.
Field Separator	Identifier of each field end of final data **NOTE** If HDFS serves as a destination link and **File Format** is set to **BINARY_FILE**, the value of **Field Separator** in the advanced properties is invalid.

hive-connector

Table 12-290 Destination link properties of **hive-connector**

Parameter	Description
Database	Name of the Hive database storing final data. You can query and select it on the interface.
Table	Name of the Hive table saving final data. You can query and select it on the interface.

12.17.7 Managing Loader Jobs

Scenario

You can create, view, edit, and delete jobs on the Loader page.

This section applies to versions earlier than MRS 3.x.

Prerequisites

You have accessed the Loader page. For details, see **Loader Page**.

Creating a Job

Step 1 On the Loader page, click **New job**.

Step 2 In **Connection**, set parameters.

1. In **Name**, enter a job name.
2. In **From link** and **To link**, select links accordingly.

   After you select a link of a type, data is obtained from the specified source and saved to the destination.

   NOTE

   If no available link exists, click **Add a new link**.

Step 3 In **From**, configure the job of the source link.

For details, see **Source Link Configurations of Loader Jobs**.

Step 4 In **To**, configure the job of the destination link.

For details, see **Destination Link Configurations of Loader Jobs**.

Step 5 Check whether a database link is selected in **To link**.

Database links include:

- generic-jdbc-connector
- hbase-connector
- hive-connector

If you set **To link** to a database link, you need to configure a mapping between service data and a field in the database table.

- If you set it to a database link, go to **Step 6**.
- If you do not set it to a database link, go to **Step 7**.

Step 6 In **Field Mapping**, enter a field mapping. Then proceed to **Step 7**.

Field Mapping specifies a mapping between each column of user data and a field in the database table.

Table 12-291 Field Mapping properties

Parameter	Description
Column Num	Field sequence of service data
Sample	First row of sample values of service data
Column Family	When **To link** is **hbase-connector**, you can select a column family for storing data.
Destination Field	Field for storing data
Type	Type of the field selected by the user
Row Key	When **To link** is **hbase-connector**, you need to select **Destination Field** as a row key.

NOTE

If the value of **From** is a connector of a file type, for example, SFTP, FTP, OBS, and HDFS files, the value of **Field Mapping** is the first row of data in the file. Ensure that the first row of data is complete. Otherwise, the Loader job will not extract columns that are not mapped.

Step 7 In **Task Config**, set job running parameters.

Table 12-292 Loader job running properties

Parameter	Description
Extractors	Number of Map tasks
Loaders	Number of Reduce tasks This parameter is displayed only when the destination field is HBase or Hive.
Max. Error Records in a Single Shard	Error record threshold. If the number of error records of a single Map task exceeds the threshold, the task automatically stops and the obtained data is not returned. **NOTE** Data is read and written in batches for **MYSQL** and **MPPDB** of **generic-jdbc-connector** by default. Errors are recorded once at most for each batch of data.
Dirty Data Directory	Specifies the directory for saving dirty data. If you leave this parameter blank, dirty data will not be saved.

Step 8 Click **Save**.

----End

Viewing a Job

Step 1 Access the Loader page. The Loader job management page is displayed by default.

- If Kerberos authentication is enabled for the cluster, all jobs created by the current user are displayed by default and other users' jobs cannot be displayed.
- If Kerberos authentication is disabled for the cluster, all Loader jobs of the cluster are displayed.

Step 2 In **Sqoop Jobs**, enter a job name to filter the job.

Step 3 Click **Refresh** to obtain the latest job status.

----End

Editing a Job

Step 1 Access the Loader page. The Loader job management page is displayed by default.

Step 2 Click the job name to go to the edit page.

Step 3 Modify the job configuration parameters based on service requirements.

Step 4 Click **Save**.

NOTE

Basic job operations in the navigation bar on the left are **Run**, **Copy**, **Delete**, **Disable**, **History Record**, and **Show Job JSON Definition**.

----End

Deleting a Job

Step 1 Access the Loader page.

Step 2 In the row of the specified job, click ✖.

You can also select one or more jobs and click **Delete** Job in the upper right corner of the job list.

Step 3 In the dialog box, click **Yes, delete it**.

If the state of a Loader job is **Running**, the job fails to be deleted.

----End

12.17.8 Preparing a Driver for MySQL Database Link

Scenario

As a component for batch data export, Loader can import and export data using a relational database.

Prerequisites

You have prepared service data.

Procedure

Procedure for versions earlier than MRS cluster 3.*x*:

Step 1 Download the MySQL JDBC driver **mysql-connector-java-5.1.21.jar** from the MySQL official website. For details about how to select the MySQL JDBC driver, see the following table.

Table 12-293 Version information

JDBC Driver Version	MySQL Version
Connector/J 5.1	MySQL 4.1, MySQL 5.0, MySQL 5.1, and MySQL 6.0 alpha
Connector/J 5.0	MySQL 4.1, MySQL 5.0 servers, and distributed transaction (XA)

JDBC Driver Version	MySQL Version
Connector/J 3.1	MySQL 4.1, MySQL 5.0 servers, and MySQL 5.0 except distributed transaction (XA)
Connector/J 3.0	MySQL 3.x and MySQL 4.1

Step 2 Upload **mysql-connector-java-5.1.21.jar** to the Loader installation directory on the active and standby MRS Master nodes.

- For versions earlier than MRS 3.x, upload the package to **/opt/Bigdata/MRS_XXX/install/FusionInsight-Sqoop-1.99.7/FusionInsight-Sqoop-1.99.7/server/jdbc/**.

  In the preceding path, **XXX** indicates the MRS version number. Change it based on site requirements.

Step 3 Change the owner of the **mysql-connector-java-5.1.21.jar** package to **omm:wheel**.

Step 4 Modify the **jdbc.properties** configuration file.

Change the key value of **MYSQL** to **mysql-connector-java-5.1.21.jar**, for example, **MYSQL=mysql-connector-java-5.1.21.jar**.

Step 5 Restart the Loader service.

----End

Procedure for MRS cluster 3.*x* and later versions:

Modify the permission on the JAR package of the relational database driver.

Step 1 Log in to the active and standby management nodes of the Loader service, obtain the driver JAR package of the relational database, and save it to the following directory on the active and standby Loader nodes: **${BIGDATA_HOME}/FusionInsight_Porter_8.1.0.1/install/FusionInsight-Sqoop-1.99.3/FusionInsight-Sqoop-1.99.3/server/webapps/loader/WEB-INF/ext-lib**

NOTE

The version 8.1.0.1 is used as an example. Replace it with the actual version number.

Step 2 Run the following commands as user **root** on the active and standby nodes of the Loader service to change the permission:

cd ${BIGDATA_HOME}/FusionInsight_Porter_8.1.0.1/install/FusionInsight-Sqoop-1.99.3/FusionInsight-Sqoop-1.99.3/server/webapps/loader/WEB-INF/ext-lib

chown omm:wheel *JAR package name*

chmod 600 *JARpackage name*

Step 3 Log in to FusionInsight Manager. Choose **Cluster** and click the target cluster name. In the navigation pane on the left, choose **Services** > **Loader**. In the upper

right corner, choose **More**, select **Restart Service**, and enter the password of the administrator to restart the Loader service.

----End

12.17.9 Loader Log Overview

Log Description

Log path: The default storage path of Loader log files is **/var/log/Bigdata/loader/Log category**.

- runlog: /var/log/Bigdata/loader/runlog (run logs)
- scriptlog: /var/log/Bigdata/loader/scriptlog/ (script execution logs)
- catalina: /var/log/Bigdata/loader/catalina (Tomcat startup and stop logs)
- audit: /var/log/Bigdata/loader/audit (audit logs)

Log archive rule:

The automatic compression and archiving function are enabled for Loader run logs and audit logs. By default, when the size of a log file exceeds 10 MB, the log file is automatically compressed into a log file named in the following rule: *<Original log file name>-<yyyy-mm-dd_hh-mm-ss>.[ID]***.log.zip**. A maximum of 20 latest compressed files are reserved. The number of compressed files can be configured on the Manager portal.

Table 12-294 Loader log list

Log Type	Log File Name	Description
Run log	loader.log	Loader system log file that records most of the logs generated when the TelcoFS system is running.
	loader-omm-***-pid***-gc.log.*.current	Loader process GC log file
	sqoopInstanceCheck.log	Loader instance health check log file
Audit log	default.audit	Loader operation audit log file that records operations such as adding, deleting, modifying, and querying jobs and user login
Tomcat log	catalina.out	Tomcat run log file.
	catalina. <yyyy-mm-dd >.log	Tomcat run log file
	host-manager. <yyyy-mm-dd >.log	Tomcat run log file

Log Type	Log File Name	Description
	localhost_access_log. <yyyy-mm-dd >.txt	Tomcat run log file
	manager <yyyy-mm-dd >.log	Tomcat run log file
	localhost. <yyyy-mm-dd >.log	Tomcat run log file
Script log	postInstall.log	Loader installation script log file Log file generated during the execution of the Loader installation script (**postInstall.sh**)
	preStart.log	Pre-startup script log file of the Loader service During startup of the Loader service, a series of preparation operations are first performed (by executing **preStart.sh**), such as generating the keytab file. This log file records information about these operations
	loader_ctl.log	Log file generated when Loader executes the service start and stop script (**sqoop.sh**)

Log Level

Table 12-295 describes the log levels provided by Loader. The priorities of log levels are ERROR, WARN, INFO, and DEBUG in descending order. Logs whose levels are higher than or equal to the specified level are printed. The number of printed logs decreases as the specified log level increases.

Table 12-295 Log levels

Level	Description
ERROR	Error information about the current event processing.
WARN	Exception information about the current event processing.

Level	Description
INFO	Normal running status information about the system and events.
DEBUG	System information and system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of Loader by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 On the menu bar on the left, select the log menu of the target role.

Step 3 Select a desired log level.

Step 4 Save the configuration. In the displayed dialog box, click **OK** to make the configurations take effect.

NOTE

The configurations take effect immediately without the need to restart the service.

----End

Log Formats

The following table lists the Loader log formats.

Table 12-296 Log formats

Log Type	Format	Example
Run log	<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|<Thread that generates the log>|<Message in the log>|<Location of the log event>	2015-06-29 14:54:35,553 | INFO | [localhost-startStop-1] | ConnectionRequestHandler initialized | org.apache.sqoop.handler.ConnectionRequestHandler.<init>(ConnectionRequestHandler.java:100)

Log Type	Format	Example
Audit log	<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|default|<Message in the log>|<Location of the log event>	2015-06-29 15:35:40,969 INFO default: UserName=admin, UserIP=10.52.0.111, Time=2015-06-29 15:35:40,969, Operation=submit, Resource=submission@21, Result=Failure, Detail={[reason:GET_SFTP_SESSION_FAILED:Failed to get sftp session - 10.162.0.35 (caused by: Auth cancel)]; [config:null]}

12.17.10 Example: Using Loader to Import Data from OBS to HDFS

Scenario

If you need to import a large volume of data from the external cluster to the internal cluster, import it from OBS to HDFS.

Prerequisites

- You have prepared service data.
- You have created an analysis cluster.

Procedure

Step 1 Upload service data to your OBS file system.

Step 2 Obtain the AK/SK information and create an OBS and HDFS link.

For details, see **Loader Link Configuration**.

Step 3 Access the Loader page.

If Kerberos authentication is enabled in the analysis cluster, refer to instructions in **Accessing the Hue Web UI**.

Step 4 Click **New Job**.

Step 5 In **Information**, set parameters.

1. In **Name**, enter a job name. For example, **obs2hdfs**.
2. In **From link**, select the OBS link you create.
3. In **To link**, select the HDFS link you create.

Step 6 In **From**, set source link parameters.

1. In **Bucket Name**, enter a name of the OBS file system.
2. In **Input directory or file**, enter a detailed location of service data in the file system.

   If it is a single file, enter a complete path containing the file name. If it is a directory, enter the complete path of the directory.
3. In **File format**, enter the type of the service data file.

For details, see **obs-connector**.

Step 7 In **To**, set destination link parameters.

1. In **Output directory**, enter the directory for storing service data in HDFS.

   If Kerberos authentication is enabled in the cluster, the current user accessing Loader needs to have the permission to write data to the directory.
2. In **File format**, enter the type of the service data file.

   The type must correspond to the type in **Step 6.3**.
3. In **Compression codec**, enter a compression algorithm. For example, if you do not compress data, select **NONE**.
4. In **Overwrite**, select **True**.
5. Click **Show Senior Parameter** and set **Line Separator**.
6. Set **Field Separator**.

For details, see **hdfs-connector**.

Step 8 In **Task Config**, set job running parameters.

1. In **Extractors**, enter the number of Map tasks.
2. In **Loaders**, enter the number of Reduce tasks.

   If the destination link is an HDFS link, **Loaders** is hidden.
3. In **Max error records in single split**, enter an error record threshold.
4. In **Dirty data directory**, enter a directory for saving dirty data, for example, **/user/sqoop/obs2hdfs-dd**.

Step 9 Click **Save and execute**.

On the **Manage jobs** page, view the job running result. You can click **Refresh** to obtain the latest job status.

----End

12.17.11 Common Issues About Loader

12.17.11.1 How to Resolve the Problem that Failed to Save Data When Using Internet Explorer 10 or Internet Explorer 11 ?

Question

Internet Explorer 11 or Internet Explorer 10 is used to access the web UI of Loader. After data is submitted, an error occurs.

Answer

- Symptom

  a. When the submitted data is saved, a similar error occurs: Invalid query parameter jobgroup id. cause: [jobgroup].

- Causse

  Some Internet Explorer 11 versions convert POST requests into GET requests after receiving the HTTP 307 response. As a result, POST data cannot be delivered to the server.

- Solution

  Use Google Chrome.

12.17.11.2 Differences Among Connectors Used During the Process of Importing Data from the Oracle Database to HDFS

Question

Three types of connectors are available for importing data from the Oracle database to HDFS using Loader. That is, generic-jdbc-connector, oracle-connector, and oracle-partition-connector. Which one should I select? What are the differences between them?

Answers

- generic-jdbc-connector

  Reads data from the Oracle database in JDBC mode. It is applicable to databases that support JDBC.

  In this mode, data loading performance of Loader is subject to data distribution in a partition column. When data skew occurs (data has only one value or several values) in a partition column, a few Maps process a significant portion of data. As a result, the index becomes invalid, causing a sharp decline in SQL query performance.

  generic-jdbc-connector supports view import and export, but oracle-partition-connector and oracle-connector do not support. Therefore, only this connector can be used to import views.

- Both **oracle-partition-connector** and **oracle-connector**

  can use the ROWID of Oracle for partitioning. oracle-partition-connector is self-developed and oracle-connector is an open-source edition. The two types of connectors share similar performance.

  oracle-connector requires more system table permissions. The following lists the read permissions required by the system tables of **oracle-connector** and **oracle-connector**.

  – **oracle-connector**: dba_tab_partitions, dba_constraints, dba_tables t, dba_segments, v$version, dba_objects, v$instance, SYS_CONTEXT function, dba_extents, and dba_tab_subpartitions

  – **oracle-partition-connector**: DBA_OBJECTS and DBA_EXTENTS

  Compared with **generic-jdbc-connector**, **oracle-partition-connector** and **oracle-connector** have the following advantages:

a. Load balancing: Number and scope of data segments are determined by the storage structure (data blocks) of the source table rather than the data on the source table. In terms of granularity, a data block can occupy a partition.
b. Stable performance: Invalid index faults caused by data skew and bound variable snooping can be completely eliminated.
c. Fast query speed: Using data segmentation delivers a higher query speed than that of using index.
d. Excellent horizontal scalability: The number of generated segments increases with the increase of data volume. In this case, ideal performance can be delivered when you increase the number of concurrent tasks. Contrarily, decreasing concurrent tasks saves resources.
e. Simplified data segmentation logic: Problems like precision loss, type compatibility, and bound variables can be prevented.
f. Enhanced usability: Users do not need to create partition columns and tables for Loader.

12.18 Using MapReduce

12.18.1 Configuring the Log Archiving and Clearing Mechanism

Scenario

Job and task logs are generated during execution of a MapReduce application.

- Job logs are generated by the MRApplicationMaster, which record details about the start and running time of jobs and each task, Counter value, and other information. After being analyzed by HistoryServer, the job logs are used to view job execution details.
- A task log records the log information generated by each task running in a container. By default, task logs are stored only on the local disk of each NodeManager. After the log aggregation function is enabled, the NodeManager merges local task logs and writes them into HDFS after job execution completes.

The job logs and task logs of the MapReduce are stored on HDFS (when the log aggregation function is enabled). If the mechanism for periodically archiving and deleting log files is not configured for a cluster with a large number of computation tasks, the log files will occupy large memory space of HDFS and increase the cluster load.

Log archive is implemented by Hadoop Archives. The number (number of Map tasks) of concurrent archiving tasks started by the Hadoop Archives is related to the total size of log files to be archived. The formula is as follows: Number of concurrent archive tasks = Total size of log files to be archived/Size of archive files.

Configuration

Go to the **All Configurations** page of the MapReduce service. For details, see **Modifying Cluster Service Configuration Parameters**.

Enter a parameter name in the search box. In addition, you need to configure the following information in the **mapred-site.xml** configuration file in the *Client installation directory*/**HDFS/hadoop/etc/hadoop/ directory** on the MapReduce client node:

Table 12-297 Parameter description

Parameter	Description	Default Value
mapreduce.jobhistory.cleaner.enable	Whether to enable the job log file deletion function.	true
mapreduce.jobhistory.cleaner.interval-ms	Period for starting a log file cleanup. Only log files whose retention period is longer than the time specified by **mapreduce.jobhistory.max-age-ms** can be deleted.	86,400,000 ms (1 day)
mapreduce.jobhistory.max-age-ms	Log files whose retention period is longer than the retention period in milliseconds specified by this parameter will be deleted.	1,296,000,000 ms (15 days)

You can configure the following parameters in the **yarn-site.xml** file on the ResourceManager, NodeManager, and MapReduce HistoryServer nodes. The **yarn.nodemanager.remote-app-log-dir** and **yarn.nodemanager.remote-app-log-archive-dir** parameters need to be configured on the Yarn client, and the configurations of the ResourceManager, NodeManager, and MapReduce HistoryServer nodes must be the same as those on the Yarn client.

Table 12-298 Parameter description

Parameter	Description	Default Value
yarn.nodemanager.remote-app-log-dir	Indicates the HDFS path for aggregating the MapReduce job logs.	/tmp/logs
yarn.nodemanager.remote-app-log-archive-dir	Indicates the HDFS path for archiving the MapReduce job logs.	/tmp/archived

Parameter	Description	Default Value
yarn.log-aggregation.archive.files.minimum	Indicates the minimum number of archived MapReduce job log files. The archiving task starts when the number of files in the **yarn.nodemanager.remote-app-log-dir** folder is greater than or equal to the value of this parameter. This parameter applies to MRS 3.*x*.	5,000
yarn.log-aggregation.archive-check-interval-seconds	Indicates the MapReduce job log archiving interval, in seconds. Log files are archived only when the number of log files reaches the value of **yarn.log-aggregation.archive.files.minimum**. The archiving function is disabled when the period is set to **0** or **-1**. This parameter applies to MRS 3.*x*.	-1
yarn.log-aggregation.retain-seconds	Indicates the retention period on HDFS for archiving the MapReduce job logs. The value **-1** indicates that log files are stored permanently.	1,296,000
yarn.log-aggregation.retain-check-interval-seconds	Indicates the check period (in seconds) of the MapReduce job log deletion task. If this parameter is set to **-1**, the check period is one tenth of the log retention period.	86400

12.18.2 Reducing Client Application Failure Rate

Scenario

When the network is unstable or the cluster I/O and CPU are overloaded, client applications might encounter running failures.

Configuration

Adjust the following parameters in the **mapred-site.xml** configuration file on the client to reduce the client application failure rate:

NOTE

The **mapred-site.xml** configuration file is in the **conf** directory of the client installation path, for example, **/opt/client/Yarn/config**.

Table 12-299 Parameter description

Parameter	Description	Default Value
mapreduce.reduce.shuffle.max-host-failures	Indicates the number of allowed failures of an MR task to read remote shuffle data in the Reduce process. When the number is set to be over 5, the client application failure rate can be reduced. This parameter applies to MRS 3.*x*.	5
mapreduce.client.submit.file.replication	Indicates the backup of job files on HDFS. MR tasks are dependent on the job files during running. When the number of backups is set to be over 10, the client application failure rate can be reduced.	10

12.18.3 Transmitting MapReduce Tasks from Windows to Linux

Scenarios

If you want to transmit a job from Windows to Linux, set **mapreduce.app-submission.cross-platform** to **true**. If this parameter is unavailable for a cluster or its value is **false**, the function of transmitting MapReduce tasks from Windows to Linux is not supported. In this case, perform the following operations to add this parameter or change its value to enable this function:

NOTE

This section applies to MRS 3.*x* or later.

Configuration Description

Adjust the following parameter in the **mapred-site.xml** configuration file on the client to enable the running of MapReduce tasks: The **mapred-site.xml** configuration file is in the **config** directory of the client installation path, for example, **/opt/client/Yarn/config**.

Table 12-300 Parameters

Parameter	Description	Default Value
mapreduce.app-submission.cross-platform	Indicates whether to support running of MapReduce tasks after they are transmitted from Windows to Linux. When the parameter value is **true**, the running of MapReduce tasks is supported. When the parameter value is **false**, the running of MapReduce tasks is not supported.	true

12.18.4 Configuring the Distributed Cache

Scenarios

NOTE

This section applies to MRS 3.*x* or later.

Distributed caching is useful in the following scenarios:

Rolling Upgrade

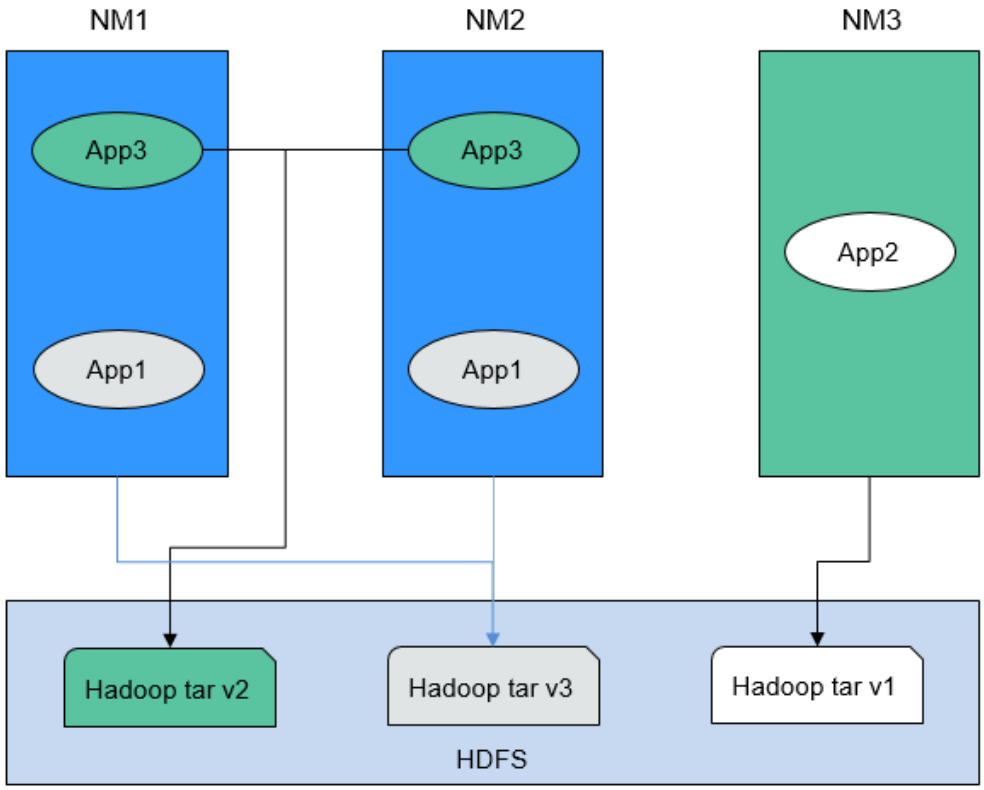
During the upgrade, applications must keep the text content (JAR file or configuration file) unchanged. The content is not based on Yarn of the current version, but on the version when it is submitted. This is a challenging issue. Generally, applications (such as MapReduce, Hive, and Tez) need to be installed locally. Libraries need to be installed on all cluster servers (clients and servers). When a rolling upgrade or downgrade starts in the cluster, the version of the locally installed library changes during application running. During the rolling upgrade, only a few NodeManagers are upgraded first. These NodeManagers obtain the software of the latest version. This leads to inconsistent behavior and can result in run-time errors.

Co-existence of Multiple Yarn Versions

Cluster administrators may run tasks that use multiple versions of Yarn and Hadoop JARs in a cluster. However, this task is difficult to be implemented because the JARs have been localized and have only one version.

The MapReduce application framework can be deployed through the distributed cache and does not depend on the static version copied during installation. Therefore, you can store multiple versions of Hadoop in HDFS and configure the **mapred-site.xml** file to specify the default version used by the task. You can run different versions of MapReduce by setting proper configuration attributes without using the versions deployed in the cluster.

Figure 12-36 Clusters with NodeManagers and Applications of multiple versions



As shown in **Figure 12-36**, the application can use Hadoop JARs in HDFS instead of the local version. Therefore, during the rolling upgrade, even if NodeManager has been upgraded, the application can still run Hadoop of the earlier version.

Configuration Description

Step 1 Save the MapReduce **.tar** package of the specified version to a directory that can be accessed by applications in HDFS, as shown in the following command.

$HADOOP_HOME/**bin/hdfs dfs -put** *hadoop-x.tar.gz /mapred/framework/*

Step 2 Set parameters in the **mapred-site.xml** file based on **Table 12-301**.

Table 12-301 Distributed cache parameters

Parameter	Description	Default Value
mapreduce.application.framework.path	Indicates the URL directing to the archive location. **NOTE** This property can also create an alias for the archive if the URL fragment identity name is specified as follows. In this example, the alias is set to **mr-framework**. <property> <name>mapreduce.application.framework.path</name> <value>hdfs:/mapred/framework/hadoop-x.tar.gz#mr-framework</value> </property>	NA

Parameter	Description	Default Value
mapreduce.application.classpath	Indicates the parameter property, which contains the MapReduce JARs in the class directory. **NOTE** For example, the alias **mr-framework** used in the framework path is used to match the directory. <property> <name>mapreduce.application.classpath</name> <value>$PWD/mr-framework/hadoop/share/hadoop/mapreduce/*:$PWD/mr-framework/hadoop/share/hadoop/mapreduce/lib/*:$PWD/mr-framework/hadoop/share/hadoop/common/*:$PWD/mr-framework/hadoop/share/hadoop/common/lib/*:$PWD/mr-framework/hadoop/share/hadoop/yarn/*:$PWD/mr-framework/hadoop/share/hadoop/yarn/lib/*:$PWD/mr-framework/hadoop/share/hadoop/hdfs/*:$PWD/mr-framework/hadoop/share/hadoop/hdfs/lib/*:/etc/hadoop/conf/secure</value></property>	N/A

You can upload MapReduce tarballs of multiple versions to HDFS. Different **mapred-site.xml** files indicate different locations. After that, you can run tasks for a specific **mapred-site.xml** file. The following is an example of running an MapReduce task for the MapReduce tarball of the *x* version:

hadoop jar *share/hadoop/mapreduce/hadoop-mapreduce-examples-*.jar pi* **-conf etc/hadoop-x/mapred-site.xml** *10 10*

----End

12.18.5 Configuring the MapReduce Shuffle Address

Scenario

When the MapReduce shuffle service is started, it attempts to bind an IP address based on local host. If the MapReduce shuffle service is required to connect to a specific IP address, no configuration is available. The following description allows you to configure a connection to a specific IP address.

Configuration

To bind a specific IP address to the MapReduce shuffle service, set the following parameters in the **mapred-site.xml** configuration file of the node where the NodeManager instance resides:

Table 12-302 Parameter description

Parameter	Description	Default Value
mapreduce.shuffle.address	Indicates the specified address to run the shuffle service. The format is *IP:PORT*. The default value is empty. If this parameter is left empty, the local host IP address is bound. The default port number is 13562. **NOTE** If the value of *PORT* is different from that of **mapreduce.shuffle.port**, the **mapreduce.shuffle.port** value does not take effect.	-

12.18.6 Configuring the Cluster Administrator List

Scenario

This function is used to specify the MapReduce cluster administrator.

The administrator list is specified by **mapreduce.cluster.administrators**. The cluster administrator **admin** has all operation permissions.

Configuration

On the **All Configurations** page of the MapReduce service, enter a parameter name in the search box. For details, see **Modifying Cluster Service Configuration Parameters**.

Table 12-303 Parameter description

Parameter	Description	Default Value
mapreduce.cluster.acls.enabled	Indicates whether to enable permission control on Job History Server.	true
mapreduce.cluster.administrators	Indicates the administrator list of the MapReduce cluster. You can configure both users and user groups. Multiple users or user groups are separated by commas (,), and users and user groups are separated by spaces, for example, userA,userB groupA,groupB. The value * indicates all users or user groups.	For versions earlier than MRS 3.x: mapred For MRS 3.*x* or later: mapred supergroup,System_administrator_186

12.18.7 Introduction to MapReduce Logs

Log Description

Log paths:

- JobhistoryServer: **/var/log/Bigdata/mapreduce/jobhistory** (run log) and **/var/log/Bigdata/audit/mapreduce/jobhistory** (audit log)
- Container: **/srv/BigData/hadoop/data1/nm/containerlogs/application_${appid}/container_{$contid}**

NOTE

The logs of running tasks are stored in the preceding paths. After the running is complete, the system determines whether to aggregate the logs to an HDFS directory based on the YARN configuration. For details, see **Common YARN Parameters**.

Log archive rule:

The automatic compression and archive function is enabled for MapReduce logs. By default, a log file is automatically compressed when the size of the log file is greater than 50 MB. The name of the compressed log file is in the following format: *<Name of the original log>-<yyyy-mm-dd_hh-mm-ss>.[NO.]***.log.zip**. A maximum of 100 latest compressed files are reserved. The number of compressed files can be configured on the parameter configuration page.

In MapReduce, JobhistoryServer cleans the old log files stored in HDFS periodically. The default storage directory is **/mr-history/done**. **mapreduce.jobhistory.max-age-ms** is used to set the cleanup interval. The default value of this parameter is 1,296,000,000 ms, which indicates 15 days.

Table 12-304 MapReduce log list

Type	Name	Description
Run log	jhs-daemon-start-stop.log	Startup log file of the daemon process
	hadoop-<SSH_USER>-jhshadaemon-<hostname>.log	Run log file of the daemon process
	hadoop-<SSH_USER>-<process_name>-<hostname>.out	Log that records the MapReduce running environment information
	historyserver-<SSH_USER>-<DATE>-<PID>-gc.log	Log that records the garbage collection of the MapReduce service
	jhs-haCheck.log	Log that records the active and standby status of MapReduce instances

Type	Name	Description
	yarn-start-stop.log	Log that records the startup and stop of the MapReduce service
	yarn-prestart.log	Log that records cluster operations before the MapReduce service startup
	yarn-postinstall.log	Work log before the MapReduce service startup and after the installation
	yarn-cleanup.log	Log that records the cleanup logs about the uninstallation of the MapReduce service
	mapred-service-check.log	Log that records the health check details of the MapReduce service
	container_{$contid}	Container log
	hadoop-<SSH_USER>-<process_name>-<hostname>.log	MR run log
	mapred-switch-jhs.log	MR active/standby switchover log
	env.log	Environment information log before the instance is started or stopped
Audit log	mapred-audit-jobhistory.log	MapReduce operation audit log
	SecurityAuth.audit	MapReduce security audit log

Log Level

Table 12-305 describes the log levels supported by MapReduce The log levels are FATAL, ERROR, WARN, INFO, and DEBUG from high priority to low. Logs whose levels are higher than or equal to the specified level are printed. The number of printed logs decreases as the specified log level increases.

Table 12-305 Log level

Level	Description
FATAL	Logs of this level record critical error information about the current event processing.
ERROR	Logs of this level record error information about the current event processing.
WARN	Logs of this level record unexpected alarm information about the current event processing.
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record the system information and system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of the MapReduce service. For details, see **Modifying Cluster Service Configuration Parameters**.

Step 2 On the left menu bar, select the log menu of the target role.

Step 3 Select a desired log level.

Step 4 Save the configuration. In the displayed dialog box, click **OK** to make the configurations take effect.

NOTE

The configurations take effect immediately without restarting the service.

----End

Log Format

The following table lists the MapReduce log formats.

Table 12-306 Log format

Type	Format	Example
Run log	<*yyyy-MM-dd HH:mm:ss,SSS*>|<*Log level*>|<*Name of the thread that generates the log*>|<*Message in the log*>|<*Location where the log event occurs*>	2020-01-26 14:18:59,109 | INFO | main | Client environment:java.compiler=<NA> | org.apache.zookeeper.Environment.logEnv(Environment.java:100)

Type	Format	Example
Audit log	<*yyyy-MM-dd HH:mm:ss,SSS*>|<*Log level*>|<*Name of the thread that generates the log*>|<*Message in the log*>|<*Location where the log event occurs*>	2020-01-26 14:24:43,605 | INFO | main-EventThread | USER=omm OPERATION=refreshAdminAcls TARGET=AdminService RESULT=SUCCESS | org.apache.hadoop.yarn.server.resourcemanager.RMAuditLogger$LogLevel $6.printLog(RMAuditLogger.java:91)

12.18.8 MapReduce Performance Tuning

12.18.8.1 Optimization Configuration for Multiple CPU Cores

Scenario

Optimization can be performed when the number of CPU cores is large, for example, the number of CPU cores is three times the number of disks.

Procedure

You can set the following parameters in either of the following ways:

- Configuration on the server:

  On the **All Configurations** page of the Yarn service, enter a parameter name in the search box. For details, see **Modifying Cluster Service Configuration Parameters**.

- Configuration on the client:

  Modify the corresponding configuration file on the client.

  NOTE

  - Path of configuration files on the HDFS client: *Client installation directory*/**HDFS/hadoop/etc/hadoop/hdfs-site.xml**
  - Path of configuration files on the Yarn client: *Client installation directory*/**HDFS/hadoop/etc/hadoop/yarn-site.xml**.
  - Path of configuration files on the MapReduce client: *Client installation directory*/**HDFS/hadoop/etc/hadoop/mapred-site.xml**.

Table 12-307 Settings of multiple CPU cores

Configuration	Description	Parameter	Default Value	Server/ Client	Impact	Remarks
Number of slots in a node container	The combination of the following parameters determines the number of concurrent tasks (Map and Reduce tasks) of each node: • yarn.nodemanager.resource.memory-mb • mapreduce.map.memory.mb • mapreduce.reduce.memory.mb	yarn.nodemanager.resource.memory-mb **NOTE** For versions earlier than MRS 3.x: You need to configure this parameter on the MRS console. For MRS 3.*x* or later: You need to configure this parameter on FusionInsight Manager.	Versions earlier than MRS 3.*x*: 8192 MRS 3.*x* or later: 16384	Server	If data needs to be read from and written into disks for all tasks (Map/ Reduce tasks), a disk may be accessed by multiple processes at the same time, which leads to poor disk I/O performance. To ensure disk I/O performance, the number of concurrent access requests from a client to a disk cannot exceed 3.	The maximum number of concurrent containers must be [2.5 x Number of disks configured in Hadoop].
		mapreduce.map.memory.mb **NOTE** You need to set this parameter in the configuration file on the client in the *Client installation directory*/**HDFS/hadoop/etc/hadoop/mapred-site.xml** path.	4096	Client		

Configuration	Description	Parameter	Default Value	Server/Client	Impact	Remarks
		mapreduce.reduce.memory.mb **NOTE** You need to set this parameter in the configuration file on the client in the *Client installation directory*/**HDFS/hadoop/etc/hadoop/mapred-site.xml** path.	4096	Client		

Configuration	Description	Parameter	Default Value	Server/ Client	Impact	Remarks
Map output and compression	The Map task output before being written into disks can be compressed. This can save disk space, offer faster data write, and reduce the data traffic delivered to Reducer. You need to configure the following parameters on the client: ● **mapreduce.map.output.compress**: The Map task output can be compressed before it is transmitted over the network. It is a per-job	mapreduce.map.output.compress **NOTE** You need to set this parameter in the configuration file on the client in the *Client installation directory*/**HDFS/hadoop/etc/hadoop/mapred-site.xml** path.	true	Client	The disk I/O is the bottleneck. Therefore, use a compression algorithm with a high compression rate.	Snappy is used. The benchmark test results show that Snappy delivers high performance and efficiency.
		mapreduce.map.output.compress.codec **NOTE** You need to set this parameter in the configuration file on the client in the *Client installation directory*/**HDFS/hadoop/etc/hadoop/mapred-site.xml** path.	org.apache.hadoop.io.compress.Lz4Codec	Client		

Configuration	Description	Parameter	Default Value	Server/ Client	Impact	Remarks
	configuration. • **mapreduce.map.output.compress.codec**: the codec used for data compression					
Spills	mapreduce.map.sort.spill.percent	mapreduce.map.sort.spill.percent **NOTE** You need to set this parameter in the configuration file on the client in the *Client installation directory*/**HDFS/hadoop/etc/hadoop/mapred-site.xml** path.	0.8	Client	Disk I/Os are the bottleneck. You can set the value of **mapreduce.task.io.sort.mb** to minimize the memory spilled to the disk.	-

Configuration	Description	Parameter	Default Value	Server/ Client	Impact	Remarks
Data packet size	When the HDFS client writes data to a data node, the data will be accumulated until a packet is generated. Then, the packet is transmitted over the network. **dfs.client-write-packet-size** specifies the data packet size. It can be specified by each job.	dfs.client-write-packet-size **NOTE** You need to set this parameter in the configuration file on the client in the *Client installation directory*/**HDFS/hadoop/etc/hadoop/hdfs-site.xml/** path.	262144	Client	The data node receives data packets from the HDFS client and writes data into disks through single threads. When disks are in the concurrent write state, increasing the data packet size can reduce the disk seek time and improve the I/O performance.	dfs.client-write-packet-size = 262144

12.18.8.2 Determining the Job Baseline

Scenario

The performance optimization effect is verified by comparing actual values with the baseline data. Therefore, determining optimal job baseline is critical to performance optimization.

When determining the job baseline, comply with the following rules:

- Making full use of cluster resources
- Setting the number of Map and Reduce tasks appropriately
- Setting the runtime of each task appropriately

Procedure

- **Rule 1: Making full use of cluster resources**

  Enable all nodes to handle tasks as actively as they can when a job is executed. Maximizing the number of concurrent tasks helps make full use of resources. You can achieve this purpose by adjusting the data volume to be processed and the number of Map and Reduce tasks.

  You can set **mapreduce.job.reduces** to control the number of Reduce tasks.

  The number of Map tasks depends on the InputFormat type and whether the data file to be processed can be split. By default, TextFileInputFormat allocates Map tasks based on the number of blocks, that is, one Map task for each block. You can adjust the following parameters to improve resource utilization.

  Parameter portal:

  On the **All Configurations** page of the Yarn service, enter a parameter name in the search box. For details, see **Modifying Cluster Service Configuration Parameters**.

Parameter	Description	Default Value
mapreduce.input.fileinputformat.split.maxsize	Indicates the maximum size of the data block into which the Map input information is to be split. The shard size can be calculated based on its size customized by the user and the block size of each file. The formula is as follows: `splitSize = Math.max(minSize, Math.min(maxSize, blockSize))` If **maxSize** is bigger than **blockSize**, a block is a shard. If **maxSize** is smaller than **blockSize**, a block will be split into multiple shards. If the size of the remaining data in a block is smaller than **splitSize**, the remaining data will be treated as a separated shard.	-
mapreduce.input.fileinputformat.split.minsize	Indicates the minimum size of a data shard.	0

- **Principle 2: Setting Reduce tasks to be executed in one round.**

  Avoid the following scenarios:

  – Most of Reduce tasks are completed in the first round, but there is still one Reduce task left running. The execution of the last Reduce task extends the runtime of the job. Therefore, reduce the number of Reduce tasks to enable all of them to run at the same time.

  - All Map tasks are completed, but there are still Reduce tasks running on some nodes. In this case, the cluster resources are not fully utilized. You need to increase the number of Reduce tasks to enable each node to handle tasks.

- **Rule 3: Setting the runtime of each task appropriately**

  If each Map or Reduce task of a job takes only a few seconds, most time of the job is wasted on scheduling tasks and starting and stopping processes. Therefore, you need to increase the data volume to be processed in each task. The preferred processing time for each task is 1 minute.

  You can configure the following parameters to adjust the processing time in a task.

  Parameter portal:

  On the **All Configurations** page of the Yarn service, enter a parameter name in the search box. For details, see **Modifying Cluster Service Configuration Parameters**.

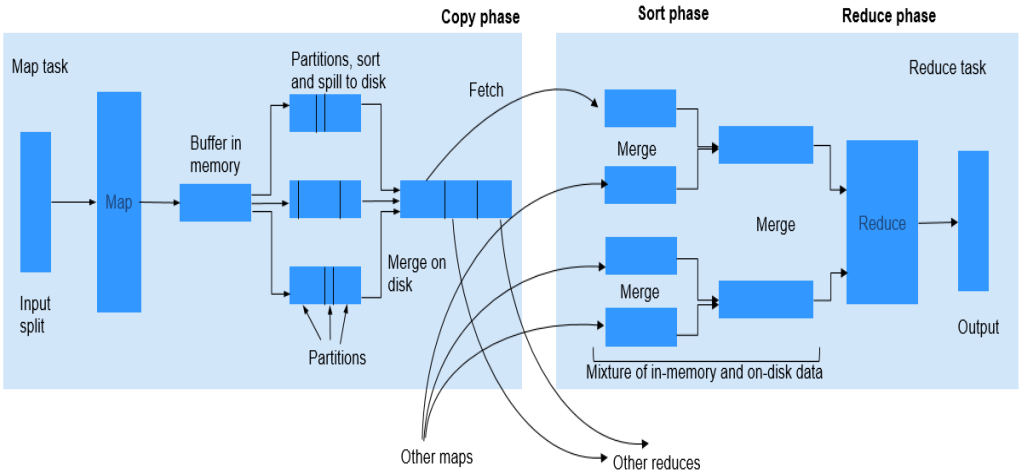
Parameter	Description	Default Value
mapreduce.input.fileinputformat.split.maxsize	Indicates the maximum size of the data block into which the Map input information is to be split. The shard size can be calculated based on its size customized by the user and the block size of each file. The formula is as follows: `splitSize = Math.max(minSize, Math.min(maxSize, blockSize))` If **maxSize** is bigger than **blockSize**, a block is a shard. If **maxSize** is smaller than **blockSize**, a block will be split into multiple shards. If the size of the remaining data in a block is smaller than **splitSize**, the remaining data will be treated as a separated shard.	-
mapreduce.input.fileinputformat.split.minsize	Indicates the minimum size of a data shard.	0

12.18.8.3 Streamlining Shuffle

Scenario

During the shuffle procedure of MapReduce, the Map task writes intermediate data into disks, and the Reduce task copies and adds the data to the reduce function. Hadoop provides lots of parameters for the optimization.

Figure 12-37 Shuffle process



Procedure

1. **Improving Performance in Map Phase**
   - Determine the memory used by Map.

     To determine whether Map has sufficient memory, check the number of GCs and the ratio of the GC time over the total task time in counters of completed jobs. Normally, the GC time cannot exceed 10% of the task time (that is, GC time elapsed (ms)/CPU time spent (ms) < 10%).

     You can improve Map performance by adjusting the following parameters.

     Parameter portal:

     On the **All Configurations** page of the Yarn service, enter a parameter name in the search box. For details, see **Modifying Cluster Service Configuration Parameters**.

     Table 12-308 Parameter description

Parameter	Description	Default Value
mapreduce.map.memory.mb	Memory restriction of a Map task.	4096

Parameter	Description	Default Value
mapreduce.map.java.opts	JVM parameter of the Map subtask. If this parameter is set, it will replace the **mapred.child.java.opts** parameter. If **-Xmx** is not set, the value of **Xmx** is calculated based on **mapreduce.map.memory.mb** and **mapreduce.job.heap.memory-mb.ratio**.	For versions earlier than MRS 3.*x*: -Xmx2048M -Djava.net.preferIPv4Stack=true For MRS cluster 3.*x* and later versions: ● Clusters with Kerberos authentication enabled: -Djava.net.preferIPv4Stack=true -Djava.net.preferIPv6Addresses=false -Djava.security.krb5.conf=*${BIGDATA_HOME}*/common/runtime/krb5.conf -Dbeetle.application.home.path=*${BIGDATA_HOME}*/common/runtime/security/config ● Clusters with Kerberos authentication disabled: -Djava.net.preferIPv4Stack=true -Djava.net.preferIPv6Addresses=false -Dbeetle.application.home.path=*${BIGDATA_HOME}*/common/runtime/security/config

It is recommended that the **-Xmx** in **mapreduce.map.java.opts** is 0.8 times the value of **mapreduce.map.memory.mb**.

– Using Combiner

Combiner is an optional procedure in the Map phase, in which the intermediate results with the same key value are combined. Generally, set

the reduce class to combiner. Combiner helps reduce the intermediate result output of Map, thereby consuming less network bandwidth during the shuffle process. You can use the following API to set a combiner class for a specific job.

Table 12-309 Combiner API

Class	API	Description
org.apache.hadoop.mapreduce.Job	public void setCombinerClass(Class<? extends Reducer> cls)	API used to set a combiner class for a specific job.

2. **Improving Performance in Copy Phase**
   - Compress data.

     Compress the intermediate output of Map. Data compression reduces the data to be transferred over the network. However, data compression and decompression consume more CPU. Determine whether to compress the intermediate results of Map based on site requirements. If a task is bandwidth-intensive, data compression improves processing performance. As for the bulkload optimization, compression of the intermediate output improves the performance by 60%.

     To improve copy performance, set **mapreduce.map.output.compress** to **true** and **mapreduce.map.output.compress.codec** to **org.apache.hadoop.io.compress.SnappyCodec**.
3. **Improving Performance in Merge Phase**

   To improve merge performance, configure the following parameters to reduce the number of times that Reduce writes data to disks.

   Parameter portal:

   On the **All Configurations** page of the Yarn service, enter a parameter name in the search box. For details, see **Modifying Cluster Service Configuration Parameters**.

Table 12-310 Parameter description

Parameter	Description	Default Value
mapreduce.reduce.merge.inmem.threshold	Threshold of the number of files for the in-memory merge process. When the accumulated number of files reaches the threshold, the process of in-memory merge and spilling to disks is initiated. If the value is less than or equal to **0**, the threshold does not take effect and the merge is triggered only based on the RAMFS memory usage.	1000
mapreduce.reduce.shuffle.merge.percent	Usage threshold for initiating in-memory merge, indicating the percentage of memory allocated to the Map outputs (defined by **mapreduce.reduce.shuffle.input.buffer.percent**).	0.66
mapreduce.reduce.shuffle.input.buffer.percent	Percentage of memory to be allocated from the maximum heap size to storing Map outputs during the Shuffle.	0.70
mapreduce.reduce.input.buffer.percent	Percentage of memory (relative to the maximum heap size) to retain Map outputs during the Reduce. When the Shuffle is completed, all remaining Map outputs in memory must use less than this threshold before the Reduce begins.	0.0

12.18.8.4 AM Optimization for Big Tasks

Scenario

A big job containing 100,000 Map tasks fails. It is found that the failure is triggered by the slow response of ApplicationMaster (AM).

When the number of tasks increases, the number of objects managed by the AM increases, which requires much more memory for management. The default memory heap for AM is 1 GB.

Procedure

You can improve the AM performance by setting the following parameters.

Navigation path for setting parameters:

Adjust the following parameters in the **mapred-site.xml** configuration file on the client to adjust the following parameters: The **mapred-site.xml** configuration file is in the **conf** directory of the client installation path, for example, **/opt/client/Yarn/config**.

Parameter	Description	Default Value
yarn.app.mapreduce.am.resource.mb	This parameter must be greater than the heap size specified by **yarn.app.mapreduce.am.command-opts**. Unit: MB	1536
yarn.app.mapreduce.am.command-opts	Indicates the JVM startup parameters loaded to MapReduce ApplicationMaster.	For versions earlier than MRS 3.x: -Xmx1024m -XX:CMSFullGCsBeforeCompaction=1 -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:+UseCMSCompactAtFullCollection -verbose:gc MRS 3.x or later: -Xmx1024m -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -verbose:gc -Djava.security.krb5.conf=${KRB5_CONFIG} -Dhadoop.home.dir=*${BIGDATA_HOME}*/FusionInsight_HD_*xxx*/install/FusionInsight-Hadoop-*xxx*/hadoop

12.18.8.5 Speculative Execution

Scenario

If a cluster has hundreds or thousands of nodes, the hardware or software fault of a node may prolong the execution time of the entire task (as most tasks are already completed, the system is still waiting for the task running on the faulty node). Speculative execution allows a task to be executed on multiple machines. You can disable speculative execution for small clusters.

Procedure

Navigation path for setting parameters:

On the **All Configurations** page of the Yarn service, enter a parameter name in the search box. For details, see **Modifying Cluster Service Configuration Parameters**.

Parameter	Description	Default Value
mapreduce.map.speculative	Sets whether to execute multiple instances of some map tasks concurrently. **true** indicates that speculative execution is enabled.	false
mapreduce.reduce.speculative	Sets whether to execute multiple instances of some reduce tasks concurrently. **true** indicates that speculative execution is enabled.	false

12.18.8.6 Using Slow Start

Scenario

The Slow Start feature specifies the proportion of Map tasks to be completed before Reduce tasks are started. If the Reduce tasks are started too early, resources will be occupied, thereby reducing task running efficiency. However, if the Reduce tasks are started at an appropriate time, resource usage during shuffle and task running efficiency will be improved. For example, the MapReduce job includes 15 Map tasks and a cluster can start 10 Map tasks, there are 5 Map tasks remained after a round of Map tasks is completed and the cluster has available resources. In this case, you can configure the value of Slow Start to a value less than 1 (for example, 0.8), then the Reduce tasks can make use of the remaining cluster resources.

Procedure

Parameter portal:

On the **All Configurations** page of the MapReduce service, enter a parameter name in the search box. For details, see **Modifying Cluster Service Configuration Parameters**.

Parameter	Description	Default Value
mapreduce.job.reduce.slowstart.completedmaps	Fraction of the number of Maps in the job which should be completed before Reduces are scheduled for the job. By default, the Reduce tasks start when all the Map tasks are completed.	1.0

12.18.8.7 Optimizing Performance for Committing MR Jobs

Scenario

By default, if an MR job generates a large number of output files, it takes a long time for the job to commit the temporary outputs of a task to the final output

directory in the commit phase. In large clusters, the time-consuming commit process of jobs greatly affects the performance.

In this case, you can set the **mapreduce.fileoutputcommitter.algorithm.version** to **2** to improve the performance in the commit phase of MR jobs.

Procedure

Navigation path for setting parameters:

On the **All Configurations** page of the Yarn service, enter a parameter name in the search box. For details, see **Modifying Cluster Service Configuration Parameters**.

Table 12-311 Parameter description

Parameter	Description	Default Value
mapreduce.fileoutputcommitter.algorithm.version	Indicates the algorithm version submitted by a job. The value is **1** or **2**. **NOTE** **2** is the recommended algorithm version. This algorithm enables tasks to directly commit the output results of each task to the final result output directory, reducing the time for the results of large jobs are committed.	2

12.18.9 Common Issues About MapReduce

12.18.9.1 Why Does It Take a Long Time to Run a Task Upon ResourceManager Active/Standby Switchover?

Question

MapReduce job takes a very long time (more than 10minutes) when the ResourceManager switch while the job is running.

Answer

This is because, ResorceManager HA is enabled but the ResourceManager work preserving restart is not enabled.

If ResorceManager work preserving restart is not enabled, then ResorceManager switch containers are killed which causes the ResorceManager to timeout the ApplicationMaster. For ResorceManager work preserving restart feature details, see **http://hadoop.apache.org/docs/r3.1.1/hadoop-yarn/hadoop-yarn-site/ResourceManagerRestart.html**.

The following method can be used to solve the issue:

Enable the ResorceManager work preserving restart feature by configuring the following parameter.

yarn.resourcemanager.work-preserving-recovery.enabled=**true**

12.18.9.2 Why Does a MapReduce Task Stay Unchanged for a Long Time?

Question

MapReduce job is not progressing for long time

Answer

This is because of less memory. When the memory is less, the time taken by the job to copy the map output increases significantly.

In order to reduce the waiting time, increase the heap memory.

The job configuration should be tuned according to number of mappers and data size processed by each mapper. Based on the input data size, tune the following configurations accordingly for feasible performance.

- **mapreduce.reduce.memory.mb**
- **mapreduce.reduce.java.opts**

Example: If the data size is 5 GB with 10 mappers, then the ideal heap memory would be 1.5 GB. Increase the heap memory size according with the increase in data size.

12.18.9.3 Why the Client Hangs During Job Running?

Question

Why is the client unavailable when the MR ApplicationMaster or ResourceManager is moved to the D state during job running?

Answer

When a task is running, the MR ApplicationMaster or ResourceManager is moved to D state (uninterrupted sleep state) or T state (stopped state). The client waits to return the task running state, but the MR ApplicationMaster does not return. Therefore, the client remains in the waiting state.

To avoid the preceding scenario, use the **ipc.client.rpc.timeout** configuration item in the **core-site.xml** file to set the client timeout interval.

The value of this parameter is millisecond. The default value is **0**, indicating that no timeout occurs. The client timeout interval ranges from 0 ms to 2,147,483,647 ms.

NOTE

- If the Hadoop process is in the D state, restart the node where the process is located.
- The **core-site.xml** configuration file is stored in the **conf** directory of the client installation path, for example, **/opt/hadoopClient/Yarn/config**.

12.18.9.4 Why Cannot HDFS_DELEGATION_TOKEN Be Found in the Cache?

Question

In security mode, why delegation token HDFS_DELEGATION_TOKEN is not found in the cache?

Answer

In MapReduce, by default HDFS_DELEGATION_TOKEN will be canceled after the job completion. So if the token has to be re- used for the next job then the token will not be found in the cache.

To re-use the same token in subsequent job set the below parameter for the MR job configuration. When it is false the user can re-sue the same token.

```
jobConf.setBoolean("mapreduce.job.complete.cancel.delegation.tokens", false);
```

12.18.9.5 How Do I Set the Task Priority When Submitting a MapReduce Task?

Question

How do I set the job priority when submitting a MapReduce task?

Answer

You can add the parameter **-Dmapreduce.job.priority=<priority>** in the command to set task priority when submitting MapReduce tasks on the client. The format is as follows:

yarn jar *<jar> [mainClass]* ***-Dmapreduce.job.priority=****<priority> [path1] [path2]*

The parameters in the command are described as follows:

- *<jar>*: specifies the name of the JAR package to be run.
- *[mainClass]*: specifies the **main** method of the class for an application project in a JAR file.
- *<priority>*: specifies the priority of a task. The value can be **VERY_HIGH**, **HIGH**, **NORMAL**, **LOW**, or **VERY_LOW**.
- *[path1]*: specifies the data input path.
- *[path2]*: specifies the data output path.

For example, set the **/opt/client/HDFS/hadoop/share/hadoop/mapreduce/hadoop-mapreduce-examples*.jar** package to a high-priority task.

yarn jar /opt/client/HDFS/hadoop/share/hadoop/mapreduce/hadoop-mapreduce-examples*.jar wordcount -Dmapreduce.job.priority=VERY_HIGH /DATA.txt /out/

12.18.9.6 Why Physical Memory Overflow Occurs If a MapReduce Task Fails?

Question

The HBase bulkload task has 210,000 Map tasks and 10,000 Reduce tasks. The MapReduce task fails to be executed, and the physical memory of ApplicationMaster overflows.

```
For more detailed output, check the application tracking page:https://bigdata-55:8090/cluster/app/
application_1449841777199_0003
Then click on links to logs of each attempt.
Diagnostics: Container [pid=21557,containerID=container_1449841777199_0003_02_000001] is running
beyond physical memory limits
Current usage: 1.0 GB of 1 GB physical memory used; 3.6 GB of 5 GB virtual memory used. Killing container.

Container killed on request. Exit code is 143
Container exited with a non-zero exit code 143
Failing this attempt. Failing the application.
```

Answer

This is a performance specification problem. The root cause of the MapReduce task execution failure is the memory overflow of ApplicationMaster, that is, the NodeManager kills the task due to the physical memory overflow.

Solutions:

Increase the memory of ApplicationMaster and optimize the following parameters in the **mapred-site.xml** configuration file on the client:

- **yarn.app.mapreduce.am.resource.mb**
- **yarn.app.mapreduce.am.command-opts**. The recommended value of **-Xmx** is 0.8 x **yarn.app.mapreduce.am.resource.mb**.

Specification:

ApplicationMaster supports 24,000 concurrent containers when the configuration is as follows:

- **yarn.app.mapreduce.am.resource.mb**=2048
- In **yarn.app.mapreduce.am.command-opts**, **-Xmx** is **1638m**.

12.18.9.7 After the Address of MapReduce JobHistoryServer Is Changed, Why the Wrong Page is Displayed When I Click the Tracking URL on the ResourceManager WebUI?

Question

After the address of MapReduce JobHistoryServer is changed, why the wrong page is displayed when I click the tracking URL on the ResourceManager WebUI?

Answer

JobHistoryServer address (mapreduce.jobhistory.address / mapreduce.jobhistory.webapp.<https.>address) is the parameter of MapReduce. The MapReduce client will submit the address together with jobs to ResourceManager. After ResourceManager completing the jobs, the parameter is saved in RMStateStore as the target address for viewing history job information.

If the JobHistoryServer address is changed, update the address in the configuration file of the MapReduce client in time. If the address is not updated, the page of earlier JobHistoryServer is displayed when you click the tracking URL of the new job. The target address of information about MapReduce jobs running before the change of address cannot be changed, so the wrong page is also displayed when you click the tracking URL. You can check the history information by accessing the new JobHistoryServer address.

12.18.9.8 MapReduce Job Failed in Multiple NameService Environment

Question

MapReduce or Yarn job fails in multiple nameService environment using viewFS.

Answer

When using viewFS only the mount directories are accessible, so the most possible cause is that the path configured is not in one of the mounted paths. For example:

```
<property>
<name>fs.defaultFS</name>
<value>viewfs://ClusterX/</value>
</property>
<property>
<name>fs.viewfs.mounttable.ClusterX.link./folder1</name>
<value>hdfs://NS1/folder1</value>
</property>
<property>
<name>fs.viewfs.mounttable.ClusterX.link./folder2</name>
<value>hdfs://NS2/folder2</value>
</property>
```

For all the MR properties which depends on HDFS, should use the paths inside mount folders.

Incorrect:

```
<property>
<name>yarn.app.mapreduce.am.staging-dir</name>
<value>/tmp/hadoop-yarn/staging</value>
</property>
```

As the root folder (/) is not accessible in viewFS.

Correct:

```
<property>
<name>yarn.app.mapreduce.am.staging-dir</name>
<value>/folder1/tmp/hadoop-yarn/staging</value>
</property>
```

12.18.9.9 Why a Fault MapReduce Node Is Not Blacklisted?

Question

MapReduce task fails and the ratio of fault nodes to all nodes is smaller than the blacklist threshold configured by **yarn.resourcemanager.am-scheduling.node-blacklisting-disable-threshold**. Why the fault node not be blacklisted?

Answer

If the blacklisted percentage exceeds the threshold, all blacklisted nodes are released. Traditionally, the blacklist percentage is the ratio of fault nodes to all nodes in the cluster. Currently, each node has a label expression. Therefore, the blacklist percentage needs to be calculated based on the number of nodes related to valid node label expressions. In other way, the blacklist percentage is the ratio of fault nodes related to valid node label expressions.

Assume that there are 100 nodes in the cluster, including 10 nodes (labelA) related to valid node label expressions. Assume that all nodes related to valid node label expressions are faulty and default blacklist threshold is 0.33. In traditional calculation method, 10/100 = 0.1, which is far smaller than the threshold (0.33). In this case, the 10 nodes will never get released. Therefore, MapReduce always cannot obtain nodes and applications cannot run properly. In practice, the blacklist percentage needs to be calculated based on the total number of nodes related to valid node label expressions: 10/10 = 1 is greater than the blacklist threshold and all nodes are released.

Therefore, even the ratio of fault nodes to all nodes in the cluster is below the threshold, all nodes in the blacklist are released.

12.19 Using Oozie

12.19.1 Using Oozie from Scratch

Oozie is an open-source workflow engine that is used to schedule and coordinate Hadoop jobs.

Oozie can be used to submit a wide array of jobs, such as Hive, Spark2x, Loader, MapReduce, Java, DistCp, Shell, HDFS, SSH, SubWorkflow, Streaming, and scheduled jobs.

This section describes how to use the Oozie client to submit a MapReduce job.

Prerequisites

The client has been installed. For example, the installation directory is **/opt/client**. The client directory in the following operations is only an example. Change it based on the actual installation directory onsite.

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory, for example, **/opt/Bigdata/client**:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Check the cluster authentication mode.

- If the cluster is in security mode, run the following command to authenticate the user: *UserOozie* indicates the user who submits tasks.

  kinit *UserOozie*

- If the cluster is in normal mode, go to **Step 5**.

Step 5 Upload the Oozie configuration file and JAR package to HDFS.

hdfs dfs -mkdir /user/*UserOozie*

hdfs dfs -put -f /opt/client/Oozie/oozie-client-*/examples /user/*UserOozie/*

NOTE

- **/opt/client/** is an example client installation directory. Change it to the actual installation directory.
- **UserOozie** indicates the name of the user who submits jobs.

Step 6 Run the following commands to modify the job execution configuration file:

cd /opt/client/Oozie/oozie-client-*/examples/apps/map-reduce/

vi job.properties

```
nameNode=hdfs://hacluster
resourceManager=10.64.35.161:8032 (10.64.35.161 is the service plane IP address of the Yarn resourceManager (active) node, and 8032 is the port number of yarn.resourcemanager.port)
queueName=default
examplesRoot=examples
user.name=admin
oozie.wf.application.path=${nameNode}/user/${user.name}/${examplesRoot}/apps/map-reduce# HDFS upload path
outputDir=map-reduce
oozie.wf.rerun.failnodes=true
```

Step 7 Run the following command to execute the Oozie job:

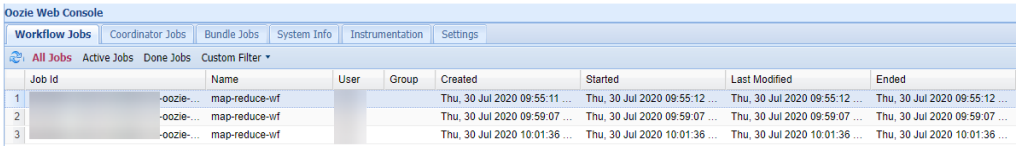
oozie job -oozie https://*Host name of the Oozie role*:21003/oozie/ -config job.properties -run

```
[root@kwephispra44947 map-reduce]# oozie job -oozie https://kwephispra44948:21003/oozie/ -config job.properties -run
.....
job: 0000000-200730163829770-oozie-omm-W
```

Step 8 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**.

Step 9 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Oozie**, click the hyperlink next to **Oozie WebUI** to go to the Oozie page, and view the task execution result on the Oozie web UI.

Figure 12-38 Task execution result



----End

12.19.2 Using the Oozie Client

Scenario

This section describes how to use the Oozie client in an O&M scenario or service scenario.

Prerequisites

- The client has been installed. For example, the installation directory is **/opt/client**. The client directory in the following operations is only an example.
- Service component users are created by the administrator as required. In security mode, machine-machine users need to download the keytab file. A human-machine user must change the password upon the first login.

Using the Oozie Client

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to switch to the client installation directory (change it to the actual installation directory):

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Check the cluster authentication mode.

- If the cluster is in security mode, run the following command to authenticate the user: *exampleUser* indicates the name of the user who submits tasks.

kinit *exampleUser*

- If the cluster is in normal mode, go to **Step 5**.

Step 5 Perform the following operations to configure Hue:

1. Configure the Spark2x environment (skip this step if the Spark2x task is not involved):

   hdfs dfs -put /opt/client/Spark2x/spark/jars/*.jar /user/oozie/share/lib/spark2x/

   When the JAR package in the HDFS directory **/user/oozie/share** changes, you need to restart the Oozie service.

2. Upload the Oozie configuration file and JAR package to HDFS.

   hdfs dfs -mkdir /user/*exampleUser*

   hdfs dfs -put -f /opt/client/Oozie/oozie-client-*/examples /user/*exampleUser*/

   NOTE

   - *exampleUser* indicates the name of the user who submits tasks.
   - If the user who submits the task and other files except **job.properties** are not changed, client installation directory **Oozie/oozie-client-*/examples** can be repeatedly used after being uploaded to HDFS.
   - Resolve the JAR file conflict between Spark and Yarn about Jetty.

     hdfs dfs -rm -f /user/oozie/share/lib/spark/jetty-all-9.2.22.v20170606.jar
   - In normal mode, if **Permission denied** is displayed during the upload, run the following commands:

     su - omm

     source /opt/client/bigdata_env

     hdfs dfs -chmod -R 777 /user/oozie

     exit

----End

12.19.3 Using Oozie Client to Submit an Oozie Job

12.19.3.1 Submitting a Hive Job

Scenario

This section describes how to use the Oozie client to submit a Hive job.

Hive jobs are divided into the following types:

- Hive job

  Hive job that is connected in JDBC mode
- Hive2 job

  Hive job that is connected in Beeline mode

This section describes how to submit a Hive job using the Oozie client.

NOTE

- The procedure for submitting a Hive2 job using the Oozie client is the same as that for submitting a Hive job. You only need to change **/Hive** in the procedure to **/Hive2**.

  For example, if the Hive job running directory is **/opt/client/Oozie/oozie-client-*/examples/apps/hive/**, then the running directory of Hive2 is **/opt/client/Oozie/oozie-client-*/examples/apps/hive2/**.
- You are advised to download the latest client.

Prerequisites

- The Hive and Oozie components and clients have been installed and are running properly.
- You have created or obtained the human-machine account and password for accessing the Oozie service.

  NOTE

  - This user must belong to the **hadoop**, **supergroup**, and **hive** groups and be assigned with the Oozie role operation permission. If the multi-instance function is enabled for Hive, the user must belong to a specific Hive instance group, for example, **hive3**.
  - This user must also be assigned the **manager_viewer** role at least.
- You have obtained the URL of the Oozie server (any instance) in the running state, for example, **https://10.1.130.10:21003/oozie**.
- You have obtained the name of the Oozie server, for example, **10-1-130-10**.
- You have obtained the IP address of the active Yarn ResourceManager, for example, **10.1.130.11**.

Procedure

Step 1 Log in to the node where the Oozie client is installed as the client installation user.

Step 2 Run the following command to obtain the installation environment. **/opt/client/** is an example client installation path.

source /opt/client/bigdata_env

Step 3 Check the cluster authentication mode.

- If the cluster is in security mode, run the **kinit** command to authenticate users.

  For example, the **oozieuser** user is authenticated using the following command:

  kinit oozieuser
- If the cluster is in normal mode, go to **Step 4**.

Step 4 Run the following command to go to the example directory:

cd /opt/client/Oozie/oozie-client-*/examples/apps/hive/

Table 12-312 lists the files that you need to pay attention to in the directory.

Table 12-312 File description

File	Description
hive-site.xml	Configuration file of a Hive job
job.properties	Parameter definition file of a workflow
script.q	SQL script of a Hive job
workflow.xml	Rule definition file of a workflow

Step 5 Run the following command to edit the **job.properties** file:

vi job.properties

Perform the following modifications:

Change the value of **userName** to the name of the human-machine user who submits the job, for example, **userName=oozieuser**.

Step 6 Run the **oozie job** command to run the workflow file:

oozie job -oozie https://*Host name of the Oozie role*:**21003/oozie/ -config job.properties -run**

NOTE

- The command parameters are described as follows:
  -oozie URL of the Oozie server that executes a job
  -config Workflow property file
  -run Executing a workflow
- If a job ID, for example, **job: 0000021-140222101051722-oozie-omm-W**, is displayed after the workflow file is executed, the job is successfully submitted. You can view the execution results on the Oozie management page.
  Log in to the Oozie web UI at **https**://*IP address of the Oozie role*:**21003/oozie** as user **oozieuser**.
  On the Oozie web UI, you can view the submitted workflow information based on the job ID in the table on the page.

----End

12.19.3.2 Submitting a Spark2x Job

Scenario

This section describes how to submit a Spark2x job using the Oozie client.

NOTE

You are advised to download the latest client.

Prerequisites

- The Spark2x and Oozie components and clients have been installed and are running properly.

If the current client is an earlier version, you need to download and install the client again.

- You have created or obtained the human-machine account and password for accessing the Oozie service.

  NOTE

  - This user must belong to the **hadoop**, **supergroup**, and **hive** groups and be assigned with the Oozie role operation permission. If the multi-instance function is enabled for Hive, the user must belong to a specific Hive instance group, for example, **hive3**.
  - This user must also be assigned the **manager_viewer** role at least.

- You have obtained the URL of the Oozie server (any instance) in the running state, for example, **https://10.1.130.10:21003/oozie**.
- You have obtained the name of the Oozie server, for example, **10-1-130-10**.
- You have obtained the IP address of the active Yarn ResourceManager, for example, **10.1.130.11**.

Procedure

Step 1 Log in to the node where the Oozie client is installed as the client installation user.

Step 2 Run the following command to obtain the installation environment. **/opt/client/** is an example client installation path.

source /opt/client/bigdata_env

Step 3 Check the cluster authentication mode.

- If the cluster is in security mode, run the **kinit** command to authenticate users.

  For example, the **oozieuser** user is authenticated using the following command:

  kinit oozieuser

- If the cluster is in normal mode, go to **Step 4**.

Step 4 Run the following command to go to the example directory:

cd /opt/client/Oozie/oozie-client-*/examples/apps/spark2x/

Table 12-313 lists the files that you need to pay attention to in the directory.

Table 12-313 File description

File	Description
job.properties	Parameter definition file of a workflow
workflow.xml	Rule definition file of a workflow
lib	Directory of the JAR file on which a workflow depends

Step 5 Run the following command to edit the **job.properties** file:

vi job.properties

Perform the following modifications:

Change the value of **userName** to the name of the human-machine user who submits the job, for example, **userName=oozieuser**.

Step 6 Run the **oozie job** command to run the workflow file:

oozie job -oozie https://*Host name of the Oozie role*:**21003/oozie/ -config job.properties -run**

NOTE

- The command parameters are described as follows:

  -oozie URL of the Oozie server that executes a job

  -config Workflow property file

  -run Executing a workflow

- If a job ID, for example, **job: 0000021-140222101051722-oozie-omm-W**, is displayed after the workflow file is executed, the job is successfully submitted. You can view the execution results on the Oozie management page.

  Log in to the Oozie web UI at **https**://*IP address of the Oozie role*:**21003/oozie** as user **oozieuser**.

  On the Oozie web UI, you can view the submitted workflow information based on the job ID in the table on the page.

----End

12.19.3.3 Submitting a Loader Job

Scenario

This section describes how to submit a Loader job using the Oozie client.

NOTE

You are advised to download the latest client.

Prerequisites

- The Hive and Oozie components and clients have been installed and are running properly.
- You have created or obtained the human-machine account and password for accessing the Oozie service.

  NOTE

  - This user must belong to the **hadoop**, **supergroup**, and **hive** groups and be assigned with the Oozie role operation permission. If the multi-instance function is enabled for Hive, the user must belong to a specific Hive instance group, for example, **hive3**.
  - This user must also be assigned the **manager_viewer** role at least.
- You have obtained the URL of the Oozie server (any instance) in the running state, for example, **https://10.1.130.10:21003/oozie**.

- You have obtained the name of the Oozie server, for example, **10-1-130-10**.
- You have obtained the IP address of the active Yarn ResourceManager, for example, **10.1.130.11**.
- You have created a Loader job to be scheduled and obtained the job ID.

Procedure

Step 1 Log in to the node where the Oozie client is installed as the client installation user.

Step 2 Run the following command to obtain the installation environment. **/opt/client/** is an example client installation path.

source /opt/client/bigdata_env

Step 3 Check the cluster authentication mode.

- If the cluster is in security mode, run the **kinit** command to authenticate users.

  For example, the **oozieuser** user is authenticated using the following command:

  kinit oozieuser
- If the cluster is in normal mode, go to **Step 4**.

Step 4 Run the following command to go to the example directory:

cd /opt/client/Oozie/oozie-client-*/examples/apps/sqoop/

Table 12-314 lists the files that you need to pay attention to in the directory.

Table 12-314 File description

File	Description
job.properties	Parameter definition file of a workflow
workflow.xml	Rule definition file of a workflow

Step 5 Run the following command to edit the **job.properties** file:

vi job.properties

Perform the following modifications:

Change the value of **userName** to the name of the human-machine user who submits the job, for example, **userName=oozieuser**.

Step 6 Run the following command to edit the **workflow.xml** file:

vi workflow.xml

Perform the following modifications:

Change the value of **command** to the ID of the Loader job to be scheduled, for example, **1**.

Upload the **workflow.xml** file to the HDFS path in the **job.properties** file.

hdfs dfs -put -f workflow.xml /user/userName/examples/apps/sqoop

Step 7 Run the **oozie job** command to run the workflow file:

oozie job -oozie https://*Host name of the Oozie role*:21003/oozie/ -config job.properties -run

NOTE

- The command parameters are described as follows:

  -oozie URL of the Oozie server that executes a job

  -config Workflow property file

  -run Executing a workflow
- If a job ID, for example, **job: 0000021-140222101051722-oozie-omm-W**, is displayed after the workflow file is executed, the job is successfully submitted. You can view the execution results on the Oozie management page.

  Log in to the Oozie web UI at **https**://*IP address of the Oozie role*:**21003/oozie** as user **oozieuser**.

  On the Oozie web UI, you can view the submitted workflow information based on the job ID in the table on the page.

----End

12.19.3.4 Submitting a DistCp Job

Scenario

This section describes how to submit a DistCp job using the Oozie client.

NOTE

You are advised to download the latest client.

Prerequisites

- The HDFS and Oozie components and clients have been installed and are running properly.

  If the current client is an earlier version, you need to download and install the client again.
- You have created or obtained the human-machine account and password for accessing the Oozie service.

  NOTE

  - This user must belong to the **hadoop**, **supergroup**, and **hive** groups and be assigned with the Oozie role operation permission. If the multi-instance function is enabled for Hive, the user must belong to a specific Hive instance group, for example, **hive3**.
  - This user must also be assigned the **manager_viewer** role at least.
- You have obtained the URL of the Oozie server (any instance) in the running state, for example, **https://10.1.130.10:21003/oozie**.
- You have obtained the name of the Oozie server, for example, **10-1-130-10**.
- You have obtained the IP address of the active Yarn ResourceManager, for example, **10.1.130.11**.

Procedure

Step 1 Log in to the node where the Oozie client is installed as the client installation user .

Step 2 Run the following command to obtain the installation environment. **/opt/client/** is an example client installation path.

source /opt/client/bigdata_env

Step 3 Check the cluster authentication mode.

- If the cluster is in security mode, run the **kinit** command to authenticate users.

  For example, the **oozieuser** user is authenticated using the following command:

  kinit oozieuser
- If the cluster is in normal mode, go to **Step 4**.

Step 4 Run the following command to go to the example directory:

cd /opt/client/Oozie/oozie-client-*/examples/apps/distcp/

Table 12-315 lists the files that you need to pay attention to in the directory.

Table 12-315 File description

File	Description
job.properties	Parameter definition file of a workflow
workflow.xml	Rule definition file of a workflow

Step 5 Run the following command to edit the **job.properties** file:

vi job.properties

Perform the following modifications:

Change the value of **userName** to the name of the human-machine user who submits the job, for example, **userName=oozieuser**.

Step 6 Whether DistCp is not deployed across security clusters.

- If yes, go to **Step 7**.
- If no, go to **Step 9**.

Step 7 Establish cross-Manager mutual trust between two clusters.

Step 8 Run the following commands to back up and modify the **workflow.xml** file:

cp workflow.xml workflow.xml.bak

vi workflow.xml

Modify the following content:

```
<workflow-app xmlns="uri:oozie:workflow:1.0" name="distcp-wf">
   <start to="distcp-node"/>
```

```
  <action name="distcp-node">
     <distcp xmlns="uri:oozie:distcp-action:1.0">
        <resource-manager>${resourceManager}</resource-manager>
        <name-node>${nameNode}</name-node>
        <prepare>
           <delete path="hdfs://target_ip:target_port/user/${userName}/${examplesRoot}/output-data/${outputDir}"/>
        </prepare>
        <configuration>
           <property>
              <name>mapred.job.queue.name</name>
              <value>${queueName}</value>
           </property>
           <property>
              <name>oozie.launcher.mapreduce.job.hdfs-servers</name>
              <value>hdfs://source_ip:source_port,hdfs://target_ip:target_port</value>
           </property>
        </configuration>
        <arg>${nameNode}/user/${userName}/${examplesRoot}/input-data/text/data.txt</arg>
        <arg>hdfs://target_ip:target_port/user/${userName}/${examplesRoot}/output-data/${outputDir}/data.txt</arg>
        </distcp>
     <ok to="end"/>
     <error to="fail"/>
  </action>
  <kill name="fail">
     <message>DistCP failed, error message[${wf:errorMessage(wf:lastErrorNode())}]</message>
  </kill>
  <end name="end"/>
</workflow-app>
```

target_ip:target_port is the HDFS active NameNode address of the other trusted cluster, for example, **10.10.10.233:25000**.

source_ip:source_port indicates the HDFS active NameNode address of the source cluster, for example, **10.10.10.223:25000**.

Change the two IP addresses and port numbers based on the site requirements.

Step 9 Run the **oozie job** command to run the workflow file:

oozie job -oozie https://*Host name of the Oozie role*:21003/oozie/ -config job.properties -run

NOTE

- The command parameters are described as follows:

  -oozie URL of the Oozie server that executes a job

  -config Workflow property file

  -run Executing a workflow

- If a job ID, for example, **job: 0000021-140222101051722-oozie-omm-W**, is displayed after the workflow file is executed, the job is successfully submitted. You can view the execution results on the Oozie management page.

  Log in to the Oozie web UI at **https**://*IP address of the Oozie role*:**21003/oozie** as user **oozieuser**.

  On the Oozie web UI, you can view the submitted workflow information based on the job ID in the table on the page.

----End

12.19.3.5 Submitting Other Jobs

Scenario

In addition to Hive, Spark2x, and Loader jobs, MapReduce, Java, Shell, HDFS, SSH, SubWorkflow, Streaming, and scheduled jobs can be submitted using the Oozie client.

NOTE

You are advised to download the latest client.

Prerequisites

- The Oozie component and its client have been installed and are running properly.
- You have created or obtained the human-machine account and password for accessing the Oozie service.

  NOTE

  - Shell job:

    This user must belong to the **hadoop** and **supergroup** groups and be assigned the Oozie role operation permission. The Shell script must have the execution permission on each NodeManager.
  - SSH job:

    This user must belong to the **hadoop** and **supergroup** groups and be assigned the Oozie role operation permission. The mutual trust configuration is complete.
  - Other jobs:

    This user must belong to the **hadoop** and **supergroup** groups and be assigned the Oozie role operation permission and other required permissions.
  - This user must also be assigned the **manager_viewer** role at least.
- You have obtained the URL of the Oozie server (any instance) in the running state, for example, **https://10.1.130.10:21003/oozie**.
- You have obtained the name of the Oozie server, for example, **10-1-130-10**.
- You have obtained the IP address of the active Yarn ResourceManager, for example, **10.1.130.11**.

Procedure

Step 1 Log in to the node where the Oozie client is installed as the client installation user.

Step 2 Run the following command to obtain the installation environment. **/opt/client/** is an example client installation path.

source /opt/client/bigdata_env

Step 3 Check the cluster authentication mode.

- If the cluster is in security mode, run the **kinit** command to authenticate users.

  For example, the **oozieuser** user is authenticated using the following command:

  kinit oozieuser

- If the cluster is in normal mode, go to **Step 4**.

Step 4 Go to the example directory based on the type of the task you submit.

Table 12-316 List of example directories

Job Type	Example Directory
MapReduce job	*Client installation directory*/**Oozie/oozie-client-*/examples/apps/map-reduce**
Java job	*Client installation directory*/**Oozie/oozie-client-*/examples/apps/java-main**
Shell job	*Client installation directory*/**Oozie/oozie-client-*/examples/apps/shell**
Streaming job	*Client installation directory*/**Oozie/oozie-client-*/examples/apps/shell**
SubWorkflow job	*Client installation directory*/**Oozie/oozie-client-*/examples/apps/subwf**
SSH job	*Client installation directory*/**Oozie/oozie-client-*/examples/apps/ssh**
Scheduled job	*Client installation directory*/**Oozie/oozie-client-*/examples/apps/cron**

NOTE

The examples of other jobs contain HDFS job examples.

Table 12-317 lists the files that you need to pay attention to in the example directory.

Table 12-317 File description

File	Description
job.properties	Parameter definition file of a workflow
workflow.xml	Rule definition file of a workflow
lib	Directory of the JAR file on which a workflow depends
coordinator.xml	Scheduled job configuration file which can be used to set a scheduled policy. The file is in the **cron** directory.
oozie_shell.sh	Shell script file required for submitting shell jobs. The file is in the **shell** directory.

Step 5 Run the following command to edit the **job.properties** file:

vi job.properties

Perform the following modifications:

Change the value of **userName** to the name of the human-machine user who submits the job, for example, **userName=oozieuser**.

Step 6 Run the **oozie job** command to run the workflow file:

oozie job -oozie https://*Host name of the oozie role***:21003/oozie -config** *File path of job.properties* **-run**

Example:

oozie job -oozie https://10-1-130-10:21003/oozie -config

/opt/client/Oozie/oozie-client-*/examples/apps/map-reduce/job.properties -run

NOTE

- The command parameters are described as follows:

  -oozie URL of the Oozie server that executes a job

  -config Workflow property file

  -run Executing a workflow

- If a job ID, for example, **job: 0000021-140222101051722-oozie-omm-W**, is displayed after the workflow file is executed, the job is successfully submitted. You can view the execution results on the Oozie management page.

  Log in to the Oozie web UI at **https**://*IP address of the Oozie role*:**21003/oozie** as user **oozieuser**.

  On the Oozie web UI, you can view the submitted workflow information based on the job ID in the table on the page.

----End

12.19.4 Using Hue to Submit an Oozie Job

12.19.4.1 Creating a Workflow

Scenario

You can submit an Oozie job on the Hue management page, but a workflow must be created before the job is submitted.

Prerequisites

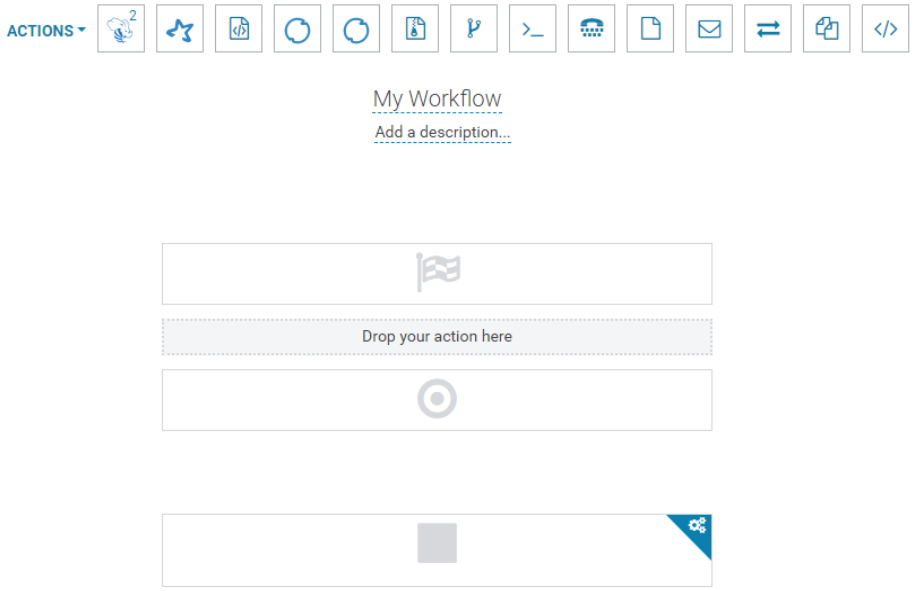
Before using Hue to submit an Oozie job, configure the Oozie client and upload the sample configuration file and JAR file to the specified HDFS directory. For details, see **Using the Oozie Client**.

Procedure

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 In the navigation tree on the left, click  and choose **Workflow** to open the Workflow editor.

Step 3 Select **Actions** from the **DOCUMENTS** drop-down list, select the job type to be created and drag it to the operation area.



For submitting different job types, follow instructions in the following sections:

- **Submitting a Hive2 Job**
- **Submitting a Spark2x Job**
- **Submitting a Java Job**
- **Submitting a Loader Job**
- **Submitting a MapReduce Job**
- **Submitting a Sub-workflow Job**
- **Submitting a Shell Job**
- **Submitting an HDFS Job**
- **Submitting a Streaming Job**
- **Submitting a DistCp Job**

----End

12.19.4.2 Submitting a Workflow Job

12.19.4.2.1 Submitting a Hive2 Job

Scenario

This section describes how to submit an Oozie job of the Hive2 type on the Hue web UI.

Procedure

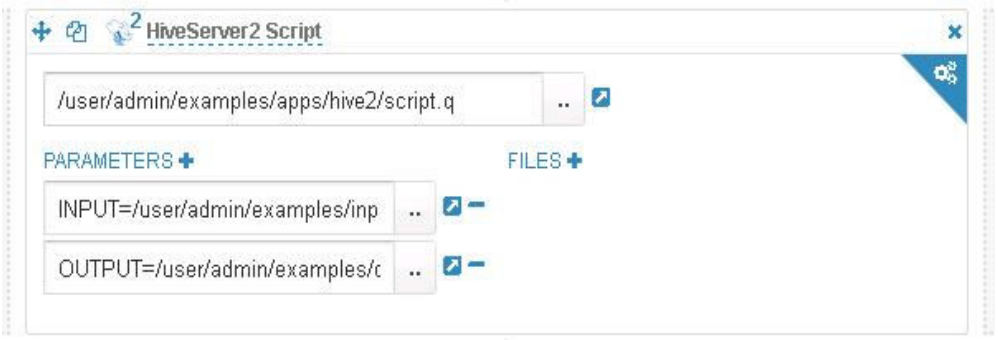
Step 1 Create a workflow. For details, see **Creating a Workflow**.

Step 2 On the workflow editing page, select  next to **HiveServer2 Script** and drag it to the operation area.

Step 3 In the **HiveServer2 Script** dialog box that is displayed, configure the script path in the HDFS, for example, **/user/admin/examples/apps/hive2/script.q**, and click **Add**.

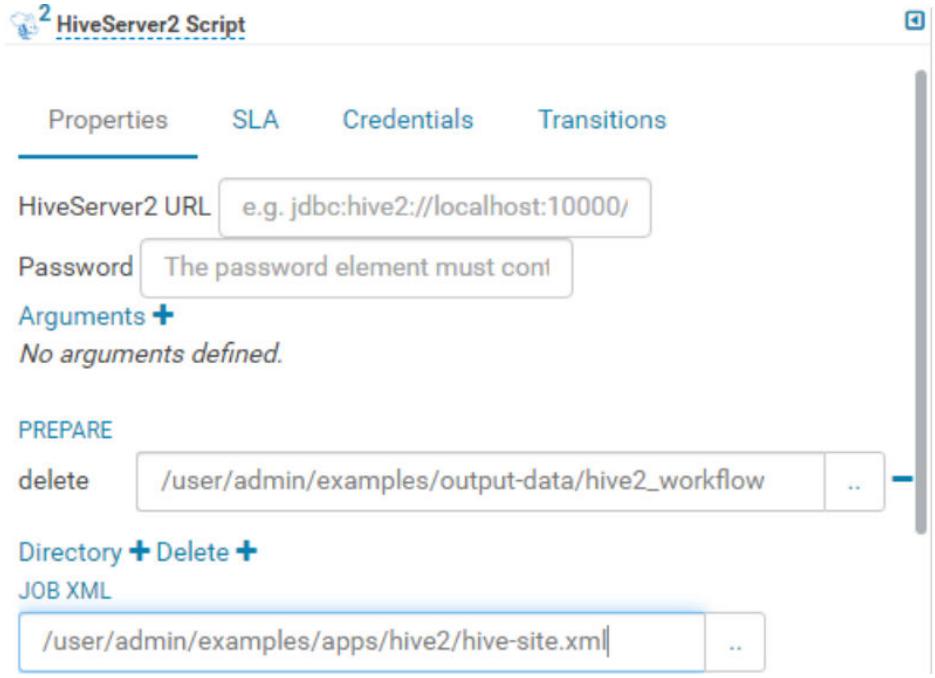
Step 4 Click **PARAMETER+** to add input and output parameters.

For example, if the input parameter is **INPUT=/user/admin/examples/input-data/table**, the output parameter is **OUTPUT=/user/admin/examples/output-data/hive2_workflow**.



Step 5 Click the configuration button  in the upper right corner. On the configuration page that is displayed, click **Delete +** to delete a directory, for example, **/user/admin/examples/output-data/hive2_workflow**.

Step 6 Configure the job XML, for example, to the HDFS path **/user/admin/examples/apps/hive2/hive-site.xml**.



NOTE

If the preceding parameters and values are modified, you can query them in **Oozie client installation directory//oozie-client-*/conf/hive-site.xml**.

Step 7 Click in the upper right corner of the Oozie editor.

If you need to modify the job name before saving the job (default value: **My Workflow**), click the name directly for modification, for example, **Hive2-Workflow**.

Step 8 After the configuration is saved, click , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

----End

12.19.4.2.2 Submitting a Spark2x Job

Scenario

This section describes how to submit an Oozie job of the Spark2x type on Hue.

Procedure

Step 1 Create a workflow. For details, see **Creating a Workflow**.

Step 2 On the workflow editing page, select next to **Spark program** and drag it to the operation area.

Step 3 In the Spark window that is displayed, set the value of **Files**, for example, to **hdfs://hacluster/user/admin/examples/apps/spark2x/lib/oozie-examples.jar**.

Set the value of **jar/py name**, for example, to **org.apache.oozie.example.SparkFileCopy**, and click **Add**.

Step 4 Set the value of **Main class**, for example, **org.apache.oozie.example.SparkFileCopy**.

Step 5 Click **PARAMETER+** to add related input and output parameters.

For example, add the following parameters:

- **hdfs://hacluster/user/admin/examples/input-data/text/data.txt**
- **hdfs://hacluster/user/admin/examples/output-data/spark_workflow**

Step 6 In the **Options list** text box, specify Spark parameters, for example, **--conf spark.yarn.archive=hdfs://hacluster/user/spark2x/jars/8.1.0.1/spark-archive-2x.zip --conf spark.eventLog.enabled=true --conf spark.eventLog.dir=hdfs://hacluster/spark2xJobHistory2x**.

NOTE

The version 8.1.0.1 is used as an example. Replace it with the actual version number.

Step 7 Click the configuration button  in the upper right corner. Set the value of **Spark Master**, for example, to **yarn-cluster**. Set the value of **Mode**, for example, **cluster**.

Step 8 On the configuration page that is displayed, click **Delete +** to delete a directory, for example, **hdfs://hacluster/user/admin/examples/output-data/spark_workflow**.

Step 9 Click **PROPERTIES+** and add **sharelib** used by Oozie. Enter the attribute name **oozie.action.sharelib.for.spark** in the left text box and the attribute value **spark2x** in the right text box.

Step 10 Click  in the upper right corner of the Oozie editor.

If you need to modify the job name before saving the job (default value: **My Workflow**), click the name directly for modification, for example, **Spark-Workflow**.

Step 11 After the configuration is saved, click  , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

----End

12.19.4.2.3 Submitting a Java Job

Scenario

This section describes how to submit an Oozie job of the Java type on the Hue web UI.

Procedure

Step 1 Create a workflow. For details, see **Creating a Workflow**.

Step 2 On the workflow editing page, select  next to **Java program** and drag it to the operation area.

Step 3 In the **Jar program** window that is displayed, set the value of **Jar name**, for example, **/user/admin/examples/apps/java-main/lib/oozie-examples-5.1.0.jar**. Set the value of **Main class**, for example, **org.apache.oozie.example.DemoJavaMain**. Click **Add**.

Step 4 Click  in the upper right corner of the Oozie editor.

If you need to modify the job name before saving the job (default value: **My Workflow**), click the name directly for modification, for example, **Java-Workflow**.

Step 5 After the configuration is saved, click  , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

----End

12.19.4.2.4 Submitting a Loader Job

Scenario

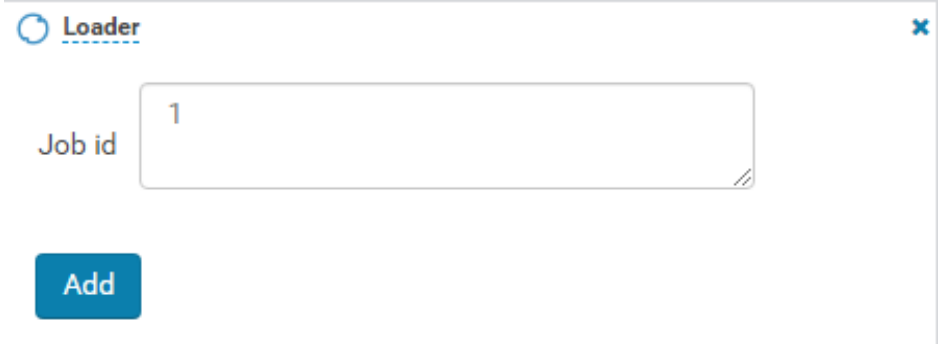
This section describes how to submit an Oozie job of the Loader type on the Hue web UI.

Procedure

Step 1 Create a workflow. For details, see **Creating a Workflow**.

Step 2 On the workflow editing page, select  next to **Loader** and drag it to the operation area.

Step 3 In the **Loader** window that is displayed, set **Job id**, for example, to **1**. Click **Add**.



NOTE

Job id is the ID of the Loader job to be orchestrated and can be obtained from the Loader page.

You can create a Loader job to be scheduled and obtain its job ID. For details, see **Using Loader**.

Step 4 Click in the upper right corner of the Oozie editor.

If you need to modify the job name before saving the job (default value: **My Workflow**), click the name directly for modification, for example, **Loader-Workflow**.

Step 5 After the configuration is saved, click , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

----End

12.19.4.2.5 Submitting a MapReduce Job

Scenario

This section describes how to submit an Oozie job of the MapReduce type on the Hue web UI.

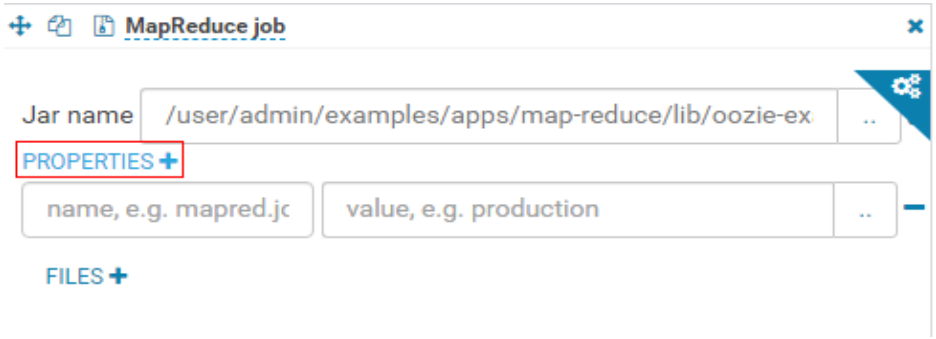
Procedure

Step 1 Create a workflow. For details, see **Creating a Workflow**.

Step 2 On the workflow editing page, select next to **MapReduce job** and drag it to the operation area.

Step 3 In the displayed **MapReduce job** dialog box, set **Jar name**, for example, to **/user/admin/examples/apps/map-reduce/lib/oozie-examples-5.1.0.jar**. Click **Add**.

Step 4 Click **PROPERTIES+** to add input and output properties.



For example, set the value of **mapred.input.dir** to **/user/admin/examples/input-data/text** and set the value of **mapred.output.dir** to **/user/admin/examples/output-data/map-reduce_workflow**.

Step 5 Click the configuration button  in the upper right corner. On the configuration page that is displayed, click **Delete +** to delete a directory, for example, **/user/admin/examples/output-data/map-reduce_workflow**.

Step 6 Click  in the upper right corner of the Oozie editor.

If you need to modify the job name before saving the job (default value: **My Workflow**), click the name directly for modification, for example, **MapReduce-Workflow**.

Step 7 After the configuration is saved, click  , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

----End

12.19.4.2.6 Submitting a Sub-workflow Job

Scenario

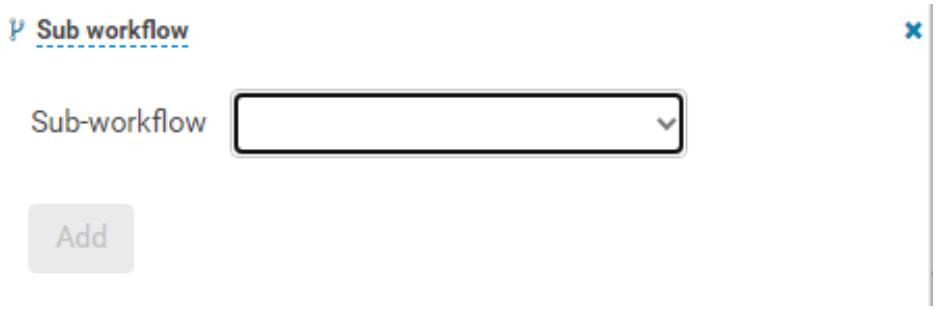
This section describes how to submit an Oozie job of the Sub-workflow type on the Hue web UI.

Procedure

Step 1 Create a workflow. For details, see **Creating a Workflow**.

Step 2 On the workflow editing page, select  next to **Sub workflow** and drag it to the operation area.

Step 3 In the **Sub workflow** dialog box that is displayed, set **Sub-workflow**, for example, to **Java-Workflow** (one of the created workflows) from the drop-down list box, and click **Add**.



Step 4 Click in the upper right corner of the Oozie editor.

If you need to modify the job name before saving the job (default value: **My Workflow**), click the name directly for modification, for example, **Subworkflow-Workflow**.

Step 5 After the configuration is saved, click  , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

----End

12.19.4.2.7 Submitting a Shell Job

Scenario

This section describes how to submit an Oozie job of the Shell type on the Hue web UI.

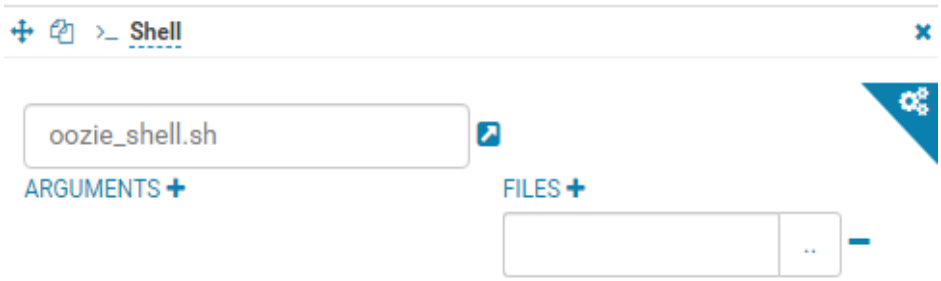
Procedure

Step 1 Create a workflow. For details, see **Creating a Workflow**.

Step 2 On the workflow editing page, select  next to **Shell** and drag it to the operation area.

Step 3 In the **Shell** window that is displayed, set **Shell command**, for example, to **oozie_shell.sh**, and click **Add**.

Step 4 Click **FILE+** to add the Shell command execution file and Oozie example execution file, for example, **/user/admin/examples/apps/shell/oozie_shell.sh**.



Step 5 Click  in the upper right corner of the Oozie editor.

If you need to modify the job name before saving the job (default value: **My Workflow**), click the name directly for modification, for example, **Shell-Workflow**.

Step 6 After the configuration is saved, click  , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

NOTE

- When configuring a shell command as a Linux command, specify it as the original command instead of the shortcut key command. For example, do not set **ls -l** to **ll**. You can configure it as the shell command **ls**, and add a parameter **-l**.
- When uploading the shell script to HDFS on Windows, make sure that the shell script format is Unix. If the format is incorrect, the shell job fails to be submitted.

----End

12.19.4.2.8 Submitting an HDFS Job

Scenario

This section describes how to submit an Oozie job of the HDFS type on the Hue web UI.

Procedure

Step 1 Create a workflow. For details, see **Creating a Workflow**.

Step 2 On the workflow editing page, select  next to **Fs** and drag it to the operation area.

Step 3 In the **Fs** window that is displayed, click **Add**.

Step 4 Click **CREATE DIRECTORY+** to add the HDFS directories to be created, for example, **/user/admin/examples/output-data/mkdir_workflow** and **/user/admin/examples/output-data/mkdir_workflow1**.

Step 5 Click  in the upper right corner of the Oozie editor.

If you need to modify the job name before saving the job (default value: **My Workflow**), click the name directly for modification, for example, **HDFS-Workflow**.

Step 6 After the configuration is saved, click  , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

----End

12.19.4.2.9 Submitting a Streaming Job

Scenario

This section describes how to submit an Oozie job of the Streaming type on the Hue web UI.

Procedure

Step 1 Create a workflow. For details, see **Creating a Workflow**.

Step 2 On the workflow editing page, select  next to **Streaming** and drag it to the operation area.

Step 3 In the **Streaming** window that is displayed, set **Mapper**, for example, to **/bin/cat**. Set **Reducer**, for example, to **/usr/bin/wc**. Click **Add**.

Step 4 Click **FILE+** to add the files required for running.

for example, **/user/oozie/share/lib/mapreduce-streaming/hadoop-streaming-3.1.1.jar** and **/user/oozie/share/lib/mapreduce-streaming/oozie-sharelib-streaming-5.1.0.jar**.

Step 5 Click the configuration button  in the upper right corner. On the configuration page that is displayed, click **Delete+** to delete a directory, for example, **/user/admin/examples/output-data/streaming_workflow**.

Step 6 Click **PROPERTIES+** to add the following properties:

- Enter the property name **mapred.input.dir** in the left box and enter the property value **/user/admin/examples/input-data/text** in the right box.
- Enter the property name **mapred.output.dir** in the left box and enter the attribute value **/user/admin/examples/output-data/streaming_workflow** in the right box.

Step 7 Click  in the upper right corner of the Oozie editor.

If you need to modify the job name before saving the job (default value: **My Workflow**), click the name directly for modification, for example, **Streaming-Workflow**.

Step 8 After the configuration is saved, click  , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

----End

12.19.4.2.10 Submitting a DistCp Job

Scenario

This section describes how to submit an Oozie job of the DistCp type on the Hue web UI.

Procedure

Step 1 Create a workflow. For details, see **Creating a Workflow**.

Step 2 On the workflow editing page, select next to **Distcp** and drag it to the operation area.

Step 3 Determine whether the current DistCp operation is performed across clusters.

- If yes, go to **Step 4**.
- If no, go to **Step 7**.

Step 4 Establish cross-Manager mutual trust between two clusters.

Step 5 In the **Distcp** window that is displayed, set the value of **Source**, for example, to **hdfs://hacluster/user/admin/examples/input-data/text/data.txt**. Set **Destination**, for example, to **hdfs://target_ip:target_port/user/admin/examples/output-data/distcp-workflow/data.txt**. Click **Add**.

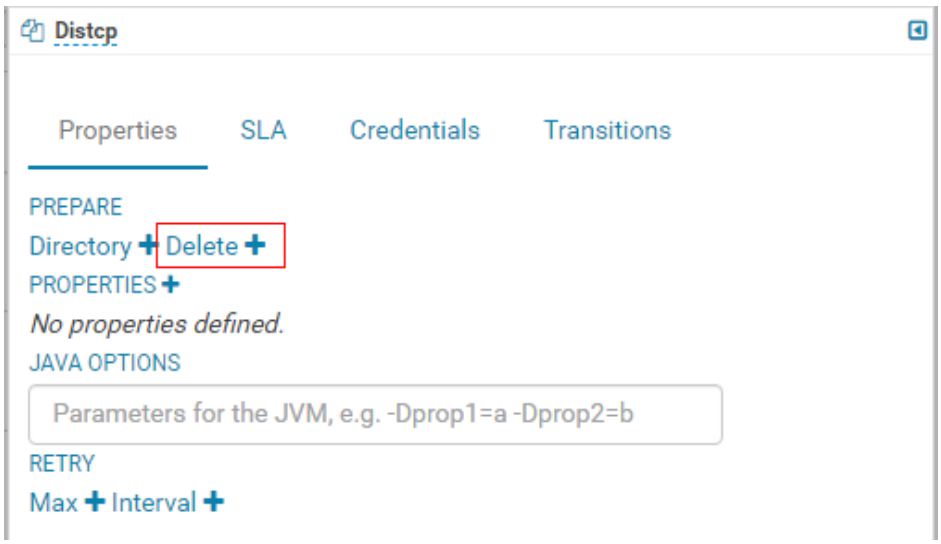
Step 6 Click the configuration button in the upper right corner. On the **Properties** tab page, click **PROPERTIES+**, enter the attribute name **oozie.launcher.mapreduce.job.hdfs-servers** in the text box on the left, enter the attribute value **hdfs://***source_ip:source_port*,**hdfs://***target_ip:target_port* in the text box on the right, and go to **Step 8**.

NOTE

source_ip: service address of the HDFS NameNode in the source cluster
source_port: port number of the HDFS NameNode in the source cluster.
target_ip: service address of the HDFS NameNode in the target cluster
target_port: port number of the HDFS NameNode in the target cluster.

Step 7 In the **Distcp** window that is displayed, set the value of **Source**, for example, to **/user/admin/examples/input-data/text/data.txt**. Set **Destination**, for example, to **/user/admin/examples/output-data/distcp-workflow/data.txt**. Click **Add**.

Step 8 Click in the upper right corner. On the configuration page that is displayed, click **Delete+** and add the directory to be deleted, for example, **/user/admin/examples/output-data/distcp-workflow**.



Step 9 Click in the upper right corner of the Oozie editor.

If you need to modify the job name before saving the job (default value: **My Workflow**), click the name directly for modification, for example, **Distcp-Workflow**.

Step 10 After the configuration is saved, click  , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

----End

12.19.4.2.11 Example of Mutual Trust Operations

Scenario

This section guides you to enable unidirectional password-free mutual trust when Oozie nodes are used to execute shell scripts of external nodes through SSH jobs.

Prerequisites

You have installed Oozie, and it can communicate with external nodes (nodes connected using SSH).

Procedure

Step 1 Ensure that the user used for SSH connection exists on the external node, and the user directory **~/.ssh** exists.

Step 2 Log in to the Oozie node as user **omm** and run the **ssh-keygen -t rsa** command to generate public and private keys.

Step 3 Run the **cat ~/.ssh/id_rsa.pub >> ~/.ssh/authorized_keys** statement to add the public key to the **authorized_keys** file.

Step 4 Upload the **id_rsa.pub** file to an existing directory, for example, **/opt/**, on the external node as user **root**.

scp ~/.ssh/id_rsa.pub root@*IP address of the external node***:/opt/id_rsa.pub**

Step 5 Log in to the external node where the shell is located and go to the directory described in **Step 4**. The **id_rsa.pub** file can be found.

Run the **cat id_rsa.pub >> ~/.ssh/authorized_keys** statement to add the public key to the **authorized_keys** file of the shell user.

Step 6 Change the permission on the directory.

chmod 700 ~/.ssh

chmod 600 /opt/id_rsa.pub

chmod 600 ~/.ssh/authorized_keys

NOTE

- The user of the node where shell resides (external node) has the permission to execute shell scripts and access all directories and files involved in the Shell scripts.
- If Oozie has multiple nodes, perform **Step 2** to **Step 6** on all Oozie nodes.

----End

12.19.4.2.12 Submitting an SSH Job

Scenario

This section guides you to submit an Oozie job of the SSH type on the Hue web UI.

Due to security risks, SSH jobs cannot be submitted by default. To use the SSH function, you need to manually enable it.

Procedure

Step 1 Enable the SSH function.

1. On FusionInsight Manager, choose **Cluster** > **Services** > **Oozie** and click the **Configurations** tab and then **All Configurations**. In the navigation pane on the left, choose **oozie(Role)** > **Security**, change the value of **oozie.job.ssh.enable** to **true**, and click **Save**. In the displayed dialog box, click **OK** to save the configuration.
2. On the **Dashboard** page of Oozie, choose **More** > **Restart Service** in the upper-right corner to restart Oozie.

Step 2 Create a workflow. For details, see **Creating a Workflow**.

Step 3 For details about how to add the trust relationship, see **Example of Mutual Trust Operations**.

Step 4 On the workflow editing page, select the **Ssh** button  and drag it to the operation area.

Step 5 In the **Ssh** window that is displayed, set **User and Host** and **Ssh command** commands and click **Add**.

Step 6 Click  in the upper right corner of the Oozie editor.

If you need to modify the job name before saving the job (default value: **My Workflow**), click the name directly for modification, for example, **Ssh-Workflow**.

Step 7 After the configuration is saved, click  , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

----End

12.19.4.2.13 Submitting a Hive Script

Scenario

This section describes how to submit a Hive job on the Hue web UI.

Procedure

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 In the navigation tree on the left, click  and choose **Workflow** to open the Workflow editor.

Step 3 Click **Documents**, click  to select a Hive script from the operation list, and drag it to the operation page.

Step 4 In the **HiveServer2 Script** dialog box that is displayed, select the saved Hive script. For details about how to save the Hive script, see **Using HiveQL Editor on the Hue Web UI**. Select a script and click **Add**.

Step 5 Configure the Job XML, for example, to the HDFS path **/user/admin/examples/apps/hive2/hive-site.xml**. For details, see **Submitting a Hive2 Job**.

Step 6 Click  in the upper right corner of the Oozie editor.

Step 7 After the configuration is saved, click  , and submit the job.

After the job is submitted, you can view the related contents of the job, such as the detailed information, logs, and processes, on Hue.

----End

12.19.4.3 Submitting a Coordinator Periodic Scheduling Job

Scenario

This section describes how to submit a job of the periodic scheduling type on the Hue web UI.

Prerequisites

Required workflow jobs have been configured before the coordinator task is submitted.

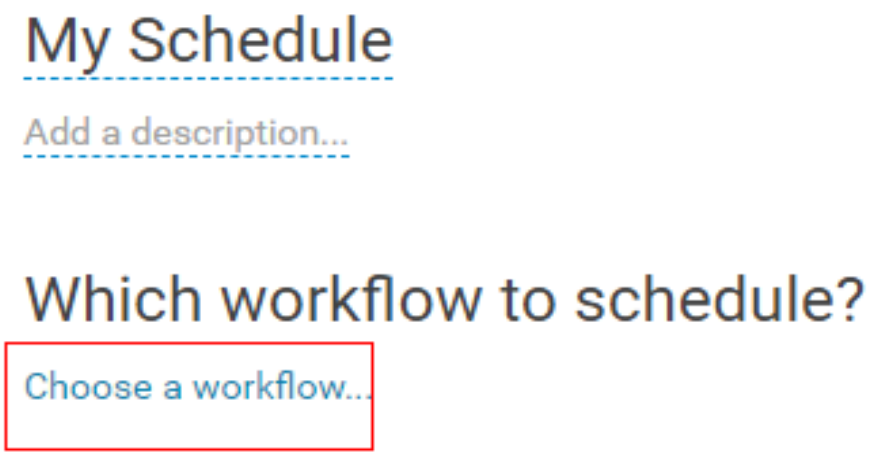
Procedure

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 In the navigation tree on the left, click  and choose **Schedule** to open the Coordinator editor.

Step 3 On the job editing page, click **My Schedule** to change the job name.

Step 4 Click **Choose a Workflow...** to select the workflow to be orchestrated.



Step 5 Select a workflow, set the job execution frequency as prompted, and click  in the upper right corner to save the workflow job.

NOTE

Because the time zone is changed, the difference between the time and the local time may be several hours.

Step 6 Click  in the upper right corner of the editor, set the start value and end value of the time range for executing the scheduled job, and click **Submit** to submit the job.

NOTE

Because the time zone is changed, the difference between the time and the local time may be several hours.

----End

12.19.4.4 Submitting a Bundle Batch Processing Job

Scenario

In the case that multiple scheduled jobs exist at the same time, you can manage the jobs in batches over the Bundle task. This section describes how to submit a job of the batch type on the Hue web UI.

Prerequisites

Required related workflow and Coordinator jobs have been configured before the Bundle batch processing job is submitted.

Procedure

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

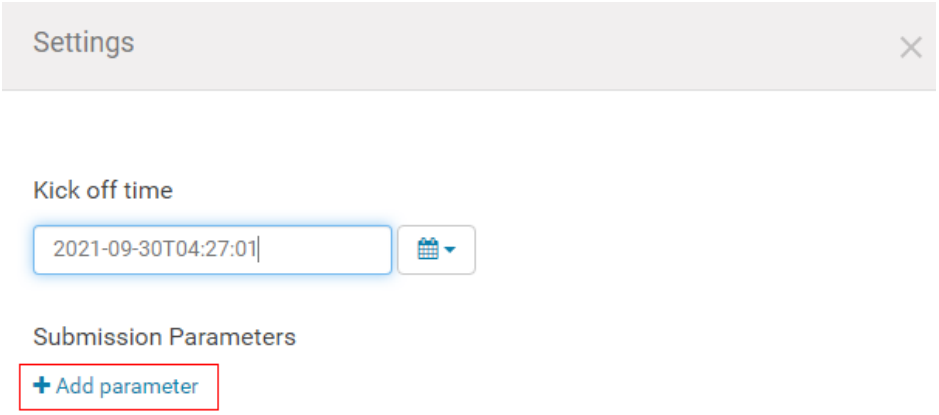
Step 2 In the navigation tree on the left, click  and choose **Bundle** to open the Bundle editor.

Step 3 On the job editing page, click **My Bundle** to change the job name.

Step 4 Click **+Add a coordinator** to select the Coordinator job to be orchestrated.

Step 5 Set the start time and the end time for the scheduled coordinator jobs as prompted and click  in the upper right corner to save the job.

Step 6 Click in the upper right corner of the editor, select  from the displayed menu, set the start time of the bundle task, click **+Add parameter** to add parameters, and close the dialog box to save the settings.



NOTE

Because the time zone is changed, the difference between the time and the local time may be several hours.

Step 7 Click  in the upper right corner of the editor. In the dialog box that is displayed, click **Submit** to submit the job.

----End

12.19.4.5 Querying the Operation Results

Scenario

After the jobs are submitted, you can view the execution status of a specific job on Hue.

Procedure

Step 1 Access the Hue web UI. For details, see **Accessing the Hue Web UI**.

Step 2 Click  . On the displayed page, you can view information about the Workflow, Schedule, and Bundle tasks.

----End

12.19.5 Oozie Log Overview

Log Description

Log path: The default storage paths of Oozie log files are as follows:

- Run log: **/var/log/Bigdata/oozie**
- Audit log: **/var/log/Bigdata/audit/oozie**

Log archiving rule: Oozie logs are classified into run logs, script logs, and audit logs. The maximum size of a run log file is 20 MB, and a maximum of 20 run log files can be reserved. The maximum size of an audit log file is 20 MB, and a maximum of 20 audit log files can be reserved.

NOTE

A compressed log file is generated for **oozie.log** every hour. 720 compressed files (log files of one month) are retained by default.

Table 12-318 Oozie log list

Log Type	Log File Name	Description
Run log	jetty.log	Oozie built-in jetty server log file, which is used to process the request and response information of OozieServlet
	jetty.out	Oozie process startup log file
	oozie_db_temp.log	Oozie database connection log
	oozie-instrumentation.log	Oozie dashboard log file, which records the Oozie running status and configuration information of each component
	oozie-jpa.log	openJPa run log file
	oozie.log	Oozie run log file
	oozie-<SSH_USER>-<DATE>-<PID>-gc.log	Log file that records the garbage collection of the Oozie service
	oozie-ops.log	Oozie operation log file
	check-serviceDetail.log	Oozie health check logs

Log Type	Log File Name	Description
	oozie-error.log	Oozie running error logs
	threadDump-<DATE>.log	Log file that records stack information when the service process exits normally
Script logs	postinstallDetail.log	Work log file generated after the installation and before the startup
	prestartDetail.log	Pre-startup log file
	startDetail.log	Service startup log file
	stopDetail.log	Service stop log file
	upload-sharelib.log	Operation logs uploaded by **sharelib**
Audit log	oozie-audit.log	Audit log

Log Level

Table 12-319 describes the log levels provided by Oozie.

The priorities of log levels are ERROR, WARN, INFO, and DEBUG in descending order. Logs whose levels are higher than or equal to the set level are printed. The number of printed logs decreases as the configured log level increases.

Table 12-319 Log levels

Level	Description
ERROR	Logs of this level record abnormal information about events that cause process exceptions.
WARN	Logs of this level record exception information about the current event processing.
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record system information and information about database underlying data transmission.

To modify log levels, perform the following operations:

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Oozie** > **Configurations**.

Step 3 Select **All Configurations**.

Step 4 On the menu bar on the left, select the log menu of the target role.

Step 5 Select a desired log level.

Step 6 Click **Save**, and then click **OK**. The settings take effect after the processing is complete.

----End

Log Formats

The following table lists the Oozie log formats.

Table 12-320 Log formats

Log Type	Format	Example
Run log	*<yyyy-MM-dd HH:mm:ss,SSS><Log level><Location where the log event occurs><Log level><Message in the log>*	2015-05-29 21:01:45,268 INFO StatusTransitService$StatusTransitRunnable:539 - USER[-] GROUP[-] Released lock for [org.apache.oozie.service.StatusTransitService]
Script logs	*<yyyy-MM-dd HH:mm:ss,SSS><Host name > <Log level > <Message in the log>*	2015-06-01 17:18:03 001 suse11-192-168-0-111 oozie INFO Running oozie service check script
Audit log	*<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|< Thread name > | Message in the log | Location where the log event occurs*	2015-06-01 22:38:41,323 | INFO | http-bio-21003-exec-8 | IP [192.168.0.111] USER [null], GROUP [null], APP [null], JOBID [null], OPERATION [null], PARAMETER [null], RESULT [SUCCESS], HTTPCODE [200], ERRORCODE [null], ERRORMESSAGE [null] | org.apache.oozie.util.XLog.log(XLog.java:539)

12.19.6 Common Issues About Oozie

12.19.6.1 Oozie Scheduled Tasks Are Not Executed on Time

Question

Why are not Coordinator scheduled jobs executed on time on the Hue or Oozie client?

Answer

Use UTC time. For example, set **start=2016-12-20T09:00Z** in **job.properties** file.

12.19.6.2 Why Update of the share lib Directory of Oozie on HDFS Does Not Take Effect?

Symptom

A new JAR package is uploaded to the **/user/oozie/share/lib** directory on HDFS. However, an error indicating that the class cannot be found is reported during task execution.

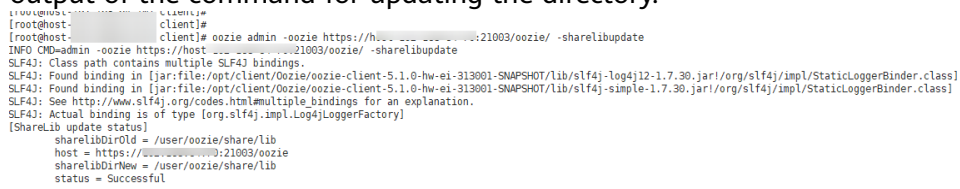
Solution

Run the following command on the client to refresh the directory:

oozie admin -oozie https://xxx.xxx.xxx.xxx:21003/oozie -sharelibupdate

12.19.6.3 Common Oozie Troubleshooting Methods

1. Check the job logs on Yarn. Run the command executed through Hive SQL using beeline to ensure that Hive is running properly.
2. If error information such as "classnotfoundException" is displayed, check whether the JAR package of the faulty class exists in the **/user/oozie/share/lib** directory of each component. If no, add the JAR package and go to **Why Update of the share lib Directory of Oozie on HDFS Does Not Take Effect?**. If the faulty class still cannot be found after the **share lib** directory is updated, check whether **sharelibDirNew** is **/user/oozie/share/lib** in the output of the command for updating the directory.



3. If "NosuchMethodError" is displayed, check whether the JAR packages of each component in the **/user/oozie/share/lib** directory have multiple versions. Note that the JAR packages uploaded by the service cannot conflict with each other. You can check whether a JAR package conflict occurs based on the loaded JAR packages in Oozie run logs on Yarn.
4. If the self-developed code is abnormal, run the Oozie sample to check whether Oozie is running properly.
5. Contact technical support personnel. By using this method, you must collect run logs of Oozie on Yarn, Oozie logs, and component run logs. For example, if an exception occurs when Hive runs on Oozie, you need to collect Hive logs.

12.20 Using Presto

12.20.1 Accessing the Presto Web UI

You can view the Presto statistics on the graphical Presto web UI. You are advised to use Google Chrome to access the Presto web UI because it cannot be accessed using Internet Explorer.

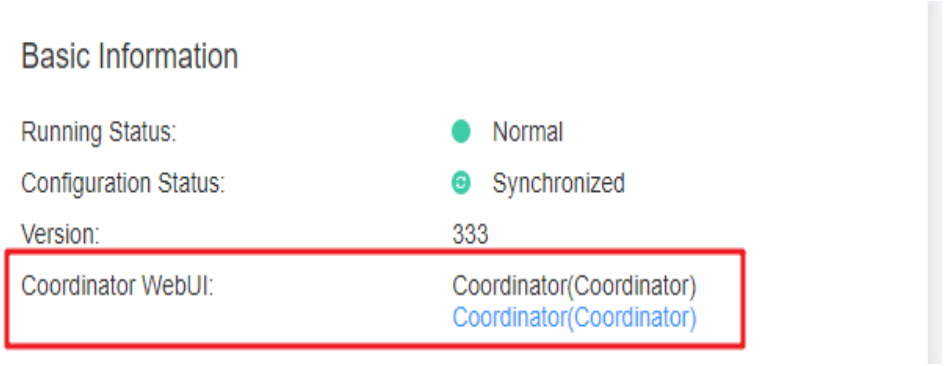
Prerequisites

- Presto has been installed in a cluster.
- The cluster client has been installed, for example, in the **/opt/client** directory. The client directory in the following operations is only an example. Change it based on the actual installation directory onsite.

Accessing the Presto Web UI

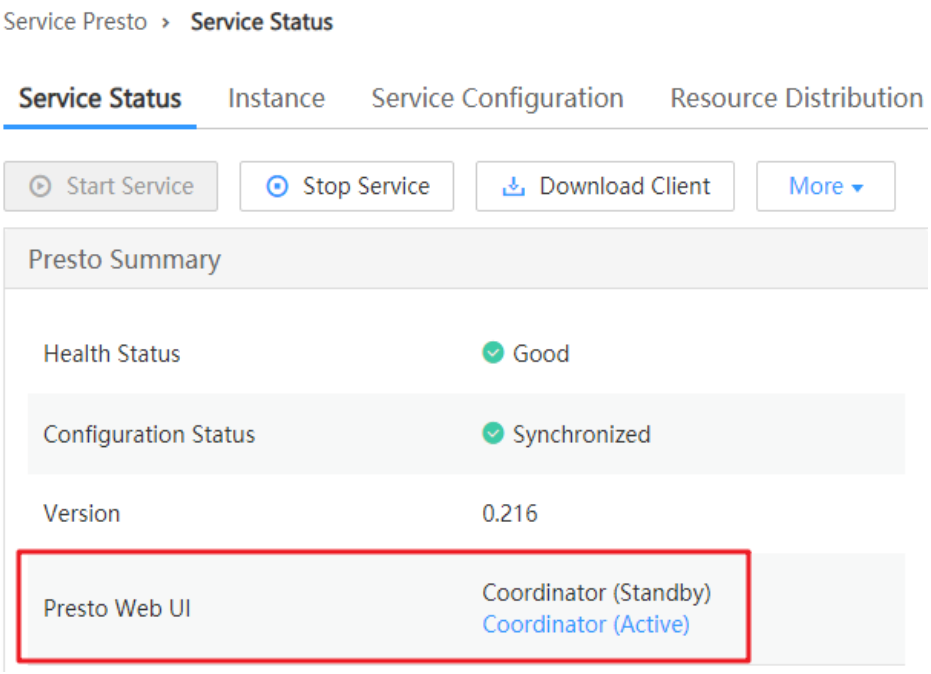
- Method 1 (for MRS 3.*x* or later)
  a. Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the target cluster* > **Services**.
  b. Select **Presto**. In the **Basic Information** area, click **Coordinator(Coordinator)** next to **Coordinator WebUI**. The Coordinator web UI is displayed.

  Figure 12-39 Coordinator WebUI

- Method 2 (for versions earlier than MRS 3.*x*)
  a. Log in to MRS Manager and choose **Services**.
  b. Select **Presto**. In the **Presto Summary** area, click **Coordinator (Active)** next to **Presto Web UI**. The Presto web UI is displayed.

Figure 12-40 Presto WebUI



NOTE

When accessing the Presto web UI for the first time, you must add the address to the trusted site list.

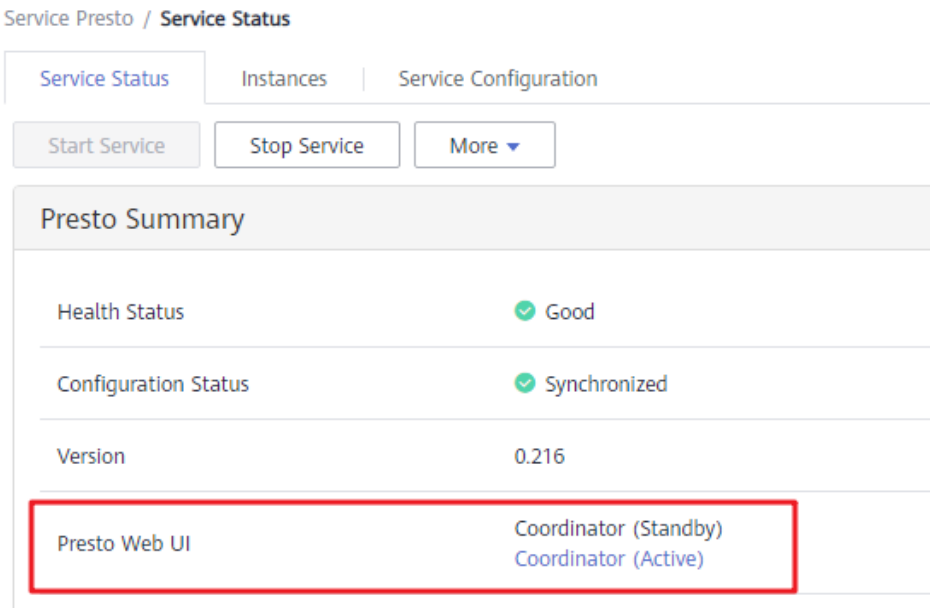
- Method 3 (for MRS 1.9.2 or later)
  a. Log in to the MRS console, click the target cluster name to go to the cluster details page, and click the **Components** tab.

     NOTE

     If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

  b. Click **Presto**. In the **Presto Summary** area, click **Coordinator (Active)** next to **Presto Web UI**. The Presto web UI is displayed.

Figure 12-41 Presto WebUI



12.20.2 Using a Client to Execute Query Statements

You can perform an interactive query on an MRS cluster client. For clusters with Kerberos authentication enabled, users who submit topologies must belong to the **presto** group.

The Presto component of MRS 3.x does not support Kerberos authentication.

Prerequisites

- The password of user **admin** has been obtained. The password of user **admin** is specified by the user during MRS cluster creation.
- The client has been updated.
- The Presto client has been manually installed for MRS 3.*x* clusters.

Procedure

Step 1 For clusters with Kerberos authentication enabled, log in to MRS Manager and create a role with the **Hive Admin Privilege** permission.

Step 2 Create a user that belongs to the **Presto** and **Hive** groups, bind the role created in **Step 1** to the user, and download the user authentication file.

Step 3 Upload the downloaded **user.keytab** and **krb5.conf** files to the node where the MRS client resides.

NOTE

For clusters with Kerberos authentication enabled, **Step 2** to **Step 3** must be performed. For normal clusters, start from **Step 4**.

Step 4 Prepare a client based on service conditions and log in to the node where the client is installed.

Step 5 Run the following command to switch the user:

sudo su - omm

Step 6 Run the following command to switch to the client directory, for example, **/opt/client**.

cd /opt/client

Step 7 Run the following command to configure environment variables:

source bigdata_env

Step 8 Connect to the Presto Server. The following provides two client connection methods based on the client type.

- Using the client provided by MRS
  - For clusters with Kerberos authentication disabled, run the following command to connect to the Presto Server of the cluster:

    presto_cli.sh
  - For clusters with Kerberos authentication disabled, run the following command to connect to the Presto Server of other clusters. In the command, **ip** indicates the floating IP address of the cluster Presto Server, which can be obtained by searching for **PRESTO_COORDINATOR_FLOAT_IP** in the Presto configuration items. **port** indicates the Presto Server port number and is set to **7520** by default.

    presto_cli.sh --server *http://ip:port*
  - For clusters with Kerberos authentication enabled, run the following command to connect to the Presto Server of the cluster:

    presto_cli.sh --krb5-config-path *krb5.conf file path* --krb5-principal *User's principal* --krb5-keytab-path *user.keytab file path* --user *presto username*
  - For clusters with Kerberos authentication enabled, run the following command to connect to the Presto Server of other clusters. In the command, **ip** indicates the floating IP address of the cluster Presto Server, which can be obtained by searching for **PRESTO_COORDINATOR_FLOAT_IP** in the Presto configuration items. **port** indicates the Presto Server port number and is set to **7521** by default.

    presto_cli.sh --krb5-config-path *krb5.conf file path* --krb5-principal *User's principal* --krb5-keytab-path *user.keytab file path* --server *https://ip:port* --krb5-remote-service-name *Presto Server name*
- Using the native client

  The native client of Presto is **Presto/presto/bin/presto** in the client directory.

Step 9 Run a query statement, for example, **show catalogs**.

NOTE

For clusters with Kerberos authentication enabled, when querying **Hive Catalog** data, the user who runs the Presto client must have the permission to access Hive tables and run the **grant all on table [table_name] to group hive** command in Hive beeline to grant permissions to the Hive group.

Step 10 After the query is complete, run the following command to exit the client:

quit

----End

12.21 Using Ranger (MRS 3.*x*)

12.21.1 Logging In to the Ranger Web UI

Ranger provides a centralized permission management framework to implement fine-grained permission control on components such as HDFS, HBase, Hive, and Yarn. In addition, Ranger also provides a web UI for administrators to perform operations.

Ranger User Type

Ranger users are classified into **admin**, **user**, and **auditor**. Different users have different permissions to view and operate the Ranger management interface.

- **Admin**: A security administrator can view all page content, manage permission management plug-ins and access control policies, view audit information, and set user types.
- **Auditor**: An audit administrator can view the permission management plug-ins and access control policies.
- **User**: A common user who can be assigned with specific permissions by the administrator.

Logging In to the Ranger Web UI

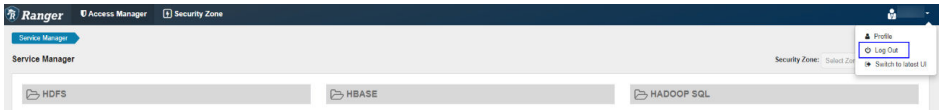
Security mode (Kerberos authentication is enabled for clusters)

Step 1 Log in to FusionInsight Manager as user **admin**. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > **Services** > **Ranger**. The Ranger service overview page is displayed.

Step 2 Click **RangerAdmin** in the **Basic Information** area. The Ranger web UI is displayed.

- The **admin** user in Ranger belongs to the **User** type and can only view the **Access Manager** as well as **Security Zone** pages.
- To view all management pages, switch to user **rangeradmin** or other users who have the Ranger administrator permissions.

  a. On the Ranger WebUI, click the user name in the upper right corner and choose **Log Out** to log out of the Ranger WebUI.



b. Log in to the system as user **rangeradmin** (default password: **Rangeradmin@123**) or another user who has the Ranger administrator permissions.

----End

Normal mode (Kerberos authentication is disabled for clusters)

Step 1 Log in to FusionInsight Manager as user **admin**. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > **Services** > **Ranger**. The Ranger service overview page is displayed.

Step 2 Click **RangerAdmin** in the **Basic Information** area. The Ranger web UI is displayed.

The **admin** user in Ranger belongs to the **Admin** type and can view all management pages of Ranger without switching to user **rangeradmin**.

NOTE

When a user logs in to the Ranger WebUI as user **rangeradmin** in normal mode, error 401 is reported.

----End

On the homepage of Ranger web UI, you can view the permission management plug-ins of the services integrated in Ranger. The plug-ins can be used to set more fine-grained permissions. For details about functions of main operations you can perform on the page, see **Table 12-321**.

Table 12-321 Functions of each operation portal on the Ranger page

Portal	Function
Access Manager	You can view the permission management plug-ins of each service integrated in Ranger. The plug-ins can be used to set more fine-grained permissions. For details, see **Configuring Component Permission Policies**.
Audit	You can view the audit logs related to Ranger running and permission control. For details, see **Viewing Ranger Audit Information**.
Security Zone	Administrators can divide resources of each component into multiple security zones where different administrators set security policies for specified resources of services to facilitate management. For details, see **Configuring a Security Zone**.
Settings	You can view Ranger permission settings, such as users, user groups, and roles. For details, see **Viewing Ranger Permission Information**.

12.21.2 Enabling Ranger Authentication

Scenario

This section guides you how to enable Ranger authentication. Ranger authentication is enabled by default in security mode and disabled by default in normal mode.

Procedure

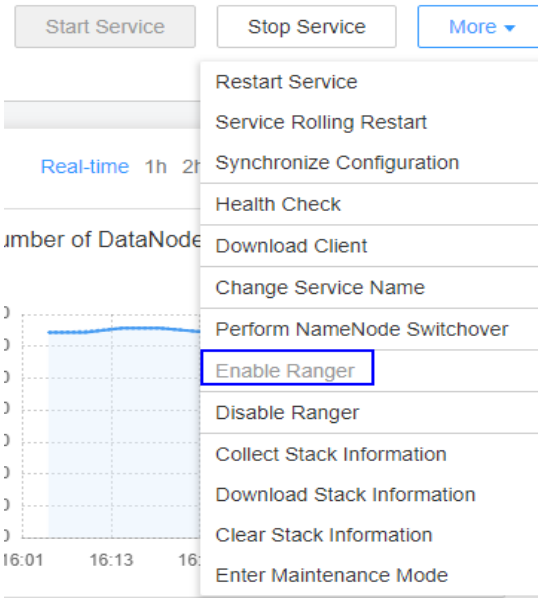
Step 1 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > **Services** > *Name of the service for which Ranger authentication is enabled*.

Step 2 In the upper right corner of the **Dashboard** page, click **More** and select **Enable Ranger**. In the displayed dialog box, enter the password and click **OK**. After the operation is successful, click **Finish**.

NOTE

If **Enable Ranger** is dimmed, Ranger authentication is enabled, as shown in **Figure 12-42**.

Figure 12-42 Enabling Ranger Authentication



Step 3 Perform a rolling service restart or restart the service.

----End

12.21.3 Configuring Component Permission Policies

In the newly installed MRS cluster, Ranger is installed by default, with the Ranger authentication model enabled. The administrator can set fine-grained security policies for accessing component resources through the component permission plug-ins.

Currently, the following components in a cluster in security mode support Ranger: HDFS, Yarn, HBase, Hive, Spark2x, Kafka, Storm..

Configuring User Permission Policies Using Ranger

Step 1 Log in to the Ranger management page as the administrator.

Step 2 In the **Service Manager** area on the Ranger homepage, click the permission plug-in name of a component. The page for security access policy list of the component is displayed.

NOTE

In the policy list of each component, many items are generated by default to ensure the permissions of some default users or user groups (such as the **supergroup** user group). Do not delete these items. Otherwise, the permissions of the default users or user groups are affected.

Step 3 Click **Add New Policy** and configure resource access policies for related users or user groups based on the service scenario plan.

The following policies are examples for different components:

- **Adding a Ranger Access Permission Policy for HDFS**
- **Adding a Ranger Access Permission Policy for HBase**
- **Adding a Ranger Access Permission Policy for Hive**
- **Adding a Ranger Access Permission Policy for Yarn**
- **Adding a Ranger Access Permission Policy for Spark2x**
- **Adding a Ranger Access Permission Policy for Kafka**
- **Adding a Ranger Access Permission Policy for Storm**

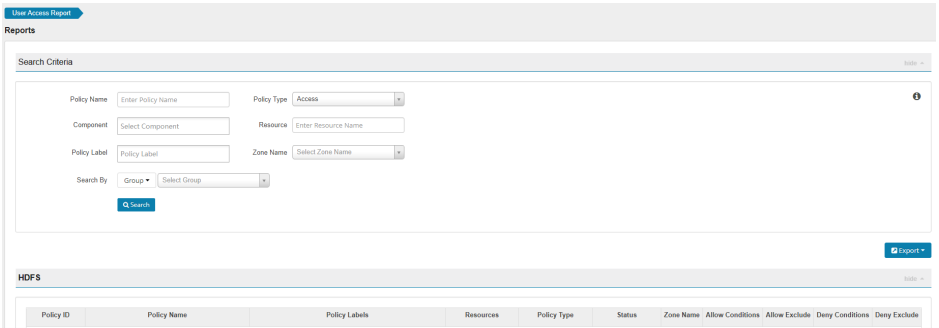
After the policies are added, wait for about 30 seconds for them to take effect.

NOTE

Each time a component is started, the system checks whether the default Ranger service of the component exists. If the service does not exist, the system creates the Ranger service and adds a default policy for it. If a service is deleted by mistake, you can restart or restart the corresponding component service in rolling mode to restore the service. If the default policy is deleted by mistake, you can manually delete the service and then restart the component service.

Step 4 Choose **Access Manager** > **Reports** to view all security access policies of each component.

If there are many system policies, filter and search for policies by the policy name, policy type, component, resource, policy label, security zone, user, or user group. Alternatively, click **Export** to export related policies.



NOTE

- Generally, only one policy can be configured for a fixed resource object. If multiple policies are configured for the same resource object, the policies cannot be saved.
- For details about the priorities of different policies, see **Condition Priorities of the Ranger Permission Policy**.

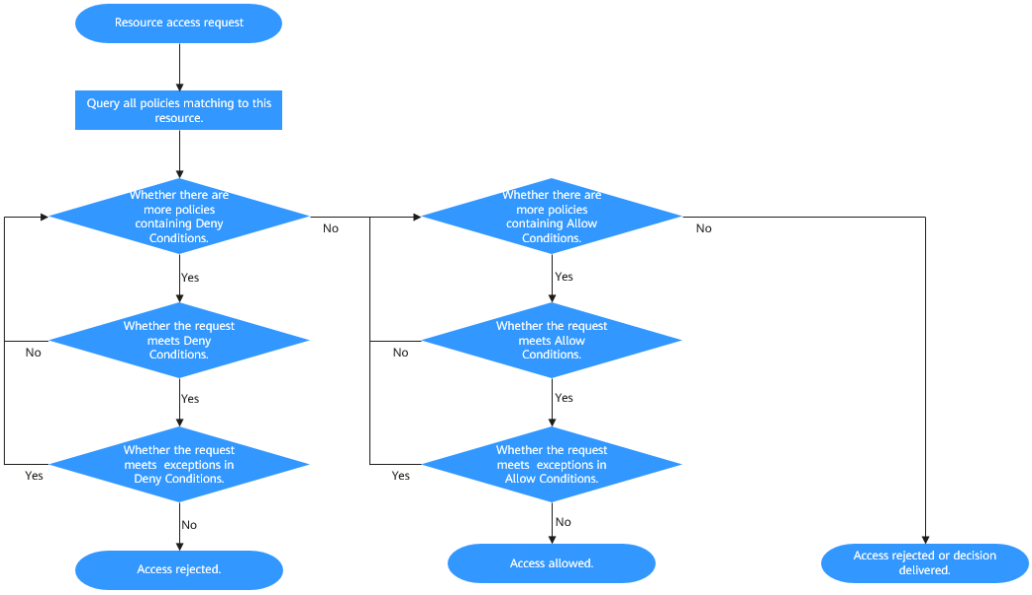
----End

Condition Priorities of the Ranger Permission Policy

When configuring a permission policy for a resource, you can configure Allow Conditions, Exclude from Allow Conditions, Deny Conditions, and Exclude from Deny Conditions for the resource, to meet unexpected requirements in different scenarios.

The priorities of different conditions are listed in descending order: Exclude from Deny Conditions > Deny Conditions > Exclude from Allow Conditions > Allow Conditions

The following figure shows the process of determining condition priorities. If the component resource request does not match the permission policy in Ranger, the system rejects the access by default. However, for HDFS and Yarn, the system delivers the decision to the access control layer of the component for determination.



For example, if you want to grant the read and write permissions of the **FileA** folder to the **groupA** user group, but the user in the group is not **UserA**, you can add an allowed condition and an exception condition.

12.21.4 Viewing Ranger Audit Information

The administrator can view audit logs of the Ranger running and the permission control after Ranger authentication is enabled on the Ranger web UI.

Viewing Ranger Audit Information

Step 1 Log in to the Ranger management page.

Step 2 Click **Audit** to view the audit information. For details about the content on each tab page, see **Table 12-322**. If there are a large number of items, click the search box and filter the items based on the keyword field.

Table 12-322 Audit information

Tab	Description
Access	Records audit information about users' access to component resources through Ranger authentication.
Admin	Records operation audit information on Ranger, such as the creation, update, and deletion of security access policies, component permission policies, and roles.
Login Sessions	Records session audit information for users who have logged in to Ranger.
Plugins	Records permission policy information of components in Ranger.
Plugin Status	Records audit information about permission policies of each component node.
User Sync	Records synchronized audit information of LDAP and Ranger users.

----End

12.21.5 Configuring a Security Zone

Security zone can be configured using Ranger. Administrators can divide resources of each component into multiple security zones where administrators set security policies for specified resources in the zones to facilitate management. Policies defined in a security zone apply only to resources in the zone. After service resources are allocated to the security zone, the access permission policies for the resources in the non-security zone do not take effect. The administrator of a security zone can set policies only in the security zone that the administrator belongs to.

Adding a Security Zone

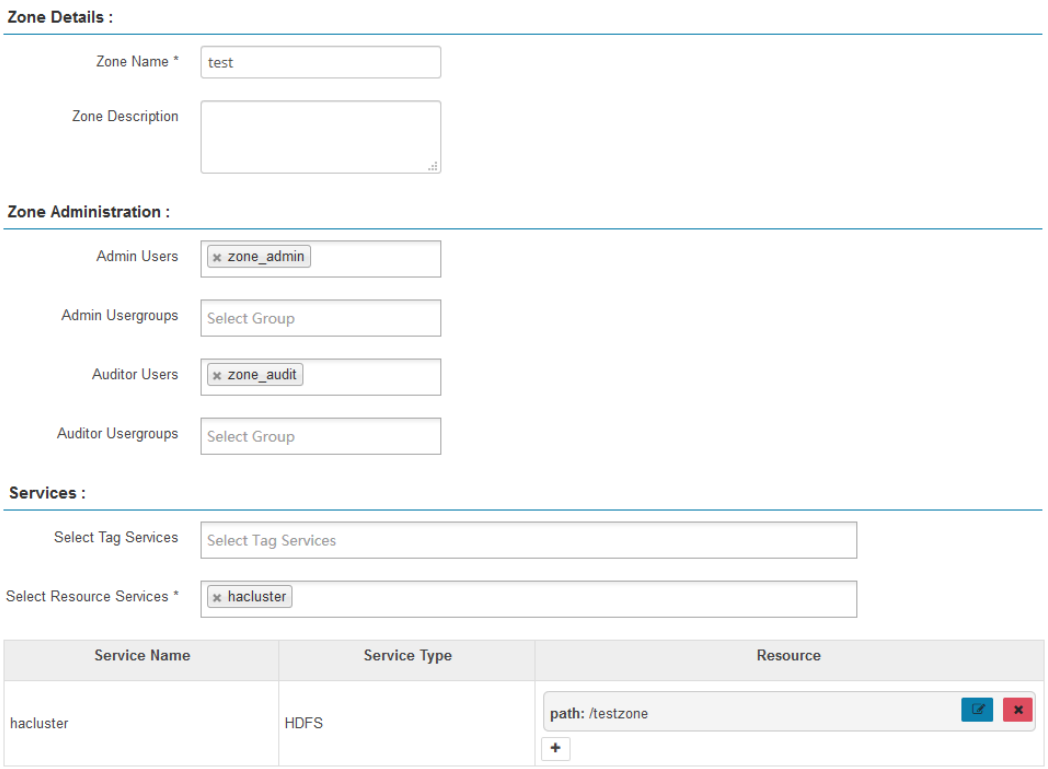
Step 1 Log in to the Ranger management page as the Ranger administrator.

Step 2 Click **Security Zone**. On the zone list page, click  to add a zone.

Table 12-323 Parameters for configuring a security zone

Parameter	Description	Example Value
Zone Name	Security zone	test
Zone Description	Description of the security zone	-
Admin Users/ Admin Usergroups	Management users and user groups in a security zone. You can add and modify permission policies for related resources in the security zone. At least one user or user group must be configured.	zone_admin
Auditor Users/ Auditor Usergroups	Audit users or user groups to be added. You can view the resource permission policies in the security zone. At least one user or user group must be configured.	zone_user
Select Tag Services	Tag information of a service	-
Select Resource Services	Services and resources in a security zone. After selecting a service, you need to add specific resource objects in the **Resource** column, such as the file directories of the HDFS server, Yarn queues, Hive databases and tables, and HBase tables and columns.	/testzone

For example, to create a security zone for the **/testzone** directory in HDFS, the configuration is as follows:



Step 3 Click **Save** and wait until the security zone is added successfully.

The Ranger administrator can view all security zones on the **Security Zone** page and click **Edit** to modify the attributes of a security zone. If resources do not need to be managed in a security zone, the Ranger administrator can click **Delete** to delete the security zone.

----End

Configuring Permission Policies in a Security Zone

Step 1 Log in to the Ranger management page as the administrator of a security zone.

Step 2 Select a security zone from the **Security Zone** drop-down list in the upper right corner of the Ranger home page to switch to the permission view of the security zone.

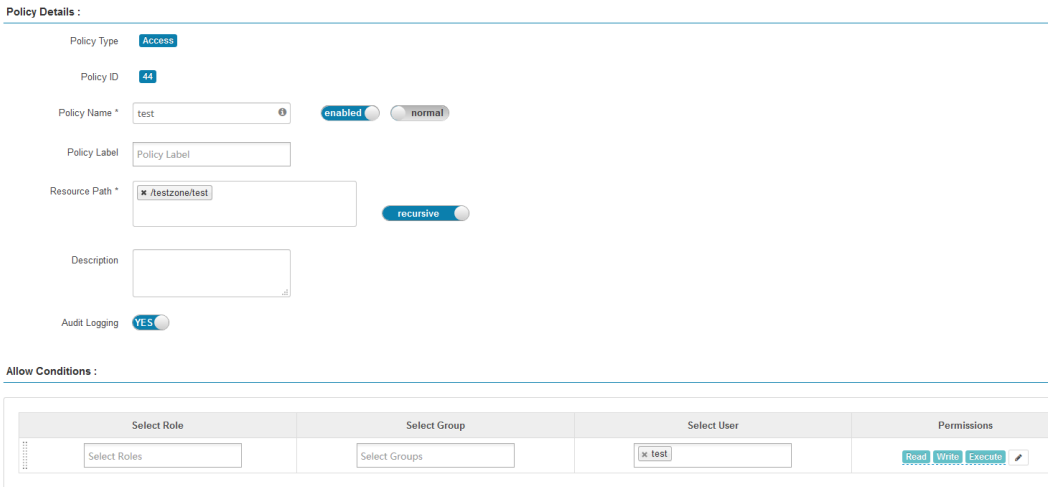
Step 3 Click the permission plug-in name of a component. The page for security access policy list of the component is displayed.

NOTE

In the policy list of each component, the default items generated by the system are automatically inherited to the security zone to ensure the permissions of some default users or user groups in the cluster.

Step 4 Click **Add New Policy** and configure resource access policies for related users or user groups based on the service scenario plan.

In this example, a policy that allows user test to access the **/testzone/test** directory is configured in the security zone.



The following access policies are examples for different components:

- **Adding a Ranger Access Permission Policy for HDFS**
- **Adding a Ranger Access Permission Policy for HBase**
- **Adding a Ranger Access Permission Policy for Hive**
- **Adding a Ranger Access Permission Policy for Yarn**
- **Adding a Ranger Access Permission Policy for Spark2x**
- **Adding a Ranger Access Permission Policy for Kafka**
- **Adding a Ranger Access Permission Policy for Storm**

After the policies are added, wait for about 30 seconds for them to take effect.

NOTE

- Policies defined in a security zone apply only to resources in the zone. After service resources are allocated to the security zone, the access permission policies for the resources in the non-security zone do not take effect.
- To configure access policies for resources outside the current security zone, click **Security Zone** in the upper right corner of the Ranger homepage to exit the current security zone.

----End

12.21.6 Changing the Ranger Data Source to LDAP for a Normal Cluster

By default, the Ranger data source of the security cluster can be accessed by FusionInsight Manager LDAP users. By default, the Ranger data source of a common cluster can be accessed by Unix users.

Prerequisites

- The cluster is in normal mode.
- The Ranger component has been installed.

Procedure

Step 1 Log in to the MRS console.

Step 2 Choose **Clusters** > **Active Clusters**, select a running cluster, and click its name to switch to the cluster details page.

Step 3 Click **Nodes** and select the node group whose **Node Type** is **Master**.

Step 4 Go to the ECS page of the active Master node and click **Remote Login**.

Step 5 Log in to a Master node as user **root**, go to the **/opt/Bigdata/components/FusionInsight_HD_8.1.0.1/Ranger** directory, and change the value of **ranger.usersync.sync.source** in the **configurations.xml** file to **ldap**.

```
ranger.usersync.sync.source
<value model="NoSec">ldap</value>
```

NOTE

Change the value of this parameter on all Master nodes.

Step 6 Run the following commands on the active Master node to restart the controller process:

su - omm

sh /opt/Bigdata/om-server_8.1.0.1/om/sbin/restart-controller.sh

NOTE

When the controller process is restarted, the MRS Manager page cannot be accessed for a short period of time, which is normal. After the controller process is restarted, you can access the MRS Manager page properly.

Step 7 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > **Services** > **Ranger**. In the upper right corner of the **Dashboard** page, click **More** and choose **Synchronize Configuration**.

Step 8 On the Ranger instance page, select the **UserSync** instance and choose **More** > **Restart Instance**.

Step 9 On the **Dashboard** page of the Ranger service, click **RangerAdmin** and choose **Settings** > **Users/Groups/Roles** to check whether LDAP users exist.

----End

12.21.7 Viewing Ranger Permission Information

You can view Ranger permission settings, such as users, user groups, and roles.

Viewing Ranger Permission Information

Step 1 Log in to the Ranger management page as the administrator.

Step 2 Choose **Settings** > **Users**/**Groups**/**Roles** to view information about users, user groups, or roles in the system.

- Users: displays all user information synchronized from LDAP or OS to Ranger.
- Groups: displays information about all user groups and role information synchronized from LDAP or OS to Ranger.
- Roles: displays information about roles created in Ranger.

NOTE

- The users, roles, user groups created on FusionInsight Manager are automatically synchronized to Ranger periodically. The default period is 300,000 milliseconds (5 minutes). After roles and user groups in FusionInsight Manager are synchronized to Ranger, they become user groups. Only roles and user groups that are associated with users can be automatically synchronized to Ranger.
- The role created on the Ranger page is a set of users or user groups, which is used to flexibly set the permission access policies of components. The role is different from that on FusionInsight Manager.

----End

Adjusting Ranger User Types

Step 1 Log in to the Ranger management page.

To change the Ranger user type, you must log in as an **admin** user. For details about the user types, see **Ranger User Type**.

Step 2 Choose **Settings** > **Users**/**Groups**/**Roles**. In the list of users, click the name of the user whose type you want to change.

Step 3 Set **Select Role** to the type to be modified.

Step 4 Click **Save**.

----End

Creating a Ranger Role

The administrator can flexibly configure permission access policies for components based on users, user groups, or roles. User and user group information is automatically synchronized from LDAP, and roles can be manually added.

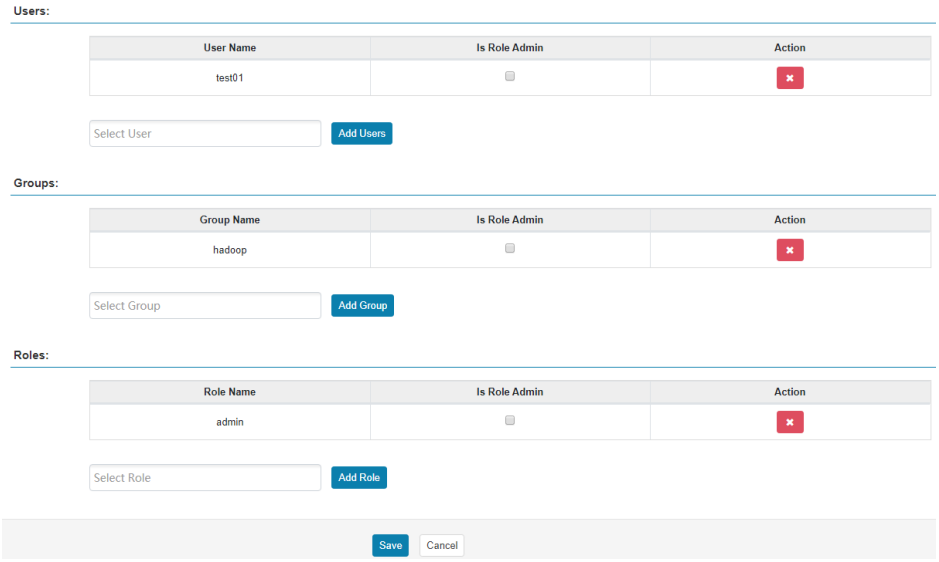
Step 1 Log in to the Ranger management page.

Step 2 Choose **Settings** > **Users**/**Groups**/**Roles** > **Roles** > **Add New Role**.

Step 3 Enter the role name and description as prompted.

Step 4 Add users, user groups, and sub-roles to the role.

- In the **Users** area, select a created user in the system and click **Add Users**.
- In the **Groups** area, select a created user group and click **Add Group**.
- In the **Roles** area, select a created role in the system and click **Add Role**.



Step 5 Click **Save**. The role is added successfully.

----End

12.21.8 Adding a Ranger Access Permission Policy for HDFS

Scenario

The administrator can use Ranger to configure the read, write, and execution permissions on HDFS directories or files for HDFS users.

Prerequisites

- The Ranger service has been installed and is running properly.
- You have created users, user groups, or roles for which you want to configure permissions.

Procedure

Step 1 Log in to the Ranger management page.

Step 2 On the homepage, click the component plug-in name in the **HDFS** area, for example, **hacluster**.

Step 3 Click **Add New Policy** to add an HDFS permission control policy.

Step 4 Configure the parameters listed in the table below based on the service demands.

Table 12-324 HDFS permission parameters

Parameter	Description
Policy Name	Policy name, which can be customized and must be unique in the service.
Policy Conditions	IP address filtering policy, which can be customized. You can enter one or more IP addresses or IP address segments. The IP address can contain the wildcard character (*), for example, **192.168.1.10**,**192.168.1.20**, or **192.168.1.***.
Policy Label	A label specified for the current policy. You can search for reports and filter policies based on labels.
Resource Path	Resource path, which is the HDFS path folder or file to which the current policy applies. You can enter multiple values and use the wildcard (*), for example, **/test/***. To enable a subdirectory to inherit the permission of its upper-level directory, enable the recursion function. If recursion is enabled for the parent directory and a policy is configured for the subdirectory, the policy configured for the subdirectory is used. • **non-recursive**: recursion disabled • **recursive**: recursion enabled
Description	Policy description.
Audit Logging	Whether to audit the policy.

Parameter	Description
Allow Conditions	Permission and exception conditions allowed by a policy. The priority of an exception condition is higher than that of a normal condition. In the **Select Role**, **Select Group**, and **Select User** columns, select the role, user group, or user to which the permission is to be granted, click **Add Conditions**, add the IP address range to which the policy applies, and click **Add Permissions** to add the corresponding permission. • **Read**: permission to read data • **Write**: permission to write data • **Execute**: execution permission • **Select/Deselect All**: Select or deselect all. If users or user groups in the current condition need to manage this policy, select **Delegate Admin**. These users or user groups will become the agent administrators. The agent administrators can update and delete this policy and create sub-policies based on the original policy. To add multiple permission control rules, click  . To delete a permission control rule, click  . Exclude from Allow Conditions: exception rules excluded from the allowed conditions
Deny All Other Accesses	Whether to reject all other access requests. • **True**: All other access requests are rejected. • **False**: **Deny Conditions** can be configured.
Deny Conditions	Policy rejection condition, which is used to configure the permissions and exceptions to be denied in the policy. The configuration method is the same as that of **Allow Conditions**. The priority of the rejection condition is higher than that of the allowed conditions configured in **Allow Conditions**. **Exclude from Deny Conditions**: exception rules excluded from the denied conditions

For example, to add the write permission for the **/user/test** directory of user **testuser**, the configuration is as follows:

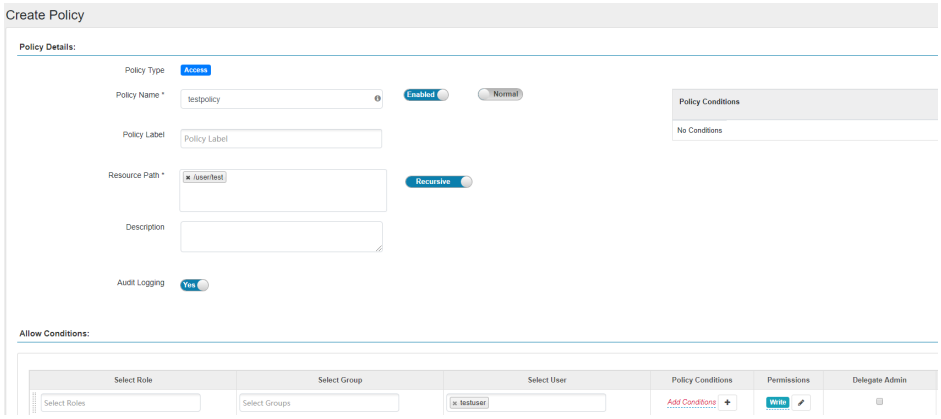


Table 12-325 Setting permissions

Task	Role Authorization
Setting the HDFS administrator permission	1. On the homepage, click the component plug-in name in the **HDFS** area, for example, **hacluster**. 2. Select the policy whose **Policy Name** is **all - path** and click  to edit the policy. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list.
Setting the permission for users to check and recover HDFS	1. Add a folder or a file path in **Resource Path**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Read** and **Execute**.
Setting the permission for users to read directories or files of other users	1. Add a folder or a file path in **Resource Path**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Read** and **Execute**.
Setting the permission for users to write data to files of other users	1. Add a folder or a file path in **Resource Path**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Write** and **Execute**.
Setting the permission for users to create or delete sub-files or sub-directories in the directory of other users	1. Add a folder or a file path in **Resource Path**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Write** and **Execute**.

Task	Role Authorization
Setting the permission for users to execute directories or files of other users	1. Add a folder or a file path in **Resource Path**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Execute**.
Setting the permission for allowing subdirectories to inherit all permissions of their parent directories	1. Add a folder or a file path in **Resource Path**. 2. Enable the recursion function. **Recursive** indicates that recursion is enabled.

Step 5 (Optional) Add the validity period of the policy. Click **Add Validity period** in the upper right corner of the page, set **Start Time** and **End Time**, and select **Time Zone**. Click **Save**. To add multiple policy validity periods, click  . To delete a policy validity period, click  .

Step 6 Click **Add** to view the basic information about the policy in the policy list. After the policy takes effect, check whether the related permissions are normal.

To disable a policy, click  to edit the policy and set the policy to **Disabled**.

If a policy is no longer used, click  to delete it.

----End

12.21.9 Adding a Ranger Access Permission Policy for HBase

Scenario

Administrators can use Ranger to configure permissions on HBase tables, column families, and columns for HBase users.

Prerequisites

- The Ranger service has been installed and is running properly.
- You have created users, user groups, or roles for which you want to configure permissions.

Procedure

Step 1 Log in to the Ranger management page.

Step 2 On the home page, click the component plug-in name in the **HBASE** area, for example, **HBase**.

Step 3 Click **Add New Policy** to add an HBase permission control policy.

Step 4 Configure the parameters listed in the table below based on the service demands.

Table 12-326 HBase permission parameters

Parameter	Description
Policy Name	Policy name, which can be customized and must be unique in the service.
Policy Conditions	IP address filtering policy, which can be customized. You can enter one or more IP addresses or IP address segments. The IP address can contain the wildcard character (*), for example, **192.168.1.10**,**192.168.1.20**, or **192.168.1.***.
Policy Label	A label specified for the current policy. You can search for reports and filter policies based on labels.
HBase Table	Name of a table to which the policy applies. The value can contain wildcard (*). For example, **table1:*** indicates all tables in **table1**. The **Include** policy applies to the current input object, and the **Exclude** policy applies to objects other than the current input object. **NOTE** The value of **hbase.rpc.protection** of the HBase service plug-in on Ranger must be the same as that of **hbase.rpc.protection** on the HBase server. For details, see **When an HBase Policy Is Added or Modified on Ranger, Wildcard Characters Cannot Be Used to Search for Existing HBase Tables**.
HBase Column-family	Name of the column families to which the policy applies. The **Include** policy applies to the current input object, and the **Exclude** policy applies to objects other than the current input object.
HBase Column	Name of the column to which the policy applies. The **Include** policy applies to the current input object, and the **Exclude** policy applies to objects other than the current input object.
Description	Policy description.
Audit Logging	Whether to audit the policy.

Parameter	Description
Allow Conditions	Policy allowed condition. You can configure permissions and exceptions allowed by the policy. In the **Select Role**, **Select Group**, and **Select User** columns, select the role, user group, or user to which the permission is to be granted, click **Add Conditions**, add the IP address range to which the policy applies, and click **Add Permissions** to add the corresponding permission. • **Read**: permission to read data • **Write**: permission to write data • **Create**: permission to create data • **Admin**: permission to manage data • **Select/Deselect All**: Select or deselect all. If users or user groups in the current condition need to manage this policy, select **Delegate Admin**. These users or user groups will become the agent administrators. The agent administrators can update and delete this policy and create sub-policies based on the original policy. To add multiple permission control rules, click  . To delete a permission control rule, click  . Exclude from Allow Conditions: policy exception conditions
Deny All Other Accesses	Whether to reject all other access requests. • **True**: All other access requests are rejected. • **False**: **Deny Conditions** can be configured.
Deny Conditions	Policy rejection condition, which is used to configure the permissions and exceptions to be denied in the policy. The configuration method is similar to that of **Allow Conditions**. The priority of **Deny Conditions** is higher than that of allowed conditions configured in **Allow Conditions**. **Exclude from Deny Conditions**: exception rules excluded from the denied conditions

Table 12-327 Setting permissions

Task	Role Authorization
Setting the HBase administrator permission	1. On the home page, click the component plug-in name in the **HBase** area, for example, **HBase**. 2. Select the policy whose **Policy Name** is **all - table, column-family, column** and click  to edit the policy. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list.
Setting the permission for users to create tables	1. In **HBase Table**, specify a table name. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Create**. 4. This user hase the following permissions: create table drop table truncate table alter table enable table flush table flush region compact disable enable desc
Setting the permission for users to write data to tables	1. In **HBase Table**, specify a table name. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Write**. 4. The user has the **put**, **delete**, **append**, **incr** and **bulkload** operation permissions.
Setting the permission for users to read data from tables	1. In **HBase Table**, specify a table name. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Read**. 4. This user hase the **get** and **scan** permissions.

Task	Role Authorization
Setting the permission for users to manage namespaces or tables	1. In **HBase Table**, specify a table name. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Admin**. 4. The user has the **rsgroup**, **peer**, **assign** and **balance** operation permissions.
Setting the permission for reading data from or writing data to columns	1. In **HBase Table**, specify a table name. 2. In **HBase Column-family**, specify the column family name. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **Read** and **Write**.

NOTE

If a user performs the **desc** operation in **hbase shell**, the user must be granted the read permission on the **hbase:qouta** table.

Step 5 (Optional) Add the validity period of the policy. Click **Add Validity period** in the upper right corner of the page, set **Start Time** and **End Time**, and select **Time Zone**. Click **Save**. To add multiple policy validity periods, click  . To delete a policy validity period, click  .

Step 6 Click **Add** to view the basic information about the policy in the policy list. After the policy takes effect, check whether the related permissions are normal.

To disable a policy, click  to edit the policy and set the policy to **Disabled**.

If a policy is no longer used, click  to delete it.

----End

12.21.10 Adding a Ranger Access Permission Policy for Hive

Scenario

The administrator can use Ranger to set permissions for Hive users. The default administrator account of Hive is **hive** and the initial password is **Hive@123**.

Prerequisites

- The Ranger service has been installed and is running properly.
- You have created users, user groups, or roles for which you want to configure permissions.

- The users must be added to the **hive** group.

Procedure

Step 1 Log in to the Ranger management page.

Step 2 On the home page, click the component plug-in name in the **HADOOP SQL** area, for example, **Hive**.

Step 3 On the **Access** tab page, click **Add New Policy** to add a Hive permission control policy.

Step 4 Configure the parameters listed in the table below based on the service demands.

Table 12-328 Hive permission parameters

Parameter	Description
Policy Name	Policy name, which can be customized and must be unique in the service.
Policy Conditions	IP address filtering policy, which can be customized. You can enter one or more IP addresses or IP address segments. The IP address can contain the wildcard character (*), for example, **192.168.1.10**, **192.168.1.20**, or **192.168.1.***.
Policy Label	A label specified for the current policy. You can search for reports and filter policies based on labels.
database	Name of the Hive database to which the policy applies. The **Include** policy applies to the current input object, and the **Exclude** policy applies to objects other than the current input object.
table	Name of the Hive table to which the policy applies. To add a UDF-based policy, switch to UDF and enter the UDF name. The **Include** policy applies to the current input object, and the **Exclude** policy applies to objects other than the current input object.
Hive Column	Name of the column to which the policy applies. The value * indicates all columns. The **Include** policy applies to the current input object, and the **Exclude** policy applies to objects other than the current input object.
Description	Policy description.
Audit Logging	Whether to audit the policy.

Parameter	Description
Allow Conditions	Policy allowed condition. You can configure permissions and exceptions allowed by the policy. In the **Select Role**, **Select Group**, and **Select User** columns, select the role, user group, or user to which the permission is to be granted, click **Add Conditions**, add the IP address range to which the policy applies, and click **Add Permissions** to add the corresponding permission. ● select: permission to query data ● update: permission to update data ● Create: permission to create data ● Drop: permission to drop data ● Alter: permission to alter data ● Index: permission to index data ● All: all permissions ● Read: permission to read data ● Write: permission to write data ● Temporary UDF Admin: temporary UDF management permission ● Select/Deselect All: Select or deselect all. To add multiple permission control rules, click . If users or user groups in the current condition need to manage this policy, select **Delegate Admin**. These users will become the agent administrators. The agent administrators can update and delete this policy and create sub-policies based on the original policy.
Deny Conditions	Policy rejection condition, which is used to configure the permissions and exceptions to be denied in the policy. The configuration method is similar to that of **Allow Conditions**.

Table 12-329 Setting permissions

Task	Role Authorization
role admin operation	1. On the home page, click **Settings** and choose **Roles**. 2. Click the role with **Role Name** set to **admin**. In the **Users** area, click **Select User** and select a username. 3. Click **Add Users**, select **Is Role Admin** in the row where the username is located, and click **Save**. **NOTE** Only user **rangeradmin** has the permission to access the **Settings** option on the Ranger page. After being bound to the Hive administrator role, perform the following operations during each maintenance operation: 1. Log in to the node where the Hive client is installed as the client installation user. 2. Run the following command to configure environment variables: For example, if the Hive client installation directory is **/opt/hiveclient**, run **source /opt/hiveclient/bigdata_env**. 3. Run the following command to authenticate the user: **kinit** *Hive service user* 4. Run the following command to log in to the client tool: **beeline** 5. Run the following command to update the administrator permissions: **set role admin;**
Creating a database table	1. Enter the policy name in **Policy Name**. 2. Enter or select the corresponding database on the right side of **database** and enter or select ***** on the right side of **column**. (To create a table, enter or select the corresponding table on the right side of **table**.) 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **Create**.
Deleting a table	1. Enter the policy name in **Policy Name**. 2. Enter or select the corresponding database on the right side of **database** and enter and select ***** on the right side of **column**. (To delete a table, enter or select the corresponding table on the right side of **table**.) 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **Drop**.

Task	Role Authorization
Query operation (**select**, **desc**, and **show**)	1. Enter the policy name in **Policy Name**. 2. Enter or select the corresponding database on the right side of **database** and enter or select ***** (***** indicates all columns) on the right side of **column**. (To create a table, enter or select the corresponding table on the right side of **table**.) 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **select**.
Alter operation	1. Enter the policy name in **Policy Name**. 2. Enter and select the corresponding database on the right side of **database** and enter or select ***** on the right side of **column**. (For tables, enter or select the corresponding table on the right side of **table**.) 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **Alter**.
LOAD operation	1. Enter the policy name in **Policy Name**. 2. On the right side of **database**, enter or select the corresponding database. On the right side of **table**, enter or select the corresponding table. On the right side of **column**, enter a column and select *****. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **update**.
INSERT and **DELETE** operations	1. Enter the policy name in **Policy Name**. 2. On the right side of **database**, enter or select the corresponding database. On the right side of **table**, enter or select the corresponding table. On the right side of **column**, enter a column and select *****. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **update**. 5. Configure the **submit** permission on the Yarn task queue. For details about how to configure the permission, see **Adding a Ranger Access Permission Policy for Yarn**.

Task	Role Authorization
GRANT/REVOKE operation	1. Enter the policy name in **Policy Name**. 2. On the right side of **database**, enter or select the corresponding database. On the right side of **table**, enter or select the corresponding table. On the right side of **column**, enter a column and select *****. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Select **Delegate Admin**.
ADD JAR operation	1. Enter the policy name in **Policy Name**. 2. Click **database**, and select **global** from the drop-down list. On the right of **global**, enter related information or select *****. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **Temporary UDF Admin**.
UDF operation	1. Enter the policy name in **Policy Name**. 2. Enter or select the corresponding database on the right of **database**, and enter the corresponding udf function name on the right of **udf**. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select required permissions for the user (**udf** supports the **Create**, **select**, and **Drop** permissions).
VIEW operation	1. Enter the policy name in **Policy Name**. 2. On the right side of **database**, enter or select the corresponding database. On the right side of **table**, enter or select the corresponding table to be viewed. On the right side of **column**, enter a column and select *****. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select permissions for the user as required.
dfs command operation	The **dfs** operation can be performed only after you have run the **set role admin** command.
Operations on other user database tables	1. Perform the preceding operations to add the corresponding permissions. 2. Grant the read, write, and execution permissions on the HDFS paths of other user database tables to the user. For details, see **Adding a Ranger Access Permission Policy for HDFS**.

NOTE

- If you have specified an HDFS path when running commands, you need to be granted with the read, write, and execution permissions on the HDFS paths. For details, see **Adding a Ranger Access Permission Policy for HDFS**. You do not need to configure the Ranger policy of HDFS. You can use the Hive permission plug-in to add permissions to the role and assign the role to the corresponding user. If the HDFS Ranger policy can match the file or directory permission of the Hive database table, the HDFS Ranger policy is preferentially used.
- The URL policy in the Ranger policy is involved in the scenario where the Hive table is stored on OBS. Set the URL to the complete path of the object on OBS. The Read and Write permissions are used together with the URL. URL policies are not involved in other scenarios.
- The global policy in the Ranger policy is used only with the **Temporary UDF Admin** permission to control the upload of UDF packages.
- The **hiveservice** policy in the Ranger policy is used only with the **Service Admin** permission to control the permission to run the **kill query <queryId>** command to end the task that is being executed.
- The **lock**, **index**, **refresh**, and **replAdmin** permissions are not supported.
- Run the **show grant** command to view the table permission. The **grantor** column of the table **owner** is displayed as user **hive**. If the Ranger page is used or the **grant** command is used to grant permissions in the background, the **grantor** column is displayed as the corresponding user. To view the result of using the Hive permission plug-in, set **hive-ext.ranger.previous.privileges.enable** to **true** and run the **show grant** command.

Step 5 Click **Add** to view the basic information about the policy in the policy list. After the policy takes effect, check whether the related permissions are normal.

To disable a policy, click  to edit the policy and set the policy to **Disabled**.

If a policy is no longer used, click  to delete it.

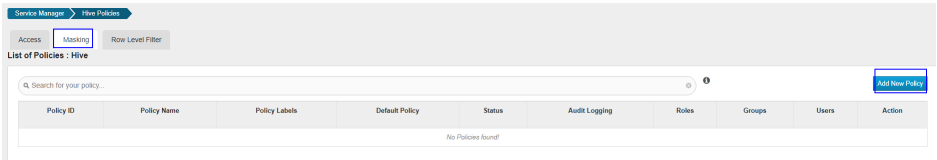
----End

Hive Data Masking

Ranger supports data masking for Hive data. It can process the returned result of the **select** operation you performed to mask sensitive information.

Step 1 Log in to the Ranger web UI. Click **Hive** in the **HADOOP SQL** area on the homepage.

Step 2 On the **Masking** tab page, click **Add New Policy** to add a Hive permission control policy.



Step 3 Configure the parameters listed in the table below based on the service demands.

Table 12-330 Hive data masking parameters

Parameter	Description
Policy Name	Policy name, which can be customized and must be unique in the service.
Policy Conditions	IP address filtering policy, which can be customized. You can enter one or more IP addresses or IP address segments. The IP address can contain the wildcard character (*), for example, **192.168.1.10**, **192.168.1.20**, or **192.168.1.***.
Policy Label	A label specified for the current policy. You can search for reports and filter policies based on labels.
Hive Database	Name of the Hive database to which the current policy applies.
Hive Table	Name of the Hive table to which the current policy applies.
Hive Column	Column name.
Description	Policy description.
Audit Logging	Whether to audit the policy.

Parameter	Description
Mask Conditions	In the **Select Role**, **Select Group**, and **Select User** columns, select the object to which the permission is to be granted, click **Add Conditions**, add the IP address range to which the policy applies, then click **Add Permissions**, and select **select**. Click **Select Masking Option** and select a data masking policy. • Redact: Use **x** to mask all letters and **n** to mask all digits. • Partial mask: show last 4: Only the last four characters are displayed, and the rest characters are displayed using **x**. • Partial mask: show first 4: Only the first four characters are displayed, and the rest characters are displayed using **x**. • Hash: Replace the original value with the hash value. The Hive built-in function **mask_hash** is used. This is valid only for fields of the string, character, and varchar types. NULL is returned for fields of other types. • Nullify: Replace the original value with the NULL value. • Unmasked (retain original value): Keep the original value. • Date: show only year: Only the year part of the date string is displayed, and the default month and date start from January and Monday (**01/01**). • Custom: You customize policies using any valid return data type which is the same as the data type in the masked column. To add a multi-column masking policy, click  .

Step 4 Click **Add** to view the basic information about the policy in the policy list.

Step 5 After you perform the **select** operation on a table configured with a data masking policy on the Hive client, the system processes and displays the data.

NOTE

To process data, you must have the permission to submit tasks to the Yarn queue.

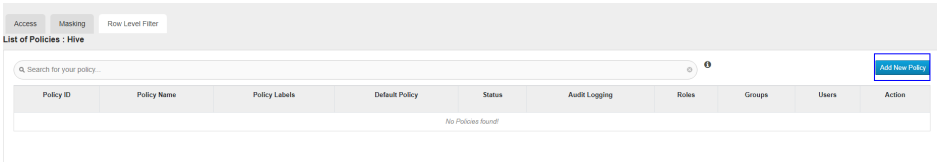
----End

Hive Row-Level Data Filtering

Ranger allows you to filter data at the row level when you perform the **select** operation on Hive data tables.

Step 1 Log in to the Ranger web UI. Click **Hive** in the **HADOOP SQL** area on the homepage.

Step 2 On the **Row Level Filter** tab page, click **Add New Policy** to add a row data filtering policy.



Step 3 Configure the parameters listed in the table below based on the service demands.

Table 12-331 Parameters for filtering Hive row data

Parameter	Description
Policy Name	Policy name, which can be customized and must be unique in the service.
Policy Conditions	IP address filtering policy, which can be customized. You can enter one or more IP addresses or IP address segments. The IP address can contain the wildcard character (*), for example, **192.168.1.10**, **192.168.1.20**, or **192.168.1.***.
Policy Label	A label specified for the current policy. You can search for reports and filter policies based on labels.
Hive Database	Name of the Hive database to which the current policy applies.
Hive Table	Name of the Hive table to which the current policy applies.
Description	Policy description.
Audit Logging	Whether to audit the policy.
Row Filter Conditions	In the **Select Role**, **Select Group**, and **Select User** columns, select the object to which the permission is to be granted, click **Add Conditions**, add the IP address range to which the policy applies, then click **Add Permissions**, and select **Select**. Click **Row Level Filter** and enter data filtering rules. For example, if you want to filter the data in the **zhangsan** row in the **name** column of **table A**, the filtering rule is **name <>'zhangsan'**. For more information, see the official Ranger document. To add more rules, click  .

Step 4 Click **Add** to view the basic information about the policy in the policy list.

Step 5 After you perform the **select** operation on a table configured with a data masking policy on the Hive client, the system processes and displays the data.

NOTE

To process data, you must have the permission to submit tasks to the Yarn queue.

----End

12.21.11 Adding a Ranger Access Permission Policy for Yarn

Scenario

The administrator can use Ranger to configure Yarn administrator permissions for Yarn users, allowing them to manage Yarn queue resources.

Prerequisites

- The Ranger service has been installed and is running properly.
- You have created users, user groups, or roles for which you want to configure permissions.

Procedure

Step 1 Log in to the Ranger management page.

Step 2 On the home page, click the component plug-in name in the **YARN** area, for example, **Yarn**.

Step 3 Click **Add New Policy** to add a Yarn permission control policy.

Step 4 Configure the parameters listed in the table below based on the service demands.

Table 12-332 Yarn permission parameters

Parameter	Description
Policy Name	Policy name, which can be customized and must be unique in the service.
Policy Conditions	IP address filtering policy, which can be customized. You can enter one or more IP addresses or IP address segments. The IP address can contain the wildcard character (*), for example, **192.168.1.10**,**192.168.1.20**, or **192.168.1.***.
Policy Label	A label specified for the current policy. You can search for reports and filter policies based on labels.
Queue	Queue name. The wildcard (*) is supported. To enable a sub-queue to inherit the permission of its upper-level queue, enable the recursion function. • **Non-recursive**: recursion disabled • **Recursive**: recursion enabled
Description	Policy description.
Audit Logging	Whether to audit the policy.

Parameter	Description
Allow Conditions	Policy allowed condition. You can configure permissions and exceptions allowed by the policy. In the **Select Role**, **Select Group**, and **Select User** columns, select the role, user group, or user to which the permission is to be granted, click **Add Conditions**, add the IP address range to which the policy applies, and click **Add Permissions** to add the corresponding permission. • submit-app: permission to submit queue tasks • admin-queue: permission to manage queue tasks • Select/Deselect All: Select or deselect all. If users or user groups in the current condition need to manage this policy, select **Delegate Admin**. These users will become the agent administrators. The agent administrators can update and delete this policy and create sub-policies based on the original policy. To add multiple permission control rules, click  . To delete a permission control rule, click  . Exclude from Allow Conditions: policy exception conditions
Deny All Other Accesses	Whether to reject all other access requests. • True: All other access requests are rejected. • **False**: **Deny Conditions** can be configured.
Deny Conditions	Policy rejection condition, which is used to configure the permissions and exceptions to be denied in the policy. The configuration method is similar to that of **Allow Conditions**. The priority of **Deny Conditions** is higher than that of allowed conditions configured in **Allow Conditions**. Exclude from Deny Conditions: exception rules excluded from the denied conditions

Table 12-333 Setting permissions

Task	Role Authorization
Setting the Yarn administrator permission	1. On the home page, click the component plug-in name in the **YARN** area, for example, **Yarn**. 2. Select the policy whose **Policy Name** is **all - queue** and click  to edit the policy. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list.

Task	Role Authorization
Setting the permission for a user to submit tasks in a specified Yarn queue	1. In **Queue**, specify a queue name. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **submit-app**.
Setting the permission for a user to manage tasks in a specified Yarn queue	1. In **Queue**, specify a queue name. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **admin-queue**.

Step 5 (Optional) Add the validity period of the policy. Click **Add Validity period** in the upper right corner of the page, set **Start Time** and **End Time**, and select **Time Zone**. Click **Save**. To add multiple policy validity periods, click  . To delete a policy validity period, click  .

Step 6 Click **Add** to view the basic information about the policy in the policy list. After the policy takes effect, check whether the related permissions are normal.

To disable a policy, click  to edit the policy and set the policy to **Disabled**.

If a policy is no longer used, click  to delete it.

----End

NOTE

The permissions on Ranger Yarn are independent of each other. There is inclusion relationship among the permissions. Currently, the following permissions are supported:

- **submit-app**: permission to submit queue tasks
- **admin-queue**: permission to manage queue tasks

Although the **admin-queue** has the permission to submit tasks, it does not have the inclusion relationship with the **submit-app** permission.

12.21.12 Adding a Ranger Access Permission Policy for Spark2x

Scenario

The administrator can use Ranger to set permissions for Spark2x users.

NOTE

1. After Ranger authentication is enabled or disabled on Spark2x, you need to restart Spark2x.
2. Download the client again or manually update the client configuration file *Client installation directory*/**Spark2x/spark/conf/spark-defaults.conf**.

   Enable Ranger: **spark.ranger.plugin.authorization.enable=true**

   Disable Ranger: **spark.ranger.plugin.authorization.enable=false**
3. In Spark2x, spark-beeline (applications connected to JDBCServer) supports the Ranger IP address filtering policy (**Policy Conditions** in the Ranger permission policy), while spark-submit and spark-sql do not.

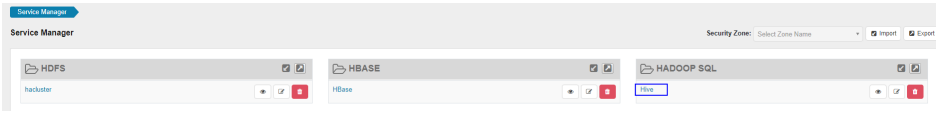
Prerequisites

- The Ranger service has been installed and is running properly.
- The Ranger authentication function of the Hive service has been enabled. After the Hive service is restarted, the Spark2x service is restarted.
- You have created users, user groups, or roles for which you want to configure permissions.
- The created user has been added to the **hive** user group.

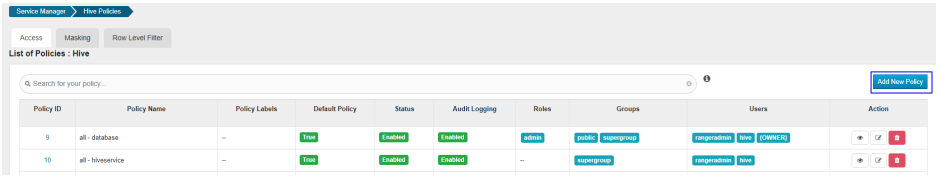
Procedure

Step 1 Log in to the Ranger management page.

Step 2 On the home page, click the component plug-in name in the **HADOOP SQL** area, for example, **Hive**.



Step 3 On the **Access** tab page, click **Add New Policy** to add a Spark2x permission control policy.



Step 4 Configure the parameters listed in the table below based on the service demands.

Table 12-334 Spark2x permission parameters

Parameter	Description
Policy Name	Policy name, which can be customized and must be unique in the service.

Parameter	Description
Policy Conditions	IP address filtering policy, which can be customized. You can enter one or more IP addresses or IP address segments. The IP address can contain the wildcard character (*), for example, **192.168.1.10**,**192.168.1.20**, or **192.168.1.***.
Policy Label	A label specified for the current policy. You can search for reports and filter policies based on labels.
database	Name of the Spark2x database to which the policy applies. The **Include** policy applies to the current input object, and the **Exclude** policy applies to objects other than the current input object.
table	Name of the Spark2x table to which the policy applies. To add a UDF-based policy, switch to UDF and enter the UDF name. The **Include** policy applies to the current input object, and the **Exclude** policy applies to objects other than the current input object.
column	Name of the column to which the policy applies. The value ***** indicates all columns. The **Include** policy applies to the current input object, and the **Exclude** policy applies to objects other than the current input object.
Description	Policy description.
Audit Logging	Whether to audit the policy.

Parameter	Description
Allow Conditions	Policy allowed condition. You can configure permissions and exceptions allowed by the policy. In the **Select Role**, **Select Group**, and **Select User** columns, select the role, user group, or user to which the permission is to be granted, click **Add Conditions**, add the IP address range to which the policy applies, and click **Add Permissions** to add the corresponding permission. ● select: permission to query data ● update: permission to update data ● Create: permission to create data ● Drop: permission to drop data ● Alter: permission to alter data ● Index: permission to index data ● All: all permissions ● Read: permission to read data ● Write: permission to write data ● Temporary UDF Admin: temporary UDF management permission ● Select/Deselect All: Select or deselect all. To add multiple permission control rules, click  . If users or user groups in the current condition need to manage this policy, select **Delegate Admin**. These users will become the agent administrators. The agent administrators can update and delete this policy and create sub-policies based on the original policy.
Deny Conditions	Policy rejection condition, which is used to configure the permissions and exceptions to be denied in the policy. The configuration method is similar to that of **Allow Conditions**.

Table 12-335 Setting permissions

Task	Operation
role admin operation	1. On the home page, click **Settings** and choose **Roles** > **Add New Role**. 2. Set **Role Name** to **admin**. In the **Users** area, click **Select User** and select a username. 3. Click **Add Users**, select **Is Role Admin** in the row where the username is located, and click **Save**. **NOTE** After being bound to the Hive administrator role, perform the following operations during each maintenance operation: 1. Log in to the node where the Hive client is installed as the client installation user. 2. Run the following command to configure environment variables: For example, if the Spark2x client installation directory is **/opt/client**, run **source /opt/client/bigdata_env**. 3. Run the following command to perform user authentication: **kinit Spark2x***Service user* 4. Run the following command to log in to the client tool: **spark-beeline** 5. Run the following command to update the administrator permissions: **set role admin;**
Creating a database table	1. Enter the policy name in **Policy Name**. 2. Enter and select the corresponding database on the right of **database**. (If you want to create a database, enter the name of the database to be created or enter ***** to indicate a database with any name, and then select the name.) Enter and select the corresponding table name on the right of **table** and **column**. Wildcard characters (*) are supported. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **Create**.

Task	Operation
Deleting a table	1. Enter the policy name in **Policy Name**. 2. Enter and select the corresponding database on the right of **database**. (If you want to delete a database, enter the name of the database to be created or enter ***** to indicate a database with any name, and then select the name.) Enter and select the corresponding table name on the right of **table** and **column**. Wildcard characters (*) are supported. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **Drop**. **NOTE** For CarbonData tables, only the owner of the corresponding database or table can perform the **drop** operation.
ALTER operation	1. Enter the policy name in **Policy Name**. 2. Enter and select the corresponding database on the right of **database**, enter and select the corresponding table on the right of **table**, and enter and select the corresponding column name on the right of **column**. Wildcard characters (*) are supported. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **Alter**.
LOAD operation	1. Enter the policy name in **Policy Name**. 2. Enter and select the corresponding database on the right of **database**, enter and select the corresponding table on the right of **table**, and enter and select the corresponding column name on the right of **column**. Wildcard characters (*) are supported. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **update**.

Task	Operation
INSERT operation	1. Enter the policy name in **Policy Name**. 2. Enter and select the corresponding database on the right of **database**, enter and select the corresponding table on the right of **table**, and enter and select the corresponding column name on the right of **column**. Wildcard characters (*) are supported. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **update**. 5. The user also needs to have the **submit-app** permission of the Yarn task queue. By default, the Hadoop user group has the **submit-app** permission of all Yarn task queues. For details about how to load a network instance to a cloud connection, see **Adding a Ranger Access Permission Policy for Yarn**.
GRANT operation	1. Enter the policy name in **Policy Name**. 2. Enter and select the corresponding database on the right of **database**, enter and select the corresponding table on the right of **table**, and enter and select the corresponding column name on the right of **column**. Wildcard characters (*) are supported. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Select **Delegate Admin**.
ADD JAR operation	1. Enter the policy name in **Policy Name**. 2. Click **database**, and select **global** from the drop-down list. On the right of **global**, enter related information and select ***. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **Temporary UDF Admin**.

Task	Operation
VIEW and **INDEX** permissions	1. Enter the policy name in **Policy Name**. 2. On the right side of **database**, enter the database name and select the corresponding database. (If you want to delete a database, enter the database name and select *.) On the right side of **table**, enter a table name and select the view and index names. On the right side of **column**, enter a Hive column name, and select *. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select permissions for the user as required.
Operations on other user database tables	1. Perform the preceding operations to add the corresponding permissions. 2. Grant the read, write, and execution permissions on the HDFS paths of other user database tables to the current user. For details, see **Adding a Ranger Access Permission Policy for HDFS**.

NOTE

After Spark SQL access policy is added on Ranger, you need to add the corresponding path access policies in the HDFS access policy. Otherwise, data files cannot be accessed. For details, see **Adding a Ranger Access Permission Policy for HDFS**.

- The global policy in the Ranger policy is only used to associate with the **Temporary UDF Admin** permission to control the upload of UDF packages.
- When Ranger is used to control Spark SQL permissions, the **empower** syntax is not supported.

Step 5 Click **Add** to view the basic information about the policy in the policy list. After the policy takes effect, check whether the related permissions are normal.

To disable a policy, click  to edit the policy and set the policy to **Disabled**.

If a policy is no longer used, click  to delete it.

----End

Data Masking of the Spark2x Table

Ranger supports data masking for Spark2x data. It can process the returned result of the **select** operation you performed to mask sensitive information.

Step 1 Log in to the Ranger WebUI and click the component plug-in name, for example, **Hive**, in the **HADOOP SQL** area on the home page.

Step 2 On the **Masking** tab page, click **Add New Policy** to add a Spark2x permission control policy.

Step 3 Configure the parameters listed in the table below based on the service demands.

Table 12-336 Spark2x data masking parameters

Parameter	Description
Policy Name	Policy name, which can be customized and must be unique in the service.
Policy Conditions	IP address filtering policy, which can be customized. You can enter one or more IP addresses or IP address segments. The IP address can contain the wildcard character (*), for example, **192.168.1.10**,**192.168.1.20**, or **192.168.1.***.
Policy Label	A label specified for the current policy. You can search for reports and filter policies based on labels.
Hive Database	Name of the Spark2x database to which the current policy applies.
Hive Table	Name of the Spark2x table to which the current policy applies.
Hive Column	Name of the Spark2x column to which the current policy applies.
Description	Policy description.
Audit Logging	Whether to audit the policy.

Parameter	Description
Mask Conditions	In the **Select Group** and **Select User** columns, select the user group or user to which the permission is to be granted, click **Add Conditions**, add the IP address range to which the policy applies, then click **Add Permissions**, and select **select**. Click **Select Masking Option** and select a data masking policy. ● Redact: Use **x** to mask all letters and **n** to mask all digits. ● Partial mask: show last 4: Only the last four characters are displayed. ● Partial mask: show first 4: Only the first four characters are displayed. ● Hash: Perform hash calculation for data. ● Nullify: Replace the original value with the NULL value. ● Unmasked(retain original value): The original data is displayed. ● Date: show only year: Only the year information is displayed. ● Custom: You can use any valid Hive UDF (returns the same data type as the data type in the masked column) to customize the policy. To add a multi-column masking policy, click  .
Deny Conditions	Policy rejection condition, which is used to configure the permissions and exceptions to be denied in the policy. The configuration method is similar to that of **Allow Conditions**.

----End

Spark2x Row-Level Data Filtering

Ranger allows you to filter data at the row level when you perform the **select** operation on Spark2x data tables.

Step 1 Log in to the Ranger WebUI and click the component plug-in name, for example, **Hive**, in the **HADOOP SQL** area on the home page.

Step 2 On the **Row Level Filter** tab page, click **Add New Policy** to add a row data filtering policy.

Step 3 Configure the parameters listed in the table below based on the service demands.

Table 12-337 Parameters for filtering Spark2x row data

Parameter	Description
Policy Name	Policy name, which can be customized and must be unique in the service.
Policy Conditions	IP address filtering policy, which can be customized. You can enter one or more IP addresses or IP address segments. The IP address can contain the wildcard character (*), for example, **192.168.1.10**,**192.168.1.20**, or **192.168.1.***.
Policy Label	A label specified for the current policy. You can search for reports and filter policies based on labels.
Hive Database	Name of the Spark2x database to which the current policy applies.
Hive Table	Name of the Spark2x table to which the current policy applies.
Description	Policy description.
Audit Logging	Whether to audit the policy.
Row Filter Conditions	In the **Select Role**, **Select Group**, and **Select User** columns, select the object to which the permission is to be granted, click **Add Conditions**, add the IP address range to which the policy applies, then click **Add Permissions**, and select **select**. Click **Row Level Filter** and enter data filtering rules. For example, if you want to filter the data in the **zhangsan** row in the **name** column of **table A**, the filtering rule is **name <>'zhangsan'**. For more information, see the official Ranger document. To add more rules, click  .

Step 4 Click **Add** to view the basic information about the policy in the policy list.

Step 5 After you perform the **select** operation on a table configured with a data masking policy on the Spark2x client, the system processes and displays the data.

----End

12.21.13 Adding a Ranger Access Permission Policy for Kafka

Scenario

The administrator can use Ranger to configure the read, write, and management permissions of the Kafka topic and the management permission of the cluster for the Kafka user. This section describes how to add the production permission of the **test** topic for the **test** user.

Prerequisites

- The Ranger service has been installed and is running properly.
- You have created users, user groups, or roles for which you want to configure permissions.

Procedure

Step 1 Log in to the Ranger management page.

Step 2 On the home page, click the component plug-in name in the **KAFKA** area, for example, **Kafka**.

Step 3 Click **Add New Policy** to add a Kafka permission control policy.

Step 4 Configure the following parameters based on the service demands.

Table 12-338 Kafka permission parameters

Parameter	Description
Policy Type	Access type.
Policy Conditions	IP address filtering policy, which can be customized. You can enter one or more IP addresses or IP address segments. The IP address can contain the wildcard character (*), for example, **192.168.1.10**,**192.168.1.20**, or **192.168.1.***.
Policy Name	Policy name, which can be customized and must be unique in the service.
Policy Label	A label specified for the current policy. You can search for reports and filter policies based on labels.
topic	Name of the topic applicable to the current policy. You can enter multiple values. The value can contain wildcards, such as **test**, **test***, and *. The **Include** policy applies to the current input object, and the **Exclude** policy applies to objects other than the current input object.
Description	Policy description.
Audit Logging	Whether to audit the policy.

Parameter	Description
Allow Conditions	Permission and exception conditions allowed by a policy. The priority of an exception condition is higher than that of a normal condition. In the **Select Role**, **Select Group**, and **Select User** columns, select the role, user group, or user to which you want to assign permissions. Click **Add Conditions**, add the IP address range to which the policy applies, and click **Add Permissions** to add corresponding permissions. ● Publish: production permission ● Consume: consumption permission ● Describe: query permission ● Create: topic creation permission ● Delete: topic deletion permission ● Describe Configs: configuration query permission ● Alter: permission to change the number of partitions of a topic. ● Alter Configs: configuration modification permission ● Select/Deselect All: Select or deselect all. To add multiple permission control rules, click  . If users or user groups in the current condition need to manage this policy, select **Delegate Admin**. These users will become the agent administrators. The agent administrators can update and delete this policy and create sub-policies based on the original policy.
Deny Conditions	Policy rejection condition, which is used to configure the permissions and exceptions to be denied in the policy. The configuration method is the same as that of **Allow Conditions**. The priority of the rejection condition is higher than that of the allowed conditions configured in **Allow Conditions**.

For example, to add the production permission for the **test** topic of user **testuser**, configure the following information:

Figure 12-43 Kafka permission parameters

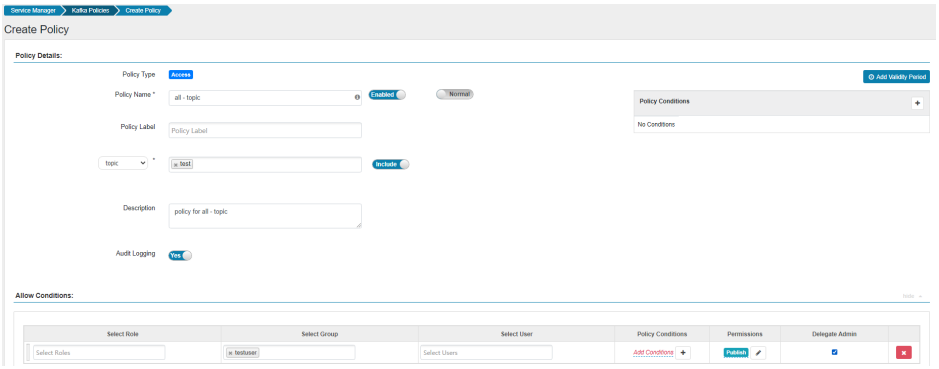


Table 12-339 Setting permissions

Scenario	Role Authorization
Setting the Kafka administrator permissions	1. On the home page, click the component plug-in name in the **KAFKA** area, for example, **Kafka**. 2. Select the policy whose **Policy Name** is **all - topic** and click  to edit the policy. 3. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 4. Click **Add Permissions** and select **Select/ Deselect All**.
Setting the permission for a user to create a topic	1. Specify a topic name in **topic**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Create**. **NOTE** Currently, the Kafka kernel supports the **--zookeeper** and **--bootstrap-server** methods to create topics. The **--zookeeper** method will be deleted from the community in later versions. Therefore, you are advised to use the **--bootstrap-server** method to create topics. Note: Currently, Kafka supports only the authentication of topic creation in **--bootstrap-server** mode and does not support that in **--zookeeper** mode.

Scenario	Role Authorization
Setting the permission for a user to delete a topic	1. Specify a topic name in **topic**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Delete**. **NOTE** Currently, the Kafka kernel supports the **--zookeeper** and **--bootstrap-server** methods to delete topics. The **--zookeeper** method will be deleted from the community in later versions. Therefore, you are advised to use the **--bootstrap-server** method to delete topics. Note: Currently, Kafka supports only the authentication of topic deletion in **--bootstrap-server** mode and does not support that in **--zookeeper** mode.
Setting the permission for a user to query a topic	1. Specify a topic name in **topic**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Describe** and **Describe Configs**. **NOTE** Currently, the Kafka kernel supports the **--zookeeper** and **--bootstrap-server** methods to query topics. The **--zookeeper** method will be deleted from the community in later versions. Therefore, you are advised to use the **--bootstrap-server** method to query topics. Note: Currently, Kafka supports only the authentication of topic query in **--bootstrap-server** mode and does not support that in **--zookeeper** mode.
Setting the production permission of a user on a topic	1. Specify a topic name in **topic**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Publish**.
Setting the consumption permission of a user on a topic	1. Specify a topic name in **topic**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Consume**. **NOTE** During topic consumption, offset management is involved. Therefore, the **Consume** permission of **ConsumerGroup** must be enabled at the same time. For details, see **Setting a User's Permission to Submit ConsumerGroup Offsets**.
Setting the permission for a user to expand a topic (by adding partitions)	1. Specify a topic name in **topic**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Alter**.

Scenario	Role Authorization
Setting the permission for a user to modify the topic configuration	Currently, the Kafka kernel does not support to modify topic parameters based on **--bootstrap-server**. Therefore, Ranger does not support authentication for this behavior.
Setting all the management permissions of a user on a cluster	1. Enter a cluster name and select the cluster on the right side of **cluster**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Kafka Admin**.
Setting the permission for a user to create a cluster	1. On the home page, click the component plug-in name in the **KAFKA** area, for example, **Kafka**. 2. Select the policy whose **Policy Name** is **all - cluster** and click  to edit the policy. 3. Enter a cluster name and select the cluster on the right side of **cluster**. 4. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 5. Click **Add Permissions** and select **Create**. **NOTE** The authentication of the **Create** operation of a cluster involves the following two scenarios: 1. After the **auto.create.topics.enable** parameter is enabled in the cluster, the client sends data to a topic that has not been created in the service. In this case, the system checks whether the user has the **Create** permission of the cluster. 2. If a user creates a large number of topics and is granted the **Cluster Create** permission, the user can create any topic in the cluster.
Setting the permission for a user to modify the cluster configuration	1. Enter a cluster name and select the cluster on the right side of **cluster**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Alter Configs**. **NOTE** The configuration modification permission allows you to modify the Broker and Broker Logger configurations. After the configuration modification permission is granted to a user, the user can query configuration details even if the user does not have the query permission. (The configuration modification permission includes the configuration query permission.)

Scenario	Role Authorization
Setting the permission for a user to query the cluster configuration	1. Enter a cluster name and select the cluster on the right side of **cluster**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Describe** and **Describe Configs**. **NOTE** You can only query Broker and Broker Logger information in the cluster, excluding topics.
Setting the Idempotent Write permission in a cluster for a user	1. Enter a cluster name and select the cluster on the right side of **cluster**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Idempotent Write**. **NOTE** This permission authenticates the **Idempotent Produce** behavior of the user's client.
Setting the permission to migrate partitions in a cluster for a user	1. Enter a cluster name and select the cluster on the right side of **cluster**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Alter**. **NOTE** The **Alter** permission of a cluster can be used to control permissions in the following scenarios: 1. In the **Partition Reassign** scenario, migrate the storage directory of replicas. 2. Elect a leader replica in each partition of the cluster. 3. Add or delete ACLs. Operations in scenarios **Step 4.1** and **Step 4.2** are between a controller and broker and between brokers in the cluster. When a cluster is created, this permission is granted to the built-in Kafka user by default. It is meaningless for a common user to be granted with this permission. Scenario **Step 4.3** involves the ACL management. ACLs are designed for authentication. Currently, Kafka authentication is hosted to Ranger. Therefore, this scenario is not involved (the configuration does not take effect).

Scenario	Role Authorization
Setting the Cluster Action permission in a cluster for a user	1. Enter a cluster name and select the cluster on the right side of **cluster**. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Cluster Action**. **NOTE** This permission controls the synchronization between the leader and follower replicas in the cluster and the communication between nodes. It has been granted to the built-in Kakfa user during cluster creation. It is meaningless for a common user to grant this permission.
Setting the TransactionalId permission for a user	1. On the home page, click the component plug-in name in the **KAFKA** area, for example, **Kafka**. 2. Select the policy whose **Policy Name** is **all - transactionalid** and click  to edit the policy. 1. Set **transactionalid** to a transaction ID. 2. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 3. Click **Add Permissions** and select **Publish** and **Describe**. **NOTE** The **Publish** permission is used to authenticate client requests for which the transaction feature is enabled, for example, starting and ending a transaction, submitting an offset, and generating transactional data. The **Describe** permission is used to authenticate the requests from the client and coordinator that have enabled the transaction feature. If the transaction feature is enabled, you are advised to grant both the **Publish** and **Describe** permissions to users.

Scenario	Role Authorization
Setting the DelegationToken permission for a user	1. On the home page, click the component plug-in name in the **KAFKA** area, for example, **Kafka**. 2. Select the policy whose **Policy Name** is **all - delegationtoken** and click  to edit the policy. 3. Set **delegationtoken** to a delegation token. 4. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 5. Click **Add Permissions** and select **Describe**. **NOTE** Currently, Ranger only controls the query permission of DelegationToken, but does not control its **create**, **renew**, and **expire** permissions.
Setting the permission for a user to query ConsumerGroup Offsets	1. On the home page, click the component plug-in name in the **KAFKA** area, for example, **Kafka**. 2. Select the policy whose **Policy Name** is **all - consumergroup** and click  to edit the policy. 3. In **consumergroup**, configure the consumer group to be managed. 4. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 5. Click **Add Permissions** and select **Describe**.
Set the user's submission permission on **ConsumerGroup Offsets**.	1. On the home page, click the component plug-in name in the **KAFKA** area, for example, **Kafka**. 2. Select the policy whose **Policy Name** is **all - consumergroup** and click  to edit the policy. 3. In **consumergroup**, configure the consumer group to be managed. 4. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 5. Click **Add Permissions** and select **Consume**. **NOTE** After a user is granted with the **Consume** permission of **ConsumerGroup**, the user is also granted with the **Describe** permission.

Scenario	Role Authorization
Setting the permission for a user to delete ConsumerGroup Offsets	1. On the home page, click the component plug-in name in the **KAFKA** area, for example, **Kafka**. 2. Select the policy whose **Policy Name** is **all - consumergroup** and click  to edit the policy. 3. In **consumergroup**, configure the consumer group to be managed. 4. In the **Allow Conditions** area, select a user from the **Select User** drop-down list. 5. Click **Add Permissions** and select **Delete**. **NOTE** When a user is granted with the **Delete** permission of **ConsumerGroup**, the user is also granted with the **Describe** permission.

Step 5 (Optional) Add the validity period of the policy. Click **Add Validity period** in the upper right corner of the page, set **Start Time** and **End Time**, and select **Time Zone**. Click **Save**. To add multiple policy validity periods, click  . To delete a policy validity period, click  .

Step 6 Click **Add** to view the basic information about the policy in the policy list. After the policy takes effect, check whether the related permissions are normal.

To disable a policy, click  to edit the policy and set the policy to **Disabled**.

If a policy is no longer used, click  to delete it.

----End

12.21.14 Adding a Ranger Access Permission Policy for Storm

Scenario

The administrator can use Ranger to set permissions for Storm users.

Prerequisites

- The Ranger service has been installed and is running properly.
- You have created users, user groups, or roles for which you want to configure permissions.
- The Ranger authentication function has been enabled on the page. The option in the following figure controls whether to enable the Ranger plug-in for permission control. If the function is enabled, the Ranger authentication is used. Otherwise, the authentication mechanism of the component is used.

Procedure

Step 1 Log in to the Ranger web UI. Click **Storm** in the **STORM** area on the homepage.

Step 2 Click **Add New Policy** to add a Storm permission control policy.

Step 3 Configure the parameters listed in the table below based on the service demands.

Table 12-340 Storm permission parameters

Parameter	Description
Policy Conditions	IP address filtering policy, which can be customized. You can enter one or more IP addresses or IP address segments. The IP address can contain the wildcard character (*), for example, **192.168.1.10**,**192.168.1.20**, or **192.168.1.***.
Policy Name	Policy name, which can be customized and must be unique in the service. The **include** policy applies to the current input object, and the **exclude** policy applies to objects other than the current input object.
Policy Label	A label specified for the current policy. You can search for reports and filter policies based on labels.
Storm Topology	Name of the topology to which the current policy applies. One or more values can be entered.
Description	Policy description.
Audit Logging	Whether to audit the policy.

Parameter	Description
Allow Conditions	Policy allowed condition. You can configure permissions and exceptions allowed by the policy. In the **Select Role**, **Select Group**, and **Select User** columns, select the role, user group, or user to which the permission is to be granted, click **Add Conditions**, add the IP address range to which the policy applies, and click **Add Permissions** to add the corresponding permissions. • **Submit Topology**: Submit a topology. **NOTE** The Submit Topology permission takes effect only when **Storm Topology** is set to *****. • **File Upload**: Upload a file. • **File Download**: Download a file. • **Kill Topology**: Delete a topology. • **Rebalance**: Perform the rebalance operation. • **Activate**: Activate the topology permission. • **Deactivate**: Deactivate the topology permission. • **Get Topology Conf**: Obtain topology configurations. • **Get Topology**: Obtain a topology. • **Get User Topology**: Obtain user's topology. • **Get Topology Info**: Obtain topology information. • **Upload New Credential**: Upload a new credential. • **Select/Deselect All**: Select or deselect all. To add multiple permission control rules, click  . If users or user groups in the current condition need to manage this policy, select **Delegate Admin**. These users will become the agent administrators. The agent administrators can update and delete this policy and create sub-policies based on the original policy.
Deny Conditions	Policy rejection condition, which is used to configure the permissions and exceptions to be denied in the policy. The configuration method is similar to that of **Allow Conditions**.

Step 4 (Optional) Add the validity period of the policy. Click **Add Validity period** in the upper right corner of the page, set **Start Time** and **End Time**, and select **Time Zone**. Click **Save**. To add multiple policy validity periods, click  . To delete a policy validity period, click  .

Step 5 Click **Add** to view the basic information about the policy in the policy list. After the policy takes effect, check whether the related permissions are normal.

To disable a policy, click  to edit the policy and set the policy to **Disabled**.

If a policy is no longer used, click  to delete it.

----End

12.21.15 Ranger Log Overview

Log Description

Log path: The default storage path of Ranger logs is **/var/log/Bigdata/ranger/***Role name*.

- RangerAdmin: /var/log/Bigdata/ranger/rangeradmin (run logs)
- TagSync: /var/log/Bigdata/ranger/tagsync (run logs)
- UserSync: /var/log/Bigdata/ranger/usersync (run logs)

Log archive rule: The automatic compression and archive function is enabled for Ranger logs. By default, when the size of a log file exceeds 20 MB, the log file is automatically compressed. The naming rule of the compressed log file is as follows: *<Original log file name>-<yyyy-mm-dd_hh-mm-ss>.[ID]***.log.zip**. A maximum of 20 compressed file are retained.

Table 12-341 HDFS log list

Type	Name	Description
RangerAdmin run log file	access_log.*<DATE>*.log	Tomcat access log
	catalina.out	Tomcat service run log
	gc-worker.log	RangerAdmin garbage collection (GC) log
	postinstallDetail.log	Work log generated after an instance is started before installation
	prestartDetail.log	Log that records preparations before instance startup
	ranger-admin-*<hostname>*.log	RangerAdmin run log

Type	Name	Description
	ranger_admin_sql-*<hostname>*.log	RangerAdmin log used to retrieve DBService
	startDetail.log	Instance startup log
TagSync run log	cleanupDetail.log	Instance clearing log
	gc-worker.log	GC log file of an instance
	postinstallDetail.log	Work log generated after an instance is started before installation
	prestartDetail.log	Log that records preparations before instance startup
	ranger-tagsync-*<hostname>*.log	TagSync run log
	startDetail.log	Instance startup log
	tagsync.out	TagSync run log
UserSync run log	auth.log	UnixAuth service run log
	cleanupDetail.log	Instance clearing log
	gc-worker.log	GC log file of an instance
	postinstallDetail.log	Work log generated after an instance is started before installation
	prestartDetail.log	Log that records preparations before instance startup
	ranger-usersync-*<hostname>*.log	UserSync run log
	startDetail.log	Instance startup log

Log Levels

Table 12-342 describes the log levels provided by HDFS. The priorities of log levels are FATAL, ERROR, WARN, INFO, and DEBUG in descending order. Logs whose levels are higher than or equal to the specified level are printed. The number of printed logs decreases as the specified log level increases.

Table 12-342 Log levels

Level	Description
FATAL	Logs of this level record fatal error information about the current event processing that may result in a system crash.
ERROR	Logs of this level record error information about the current event processing, which indicates that system running is abnormal.
WARN	Logs of this level record abnormal information about the current event processing. These abnormalities will not result in system faults.
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record the system information and system debugging information.

To modify log levels, perform the following operations:

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **Ranger** > **Configurations**.

Step 3 Select **All Configurations**.

Step 4 On the menu bar on the left, select the log menu of the target role.

Step 5 Select a desired log level.

Step 6 Click **Save**. In the displayed dialog box, click **OK** to make the configuration take effect.

NOTE

The configurations take effect immediately without the need to restart the service.

----End

Log Formats

The following table lists the Ranger log formats.

Table 12-343 Log formats

Type	Format	Example Value
Run log	*<yyyy-MM-dd HH:mm:ss,SSS>*|*<Log level>*|*<Name of the thread that generates the log>*|*<Message in the log>*|*<Location where the log event occurs>*	2020-04-29 20:09:28,543 | INFO | http-bio-21401-exec-56 | Request comes from API call, skip cas filter. | CasAuthenticationFilter-Wrapper.java:25

12.21.16 Common Issues About Ranger

12.21.16.1 Why Ranger Startup Fails During the Cluster Installation?

Problem

During cluster installation, Ranger fails to be started, and the error message "ERROR: cannot drop sequence X_POLICY_REF_ACCESS_TYPE_SEQ " is displayed in the task list of the Manager process. How do I resolve this problem and properly install Ranger?

Answer

This issue may occur when two RangerAmdin instances are installed. If the instance installation fails, manually restart one RangerAdmin instance and then restart the other instance.

12.21.16.2 How Do I Determine Whether the Ranger Authentication Is Used for a Service?

Question

How do I determine whether the Ranger authentication is enabled for a service that supports the authentication?

Answer

Log in to FusionInsight Manager and choose **Cluster** > **Services** > *Name of the desired service*. On the service details page, click **More** and check whether the **Enable Ranger** option is available.

- If yes, the Ranger authentication plug-in is not enabled for the service. You can click **Enable Ranger** to enable the function.
- If no, the Ranger authentication plug-in has been enabled for the service. You can configure the permission policy for accessing the service resources on the Ranger management page.

12.21.16.3 Why Cannot a New User Log In to Ranger After Changing the Password?

Question

When a new user logs in to Ranger, why is the 401 error reported after the password is changed?

Answer

The UserSync synchronizes user data at an interval of 5 minutes by default. Therefore, a new user created on Manager cannot log in to the Ranger before the user data is successfully synchronized because the Ranger database does not have the user information. The user can log in to the Ranger only after the specified interval ends.

In non-security mode, the Ranger does not synchronize user data from Manager. Therefore, only the **admin** user can log in to the Ranger page.

12.21.16.4 When an HBase Policy Is Added or Modified on Ranger, Wildcard Characters Cannot Be Used to Search for Existing HBase Tables

Question

When a Ranger access permission policy is added for HBase and wildcard characters are used to search for an existing HBase table in the policy, the table cannot be found. The following error is reported in **/var/log/Bigdata/ranger/rangeradmin/ranger-admin-*log**:

```
Caused by: javax.security.sasl.SaslException: No common protection layer between client and server

annelHandlerContext.java:362)
```

Answer

The value of **hbase.rpc.protection** of the HBase service plug-in on Ranger must be the same as that of **hbase.rpc.protection** on the HBase server.

Step 1 Log in to the Ranger management page. For details, see **Logging In to the Ranger Web UI**.

Step 2 In the **HBASE** area on the home page, click the component plug-in name, for example, the  button of HBase.

Step 3 Search for the configuration item **hbase.rpc.protection** and change its value to the value of **hbase.rpc.protection** on the HBase server.

Step 4 Click **Save**.

----End

12.22 Using Spark

12.22.1 Precautions

This section applies to versions earlier than MRS 3.x.

12.22.2 Getting Started with Spark

This section describes how to use Spark to submit a SparkPi job. SparkPi, a typical Spark job, is used to calculate the value of Pi (π).

Procedure

Step 1 Prepare the SparkPi program.

Multiple open-source Spark sample programs are provided, including SparkPi. Click **https://archive.apache.org/dist/spark/spark-2.1.0/spark-2.1.0-bin-hadoop2.7.tgz** to download the software package.

Decompress the software package to obtain the **spark-examples_2.11-2.1.0.jar** file, the sample program package, in the **spark-2.1.0-bin-hadoop2.7/examples/jars** directory. The **spark-examples_2.11-2.1.0.jar** sample program package contains the SparkPi program.

Step 2 Upload data to OBS.

1. Log in to OBS Console.
2. Choose **Parallel File System** > **Create Parallel File System** to create a file system named **sparkpi**.

   sparkpi is only an example. The file system name must be globally unique. Otherwise, the parallel file system fails to be created. Use the default values for other parameters.
3. Click the file system name **sparkpi** and click **Files**.
4. Click **Create Folder** to create the **program** folder..
5. Go to the **program** folder, click **Upload Object**, select the program package downloaded in **Step 1** from the local PC, and set **Storage Class** to **Standard**.

Step 3 Log in to the MRS console. In the left navigation pane, choose **Clusters** > **Active Clusters**, and click a cluster name.

Step 4 Submit the SparkPi job.

On the MRS console, click the **Jobs** tab and click **Create**. The **Create Job** page is displayed.

- Set **Type** to **SparkSubmit**.
- Set **Name** to **sparkPi**.
- Set **Program Path** to the path where programs are stored on OBS, for example, **obs://sparkpi/program/spark-examples_2.11-2.1.0.jar**.
- In **Program Parameter**, select **--class** for **Parameter** and set **Value** to **org.apache.spark.examples.SparkPi**.
- Set **Parameters** to **10**.
- Leave **Service Parameter** blank.

A job can be submitted only when the cluster is in the **Running** state.

After a job is submitted successfully, it is in the **Accepted** state by default. You do not need to manually execute the job.

Step 5 View the job execution result.

1. Go to the **Jobs** tab page and view job execution status.

   The job execution takes a while. After the jobs are complete, refresh the job list.

   Once a job has succeeded or failed, you cannot execute it again. However, you can add or copy a job, and set job parameters to submit a job again.

2. Go to the native Yarn page and view the job output information.

   a. On the **Jobs** tab page, locate the row that contains the target job and click **View Details** in the **Operation** column to obtain the actual job ID.

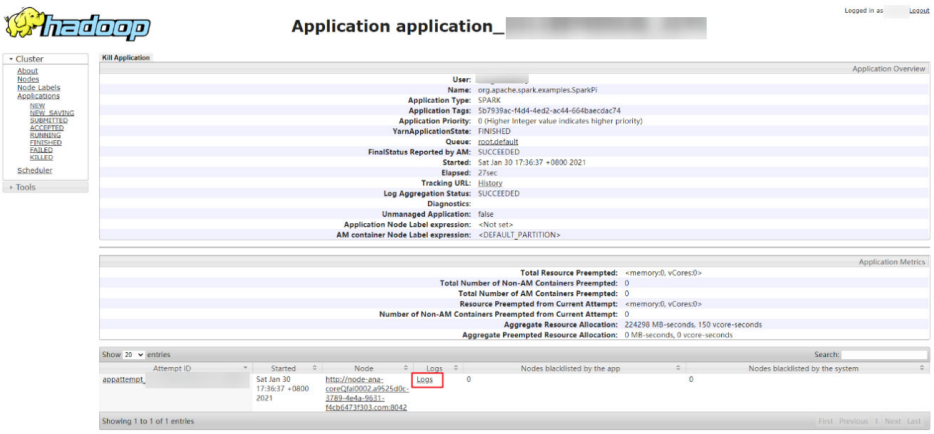
   b. Log in to Manager and choose **Services** > **Yarn** > **ResourceManager WebUI** > **ResourceManager (Active)**. The Yarn page is displayed.

   c. Click the ID corresponding to the actual job ID.

   Figure 12-44 Yarn Web UI

   d. Click **Logs** in the job log area.

Figure 12-45 SparkPi job logs

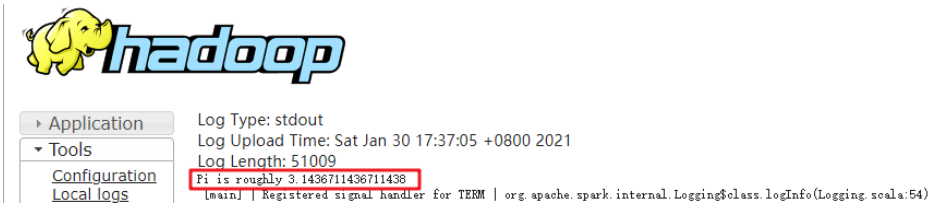


e. Click **here** to obtain more detailed logs.

Figure 12-46 More detailed logs of sparkPi jobs

f. Obtain the job execution result.

Figure 12-47 sparkPi job execution result



----End

12.22.3 Getting Started with Spark SQL

Spark provides the Spark SQL language that is similar to SQL to perform operations on structured data. This section describes how to use Spark SQL from scratch. Create a table named **src_data**, write a data record in each row of the table, and store the data in the **mrs_20160907** cluster. Then use SQL statements to query data in the table, and delete the table at last.

Prerequisites

You have obtained the AK/SK for writing data from an OBS data source to a Spark SQL table. To obtain it, perform as follows:

1. Log in to the management console.
2. Click the username and select **My Credentials** from the drop-down list.
3. On the displayed **My Credentials** page, click **Access Keys**.

4. Click **Create Access Key** to switch to the **Create Access Key** dialog box.
5. Enter the password and , and click **OK** to download the access key. Keep the access key secure.

Procedure

Step 1 Prepare data sources for Spark SQL analysis.

The sample text file is as follows:

```
abcd3ghji
efgh658ko
1234jjyu9
7h8kodfg1
kk99icxz3
```

Step 2 Upload data to OBS.

1. Log in to OBS Console.
2. Choose **Parallel File System** > **Create Parallel File System** to create a file system named **sparksql**.

   sparksql is only an example. The file system name must be globally unique. Otherwise, the parallel file system fails to be created.
3. Click the name of the **sparksql** file system and click **Files**.
4. Click **Create Folder** to create the **input** folder.
5. Go to the **input** folder, choose **Upload File** > **add file**, select the local TXT file, and click **Upload**.

Step 3 Log in to the MRS console. In the left navigation pane, choose **Clusters** > **Active Clusters**, and click a cluster name.

Step 4 Import the text file from OBS to HDFS.

1. Click the **Files** tab.
2. On the **HDFS File List** tab page, click **Create Folder**, and create a folder named **userinput**.
3. Go to the **userinput** folder, and click **Import Data**.
4. Select the OBS and HDFS paths and click **OK**.

   OBS Path: **obs://sparksql/input/sparksql-test.txt**

   HDFS Path: **/user/userinput**

Step 5 Submit the SQL statement.

1. On the MRS console, select **Job Management**.

   A job can be submitted only when the **mrs_20160907** cluster is in the **Running** state.
2. Enter the Spark SQL statement for table creation.

   When entering Spark SQL statements, ensure that the statement characters are not more than 10,000.

   Syntax:

   CREATE [EXTERNAL] **TABLE** [IF NOT EXISTS] *table_name* [(col_name data_type [COMMENT col_comment], ...)] [COMMENT table_comment] [PARTITIONED **BY** (col_name data_type [COMMENT col_comment], ...)]

[CLUSTERED **BY** (col_name, col_name, ...) [SORTED **BY** (col_name [ASC|DESC], ...)] INTO num_buckets BUCKETS] [ROW FORMAT row_format] [STORED **AS** file_format] [LOCATION hdfs_path];

You can use the following two methods to create a table example:

- Method 1: Create table **src_data** and write data in every row.
  - The data source is stored in the folder of HDFS: ***create external table*** *src_data* ***(line string) row format delimited fields terminated by '||n' stored as textfile location*** *'/user/userinput*';
  - The data source is stored in the **/sparksql/input** folder of OBS: **create external table** *src_data* **(line string) row format delimited fields terminated by '\\n' stored as textfile location** *'obs://AK:SK@sparksql/input*';

    For details about how to obtain the AK/SK, see **Prerequisites**.
- Method 2: Create table **src_data1** and load data to the table in batches.

  create table *src_data1* **(line string) row format delimited fields terminated by ','** ;

  load data inpath *'/user/userinput/sparksql-test.txt'* **into table** *src_data1*;

  NOTE

  When method 2 is used, the data from OBS cannot be loaded to the created tables directly.

3. Enter the Spark SQL statement for table query.

   Syntax:

   SELECT col_name **FROM** *table_name*;

   Example of querying all data in the **src_data** table:

   select * from src_data;

4. Enter the Spark SQL statement for table deletion.

   Syntax:

   DROP TABLE [IF EXISTS] *table_name*;

   Example of deleting the **src_data** table:

   drop table src_data;

5. Click **Check** to check the statement correctness.
6. Click **OK**.

   After the Spark SQL statements are submitted, the statement execution results are displayed in the result column.

Step 6 Delete the cluster.

----End

12.22.4 Using the Spark Client

After an MRS cluster is created, you can create and submit jobs on the client. The client can be installed on nodes inside or outside the cluster.

- Nodes inside the cluster: After an MRS cluster is created, the client has been installed on the master and core nodes in the cluster by default. For details, see . Then, log in to the node where the MRS client is installed..
- Nodes outside the cluster: You can install the client on nodes outside a cluster. For details about how to install a client, see , and log in to the node where the MRS client is installed..

Using the Spark Client

Step 1 Based on the client location, log in to the node where the client is installed. For details, see , or .

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, run the following command to authenticate the user. In normal mode, user authentication is not required.

kinit *Component service user*

Step 5 Run the Spark shell command. The following provides an example:

spark-beeline

----End

12.22.5 Accessing the Spark Web UI

The Spark web UI is used to view the running status of Spark applications. Google Chrome is recommended for better user experience.

Spark has two web UIs.

- Spark UI: used to display the status of running applications.

  The UI includes the following parts: Jobs, Stages, Storage, Environment, Executors, SQL, and JDBC/ODBC Server. The Streaming application has the Streaming tab in addition to the preceding parts.
- History Server UI: used to display the status of Spark applications that are complete or incomplete.

  The UI includes the application ID, application name, start time, end time, execution time, and owner information.

Spark UI

Step 1 Access the component management page.

- For versions earlier than MRS 3.*x*, click the cluster name to go to the cluster details page and choose **Components**.

NOTE

If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the desired cluster* > **Services**.

Step 2 Select **Yarn**. In the **Yarn Summary** area, click **ResourceManager** in **ResourceManager Web UI** to access the web UI.

Step 3 Locate the Spark application. Click **ApplicationMaster** in the last column of the application information. The Spark UI is displayed.

Figure 12-48 ApplicationMaster

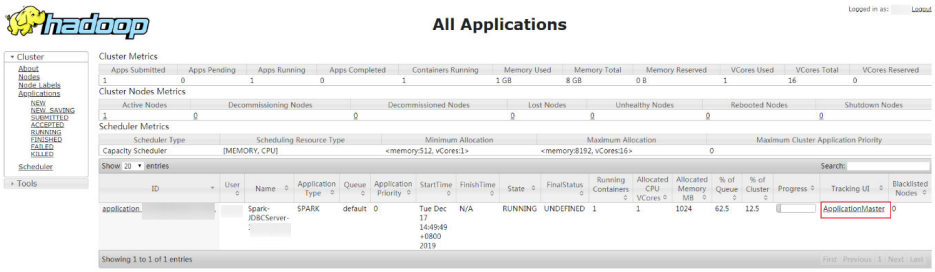


Figure 12-49 Spark UI

----End

History Server

Step 1 Access the component management page.

- For versions earlier than MRS 3.*x*, click the cluster name to go to the cluster details page and choose **Components**.

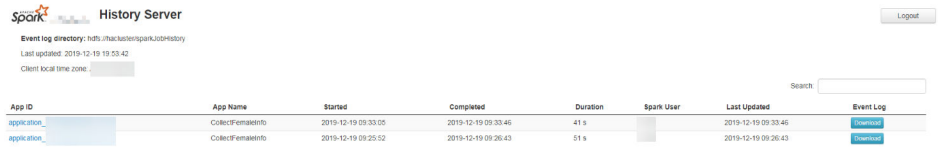
NOTE

If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the desired cluster* > **Services**.

Step 2 Select **Spark**. In the **Spark Summary** area, click **JobHistory** corresponding to **Spark Web UI** to access the web UI.

Figure 12-50 Spark History Server



----End

12.22.6 Interconnecting Spark with OpenTSDB

12.22.6.1 Creating a Table and Associating It with OpenTSDB

Function

MRS Spark can be used to access the data source of OpenTSDB, create and associate tables in the Spark, and query and insert the OpenTSDB data.

Use the **CREATE TABLE** command to create a table and associate it with an existing metric in OpenTSDB.

NOTE

If no metric exists in OpenTSDB, an error will be reported when the corresponding table is queried.

Syntax

```
CREATE TABLE [IF NOT EXISTS] OPENTSDB_TABLE_NAME   USING OPENTSDB OPTIONS (
'metric' = 'METRIC_NAME',
'tags' = 'TAG1,TAG2'
);
```

Keyword

Parameter	Description
metric	Indicates the name of the metric in OpenTSDB corresponding to the table to be created.
tags	Indicates the tags corresponding to the metric. The tags are used for classification, filtering, and quick retrieval. You can set 1 to 8 tags, which are separated by commas (,). The parameter value includes values of all tagKs in the corresponding metric.

Precautions

When creating a table, you do not need to specify the **timestamp** and **value** fields. The system automatically builds the following fields based on the specified tags. The fields **TAG1** and **TAG2** are specified by tags.

- TAG1 String

- TAG2 String
- timestamp Timestamp
- value double

Example

Create table **opentsdb_table** and associate it with metric **city.temp** of the OpenTSDB component.

```
CREATE table opentsdb_table using opentsdb OPTIONS ('metric'='city.temp',  'tags'='city,location');
```

12.22.6.2 Inserting Data to the OpenTSDB Table

Function

Run the **INSERT INTO** statement to insert the data in the table to the associated OpenTSDB metric.

Syntax

```
INSERT INTO TABLE_NAME SELECT * FROM SRC_TABLE;
INSERT INTO TABLE_NAME VALUES(XXX);
```

Keyword

Parameter	Description
TABLE_NAME	Indicates the name of the associated OpenTSDB table.
SRC_TABLE	Indicates the name of the table from which data is obtained. This parameter can be set to a name of a common table.

Precautions

- The inserted data cannot be **null**. If the inserted data is the same as the original data or only the **value** is different, the inserted data overwrites the original data.
- **INSERT OVERWRITE** is not supported.
- You are advised not to concurrently insert data into a table. If you concurrently insert data into a table, there is a possibility that conflicts occur, leading to data insertion failures.
- The **TIMESTAMP** format supports only yyyy-MM-dd hh:mm:ss.

Example

Insert data into table **opentsdb_table**.

```
insert into opentsdb_table values('city1','city2','2018-05-03 00:00:00',21);
```

12.22.6.3 Querying an OpenTSDB Table

This **SELECT** command is used to query data in an OpenTSDB table.

Syntax

```
SELECT * FROM table_name WHERE tagk=tagv LIMIT number;
```

Keyword

Parameter	Description
LIMIT	Used to limit the query results.
number	Only the INT type is supported.

Precautions

- The to-be-queried table must exist. Otherwise, an error is reported.
- The value of **tagv** must exist. Otherwise, an error occurs.

Example

Query data in the **opentsdb_table** table.

```
SELECT * FROM opentsdb_table LIMIT 100;
SELECT * FROM opentsdb_table WHERE city='city1';
```

12.22.6.4 Modifying the Default Configuration Data

By default, OpenTSDB connects to the local TSD process of the node where the Spark executor resides. In MRS, use the default configuration.

Table 12-344 OpenTSDB data source configuration

Parameter	Description	Example Value
spark.sql.datasource.opentsdb.host	Indicates the IP address of the connected TSD process.	Null (default value) **xx.xx.xx.xx** indicates the IP address. Separate multiple IP addresses with commas (,).
spark.sql.datasource.opentsdb.port	Indicates the port number of the TSD process.	4242 (default value)

spark.sql.datasource.opentsdb.randomSeed	Indicates whether to use the random seed when the **spark.sql.datasource.opentsdb.host** is set to multiple addresses. If this parameter is set to **false**, all executors on the same node are connected to the same host. In this way, **spark.blacklist.enabled=true** can be used to implement task fault tolerance.	false (default value)

Example

Run the **set** statement in **spark-sql** and **spark-beeline**, and then run other SQL statements.

```
set spark.sql.datasource.opentsdb.host = 192.168.2.143,192.168.2.158;
SELECT * FROM opentsdb_table ;
```

12.23 Using Spark2x

12.23.1 Precautions

This section applies to MRS 3.*x* or later.

12.23.2 Basic Operation

12.23.2.1 Getting Started

This section describes how to use Spark2x to submit Spark applications, including Spark Core and Spark SQL. Spark Core is the kernel module of Spark. It executes tasks and is used to compile Spark applications. Spark SQL is a module that executes SQL statements.

Scenario Description

Develop a Spark application to perform the following operations on logs about netizens' dwell time for online shopping on a weekend.

- Collect statistics on female netizens who dwell on online shopping for more than 2 hours on the weekend.
- The first column in the log file records names, the second column records genders, and the third column records the dwell durations in the unit of minute. Three columns are separated by comma (,).

log1.txt: logs collected on Saturday

```
LiuYang,female,20
YuanJing,male,10
GuoYijun,male,5
CaiXuyu,female,50
Liyuan,male,20
FangBo,female,50
LiuYang,female,20
YuanJing,male,10
GuoYijun,male,50
CaiXuyu,female,50
FangBo,female,60
```

log2.txt: logs collected on Sunday

```
LiuYang,female,20
YuanJing,male,10
CaiXuyu,female,50
FangBo,female,50
GuoYijun,male,5
CaiXuyu,female,50
Liyuan,male,20
CaiXuyu,female,50
FangBo,female,50
LiuYang,female,20
YuanJing,male,10
FangBo,female,50
GuoYijun,male,50
CaiXuyu,female,50
FangBo,female,60
```

Prerequisites

- On Manager, you have created a user and granted the HDFS, Yarn, Kafka, and Hive permissions to the user.
- You have installed and configured tools such as IntelliJ IDEA and JDK based on the development language.
- You have installed the Spark2x client and configured the client network connection.
- For Spark SQL programs, you have started Spark SQL or Beeline on the client to enter SQL statements.

Procedure

Step 1 Obtain the sample project and import it to IDEA. Import the JAR package on which the sample project depends. Use IDEA to configure and generate JAR packages.

Step 2 Prepare the data required by the sample project.

Save the original log files in the scenario description to the HDFS system.

1. Create two text files (**input_data1.txt** and **input_data2.txt**) on the local host and copy the content in the **log1.txt** and **log2.txt** files to the **input_data1.txt** and **input_data2.txt** files, respectively.
2. Create the **/tmp/input** directory in HDFS, and upload **input_data1.txt** and **input_data2.txt** to the **/tmp/input** directory:

Step 3 Upload the generated JAR package to the Spark2x running environment (Spark2x client), for example, **/opt/female**.

Step 4 Go the client directory, configure the environment variables, and log in to the system. When you use a client to connect to a specific instance in a scenario where multiple Spark2x instances are installed or Spark and Spark2x instances are installed, run the following commands to load the environment variables of the instance.

source bigdata_env

source Spark2x/component_env

kinit <*service user for authentication***>**

Step 5 Run the following script in the **bin** directory to submit the Spark application:

spark-submit --class *com.xxx.bigdata.spark.examples.FemaleInfoCollection* ***--master yarn-client*** */opt/female/FemaleInfoCollection.jar <inputPath>*

NOTE

- **FemaleInfoCollection.jar** is the JAR package generated in **Step 1**.
- **<inputPath>** is the directory created in **Step 2.2**.

Step 6 (Optional) After calling the **spark-sql** or **spark-beeline** script in the **bin** directory, directly enter SQL statements to perform operations such as query.

For example, create a table, insert a piece of data, and then query the table.

```
spark-sql> CREATE TABLE TEST(NAME STRING, AGE INT);
Time taken: 0.348 seconds
spark-sql>INSERT INTO TEST VALUES('Jack', 20);
Time taken: 1.13 seconds
spark-sql> SELECT * FROM TEST;
Jack	20
Time taken: 0.18 seconds, Fetched 1 row(s)
```

Step 7 View the running result of the Spark application.

- View the running result data in a specified file.

  The storage path and format of the result data are specified by the Spark application.

- Check the running status on the web page.

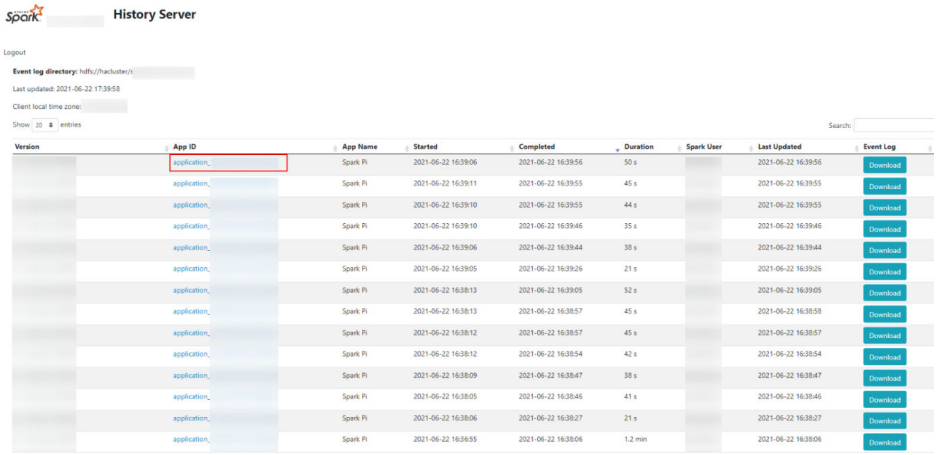
  a. Log in to Manager. Select **Spark2x** from the **Service** drop-down list.

  b. Go to the Spark2x overview page and click an instance in the Spark web UI, for example, **JobHistory2x(host2)**.

  c. The History Server UI is displayed.

  The History Server UI is used to display the status of Spark applications that are complete or incomplete.

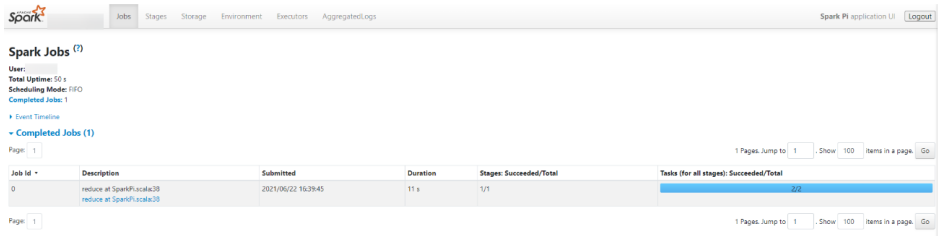
Figure 12-51 History Server UI



d. Select an application ID and click this page to go to the Spark UI of the application.

Spark UI: used to display the status of running applications.

Figure 12-52 Spark UI



- View Spark logs to learn application runtime conditions.

  View **Spark2x Logs** to learn application running status, and adjust applications based on log information.

----End

12.23.2.2 Configuring Parameters Rapidly

Overview

This section describes how to quickly configure common parameters and lists parameters that are not recommended to be modified when Spark2x is used.

Common parameters to be configured

Some parameters have been adapted during cluster installation. However, the following parameters need to be adjusted based on application scenarios. Unless otherwise specified, the following parameters are configured in the **spark-defaults.conf** file on the Spark2x client.

Table 12-345 Common parameters to be configured

Configuration Item	Description	Default Value
spark.sql.parquet.compression.codec	Used to set the compression format of a non-partitioned Parquet table. Set the queue in the **spark-defaults.conf** configuration file on the JDBCServer server.	snappy
spark.dynamicAllocation.enabled	Indicates whether to use dynamic resource scheduling, which is used to adjust the number of executors registered with the application according to scale. Currently, this parameter is valid only in Yarn mode. The default value for JDBCServer is **true**, and that for the client is **false**.	false
spark.executor.memory	Indicates the memory size used by each executor process. Its character sting is in the same format as the JVM memory (example: 512 MB or 2 GB).	4G
spark.sql.autoBroadcastJoinThreshold	Indicates the maximum value for the broadcast configuration when two tables are joined. ● When the size of a field in a table involved in an SQL statement is less than the value of this parameter, the system broadcasts the SQL statement. ● If the value is set to **-1**, broadcast is not performed.	10485760
spark.yarn.queue	Specifies the Yarn queue where JDBCServer resides. Set the queue in the **spark-defaults.conf** configuration file on the JDBCServer server.	default
spark.driver.memory	In a large cluster, you are advised to configure the memory used by the 32 GB to 64 GB driver process, that is, the SparkContext initialization process (for example, 512 MB and 2 GB).	4G

Configuration Item	Description	Default Value
spark.yarn.security.credentials.hbase.enabled	Indicates whether to enable the function of obtaining HBase tokens. If the Spark on HBase function is required and a security cluster is configured, set this parameter to **true**. Otherwise, set this parameter to **false**.	false
spark.serializer	Used to serialize the objects that are sent over the network or need to be cached. The default value of Java serialization applies to any Serializable Java object, but the running speed is slow. Therefore, you are advised to use **org.apache.spark.serializer.KryoSerializer** and configure Kryo serialization. It can be any subclass of **org.apache.spark.serializer.Serializer**.	org.apache.spark.serializer.JavaSerializer
spark.executor.cores	Indicates the number of kernels used by each executor. Set this parameter in standalone mode and Mesos coarse-grained mode. When there are sufficient kernels, the application is allowed to execute multiple executable programs on the same worker. Otherwise, each application can run only one executable program on each worker.	1
spark.shuffle.service.enabled	Indicates a long-term auxiliary service in NodeManager for improving shuffle computing performance.	false
spark.sql.adaptive.enabled	Indicates whether to enable the adaptive execution framework.	false
spark.executor.memoryOverhead	Indicates the heap memory to be allocated to each executor, in MB. This is the memory that occupies the overhead of the VM, similar to the internal string and other built-in overhead. The value increases with the executor size (usually 6% to 10%).	1 GB
spark.streaming.kafka.direct.lifo	Indicates whether to enable the LIFO function of Kafka.	false

Parameters Not Recommended to Be Modified

The following parameters have been adapted during cluster installation. You are not advised to modify them.

Table 12-346 Parameters not recommended to be modified

Configuration Item	Description	Default Value or Configuration Example
spark.password.factory	Selects the password parsing mode.	org.apache.spark.om.util.FIPasswordFactory
spark.ssl.ui.protocol	Sets the SSL protocol of the UI.	TLSv1.2
spark.yarn.archive	Archives Spark JAR files, which are distributed to Yarn cache. If this parameter is set, the value will replace **<code> spark.yarn.jars </code>** and be archived in the containers of all applications. The archive should contain the JAR files in its root directory. Archives can also be hosted on HDFS to speed up file distribution.	hdfs://hacluster/user/spark2x/jars/8.1.0.1/spark-archive-2x.zip **NOTE** The version 8.1.0.1 is used as an example. Replace it with the actual version number.
spark.yarn.am.extraJavaOptions	Indicates a string of extra JVM options to pass to the YARN ApplicationMaster in client mode. Use **spark.driver.extraJavaOptions** in cluster mode.	-Dlog4j.configuration=./__spark_conf__/__hadoop_conf__/log4j-executor.properties -Djava.security.auth.login.config=./__spark_conf__/__hadoop_conf__/jaas-zk.conf -Dzookeeper.server.principal=zookeeper/hadoop.<*system domain name*> -Djava.security.krb5.conf=./__spark_conf__/__hadoop_conf__/kdc.conf -Djdk.tls.ephemeralDHKeySize=2048
spark.shuffle.servicev2.port	Indicates the port for the shuffle service to monitor requests for obtaining data.	27338

Configuration Item	Description	Default Value or Configuration Example
spark.ssl.historyServer.enabled	Sets whether the history server uses SSL.	true
spark.files.overwrite	When the target file exists and its content does not match that of the source file, whether to overwrite the file added through **SparkContext.addFile()**.	false
spark.yarn.cluster.driver.extraClassPath	Indicates the extraClassPath of the driver in Yarn-cluster mode. Set the parameter to the path and parameters of the server.	${BIGDATA_HOME}/common/runtime/security
spark.driver.extraClassPath	Indicates the extra class path entries attached to the class path of the driver.	${BIGDATA_HOME}/common/runtime/security
spark.yarn.dist.innerfiles	Sets the files that need to be uploaded to HDFS from Spark in Yarn mode.	/Spark_path/spark/conf/s3p.file,/Spark_path/spark/conf/locals3.jceks *Spark_path* is the installation path of the Spark client.
spark.sql.bigdata.register.dialect	Registers the SQL parser.	org.apache.spark.sql.hbase.HBaseSQLParser
spark.shuffle.manager	Indicates the data processing mode. There are two implementation modes: sort and hash. The sort shuffle has a higher memory utilization. It is the default option in Spark 1.2 and later versions.	SORT

Configuration Item	Description	Default Value or Configuration Example
spark.deploy.zookeeper.url	Indicates the address of ZooKeeper. Multiple addresses are separated by commas (,).	For example: host1:2181,host2:2181,host3:2181
spark.broadcast.factory	Indicates the broadcast mode.	org.apache.spark.broadcast.TorrentBroadcastFactory
spark.sql.session.state.builder	Session state constructor.	org.apache.spark.sql.hive.FIHiveACLSessionStateBuilder
spark.executor.extraLibraryPath	Sets the special library path used when the executor JVM is started.	${BIGDATA_HOME}/FusionInsight_HD_8.1.0.1/install/FusionInsight-Hadoop-3.1.1/hadoop/lib/native
spark.ui.customErrorPage	Indicates whether to display the custom error information page when an error occurs on the page.	true
spark.httpdProxy.enable	Indicates whether to use the httpd proxy.	true
spark.ssl.ui.enabledAlgorithms	Sets the SSL algorithm of UI.	TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_DHE_RSA_WITH_AES_256_GCM_SHA384,TLS_DHE_DSS_WITH_AES_256_GCM_SHA384,TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,TLS_DHE_DSS_WITH_AES_128_GCM_SHA256
spark.ui.logout.enabled	Sets the logout button for the web UI of the Spark component.	true
spark.security.hideInfo.enabled	Indicates whether to hide sensitive information on the UI.	true

Configuration Item	Description	Default Value or Configuration Example
spark.yarn.cluster.driver.extraLibraryPath	Indicates the **extraLibraryPath** of the driver in Yarn-cluster mode. Set this parameter to the path and parameters of the server.	${BIGDATA_HOME}/FusionInsight_HD_8.1.0.1/install/FusionInsight-Hadoop-3.1.1/hadoop/lib/native
spark.driver.extraLibraryPath	Sets a special library path for starting the driver JVM.	${DATA_NODE_INSTALL_HOME}/hadoop/lib/native
spark.ui.killEnabled	Allows stages and jobs to be stopped on the web UI.	true
spark.yarn.access.hadoopFileSystems	Spark can access multiple NameService instances. If there are multiple NameService instances, set this parameter to all the NameService instances and separate them with commas (,).	hdfs://hacluster,hdfs://hacluster

Configuration Item	Description	Default Value or Configuration Example
spark.yarn.cluster.driver.extraJavaOptions	Indicates extra JVM option passed to the executor, for example, GC setting and logging. Do not set Spark attributes or heap size using this option. Instead, set Spark attributes using the SparkConf object or the **spark-defaults.conf** file specified when the spark-submit script is called. Set heap size using **spark.executor.memory**.	-Xloggc:<LOG_DIR>/gc.log -XX:+PrintGCDetails -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=20 -XX:GCLogFileSize=10M -Dlog4j.configuration=./__spark_conf__/__hadoop_conf__/log4j-executor.properties -Djava.security.auth.login.config=./__spark_conf__/__hadoop_conf__/jaas-zk.conf -Dzookeeper.server.principal=zookeeper/hadoop.*<system domain name>* -Djava.security.krb5.conf=./__spark_conf__/__hadoop_conf__/kdc.conf -Djetty.version=x.y.z -Dorg.xerial.snappy.tempdir=${BIGDATA_HOME}/tmp/spark2x_app -Dcarbon.properties.filepath=./__spark_conf__/__hadoop_conf__/carbon.properties -Djdk.tls.ephemeralDHKeySize=2048
spark.driver.extraJavaOptions	Indicates a series of extra JVM options passed to the driver,	-Xloggc:${SPARK_LOG_DIR}/indexserver-omm-%p-gc.log -XX:+PrintGCDetails -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGCDateStamps -XX:MaxDirectMemorySize=512M -XX:MaxMetaspaceSize=512M -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=20 -XX:GCLogFileSize=10M -XX:OnOutOfMemoryError='kill -9 %p' -Djetty.version=x.y.z -Dorg.xerial.snappy.tempdir=${BIGDATA_HOME}/tmp/spark2x/JDBCServer/snappy_tmp -Djava.io.tmpdir=${BIGDATA_HOME}/tmp/spark2x/JDBCServer/io_tmp -Dcarbon.properties.filepath=${SPARK_CONF_DIR}/carbon.properties -Djdk.tls.ephemeralDHKeySize=2048 -Dspark.ssl.keyStore=${SPARK_CONF_DIR}/child.keystore #{java_stack_prefer}
spark.eventLog.overwrite	Indicates whether to overwrite any existing file.	false

Configuration Item	Description	Default Value or Configuration Example
spark.eventLog.dir	Indicates the directory for logging Spark events if **spark.eventLog.enabled** is set to **true**. In this directory, Spark creates a subdirectory for each application and logs events of the application in the subdirectory. You can also set a unified address similar to the HDFS directory so that the History Server can read historical files.	hdfs://hacluster/spark2xJobHistory2x
spark.random.port.min	Sets the minimum random port.	22600
spark.authenticate	Indicates whether Spark authenticates its internal connections. If the application is not running on Yarn, see **spark.authenticate.secret**.	true
spark.random.port.max	Sets the maximum random port.	22899
spark.eventLog.enabled	Indicates whether to log Spark events, which are used to reconstruct the web UI after the application execution is complete.	true

Configuration Item	Description	Default Value or Configuration Example
spark.executor.extraJavaOptions	Indicates extra JVM option passed to the executor, for example, GC setting and logging. Do not set Spark attributes or heap size using this option.	-Xloggc:<LOG_DIR>/gc.log -XX:+PrintGCDetails -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=20 -XX:GCLogFileSize=10M -Dlog4j.configuration=./log4j-executor.properties -Djava.security.auth.login.config=./jaas-zk.conf -Dzookeeper.server.principal=zookeeper/hadoop.*<system domain name>* -Djava.security.krb5.conf=./kdc.conf -Dcarbon.properties.filepath=./carbon.properties -Xloggc:<LOG_DIR>/gc.log -XX:+PrintGCDetails -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=20 -XX:GCLogFileSize=10M -Dlog4j.configuration=./__spark_conf__/__hadoop_conf__/log4j-executor.properties -Djava.security.auth.login.config=./__spark_conf__/__hadoop_conf__/jaas-zk.conf -Dzookeeper.server.principal=zookeeper/hadoop.*<system domain name>* -Djava.security.krb5.conf=./__spark_conf__/__hadoop_conf__/kdc.conf -Dcarbon.properties.filepath=./__spark_conf__/__hadoop_conf__/carbon.properties -Djdk.tls.ephemeralDHKeySize=2048
spark.sql.authorization.enabled	Indicates whether to enable authentication for the Hive client.	true

12.23.2.3 Common Parameters

Overview

This section describes common configuration items used in Spark. Subsections are divided by feature so that you can quickly find required configuration items. If you

use MRS clusters, most parameters described in this section have been adapted and you do not need to configure them again. For details about the parameters that need to be configured based on the site requirements, see **Configuring Parameters Rapidly**.

Configuring the Number of Stage Retries

When FetchFailedException occurs in a Spark task, a stage retry is triggered. To prevent infinite stage retries, the number of stage retries is limited. The number of retry times can be adjusted based on the site requirements.

Configure the following parameters in the **spark-defaults.conf** file on the Spark client.

Table 12-347 Parameter description

Parameter	Description	Default Value
spark.stage.maxConsecutiveAttempts	Indicates the maximum number of stage retries.	4

Configuring Whether to Use Cartesian Product

To enable the Cartesian product function, configure the following parameter in the **spark-defaults.conf** configuration file of Spark.

Table 12-348 Cartesian product parameters

Parameter	Description	Default Value
spark.sql.crossJoin.enabled	Indicates whether to allow implicit Cartesian product execution. • **true**: Implicit Cartesian product execution is allowed. • **false**: Implicit Cartesian product execution is not allowed. In this case, only CROSS JOIN can be explicitly included in the query.	true

NOTE

- For JDBC applications, configure this parameter in the **spark-defaults.conf** configuration file of the server.
- For tasks submitted by the Spark client, configure this parameter in the **spark-defaults.conf** configuration file of the client.

Configuring Security Authentication for Long-Time Spark Tasks

In security mode, if the **kinit** command is used for security authentication when the Spark CLI (such as spark-shell, spark-sql, or spark-submit) is used, the task fails due to authentication expiration when the task is running for a long time.

Set the following parameters in the **spark-defaults.conf** configuration file on the client. After the configuration is complete, run the Spark CLI again.

NOTE

If this parameter is set to **true**, ensure that the values of **keytab** and **principal** in **spark-defaults.conf** and **hive-site.xml** are the same.

Table 12-349 Parameter description

Parameter	Description	Default Value
spark.kerberos.principal	Indicates the principal user who has the Spark operation permission. Contact the administrator to obtain the principal user.	-
spark.kerberos.keytab	Indicates the name and path of the keytab file used to configure Spark operation permissions. Contact the administrator to obtain the keytab file.	-
spark.security.bigdata.loginOnce	Indicates whether the principal user logs in to the system only once. **true**: single login; **false**: multiple logins. The difference between a single login and multiple logins is as follows: The Spark community uses the Kerberos user to log in to the system for multiple times. However, the TGT or token may expire, causing the application to fail to run for a long time. The Kerberos login mode of DataSight is modified to allow users to log in only once, which effectively resolves the expiration problem. The restrictions are as follows: The principal and keytab configuration items of Hive must be the same as those of Spark. **NOTE** If this parameter is set to **true**, ensure that the values of **keytab** and **principal** in **spark-defaults.conf** and **hive-site.xml** are the same.	true

Python Spark

Python Spark is the third programming language of Spark except Scala and Java. Different from Java and Scala that run on the JVM platform, Python Spark has its own Python process as well as the JVM process. The following configuration items

apply only to Python Spark scenarios. However, other configuration items can also take effect in Python Spark scenarios.

Table 12-350 Parameter description

Parameter	Description	Default Value
spark.python.profile	Indicates whether to enable profiling on the Python worker. Use **sc.show_profiles()** to display the analysis results or display the analysis results before the Driver exits. You can use **sc.dump_profiles(path)** to dump the results to a disk. If some analysis results have been manually displayed, they will not be automatically displayed before the driver exits. By default, **pyspark.profiler.BasicProfiler** is used. You can transfer the specified profiler during SparkContext initialization to overwrite the default profiler.	false
spark.python.worker.memory	Indicates the memory size that can be used by each Python worker process during aggregation. The value format is the same as that of the specified JVM memory, for example, 512 MB and 2 GB. If the memory used by a process during aggregation exceeds the value of this parameter, data will be written to disks.	512m
spark.python.worker.reuse	Indicates whether to reuse Python workers. If the reuse function is enabled, a fixed number of Python workers will be reused by the next batch of submitted tasks instead of forking a Python process for each task. This function is useful in large-scale broadcasting because the data does not need to be transferred from the JVM to the Python workers again for the next batch of submitted tasks.	true

Dynamic Allocation

Dynamic resource scheduling is a unique feature of the On Yarn mode. This function can be used only after Yarn External Shuffle is enabled. When Spark is used as a resident service, dynamic resource scheduling greatly improves resource utilization. For example, the JDBCServer process does not accept JDBC requests in most of the time. Therefore, releasing resources in this period greatly reduces the waste of cluster resources.

Table 12-351 Parameter description

Parameter	Description	Default Value
spark.dynamicAllocation.enabled	Indicates whether to use dynamic resource scheduling, which is used to adjust the number of executors registered with the application according to scale. Currently, this parameter is valid only in Yarn mode. To enable dynamic resource scheduling, set **spark.shuffle.service.enabled** to **true**. Related parameters are as follows: **spark.dynamicAllocation.minExecutors**, **spark.dynamicAllocation.maxExecutors**, and **spark.dynamicAllocation.initialExecutors**.	• JDBCServer2x: true • SparkResource2x: false
spark.dynamicAllocation.minExecutors	Indicates the minimum number of executors.	0
spark.dynamicAllocation.initialExecutors	Indicates the number of initial executors.	spark.dynamicAllocation.minExecutors
spark.dynamicAllocation.maxExecutors	Indicates the maximum number of executors.	2048
spark.dynamicAllocation.schedulerBacklogTimeout	Indicates the first timeout period for scheduling. The unit is second.	1s
spark.dynamicAllocation.sustainedSchedulerBacklogTimeout	Indicates the second and later timeout interval for scheduling.	1s
spark.dynamicAllocation.executorIdleTimeout	Indicates the idle timeout interval for common executors. The unit is second.	60

Parameter	Description	Default Value
spark.dynamicAllocation.cachedExecutorIdleTimeout	Indicates the idle timeout interval for executors with cached blocks.	• JDBCServer2x: 2147483647s • IndexServer2x: 2147483647s • SparkResource2x: 120

Spark Streaming

Spark Streaming is a streaming data processing function provided by the Spark batch processing platform. It processes data input from external systems in **mini-batch** mode.

Configure the following parameters in the **spark-defaults.conf** file on the Spark client.

Table 12-352 Parameter description

Parameter	Description	Default Value
spark.streaming.receiver.writeAheadLog.enable	Indicates whether to enable the write-ahead log (WAL) function. After this function is enabled, all input data received by the receiver is saved in the WAL. WAL ensures that data can be restored if the driver program becomes faulty.	false
spark.streaming.unpersist	Determines whether to automatically remove RDDs generated and saved by Spark Streaming from the Spark memory. If this function is enabled, original data received by Spark Streaming is also automatically cleared. If this function is disabled, original data and RDDs cannot be automatically cleared. External applications can access the data in Streaming. This, however, occupies more Spark memory resources.	true

Spark Streaming Kafka

The receiver is an important component of Spark Streaming. It receives external data, encapsulates the data into blocks, and provides the blocks for Streaming to

consume. The most common data source is Kafka. Spark Streaming integrates Kafka to ensure reliability and can directly use Kafka as the RDD input.

Table 12-353 Parameter description

Parameter	Description	Default Value
spark.streaming.kafka.maxRatePerPartition	Indicates the maximum rate (number of records per second) for reading data from each Kafka partition if the Kafka direct stream API is used.	-
spark.streaming.blockInterval	Indicates the interval (ms) for accumulating data received by a Spark Streaming receiver into a data block before the data is stored in Spark. A minimum value of 50 ms is recommended.	200ms
spark.streaming.receiver.maxRate	Indicates the maximum rate (number of records per second) for each receiver to receive data. The value **0** or a negative value indicates no limit to the rate.	-
spark.streaming.receiver.writeAheadLog.enable	Indicates whether to use ReliableKafkaReceiver. This receiver ensures the integrity of streaming data.	false

Netty/NIO and Hash/Sort Configuration

Shuffle is critical for big data processing, and the network is critical for the entire shuffle process. Currently, Spark supports two shuffle modes: hash and sort. There are two network modes: Netty and NIO.

Table 12-354 Parameter description

Parameter	Description	Default Value
spark.shuffle.manager	Indicates the data processing mode. There are two implementation modes: sort and hash. The sort shuffle has a higher memory utilization. It is the default option in Spark 1.2 and later versions.	SORT

Parameter	Description	Default Value
spark.shuffle.consolidateFiles	(Only in hash mode) To merge intermediate files created during shuffle, set this parameter to **true**. Decreasing the number of files to be created can improve the processing performance of the file system and reduce risks. If the **ext4** or **xfs** file system is used, you are advised to set this parameter to **true**. Due to file system restrictions, this setting on **ext3** may reduce the processing performance of a server with more than eight cores.	false
spark.shuffle.sort.bypassMergeThreshold	This parameter is valid only when **spark.shuffle.manager** is set to **sort**. When Map aggregation is not performed and the number of partitions for Reduce tasks is less than or equal to the value of this parameter, do not merge and sort data to prevent performance deterioration caused by unnecessary sorting.	200
spark.shuffle.io.maxRetries	(Only in Netty mode) If this parameter is set to a non-zero value, fetch failures caused by I/O-related exceptions will be automatically retried. This retry logic helps the large shuffle keep stable when long GC pauses or intermittent network disconnections occur.	12
spark.shuffle.io.numConnectionsPerPeer	(Only in Netty mode) Connections between hosts are reused to reduce the number of connections between large clusters. For a cluster with many disks but a few hosts, this function may make concurrent requests unable to occupy all disks. Therefore, you can increase the value of this parameter.	1
spark.shuffle.io.preferDirectBufs	(Only in Netty mode) The off-heap buffer is used to reduce GC during shuffle and cache block transfer. In an environment where off-heap memory is strictly limited, you can disable it to force all applications from Netty to use heap memory.	true
spark.shuffle.io.retryWait	(Only in Netty mode) Specifies the duration for waiting for fetch retry, in seconds. The maximum delay caused by retry is **maxRetries** x **retryWait**. The default value is 15 seconds.	5

Common Shuffle Configuration

Table 12-355 Parameter description

Parameter	Description	Default Value
spark.shuffle.spill	If this parameter is set to **true**, data is overflowed to the disk to limit the memory usage during a Reduce task.	true
spark.shuffle.spill.compress	Indicates whether to compress the data overflowed during shuffle. The algorithm specified by **spark.io.compression.codec** is used for data compression.	true
spark.shuffle.file.buffer	Specifies the size of the memory buffer for storing output streams of each shuffle file, in KB. These buffers can reduce the number of disk seek and system calls during the creation of intermediate shuffle file streams. You can also set this parameter by setting **spark.shuffle.file.buffer.kb**.	32KB
spark.shuffle.compress	Indicates whether to compress the output files of a Map task. You are advised to compress the broadcast variables. using **spark.io.compression.codec**.	true
spark.reducer.maxSizeInFlight	Specifies the maximum output size of the Map task that fetches data from each Reduce task, in MB. Each output requires a buffer, which is the fixed memory overhead of each Reduce task. Therefore, keep the value small unless there is a large amount of memory. You can also set this parameter by setting **spark.reducer.maxMbInFlight**.	48MB

Driver Configuration

Spark driver can be considered as the client of Spark applications. All code parsing is completed in this process. Therefore, the parameters of this process are especially important. The following describes how to configure parameters for Spark driver.

- **JavaOptions**: parameter following **-D** in the Java command, which can be obtained by **System.getProperty**
- **ClassPath**: path for loading the Java classes and Native library
- **Java Memory and Cores**: memory and CPU usage of the Java process
- **Spark Configuration**: Spark internal parameter, which is irrelevant to the Java process

Table 12-356 Parameter description

Parameter	Description	Default Value
spark.driver.extraJavaOptions	Indicates a series of extra JVM options passed to the driver, for example, GC setting and logging. Note: In client mode, this configuration cannot be set directly in the application using SparkConf because the driver JVM has been started. You can use **--driver-java-options** or the default property file to set the parameter.	For details, see **Configuring Parameters Rapidly**.
spark.driver.extraClassPath	Indicates the extra class path entries attached to the class path of the driver. Note: In client mode, this configuration cannot be set directly in the application using SparkConf because the driver JVM has been started. You can use **--driver-java-options** or the default property file to set the parameter.	For details, see **Configuring Parameters Rapidly**.
spark.driver.userClassPathFirst	(Trial) Indicates whether to allow JAR files added by users to take precedence over Spark JAR files when classes are loaded in the driver. This feature can be used to mitigate conflicts between Spark dependencies and user dependencies. This feature is in the trial phase and is used only in cluster mode.	false
spark.driver.extraLibraryPath	Sets a special library path for starting the driver JVM. Note: In client mode, this configuration cannot be set directly in the application using SparkConf because the driver JVM has been started. You can use **--driver-java-options** or the default property file to set the parameter.	• JDBCServer2x: ${SPARK_INSTALL_HOME}/spark/native • SparkResource2x: ${DATA_NODE_INSTALL_HOME}/hadoop/lib/native

Parameter	Description	Default Value
spark.driver.cores	Specifies the number of cores used by the driver process. This parameter is available only in cluster mode.	1
spark.driver.memory	Indicates the memory used by the driver process, that is, the memory used by the SparkContext initialization process (for example, 512 MB and 2 GB). Note: In client mode, this configuration cannot be set directly in the application using SparkConf because the driver JVM has been started. You can use **--driver-java-options** or the default property file to set the parameter.	4G
spark.driver.maxResultSize	Indicates the total size of serialization results of all partitions for each Spark action operation (for example, collect). The value must be at least 1 MB. If this parameter is set to **0**, the size is not limited. If the total amount exceeds this limit, the task will be aborted. If the value is too large, the memory of the driver may be insufficient (depending on the object memory overhead of **spark.driver.memory** and JVM). Set a proper limit to ensure sufficient memory for the driver.	1G
spark.driver.host	Specifies the host name or IP address for the driver to listen on, which is used for the driver to communicate with the executor.	(local hostname)
spark.driver.port	Specifies the port for the driver to listen on, which is used for the driver to communicate with the executor.	(random)

ExecutorLauncher Configuration

ExecutorLauncher exists only in Yarn-client mode. In Yarn-client mode, ExecutorLauncher and the driver are not in the same process. Therefore, you need to configure parameters for ExecutorLauncher.

Table 12-357 Parameter description

Parameter	Description	Default Value
spark.yarn.am.extraJavaOptions	Indicates a string of extra JVM options to pass to the YARN ApplicationMaster in client mode. Use **spark.driver.extraJavaOptions** in cluster mode.	For details, see **Configuring Parameters Rapidly**.
spark.yarn.am.memory	Indicates the amount of memory to use for the YARN ApplicationMaster in client mode, in the same format as JVM memory strings (for example, 512 MB or 2 GB). In cluster mode, use **spark.driver.memory** instead.	1G
spark.yarn.am.memoryOverhead	This parameter is the same as **spark.yarn.driver.memoryOverhead**. However, this parameter applies only to ApplicationMaster in client mode.	-
spark.yarn.am.cores	Indicates the number of cores to use for the YARN ApplicationMaster in client mode. Use **spark.driver.cores** in cluster mode.	1

Executor Configuration

An executor is a Java process. However, unlike the driver and ApplicationMaster, an executor can have multiple processes. Spark supports only same configurations. That is, the process parameters of all executors must be the same.

Table 12-358 Parameter description

Parameter	Description	Default Value
spark.executor.extraJavaOptions	Indicates extra JVM option passed to the executor, for example, GC setting and logging. Do not set Spark attributes or heap size using this option. Instead, set Spark attributes using the SparkConf object or the **spark-defaults.conf** file specified when the spark-submit script is called. Set heap size using **spark.executor.memory**.	For details, see **Configuring Parameters Rapidly**.

Parameter	Description	Default Value
spark.executor.extraClassPath	Indicates the extra classpath attached to the executor classpath. This parameter ensures compatibility with historical versions of Spark. Generally, you do not need to set this parameter.	-
spark.executor.extraLibraryPath	Sets the special library path used when the executor JVM is started.	For details, see **Configuring Parameters Rapidly**.
spark.executor.userClassPathFirst	(Trial) Same function as **spark.driver.userClassPathFirst**. However, this parameter applies to executor instances.	false
spark.executor.memory	Indicates the memory size used by each executor process. Its character sting is in the same format as the JVM memory (example: 512 MB or 2 GB).	4G
spark.executorEnv.[EnvironmentVariableName]	Adds the environment variable specified by **EnvironmentVariableName** to the executor process. You can specify multiple environment variables.	-
spark.executor.logs.rolling.maxRetainedFiles	Sets the number of latest log files to be retained by the system during rolling. The old log files are deleted. This function is disabled by default.	-
spark.executor.logs.rolling.size.maxBytes	Sets the maximum size of the executor log file for rolling. This function is disabled by default. The value is in bytes. To automatically clear old logs, see **spark.executor.logs.rolling.maxRetainedFiles**.	-
spark.executor.logs.rolling.strategy	Sets the executor log rolling policy. Rolling is disabled by default. The value can be **time** (time-based rolling) or **size** (size-based rolling). If this parameter is set to **time**, the value of the **spark.executor.logs.rolling.time.interval** attribute is used as the log rolling interval. If this parameter is set to **size**, **spark.executor.logs.rolling.size.maxBytes** is used to set the maximum size of the file for rolling.	-

Parameter	Description	Default Value
spark.executor.logs.rolling.time.interval	Sets the time interval for executor log rolling. This function is disabled by default. The value can be **daily**, **hourly**, **minutely**, or any number of seconds. To automatically clear old logs, see **spark.executor.logs.rolling.maxRetainedFiles**.	daily

WebUI

The Web UI displays the running process and status of the Spark application.

Table 12-359 Parameter description

Parameter	Description	Default Value
spark.ui.killEnabled	Allows stages and jobs to be stopped on the web UI. **NOTE** For security purposes, the default value of this parameter is set to **false** to prevent misoperations. To enable this function, set this parameter to **true** in the **spark-defaults.conf** configuration file. Exercise caution when performing this operation.	true
spark.ui.port	Specifies the port for your application's dashboard, which displays memory and workload data.	• JDBCServer2x: **4040** • SparkResource2x: 0 • IndexServer2x: 22901
spark.ui.retainedJobs	Specifies the number of jobs recorded by the Spark UI and status API before GC.	1000
spark.ui.retainedStages	Specifies the number of stages recorded by the Spark UI and status API before GC.	1000

HistoryServer

A History Server reads the **EventLog** file in the file system and displays the running status of the Spark application.

Table 12-360 Parameter description

Parameter	Description	Default Value
spark.history.fs.logDirectory	Specifies the log directory of a History Server.	-
spark.history.ui.port	Specifies the port for JobHistory listening to connection.	18080
spark.history.fs.updateInterval	Specifies the update interval of the information displayed on a History Server, in seconds. Each update checks for changes made to the event logs in the persistent store.	10s
spark.history.fs.update.interval.seconds	Specifies the interval for checking the update of each event log. This parameter has the same function as **spark.history.fs.updateInterval**. **spark.history.fs.updateInterval** is recommended.	10s
spark.history.updateInterval	This parameter has the same function as **spark.history.fs.update.interval.seconds** and **spark.history.fs.updateInterval**. **spark.history.fs.updateInterval** is recommended.	10s

History Server UI Timeout and Maximum Number of Access Times

Table 12-361 Parameter description

Parameter	Description	Default Value
spark.session.maxAge	Specifies the session timeout interval, in seconds. This parameter applies only to the security mode. This parameter cannot be set in normal mode.	600
spark.connection.maxRequest	Specifies the maximum number of concurrent client access requests to JobHistory.	5000

EventLog

During the running of Spark applications, the running status is written into the file system in JSON format in real time for the History Server service to read and reproduce the application running status.

Table 12-362 Parameter description

Parameter	Description	Default Value
spark.eventLog.enabled	Indicates whether to log Spark events, which are used to reconstruct the web UI after the application execution is complete.	true
spark.eventLog.dir	Indicates the directory for logging Spark events if **spark.eventLog.enabled** is set to **true**. In this directory, Spark creates a subdirectory for each application and logs events of the application in the subdirectory. You can also set a unified address similar to the HDFS directory so that the History Server can read historical files.	hdfs://hacluster/spark2xJobHistory2x
spark.eventLog.compress	Indicates whether to compress logged events when **spark.eventLog.enabled** is set to **true**.	false

Periodic Clearing of Event Logs

Event logs on JobHistory increases with submitted tasks. Too many event log files exist as the number of submitted tasks increases. Spark provides the function for periodically clearing event logs. You can enable this function and set the clearing interval using related parameters.

Table 12-363 Parameter description

Parameter	Description	Default Value
spark.history.fs.cleaner.enabled	Indicates whether to enable the clearing function.	true
spark.history.fs.cleaner.interval	Indicates the check interval of the clearing function.	1d
spark.history.fs.cleaner.maxAge	Indicates the maximum duration for storing logs.	4d

Kryo

Kryo is a highly efficient Java serialization framework, which is integrated into Spark by default. Almost all Spark performance tuning requires the process of converting the default serializer of Spark into a Kryo serializer. Kryo serialization

supports only serialization at the Spark data layer. To configure Kryo serialization, set **spark.serializer** to **org.apache.spark.serializer.KryoSerializer** and configure the following parameters to optimize Kryo serialization performance:

Table 12-364 Parameter description

Parameter	Description	Default Value
spark.kryo.classesToRegister	Specifies the name of the class that needs to be registered with Kryo when Kryo serialization is used. Multiple classes are separated by commas (,).	-
spark.kryo.referenceTracking	Indicates whether to trace the references to the same object when Kryo is used to serialize data. This function is applicable to the scenario where the object graph has circular references or the same object has multiple copies. Otherwise, you can disable this function to improve performance.	true
spark.kryo.registrationRequired	Indicates whether Kryo is used to register an object. When this parameter is set to **true**, an exception is thrown if an object that is not registered with Kryo is serialized. When it is set to **false** (default value), Kryo writes unregistered class names to the serialized object. This operation causes a large amount of performance overhead. Therefore, you need to enable this option before deleting a class from the registration queue.	false
spark.kryo.registrator	If Kryo serialization is used, use Kryo to register the class with the custom class. Use this property if you need to register a class in a custom way, such as specifying a custom field serializer. Otherwise, use **spark.kryo.classesToRegister**, which is simpler. Set this parameter to a class that extends KryoRegistrator.	-
spark.kryoserializer.buffer.max	Specifies the maximum size of the Kryo serialization buffer, in MB. The value must be greater than the object that attempts to be serialized. If the error "buffer limit exceeded" occurs in Kryo, increase the value of this parameter. You can also set this parameter by setting **spark.kryoserializer.buffer.max**.	64MB

Parameter	Description	Default Value
spark.kryoserializer.buffer	Specifies the initial size of the Kryo serialization buffer, in MB. Each core of each worker has a buffer. If necessary, the buffer size will be increased to the value of **spark.kryoserializer.buffer.max**. You can also set this parameter by setting **spark.kryoserializer.buffer**.	64KB

Broadcast

Broadcast is used to transmit data blocks between Spark processes. In Spark, broadcast can be used for JAR packages, files, closures, and returned results. Broadcast supports two modes: Torrent and HTTP. The Torrent mode divides data into small fragments and distributes them to clusters. Data can be obtained remotely if necessary. The HTTP mode saves files to the local disk and transfers the entire files to the remote end through HTTP if necessary. The former is more stable than the latter. Therefore, Torrent is the default broadcast mode.

Table 12-365 Parameter description

Parameter	Description	Default Value
spark.broadcast.factory	Indicates the broadcast mode.	org.apache.spark.broadcast.TorrentBroadcastFactory
spark.broadcast.blockSize	Indicates the block size of **TorrentBroadcastFactory**. If the value is too large, the concurrency during broadcast is reduced (the speed is slow). If the value is too small, BlockManager performance may be affected.	4096
spark.broadcast.compress	Indicates whether to compress broadcast variables before sending them. You are advised to compress the broadcast variables.	true

Storage

Spark features in-memory computing. Spark Storage is used to manage memory resources. Storage stores data blocks generated during RDD caching. The heap memory in the JVM acts as a whole. Therefore, **Storage Memory Size** is an important concept during Spark Storage management.

Table 12-366 Parameter description

Parameter	Description	Default Value
spark.storage.memoryMapThreshold	Specifies the block size. If the size of a block exceeds the value of this parameter, Spark performs memory mapping for the disk file. This prevents Spark from mapping too small blocks during memory mapping. Generally, memory mapping for blocks whose page size is close to or less than that of the operating system has high overhead.	2m

PORT

Table 12-367 Parameter description

Parameter	Description	Default Value
spark.ui.port	Specifies the port for your application's dashboard, which displays memory and workload data.	• JDBCServer2x: **4040** • SparkResource2x: 0
spark.blockManager.port	Specifies all ports listened by BlockManager. These ports are on both the driver and executor.	**Range of Random Ports**
spark.driver.port	Specifies the port for the driver to listen on, which is used for the driver to communicate with the executor.	**Range of Random Ports**

Range of Random Ports

All random ports must be within a certain range.

Table 12-368 Parameter description

Parameter	Description	Default Value
spark.random.port.min	Sets the minimum random port.	22600
spark.random.port.max	Sets the maximum random port.	22899

TIMEOUT

By default, computation tasks that can well process medium-scale data are configured in Spark. However, if the data volume is too large, the tasks may fail due to timeout. In the scenario with a large amount of data, the timeout parameter in Spark needs to be assigned a larger value.

Table 12-369 Parameter description

Parameter	Description	Default Value
spark.files.fetchTimeout	Specifies the communication timeout (in seconds) when fetching files added using **SparkContext.addFile()** of the driver.	60s
spark.network.timeout	Specifies the default timeout for all network interactions, in seconds. You can use this parameter to replace **spark.core.connection.ack.wait.timeout**, **spark.akka.timeout**, **spark.storage.blockManagerSlaveTimeoutMs**, or **spark.shuffle.io.connectionTimeout**.	360s
spark.core.connection.ack.wait.timeout	Specifies the timeout for a connection to wait for a response, in seconds. To avoid long-time waiting caused by GC, you can set this parameter to a larger value.	60

Encryption

Spark supports SSL for Akka and HTTP (for the broadcast and file server) protocols, but does not support SSL for the web UI and block transfer service.

SSL must be configured on each node and configured for each component involved in communication using a particular protocol.

Table 12-370 Parameter description

Parameter	Description	Default Value
spark.ssl.enabled	Indicates whether to enable SSL connections for all supported protocols. All SSL settings similar to **spark.ssl.*xxx*** indicate the global configuration of all supported protocols. To override the global configuration of a particular protocol, you must override the property in the namespace specified by the protocol. Use **spark.ssl.YYY.XXX** to overwrite the global configuration of the particular protocol specified by **YYY**. **YYY** can be either **akka** for Akka-based connections or **fs** for the broadcast and file server.	false
spark.ssl.enabledAlgorithms	Indicates the comma-separated list of passwords. The specified passwords must be supported by the JVM.	-
spark.ssl.keyPassword	Specifies the password of a private key in the keystore.	-
spark.ssl.keyStore	Specifies the path of the keystore file. The path can be absolute or relative to the directory where the component is started.	-
spark.ssl.keyStorePassword	Specifies the password of the keystore.	-
spark.ssl.protocol	Specifies the protocol name. This protocol must be supported by the JVM. The reference list of protocols is available on this page.	-
spark.ssl.trustStore	Specifies the path of the truststore file. The path can be absolute or relative to the directory where the component is started.	-
spark.ssl.trustStorePassword	Specifies the password of the truststore.	-

Security

Spark supports shared key-based authentication. You can use **spark.authenticate** to configure authentication. This parameter controls whether the Spark communication protocol uses the shared key for authentication. This authentication is a basic handshake that ensures that both sides have the same shared key and are allowed to communicate. If the shared keys are different, the communication is not allowed. You can create shared keys as follows:

- For Spark on Yarn deployments, set **spark.authenticate** to **true**. Then, shared keys are automatically generated and distributed. Each application exclusively occupies a shared key.

- For other types of Spark deployments, configure Spark parameter **spark.authenticate.secret** on each node. All masters, workers, and applications use this key.

Table 12-371 Parameter description

Parameter	Description	Default Value
spark.acls.enable	Indicates whether to enable Spark ACLs. If Spark ACLs are enabled, the system checks whether the user has the permission to access and modify jobs. Note that this requires the user to be identifiable. If the user is identified as invalid, the check will not be performed. Filters can be used to verify and set users on the UI.	true
spark.admin.acls	Specifies the comma-separated list of users/administrators that have the permissions to view and modify all Spark jobs. This list can be used if you are running on a shared cluster and working with the help of an administrator or developer.	admin
spark.authenticate	Indicates whether Spark authenticates its internal connections. If the application is not running on Yarn, see **spark.authenticate.secret**.	true
spark.authenticate.secret	Sets the key for authentication between Spark components. This parameter must be set if Spark does not run on Yarn and authentication is disabled.	-
spark.modify.acls	Specifies the comma-separated list of users who have the permission to modify Spark jobs. By default, only users who have enabled Spark jobs have the permission to modify the list (for example, delete the list).	-
spark.ui.view.acls	Specifies the comma-separated list of users who have the permission to access the Spark web UI. By default, only users who have enabled Spark jobs have the access permission.	-

Enabling the Authentication Mechanism Between Spark Processes

Spark processes support shared key-based authentication. You can configure **spark.authenticate** to control whether Spark performs authentication during communication. In this authentication mode, the two communication parties share the same key only using simple handshakes.

Configure the following parameters in the **spark-defaults.conf** file on the Spark client.

Table 12-372 Parameter description

Parameter	Description	Default Value
spark.authenticate	For Spark on Yarn deployments, set this parameter to **true**. Then, keys are automatically generated and distributed, and each application uses a unique key.	true

Compression

Data compression is policy that optimizes memory usage at the expense of CPU. Therefore, when the Spark memory is severely insufficient (this issue is common due to the characteristics of in-memory computing), data compression can greatly improve performance. Spark supports three types of compression algorithm: Snappy, LZ4, and LZF. Snappy is the default compression algorithm and invokes the native method to compress and decompress data. In Yarn mode, pay attention to the impact of non-heap memory on the container process.

Table 12-373 Parameter description

Parameter	Description	Default Value
spark.io.compression.codec	Indicates the codec for compressing internal data, such as RDD partitions, broadcast variables, and shuffle output. By default, Spark supports three types of compression algorithm: LZ4, LZF, and Snappy. You can specify algorithms using fully qualified class names, such as **org.apache.spark.io.LZ4CompressionCodec**, **org.apache.spark.io.LZFCompressionCodec**, and **org.apache.spark.io.SnappyCompression-Codec**.	lz4
spark.io.compression.lz4.block.size	Indicates the block size (bytes) used in LZ4 compression when the LZ4 compression algorithm is used. When LZ4 is used, reducing the block size also reduces the shuffle memory usage.	32768
spark.io.compression.snappy.block.size	Indicates the block size (bytes) used in Snappy compression when the Snappy compression algorithm is used. When Snappy is used, reducing the block size also reduces the shuffle memory usage.	32768
spark.shuffle.compress	Indicates whether to compress the output files of a Map task. You are advised to compress the broadcast variables. using **spark.io.compression.codec**.	true

Parameter	Description	Default Value
spark.shuffle.spill.compress	Indicates whether to compress the data overflowed during shuffle using **spark.io.compression.codec**.	true
spark.eventLog.compress	Indicates whether to compress logged events when **spark.eventLog.enabled** is set to **true**.	false
spark.broadcast.compress	Indicates whether to compress broadcast variables before sending them. You are advised to compress the broadcast variables.	true
spark.rdd.compress	Indicates whether to compress serialized RDD partitions (for example, the **StorageLevel.MEMORY_ONLY_SER** partition). Substantial space can be saved at the cost of some extra CPU time.	false

Reducing the Probability of Abnormal Client Application Operations When Resources Are Insufficient

When resources are insufficient, ApplicationMaster tasks must wait and will not be processed until enough resources are available for use. If the actual waiting time exceeds the configured waiting time, the ApplicationMaster tasks will be deleted. Adjust the following parameters to reduce the probability of abnormal client application operation.

Configure the following parameters in the **spark-defaults.conf** file on the client.

Table 12-374 Parameter description

Parameter	Description	Default Value
spark.yarn.applicationMaster.waitTries	Specifies the number of the times that ApplicationMaster waits for Spark master, which is also the times that ApplicationMaster waits for SparkContext initialization. Enlarge this parameter value to prevent ApplicationMaster tasks from being deleted and reduce the probability of abnormal client application operations.	10
spark.yarn.am.memory	Specifies the ApplicationMaster memory. Enlarge this parameter value to prevent ApplicationMaster tasks from being deleted by ResourceManager due to insufficient memory and reduce the probability of abnormal client application operations.	1G

12.23.2.4 Spark on HBase Overview and Basic Applications

Scenario

Spark on HBase allows users to query HBase tables in Spark SQL and to store data for HBase tables by using the Beeline tool. You can use HBase APIs to create, read data from, and insert data into tables.

Procedure

Step 1 Log in to Manager and choose **Cluster** > *Name of the desired cluster* > **Cluster Properties** to check whether the cluster is in security mode.

- If yes, go to **Step 2**.
- If no, go to **Step 5**.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Service** > **Spark2x** > **Configuration** > **All Configurations** > **JDBCServer2x** > **Default**, and modify the following parameter.

Table 12-375 Parameter list 1

Parameter	Default Value	Changed To
spark.yarn.security.credentials.hbase.enabled	false	true

NOTE

To ensure that Spark2x can access HBase for a long time, do not modify the following parameters of the HBase and HDFS services:

- dfs.namenode.delegation.token.renew-interval
- dfs.namenode.delegation.token.max-lifetime
- hbase.auth.key.update.interval
- hbase.auth.token.max.lifetime (The value is fixed to **604800000** ms, that is, 7 days.)

If the preceding parameter configuration must be modified based on service requirements, ensure that the value of the HDFS parameter **dfs.namenode.delegation.token.renew-interval** is not greater than the values of the HBase parameters **hbase.auth.key.update.interval**, **hbase.auth.token.max.lifetime**, and **dfs.namenode.delegation.token.max-lifetime**.

Step 3 Choose **SparkResource2x** > **Default** and modify the following parameters.

Table 12-376 Parameter list 2

Parameter	Default Value	Changed To
spark.yarn.security.credentials.hbase.enabled	false	true

Step 4 Restart the Spark2x service for the configuration to take effect.

NOTE

To use the Spark on HBase function on the Spark2x client, you need to download and install the Spark2x client again.

Step 5 On the Spark2x client, use the spark-sql or spark-beeline connection to query tables created by Hive on HBase. You can create an HBase table by running SQL commands or create an external table to associate the HBase table. Before creating tables, ensure that HBase tables exist in HBase. The HBase table **table1** is used as an example.

1. Run the following commands to create the HBase table using the Beeline tool:

   create table *hbaseTable*

   (

   id string,

   name string,

   age int

)

   using org.apache.spark.sql.hbase.HBaseSource

   options(

   hbaseTableName *"table1"***,**

   keyCols *"id"***,**

   colsMapping "

   name=cf1.cq1,

   age=cf1.cq2

   ");

   NOTE

   - **hbaseTable**: name of the created Spark table
   - **id string,name string**, **age int**: field name and field type of the Spark table
   - **table1**: name of the HBase table
   - *id*: row key column name of the HBase table
   - *name=cf1.cq1*, *age=cf1.cq2*: mapping between columns in the Spark table and columns in the HBase table. The **name** column of the Spark table maps the **cq1** column in the **cf1** column family of the HBase table, and the **age** column of the Spark table maps the **cq2** column in the **cf1** column family of the HBase table.

2. Run the following command to import data to the HBase table using a CSV file:

   hbase org.apache.hadoop.hbase.mapreduce.ImportTsv -Dimporttsv.separator="," -Dimporttsv.columns=HBASE_ROW_KEY,*cf1:cq1,cf1:cq2,cf1:cq3,cf1:cq4,cf1:cq5 table1 /hperson*

   Where **table1** indicates the name of the HBase table, and **/hperson** indicates the path where the CSV file is stored.

3. Run the following command to query data in spark-sql or spark-beeline, where *hbaseTable* is the corresponding Spark table name: The command is as follows:

select * from *hbaseTable;*

----End

12.23.2.5 Spark on HBase V2 Overview and Basic Applications

Scenario

Spark on HBase V2 allows users to query HBase tables in Spark SQL and to store data for HBase tables by using the Beeline tool. You can use HBase APIs to create, read data from, and insert data into tables.

Procedure

Step 1 Log in to Manager and choose **Cluster** > *Name of the desired cluster* > **Cluster Properties** to check whether the cluster is in security mode.

- If yes, go to **Step 2**.
- If no, go to **Step 5**.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Service** > **Spark2x** > **Configuration** > **All Configurations** > **JDBCServer2x** > **Default**, and modify the following parameter.

Table 12-377 Parameter list 1

Parameter	Default Value	Changed To
spark.yarn.security.credentials.hbase.enabled	false	true

NOTE

To ensure that Spark2x can access HBase for a long time, do not modify the following parameters of the HBase and HDFS services:

- dfs.namenode.delegation.token.renew-interval
- dfs.namenode.delegation.token.max-lifetime
- hbase.auth.key.update.interval
- hbase.auth.token.max.lifetime (The value is fixed to **604800000** ms, that is, 7 days.)

If the preceding parameter configuration must be modified based on service requirements, ensure that the value of the HDFS parameter **dfs.namenode.delegation.token.renew-interval** is not greater than the values of the HBase parameters **hbase.auth.key.update.interval**, **hbase.auth.token.max.lifetime**, and **dfs.namenode.delegation.token.max-lifetime**.

Step 3 Choose **SparkResource2x** > **Default** and modify the following parameters.

Table 12-378 Parameter list 2

Parameter	Default Value	Changed To
spark.yarn.security.credentials.hbase.enabled	false	true

Step 4 Restart the Spark2x service for the configuration to take effect.

NOTE

If you need to use the Spark on HBase function on the Spark2x client, download and install the Spark2x client again.

Step 5 On the Spark2x client, use the spark-sql or spark-beeline connection to query tables created by Hive on HBase. You can create an HBase table by running SQL commands or create an external table to associate the HBase table. For details, see the following description. The following uses the HBase table **table1** as an example.

1. Run the following commands to create a table using the spark-beeline tool:

   create table *hbaseTable*1
   (*id string, name string, age int***)**
   using org.apache.spark.sql.hbase.HBaseSourceV2
   options(
   hbaseTableName *"table2"***,**
   keyCols *"id"***,**
   colsMapping "*name=cf1.cq1,age=cf1.cq2***");**

   NOTE

   - **hbaseTable1**: name of the created Spark table
   - **id string,name string**, **age int**: field name and field type of the Spark table
   - **table2**: name of the HBase table
   - *id*: row key column name of the HBase table
   - *name=cf1.cq1*, *age=cf1.cq2*: mapping between columns in the Spark table and columns in the HBase table. The **name** column of the Spark table maps the **cq1** column in the **cf1** column family of the HBase table, and the **age** column of the Spark table maps the **cq2** column in the **cf1** column family of the HBase table.

2. Run the following command to import data to the HBase table using a CSV file:

   hbase org.apache.hadoop.hbase.mapreduce.ImportTsv -Dimporttsv.separator="," -Dimporttsv.columns=HBASE_ROW_KEY,*cf1:cq1,cf1:cq2,cf1:cq3,cf1:cq4,cf1:cq5 table2 /hperson*

   Where **table2** indicates the name of the HBase table, and **/hperson** indicates the path where the CSV file is stored.

3. Run the following command to query data in spark-sql or spark-beeline. *hbaseTable1* indicates the corresponding Spark table name.

   select * from *hbaseTable1;*

----End

12.23.2.6 SparkSQL Permission Management(Security Mode)

12.23.2.6.1 Spark SQL Permissions

SparkSQL Permissions

Similar to Hive, Spark SQL is a data warehouse framework built on Hadoop, providing storage of structured data like structured query language (SQL).

MRS supports users, user groups, and roles. Permission must be assigned to roles and then roles are bound to users or user groups. Users can obtain permissions only by binding a role or joining a group that is bound with a role.

NOTE

- If the current component uses Ranger for permission control, you need to configure permission management policies based on Ranger. For details, see **Adding a Ranger Access Permission Policy for Spark2x**.
- After Ranger authentication is enabled or disabled on Spark2x, you need to restart Spark2x and download the client again or update the client configuration file **spark/conf/spark-defaults.conf**.

  Enable Ranger authentication: **spark.ranger.plugin.authorization.enable=true**

  Disable Ranger authentication: **spark.ranger.plugin.authorization.enable=false**

Permission Management

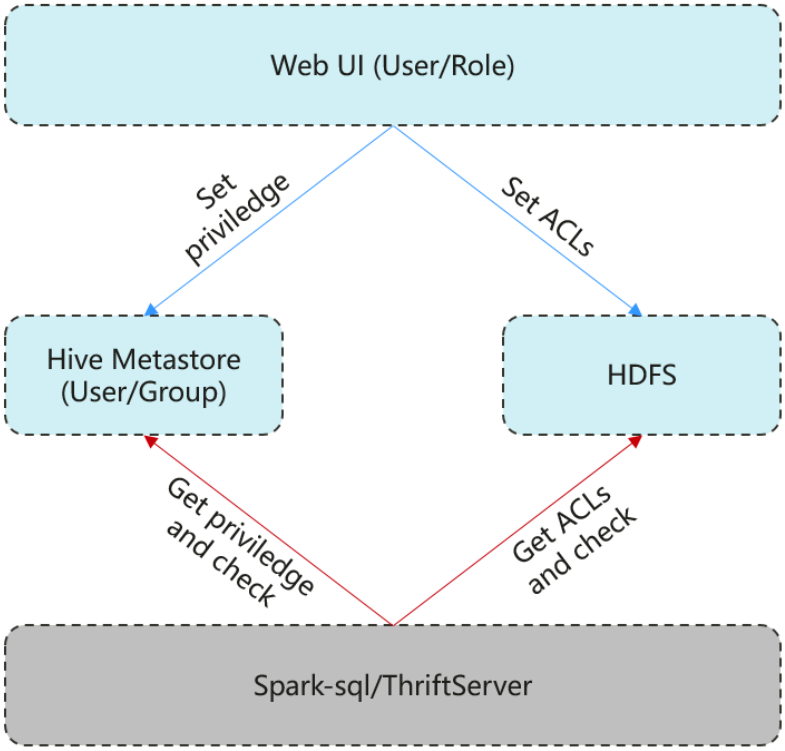
Spark SQL permission management indicates the permission system for managing and controlling users' operations on databases, to ensure that different users can operate databases separately and securely. A user can operate another user's tables and databases only with the corresponding permissions. Otherwise, operations will be rejected.

Spark SQL permission management integrates the functions of Hive management. The MetaStore service of Hive and the permission granting function on the page are required to enable Spark SQL permission management.

Figure 12-53 shows the basic architecture of SparkSQL permission management. This architecture includes two parts: granting permissions on the page, and obtaining and judging a service.

- Granting permissions on the page: Spark SQL only supports granting permissions on the page. On FusionInsight Manager, choose **System** > **Permission** to add or delete a user, user group, or a role, and to grant permissions or cancel permissions.
- Obtaining and judging a service: When the DDL and DML commands are received from a client, Spark SQL will obtain the client's permissions on database information from MetaStore, and check whether the required permissions are included. If the required permissions are included, continue the execution. If the required permissions are not included, reject the user's operations. After the MetaStore permissions are checked, ACL permission also needs to be checked on HDFS.

Figure 12-53 Spark SQL permission management architecture



Additionally, Spark SQL provides column and view permissions to meet requirements of different scenarios.

- Column permission

  Spark SQL permission control consists of metadata permission control and HDFS ACL permission control. When Hive MetaStore automatically synchronizes table permissions to the HDFS ACL, column-level permissions are not synchronized. In other words, a user with partial or all column-level permissions cannot access the entire HDFS file using the HDFS client.

  - In **spark-sql** mode, users with only column-level permissions cannot access HDFS files. Therefore, they cannot access the columns of the corresponding tables.
  - In Beeline/JDBCServer mode, permissions are assigned among users, for example, the permissions on the table created by user A are assigned to user B.

    - **hive.server2.enable.doAs**=**true** (configured in the **hive-site.xml** file on the Spark server)

      In this case, user B cannot query the information. You need to manually assign the read permission on the file in HDFS.

    - **hive.server2.enable.doAs**=false
      - Users A and B are connected by Beeline. User B can query the information.
      - User A creates a table using SQL statements, and user B can query the table in Beeline.

      However, information query is not supported in other scenarios, for example, user A uses Beeline to create a table and user B uses SQL

to query the table, or user A uses SQL to create a table and user B uses SQL to query the table. You need to manually assign the read permission on the file in HDFS.

NOTE

The **spark** user is an administrator in HDFS ACL permission control. The permission control of the Beeline client user depends only on the metadata permission on Spark.

- View permission

  View permission indicates the operation permission such as query and modification on the view of a table, regardless of the corresponding permission of a table. Namely, if you have the permission to query the view of a table, the permission to query the table is not mandatory. The view permission is applicable to the whole table but not to the columns.

  Restrictions of view and column permissions on SparkSQL are similar. The following uses the view permission as an example:

  - In spark-sql mode, if you have only the view permission but not the table permission and do not have the permission to read HDFS, you cannot access the table data stored in HDFS. That is, you cannot query the view of the table.
  - In Beeline/JDBCServer mode, permissions are assigned among users, for example, the permissions on the view created by user A are assigned to user B.

    - **hive.server2.enable.doAs**=**true** (configured in the **hive-site.xml** file on the Spark server)

      In this case, user B cannot query the information. You need to manually assign the read permission on the file in HDFS.

    - **hive.server2.enable.doAs**=false
      - Users A and B are connected by Beeline. User B can query the information.
      - User A creates a view using SQL statements, and user B can query the view in Beeline.

      However, information query is not supported in other scenarios. For example, user A uses Beeline to create a view but user B cannot use SQL to query the view, or user A uses SQL to create a view but user B cannot use SQL to query the view. You need to manually assign the read permission on the file in HDFS.

  Permission of operations on the view of a table is as follows:

  - To create a view, you must have the CREATE permission on the database and the SELECT and SELECT_of_GRANT permissions on the tables.
  - Creating and describing a view only entail the SELECT permission on the view. Querying views and tables at the same time entails the SELECT permission on other tables. For example, to perform **select * from v1 join t1**, you must have the SELECT permission on the **v1** view and **t1** table, even through the **v1** view depends on the **t1** table.

NOTE

In Beeline/JDBCServer mode, to query a view, you must have the SELECT permission on the tables. In spark-sql mode, to query a view, you must have the SELECT permission on the view and tables.

- Deleting and modifying a view entail the permission of owner on the view.

SparkSQL Permission Model

If you want to perform SQL operations using SparkSQL, you must be granted with permissions of SparkSQL databases and tables (include external tables and views). The complete permission model of SparkSQL consists of the meta data permission and HDFS file permission. Permissions required to use a database or a table is just one type of SparkSQL permission.

- Metadata permissions

  Metadata permissions are controlled at the metadata layer. Similar to traditional relational databases, SparkSQL databases involve the CREATE and SELECT permissions, and tables and columns involve the SELECT, INSERT, UPDATE, and DELETE permissions. SparkSQL also supports the permissions of **OWNERSHIP** and **ADMIN**.

- Data file permissions (that is, HDFS file permissions)

  SparkSQL database and table files are stored in HDFS. The created databases or tables are saved in the **/user/hive/warehouse** directory of HDFS by default. The system automatically creates subdirectories named after database names and database table names. To access a database or table, you must have the **Read**, **Write** and **Execute** permissions on the corresponding file in HDFS.

To perform various operations on SparkSQL databases or tables, you need to associate the metadata permission and HDFS file permission. For example, to query SparkSQL data tables, you need to associate the metadata permission **SELECT** and HDFS file permissions **Read** and **Execute**.

Using the management function of Manager GUI to manage the permissions of SparkSQL databases and tables, only requires the configuration of metadata permission, and the system will automatically associate and configure the HDFS file permission. In this way, operations on the interface are simplified, and the efficiency is improved.

Usage Scenarios and Related Permissions

Creating a database with SparkSQL service requires users to join in the hive group, without granting a role. Users have all permissions on the databases or tables created by themselves in Hive or HDFS. They can create tables, select, delete, insert, or update data, and grant permissions to other users to allow them to access the tables and corresponding HDFS directories and files.

A user can access the tables or database only with permissions. Users' permissions vary depending on different SparkSQL scenarios.

Table 12-379 SparkSQL scenarios

Typical Scenario	Required Permission
Using SparkSQL tables, columns, or databases	Permissions required in different scenarios are as follows: ● To create a table, the CREATE permission is required. ● To query data, the SELECT permission is required. ● To insert data, the INSERT permission is required.
Associating and using other components	In some scenarios, except the SparkSQL permission, other permissions may be also required. For example: Using Spark on HBase to query HBase data in SparkSQL requires HBase permissions.

In some special SparkSQL scenarios, other permissions must be configured separately.

Table 12-380 SparkSQL scenarios and required permissions

Scenario	Required Permission
Creating SparkSQL databases, tables, and external tables, or adding partitions to created Hive tables or external tables when data files specified by Hive users are saved to other HDFS directories except **/user/hive/warehouse**	● The directory must exist, the client user must be the owner of the directory, and the user must have the **Read**, **Write**, and **Execute** permissions on the directory. The user must have the **Read** and **Execute** permissions of all the upper-layer directories of the directory. ● If the Spark version is later than 2, the **Create** permission of the Hive database is required if you want to create a HBase table. However, in Spark 1.5, the **Create** permissions of both the Hive database and HBase namespace are required if you want to create a HBase table.

Scenario	Required Permission
Importing all the files or specified files in a specified directory to the table using load	• The data source is a Linux local disk, the specified directory exists, and the system user **omm** has read and execute permission of the directory and all its upper-layer directories. The specified file exists, and user **omm** has the **Read** permission on the file and has the **Read** and **Execute** permissions on all the upper-layer directories of the file. • The data source is HDFS, the specified directory exists, and the SparkSQL user is the owner of the directory and has the **Read**, **Write**, and **Execute** permissions on the directory and its subdirectories, and has the **Read** and **Execute** permissions on all its upper-layer directories. The specified file exists, and the SparkSQL user is the owner of the file and has the **Read**, **Write**, and **Execute** permissions on the file and has the **Read** and **Execute** permissions on all its upper-layer directories.
Creating or deleting functions or modifying any database	The **ADMIN** permission is required.
Performing operations on all databases and tables in Hive	The user must be added to the **supergroup** user group, and be assigned the **ADMIN** permission.
After assigning the **Insert** permission on some DataSource tables, assigning the **Write** permission on table directories in HDFS before performing the insert or analyze operation	When the **Insert** permission is assigned to the **spark datasource** table, if the table format is text, CSV, JSON, Parquet, or ORC, the permission on the table directory is not changed. After the **Insert** permission is assigned to the DataSource table of the preceding formats, you need to assign the **Write** permission to the table directories in HDFS separately so that users can perform the insert or analyze operation on the tables.

12.23.2.6.2 Creating a Spark SQL Role

Scenario

This section describes how to create and configure a SparkSQL role on Manager as the system administrator. The Spark SQL role can be configured with the administrator permission or the permission of performing operations on the table data.

Creating a database with Hive requires users to join in the **hive** group, without granting a role. Users have all permissions on the databases or tables created by themselves in Hive or HDFS. They can create tables, select, delete, insert, or update data, and grant permissions to other users to allow them to access the

tables and corresponding HDFS directories and files. The created databases or tables are saved in the **/user/hive/warehouse** directory of HDFS by default.

NOTE

- If the current component uses Ranger for permission control, you need to configure permission management policies based on Ranger. For details, see **Adding a Ranger Access Permission Policy for Spark2x**.
- After Ranger authentication is enabled or disabled on Spark2x, you need to restart Spark2x and download the client again or update the client configuration file **spark/conf/spark-defaults.conf**.

  Enable Ranger authentication: **spark.ranger.plugin.authorization.enable=true**

  Disable Ranger authentication: **spark.ranger.plugin.authorization.enable=false**

Procedure

1. Log in to Manager, and choose **System > Permission > Role**.
2. Click **Create Role** and set a role name and enter description.
3. Set **Configure Resource Permission**. For details, see **Table 12-381**.
   - **Hive Admin Privilege**: Hive administrator permissions.
   - **Hive Read Write Privileges**: Hive data table management permission, which is the operation permission to set and manage the data of created tables.

     NOTE

     - Hive role management supports the administrator permission, and the permissions of accessing tables and views, without granting the database permission.
     - The permissions of the Hive administrator do not include the permission to manage HDFS.
     - If there are too many tables in the database or too many files in tables, the permission granting may last a while. For example, if a table contains 10,000 files, the permission granting lasts about 2 minutes.

Table 12-381 Setting a role

Task	Operation
Hive administrator permission	In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** and select **Hive Admin Privilege**. After being bound to the Hive administrator role, perform the following operations during each maintenance operation: 1. Log in to the node where the Spark2x client is installed as the client installation user. 2. Run the following command to configure environment variables: For example, if the Spark2x client installation directory is **/opt/client**, run **source /opt/client/bigdata_env**. **source /opt/client/Spark2x/component_env** 3. Run the following command to perform user authentication: ***kinit*** *Hive service user* 4. Run the following command to log in to the client tool: **/opt/client/Spark2x/spark/bin/beeline -u "jdbc:hive2://<zkNode1_IP>:<zkNode1_Port>,<zkNode2_IP>:<zkNode2_Port>,<zkNode3_IP>:<zkNode3_Port>/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver2x;user.principal=spark2x/hadoop.***<*system domain name*>**@**<*system domain name*>**;saslQop=auth-conf;auth=KERBEROS;principal=spark2x/hadoop.***<*system domain name*>**@**<*system domain name*>**;"**

Task	Operation
	NOTE • **<zkNode1_IP>:<zkNode1_Port>,<zkNode2_IP>:<zkNode2_Port>,<zkNode3_IP>:<zkNode3_Port>** indicates the ZooKeeper URL, for example, 192.168.81.37:2181,192.168.195.232:2181,192.168.169.84:2181. • **sparkthriftserver** indicates a ZooKeeper directory, from which a random TriftServer or ProxyThriftServer is connected by the client. • You can log in to Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and view the value of **Local Domain**, which is the current system domain name. **spark2x/hadoop.**<*System domain name*> is the username. All letters in the system domain name contained in the username are lowercase letters. For example, **Local Domain** is set to **9427068F-6EFA-4833-B43E-60CB641E5B6C.COM**, and the username is **spark2x/hadoo.9427068f-6efa-4833-b43e-60cb641e5b6c.com**. 5. Run the following command to update the administrator permissions: **set role admin;**
Setting the permission to query a table of another user in the default database	1. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges**. 2. Click the name of the specified database in the database list. Tables in the database are displayed. 3. In the **Permission** column of the specified table, select **SELECT**.
Setting the permission to import data to a table of another user in the default database	1. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges**. 2. Click the name of the specified database in the database list. Tables in the database are displayed. 3. In the **Permission** column of the specified table, select **DELETE** and **INSERT**.

4. Click **OK**.

12.23.2.6.3 Configuring Permissions for SparkSQL Tables, Columns, and Databases

Scenario

You can configure related permissions if you need to access tables or databases created by other users. SparkSQL supports column-based permission control. If a

user needs to access some columns in tables created by other users, the user must be granted the permission for columns. The following describes how to grant table, column, and database permissions to users by using the role management function of Manager.

Procedure

The operations for granting permissions on SparkSQL tables, columns, and databases are the same as those for Hive. For details, see **Permission Management**.

NOTE

- Any permission for a table in the database is automatically associated with the HDFS permission for the database directory to facilitate permission management. When any permission for a table is canceled, the system does not automatically cancel the HDFS permission for the database directory to ensure performance. In this case, users can only log in to the database and view table names.
- When the query permission on a database is added to or deleted from a role, the query permission on tables in the database is automatically added to or deleted from the role. This mechanism is inherited from Hive.
- In Spark, the column name of the struct data type cannot contain special characters, that is, characters other than letters, digits, and underscores (_). If the column name of the struct data type contains special characters, the column cannot be displayed on the FusionInsight Manager console when you grant permissions to roles on the role page.

Concepts

SparkSQL statements are processed in SparkSQL. **Table 12-382** describes the permission requirements.

Table 12-382 Scenarios of using SparkSQL tables, columns, or databases

Scenario	Required Permission
CREATE TABLE	**CREATE**, RWX+ownership (for creating external tables - the location) **NOTE** When creating datasource tables in a specified file path, the RWX and ownership permission on the file next to the path is required.
DROP TABLE	**Ownership** (of table)
DROP TABLE PROPERTIES	**Ownership**
DESCRIBE TABLE	**Select**
SHOW PARTITIONS	**Select**
ALTER TABLE LOCATION	**Ownership**, RWX+ownership (for new location)
ALTER PARTITION LOCATION	**Ownership**, RWX+ownership (for new partition location)
ALTER TABLE ADD PARTITION	**Insert**, RWX and ownership (for partition location)

Scenario	Required Permission
ALTER TABLE DROP PARTITION	**Delete**
ALTER TABLE(all of them except the ones above)	**Update**, **Ownership**
TRUNCATE TABLE	**Ownership**
CREATE VIEW	**Select**, **Grant Of Select**, **CREATE**
ALTER VIEW PROPERTIES	**Ownership**
ALTER VIEW RENAME	**Ownership**
ALTER VIEW ADD PARTS	**Ownership**
ALTER VIEW AS	**Ownership**
ALTER VIEW DROPPARTS	**Ownership**
ANALYZE TABLE	**Search**, **Insert**
SHOW COLUMNS	**Select**
SHOW TABLE PROPERTIES	**Select**
CREATE TABLE AS SELECT	**Select**, **CREATE**
SELECT	**Select** **NOTE** The same as tables, you need to have the **Select** permission on a view when performing a SELECT operation on the view.
INSERT	**Insert**, **Delete (for overwrite)**
LOAD	**Insert**, **Delete**, RWX+ownership(input location)
SHOW CREATE TABLE	**Select**, **Grant Of Select**
CREATE FUNCTION	**ADMIN**
DROP FUNCTION	**ADMIN**
DESC FUNCTION	-
SHOW FUNCTIONS	-
MSCK (metastore check)	**Ownership**
ALTER DATABASE	**ADMIN**
CREATE DATABASE	-
SHOW DATABASES	-
EXPLAIN	**Select**
DROP DATABASE	**Ownership**

Scenario	Required Permission
DESC DATABASE	-
CACHE TABLE	**Select**
UNCACHE TABLE	**Select**
CLEAR CACHE TABLE	**ADMIN**
REFRESH TABLE	**Select**
ADD FILE	**ADMIN**
ADD JAR	**ADMIN**
HEALTHCHECK	-

12.23.2.6.4 Configuring Permissions for SparkSQL to Use Other Components

Scenario

SparkSQL may need to be associated with other components. For example, Spark on HBase requires HBase permissions. The following describes how to associate SparkSQL with HBase.

Prerequisites

- The Spark client has been installed. For example, the installation directory is **/opt/client**.
- You have obtained a user account with the administrator permissions, such as **admin**.

Procedure

- **Spark on HBase authorization**

  After the permissions are assigned, you can use statements that are similar to SQL statements to access HBase tables from SparkSQL. The following uses the procedure for assigning a user the permissions to query HBase tables as an example.

  NOTE

  Set **spark.yarn.security.credentials.hbase.enabled** to **true**.

  a. On Manager, create a role, for example, **hive_hbase_create**, and grant the permission to create HBase tables to the role.

  In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **HBase** > **HBase Scope** > **global**. Select **create** of the namespace **default**, and click **OK**.

NOTE

In this example, the created table is saved in the default database of Hive and has the CREATE permission of the default database. If you save the table to a Hive database other than **default**, perform the following operations:

In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges**, select **CREATE** for the desired database, and click **OK**.

b. On Manager, create a role, for example, **hive_hbase_submit**, and grant the permission to submit tasks to the Yarn queue.

In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Yarn** > **Scheduling Queue** > **root**. Select **Submit** of **default**, and click **OK**.

c. On Manager, create a human-machine user, for example, **hbase_creates_user**, add the user to the **hive** group, and bind the **hive_hbase_create** and **hive_hbase_submit** roles to create SparkSQL and HBase tables.

d. Log in to the node where the client is installed as the client installation user.

e. Run the following command to configure environment variables:

source /opt/client/bigdata_env

source /opt/client/Spark2x/component_env

f. Run the following command to authenticate the user:

kinit hbase_creates_user

g. Run the following commands to enter the shell environment on the Spark JDBCServer client:

/opt/client/Spark2x/spark/bin/beeline -u "jdbc:hive2://<zkNode1_IP>:<zkNode1_Port>,<zkNode2_IP>:<zkNode2_Port>,<zkNode3_IP>:<zkNode3_Port>/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver2x;user.principal=spark2x/hadoop.*<system domain name>***@***<system domain name>***;saslQop=auth-conf;auth=KERBEROS;principal=spark2x/hadoop.***<system domain name>***@***<system domain name>***;"**

h. Run the following command to create a table in SparkSQL and HBase, for example, create the **hbaseTable** table:

create table hbaseTable (id string, name string, age int) using org.apache.spark.sql.hbase.HBaseSource options (hbaseTableName "table1", keyCols "id", colsMapping = ", name=cf1.cq1, age=cf1.cq2");

The created SparkSQL table and the HBase table are stored in the Hive database **default** and the HBase namespace **default**, respectively.

i. On Manager, create a role, for example, **hive_hbase_select**, and grant the role the permission to query SparkSQL on HBase table **hbaseTable** and HBase table **hbaseTable**.

- In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **HBase** > **HBase Scope** > **global** > **default**. Select **read** for the **hbaseTable** table, and click **OK** to grant the table query permission to the HBase role.

- Edit the role. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **HBase** > **HBase Scope** > **global** > **hbase**. Select **Execute** for **hbase:meta**, and click **OK**.
- Edit the role. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges** > **default**. Select **SELECT** for the **hbaseTable** table, and click **OK**.

j. On Manager, create a human-machine user, for example, **hbase_select_user**, add the user to the **hive** group, and bind the **hive_hbase_select** role to the user for querying SparkSQL and HBase tables.

k. Run the following command to configure environment variables:

source /opt/client/bigdata_env

source /opt/client/Spark2x/component_env

l. Run the following command to authenticate users:

kinit hbase_select_user

m. Run the following commands to enter the shell environment on the Spark JDBCServer client:

/opt/client/Spark2x/spark/bin/beeline -u "jdbc:hive2://<zkNode1_IP>:<zkNode1_Port>,<zkNode2_IP>:<zkNode2_Port>,<zkNode3_IP>:<zkNode3_Port>/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=sparkthriftserver2x;user.principal=spark2x/hadoop.*<system domain name>*@*<system domain name>*;saslQop=auth-conf;auth=KERBEROS;principal=spark2x/hadoop.*<system domain name>*@*<system domain name>*;"

n. Run the following command to use a SparkSQL statement to query HBase table data:

select * from hbaseTable;

12.23.2.6.5 Configuring the Client and Server

This section describes how to configure SparkSQL permission management functions (client configuration is similar to server configuration). To enable table permission, add following configurations on the client and server:

- **spark-defaults.conf** configuration file

  Table 12-383 Parameter description (1)

Parameter	Description	Default Value
spark.sql.authorization.enabled	Specifies whether to enable permission authentication of the datasource statement. It is recommended that the parameter value be set to **true** to enable permission authentication.	true

- **hive-site.xml** configuration file

Table 12-384 Parameter description (2)

Parameter	Description	Default Value
hive.metastore.uris	Specifies the MetaStore service address of the Hive component, for example, **thrift://10.10.169.84:21088,thrift://10.10.81.37:21088**.	-
hive.metastore.sasl.enabled	Specifies whether the MetaStore service uses SASL to improve security. The table permission function must be enabled.	true
hive.metastore.kerberos.principal	Specifies the principal of the MetaStore service in the Hive component, for example, **hive/hadoop.**<*system domain name*>@<*system domain name*>.	hive-metastore/_HOST@EXAMPLE.COM
hive.metastore.thrift.sasl.qop	After the SparkSQL permission management function is enabled, set the parameter to **auth-conf**.	auth-conf
hive.metastore.token.signature	Specifies the token identifier of the MetaStore service, which is set to **HiveServer2ImpersonationToken**.	HiveServer2ImpersonationToken
hive.security.authenticator.manager	Specifies the manager authenticated by the Hive client, which is set to **org.apache.hadoop.hive.ql.security.SessionStateUserGroupAuthenticator**.	org.apache.hadoop.hive.ql.security.SessionStateUserMSGroupAuthenticator
hive.security.authorization.enabled	Specifies whether to enable client authentication, which is set to **true**.	true
hive.security.authorization.createtable.owner.grants	Specifies which permissions are granted to the owner who creates the table, which is set to **ALL**.	ALL

- **core-site.xml** configuration file of the MetaStore service

Table 12-385 Parameter description (3)

Parameter	Description	Default Value
hadoop.proxyuser.spark.hosts	Specifies the hosts from which Spark users can be masqueraded, which is set to *****, indicating all hosts.	-
hadoop.proxyuser.spark.groups	Specifies the user groups from which Spark users can be masqueraded, which is set to *****, indicating all user groups.	-

12.23.2.7 Scenario-Specific Configuration

12.23.2.7.1 Configuring Multi-active Instance Mode

Scenarios

In this mode, multiple ThriftServers coexist in the cluster and the client can randomly connect any ThriftServer to perform service operations. When one or multiple ThriftServers stop working, a client can connect to another functional ThriftServer.

Configuration Description

Log in to Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **Spark2x** > **Configurations**, click **All Configurations**, and search for and modify the following parameters.

Table 12-386 Parameter description

Parameter	Description	Default Value
spark.thriftserver.zookeeper.connection.timeout	Specifies the timeout interval of connection between ZooKeeper client and ThriftServer. The unit is millisecond.	60000
spark.thriftserver.zookeeper.session.timeout	Specifies the timeout interval of a ZooKeeper client session. The unit is millisecond.	90000
spark.thriftserver.zookeeper.retry.times	Specifies the retry times after ZooKeeper disconnection.	3
spark.yarn.queue	Specifies the Yarn queue where the JDBCServer service resides.	default

12.23.2.7.2 Configuring the Multi-tenant Mode

Scenarios

In multi-tenant mode, JDBCServers are bound with tenants. Each tenant corresponds to one or more JDBCServers, and a JDBCServer provides services for only one tenant. Different tenants can be configured with different Yarn queues to implement resource isolation.

Configuration Description

Log in to Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **Spark2x** > **Configurations**, click **All Configurations**, and search for and modify the following parameters.

Table 12-387 Parameter description

Parameter	Description	Default Value
spark.proxyserver.hash.enabled	Specifies whether to connect to ProxyServer using the Hash algorithm. ● **true** indicates using the Hash algorithm. In multi-tenant mode, this parameter must be configured to **true**. ● **false** indicates using random connection. In multi-active instance mode, this parameter must be configured to **false**.	true **NOTE** After this parameter is modified, you need to download the client again.
spark.thriftserver.proxy.enabled	Specifies whether to use the multi-tenant mode. ● **false**: The multi-instance mode is used. ● **true**: The multi-tenant mode is used.	true
spark.thriftserver.proxy.maxThriftServerPerTenancy	Specifies the maximum number of JDBCServer instances that can be started by a tenant in multi-tenant mode.	1
spark.thriftserver.proxy.maxSessionPerThriftServer	Specifies the maximum number of sessions in a single JDBCServer instance in multi-tenant mode. If the number of sessions exceeds this value and the number of JDBCServer instances does not exceed the upper limit, a new JDBCServer instance is started. Otherwise, an alarm log is output.	50

Parameter	Description	Default Value
spark.thriftserver.proxy.sessionWaitTime	Specifies the wait time before a JDBCServer instance is stopped when it has no session connections in multi-tenant mode.	180000
spark.thriftserver.proxy.sessionThreshold	In multi-tenant mode, when the session usage (formula: number of current sessions/ spark.thriftserver.proxy.maxSessionPerThriftServer x number of current JDBCServer instances) of the JDBCServer instance reaches the threshold, a new JDBCServer instance is automatically added.	100
spark.thriftserver.proxy.healthcheck.period	Specifies the period of JDBCServer health checks conducted by the JDBCServer proxy in multi-tenant mode.	60000
spark.thriftserver.proxy.healthcheck.recheckTimes	Specifies the number of JDBCServer health check retries conducted by the JDBCServer proxy in multi-tenant mode.	3
spark.thriftserver.proxy.healthcheck.waitTime	Specifies the wait time for JDBCServer to respond to a health check request sent by the JDBCServer proxy.	10000
spark.thriftserver.proxy.session.check.interval	Specifies the period of JDBCServer proxy sessions in multi-tenant mode.	6h
spark.thriftserver.proxy.idle.session.timeout	Specifies the idle time interval of a JDBCServer proxy session in multi-tenant mode. If no operation is performed within this period, the session is closed.	7d
spark.thriftserver.proxy.idle.session.check.operation	Specifies whether to check that operations still exist on a JDBCServer proxy session when the session is checked for expiration in multi-tenant mode.	true
spark.thriftserver.proxy.idle.operation.timeout	Specifies the timeout interval of an operation in multi-tenant mode. An operation that times out is closed.	5d

12.23.2.7.3 Configuring the Switchover Between the Multi-active Instance Mode and the Multi-tenant Mode

Scenarios

When using a cluster, if you want to switch between multi-active instance mode and multi-tenant mode, the following configurations are required.

- Switch from multi-tenant mode to multi-active instance mode.

  Modify the following parameters of the Spark2x service:

  - spark.thriftserver.proxy.enabled=false
  - spark.scheduler.allocation.file=#{conf_dir}/fairscheduler.xml
  - spark.proxyserver.hash.enabled=false
- Switch from multi-active instance mode to multi-tenant mode.

  Modify the following parameters of the Spark2x service:

  - spark.thriftserver.proxy.enabled=true
  - spark.scheduler.allocation.file=./__spark_conf__/__hadoop_conf__/fairscheduler.xml
  - spark.proxyserver.hash.enabled=true

Configuration Description

Log in to Manager, choose **Cluster** > *Name of the desired cluster* > **Service** > **Spark2x** > **Configuration**, click **All Configurations**, and search for and modify the following parameters.

Table 12-388 Parameter description

Parameter	Description	Default Value
spark.thriftserver.proxy.enabled	Specifies whether to use the multi-tenant mode. • **false**: The multi-instance mode is used. • **true**: The multi-tenant mode is used.	true
spark.scheduler.allocation.file	Specifies the fair scheduling file path. • If the multi-active instance mode is used, the path is changed to **#{conf_dir}/fairscheduler.xml**. • If multi-tenant mode is used, the path is changed to **./__spark_conf__/__hadoop_conf__/fairscheduler.xml**.	./__spark_conf__/__hadoop_conf__/fairscheduler.xml

Parameter	Description	Default Value
spark.proxyserver.hash.enabled	Specifies whether to connect to ProxyServer using the Hash algorithm. • **true** indicates using the Hash algorithm. In multi-tenant mode, this parameter must be configured to **true**. • **false** indicates using random connection. In multi-active instance mode, this parameter must be configured to **false**.	true **NOTE** After this parameter is modified, you need to download the client again.

12.23.2.7.4 Configuring the Size of the Event Queue

Scenarios

Functions such as UI, EventLog, and dynamic resource scheduling in Spark are implemented through event transfer. Events include SparkListenerJobStart and SparkListenerJobEnd, which record each important process.

Each event is saved to a queue after it occurs. When creating a SparkContext object, Driver starts a thread to obtain an event from the queue in sequence and sends the event to each Listener. Each Listener processes the event after detecting the event.

Therefore, when the queuing speed is faster than the read speed, the queue overflows. As a result, the overflow event is lost, affecting the UI, EventLog, and dynamic resource scheduling functions. Therefore, a configuration item is added for more flexible use. You can set a proper value based on the memory size of the driver.

Configuration Description

Navigation path for setting parameters:

Before executing an application, modify the Spark service configuration. On Manager, choose **Cluster** > ***Name of the desired cluster*** > **Service** > **Spark2x** > **Configuration** and click **All Configurations**. Enter a parameter name in the search box.

Table 12-389 Parameter description

Parameter	Description	Default Value
spark.scheduler.listenerbus.eventqueue.capacity	Specifies the size of the event queue. Configure this parameter based on the memory of the driver.	1000000

NOTE

If the following information is displayed in the Driver log, the queue overflows.

1. Common application:
   ```
   Dropping SparkListenerEvent because no remaining room in event queue.
   This likely means one of the SparkListeners is too slow and cannot keep
   up with the rate at which tasks are being started by the scheduler.
   ```
2. Spark Streaming application:
   ```
   Dropping StreamingListenerEvent because no remaining room in event queue.
   This likely means one of the StreamingListeners is too slow and cannot keep
   up with the rate at which events are being started by the scheduler.
   ```

12.23.2.7.5 Configuring Executor Off-Heap Memory

Scenario

When the executor off-heap memory is too small, or processes with higher priority preempt resources, the physical memory usage will exceed the maximal value. To prevent the physical memory usage from exceeding, set the following parameter.

Configuration

Navigation path for setting parameters:

When submitting an application, set the following parameter using **--conf** or adjust the parameter in the **spark-defaults.conf** configuration file on the client.

Table 12-390 Parameter description

Parameter	Description	Default Value
spark.executor.memoryOverhead	Indicates the off-heap memory of each executor, in MB. Increasing the value of this parameter prevents the physical memory usage from exceeding the maximal value. The value is calculated based on max(384, Executor – Memory x 0.1). The minimal value is 384.	1024

12.23.2.7.6 Enhancing Stability in a Limited Memory Condition

Scenario

A large amount of memory is required when Spark SQL executes a query, especially during Aggregate and Join operations. If the memory is limited, OutOfMemoryError may occur. Stability in a limited memory condition ensures queries to be run in limited memory without OutOfMemoryError.

NOTE

Limited memory does not mean infinitely small memory, but ensures stable queries by using disks in a scenario where memory fails to store the data amount that is several times larger than the available memory size. For example, for queries involving Join, the data of the same key used for Join needs to be stored in memory. If the data amount is too large to be stored in the available memory, OutOfMemoryError occurs.

Stability in a limited memory condition involves the following sub-functions:

1. ExternalSort

   If the memory is inadequate during sorting, partial data overflows to disks.

2. TungstenAggregate

   By default, ExternalSort is used to sort data before data aggregation. Therefore, if the memory is inadequate, the data overflows to disks during sorting. The data has been properly sorted before aggregation and only aggregation results of the current key are remained, which use a small amount of memory.

3. SortMergeJoin and SortMergeOuterJoin

   SortMergeJoin and SortMergeOuterJoinan are based on the equivalence join of sorted data. By default, ExternalSort is used to sort the data before the equivalence join. Therefore, if the memory is inadequate, the data overflows to disks during sorting. The data has been properly sorted before the equivalence join and only the data of the same key are remained, which uses a small amount of memory.

Configuration

Navigation path for setting parameters:

When submitting an application, set the following parameters using **--conf** or adjust the parameters in the **spark-defaults.conf** configuration file on the client.

Table 12-391 Parameter description

Parameter	Scenario	Description	Default Value
spark.sql.tungsten.enabled	/	Type: Boolean ● If the value is **true**, tungsten is enabled. That is, the logic plan is equivalent to the codegeneration function, and the physical plan uses the corresponding tungsten execution plan. ● If the value is **false**, tungsten is disabled.	true

Parameter	Scenario	Description	Default Value
spark.sql.codegen.wholeStage		Type: Boolean • If the value is **true**, codegeneration is enabled. That is, for some specified queries, the logic plan code will be generated dynamically when running. • If the value is **false**, codegeneration is disabled and the existing static code is used.	true

NOTE

1. To enable ExternalSort, you need to set **spark.sql.planner.externalSort** to **true** and **spark.sql.unsafe.enabled** to **false** or **spark.sql.codegen.wholeStage** to **false**.
2. To enable TungstenAggregate, use either of the following methods:

   Set **spark.sql.codegen.wholeStage** and **spark.sql.unsafe.enabled** to **true** in the configuration file or CLI.

   If neither **spark.sql.codegen.wholeStage** nor **spark.sql.unsafe.enabled** is **true** or either of them is **true**, TungstenAggregate is enabled as long as **spark.sql.tungsten.enabled** is set to **true**.

12.23.2.7.7 Viewing Aggregated Container Logs on the Web UI

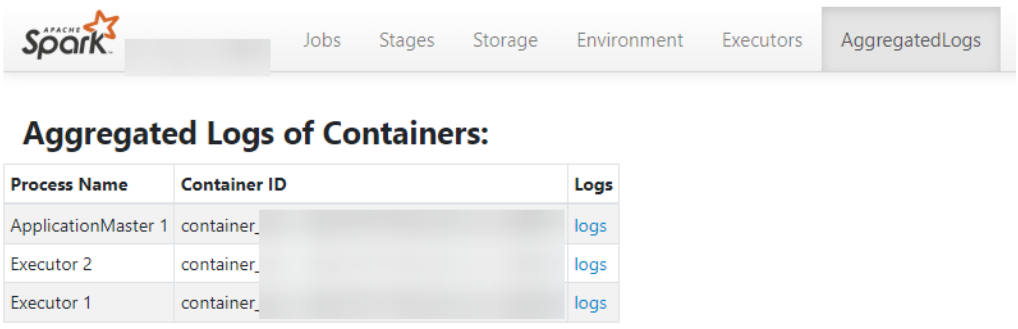
Scenarios

When **yarn.log-aggregation-enable** of Yarn is set to **true**, the container log aggregation function is enabled. Log aggregation indicates that after applications are run on Yarn, NodeManager aggregates all container logs of the node to HDFS and deletes local logs. For details, see **Configuring Container Log Aggregation**.

However, all logs will be aggregated to an HDFS directory and can only be viewed by accessing an HDFS file. Open-source Spark and Yarn do not support the function of viewing aggregated logs on the web UI.

Spark supports this function. As shown in **Figure 12-54**, the **AggregatedLogs** tab is added to the HistoryServer page. You can click **logs** to view aggregated logs.

Figure 12-54 Log aggregation page



Configuration Description

To display logs on the web UI, aggregated logs need to be parsed and presented. Spark parses aggregation logs using JobHistoryServer of Hadoop. Therefore, you can use the **spark.jobhistory.address** parameter to specify the URL of the JobHistoryServer page to parse and present the logs.

Navigation path for setting parameters:

When submitting an application, set these parameters using **--conf** or adjust the following parameter in the **spark-defaults.conf** configuration file on the client.

NOTE

- This function depends on JobHistoryServer of Hadoop. Therefore, ensure that JobHistoryServer is running properly before using the log aggregation function.
- If the parameter value is empty, the **AggregatedLogs** tab page still exists, but you cannot view logs by clicking **logs**.
- The aggregated container logs can be viewed only when the application is running and event log files of the application exist on HDFS.
- You can click the log link on the **Executors** page to view the logs of a running task. After the task completes, the logs are aggregated to HDFS, and the log link on the **Executors** page becomes invalid. In this case, you can click **logs** on the **AggregatedLogs** page to view the aggregated logs.

Table 12-392 Parameter description

Parameter	Description	Default Value
spark.jobhistory.address	URL of the JobHistoryServer page. The format is *http(s)://ip:port/jobhistory*. For example, **https://10.92.115.1:26014/jobhistory**. The default value is empty, indicating that container aggregation logs cannot be viewed on the web UI. Restart the service for the configuration to take effect.	-

12.23.2.7.8 Configuring Environment Variables in Yarn-Client and Yarn-Cluster Modes

Scenario

Values of some configuration parameters of Spark client vary depending on its work mode (YARN-Client or YARN-Cluster). If you switch Spark client between different modes without first changing values of such configuration parameters, Spark client fails to submit jobs in the new mode.

To avoid this, configure parameters as described in **Table 12-393**.

- In Yarn-Cluster mode, use the new parameters (path and parameters of Spark server).
- In Yarn-Client mode, uses the original parameters.

  They are **spark.driver.extraClassPath**, **spark.driver.extraJavaOptions**, and **spark.driver.extraLibraryPath**.

NOTE

If you choose not to add the parameters in **Table 12-393**, Spark client can continue to operate well in either mode but the mode switch requires changes to some of its configuration parameters.

Configuration Parameters

Navigation path for setting parameters:

On Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **Spark2x** > **Configurations**. Click **All Configurations** and enter a parameter name in the search box.

Table 12-393 Parameter description

Parameter	Description	Default Value
spark.yarn.cluster.driver.extraClassPath	Indicates the extraClassPath of the driver in Yarn-cluster mode. Set the parameter to the path and parameters of the server. The original parameter **spark.driver.extraClassPath** indicates the extraClassPath of Spark client. By using different parameters to separate the settings of Spark server from the settings of Spark client, you can switch Spark client to different modes without changing parameter values.	${BIGDATA_HOME}/common/runtime/security

Parameter	Description	Default Value
spark.yarn.cluster.driver.extraJavaOptions	Indicates the extraJavaOptions of Driver in Yarn-Cluster mode and is set to path and parameters of extraJavaOptions of Spark server. The original parameter **spark.driver.extraJavaOptions** indicates the path of extraJavaOptions of Spark client. By using different parameters to separate the settings of Spark server from the settings of Spark client, you can switch Spark client to different modes without changing parameter values.	-Xloggc:<LOG_DIR>/indexserver-%p-gc.log -XX:+PrintGCDetails -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=20 -XX:GCLogFileSize=10M -Dlog4j.configuration=./__spark_conf__/__hadoop_conf__/log4j-executor.properties -Dlog4j.configuration.watch=true -Djava.security.auth.login.config=./__spark_conf__/__hadoop_conf__/jaas-zk.conf -Dzookeeper.server.principal=${ZOOKEEPER_SERVER_PRINCIPAL} -Djava.security.krb5.conf=./__spark_conf__/__hadoop_conf__/kdc.conf -Djetty.version=x.y.z -Dorg.xerial.snappy.tempdir=${BIGDATA_HOME}/tmp -Dcarbon.properties.filepath=./__spark_conf__/__hadoop_conf__/carbon.properties -Djdk.tls.ephemeralDHKeySize=2048 -Dspark.ssl.keyStore=./child.keystore #{java_stack_prefer}

12.23.2.7.9 Configuring the Default Number of Data Blocks Divided by SparkSQL

Scenarios

By default, SparkSQL divides data into 200 data blocks during shuffle. In data-intensive scenarios, each data block may have excessive size. If a single data block of a task is larger than 2 GB, an error similar to the following will be reported while Spark attempts to fetch the data block:

```
Adjusted frame length exceeds 2147483647: 2717729270 - discarded
```

For example, setting the number of default data blocks to 200 causes SparkSQL to encounter an error in running a TPCDS 500-GB test. To avoid this, increase the number of default blocks in data-intensive scenarios.

Configuration parameters

Navigation path for setting parameters:

On Manager, choose **Cluster** > ***Name of the desired cluster*** > **Service** > **Spark2x** > **Configuration** and click **All Configurations**. Enter a parameter name in the search box.

Table 12-394 Parameter description

Parameter	Description	Default Value
spark.sql.shuffle.partitions	Indicates the default number of blocks divided during shuffle.	200

12.23.2.7.10 Configuring the Compression Format of a Parquet Table

Scenarios

The compression format of a Parquet table can be configured as follows:

1. If the Parquet table is a partitioned one, set the **parquet.compression** parameter of the Parquet table to specify the compression format. For example, set **tblproperties** in the table creation statement: **"parquet.compression"="snappy"**.
2. If the Parquet table is a non-partitioned one, set the **spark.sql.parquet.compression.codec** parameter to specify the compression format. The configuration of the **parquet.compression** parameter is invalid, because the value of the **spark.sql.parquet.compression.codec** parameter is read by the **parquet.compression** parameter. If the **spark.sql.parquet.compression.codec** parameter is not configured, the default value is **snappy** and will be read by the **parquet.compression** parameter.

Therefore, the **spark.sql.parquet.compression.codec** parameter can only be used to set the compression format of a non-partitioned Parquet table.

Configuration parameters

Navigation path for setting parameters:

On Manager, choose **Cluster** > ***Name of the desired cluster*** > **Service** > **Spark2x** > **Configuration**. Click **All Configurations** and enter a parameter name in the search box.

Table 12-395 Parameter description

Parameter	Description	Default Value
spark.sql.parquet.compression.codec	Used to set the compression format of a non-partitioned Parquet table.	snappy

12.23.2.7.11 Configuring the Number of Lost Executors Displayed in WebUI

Scenario

In Spark WebUI, the **Executor** page can display information about Lost Executor. Executors are dynamically recycled. If the JDBCServer tasks are large, there may be too many lost executors displayed in WebUI. Therefore, the number of displayed lost executors can be configured.

Procedure

Configure the following parameter in the **spark-defaults.conf** file on Spark client.

Table 12-396 Parameter description

Parameter	Description	Default Value
spark.ui.retainedDeadExecutors	The maximum number of Lost Executors displayed in Spark WebUI.	100

12.23.2.7.12 Setting the Log Level Dynamically

Scenarios

In some scenarios, to locate problems or check information by changing the log level,

you can add the **-Dlog4j.configuration.watch=true** parameter to the JVM parameter of a process before the process is started. After the process is started, you can modify the log4j configuration file corresponding to the process to change the log level.

The following processes support the dynamic setting of log levels: driver, executor, ApplicationMaster, JobHistory and JDBCServer.

Allowed log levels are as follows: FATAL, ERROR, WARN, INFO, DEBUG, TRACE, and ALL.

Configuration Description

Add the following parameters to the JVM parameter corresponding to a process.

Table 12-397 Parameter description

Parameter	Description	Default Value
-Dlog4j.configuration.watch	Indicates a JVM parameter of a process. If this parameter is set to **true**, the dynamic configuration of log levels is enabled.	Left blank, indicating that the dynamic configuration of log levels is disabled

Table 12-398 lists the JVM parameters of the driver, executor, and ApplicationMaster processes. Configure the following parameters in the **spark-defaults.conf** file on the Spark client. Set the log levels of the driver, executor, and ApplicationMaster processes in the log4j configuration file specified by the **-Dlog4j.configuration** parameter.

Table 12-398 JVM parameters of processes (1)

Parameter	Description	Default Log Level
spark.driver.extraJavaOptions	Indicates the JVM parameter of the driver process.	INFO
spark.executor.extraJavaOptions	Indicates the JVM parameter of the executor process.	INFO
spark.yarn.am.extraJavaOptions	Indicates the JVM parameter of the ApplicationMaster process.	INFO

Table 12-399 describes the JVM parameters of JobHistory Server and JDBCServer. Set the parameters in the **ENV_VARS** configuration file. Set the log levels of JobHistory Server and JDBCServer in the **log4j.properties** configuration file.

Table 12-399 JVM parameters of processes (2)

Parameter	Description	Default Log Level
GC_OPTS	Indicates the JVM parameter of the JobHistory Server process.	INFO
SPARK_SUBMIT_OPTS	Indicates the JVM parameter of JDBCServer.	INFO

Example:

To change the log level of the executor process to DEBUG dynamically, modify the **spark.executor.extraJavaOptions** JVM parameter of the executor process in the **spark-defaults.conf** file and run the following command to add the following configuration before the process is started:

```
-Dlog4j.configuration.watch=true
```

After the user application is submitted, change the log level in the log4j configuration file (for example, **-Dlog4j.configuration=file:${BIGDATA_HOME}/FusionInsight_Spark2x_8.1.0.1/install/FusionInsight-Spark2x-3.1.1/spark/conf/log4j-executor.properties**) specified by the **-Dlog4j.configuration** parameter in **spark.executor.extraJavaOptions** to DEBUG:

```
log4j.rootCategory=DEBUG, sparklog
```

It takes several seconds for the DEBUG level to take effect.

12.23.2.7.13 Configuring Whether Spark Obtains HBase Tokens

Scenario

When Spark is used to submit tasks, the driver obtains tokens from HBase by default. To access HBase, you need to configure the **jaas.conf** file for security authentication. If the **jaas.conf** file is not configured, the application will fail to run.

Therefore, perform the following operations based on whether the application involves HBase:

- If the application does not involve HBase, you do not need to obtain the HBase tokens. In this case, set **spark.yarn.security.credentials.hbase.enabled** to **false**.
- If the application involves HBase, set **spark.yarn.security.credentials.hbase.enabled** to **true** and configure the **jaas.conf** file on the driver as follows:

  ```
  {client}/spark/bin/spark-sql  --master yarn-client --principal {principal} --keytab {keytab} --driver-java-options "-Djava.security.auth.login.config={LocalPath}/jaas.conf"
  ```

  Specify Keytab and Principal in the **jaas.conf** file. The following is an example:

  ```
  Client {
  com.sun.security.auth.module.Krb5LoginModule required
  useKeyTab=true
  keyTab = "{LocalPath}/user.keytab"
  principal="super@<System domain name>"
  useTicketCache=false
  debug=false;
  };
  ```

Configuration

Configure the following parameter in the **spark-defaults.conf** file of the Spark client.

Table 12-400 Parameter description

Parameter	Description	Default Value
spark.yarn.security.credentials.hbase.enabled	Indicates whether HBase obtains a token. • **true**: HBase obtains a token. • **false**: HBase does not obtain a token.	false

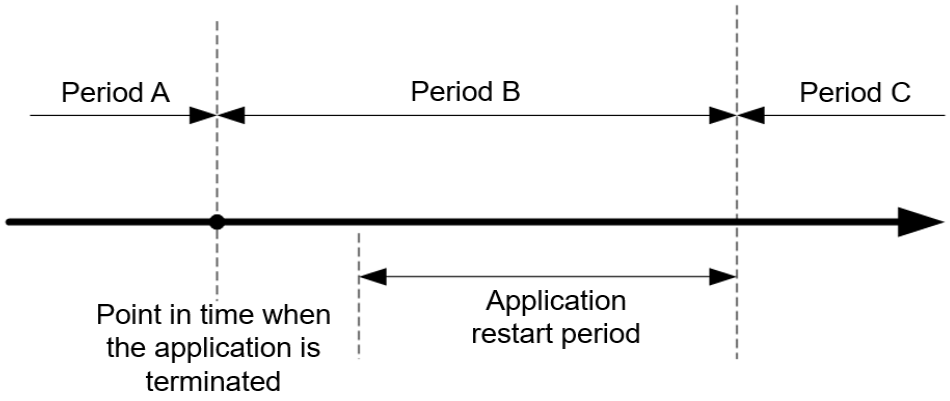
12.23.2.7.14 Configuring LIFO for Kafka

Scenario

If the Spark Streaming application is connected to Kafka, after the Spark Streaming application is terminated abnormally and restarted from the checkpoint, the system preferentially processes the tasks that are not completed before the application is terminated (Period A) and the tasks generated based on data that enters Kafka during the period (Period B) from the application termination to the restart. Then the application processes the tasks generated based on data that enters Kafka after the application is restarted (Period C). For data that enters Kafka in period B, Spark generates a corresponding number of tasks based on the end time (**batch** time). The first task reads all data, but other tasks may not read data. As a result, the task processing pressure is uneven.

If the tasks in Period A and Period B are processed slowly, the processing of tasks in period C is affected. To cope with the preceding scenario, Spark provides the last-in first-out (LIFO) function for Kafka.

Figure 12-55 Time axis for restarting the Spark Streaming application



After this function is enabled, Spark preferentially schedules tasks in Period C. If there are multiple tasks in Period C, Spark schedules and executes the tasks in the sequence of task generation. Then Spark executes the tasks in Periods A and B. For data that enters Kafka in Period B, Spark generates tasks based on the end time

and evenly distributes all data that enters Kafka in this period to each task to avoid uneven task processing pressure.

Constraints:

- This function applies only to the direct mode of Spark Streaming, and the execution result does not depend on the processing result of the previous batch (that is, stateless operation, for example, **updatestatebykey**). Multiple data input streams must be comparatively independent from each other. Otherwise, the result may change after the data is divided.
- The Kafka LIFO function can be enabled only when the application is connected to the Kafka input source.
- If both Kafka LIFO and flow control functions are enabled when the application is submitted, the flow control function is not enabled for the data that enters Kafka in Period B to ensure that the task scheduling priority for reading the data is the lowest. Flow control is enabled for the tasks in Period C after the application is restarted.

Configuration

Configure the following parameters in the **spark-defaults.conf** file on the Spark driver.

Table 12-401 Parameter description

Parameter	Description	Default Value
spark.streaming.kafka.direct.lifo	Specifies whether to enable the LIFO function of Kafka.	false
spark.streaming.kafka010.inputstream.class	Obtains the decoupled class on FusionInsight.	org.apache.spark.streaming.kafka010.HWDirectKafkaInputDStream

12.23.2.7.15 Configuring Reliability for Connected Kafka

Scenario

When the Spark Streaming application is connected to Kafka and the application is restarted, the application reads data from Kafka based on the last read topic offset and the latest offset of the current topic.

If the leader of a Kafka topic fails and the offset of the Kafka leader is greatly different from that of the Kafka follower, the Kafka follower and leader are switched over after the Kafka service is restarted. As a result, the offset of the topic decreases after the Kafka service is restarted.

- If the Spark Streaming application keeps running, the start position for reading Kafka data is greater than the end position because the offset of the topic in Kafka decreases. As a result, the application cannot read data from Kafka and reports an error.

- Before restarting the Kafka service, stop the Spark Streaming application. After the Kafka service is restarted, restart the Spark Streaming application to restore the application from the checkpoint. In this case, the Spark Streaming application records the offset position read before the termination and uses the position as the reference to read subsequent data. The Kafka offset decreases (for example, from 100,000 to 10,000). Spark Streaming consumes data only after the offset of the Kafka leader increases to 100,000. As a result, the newly sent data whose offset is between 10,000 and 100,000 is lost.

To resolve the preceding problem, you can configure reliability for Kafka connected to Spark Streaming. After the reliability function of connected Kafka is enabled:

- If the offset of a topic in Kafka decreases when the Spark Streaming application is running, the latest offset of the topic in Kafka is used as the start position for reading Kafka data and subsequent data is read.

  For a task that has been generated but has not been scheduled, if the read Kafka offset is greater than the latest offset of the topic in Kafka, the task fails to be executed.

  NOTE

  If a large number of tasks fail, the Executor is added to the blacklist. As a result, subsequent tasks cannot be deployed and run. If this happens, you can set **spark.blacklist.enabled** to disable the blacklist function. The blacklist function is enabled by default.

- If the offset of a topic in Kafka decreases, the Spark Streaming application restarts to restore the unfinished tasks. If the read Kafka offset range is greater than the latest offset of the topic in Kafka, the task is directly discarded.

NOTE

If the state function is used in the Spark Streaming application, do not enable the reliability function of connected Kafka.

Configuration

Configure the following parameter in the **spark-defaults.conf** file of the Spark client.

Table 12-402 Parameter description

Parameter	Description	Default Value
spark.streaming.Kafka.reliability	Indicates whether to enable the reliability function for Kafka connected to Spark Streaming. • **true**: The reliability function is enabled. • **false**: The reliability function is disabled.	false

12.23.2.7.16 Configuring Streaming Reading of Driver Execution Results

Scenario

When a query statement is executed, the returned result may be large (containing more than 100,000 records). In this case, JDBCServer out of memory (OOM) may occur. Therefore, the data aggregation function is provided to avoid OOM without sacrificing the performance.

Configuration

Two data aggregation function configuration parameters are provided. The two parameters are set in the **tunning** option on the Spark JDBCServer server. After the setting is complete, restart JDBCServer.

Table 12-403 Parameter description

Parameter	Description	Default Value
spark.sql.bigdata.thriftServer.useHdfsCollect	Indicates whether to save result data to HDFS instead of the memory. Advantages: The query result is stored in HDFS. Therefore, JDBCServer OOM does not occur. Disadvantages: The query is slow. ● **true**: Result data is saved to HDFS. ● **false**: This function is disabled. **NOTICE** When **spark.sql.bigdata.thriftServer.useHdfsCollect** is set to **true**, result data is saved to HDFS. However, the job description on the native JobHistory page cannot be associated with the corresponding SQL statement. In addition, the execution ID in the spark-beeline command output is null. To solve the JDBCServer OOM problem and ensure correct information display, you are advised to set **spark.sql.userlocalFileCollect**.	false

Parameter	Description	Default Value
spark.sql.uselocalFileCollect	Indicates whether to save result data to the local disk instead of memory. Advantages: In the case of small data volume, the performance loss can be ignored compared with the data storage mode using the native memory. In the case of large data volume (hundreds of millions of data records), the performance is much better than that when data is stored in the HDFS and native memory. Disadvantages: Optimization is required. In the case of large data volume, it is recommended that the JDBCServer driver memory be 10 GB and each core of the executor be allocated with 3 GB memory. ● **true**: This function is enabled. ● **false**: This function is disabled.	false
spark.sql.collect.Hive	This parameter is valid only when **spark.sql.uselocalFileCollect** is set to **true**. It indicates whether to save the result data to a disk in direct serialization mode or in indirect serialization mode. Advantage: For queries of tables with a large number of partitions, the aggregation performance of the query results is better than that of the storage mode that query results are directly stored on the disk. Disadvantages: The disadvantages are the same as those when **spark.sql.uselocalFileCollect** is enabled. ● **true**: This function is enabled. ● **false**: This function is disabled.	false
spark.sql.collect.serialize	This parameter takes effect only when both **spark.sql.uselocalFileCollect** and **spark.sql.collect.Hive** are set to **true**. The function is to further improve performance. ● **java**: Data is collected in Java serialization mode. ● **kryo**: Data is collected in kryo serialization mode. The performance is better than that when the Java serialization mode is used.	java

NOTE

spark.sql.bigdata.thriftServer.useHdfsCollect and **spark.sql.uselocalFileCollect** cannot be set to **true** at the same time.

12.23.2.7.17 Filtering Partitions without Paths in Partitioned Tables

Scenario

When you perform the ***select*** query in Hive partitioned tables, the **FileNotFoundException** exception is displayed if a specified partition path does not exist in HDFS. To avoid the preceding exception, configure **spark.sql.hive.verifyPartitionPath** parameter to filter partitions without paths.

Procedure

Perform either of the following methods to filter partitions without paths:

- Configure the following parameter in the **spark-defaults.conf** file on Spark client.

  Table 12-404 Parameter description

Parameter	Description	Default Value
spark.sql.hive.verifyPartitionPath	Whether to filter partitions without paths when reading Hive partitioned tables. **true**: enables the filtering **false**: disables the filtering	false

- When running the spark-submit command to submit an application, configure the **--conf** parameter to filter partitions without paths.

  For example:

  ```
  spark-submit --class org.apache.spark.examples.SparkPi  --conf spark.sql.hive.verifyPartitionPath=true $SPARK_HOME/lib/spark-examples_*.jar
  ```

12.23.2.7.18 Configuring Spark2x Web UI ACLs

Scenario

Users need to implement security protection for Spark2x web UI when some data on the UI cannot be viewed by other users. Once a user attempts to log in to the UI, Spark2x can check the view ACL of the user to determine whether to allow the user to access the UI.

Spark2x has two types of web UI. One is for running tasks. You can access the web UI using the application link on the native Yarn page or the REST APIs. The other one is for ended tasks. You can access the web UI using the Spark2x JobHistory service or the REST APIs.

NOTE

This section applies only to clusters in security mode (with Kerberos authentication enabled).

- Configuring the ACL of the web UI for running tasks

  For a running task, you can set the following parameters on the server:

  - **spark.admin.acls**: specifies the web UI administrator list.
  - **spark.admin.acls.groups**: specifies the administrator group list.
  - **spark.ui.view.acls**: specifies the Yarn page visitor list.
  - **spark.modify.acls.groups**: specifies the Yarn page visitor group list.
  - **spark.modify.acls**: specifies the web UI modifier list.
  - **spark.ui.view.acls.groups**: specifies the web UI modifier group list.

- Configuring the ACL of the web UI for ended tasks

  For ended tasks, use client parameter **spark.history.ui.acls.enable** to enable or disable the ACL access permission.

  If ACL control is enabled, configure client parameters **spark.admin.acls** and **spark.admin.acls.groups** to specify the web UI administrator list and administrator group list. Use client parameters **spark.ui.view.acls** and **spark.modify.acls.groups** to specify the visitor list and visitor group list that view web UI task details. Use client parameters **spark.modify.acls** and **spark.ui.view.acls.groups** to specify the visitor list and group list that modify web UI task details.

Configuration

Log in to FusionInsight Manager, choose **Cluster** > ***Name of the desired cluster*** > **Services** > **Spark2x** > **Configurations**, click **All Configurations**, search for **acl**, and modify the following parameters on the JobHistory, JDBCServer, SparkResource, and Spark pages.

Table 12-405 Parameter description

Parameter	Description	Default Value
spark.history.ui.acls.enable	Indicates whether JobHistory supports the permission verification of a single task.	true
spark.acls.enable	Indicates whether to enable Spark permission management. If this function is enabled, the system checks whether the user has the permission to access and modify task information.	true

Parameter	Description	Default Value
spark.admin.acls	Indicates the list of Spark administrators. All members in the list have the rights to manage all Spark tasks. You can configure multiple administrators and separate them from each other using commas (,).	admin
spark.admin.acls.groups	Indicates the list of Spark administrator groups. All groups in the list have the permission to manage all Spark tasks. You can configure multiple administrator groups and separate them from each other using commas (,).	-
spark.modify.acls	Indicates the list of members that have the permission to modify Spark tasks. By default, the user who starts a task has the permission to modify the task. You can configure multiple users and separate them from each other using commas (,).	-
spark.modify.acls.groups	Indicates the list of groups that have the permission to modify Spark tasks. You can configure multiple groups and separate them from each other using commas (,).	-
spark.ui.view.acls	Indicates the list of members that have the permission to access Spark tasks. By default, the user who starts a task has the permission to modify the task. You can configure multiple users and separate them from each other using commas (,).	-
spark.ui.view.acls.groups	Indicates the list of groups that have the permission to access Spark tasks. You can configure multiple groups and separate them from each other using commas (,).	-

NOTE

If you use a client to submit tasks, you must download the client again after modifying the **spark.admin.acls**, **spark.admin.acls.groups**, **spark.modify.acls**, **spark.modify.acls.groups**, **spark.ui.view.acls**, and **spark.ui.view.acls.groups** parameters.

12.23.2.7.19 Configuring Vector-based ORC Data Reading

Scenario

ORC is a column-based storage format in the Hadoop ecosystem. It originates from Apache Hive and is used to reduce the Hadoop data storage space and accelerate the Hive query speed. Similar to Parquet, ORC is not a pure column-based storage format. In the ORC format, the entire table is split based on the row group, data in each row group is stored by column, and data is compressed as much as possible to reduce storage space consumption. Vector-based ORC data reading significantly improves the ORC data reading performance. In Spark2.3, SparkSQL supports vector-based ORC data reading (this function is supported in earlier Hive versions). Vector-based ORC data reading improves the data reading performance by multiple times.

This feature can be enabled by using the following parameter.

- **spark.sql.orc.enableVectorizedReader**: specifies whether vector-based ORC data reading is supported. The default value is **true**.
- **spark.sql.codegen.wholeStage**: specifies whether to compile all stages of multiple operations into a Java method. The default value is **true**.
- **spark.sql.codegen.maxFields**: specifies the maximum number of fields (including nested fields) supported by all stages of codegen. The default value is **100**.
- **spark.sql.orc.impl**: specifies whether Hive or Spark SQL native is used as the SQL execution engine to read ORC data. The default value is **hive**.

Parameters

Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **Spark2x**, click the **Configurations** tab and then **All Configurations**, and search for the following parameters.

Parameter	Description	Default Value	Value Range
spark.sql.orc.enableVectorizedReader	Specifies whether vector-based ORC data reading is supported. The default value is **true**.	true	[true,false]
spark.sql.codegen.wholeStage	Specifies whether to compile all stages of multiple operations into a Java method. The default value is **true**.	true	[true,false]
spark.sql.codegen.maxFields	Specifies the maximum number of fields (including nested fields) supported by all stages of codegen. The default value is **100**.	100	Greater than 0

Parameter	Description	Default Value	Value Range
spark.sql.orc.impl	Specifies whether Hive or Spark SQL native is used as the SQL execution engine to read ORC data. The default value is **hive**.	hive	[hive,native]

NOTE

1. To use vector-based ORC data reading of SparkSQL, the following conditions must be met:
   - **spark.sql.orc.enableVectorizedReader** must be set to **true** (default value). Generally, the value is not changed.
   - **spark.sql.codegen.wholeStage** must be set to **true** (default value). Generally, the value is not changed.
   - The value of **spark.sql.codegen.maxFields** must be greater than or equal to the number of columns in scheme.
   - All data is of the AtomicType. Specifically, data is not null or of the UDT, array, or map type. If there is data of the preceding types, expected performance cannot be obtained.
   - **spark.sql.orc.impl** must be set to **native**. The default value is **hive**.
2. If a task is submitted using the client, modification of the following parameters takes effect only after you download the client again: **spark.sql.orc.enableVectorizedReader**, **spark.sql.codegen.wholeStage**, **spark.sql.codegen.maxFields**, and **spark.sql.orc.impl**.

12.23.2.7.20 Broaden Support for Hive Partition Pruning Predicate Pushdown

Scenario

In earlier versions, the predicate for pruning Hive table partitions is pushed down. Only comparison expressions between column names and integers or character strings can be pushed down. In version 2.3, pushdown of the null, in, and, or expressions are supported.

Parameters

Log in to FusionInsight Manager and choose **Cluster** > *Name of the desired cluster* > **Services** > **Spark2x**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab, and search for the following parameters:

Parameter	Description	Default Value	Value Range
spark.sql.hive.advancedPartitionPredicatePushdown.enabled	Specifies whether to broaden the support for Hive partition pruning predicate pushdown.	true	[true,false]

12.23.2.7.21 Hive Dynamic Partition Overwriting Syntax

Scenario

In earlier versions, when the **insert overwrite** syntax is used to overwrite partition tables, only partitions with specified expressions are matched, and partitions without specified expressions are deleted. In Spark2.3, partitions without specified expressions are automatically matched. The syntax is the same as that of the dynamic partition matching syntax of Hive.

Parameters

Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **Spark2x** > **Configurations**, click **All Configurations**, and search for the following parameter.

Parameter	Description	Default Value	Value Range
spark.sql.sources.partitionOverwrite-Mode	Specifies the mode for inserting data in partition tables by running the **insert overwrite** command, which can be **STATIC** or **DYNAMIC**. When it is set to **STATIC**, Spark deletes all partitions based on the matching conditions. When it is set to **DYNAMIC**, Spark matches partitions based on matching conditions and dynamically matches partitions without specified conditions.	STATIC	[STATIC,DYNAMIC]

12.23.2.7.22 Configuring the Column Statistics Histogram to Enhance the CBO Accuracy

Scenarios

The execution plan for SQL statements is optimized in Spark. Common optimization rules are heuristic optimization rules. Heuristic optimization rules are provided based on the characteristics of logical plans, and the data characteristics and the execution costs of operators are not considered. Spark 2.20 introduces the Cost-Based Optimization (CBO). CBO collects statistics on tables and columns and estimates the number of output records and size of each operator in bytes based on the input data sets of operators, which is the cost of executing an operator.

CBO will adjust the execution plan to minimize the end-to-end query time. The main points are as follows:

- Filter out irrelevant data as soon as possible.

- Minimize the cost of each operator.

The CBO optimization process is divided into two steps:

1. Collect statistics.
2. Estimate the output data sets of a specific operator based on the input data sets.

Table-level statistics includes: number of records and the total size of a table data file.

Column-level statistics includes: number of unique values, maximum value, minimum value, number of null values, average length, maximum length, and the histogram.

After the statistics is obtained, the execution cost of operators can be estimated. Common operators include filter and join operators.

Histogram is a type of column statistics. It can clearly describe the distribution of column data. The column data is distributed to a specified number of bins that are displayed in ascending order by size. The upper and lower limits of each bin are calculated. The amount of data in all bins is the same (a contour histogram). After the data is distributed, the cost estimation of each operator is more accurate and the optimization effect is better.

This feature can be enabled by using the following parameter.

spark.sql.statistics.histogram.enabled: specifies whether to enable the histogram function. The default value is **false**.

Parameter Configuration

Log in to FusionInsight Manager, choose **Cluster >** *Name of the desired cluster* **> Services** > **Spark2x** > **Configurations**, click **All Configurations**, and search for the following parameters.

Parameter	Description	Default Value	Value Range
spark.sql.cbo.enabled	Enables CBO to estimate the statistics for the execution plan.	false	[true,false]
spark.sql.cbo.joinReorder.enabled	Enables CBO join for reordering.	false	[true,false]
spark.sql.cbo.joinReorder.dp.threshold	Specifies the maximum number of nodes that can be joined in the dynamic planning algorithm.	12	>=1

Parameter	Description	Default Value	Value Range
spark.sql.cbo.joinReorder.card.weight	Specifies the proportion of dimension (number of rows) in the comparison of planned cost during reconnection: Number of rows x Proportion of dimension + File size x (1 - Proportion of dimension)	0.7	0-1
spark.sql.statistics.size.autoUpdate.enabled	Enables the function of automatically updating the table size when the table data volume changes. Note: If there are a large number of data files in a table, this operation is time consume, and the data processing speed is reduced.	false	[true,false]
spark.sql.statistics.histogram.enabled	After this function is enabled, a histogram is generated when column statistics is collected. Histogram can improve the estimation accuracy, but collecting histogram information requires additional workload.	false	[true,false]
spark.sql.statistics.histogram.numBins	Specifies the number of bins for the generated histogram.	254	>=2
spark.sql.statistics.ndv.maxError	Specifies the maximum estimation deviation allowed by the HyperLogLog++ algorithm when the column level statistics is generated.	0.05	0-1

Parameter	Description	Default Value	Value Range
spark.sql.statistics.percentile.accuracy	Specifies the accuracy rate of the percentile estimation when the contour histogram is generated. The larger the value is, the more accurate the estimation is. The estimation error value can be obtained through (1.0/ Accuracy rate of the percentile estimation).	10000	>=1

NOTE

- If you want the histogram to take effect in CBO, the following conditions must be met:
  - Set **spark.sql.statistics.histogram.enabled** to **true**. The default value is **false**. Change the value to **true** to enable the histogram function.
  - Set **spark.sql.cbo.enabled** to **true**. The default value is **false**. Change the value to **true** to enable CBO.
  - Set **spark.sql.cbo.joinReorder.enabled** to **true**. The default value is **false**. Change the value to **true** to enable connection reordering.
- If a client is used to submit a task, you need to download the client again after configuring the following parameters: **spark.sql.cbo.enabled**, **spark.sql.cbo.joinReorder.enabled**, **spark.sql.cbo.joinReorder.dp.threshold**, **spark.sql.cbo.joinReorder.card.weight**, **spark.sql.statistics.size.autoUpdate.enabled**, **spark.sql.statistics.histogram.enabled**, **spark.sql.statistics.histogram.numBins**, **spark.sql.statistics.ndv.maxError**, and **spark.sql.statistics.percentile.accuracy**.

12.23.2.7.23 Configuring Local Disk Cache for JobHistory

Scenarios

JobHistory can use local disks to cache the historical data of Spark applications to prevent the JobHistory memory from loading a large amount of application data, reducing the memory pressure. In addition, the cached data can be reused to improve the speed for subsequent application access.

Parameter Configuration

Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **Spark2x** > **Configurations**, click the **All Configurations** tab, and search for the following parameters:

Parameter	Description	Default Value
spark.history.store.path	Specifies the local directory for storing historical information for JobHistory. If this parameter is specified, JobHistory caches historical application data in the local disk instead of the memory.	${BIGDATA_HOME}/tmp/spark2x_JobHistory
spark.history.store.maxDiskUsage	Specifies the maximum available space of the local disk cache.	10 GB

12.23.2.7.24 Configuring Spark SQL to Enable the Adaptive Execution Feature

Scenario

The Spark SQL adaptive execution feature enables Spark SQL to optimize subsequent execution processes based on intermediate results to improve overall execution efficiency. The following features have been implemented:

1. Automatic configuration of the number of shuffle partitions

   Before the adaptive execution feature is enabled, Spark SQL specifies the number of partitions for a shuffle process by specifying the **spark.sql.shuffle.partitions** parameter. This method lacks flexibility when multiple SQL queries are performed on an application and cannot ensure optimal performance in all scenarios. After adaptive execution is enabled, Spark SQL automatically configures the number of partitions for each shuffle process, instead of using the general configuration. In this way, the proper number of partitions is automatically used during each shuffle process.

2. Dynamic adjusting of the join execution plan

   Before the adaptive execution feature is enabled, Spark SQL creates an execution plan based on the optimization results of rule-based optimization (RBO) and Cost-Based Optimization (CBO). This method ignores changes of result sets during data execution. For example, when a view created based on a large table is joined with other large tables, the execution plan cannot be adjusted to BroadcastJoin even if the result set of the view is small. After the adaptive execution feature is enabled, Spark SQL can dynamically adjust the execution plan based on the execution result of the previous stage to obtain better performance.

3. Automatic processing of data skew

   If data skew occurs during SQL statement execution, the memory overflow of an executor or slow task execution may occur. After the adaptive execution feature is enabled, Spark SQL can automatically process data skew scenarios. Multiple tasks are started for partitions where data skew occurs. Each task reads several output files obtained from the shuffle process and performs union operations on the join results of these tasks to eliminate data skew.

Parameters

Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Spark2x** > **Configurations**, click **All Configurations**, and search for the following parameter.

Parameter	Description	Default Value
spark.sql.adaptive.enabled	Specifies whether to enable the adaptive execution function. Note: If AQE and Static Partition Pruning (DPP) are enabled at the same time, DPP takes precedence over AQE during SparkSQL task execution. As a result, AQE does not take effect.	false
spark.sql.optimizer.dynamicPartitionPruning.enabled	The switch to enable DPP.	true
spark.sql.adaptive.coalescePartitions.enabled	If this parameter is set to **true** and **spark.sql.adaptive.enabled** is set to **true**, Spark combines partitions that are consecutively random played based on the target size (specified by **spark.sql.adaptive.advisoryPartitionSizeInBytes**) to prevent too many small tasks from being executed.	true
spark.sql.adaptive.coalescePartitions.initialPartitionNum	Initial number of shuffle partitions before merge. The default value is the same as the value of **spark.sql.shuffle.partitions**. This parameter is valid only when **spark.sql.adaptive.enabled** and **spark.sql.adaptive.coalescePartitions.enabled** are set to **true**. This parameter is optional. The initial number of partitions must be a positive number.	200
spark.sql.adaptive.coalescePartitions.minPartitionNum	Minimum number of shuffle partitions after merge. If this parameter is not set, the default degree of parallelism (DOP) of the Spark cluster is used. This parameter is valid only when **spark.sql.adaptive.enabled** and **spark.sql.adaptive.coalescePartitions.enable** are set to **true**. This parameter is optional. The initial number of partitions must be a positive number.	1

Parameter	Description	Default Value
spark.sql.adaptive.shuffle.targetPostShuffleInputSize	Target size of a partition after shuffling. Spark 3.0 and later versions do not support this parameter.	64MB
spark.sql.adaptive.advisoryPartitionSizeInBytes	Size of a shuffle partition (unit: byte) during adaptive optimization (**spark.sql.adaptive.enabled** is set to **true**). This parameter takes effect when Spark aggregates small shuffle partitions or splits shuffle partitions where skew occurs.	64MB
spark.sql.adaptive.fetchShuffleBlocksInBatch	Whether to obtain consecutive shuffle blocks in batches. For the same map job, reading consecutive shuffle blocks in batches can reduce I/Os and improve performance, instead of reading blocks one by one. Note that multiple consecutive blocks exist in a single read request only when **spark.sql.adaptive.enabled** and **spark.sql.adaptive.coalescePartitions.enabled** are set to **true**. This feature also relies on a relocatable serializer that uses cascading to support the codec and the latest version of the shuffle extraction protocol.	true
spark.sql.adaptive.localShuffleReader.enabled	If the value of this parameter is **true** and the value of **spark.sql.adaptive.enabled** is **true**, Spark attempts to use the local shuffle reader to read shuffle data when shuffling of partitions is not required, for example, after sort-merge join is converted to broadcast-hash join.	true
spark.sql.adaptive.skewJoin.enabled	Specifies whether to enable the function of automatic processing of the data skew in join operations. The function is enabled when this parameter is set to **true** and **spark.sql.adaptive.enabled** is set to **true**.	true

Parameter	Description	Default Value
spark.sql.adaptive.skewJoin.skewedPartitionFactor	This parameter is a multiplier used to determine whether a partition is a data skew partition. If the data size of a partition exceeds the value of this parameter multiplied by the median of the all partition sizes except this partition and exceeds the value of **spark.sql.adaptive.skewJoin.skewedPartitionThresholdInBytes**, this partition is considered as a data skew partition.	5
spark.sql.adaptive.skewJoin.skewedPartitionThresholdInBytes	If the partition size (unit: byte) is greater than the threshold as well as the product of the **spark.sql.adaptive.skewJoin.skewedPartitionFactor** value and the median partition size, skew occurs in the partition. Ideally, the value of this parameter should be greater than that of **spark.sql.adaptive.advisoryPartitionSizeInBytes.**.	256MB
spark.sql.adaptive.nonEmptyPartitionRatioForBroadcastJoin	If the ratio of non-null partitions is less than the value of this parameter when two tables are joined, broadcast hash join cannot be properly performed regardless of the partition size. This parameter is valid only when **spark.sql.adaptive.enabled** is set to **true**.	0.2

12.23.2.7.25 Configuring Event Log Rollover

Scenario

When the event log mode is enabled for Spark, that is, **spark.eventLog.enabled** is set to **true**, events are written to a configured log file to record the program running process. If a program, for example JDBCServer or Spark Streaming, runs for a long period of time and has run many jobs and tasks during this period, many events are recorded in the log file, significantly increasing the file size.

When log rollover is enabled, metadata events are written into the log file and job events are written into a new log file (whether a job event is written to the new log file depends on the file size). Metadata events include EnviromentUpdate, BlockManagerAdded, BlockManagerRemoved, UnpersistRDD, ExecutorAdded, ExecutorRemoved, MetricsUpdate, ApplicationStart, ApplicationEnd, and LogStart. Job events include StageSubmitted, StageCompleted, TaskResubmit, TaskStart,

TaskEnd, TaskGettingResult, JobStart, and JobEnd. For Spark SQL applications, job events also include ExecutionStart and ExecutionEnd.

The UI for the HistoryServer service of Spark is obtained by reading and parsing these log files. The memory size is preset before the HistoryServer process starts. Therefore, when the size of log files is large, loading and parsing these files may cause problems such as insufficient memory and driver GC.

To load large log files in small memory mode, you need to enable log rollover for large applications. Generally, it is recommended that this function be enabled for long-running applications.

Parameters

Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Spark2x** > **Configurations**, click **All Configurations**, and search for the following parameters.

Parameter	Description	Default Value
spark.eventLog.rolling.enabled	Whether to enable rollover for event log files. If this parameter is set to **true**, the size of each event log file is reduced to the configured size.	true
spark.eventLog.rolling.maxFileSize	Maximum size of the event log file to be rolled over when **spark.eventlog.rolling.enabled** is set to **true**.	128M
spark.eventLog.compression.codec	Codec used to compress event logs. By default, Spark provides four types of codecs: LZ4, LZF, Snappy, and ZSTD. If this parameter is not specified, **spark.io.compression.codec** is used.	None
spark.eventLog.logStageExecutorMetrics	Whether to write each stage peak value (for each executor) of executor metrics to the event log.	false

12.23.2.8 Adapting to the Third-party JDK When Ranger Is Used

Scenarios

When Ranger is used as the permission management service of Spark SQL, the certificate in the cluster is required for accessing RangerAdmin. If you use a third-party JDK instead of the JDK or JRE in the cluster, RangerAdmin fails to be accessed. As a result, the Spark application fails to be started.

In this scenario, you need to perform the following operations to import the certificate in the cluster to the third-party JDK or JRE.

Configuration Method

Step 1 Run the following command to export the certificate from the cluster:

1. Install the cluster client. Assume that the installation path is **/opt/client**.
2. Run the following command to go to the client installation directory.

   cd /opt/client
3. Run the following command to configure environment variables:

   source bigdata_env
4. Generate the certificate file.

   keytool -export -alias fusioninsightsubroot -storepass changeit -keystore /opt/client/JRE/jre/lib/security/cacerts -file fusioninsightsubroot.crt

Step 2 Import the certificate in the cluster to the third-party JDK or JRE.

Copy the **fusioninsightsubroot.crt** file generated in **Step 1** to the third-party JRE node, set the **JAVA_HOME** environment variable of the node, and run the following command to import the certificate:

keytool -import -trustcacerts -alias fusioninsightsubroot -storepass changeit -file fusioninsightsubroot.crt -keystore MY_JRE/lib/security/cacerts

NOTE

MY_JRE indicates the installation path of the third-party JRE. Change it based on the site requirements.

----End

12.23.3 Spark2x Logs

Log Description

Log paths:

- Executor run log: **${BIGDATA_DATA_HOME}/hadoop/data${i}/nm/containerlogs/application_${appid}/container_{$contid}**

  NOTE

  The logs of running tasks are stored in the preceding path. After the running is complete, the system determines whether to aggregate the logs to an HDFS directory based on the Yarn configuration. For details, see **Common YARN Parameters**.
- Other logs: **/var/log/Bigdata/spark2x**

Log archiving rule:

- When tasks are submitted in **yarn-client** or **yarn-cluster** mode, executor log files are stored each time when the size of the log files reaches 50 MB. A maximum of 10 log files can be reserved without being compressed.
- The JobHistory2x log file is backed up each time when the size of the log file reaches 100 MB. A maximum of 100 log files can be reserved without being compressed.

- The JDBCServer2x log file is backed up each time when the size of the log file reaches 100 MB. A maximum of 100 log files can be reserved without being compressed.
- The IndexServer2x log file is backed up each time when the size of the log file reaches 100 MB. A maximum of 100 log files can be reserved without being compressed.
- The JDBCServer2x audit log file is backed up each time when the size of the log file reaches 20 MB by default. A maximum of 20 log files can be reserved without being compressed.
- The log file size and the number of compressed files to be reserved can be configured on FusionInsight Manager.

Table 12-406 Spark2x log list

Log Type	Name	Description
SparkResource2x logs	spark.log	Spark2x service initialization log
	prestart.log	Prestart script log
	cleanup.log	Cleanup log file for instance installation and uninstallation
	spark-availability-check.log	Spark2x service health check log
	spark-service-check.log	Spark2x service check log
JDBCServer2x logs	JDBCServer-start.log	JDBCServer2x startup log
	JDBCServer-stop.log	JDBCServer2x stop log
	JDBCServer.log	JDBCServer2x run log on the server
	jdbc-state-check.log	JDBCServer2x health check log
	jdbcserver-omm-pid***-gc.log.*.current	IJDBCServer2x process GC log
	spark-omm-org.apache.spark.sql.hive.thriftserver.HiveThriftProxyServer2-***.out*	JDBCServer2x process startup log. If the process stops, the **jstack** information is printed.
JobHistory2x logs	jobHistory-start.log	JobHistory2x startup log
	jobHistory-stop.log	JobHistory2x stop log
	JobHistory.log	JobHistory2x running process log
	jobhistory-omm-pid***-gc.log.*.current	JobHistory2x process GC log

Log Type	Name	Description
	spark-omm-org.apache.spark.deploy.history.HistoryServer-***.out*	JobHistory2x process startup log. If the process stops, the **jstack** information is printed.
IndexServer2x logs	IndexServer-start.log	IndexServer2x startup log
	IndexServer-stop.log	IndexServer2x stop log
	IndexServer.log	IndexServer2x run log on the server
	indexserver-state-check.log	IndexServer2x health check log
	indexserver-omm-pid***-gc.log.*.current	IndexServer2x process GC log
	spark-omm-org.apache.spark.sql.hive.thriftserver.IndexServerProxy-***.out*	IndexServer2x process startup log. If the process stops, the **jstack** information is printed.
Audit Log	jdbcserver-audit.log ranger-audit.log	JDBCServer2x audit log

Log levels

Table 12-407 describes the log levels supported by Spark2x. The priorities of log levels are ERROR, WARN, INFO, and DEBUG in descending order. Logs whose levels are higher than or equal to the specified level are printed. The number of printed logs decreases as the specified log level increases.

Table 12-407 Log levels

Level	Description
ERROR	Error information about the current event processing
WARN	Exception information about the current event processing
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record the system information and system debugging information.

To modify log levels, perform the following operations:

NOTE

By default, the service does not need to be restarted after the Spark2x log levels are configured.

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Service** > **Spark2x** > **Configuration**.

Step 3 Select **All Configurations**.

Step 4 On the menu bar on the left, select the log menu of the target role.

Step 5 Select a desired log level.

Step 6 Click **Save**. Then, click **OK**.

----End

Log Format

Table 12-408 Log Format

Type	Format	Example
Run log	<*yyyy-MM-dd HH:mm:ss,SSS*>|<*Log level*>|<*Name of the thread that generates the log*>|<*Message in the log*>|<*Location where the log event occurs*>	2014-09-22 11:16:23,980 INFO DAGScheduler: Final stage: Stage 0(reduce at SparkPi.scala:35)

12.23.4 Obtaining Container Logs of a Running Spark Application

Container logs of running Spark applications are distributed on multiple nodes. This section describes how to quickly obtain container logs.

Scenario Description

You can run the **yarn logs** command to obtain the logs of applications running on Yarn. In different scenarios, you can run the following commands to obtain required logs:

1. Obtain complete logs of the application: **yarn logs --applicationId** *<appId>* **-out** *<outputDir>*.

   Example: **yarn logs --applicationId application_1574856994802_0016 -out /opt/test**

   The following figure shows the command output.

   a. If the application is running, container logs in the **dead** state cannot be obtained.

b. If the application is stopped, all archived container logs can be obtained.

2. Obtain logs of a specified container: **yarn logs -applicationId** *<appId>* **-containerId** *<containerId>*.

   Example: **yarn logs -applicationId application_1574856994802_0018 -containerId container_e01_1574856994802_0018_01_000003**

   The following figure shows the command output.

   a. If the application is running, container logs in the **dead** state cannot be obtained.

   b. If the application is stopped, you can obtain logs of any container.

3. Obtain container logs in any state: **yarn logs -applicationId** *<appId>* **-containerId** *<containerId>* **-nodeAddress** *<nodeAddress>*

   Example: **yarn logs -applicationId application_1574856994802_0019 -containerId container_e01_1574856994802_0019_01_000003 -nodeAddress 192-168-1-1:**8041

   Execution result: Logs of any container can be obtained.

   NOTE

   You need to set *nodeAddress* in the command. You can run the following command to obtain the value:

   yarn node -list -all

12.23.5 Small File Combination Tools

Tool Overview

In a large-scale Hadoop production cluster, HDFS metadata is stored in the NameNode memory, and the cluster scale is restricted by the memory limitation of each NameNode. If there are a large number of small files in the HDFS, a large amount of NameNode memory is consumed, which greatly reduces the read and write performance and prolongs the job running time. Based on the preceding information, the small file problem is a key factor that restricts the expansion of the Hadoop cluster.

This tool provides the following functions:

1. Checks the number of small files whose size is less than the threshold configured by the user in tables and returns the average size of all data files in the table directory.
2. Provides the function of combination table files. Users can set the average file size after combination.

Supported Table Types

Spark: Parquet, ORC, CSV, Text, and Json.

Hive: Parquet, ORC, CSV, Text, RCFile, Sequence and Bucket.

NOTE

1. After tables with compressed data are merged, Spark uses the default compression format Snappy for data compression. You can configure **spark.sql.parquet.compression.codec** (available values: **uncompressed**, **gzip**, **lzo**, and **snappy**) and **spark.sql.orc.compression.codec** (available values: **uncompressed**, **zlib**, **lzo**, and **snappy**) on the client to select the compression format for the Parquet and ORC tables. Compression formats available for Hive and Spark tables are different, except the preceding compression formats, other compression formats are not supported.
2. To merge bucket table data, you need to add the following configurations to the **hive-site.xml** file on the Spark2x client:

```
<property>
<name>hive.enforce.bucketing</name>
<value>false</value>
</property>
<property>
<name>hive.enforce.sorting</name>
<value>false</value>
</property>
```

3. Spark does not support the feature of encrypting data columns in Hive.

Tool Usage

Download and install the client. For example, the installation directory is **/opt/client**. Go to **/opt/client/Spark2x/spark/bin** and run the **mergetool.sh** script.

Environment variables loading

source /opt/client/bigdata_env

source /opt/client/Spark2x/component_env

Scanning function

Command: **sh mergetool.sh scan <db.table> <filesize>**

The format of *db.table* is *Database name*,*Table name*. *filesize* is the user-defined threshold of the small file size (unit: MB). The returned result is the number of files that is smaller than the threshold and the average size of data files in the table directory.

Example: **sh mergetool.sh scan default.table1 128**

Combination function

Command: **sh mergetool.sh merge <db.table> <filesize> <shuffle>**

The format of *db.table* is *Database name,Table name*. **filesize** is the user-defined average file size after file combination (unit: MB). **shuffle** is a Boolean value, and the value is **true** or **false**, which is used to configure whether to allow data to be shuffled during the merge.

Example: **sh mergetool.sh merge default.table1 128 false**

If the following information is displayed, the operation is successful:

```
SUCCESS: Merge succeeded
```

NOTE

1. Ensure that the current user is the owner of the merged table.
2. Before combination, ensure that HDFS has sufficient storage space, greater than the size of the combined table.
3. Table data must be combined separately. If a table is read during table data combination, the file may not be found temporarily. After the combination is complete, this problem is resolved. During the combination, do not write data to the corresponding tables. Otherwise, data inconsistency may occur.
4. If an error occurs indicating that the file does not exist when the query of data in a partitioned table is performed on the session spark-beeline/spark-sql that is always in the connected status. You can run the **refresh table***Table name* command as prompted to query the data again.
5. Configure **filesize** based on the site requirements. For example, you can set **filesize** to a value greater than the average during file merging after obtaining the average file size by file scan. Otherwise, the number of files may increase after the file merging.
6. During the file merging, data in the original tables is removed to the recycle bin. In the case of any exception occurs on the data after file merging, the data in the original tables is used to replace the damaged data. If an exception occurs during the process, restore the data in the trash directory by using the **mv** command in HDFS.
7. In the HDFS router federation scenario, if the target NameService of the table root path is different from that of the root path **/user**, you need to manually clear the original table files stored in the recycle bin during the second combination. Otherwise, the combination fails.
8. This tool uses the configuration of the client. Performance optimization can be performed modifying required configuration in the client configuration file.

shuffle configuration

For the combination function, you can roughly estimate the change on the number of partitions before and after the combination.

Generally, if the number of old partitions is greater than the number of new partitions, set **shuffle** to **false**. However, if the number of old partitions is much greater than that of new partitions (for example, more than 100 times), you can set **shuffle** to **true** to increase the degree of parallelism and improve the combination speed.

NOTICE

- If **shuffle** is set to **true** (repartition), the performance is improved. However, due to the particularity of the Parquet and ORC storage modes, repartition will reduce the compression ratio and the total size of the table in HDFS increases by 1.3 times.
- If **shuffle** is set to **false** (coalesce), the merged files may have some difference in size, which is close to the value of the configured **filesize**.

Log storage location

The default log storage path is **/tmp/SmallFilesLog.log4j**. To customize the log storage path, you can configure **log4j.appender.logfile.File** in **/opt/client/Spark2x/spark/tool/log4j.properties**.

12.23.6 Using CarbonData for First Query

Tool Overview

The first query of CarbonData is slow, which may cause a delay for nodes that have high requirements on real-time performance.

The tool provides the following functions:

- Preheat the tables that have high requirements on query delay for the first time.

Tool Usage

Download and install the client. For example, the installation directory is **/opt/client**. Go to the **/opt/client/Spark2x/spark/bin** directory and run **start-prequery.sh**.

Configure **prequeryParams.properties** by referring to **Table 12-409**.

Table 12-409 Parameters

Parameter	Description	Example
spark.prequery.period.max.minute	Maximum preheating duration, in minutes.	60
spark.prequery.tables	Table name configuration, *database.table:int*. The table name supports the wildcard (*). **int** indicates the duration (unit: day) within which the table is updated before it is preheated.	default.test*:10
spark.prequery.maxThreads	Maximum number of concurrent threads during preheating	50
spark.prequery.sslEnable	The value is **true** in security mode and **false** in non-security mode.	true
spark.prequery.driver	IP address and port number of JDBCServer. The format is *IP address:Port number*. If multiple servers need to be preheated, enter multiple *IP address:Port number* of the servers and separate them with commas (,).	192.168.0.2:22550

Parameter	Description	Example
spark.prequery.sql	SQL statement for preheating. Different statements are separated by colons (:).	SELECT COUNT(*) FROM %s;SELECT * FROM %s LIMIT 1
spark.security.url	URL required by JDBC in security mode	;saslQop=auth-conf;auth=KERBEROS;principal=spark2x/hadoop.hadoop.com@HADOOP.COM;

NOTE

The statement configured in **spark.prequery.sql** is executed in each preheated table. The table name is replaced with **%s**.

Script Usage

Command format: **sh start-prequery.sh**

To run this command, place **user.keytab** or **jaas.conf** (either of them) and **krb5.conf** (mandatory) in the **conf** directory.

NOTE

- Currently, this tool supports only Carbon tables.
- This tool initializes the Carbon environment and pre-reads table metadata to JDBCServer. Therefore, this tool is more suitable for multi-active instances and static allocation mode.

12.23.7 Spark2x Performance Tuning

12.23.7.1 Spark Core Tuning

12.23.7.1.1 Data Serialization

Scenario

Spark supports the following types of serialization:

- JavaSerializer
- KryoSerializer

Data serialization affects the Spark application performance. In specific data format, KryoSerializer offers 10X higher performance than JavaSerializer. For Int data, performance optimization can be ignored.

KryoSerializer depends on Chill of Twitter. Not all Java Serializable objects support KryoSerializer. Therefore, class must be manually registered.

Serialization involves task serialization and data serialization. Only JavaSerializer can be used for Spark task serialization. JavaSerializer and KryoSerializer can be used for data serialization.

Procedure

When the Spark program is running, a large volume of data needs to be serialized during the shuffle and RDD cache procedures. By default, JavaSerializer is used. You can also configure KryoSerializer as the data serializer to improve serialization performance.

Add the following code to enable KryoSerializer to be used:

- Implement the class registrar and manually register the class.

```
package com.etl.common;

import com.esotericsoftware.kryo.Kryo;
import org.apache.spark.serializer.KryoRegistrator;

public class DemoRegistrator implements KryoRegistrator
{
   @Override
   public void registerClasses(Kryo kryo)
   {
      //Class examples are given below. Register the custom classes.
      kryo.register(AggrateKey.class);
      kryo.register(AggrateValue.class);
   }
}
```

  You can configure **spark.kryo.registrationRequired** on Spark client. Whether to require registration with Kryo. If set to 'true', Kryo will throw an exception if an unregistered class is serialized. If set to false (the default), Kryo will write unregistered class names along with each object. Writing class names can cause significant performance overhead. This operation will affect the system performance. If the value of **spark.kryo.registrationRequired** is configured to **true**, you need to manually register the class. For a class that is not serialized, the system will not automatically write the class name, but display an exception. Compare the configuration of **true** with that of **false**, the configuration of **true** has the better performance.

- Configure KryoSerializer as the data serializer and class registrar.

```
val conf = new SparkConf()
conf.set("spark.serializer", "org.apache.spark.serializer.KryoSerializer")
.set("spark.kryo.registrator", "com.etl.common.DemoRegistrator")
```

12.23.7.1.2 Optimizing Memory Configuration

Scenario

Spark is a memory-based computing frame. If the memory is insufficient during computing, the Spark execution efficiency will be adversely affected. You can determine whether memory becomes the performance bottleneck by monitoring garbage collection (GC) and evaluating the resilient distributed dataset (RDD) size in the memory, and take performance optimization measures.

To monitor GC of node processes, add the -verbose:gc -XX:+PrintGCDetails -XX:+PrintGCTimeStamps parameter to the **spark.driver.extraJavaOptions** and **spark.executor.extraJavaOptions** in the client configuration file **conf/spark-default.conf**. If "Full GC" is frequently reported, GC needs to be optimized. Cache

the RDD and query the RDD size in the log. If a large value is found, change the RDD storage level.

Procedure

- To optimize GC, adjust the ratio of the young generation and tenured generation. Add **-XX:NewRatio** parameter to the **spark.driver.extraJavaOptions** and **spark.executor.extraJavaOptions** in the client configuration file **conf/spark-default.conf**. For example, export SPARK_JAVA_OPTS=" -XX:NewRatio=2". The new generation accounts for 1/3 of the heap, and the tenured generation accounts for 2/3.
- Optimize the RDD data structure when compiling Spark programs.
  - Use primitive arrays to replace fastutil arrays, for example, use fastutil library.
  - Avoid nested structure.
  - Avoid using String in keys.
- Suggest serializing the RDDs when developing Spark programs.

  By default, data is not serialized when RDDs are cached. You can set the storage level to serialize the RDDs and minimize memory usage. For example:

  ```
  testRDD.persist(StorageLevel.MEMORY_ONLY_SER)
  ```

12.23.7.1.3 Setting the DOP

Scenario

The degree of parallelism (DOP) specifies the number of tasks to be executed concurrently. It determines the number of data blocks after the shuffle operation. Configure the DOP to improve the processing capability of the system.

Query the CPU and memory usage. If the tasks and data are not evenly distributed among nodes, increase the DOP. Generally, set the DOP to two or three times that of the total CPUs in the cluster.

Procedure

Configure the DOP parameter using one of the following methods based on the actual memory, CPU, data, and application logic conditions:

- Configure the DOP parameter in the operation function that generates the shuffle. This method has the highest priority.

  ```
  testRDD.groupByKey(24)
  ```

- Configure the DOP using **spark.default.parallelism**. This method has the lower priority than the preceding one.

  ```
  val conf = new SparkConf();
  conf.set("spark.default.parallelism", 24);
  ```

- Configure the value of **spark.default.parallelism** in the **$SPARK_HOME/conf/spark-defaults.conf** file. This method has the lowest priority.

  ```
  spark.default.parallelism    24
  ```

12.23.7.1.4 Using Broadcast Variables

Scenario

Broadcast distributes data sets to each node. It allows data to be obtained locally when a data set is needed during a Spark task. If broadcast is not used, data serialization will be scheduled to tasks each time when a task requires data sets. It is time-consuming and makes the task get bigger.

1. If a data set will be used by each slice of a task, broadcast the data set to each node.
2. When small and big tables need to be joined, broadcast small tables to each node. This eliminates the shuffle operation, changing the join operation into a common operation.

Procedure

Add the following code to broadcast the testArr data to each node:

```
def main(args: Array[String) {
  ...
  val testArr: Array[Long] = new Array[Long](200)
  val testBroadcast: Broadcast[Array[Long]] = sc.broadcast(testArr)
  val resultRdd: RDD[Long] = inpputRdd.map(input => handleData(testBroadcast, input))
  ...
}

def handleData(broadcast: Broadcast[Array[Long]], input: String) {
  val value = broadcast.value
  ...
}
```

12.23.7.1.5 Using the external shuffle service to improve performance

Scenario

When the Spark system runs applications that contain a shuffle process, an executor process also writes shuffle data and provides shuffle data for other executors in addition to running tasks. If the executor is heavily loaded and GC is triggered, the executor cannot provide shuffle data for other executors, affecting task running.

The external shuffle service is an auxiliary service in NodeManager. It captures shuffle data to reduce the load on executors. If GC occurs on an executor, tasks on other executors are not affected.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Spark2x** > **Configurations**. Select **All Configurations**.

Step 3 Choose **SparkResource2x** > **Default** and modify the following parameters.

Table 12-410 Parameter list

Parameter	Default Value	Changed To
spark.shuffle.service.enabled	false	true

Step 4 Restart the Spark2x service for the configuration to take effect.

NOTE

To use the External Shuffle Service function on the Spark2x client, you need to download and install the Spark2x client again.

----End

12.23.7.1.6 Configuring Dynamic Resource Scheduling in Yarn Mode

Scenario

Resources are a key factor that affects Spark execution efficiency. When a long-running service (such as the JDBCServer) is allocated with multiple executors without tasks but resources of other applications are insufficient, resources are wasted and scheduled improperly.

Dynamic resource scheduling can add or remove executors of applications in real time based on the task load. In this way, resources are dynamically scheduled to applications.

Procedure

Step 1 Configure the external shuffle service.

Step 2 Log in to FusionInsight Manager, and choose **Cluster** > *Name of the desired cluster* > **Service** > **Spark2x** > **Configuration** > **All Configurations**. Enter **spark.dynamicAllocation.enabled** in the search box and set its value to **true** to enable the dynamic resource scheduling function. This function is disabled by default.

----End

Table 12-411 lists some optional configuration items.

Table 12-411 Parameters for dynamic resource scheduling

Configuration Item	Description	Default Value
spark.dynamicAllocation.minExecutors	Indicates the minimum number of executors.	0
spark.dynamicAllocation.initialExecutors	Indicates the number of initial executors.	0
spark.dynamicAllocation.maxExecutors	Indicates the maximum number of executors.	2048

Configuration Item	Description	Default Value
spark.dynamicAllocation.schedulerBacklogTimeout	Indicates the first timeout period for scheduling.	1s
spark.dynamicAllocation.sustainedSchedulerBacklogTimeout	Indicates the second and later timeout interval for scheduling.	1s
spark.dynamicAllocation.executorIdleTimeout	Indicates the idle timeout interval for common executors.	60s
spark.dynamicAllocation.cachedExecutorIdleTimeout	Indicates the idle timeout interval for executors with cached blocks.	• JDBCServer2x: 2147483647s • IndexServer2x: 2147483647s • SparkResource2x: 120

NOTE

The external shuffle service must be configured before using the dynamic resource scheduling function.

12.23.7.1.7 Configuring Process Parameters

Scenario

There are three processes in Spark on Yarn mode: driver, ApplicationMaster, and executor. The Driver and Executor handle the scheduling and running of the task. The ApplicationMaster handles the start and stop of the container.

Therefore, the configuration of the driver and executor is very important to run the Spark application. You can optimize the performance of the Spark cluster according to the following procedure.

Procedure

Step 1 Configure the driver memory.

The driver schedules tasks and communicates with the executor and the ApplicationMaster. Add driver memory when the number and parallelism level of the tasks increases.

You can configure the driver memory based on the number of the tasks.

- Set **spark.driver.memory** in **spark-defaults.conf** to a proper value.
- Add the **--driver-memory MEM** parameter to configure the memory when using the **spark-submit** command.

Step 2 Configure the number of the executors.

One core in an executor can run one task at the same time. Therefore, more tasks can be processed at the same time if you increase the number of the executors. You can add the number of the executors to increase the efficiency if resources are sufficient.

- Set **spark.executor.instance** in **spark-defaults.conf** or **SPARK_EXECUTOR_INSTANCES** in **spark-env.sh** to a proper value.
- Add the **--num-executors NUM** parameter to configure the number of the executors when using the **spark-submit** command.

Step 3 Configure the number of the executor cores.

Multiple cores in an executor can run multiple tasks at the same time, which increases the task concurrency. However, because all cores share the memory of an executor, you need to balance the memory and the number of cores.

- Set **spark.executor.cores** in **spark-defaults.conf** or **SPARK_EXECUTOR_CORES** in **spark-env.sh** to a proper value.
- When you run the **spark-submit** command, add the **--executor-cores NUM** parameter to set the number of executor cores.

Step 4 Configure the executor memory.

The executor memory is used for task execution and communication. You can increase the memory for a big task that needs more resources, and reduce the memory to increase the concurrency level for a small task that runs fast.

- Set **spark.executor.memory** in **spark-defaults.conf** or **SPARK_EXECUTOR_MEMORY** in **spark-env.sh** to a proper value.
- When you run the **spark-submit** command, add the **--executor-memory MEM** parameter to set the memory.

----End

Example

- During the **spark wordcount** calculation, the amount of data is 1.6 TB and the number of the executors is 250.

  The execution fails under the default configuration, and the **Futures timed out** and **OOM** errors occur.

  However each task of wordcount is small and runs fast, the amount of the data is big and the tasks are too many. Therefore the objects on the driver end become huge when there are many tasks. Besides the fact that the executor communicates with the driver once each task is finished, the problem of disconnection between processes caused by insufficient memory occurs.

  The application runs successfully when the memory of the Driver is set to 4 GB.

- Many errors still occurred in the default configuration when running TPC-DS test on JDBCServer, such as "Executor Lost". When there is 30 GB of driver memory, 2 executor cores, 125 executors, and 6 GB of executor memory, all tasks can be successfully executed.

12.23.7.1.8 Designing the Direction Acyclic Graph (DAG)

Scenario

Optimal program structure helps increase execution efficiency. During application programming, avoid shuffle operations and combine narrow-dependency operations.

Procedure

This topic describes how to design the DAG using the following example:

- **Data format**: Time when a vehicle passes a toll station, license plate number, toll station number, and more
- **Logic**: Two vehicles are determined to be traveling together if the following conditions are met:
  - Both vehicles pass the same toll stations in the same sequence.
  - The difference between the time that the vehicles pass the same toll station is smaller than a specified value.

There are two implementation ways for this example. **Figure 12-56** shows the logic of implementation 1 and **Figure 12-57** shows logic of implementation 2.

Figure 12-56 Implementation logic 1

Logic description:

1. Collect information about the toll stations passed by each vehicle based on the vehicle license plate number and sort the toll stations.

   The following data is obtained: vehicle license plate number 1, [(time, toll station 3), (time, toll station 2), (time, toll station 4), (time, toll station 5)]

2. Determine the sequence in which the vehicle passed through.

   (toll station 3, (vehicle license plate number 1, time, 1st toll station))

   (toll station 2, (vehicle license plate number 1, time, 2nd toll station))

   (toll station 4, (vehicle license plate number 1, time, 3rd toll station))

   (toll station 5, (vehicle license plate number 1, time, 4th toll station))

3. Aggregate data by toll station.

   toll station 1, [(vehicle license plate number 1, time, 1st toll station), (vehicle license plate number 2, time, 5th toll station), (vehicle license plate number 3, time, 2nd toll station)]

4. Determine whether the time difference that two vehicles passed through the same toll station is below the specified value. If yes, fetch information about the two vehicles.

   (vehicle license plate number 1, vehicle license plate number 2),(1st toll station, 5th toll station)

   (vehicle license plate number 1, vehicle license plate number 3),(1st toll station, 2nd toll station)

5. Aggregate data based on the vehicle license plate numbers that passed through the same toll stations.

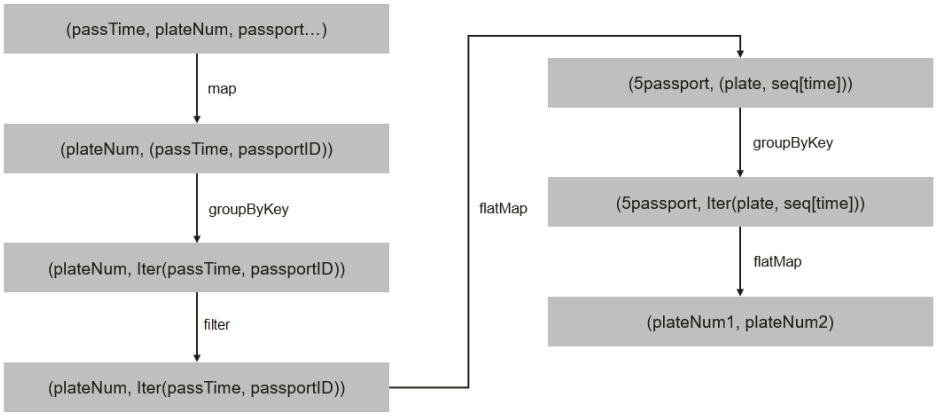
   (vehicle license plate number 1, vehicle license plate number 2), [(1st toll station, 5th toll station), (2nd toll station, 6th toll station), (1st toll station, 7th toll station), (3rd toll station, 8th toll station)]

6. If the two vehicles pass through the same toll stations in sequence, for example, toll stations 3, 4, 5 are the first, second, and third toll station passed by vehicle 1 and the 6th, 7th, and 8th toll station passed by vehicle 2, and the number of toll stations meets the specified requirements, the two vehicles are determined to be traveling together.

The logic of implementation 1 has the following disadvantages:

- The logic is complex.
- Too many shuffle operations affect performance.

Figure 12-57 Implementation logic 2



Logic description:

1. Collect information about the toll stations passed by each vehicle based on the vehicle license plate number and sort the toll stations.

   The following data is obtained: vehicle license plate number 1, [(time, toll station 3), (time, toll station 2), (time, toll station 4), (time, toll station 5)]

2. Based on the number of toll stations (the number is 3 in this example) that must be passed by these vehicles, divide the toll station sequence as follows:

toll station 3 > toll station 2 > toll station 4, (vehicle license plate number 1, [time passing through toll station 3, time passing through toll station 2, time passing through toll station 4])

toll station 2 > toll station 4 > toll station 5, (vehicle license plate number 1, [time passing through toll station 2, time passing through toll station 4, time passing through toll station 5])

3. Aggregate information about vehicles that pass the same toll stations in the same sequence.

   toll station 3 > toll station 2 > toll station 4, [(vehicle license plate number 1, [time passing through toll station 3, time passing through toll station 2, time passing through toll station 4]), (vehicle license plate number 2, [time passing through toll station 3, time passing through toll station 2, time passing through toll station 4]), (vehicle license plate number 3, [time passing through toll station 3, time passing through toll station 2, time passing through toll station 4])]

4. Determine whether the time difference that these vehicles passed through the same toll station is below the specified value. If yes, the vehicles are determined to be traveling together.

The logic of implementation 2 has the following advantages:

- The logic is simplified.
- One **groupByKey** is reduced, that is, one less shuffle operation is performed. It helps improve performance.

12.23.7.1.9 Experience

Use mapPartitions to calculate data by partition.

If the overhead of each record is high, for example:

```
rdd.map{x=>conn=getDBConn;conn.write(x.toString);conn.close}
```

Use mapPartitions to calculate data by partition.

```
rdd.mapPartitions(records => conn.getDBConn;for(item <- records)
write(item.toString); conn.close)
```

Use mapPartitions to flexibly operate data. For example, to calculate the TopN of a large data, mapPartitions can be used to calculate the TopN of each partition and then sort the TopN of all partitions when N is small. Compared with sorting full data for the TopN, this method has the higher efficiency.

Use coalesce to adjust the number of slices.

Use coalesce to adjust the number of slices. There are two coalesce functions:

```
coalesce(numPartitions: Int, shuffle: Boolean = false)
```

When **shuffle** is set to **true**, the function is the same as repartition(numPartitions:Int). Partitions are recreated using the shuffle. When **shuffle** is set to **false**, partitions of the parent resilient distributed datasets (RDD) are calculated in the same task. In this case, if the value of **numPartitions** is larger than the number of sections of the parent RDD, partitions will not be recreated.

The following scenario is encountered, you can choose the coalesce operator:

- If the previous operation involves a large number of filters, use coalesce to minimize the number of zero-loaded tasks. In coalesce(numPartitions, false), the value of **numPartitions** is smaller than the number of sections of the parent RDD.
- Use coalesce when the number of slices entered is too big to execute.
- Use coalesce when the programs are suspended in the shuffle operation because of a large number of tasks or the Linux resources are limited. In this case, use coalesce(numPartitions, true) to recreate partitions.

Configure a localDir for each disk.

During the shuffle procedure of Spark, data needs to be written into local disks. The performance bottleneck of Spark is shuffle, and the bottleneck of shuffle is the I/O. To improve the I/O performance, you can configure multiple disks to implement concurrent data writing. If a node is mounted with multiple disks, configure a Spark local Dir for each disk. This can effectively distribute shuffle files in multiple locations, improving disk I/O efficiency. The performance cannot be improved effectively if a disk is configured with multiple directories.

Collect small data sets.

The collect operation does not apply to a large data volume.

When the collect operation is performed, the Executor data will be sent to the Driver. Before performing this operation, ensure that the memory of Driver is sufficient. Otherwise, the Driver process may encounter an OutOfMemory error. If the data volume is unknown, perform the saveAsTextFile operation to write data into the HDFS. If the data volume is known and the Driver has sufficient memory, perform the collect operation.

Use reduceByKey

reduceByKey causes local aggregation on the Map side, which offers a smooth shuffle procedure. The shuffle operations, like groupByKey, will not perform aggregation on the Map side. Therefore, use reduceByKey as possible as you can, and avoid groupByKey().map(x=>(x._1,x._2.size)).

Broadcast map instead of array.

If table query is required for each record of the data transmitted from the Driver side, broadcast the data in the set/map instead of Iterator. The query speed of Set/Map is approximately O(1), while the query speed of Iterator is O(n).

Avoid data skew.

If data skew occurs (certain data volume is extremely large), the execution time of tasks is inconsistent even if there is no Garbage Collection (GC).

- Redefine the keys. Use keys of smaller granularity to optimize the task size.
- Modify the degree of parallelism (DOP).

Optimize the data structure.

- Store data by column. As a result, only the required columns are scanned when data is read.
- When using the Hash Shuffle, set **spark.shuffle.consolidateFiles** to **true** to combine the intermediate files of shuffle, minimize the number of shuffle files and file I/O operations, and improve performance. The number of final files is the number of reduce tasks.

12.23.7.2 Spark SQL and DataFrame Tuning

12.23.7.2.1 Optimizing the Spark SQL Join Operation

Scenario

When two tables are joined in Spark SQL, the broadcast function (see section "Using Broadcast Variables") can be used to broadcast tables to each node. This minimizes shuffle operations and improves task execution efficiency.

NOTE

The join operation refers to the inner join operation only.

Procedure

The following describes how to optimize the join operation in Spark SQL. Assume that both tables A and B have the **name** column. Join tables A and B as follows:

1. Estimate the table sizes.

   Estimate the table size based on the size of data loaded each time.

   You can also check the table size in the directory of the Hive database. In the **hive-site.xml** configuration file of Spark, view the Hive database directory, which is **/user/hive/warehouse** by default. The default Hive database directory for multi-instance Spark is **/user/*hive*/warehouse**, for example, **/user/hive1/warehouse**.

   ```
   <property>
     <name>hive.metastore.warehouse.dir</name>
    <value>${test.warehouse.dir}</value>
    <description></description>
   </property>
   ```

   Run the **hadoop** command to check the size of the table. For example, run the following command to view the size of table **A**:

   ```
   hadoop fs -du -s -h ${test.warehouse.dir}/a
   ```

   NOTE

   To perform the broadcast operation, ensure that at least one table is not empty.

2. Configure a threshold for automatic broadcast.

   The threshold for triggering broadcast for a table is 10485760 (that is, 10 MB) in Spark. If either of the table sizes is smaller than 10 MB, skip this step.

   Table 12-412 lists configuration parameters of the threshold for automatic broadcasting.

Table 12-412 Parameter description

Parameter	Default Value	Description
spark.sql.autoBroadcastJoinThreshold	10485760	Indicates the maximum value for the broadcast configuration when two tables are joined. • When the size of a field in a table involved in an SQL statement is less than the value of this parameter, the system broadcasts the SQL statement. • If the value is set to **-1**, broadcast is not performed. For details, visit **https://archive.apache.org/dist/spark/docs/3.1.1/sql-programming-guide.html**.

Methods for configuring the threshold for automatic broadcasting:

- Set **spark.sql.autoBroadcastJoinThreshold** in the **spark-defaults.conf** configuration file of Spark.
  ```
  spark.sql.autoBroadcastJoinThreshold = <size>
  ```
- Run the Hive command to set the threshold. Before joining the tables, run the following command:
  ```
  SET spark.sql.autoBroadcastJoinThreshold=<size>;
  ```

3. Join the tables.
   - The size of each table is smaller than the threshold.
     - If the size of table A is smaller than that of table B, run the following command:
       ```
       SELECT A.name FROM B JOIN A ON A.name = B.name;
       ```
     - If the size of table B is smaller than that of table A, run the following command:
       ```
       SELECT A.name FROM A JOIN B ON A.name = B.name;
       ```
   - One table size is smaller than the threshold, while the other table size is greater than the threshold.

     Broadcast the smaller table.
   - The size of each table is greater than the threshold.

     Compare the size of the field involved in the query with the threshold.
     - If the values of the fields in a table are smaller than the threshold, the corresponding data in the table is broadcast.
     - If the values of the fields in the two tables are greater than the threshold, do not broadcast either of the table.
4. (Optional) In the following scenarios, you need to run the Analyze command (***ANALYZE TABLE tableName COMPUTE STATISTICS noscan;***) to update metadata before performing the broadcast operation:

  - The table to be broadcasted is a newly created partitioned table and the file type is non-Parquet.
  - The table to be broadcasted is a newly updated partitioned table.

Reference

A task is ended if a timeout occurs during the execution of the to-be-broadcasted table.

By default, BroadCastJoin allows only 5 minutes for the to-be-broadcasted table calculation. If the time is exceeded, a timeout will occur. However, the broadcast task of the to-be-broadcasted table calculation is still being executed, resulting in resource waste.

The following methods can be used to address this issue:

- Modify the value of **spark.sql.broadcastTimeout** to increase the timeout duration.
- Reduce the value of **spark.sql.autoBroadcastJoinThreshold** to disable the optimization of BroadCastJoin.

12.23.7.2.2 Improving Spark SQL Calculation Performance Under Data Skew

Scenario

When multiple tables are joined in Spark SQL, skew occurs in join keys and the data volume in some Hash buckets is much higher than that in other buckets. As a result, some tasks with a large amount of data run slowly, resulting low computing performance. Other tasks with a small amount of data are quickly completed, which frees many CPUs and results in a waste of CPU resources.

If the automatic data skew function is enabled, data that exceeds the bucketing threshold is bucketed. Multiple tasks proceed data in one bucket. Therefore, CUP usage is enhanced and the system performance is improved.

NOTE

Data that has no skew is bucketed and run in the original way.

Restrictions:

- Only the join between two tables is supported.
- FULL OUTER JOIN data does not support data skew.

  For example, the following SQL statement indicates that the skew of table **a** or table **b** cannot trigger the optimization.

  select aid FROM a FULL OUTER JOIN b ON aid=bid;
- LEFT OUTER JOIN data does not support the data skew of the right table.

  For example, the following SQL statement indicates that the skew of table **b** cannot trigger the optimization.

  select aid FROM a LEFT OUTER JOIN b ON aid=bid;
- RIGHT OUTER JOIN does not support the data skew of the left table.

  For example, the following SQL statement indicates that the skew of table **a** cannot trigger the optimization.

select aid FROM a RIGHT OUTER JOIN b ON aid=bid;

Configuration Description

Add the following parameters in the following table to the **spark-defaults.conf** configuration file on the Spark driver.

Table 12-413 Parameter description

Parameter	Description	Default Value
spark.sql.adaptive.enabled	The switch to enable the adaptive execution feature. Note: If AQE and Static Partition Pruning (DPP) are enabled at the same time, DPP takes precedence over AQE during SparkSQL task execution. As a result, AQE does not take effect. The DPP in the cluster is enabled by default. Therefore, you need to disable it when enabling the AQE.	false
spark.sql.optimizer.dynamicPartitionPruning.enabled	The switch to enable DPP.	true
spark.sql.adaptive.skewJoin.enabled	Specifies whether to enable the function of automatic processing of the data skew in join operations. The function is enabled when this parameter is set to **true** and **spark.sql.adaptive.enabled** is set to **true**.	true
spark.sql.adaptive.skewJoin.skewedPartitionFactor	This parameter is a multiplier used to determine whether a partition is a data skew partition. If the data size of a partition exceeds the value of this parameter multiplied by the median of the all partition sizes except this partition and exceeds the value of **spark.sql.adaptive.skewJoin.skewedPartitionThresholdInBytes**, this partition is considered as a data skew partition.	5
spark.sql.adaptive.skewjoin.skewedPartitionThresholdInBytes	If the partition size (unit: byte) is greater than the threshold as well as the product of the **spark.sql.adaptive.skewJoin.skewedPartitionFactor** value and the median partition size, skew occurs in the partition. Ideally, the value of this parameter should be greater than that of **spark.sql.adaptive.advisoryPartitionSizeInBytes.**.	256MB
spark.sql.adaptive.shuffle.targetPostShuffleInputSize	Minimum amount of shuffle data processed by each task. The unit is byte.	67108864

12.23.7.2.3 Optimizing Spark SQL Performance in the Small File Scenario

Scenario

A Spark SQL table may have many small files (far smaller than an HDFS block), each of which maps to a partition on the Spark by default. In other words, each small file is a task. If the small files are great in number, Spark must initiate a large number of tasks. If shuffle operations exist in Spark SQL, the number of hash buckets increases, affecting performance.

In this scenario, you can manually specify the split size of each task to avoid an excessive number of tasks and improve performance.

NOTE

If the SQL logic does not involve shuffle operations, this optimization does not improve performance.

Configuration

If you want to enable small file optimization, configure the **spark-defaults.conf** file on the Spark client.

Table 12-414 Parameter description

Parameter	Description	Default Value
spark.sql.files.maxPartitionBytes	The maximum number of bytes that can be packed into a single partition when a file is read. Unit: byte	134217728 (128 MB)
spark.files.openCostInBytes	The estimated cost to open a file, measured by the number of bytes that can be scanned in the same time. This is used when putting multiple files into a partition. It is better to over estimate, then the partitions with small files will be faster than partitions with larger files.	4 MB

12.23.7.2.4 Optimizing the INSERT...SELECT Operation

Scenario

The INSERT...SELECT operation needs to be optimized if any of the following conditions is true:

- Many small files need to be queried.
- A few large files need to be queried.
- The INSERT...SELECT operation is performed by a non-spark user in Beeline/JDBCServer mode.

Procedure

Optimize the INSERT...SELECT operation as follows:

- If the table to be created is the Hive table, set the storage type to Parquet. This enables INSERT...SELECT statements to be run faster.
- Perform the INSERT...SELECT operation as a spark-sql user or spark user (if in Beeline/JDBCServer mode). In this way, it is no longer necessary to change the file owner repeatedly, accelerating the execution of INSERT...SELECT statements.

  NOTE

  In Beeline/JDBCServer mode, the executor user is the same as the driver user. The driver user is a spark user because the driver is a part of JDBCServer service and started by a spark user. If the Beeline user is not a spark user, the file owner must be changed to the Beeline user (actual user) because the executor is unaware of the Beeline user.
- If many small files need to be queried, set spark.sql.files.maxPartitionBytes and spark.files.openCostInBytes to set the maximum size in bytes of partition and combine multiple small files in a partition to reduce file amount. This accelerates file renaming, ultimately enabling INSERT...SELECT statements to be run faster.

NOTE

The preceding optimizations are not a one-size-fits-all solution. In the following scenario, it still takes long to perform the INSERT...SELECT operation:

The dynamic partitioned table contains many partitions.

12.23.7.2.5 Multiple JDBC Clients Concurrently Connecting to JDBCServer

Scenario

Multiple clients can be connected to JDBCServer at the same time. However, if the number of concurrent tasks is too large, the default configuration of JDBCServer must be optimized to adapt to the scenario.

Procedure

1. Set the fair scheduling policy of JDBCServer.

   The default scheduling policy of Spark is **FIFO**, which may cause a failure of short tasks in multi-task scenarios. Therefore, the fair scheduling policy must be used in multi-task scenarios to prevent task failure.

   a. For details about how to configure Fair Scheduler in Spark, visit **http://archive.apache.org/dist/spark/docs/3.1.1/job-scheduling.html#scheduling-within-an-application**.

   b. Configure Fair Scheduler on the JDBC client.

      i. In the Beeline command line client or the code defined by JDBC, run the following statement:

      PoolName is a scheduling pool for Fair Scheduler.

      ```
      SET spark.sql.thriftserver.scheduler.pool=PoolName;
      ```

ii. Run the SQL command. The Spark task will be executed in the preceding scheduling pool.

2. Set the **BroadCastHashJoin** timeout interval.

   There is a timeout parameter of **BroadCastHashJoin**. The task query fails if the query period exceeds the preset timeout interval. In multi-task scenarios, the Spark task of BroadCastHashJoin may fail due to resource preemption. Therefore, it is necessary to modify the timeout interval in the **spark-defaults.conf** file of JDBCServer.

   Table 12-415 Parameter description

Parameter	Description	Default Value
spark.sql.broadcastTimeout	The timeout interval in the broadcast table of **BroadcastHashJoin**. If there are many concurrent tasks, set the parameter to a larger value or a negative number.	-1 (Numeral type. The actual value is 5 minutes.)

12.23.7.2.6 Optimizing Memory when Data Is Inserted into Dynamic Partitioned Tables

Scenario

When SparkSQL inserts data to dynamic partitioned tables, the more partitions there are, the more HDFS files a single task generates and the more memory metadata occupies. In this case, Garbage Collection (GC) is severe and Out of Memory (OOM) may occur.

Assume there are 10240 tasks and 2000 partitioned. Before the rename operation of HDFS files from a temporary directory to the target directory, there is about 29 GB FileStatus metadata.

Procedure

Insert **distribute by** followed by partition fields into dynamic partition statements.

For example:

insert into table store_returns partition (sr_returned_date_sk) select sr_return_time_sk,sr_item_sk,sr_customer_sk,sr_cdemo_sk,sr_hdemo_sk,sr_addr_sk,sr_store_sk,sr_reason_sk,sr_ticket_number,sr_return_quantity,sr_return_amt,sr_return_tax,sr_return_amt_inc_tax,sr_fee,sr_return_ship_cost,sr_refunded_cash,sr_reversed_charge,sr_store_credit,sr_net_loss,sr_returned_date_sk from ${SOURCE}.store_returns **distribute by sr_returned_date_sk**;

12.23.7.2.7 Optimizing Small Files

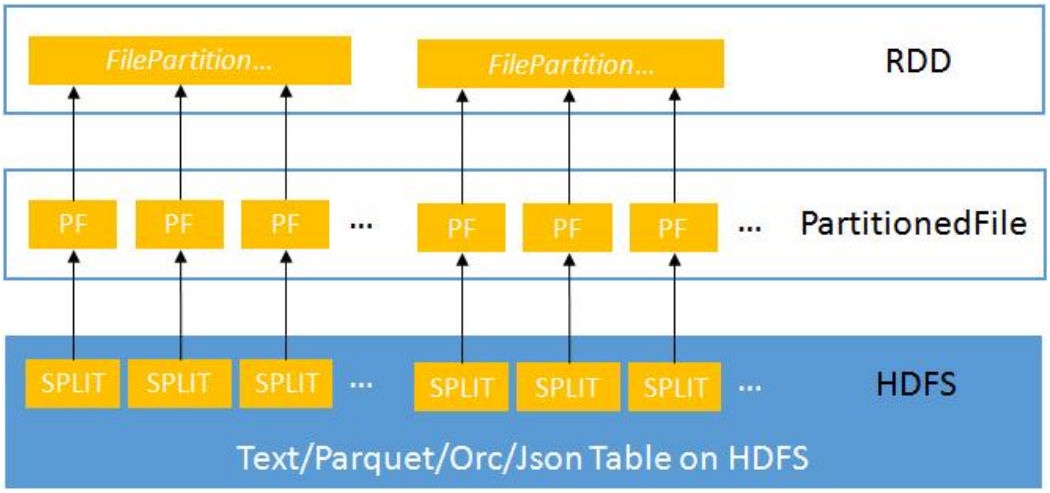
Scenario

A Spark SQL table may have many small files (far smaller than an HDFS block), each of which maps to a partition on the Spark by default. In other words, each

small file is a task. In this way, Spark has to start many such tasks. If a shuffle operation is involved in the SQL logic, the number of hash buckets soars, severely hindering system performance.

In case of massive number of small files, when DataSource creates an RDD, it splits small files in the Spark SQL table to PartitionedFiles and then merges the PartitionedFiles to a partition to avoid generating too many hash buckets during the shuffle operation. See **Figure 12-58**.

Figure 12-58 Merging small files



Procedure

If you want to enable small file optimization, configure the **spark-defaults.conf** file on the Spark client.

Table 12-416 Parameter description

Parameter	Description	Default Value
spark.sql.files.maxPartitionBytes	The maximum number of bytes that can be packed into a single partition when a file is read. Unit: byte	134217728 (128 MB)
spark.files.openCostInBytes	The estimated cost to open a file, measured by the number of bytes that can be scanned in the same time. This is used when putting multiple files into a partition. It is better to over estimate, then the partitions with small files will be faster than partitions with larger files.	4 MB

12.23.7.2.8 Optimizing the Aggregate Algorithms

Scenario

Spark SQL supports hash aggregate algorithm. Namely, use fast aggregate hashmap as cache to improve aggregate performance. The hashmap replaces the previous ColumnarBatch to avoid performance problems caused by the wide mode (multiple key or value fields) of an aggregate table.

Procedure

If you want to enable optimization of aggregate algorithm, configure following parameters in the **spark-defaults.conf** file on the Spark client.

Table 12-417 Parameter description

Parameter	Description	Default Value
spark.sql.codegen.aggregate.map.twolevel.enabled	Specifies whether to enable aggregation algorithm optimization. ● **true**: Enable ● **false**: Disable	true

12.23.7.2.9 Optimizing Datasource Tables

Scenario

Save the partition information about the datasource table to the Metastore and process partition information in the Metastore.

- Optimize the datasource tables, support syntax such as adding, deletion, and modification in the table based on partitions, improving compatibility with Hive.
- Support statements of partition tailoring and push down to the Metastore to filter unmatched partitions.

  Example:

  ```
  select count(*) from table where partCol=1;    //partCol (partition column)
  ```

  You need only to process data corresponding to partCol=1 when performing the TableScan operation in the physical plan.

Procedure

If you want to enable Datasource table optimization, configure the **spark-defaults.conf** file on the Spark client.

Table 12-418 Parameter description

Parameter	Description	Default Value
spark.sql.hive.manageFilesourcePartitions	Specifies whether to enable Metastore partition management (including datasource tables and converted Hive). ● **true** indicates enabling Metastore partition management. In this case, datasource tables are stored in Hive and Metastore is used to tailor partitions in query statements. ● **false** indicates disabling Metastore partition management.	true
spark.sql.hive.metastorePartitionPruning	Specifies whether to support pushing down predicate to Hive Metastore. ● **true** indicates supporting pushing down predicate to Hive Metastore. Only the predicate of Hive tables is supported. ● **false** indicates not supporting pushing down predicate to Hive Metastore.	true
spark.sql.hive.filesourcePartitionFileCacheSize	The cache size of the partition file metadata in the memory. All tables share a cache that can use up to specified num bytes for file metadata. This parameter is valid only when **spark.sql.hive.manageFilesourcePartitions** is set to **true**.	250 * 1024 * 1024
spark.sql.hive.convertMetastoreOrc	The processing approach of ORC tables. ● **false**: Spark SQL uses Hive SerDe to process ORC tables. ● **true**: Spark SQL uses the Spark built-in mechanism to process ORC tables.	true

12.23.7.2.10 Merging CBO

Scenario

Spark SQL supports rule-based optimization by default. However, the rule-based optimization cannot ensure that Spark selects the optimal query plan. Cost-Based Optimizer (CBO) is a technology that intelligently selects query plans for SQL statements. After CBO is enabled, the CBO optimizer performs a series of

estimations based on the table and column statistics to select the optimal query plan.

Procedure

Perform the following steps to enable CBO:

1. You need to run corresponding SQL commands to collect required table and column statistics.

   SQL commands are as follows (to be chosen as required):

   - Generate table-level statistics (table scanning):

     ANALYZE TABLE src COMPUTE STATISTICS

     This command generates **sizeInBytes** and **rowCount**.

     When you use the ANALYZE statement to collect statistics, sizes of tables not from HDFS cannot be calculated.

   - Generate table-level statistics (no table scanning):

     ANALYZE TABLE src COMPUTE STATISTICS NOSCAN

     This command generates only **sizeInBytes**. Compared with the originally generated **sizeInBytes** and **rowCount** if the **sizeInBytes** remains unchanged, **rowCount** (if any) reserves. Otherwise, **rowCount** is cleared.

   - Generate column-level statistics:

     ANALYZE TABLE src COMPUTE STATISTICS FOR COLUMNS a, b, c

     This command generates column statistics and updates table statistics for consistency. Statistics of complicated data types (such as Seq and Map) and HiveStringType cannot be generated.

   - Display statistics:

     DESC FORMATTED src

     This command displays *xxx* bytes and *xxx* rows in **Statistics** to indicate table-level statistics. You can also run the following command to display column statistics:

     DESC FORMATTED src a

   Limitation: The current statistics collection does not support statistics for partition levels for partitioned tables.

2. Configure parameters in **Table 12-419** in the **spark-defaults.conf** file on the Spark client.

   Table 12-419 Parameter description

Parameter	Description	Default Value
spark.sql.cbo.enabled	The switch to enable or disable CBO. • **true**: Enable • **false**: Disable To enable this function, ensure that statistics of related tables and columns are generated.	false

Parameter	Description	Default Value
spark.sql.cbo.joinReorder.enabled	Specifies whether to automatically adjust the sequence of consecutive inner joins by using CBO. • **true**: Enable • **false**: Disable To enable this function, ensure that statistics of related tables and columns are generated and CBO is enabled.	false
spark.sql.cbo.joinReorder.dp.threshold	Specifies the threshold of the number of tables that the sequence of consecutive inner joins is automatically adjusted by CBO. If the threshold is exceeded, the sequence of joins is not adjusted.	12

12.23.7.2.11 Optimizing SQL Query of Data of Multiple Sources

Scenario

This section describes how to enable or disable the query optimization for inter-source complex SQL.

Procedure

- (Optional) Prepare for connecting to the MPPDB data source.

  If the data source to be connected is MPPDB, a class name conflict occurs because the MPPDB Driver file **gsjdbc4.jar** and the Spark JAR package **gsjdbc4-VXXXRXXXCXXSPCXXX.jar** contain the same class name. Therefore, before connecting to the MPPDB data source, perform the following steps:

  a. Move **gsjdbc4-VXXXRXXXCXXSPCXXX.jar** from Spark. Spark running does not depend on this JAR file. Therefore, moving this JAR file to another directory (for example, the **/tmp** directory) will not affect Spark running.

     i. Log in to the Spark server and move **gsjdbc4-VXXXRXXXCXXSPCXXX.jar** from the **${BIGDATA_HOME}/FusionInsight_Spark2x_8.1.0.1/install/FusionInsight-Spark2x-3.1.1/spark/jars** directory.

     ii. Log in to the Spark client host and move **gsjdbc4-VXXXRXXXCXXSPCXXX.jar** from the **/opt/client/Spark2x/spark/jars** directory.

  b. Obtain the MPPDB Driver file **gsjdbc4.jar** from the MPPDB installation package and upload the file to the following directories:

- **/${BIGDATA_HOME}/FusionInsight_Spark2x_8.1.0.1/install/FusionInsight-Spark2x-3.1.1/spark/jars** on the Spark server.
- **/opt/client/Spark2x/spark/jars** on the Spark client.

c. Update the **/user/spark2x/jars/8.1.0.1/spark-archive-2x.zip** package stored in the HDFS.

NOTE

The version 8.1.0.1 is used as an example. Replace it with the actual version number.

i. Log in to the node where the client is installed as a client installation user. Run the following command to switch to the client installation directory, for example, **/opt/client**:

cd /opt/client

ii. Run the following command to configure environment variables:

source bigdata_env

iii. If the cluster is in security mode, run the following command to get authenticated:

kinit *Component service user*

iv. Run the following commands to create the temporary file **./tmp**, obtain **spark-archive-2x.zip** from HDFS, and decompress it to the **tmp** directory:

mkdir tmp

hdfs dfs -get /user/spark2x/jars/8.1.0.1/spark-archive-2x.zip **./**

unzip spark-archive-2x.zip -d ./tmp

v. Switch to the **tmp** directory, delete the **gsjdbc4-VXXXRXXXCXXSPCXXX.jar** file, upload the MPPDB Driver file **gsjdbc4.jar** to the **tmp** directory, and run the following command to compress the file again:

zip -r spark-archive-2x.zip *.jar

vi. Delete **spark-archive-2x.zip** from the HDFS and update the **spark-archive-2x.zip** package generated in **c.v** to the **/user/spark2x/jars/8.1.0.1/** directory in the HDFS.

hdfs dfs -rm /user/spark2x/jars/8.1.0.1/spark-archive-2x.zip

hdfs dfs -put ./spark-archive-2x.zip /user/spark2x/jars/8.1.0.1

d. Restart the Spark service. After the Spark service is restarted, restart the Spark client.

- Enable the optimization function.

  For all modules that support query pushdown, you can run the **SET** command on the **spark-beeline** client to enable the cross-source query optimization function. By default, the function is disabled.

  Pushdown configurations can be performed in dimensions of global, data sources, and tables. Commands are as follows:

  – Global (valid for all data sources):

  SET spark.sql.datasource.jdbc = project,aggregate,orderby-limit

- Data sources:

  SET spark.sql.datasource.${url} = project,aggregate,orderby-limit

- Tables:

  SET spark.sql.datasource.${url}.${table} = project,aggregate,orderby-limit

When you run the **SET** command to configure preceding parameters, you are allowed to specify multiple pushdown modules and separate them by commas. The following table lists parameters of corresponding pushdown modules.

Table 12-420 Parameters of modules

Module	Parameter Value in the SET Command
project	project
aggregate	aggregate
order by, limit over project or aggregate	orderby-limit

The following is a statement for creating an external table of MySQL:

create table if not exists pdmysql using org.apache.spark.sql.jdbc options(driver "com.mysql.jdbc.Driver", url "jdbc:mysql://ip2:3306/test", user "hive", password "*xxx*", dbtable "mysqldata");

In the preceding statement:

- ${url} = jdbc:mysql://ip2:3306/test
- ${table} = mysqldata

NOTE

- On the right of the equal sign (=) is the operators (separated by commas) to be enabled by pushdown.
- Priority: table > data source > global. If the table switch is set, the global switch of the data source is invalid for the table. If a data source switch is set, the global switch is invalid for the data source.
- The equal sign (=) is not allowed in URL. Equal signs (=) are automatically deleted in the SET clause.
- After multiple SET operations, results with different keys will not overwrite each other.

- Add functions that support query pushdown.

  In addition to query pushdown of mathematical, time, and string functions such as abs(), month(), and length(), you can run the **SET** command to add a data source that supports query pushdown. Run the following command on the Spark-beeline client:

  SET spark.sql.datasource.${datasource}.functions = fun1,fun2

- Reset the configuration set by the **SET** command.

  Currently, you can only run the **RESET** command on the **spark-beeline** client to cancel all **SET** content. After running the **RESET** command, all values in the

SET command will be cleared. Exercise caution when performing this operation.

The **SET** command is valid in the current session on the client. After the client is shut down, the content in the **SET** command turns invalid.

Alternatively, change the value of **spark.sql.locale.support** in the **spark-defaults.conf** file to **true**.

Precautions

Only MySQL, MPPDB, Hive, oracle, and PostgreSQL data sources are supported.

12.23.7.2.12 SQL Optimization for Multi-level Nesting and Hybrid Join

Scenario

This section describes the optimization suggestions for SQL statements in multi-level nesting and hybrid join scenarios.

Prerequisites

The following provides an example of complex query statements:

```
elect
s_name,
count(1) as numwait
from (
select s_name from (
select
s_name,
t2.l_orderkey,
l_suppkey,
count_suppkey,
max_suppkey
from
test2 t2 right outer join (
select
s_name,
l_orderkey,
l_suppkey from (
select
s_name,
t1.l_orderkey,
l_suppkey,
count_suppkey,
max_suppkey
from
test1 t1 join (
select
s_name,
l_orderkey,
l_suppkey
from
orders o join (
select
s_name,
l_orderkey,
l_suppkey
from
nation n join supplier s
on
s.s_nationkey = n.n_nationkey
and n.n_name = 'SAUDI ARABIA'
```

```
join lineitem l
on
s.s_suppkey = l.l_suppkey
where
l.l_receiptdate > l.l_commitdate
and l.l_orderkey is not null
) l1 on o.o_orderkey = l1.l_orderkey and o.o_orderstatus = 'F'
) l2 on l2.l_orderkey = t1.l_orderkey
) a
where
(count_suppkey > 1)
or ((count_suppkey=1)
and (l_suppkey <> max_suppkey))
) l3 on l3.l_orderkey = t2.l_orderkey
) b
where
(count_suppkey is null)
or ((count_suppkey=1)
and (l_suppkey = max_suppkey))
) c
group by
s_name
order by
numwait desc,
s_name
limit 100;
```

Procedure

Step 1 Analyze business.

Analyze business to determine whether SQL statements can be simplified through measures, for example, by combining tables to reduce the number of nesting levels and join times.

Step 2 If the SQL statements cannot be simplified, configure the driver memory.

- If SQL statements are executed through spark-submit or spark-sql, go to **Step 3**.
- If SQL statements are executed through spark-beeline, go to **Step 4**.

Step 3 During execution of SQL statements, specify the **driver-memory** parameter. An example of SQL statements is as follows:

/spark-sql --master=local[4] --driver-memory=512M -f /tpch.sql

Step 4 Before running SQL statements, change the memory size as the administrator.

1. Log in to FusionInsight Manager and choose **Cluster >** *Name of the desired cluster* **> Services** > **Spark2x** > **Configurations**.
2. On the displayed page, click **All Configurations** and search for **SPARK_DRIVER_MEMORY**.
3. Modify the **SPARK_DRIVER_MEMORY** parameter value to increase the memory size. The parameter value consists of two parts: memory size (an integer) and the unit (M or G), for example, **512M**.

----End

Reference

In the event of insufficient driver memory, the following error may be displayed during the query:

```
2018-02-11 09:13:14,683 | WARN  | Executor task launch worker for task 5 | Calling spill() on
RowBasedKeyValueBatch. Will not spill but return 0. |

12.23.7.3 Spark Streaming Tuning

Scenario

Streaming is a mini-batch streaming processing framework that features second-level delay and high throughput. To optimize Streaming is to improve its throughput while maintaining second-level delay so that more data can be processed per unit time.

NOTE

This section applies to the scenario where the input data source is Kafka.

Procedure

A simple streaming processing system consists of a data source, a receiver, and a processor. The data source is Kafka, the receiver is the Kafka data source receiver of Streaming, and the processor is Streaming.

Streaming optimization is to optimize the performance of the three components.

- **Data source optimization**

  In actual application scenarios, the data source stores the data in the local disks to ensure the error tolerance of the data. However, the calculation results of the Streaming are stored in the memory, and the data source may become the largest bottleneck of the streaming system.

Kafka can be optimized from the following aspects:

- Use Kafka-0.8.2 or later version that allows you to use new Producer APIs in asynchronous mode.
- Configure multiple Broker directories, multiple I/O threads, and a proper number of partitions for a topic.

For details, see section **Performance Tuning** in the Kafka open source documentation at **http://kafka.apache.org/documentation.html**.

- **Receiver optimization**

  Streaming has multiple data source receivers, such as Kafka, Flume, MQTT, and ZeroMQ. Kafka has the most receiver types and is the most mature receiver.

  Kafka provides three types of receiver APIs:

  - KafkaReceiver directly receives Kafka data. If the process is abnormal, data may be lost.
  - ReliableKafkaReceiver receives data displacement through ZooKeeper records.
  - DirectKafka reads data from each partition of Kafka through the RDD, ensuring high reliability.

  According to the implementation mechanism and test results, DirectKafka provides better performance than the other two APIs. Therefore, the DirectKafka API is recommended to implement the receiver.

  For details about the Kafka receivers and their optimization methods, see the Kafka open source documentation at **http://kafka.apache.org/documentation.html**.

- **Processor optimization**

  The bottom layer of Spark Streaming is executed by Spark. Therefore, most optimization measures for Spark can also be applied to Spark Streaming. The following is an example:

  - Data serialization
  - Memory configuration
  - Configuring DOP
  - Using the external shuffle service to improve performance

  NOTE

  Higher performance of Spark Streaming indicates lower overall reliability. Examples:

  If **spark.streaming.receiver.writeAheadLog.enable** is set to **false**, disk I/Os are reduced and performance is improved. However, because WAL is disabled, data is lost during fault recovery.

  Therefore, do not disable configuration items that ensure data reliability in production environments during Spark Streaming tuning.

- **Log archive optimization**

  The **spark.eventLog.group.size** parameter is used to group **JobHistory** logs of an application based on the specified number of jobs. Each group creates a file recording log to prevent **JobHistory** reading failures caused by an oversized log generated during the long-term running of the application. If this parameter is set to **0**, logs are not grouped.

  Most Spark Streaming jobs are small jobs and are generated at a high speed. As a result, frequent grouping is performed and a large number of small log

files are generated, consuming disk I/O resources. You are advised to increase the parameter value to, for example, **1000** or greater.

12.23.8 Common Issues About Spark2x

12.23.8.1 Spark Core

12.23.8.1.1 How Do I View Aggregated Spark Application Logs?

Question

How do I view the aggregated container logs on the page when the log aggregation function is enabled on YARN?

Answer

For details, see **Viewing Aggregated Container Logs on the Web UI**.

12.23.8.1.2 Why Is the Return Code of Driver Inconsistent with Application State Displayed on ResourceManager WebUI?

Question

Communication between ApplicationMaster and ResourceManager remains abnormal for a long time. Why is the driver return code inconsistent with application status on ResourceManager WebUI?

Answer

In yarn-client mode, Spark Driver and ApplicationMaster run as two independent processes. When Driver exits, it notifies ApplicationMaster to call the unregister API to deregister itself with ResourceManager.

This is a remote call and susceptible to network faults. If there exists a network fault, ApplicationMaster uses the retry mechanism of the Yarn client to try again. If the network is recovered before the maximum number of retries is reached, ApplicationMaster exits gracefully.

If the number and duration of retries are reached, ApplicationMaster fails to deregister itself, and ResourceManager declares ApplicationMaster to have exited forcibly and tries to restart ApplicationMaster. After the restart, if ApplicationMaster fails to connect to the exited Driver, ResourceManager flags the Application being failed.

This problem rarely occurs and it does not impact the display of application states by SparkSQL. You can also increase the number of Yarn client connections and the connection duration to reduce the probability of this event. For details about the configuration, see **http://hadoop.apache.org/docs/r3.1.1/hadoop-yarn/hadoop-yarn-common/yarn-default.xml**.

12.23.8.1.3 Why Cannot Exit the Driver Process?

Question

Why cannot exit the Driver process after running the **yarn application -kill applicationID** command to stop the Spark Streaming application?

Answer

Running the **yarn application -kill applicationID** command can only stop the SparkContext corresponding to Spark Streaming application, but cannot exit the current Driver process. If there are other permanent threads in the Driver process (for example, the spark shell is continually checking command input or Spark Streaming is continually reading data form data source), the Driver process will not be killed when the SparkContext is stopped. To exit the Driver process, you are advised to run the **kill -9 pid** command to kill the current Driver process by hand.

12.23.8.1.4 Why Does FetchFailedException Occur When the Network Connection Is Timed out

Question

On a large cluster of 380 nodes, run the ScalaSort test case in the HiBench test that runs the 29T data, and configure Executor as **--executor-cores 4**. The following abnormality is displayed:

```
org.apache.spark.shuffle.FetchFailedException: Failed to connect to /192.168.114.12:23242

    at io.netty.util.concurrent.SingleThreadEventExecutor$2.run(SingleThreadEventExecutor.java:111)
    ... 1 more
```

Answer

When an application is run, configure the Executor parameter as **--executor-cores 4**. The degree of parallelism (DOP) is high in a single process, resulting in that the IO is highly occupied and the task works slowly.

```
16/02/26 10:04:53 INFO TaskSetManager: Finished task 2139.0 in stage 1.0 (TID 151149) in 376455 ms on
10-196-115-2 (694/153378)
```

Because running a single task takes more than 6 minutes. The network connection is timed out and the running task fails.

Set the number of cores as 1, which is **--executor-cores 1**. A task is executed smoothly in proper time (within 15s).

```
16/02/29 02:24:46 INFO TaskSetManager: Finished task 59564.0 in stage 1.0 (TID 208574) in 15088 ms on
10-196-115-6 (59515/153378)
```

Therefore, to process the task of network connection timed out and avoid such error, you can reduce the core number of a single Executor.

12.23.8.1.5 How to Configure Event Queue Size If Event Queue Overflows?

Question

How to configure the event queue size if the following Driver log information is displayed indicating that the event queue overflows?

- Common applications

  ```
  Dropping SparkListenerEvent because no remaining room in event queue.
  This likely means one of the SparkListeners is too slow and cannot keep
  up with the rate at which tasks are being started by the scheduler.
  ```

- Spark Streaming applications

  ```
  Dropping StreamingListenerEvent because no remaining room in event queue.
  This likely means one of the StreamingListeners is too slow and cannot keep
  up with the rate at which events are being started by the scheduler.
  ```

Answer

1. Stop the application. Set the configuration option **spark.event.listener.logEnable** in the Spark configuration file **spark-**

defaults.conf to **true**. And set the configuration option **spark.eventQueue.size** to **1000W**. If you need to control the logging rate (in milliseconds), also change the value of the configuration option **spark.event.listener.logRate**.

By default, the logging rate is 1000 ms, which means that one log is printed out every 1000 ms.

2. Start the application.

   The following log information is displayed, including the event consumption rate, event production rate, and **MaxSize** (maximum size of messages in the queue).

   ```
   INFO LiveListenerBus: [SparkListenerBus]:16044 events are consumed in 5000 ms.
   INFO LiveListenerBus: [SparkListenerBus]:51381 events are produced in 5000 ms, eventQueue still has 86417 events, MaxSize: 171764.
   ```

3. Change the value of the configuration option **spark.eventQueue.size** in the Spark configuration file **spark-defaults.conf** based on the **MaxSize** in the log information.

   For example, if **MaxSize** is 250000, the appropriate message queue size is 300000.

12.23.8.1.6 What Can I Do If the getApplicationReport Exception Is Recorded in Logs During Spark Application Execution and the Application Does Not Exit for a Long Time?

Question

During Spark application execution, if the driver fails to connect to ResourceManager, the following error is reported and it does not exit for a long time. What can I do?

```
16/04/23 15:31:44 INFO RetryInvocationHandler: Exception while invoking getApplicationReport of class ApplicationClientProtocolPBClientImpl over 37 after 1 fail over attempts. Trying to fail over after sleeping for 44160ms.
java.net.ConnectException: Call From vm1/192.168.39.30 to vm1:8032 failed on connection exception: java.net.ConnectException: Connection refused; For more details see:  http://wiki.apache.org/hadoop/ConnectionRefused
```

Answer

In Spark, there is a scheduled thread that listens to the status of ApplicationMaster by connecting to ResourceManager. The connection to the ResourceManager times out. As a result, the preceding error is reported and the system keeps trying to connect to the ResourceManager. In the ResourceManager, the number of retry times is limited. By default, the number of retry times is 30 and the retry interval is about 30 seconds. The preceding error is reported during each retry. The driver exits only after the number of times is exceeded.

Table 12-421 describes the retry-related configuration items in the ResourceManager.

Table 12-421 Parameter description

Parameter	Description	Default Value
yarn.resourcemanager.connect.max-wait.ms	Maximum waiting time for connecting to the ResourceManager.	900000
yarn.resourcemanager.connect.retry-interval.ms	Interval for reconnecting to the ResourceManager.	30000

Number of retries (**yarn.resourcemanager.connect.max-wait.ms/yarn.resourcemanager.connect.retry-interval.ms**) = Maximum waiting time for connecting to the ResourceManager/Interval for reconnecting to the ResourceManager

On the Spark client, modify the **conf/yarn-site.xml** file to add and configure **yarn.resourcemanager.connect.max-wait.ms** and **yarn.resourcemanager.connect.retry-interval.ms**. In this way, the number of retry times can be changed, and the Spark application can exit in advance.

12.23.8.1.7 What Can I Do If "Connection to ip:port has been quiet for xxx ms while there are outstanding requests" Is Reported When Spark Executes an Application and the Application Ends?

Question

When Spark executes an application, an error similar to the following is reported and the application ends. What can I do?

```
2016-04-20 10:42:00,557 | ERROR | [shuffle-server-2] | Connection to 10-91-8-208/10.18.0.115:57959 has been quiet for 180000 ms while there are outstanding requests. ```

Answer

Symptom: The value of **spark.rpc.io.connectionTimeout** is less than the value of **spark.rpc.askTimeout**. In full GC or network delay scenarios, when the channel reaches the expiration time and still receives no response, the channel is terminated. When detecting that the channel is terminated, the AM considers the driver as disconnected, and the entire application is stopped.

Solution: Set the parameter in the **spark-defaults.conf** file on the Spark client by running the **set** command. During parameter configuration, ensure that the channel expiration time (**spark.rpc.io.connectionTimeout**) is greater than or equal to the RPC response timeout (**spark.rpc.askTimeout**).

Table 12-422 Parameter description

Parameter	Description	Default Value
spark.rpc.askTimeout	RPC response timeout. If this parameter is not set, the value of **spark.network.timeout** is used by default.	120s

12.23.8.1.8 Why Do Executors Fail to be Removed After the NodeManeger Is Shut Down?

Question

If the NodeManager is shut down with the Executor dynamic allocation enabled, the Executors on the node where the NodeManeger is shut down fail to be removed from the driver page after the idle time expires.

Answer

When the ResourceManager detects that the NodeManager is shut down, the driver has requested to kill Executors due to idle time expiry. However, the Executors cannot actually be killed because the NodeManager is shut down. The driver cannot detect the LOST events of these Executors and does not remove Executors from its Executor list. Therefore, the Executors are not removed from the driver page. This phenomenon is normal after the YARN NodeManager is shut down. The Executors will be removed after the NodeManager restarts.

12.23.8.1.9 What Can I Do If the Message "Password cannot be null if SASL is enabled" Is Displayed?

Question

ExternalShuffle is enabled for the application that runs Spark. Task loss occurs in the application because the message "java.lang.NullPointerException: Password cannot be null if SASL is enabled" is displayed. The following shows some key logs:

```
2016-05-13 12:05:27,093 | WARN  | [task-result-getter-2] | Lost task 98.0 in stage 22.1 (TID 193603, linux-173, 2): FetchFailed(BlockManagerId(13, 172.168.100.13, 27337),
org.apache.spark.shuffle.FetchFailedException: java.lang.NullPointerException: Password cannot be null if SASL is enabled
        at org.spark-project.guava.base.Preconditions.checkNotNull(Preconditions.java:208)
        at org.apache.spark.network.sasl.SparkSaslServer.encodePassword(SparkSaslServer.java:196)
        at org.apache.spark.network.sasl.SparkSaslServer$DigestCallbackHandler.handle(SparkSaslServer.java:166)
        at com.sun.security.sasl.digest.DigestMD5Server.validateClientResponse(DigestMD5Server.java:589)
        at com.sun.security.sasl.digest.DigestMD5Server.evaluateResponse(DigestMD5Server.java:244)
        at org.apache.spark.network.sasl.SparkSaslServer.response(SparkSaslServer.java:119)
        at org.apache.spark.network.sasl.SaslRpcHandler.receive(SaslRpcHandler.java:100)
        at org.apache.spark.network.server.TransportRequestHandler.processRpcRequest(TransportRequestHandler.java:128)
        at org.apache.spark.network.server.TransportRequestHandler.handle(TransportRequestHandler.java:99)
        at org.apache.spark.network.server.TransportChannelHandler.channelRead0(TransportChannelHandler.java:104)
```

Answer

The cause is that NodeManager restarts. When ExternalShuffle is used, Spark uses NodeManager to transmit shuffle data. Therefore, the memory of NodeManager may be seriously insufficient.

In the FusionInsight of the current version, the default memory of NodeManager is only 1 GB. When the data volume of Spark tasks is large (greater than 1 TB), the memory is severely insufficient and the message response is slow. As a result, the FusionInsight health check determines that the NodeManager process exits and forcibly restarts the NodeManager, causing the preceding problem.

Solution

Adjust the memory of the NodeManager. If the data volume is large (greater than 1 TB), the memory of NodeManager must be greater than 4 GB.

12.23.8.1.10 What Should I Do If the Message "Failed to CREATE_FILE" Is Displayed in the Restarted Tasks When Data Is Inserted Into the Dynamic Partition Table?

Question

When inserting data into the dynamic partition table, a large number of shuffle files are damaged due to the disk disconnection, node error, and the like. In this case, why the message **Failed to CREATE_FILE** is displayed in the restarted tasks?

```
2016-06-25 15:11:31,323 | ERROR | [Executor task launch worker-0] | Exception in task 15.0 in stage 10.1 (TID 1258) | org.apache.spark.Logging$class.logError(Logging.scala:96)

```

Answer

The last step of inserting data into the dynamic partition table is to read shuffle files and then write the data to the mapped partition files.

After a large number of shuffle files are damaged, a large number of tasks fail, causing the restart of jobs. Before the restart of jobs, Spark closes the handles that write table partition files. However, the HDFS cannot process the scenario of batch tasks closing handles. After tasks restart next time, the handles are not released in a timely manner on the NameNode. As a result, the message **Failed to CREATE_FILE** is displayed.

This error only occurs when a large number of shuffle files are damaged. The tasks will restart after the error occurs and the restart can be completed within milliseconds.

12.23.8.1.11 Why Tasks Fail When Hash Shuffle Is Used?

Question

When Hash shuffle is used to run a job that consists of 1000000 map tasks x 100000 reduce tasks, run logs report many message failures and Executor heartbeat timeout, leading to task failures. Why does this happen?

Answer

During the shuffle process, Hash shuffle just writes the data of different reduce partitions to their respective disk files according to hash results without sorting the data.

If there are many reduce partitions, a large number of disk files will be generated. In your case, 10^11 shuffle files, that is, 1000000 * 100000 shuffle files, will be generated. The sheer number of disk files will have a great impact on the file read and write performance. In addition, the operations such as sorting and compressing will consume a large amount of temporary memory space because a large number of file handles are open, presenting great challenges to memory

management and garbage collection and incurring the possibility that the Executor fails to respond to Driver.

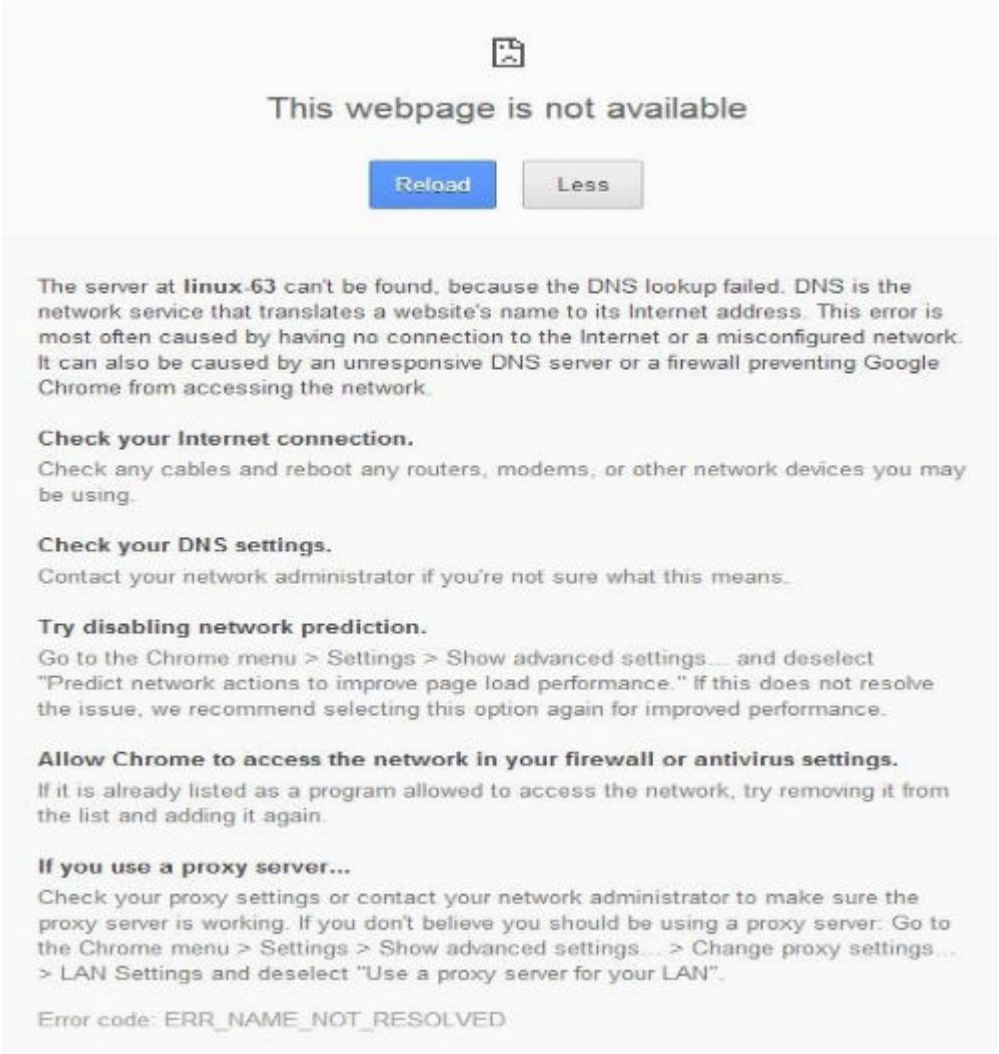
Sort shuffle, instead of Hash shuffle, is recommended to run a job.

12.23.8.1.12 What Can I Do If the Error Message "DNS query failed" Is Displayed When I Access the Aggregated Logs Page of Spark Applications?

Question

When the **http(s)://<spark ip>:<spark port>** mode is used to access the Spark JobHistory page, if the displayed Spark JobHistory page is not the page of FusionInsight Manager (the URL of FusionInsight Manager is similar to **https://<oms ip>:20026/Spark2x/JobHistory2x/xx/**), click an application and click **AggregatedLogs**, click the logs of an executor to be viewed. An error message in **Figure 12-59** is displayed.

Figure 12-59 DNS query failure



Answer

Cause: The domain name is not added to the **hosts** file of the Windows OS in the pop-up URL (for example, **https://<hostname>:20026/Spark2x/JobHistory2x/xx/history/application_xxx/jobs/**). As a result, the DNS query fails and the web page cannot be displayed.

Solution:

- You are advised to visit **Spark JobHistory** page using the FusionInsight Manager..
- If you do not want to access the **Spark JobHistory** page using the FusionInsight Manager, change **<hostname>** in the URL to the IP address or add the domain name to the **hosts** file of the Windows OS.

12.23.8.1.13 What Can I Do If Shuffle Fetch Fails Due to the "Timeout Waiting for Task" Exception?

Question

When I execute a 100 TB TPC-DS test suite in the JDBCServer mode, the "Timeout waiting for task" is displayed. As a result, shuffle fetch fails, the stage keeps retrying, and the task cannot be completed properly. What can I do?

Answer

The ShuffleService function is used in JDBCServer mode. In the reduce phase, all executors obtain data from NodeManager. When the data volume reaches a level (more than 10 TB), the NodeManager may reach the bottleneck (ShuffleService is in the NodeManager process). As a result, some tasks for obtaining data time out. Therefore, the problem occurs.

You are advised to disable ShuffleService for Spark tasks whose data volume is greater than 10 TB. That is, set **spark.shuffle.service.enabled** in the **Spark-defaults.conf** configuration file to **false**.

12.23.8.1.14 Why Does the Stage Retry due to the Crash of the Executor?

Question

When I run Spark tasks with a large data volume, for example, 100 TB TPCDS test suite, why does the Stage retry due to Executor loss sometimes? The message "Executor 532 is lost rpc with driver, but is still alive, going to kill it" is displayed, indicating that the loss of the Executor is caused by a JVM crash.

The log of the key JVM crash is as follows:

```
#
# A fatal error has been detected by the Java Runtime Environment:
#
#  Internal Error (sharedRuntime.cpp:834), pid=241075, tid=140476258551552
#  fatal error: exception happened outside interpreter, nmethods and vtable stubs at pc
0x00007fcda9eb8eb1
```

Answer

This error does not affect services. This error is caused by defects of the Oracle JVM, but not the platform code. There is the fault tolerance mechanism for Executors in Spark: the Stage retries in case of an Executor crash to ensure the success execution of tasks.

12.23.8.1.15 Why Do the Executors Fail to Register Shuffle Services During the Shuffle of a Large Amount of Data?

Question

When more than 50 terabytes of data is shuffled, some executors fail to register shuffle services due to timeout. The shuffle tasks then fail. Why? The error log is as follows:

```
2016-10-19 01:33:34,030 | WARN | ContainersLauncher #14 | Exception from container-launch with

ContainerExecutor.java:300
```

Answer

The imported data exceeds 50 TB, which exceeds the shuffle processing capability. The shuffle may fail to respond to the registration request of an executor in a timely manner due to the heavy load.

The timeout interval for an executor to register the shuffle service is 5 seconds. The maximum number of retries is 3. This parameter is not configurable.

You are advised to increase the number of task retry times and the number of allowed executor failure times.

Configure the following parameters in the **spark-defaults.conf** file on the client: If **spark.yarn.max.executor.failures** does not exist, manually add it.

Table 12-423 Parameter Description

Parameter	Description	Default Value
spark.task.maxFailures	Specifies task retry times.	4
spark.yarn.max.executor.failures	Specifies executor failure attempt times. Set **spark.dynamicAllocation.enabled** to **false**, to disable the dynamic allocation of executors.	numExecutors * 2, with minimum of 3
	Specifies executor failure attempt times. Set **spark.dynamicAllocation.enabled** to **true**, to enable the dynamic allocation of executors.	3

12.23.8.1.16 Why Does the Out of Memory Error Occur in NodeManager During the Execution of Spark Applications

Question

During the execution of Spark applications, if the YARN External Shuffle service is enabled and there are too many shuffle tasks, the **java.lang.OutofMemoryError: Direct buffer Memory** error occurs, indicating insufficient memory. The error log is as follows:

```
2016-12-06 02:01:00,768 | WARN  | shuffle-server-38 | Exception in connection from /192.168.101.95:53680 | TransportChannelHandler.java:79

    ... 10 more
```

Answer

In the Shuffle Service of YARN, the number of started threads are twice of the number of available CPU cores. The default size of direct buffer memory is 128 MB. If there are too many shuffle tasks connected at the same time, the direct buffer memory allocated to each thread service is insufficient. For example, if there are 40 CPU cores and there are 80 threads started by the Shuffle Service of YARN, the direct buffer memory allocated to each thread is less than 2 MB.

To solve this problem, increase the directory buffer memory based on the number of CPU cores in NodeManager. For example, if there are 40 of CPU cores, increase the direct buffer memory to 512 MB, that is, configure the **GC_OPTS** parameter of NodeManager as follows:

-XX:MaxDirectMemorySize=512M

NOTE

By default, **-XX:MaxDirectMemorySize** is not configured in the **GC_OPTS** parameter. To configure it, you need to add it to the **GC_OPTS** parameter as an custom option.

To configure the **GC_OPTS** parameter, log in to FusionInsight Manager, choose **Cluster >** *Name of the desired cluster* **> Services** > **Yarn** > **Configurations**, click **All Configurations**, and choose **NodeManager > System**, and then modify the **GC_OPTS** parameter.

Table 12-424 Parameter description

Parameter	Description	Default Value
GC_OPTS	The GC parameter of YARN NodeManger.	128M

12.23.8.1.17 Why Does the Realm Information Fail to Be Obtained When SparkBench is Run on HiBench for the Cluster in Security Mode?

Question

Execution of the sparkbench task (for example, Wordcount) of HiBench6 fails. The bench.log indicates that the Yarn task fails to be executed. The failure information displayed on the Yarn UI is as follows:

```
Exception in thread "main" org.apache.spark.SparkException: Unable to load YARN support

 ... 16 more
Caused by: KrbException: Cannot locate default realm
 at sun.security.krb5.Config.getDefaultRealm(Config.java:1029)
 ... 22 more
```

Answer

In C80SPC200 and later, the file stored in the **/etc/krb5.conf** directory is no longer replaced during cluster installation. Instead, the file is stored in the corresponding path on the client through parameter configurations, and HiBench does not reference the client configuration file. Solution: Use the file stored in the **/opt/client/KrbClient/kerberos/var/krb5kdc/krb5.conf** directory on the client to overwrite that in the **/etc/krb5.conf** directories of all nodes. Make a backup before the overwriting.

12.23.8.2 Spark SQL and DataFrame

12.23.8.2.1 What Do I have to Note When Using Spark SQL ROLLUP and CUBE?

Question

Suppose that there is a table src(d1, d2, m) with the following data:

```
1 a 1
1 b 1
2 b 2
```

The results for statement "select d1, sum(d1) from src group by d1, d2 with rollup" are shown as below:

```
NULL 0
1    2
2    2
1    1
1    1
2    2
```

Why the first line of the above results is (NULL,0), rather than (NULL,4)?

Answer

When conducting the rollup and cube operation, we usually perform the dimension-based analysis and what we need is the measurement result, so we would not conduct aggregation operation on the dimension.

Suppose that there is a table src(d1, d2, m), so the statement 1 "select d1, sum(m) from src group by d1, d2 with rollup" conducts the rollup operation on the dimension d1 and d2 to compute the result of m. It has actual business meaning, and its results are in line with the expectation. However, the statement 2 "select d1, sum(d1) from src group by d1, d2 with rollup" cannot be explained from the business perspective. For the statement 2, the result for all aggregations (sum/avg/max/min) is 0.

NOTE

Only when there is an aggregation operation for fields in "group by" in the rollup and cube operation, the result is 0. For non-rollup and non-cube operations, the result will be in line with the expectation.

12.23.8.2.2 Why Spark SQL Is Displayed as a Temporary Table in Different Databases?

Question

Why temporary tables of the previous database are displayed after the database is switched?

1. Create a temporary DataSource table, for example:
```
create temporary table ds_parquet
using org.apache.spark.sql.parquet
options(path '/tmp/users.parquet');
```
2. Switch to another database, and run ***show tables***. The temporary table created in the previous table is displayed.
```
0: jdbc:hive2://192.168.169.84:22550/default> show tables;
+-----------------+--------------+--+
|    tableName    | isTemporary  |
+-----------------+--------------+--+
| ds_parquet      | true         |
| cmb_tbl_carbon  | false        |
+-----------------+--------------+--+
2 rows selected (0.109 seconds)
0: jdbc:hive2://192.168.169.84:22550/default>
```

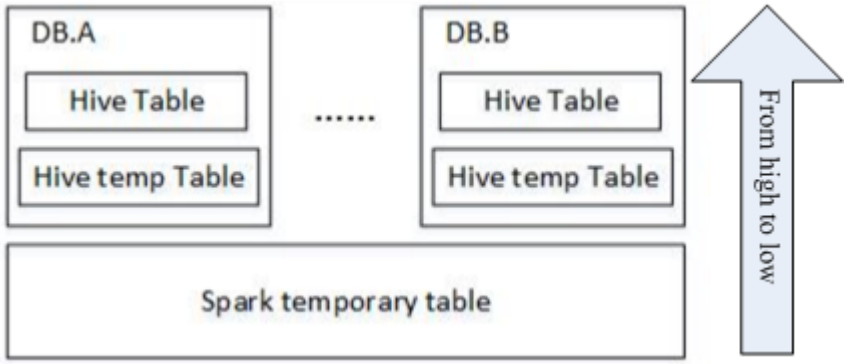
Answer

The table management hierarchy of Spark is shown in **Figure 12-60**. The lowest layer stores all temporary DataSource tables. There is no such concept as database at this layer. DataSource tables are visible in various databases.

The MetaStore of Hive is located at the upper layer. This layer distinguishes among databases. In each database, there are two types of Hive table, permanent and temporary. Therefore, Spark supports data tables of the same name at three layers.

During query, SparkSQL first checks for temporary Spark tables, then temporary Hive tables in the current database, and at last the permanent tables in the current database.

Figure 12-60 Spark table management hierarchy



When a session quits, temporary tables related to the user operation are automatically deleted. Manual deletion of temporary files is not recommended.

When deleting temporary files, use the same priority as that for query. The priorities are temporary Spark table, temporary Hive table, and permanent Hive table ranging from high to low. If you want to directly delete Hive tables but not temporary Spark tables, you can directly use the ***drop table DbName.TableName*** command.

12.23.8.2.3 How to Assign a Parameter Value in a Spark Command?

Question

Is it possible to assign parameter values through Spark commands, in addition to through a user interface or a configuration file?

Answer

Spark configuration options can be defined either in a configuration file or in Spark commands.

To assign a parameter value, run the --conf command on a Spark client. The parameter value takes effect immediately after the command is run.

The command format is --conf + parameter name + parameter value. Example command:

--conf spark.eventQueue.size=50000

12.23.8.2.4 What Directory Permissions Do I Need to Create a Table Using SparkSQL?

Question

The following error information is displayed when a new user creates a table using SparkSQL:

```
0: jdbc:hive2://192.168.169.84:22550/default> create table testACL(c string);
Error: org.apache.spark.sql.execution.QueryExecutionException: FAILED: Execution Error, return code 1 from

    at org.apache.hadoop.ipc.Server$Handler.run(Server.java:2083)
) (state=,code=0)
```

Answer

When you create a table using Spark SQL, the interface of Hive is called by the underlying system and a directory named after the table will be created in the **/user/hive/warehouse** directory. Therefore, you must have the permissions to read, write, and execute the **/user/hive/warehouse** directory or the group permission of Hive.

The**/user/hive/warehouse** is specified by the hive.metastore.warehouse.dir parameter.

12.23.8.2.5 Why Do I Fail to Delete the UDF Using Another Service?

Question

Why do I fail to delete the UDF using another service, for example, delete the UDF created by Hive using Spark SQL.

Answer

The UDF can be created using any of the following services:

1. Hive client.
2. JDBCServer API. You can connect JDBCServer to Spark Beeline or JDBC client code, and run SQL statements to create the UDF.
3. spark-sql.

The scenarios in which the UDF failed to be deleted may be as follows:

- If you use Spark Beeline to delete the UDF created by other services, you must restart the JDBCServer before the deletion. Otherwise, the deletion fails. If you use spark-sql to delete the UDF created by other services, you must restart the spark-sql before the deletion. Otherwise, the deletion fails.

  Cause: After the UDF is created, if the JDBCServer or the spark-sql has not been restarted, the newly created UDF will not be saved by the FunctionRegistry object in the thread where Spark locates. As a result, the UDF failed to be deleted.

  Solution: Restart the JDBCServer and spark-sql of the Spark client and delete the UDF.

- When creating UDF on the Hive client, the **add jar** command (e.g. **add jar /opt/test/two_udfs.jar**) is used to add the **.jar** package instead of specifying the path of **.jar** package in creating UDF statement. As a result, the **ClassNotfound** error occurs when you use other services to delete the UDF.

  Cause: When you use a service to delete the UDF, the service will load the class that corresponds to the UDF to obtain the UDF. However, the **.jar** package is added by the ***add jar*** command and jar package does not exist in the classpath of other services. As a result, the **ClassNotfound** error occurs and the UDF failed to be deleted.

  Solution: The UDF created using the preceding approach must be deleted using the same approach. No other approaches are allowed.

12.23.8.2.6 Why Cannot I Query Newly Inserted Data in a Parquet Hive Table Using SparkSQL?

Question

Why cannot I query newly inserted data in a parquet Hive table using SparkSQL? This problem occurs in the following scenarios:

1. For partitioned tables and non-partitioned tables, after data is inserted on the Hive client, the latest inserted data cannot be queried using SparkSQL.
2. After data is inserted into a partitioned table using SparkSQL, if the partition information remains unchanged, the newly inserted data cannot be queried using SparkSQL.

Answer

To improve Spark performance, parquet metadata is cached. When the parquet table is updated by Hive or another means, the cached metadata remains unchanged, resulting in SparkSQL failing to query the newly inserted data.

For a parquet Hive partition table, if the partition information remains unchanged after data is inserted, the cached metadata is not updated. As a result, the newly inserted data cannot be queried by SparkSQL.

To solve the query problem, update metadata before starting a Spark SQL query.

REFRESH TABLE table_name;

table_name indicates the name of the table to be updated. The table must exist. Otherwise, an error is reported.

When the query statement is executed, the latest inserted data can be obtained.

For details, visit **https://archive.apache.org/dist/spark/docs/3.1.1/sql-programming-guide.html#metadata-refreshing**.

12.23.8.2.7 How to Use Cache Table?

Question

What is cache table used for? Which point should I pay attention to while using cache table?

Answer

Spark SQL caches tables into memory so that data can be directly read from memory instead of disks, reducing memory overhead due to disk reads.

Note that cached tables consume Executor's memory. This means that caching large or many tables compromises Executor's stability even if compressed storage has been used to reduce memory overhead as much as possible.

If it is no longer necessary to accelerate data query by means of cache table, run the following command to uncache tables to free up memory:

uncache table *table_name*

NOTE

The Storage tab page of the Spark Driver user interface displays the cached tables.

12.23.8.2.8 Why Are Some Partitions Empty During Repartition?

Question

During the repartition operation, the number of blocks (**spark.sql.shuffle.partitions**) is set to 4,500, and the number of keys used by repartition exceeds 4,000. It is expected that data corresponding to different keys can be allocated to different partitions. However, only 2,000 partitions have data, and data corresponding to different keys is allocated to the same partition.

Answer

This is normal.

The partition to which data is distributed is obtained by performing a modulo operation on hashcode of a key. Different hashcodes may have the same modulo result. In this case, data is distributed to the same partition, as a result, some partitions do not have data, and some partitions have data corresponding to multiple keys.

You can adjust the value of **spark.sql.shuffle.partitions** to adjust the cardinality during modulo operation and improve the unevenness of data blocks. After multiple verifications, it is found that the effect is good when the parameter is set to a prime number or an odd number.

Configure the following parameters in the **spark-defaults.conf** file on the Driver client.

Table 12-425 Parameter Description

Parameter	Description	Default Value
spark.sql.shuffle.partitions	Number of shuffle data blocks during the shuffle operation.	200

12.23.8.2.9 Why Does 16 Terabytes of Text Data Fails to Be Converted into 4 Terabytes of Parquet Data?

Question

When the default configuration is used, 16 terabytes of text data fails to be converted into 4 terabytes of parquet data, and the error information below is displayed. Why?

```
Job aborted due to stage failure: Task 2866 in stage 11.0 failed 4 times, most recent failure: Lost task
2866.6 in stage 11.0 (TID 54863, linux-161, 2): java.io.IOException: Failed to connect to /10.16.1.11:23124
at org.apache.spark.network.client.TransportClientFactory.createClient(TransportClientFactory.java:214)
at org.apache.spark.network.client.TransportClientFactory.createClient(TransportClientFactory.java:167)
at org.apache.spark.network.netty.NettyBlockTransferService$$anon
$1.createAndStart(NettyBlockTransferService.scala:92)
```

Table 12-426 lists the default configuration.

Table 12-426 Parameter Description

Parameter	Description	Default Value
spark.sql.shuffle.partitions	Number of shuffle data blocks during the shuffle operation.	200
spark.shuffle.sasl.timeout	Timeout interval of SASL authentication for the shuffle operation. Unit: second	120s
spark.shuffle.io.connectionTimeout	Timeout interval for connecting to a remote node during the shuffle operation. Unit: second	120s
spark.network.timeout	Timeout interval for all network connection operations. Unit: second	360s

Answer

The current data volume is 16 TB, but the number of partitions is only 200. As a result, each task is overloaded and the preceding problem occurs.

To solve the preceding problem, you need to adjust the parameters.

- Increase the number of partitions to divide the task into smaller ones.

- Increase the timeout interval during task execution.

Configure the following parameters in the **spark-defaults.conf** file on the client:

Table 12-427 Parameter Description

Parameter	Description	Recommended Value
spark.sql.shuffle.partitions	Number of shuffle data blocks during the shuffle operation.	4501
spark.shuffle.sasl.timeout	Timeout interval of SASL authentication for the shuffle operation. Unit: second	2000s
spark.shuffle.io.connectionTimeout	Timeout interval for connecting to a remote node during the shuffle operation. Unit: second	3000s
spark.network.timeout	Timeout interval for all network connection operations. Unit: second	360s

12.23.8.2.10 Why the Operation Fails When the Table Name Is TABLE?

Question

When the table name is set to **table**, why the error information similar to the following is displayed after the **drop table table** command or other command is run?

```
16/07/12 18:56:29 ERROR SparkSQLDriver: Failed in [drop table table]
java.lang.RuntimeException: [1.1] failure: identifier expected
table
^
at scala.sys.package$.error(package.scala:27)
at org.apache.spark.sql.catalyst.SqlParserTrait$class.parseTableIdentifier(SqlParser.scala:56)
at org.apache.spark.sql.catalyst.SqlParser$.parseTableIdentifier(SqlParser.scala:485)
```

Answer

The word table is a keyword of Spark SQL statements and must not be used as a table name.

12.23.8.2.11 Why Is a Task Suspended When the ANALYZE TABLE Statement Is Executed and Resources Are Insufficient?

Question

When the ***analyze table*** statement is executed using spark-sql, the task is suspended and the information below is displayed. Why?

```
spark-sql> analyze table hivetable2 compute statistics;
Query ID = root_20160716174218_90f55869-000a-40b4-a908-533f63866fed
Total jobs = 1
Launching Job 1 out of 1
Number of reduce tasks is set to 0 since there's no reduce operator
16/07/20 17:40:56 WARN JobResourceUploader: Hadoop command-line option parsing not performed.
Implement the Tool interface and execute your application with ToolRunner to remedy this.
Starting Job = job_1468982600676_0002, Tracking URL = http://10-120-175-107:8088/proxy/
application_1468982600676_0002/
Kill Command = /opt/hadoopclient/HDFS/hadoop/bin/hadoop job  -kill job_1468982600676_0002
```

Answer

When the statement is executed, the SQL statement starts the ***analyze table hivetable2 compute statistics*** MapReduce tasks. On the ResourceManager Web UI of Yarn, the task is not executed due to insufficient resources. As a result, the task is suspended.

Figure 12-61 ResourceManager Web UI

You are advised to add **noscan** when running the ***analyze table*** statement. The function of this statement is the same as that of the ***analyze table hivetable2 compute statistics*** statement. The command is as follows:

```
spark-sql> analyze table hivetable2 compute statistics noscan
```

This command does not start MapReduce tasks and does not occupy Yarn resources. Therefore, the tasks can be executed.

12.23.8.2.12 If I Access a parquet Table on Which I Do not Have Permission, Why a Job Is Run Before "Missing Privileges" Is Displayed?

Question

If I access a parquet table on which I do not have permission, why a job is run before "Missing Privileges" is displayed?

Answer

The execution sequence of Spark SQL statement parse the table in the statement first, then obtain the metadata in the table, and finally check the permission.

The metadata of a parquet table contains the Split information (which is read by HDFS API) about files. If the table contains many files, the HDFS API reads data in serial mode, in which degrades the performance. If the number of files in the table exceeds the threshold *spark.sql.sources.parallelSplitDiscovery.threshold*, a job will be generated to use Executor to read the data in parallel mode.

The permission authentication is executed after the metadata is obtained. Therefore, when the number of files in the table exceeds the threshold, a job is run before the permission authentication error message **Missing Privileges**.

12.23.8.2.13 Why Do I Fail to Modify MetaData by Running the Hive Command?

Question

When do I fail to modify the metadata in the datasource and Spark on HBase table by running the Hive command?

Answer

The current Spark version does not support modifying the metadata in the datasource and Spark on HBase tables by running the Hive command.

12.23.8.2.14 Why Is "RejectedExecutionException" Displayed When I Exit Spark SQL?

Question

After successfully running Spark tasks with large data volume, for example, 2-TB TPCDS test suite, why is the abnormal stack information **"RejectedExecutionException"** displayed sometimes? The log is as follows:

```
16/07/16 10:19:56 ERROR TransportResponseHandler: Still have 2 requests outstanding when connection from linux-192/10.1.1.5:59250 is closed
java.util.concurrent.RejectedExecutionException: Task scala.concurrent.impl.CallbackRunnable@5fc1ab rejected from java.util.concurrent.ThreadPoolExecutor@52fa7e19[Terminated, pool size = 0, active threads = 0, queued tasks = 0, completed tasks = 3025]
```

Answer

When Spark SQL is closed, the application and the message channel are closed. If there are unprocessed messages, the connection should be closed to rectify the exception. If the thread pool inside Scala is closed, the abnormal stack information "RejectedExecutionException" is displayed. This abnormal stack information will not be displayed if the thread pool inside Scala is not closed.

The error occurs when the application is successfully run and closed. Therefore, the error will not affect the services.

12.23.8.2.15 What Should I Do If the JDBCServer Process is Mistakenly Killed During a Health Check?

Question

During a health check, if the concurrent statements exceed the threshold of the thread pool, the health check statements fail to be executed, the health check program times out, and the Spark JDBCServer process is killed.

Answer

There are two thread poolsHiveServer2-Handler-Pool and HiveServer2-Background-Pool in the current JDBCServer. The HiveServer2-Handler-Pool is used to connect sessions and the HiveServer2-Background-Pool is used to run Spark SQL statements.

The current health check mechanism establishes a session connection and runs the health check command ***HEALTHCHECK*** in the thread of the session to check the health condition of the Spark JDBCServer. Therefore, one thread must be reserved for the HiveServer2-Handler-Pool respectively to connect sessions and run statements for the health check. Otherwise, the session connection and statement running will fail and the Spark JDBCServer will be killed because it is mistakenly considered unhealthy. For example, if there are 100 threads in the HiveServer2-Handler-Pool respectively, a maximum of 99 sessions can be connected.

12.23.8.2.16 Why No Result Is found When 2016-6-30 Is Set in the Date Field as the Filter Condition?

Question

Why no result is found when 2016-6-30 is set in the date field as the filter condition?

As shown in the following figure, trx_dte_par in the select count (*) from trxfintrx2012 a where trx_dte_par='2016-6-30' statement is a date field. However, no search result is found when the filter condition is where trx_dte_par='2016-6-30'. Search results are found only when the filter condition is where trx_dte_par='2016-06-30'.

Figure 12-62 Example

```
0: jdbc:hive2://ha-cluster/default> select count(*)
0: jdbc:hive2://ha-cluster/default>   from TRXFINTRX2012 a
0: jdbc:hive2://ha-cluster/default>   where trx_dte_par = '2016-6-30';
+------+--+
| _c0  |
+------+--+
| 0    |
+------+--+
1 row selected (0.498 seconds)
0: jdbc:hive2://ha-cluster/default> select count(*)
0: jdbc:hive2://ha-cluster/default>   from TRXFINTRX2012 a
0: jdbc:hive2://ha-cluster/default>   where trx_dte_par = '2016-06-30';
+----------+--+
|   _c0    |
+----------+--+
| 8520808  |
+----------+--+
1 row selected (15.788 seconds)
```

Answer

If a data string of the date type is present in Spark SQL statements, the Spark SQL will search the matching character string without checking the date format. In this case, if the date format in the SQL statement is incorrect, the query will fail. For example, if the data format is yyyy-mm-dd, then no search results matching '2016-6-30' will be found.

12.23.8.2.17 Why Does the "--hivevar" Option I Specified in the Command for Starting spark-beeline Fail to Take Effect?

Question

Why does the ***--hivevar*** option I specified in the command for starting spark-beeline fail to take effect?

In the V100R002C60 version, if I use the ***--hivevar <VAR_NAME>=<var_value>*** option to define a variable in the command for starting spark-beeline, no error is reported in spark-beeline. However, if the variable *<VAR_NAME>* is used in SQL, the variable cannot be parsed and the <VAR_NAME> exception is reported.

For example:

1. Run the following command to start the spark-beeline:

   spark-beeline --hivevar <VAR_NAME>=<var_value>

2. After spark-beeline is started successfully, I run the SQL statements ***DROP TABLE ${VAR_NAME}*** in spark-beeline. The VAR_NAME exception occurs.

Answer

In the V100R002C60 version, the ***--hivevar <VAR_NAME>=<var_value>*** feature of Hive is not supported in Spark because multi-session management function is added. Therefore, the ***--hivevar*** option in the command for starting spark-beeline is invalid.

12.23.8.2.18 Why Does the "Permission denied" Exception Occur When I Create a Temporary Table or View in Spark-beeline?

Question

In normal mode, when I create a temporary table or view in spark-beeline, the error message "Permission denied" is displayed, indicating that I have no permissions on the HDFS directory. The error log information is as follows:

```
org.apache.hadoop.security.AccessControlException Permission denied: user=root, access=EXECUTE,
inode="/tmp/spark/sparkhive-scratch/omm/e579a76f-43ed-4014-8a54-1072c07ceeff/_tmp_space.db/
52db1561-60b0-4e7d-8a25-c2eaa44850a9":omm:hadoop:drwx------
```

Answer

In normal mode, if you run the spark-beeline command as a non-omm user, **root** user for example, without specifying the **-n** parameter, your account is still the root user. After spark-beeline is started, a new HDFS directory is created by JDBCServer. In the current version of DataSight, the user that starts the JDBCServer is **omm**. In versions earlier than DataSight V100R002C30, the user is **root**. Therefore, the owner of the HDFS directory is **omm** and the group is **hadoop**. The HDFS directory is used when you create a temporary table or view in spark-beeline and the user **root** is a common user in HDFS and has no permissions on the directory of user **omm**. As a result, the "Permission denied" exception occurs.

In normal mode, only user **omm** can create a temporary table or view. To solve this problem, you can specify the **-n omm** option for user **omm** when starting spark-beeline. In this way, you have the permissions to perform operations on the HDFS directory.

12.23.8.2.19 Why Is the "Code of method ... grows beyond 64 KB" Error Message Displayed When I Run Complex SQL Statements?

Question

When I run a complex SQL statement, for example, SQL statements with multiple layers of nesting statements and a single layer statement contains a large number of logic clauses such as case when, an error message indicating that the code of a certain method exceeds 64 KB is displayed. The log is as follows:

```
java.util.concurrent.ExecutionException: java.lang.Exception: failed to compile:
org.codehaus.janino.JaninoRuntimeException: Code of method "(Lorg/apache/spark/sql/catalyst/expressions/
GeneratedClass$SpecificUnsafeProjection;Lorg/apache/spark/sql/catalyst/InternalRow;)V" of class
"org.apache.spark.sql.catalyst.expressions.GeneratedClass$SpecificUnsafeProjection" grows beyond 64 KB
```

Answer

If Project Tungsten is enabled, Spark will use codegen method to generate Java code for part of execution plan. However, each function in Java code to be compiled by JDK must be less than 64 KB. If complex SQL statements are run, the function in the Java code generated by codegen may exceed 64 KB, causing compilation failure.

To solve the problem, go to the **spark-defaults.conf** file on the client and set the **spark.sql.codegen.wholeStage** parameter to **false** to disable Project Tungsten.

12.23.8.2.20 Why Is Memory Insufficient if 10 Terabytes of TPCDS Test Suites Are Consecutively Run in Beeline/JDBCServer Mode?

Question

When the driver memory is set to 10 GB and the 10 TB TPCDS test suites are continuously run in Beeline/JDBCServer mode, SQL statements fail to be executed due to insufficient driver memory. Why?

Answer

By default, 1000 UI data records of jobs and stages are reserved in the memory.

The function of overflowing UI data to disks has been added to optimize large clusters. The overflow condition is that the size of UI data in each stage reaches the minimum threshold 5 MB. If the number of tasks in each stage is small, the size of UI data in the stage may not reach the threshold. As a result, the UI data in the stage is cached in the memory until the number of UI data records reaches the upper limit (1000 by default). Only then the old UI data is cleared from the memory.

Therefore, before the old UI data is cleared, the UI data occupies a large amount of memory. As a result, the driver memory is insufficient when 10 terabytes of TPCDS test suites are executed.

Workaround:

- Set **spark.ui.retainedJobs** and **spark.ui.retainedStages** based on service requirements to specify the number of UI data records of jobs and stages to be reserved. For details, see **Table 12-359** in **Common Parameters**.

- If a large amount of UI data of jobs and stages needs to be reserved, increase the memory of the driver by setting the **spark.driver.memory** parameter. For details, see **Table 12-356** in **Common Parameters**.

12.23.8.2.21 Why Are Some Functions Not Available when Another JDBCServer Is Connected?

Question

Scenario 1

I set up permanent functions using the **add jar** statement. After Beeline connects to different JDBCServer or JDBCServer is restarted, I have to run the **add jar** statement again.

Figure 12-63 Error information in scenario 1

```
0: jdbc:hive2://192.168.91.247:23040/default> create function a1 as '                                                    ';
+---------+--+

Scenario 2

The **show functions** statement can be used to query functions, but not obtain functions. The reason is that connected JDBC node does not contain jar packages of the corresponding path. However, after I add corresponding **.jar** packages, the **show functions** statement can be used to obtain functions.

Figure 12-64 Error information in scenario 2

Answer

Scenario 1

The ***add jar*** statement is used to load jars to the jarClassLoader of the JDBCServer connected currently. The ***add jar*** statement is not shared by different JDBCServer. After the JDBCServer restarts, new jarClassLoader is created. So the add jar statement needs to be run again.

There are two methods to add jar packages: You can run the **spark-sql --jars /opt/test/two_udfs.jar** statement to add the jar package during the startup of the Spark SQL process; or run the **add jar /opt/test/two_udfs.jar** statement to add the jar package after the Spark SQL process is started. Note that the path following the add jar statement can be a local path or an HDFS path.

Scenario 2

The show functions statement is used to obtain all functions in the current database from the external catalog. If functions are used in SQL, thriftJDBC-server loads **.jar** files related to the function.

If **.jar** files do not exist, the function cannot obtain corresponding **.jar** files. Therefore, the corresponding **.jar** files need to be added.

12.23.8.2.22 Why Does Spark2x Have No Access to DataSource Tables Created by Spark1.5?

Question

When Spark2x accesses the DataSource table created by Spark1.5, a message is displayed indicating that schema information cannot be obtained. As a result, the table cannot be accessed. Why?

Answer

- Cause analysis:

  This is because the formats of the DataSource table information stored in Spark2x and Spark1.5 are inconsistent. Spark 1.5 divides schema information into multiple parts and uses **path.park.0** as the key for storage. Spark 1.5 reads information from each part and reassembles the information into complete one. Spark2x directly uses the corresponding key to obtain the corresponding information. In this case, when Spark2x reads the DataSource table created by Spark1.5, the information corresponding to the key cannot be read. As a result, the DataSource table information fails to be parsed.

  When processing Hive tables, Spark2x and Spark1.5 use the same storage mode. Therefore, Spark2x can directly read tables created by Spark1.5.

- Workaround:

  In Spark2x, create a foreign table to point to the actual data in the Spark1.5 table. In this way, the DataSource table created by Spark1.5 can be read in Spark2x. In addition, after Spark1.5 updates data, Spark2x can detect the change. The reverse is also true. In this way, Spark2x can access the DataSource table created by Spark1.5.

12.23.8.2.23 Why Does Spark-beeline Fail to Run and Error Message "Failed to create ThriftService instance" Is Displayed?

Question

Why does "Failed to create ThriftService instance" occur when spark beeline fails to run?

Beeline logs are as follows:

```
Error: Failed to create ThriftService instance (state=,code=0)
Beeline version 1.2.1.spark by Apache Hive
[INFO] Unable to bind key for unsupported operation: backward-delete-word
[INFO] Unable to bind key for unsupported operation: backward-delete-word

```

Answer

This problem occurs when the network is unstable. When a timed-out exception occurs in beeline, Spark does not attempt to reconnect to beeline. Therefore, you need to restart spark-beeline for reconnection.

12.23.8.2.24 Why Cannot I Query Newly Inserted Data in an ORC Hive Table Using Spark SQL?

Question

Why cannot I query newly inserted data in an ORC Hive table using Spark SQL? This problem occurs in the following scenarios:

- For partitioned tables and non-partitioned tables, after data is inserted on the Hive client, the latest inserted data cannot be queried using Spark SQL.
- After data is inserted into a partitioned table using Spark SQL, if the partition information remains unchanged, the newly inserted data cannot be queried using Spark SQL.

Answer

To improve Spark performance, ORC metadata is cached. When the ORC table is updated by Hive or another means, the cached metadata remains unchanged, resulting in Spark SQL failing to query the newly inserted data.

For an ORC Hive partition table, if the partition information remains unchanged after data is inserted, the cached metadata is not updated. As a result, the newly inserted data cannot be queried by Spark SQL.

Solution

1. To solve the query problem, update metadata before starting a Spark SQL query.

   REFRESH TABLE *table_name*;

table_name indicates the name of the table to be updated. The table must exist. Otherwise, an error is reported.

When the query statement is executed, the latest inserted data can be obtained.

2. Run the following command to disable Spark optimization when using Spark:

   set spark.sql.hive.convertMetastoreOrc=false;

12.23.8.3 Spark Streaming

12.23.8.3.1 What Can I Do If Spark Streaming Tasks Are Blocked?

Question

After a Spark Streaming task is run and data is input, no processing result is displayed. Open the web page to view the Spark job execution status. The following figure shows that two jobs are waiting to be executed but cannot be executed successfully.

Figure 12-65 Active Jobs

Active Jobs (2)

Job Id	Description	Submitted	Duration	Stages: Succeeded/Total
3	print at test2StreamFromKafka.scala:31	2015/05/25 18:28:55	63.7 h	0/3
2	start at test2StreamFromKafka.scala:34	2015/05/25 18:28:55	63.7 h	0/1

Check the completed jobs. Only two jobs are found, indicating that Spark Streaming does not trigger data computing tasks. (By default, Spark Streaming has two jobs that attempt to run. See the figure below.)

Figure 12-66 Completed Jobs

Completed Jobs (2)

Job Id	Description	Submitted	Duration	Stages: Succeeded/Total
1	print at test2StreamFromKafka.scala:31	2015/05/25 18:28:55	0.7 s	2/2 (1 skipped)
0	start at test2StreamFromKafka.scala:34	2015/05/25 18:28:54	1 s	2/2

Answer

After fault locating, it is found that the number of computing cores of Spark Streaming is less than the number of receivers. As a result, after some receivers are started, no resource is available to run computing tasks. Therefore, the first task keeps waiting and subsequent tasks keep queuing. **Figure 12-65** is an example of two queuing tasks.

To address this problem, it is advised to check whether the number of Spark cores is greater than the number of receivers when two tasks are queuing.

NOTE

Receiver is a permanent Spark job in Spark Streaming. It is common for Spark, but its life cycle is the same as that of a Spark Streaming task and occupies one computing core.

Pay attention to the relationship between the number of cores and the number of receivers in scenarios where default configurations are often used, such as debugging and testing.

12.23.8.3.2 What Should I Pay Attention to When Optimizing Spark Streaming Task Parameters?

Question

When Spark Streaming tasks are running, the data processing performance does not improve significantly as the number of executors increases. What should I pay attention to if I perform parameter optimization?

Answer

When the number of executor cores is 1, comply with the following rules to optimize Spark Streaming running parameters:

- The Spark task processing speed is related to the number of partitions in Kafka. When the number of partitions is less than the specified number of executors, the number of actually used executors is the same as the number of partitions, and other executors will be idle. Therefore, the number of executors must be less than or equal to the number of partitions.
- When data skew occurs on different partitions of Kafka, the executor corresponding to the partition with a large amount of data touches the glass ceiling of data processing. Therefore, when the Producer program is executed, data is sent to each partition on average to improve the processing speed.
- When partition data is evenly distributed, increasing the number of partitions and executors will improve the Spark processing speed. (When the number of partitions is the same as that of executors, the processing speed is the fastest.)
- When partition data is evenly distributed, ensure that the number of partitions is an integer multiple of the number of executors for proper allocation of resources.

12.23.8.3.3 Why Does the Spark Streaming Application Fail to Be Submitted After the Token Validity Period Expires?

Question

Change the validity period of the Kerberos ticket and HDFS token to 5 minutes, set **dfs.namenode.delegation.token.renew-interval** to a value less than 60 seconds, and submit the Spark Streaming application. If the token expires, the error message below is displayed, and the application exits. Why?

```
token (HDFS_DELEGATION_TOKEN token 17410 for spark2x) is expired
```

Answer

- Possible causes:

The credential refresh thread of the ApplicationMaster process uploads the updated credential file to the HDFS based on the *token renew period multiplied by 0.75*.

In the executor process, the credential refresh thread obtains the updated credential file from the HDFS based on the time ratio of the *token renewal period multiplied by 0.8* to update the token in UserGroupInformation, preventing the token from being invalid.

When the credential refresh thread of the executor process detects that the current time is later than the credential file update time (*token renew period x 0.8*), it waits for 1 minute and then obtains the latest credential file from the HDFS to ensure that the AM has stored the updated credential file in the HDFS.

When the value of **dfs.namenode.delegation.token.renew-interval** is less than 60 seconds, the started executor detects that the current time is later than the time when the credential file is updated. One minute later, the executor obtains the latest credential file from the HDFS. However, the token is already invalid, and the task fails to be executed. Then, other executor processes retry within 1 minute. The task also fails to run on other executors. As a result, the executors that fail to run are added to the blacklist. If no executors are available, the application exits.

- Solution:

  In the Spark application scenario, set **dfs.namenode.delegation.token.renew-interval** to a value greater than 80 seconds. For details about the **dfs.namenode.delegation.token.renew-interval** parameter, see **Table 12-428**.

  Table 12-428 Parameter description

Parameter	Description	Default Value
dfs.namenode.delegation.token.renew-interval	This parameter is a server parameter. It specifies the maximum lifetime to renew a token. Unit: milliseconds.	86400000

12.23.8.3.4 Why does Spark Streaming Application Fail to Restart from Checkpoint When It Creates an Input Stream Without Output Logic?

Question

Spark Streaming application creates one input stream without output logic. The application fails to restart from checkpoint and an error will be shown like below:

```
17/04/24 10:13:57 ERROR Utils: Exception encountered

```

Answer

When Streaming Context starts, DStream checkpoint object of application should be serialized with application set to checkpoint and Dstream context will be used during this serialization.

Dstream.context is the Dstream which Streaming Context relies on to check reversely from output Stream, set the context one by one. If Spark Streaming application creates one input stream which does not have output logic, there will be no context set for the input stream. 'NullPointerException' will be reported during serialization.

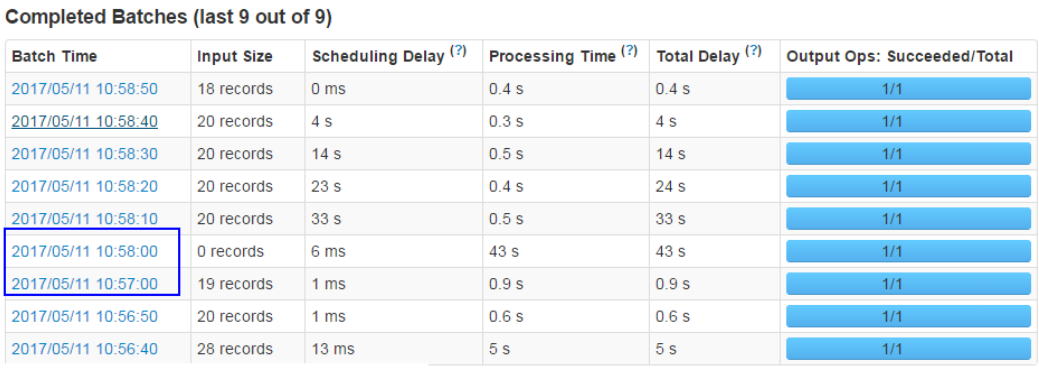
Solution: If there is no input logic for the output stream in the application, delete the input stream in the code or add the relevant output logic for that input stream.

12.23.8.3.5 Why Is the Input Size Corresponding to Batch Time on the Web UI Set to 0 Records When Kafka Is Restarted During Spark Streaming Running?

Question

When the Kafka is restarted during the execution of the Spark Streaming application, the application cannot obtain the topic offset from the Kafka. As a result, the job fails to be generated. As shown in **Figure 12-67**, **2017/05/11 10:57:00-2017/05/11 10:58:00** indicates the Kafka restart time. After the restart is successful at 10:58:00 on May,11,2017, the value of **Input Size** is **0 records**.

Figure 12-67 On the Web UI, the **input size** corresponding to the **batch time** is **0 records**.



Completed Batches (last 9 out of 9)

Batch Time	Input Size	Scheduling Delay (?)	Processing Time (?)	Total Delay (?)	Output Ops: Succeeded/Total
2017/05/11 10:58:50	18 records	0 ms	0.4 s	0.4 s	1/1
2017/05/11 10:58:40	20 records	4 s	0.3 s	4 s	1/1
2017/05/11 10:58:30	20 records	14 s	0.5 s	14 s	1/1
2017/05/11 10:58:20	20 records	23 s	0.4 s	24 s	1/1
2017/05/11 10:58:10	20 records	33 s	0.5 s	33 s	1/1
2017/05/11 10:58:00	0 records	6 ms	43 s	43 s	1/1
2017/05/11 10:57:00	19 records	1 ms	0.9 s	0.9 s	1/1
2017/05/11 10:56:50	20 records	1 ms	0.6 s	0.6 s	1/1
2017/05/11 10:56:40	28 records	13 ms	5 s	5 s	1/1

Answer

After Kafka is restarted, the application supplements the missing RDD between 10:57:00 on May 11, 2017 and 10:58:00 on May 11, 2017 based on the batch time. Although the number of read data records displayed on the UI is **0**, the missing data is processed in the supplemented RDD. Therefore, no data loss occurs.

The data processing mechanism during the Kafka restart period is as follows:

The Spark Streaming application uses the **state** function (for example, **updateStateByKey**). After Kafka is restarted, the Spark Streaming application generates a batch task at 10:58:00 on May 11, 2017. The missing RDD between10:57:00 on May 11, 2017 and 10:58:00 on May 11, 2017 is supplemented based on the batch time (data that is not read in Kafka before Kafka restart, which belongs to the batch before 10:57:00 on May 11, 2017).

12.23.8.4 Why the Job Information Obtained from the restful Interface of an Ended Spark Application Is Incorrect?

Question

The job information obtained from the restful interface of an ended Spark application is incorrect: the value of **numActiveTasks** is negative, as shown in Figure 12-68:

Figure 12-68 job information

```
[ {
  "jobId" : 0,
  "name" : "reduce at SparkPi.scala:36",
  "submissionTime" : "2016-05-28T09:35:34.415GMT",
  "completionTime" : "2016-05-28T09:35:35.686GMT",
  "stageIds" : [ 0 ],
  "status" : "SUCCEEDED",
  "numTasks" : 2,
  "numActiveTasks" : -1,
  "numCompletedTasks" : 2,
  "numSkippedTasks" : 2,
  "numFailedTasks" : 0,
  "numActiveStages" : 0,
  "numCompletedStages" : 1,
  "numSkippedStages" : 0,
  "numFailedStages" : 0
} ]
```

NOTE

numActiveTasks indicates the number of active tasks.

Answer

The job information can be obtained in either of the following methods:

- Set **spark.history.briefInfo.gather=true** and then view the brief JobHistory information.
- Visit the JobHistory2x page of Spark (URL: https://IP:port/api/v1/<appid>/jobs/).

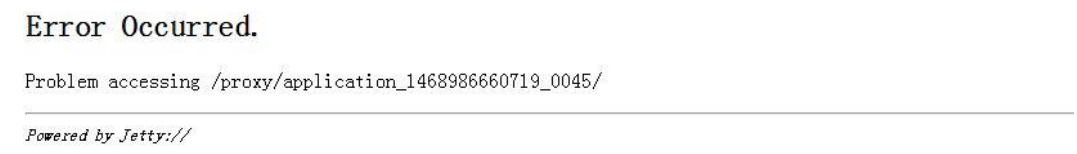
The value of **numActiveTasks** in the job information is calculated from the difference between the number of SparkListenerTaskStart events and the number

of SparkListenerTaskEnd events in the **eventLog** file. If some events are not recorded in the **eventLog** file, the job information obtained from the restful interface is incorrect.

12.23.8.5 Why Cannot I Switch from the Yarn Web UI to the Spark Web UI?

Question

In FusionInsight, the Spark application is run in yarn-client mode on the client. The following error occurs during the switch from the Yarn web UI to the application web UI:



The YARN ResourceManager log shows the following information:

```
2016-07-21 16:35:27,099 | INFO  | Socket Reader #1 for port 8032 | Auth successful for mapred/
hadoop.<System domain name>@<System domain name> (auth:KERBEROS) | Server.java:1388
2016-07-21 16:35:27,105 | INFO  | 1526016381@qtp-1178290888-1015 | admin is accessing unchecked

appattempt_1468986660719_0045_000001 with final state: FINISHING,
and exit status: -1000 | RMAppAttemptImpl.java:1253
```

Answer

On FusionInsight Manager, the IP address of the Yarn service is in the 192 network segment.

In Yarn logs, the IP address of Spark web UI read by Yarn is http://10.120.169.53:23011, which is in the 10 network segment. The IP addresses in the 192 network segment cannot communicate with those in the 10 network segment. As a result, the Spark web UI fails to be accessed.

Solution:

Log in to the client whose IP address is **10.120.169.53** and change the IP address in the **/etc/hosts** file to the IP address in the 192 network segment. Run the Spark application again. The Spark web UI is displayed.

12.23.8.6 What Can I Do If an Error Occurs when I Access the Application Page Because the Application Cached by HistoryServer Is Recycled?

Question

An error occurs when I access a Spark application page on the HistoryServer page.

Check the HistoryServer logs. The "FileNotFound" exception is found. The related logs are as follows:

```
2016-11-22 23:58:03,694 | WARN  | [qtp55429210-232] | /history/application_1479662594976_0001/stages/stage/ | org.sparkproject.jetty.servlet.ServletHandler.doHandle(ServletHandler.java:628)
java.io.FileNotFoundException: ${BIGDATA_HOME}/tmp/spark/jobHistoryTemp/blockmgr-5f1f6aca-2303-4290-9845-88fa94d78480/09/temp_shuffle_11f82aaf-e226-46dc-b1f0-002751557694 (No such file or directory)
```

Answer

If a Spark application with a large number of tasks is run on the HistoryServer page, the memory overflows to disk and files with the **temp_shuffle** prefix are generated.

By default, HistoryServer caches 50 Spark applications (determined by the **spark.history.retainedApplications** configuration item). When the number of Spark applications in the memory exceeds 50, HistoryServer reclaims the first cached Spark application and clears the corresponding **temp_shuffle** file.

When a user is viewing Spark applications to be recycled, the **temp_shuffle** file may not be found. As a result, the current page cannot be accessed.

If the preceding problem occurs, use either of the following methods to solve the problem:

- Access the HistoryServer page of the Spark application again. The correct page information is displayed.
- If more than 50 Spark applications need to be accessed at the same time, increase the value of **spark.history.retainedApplications**.

  Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Service** > **Spark2x** > **Configuration**, and click **All Configurations**. In the navigation tree on the left, choose **JobHistory2x** > **GUI**, and set parameters.

  Table 12-429 Parameter description

Parameter	Description	Default Value
spark.history.retainedApplications	Number of Spark applications cached by HistoryServer. When the number of applications to be cached exceeds the value of this parameter, HistoryServer reclaims the first cached Spark application.	50

12.23.8.7 Why Is not an Application Displayed When I Run the Application with the Empty Part File?

Question

When I run an application with an empty part file in HDFS with the log grouping function enabled, why is not the application displayed on the homepage of JobHistory?

Answer

On the JobHistory page, information about applications is updated only with changed sizes of part files in HDFS. If a file is read for the first time, its size is compared with 0. The file is read only when the file size is greater than 0.

When the log grouping function is enabled, if the application you run does not have jobs in running status, the part file is empty. As a result, JobHistory does not read the part file and the application information is not displayed on the JobHistory page. However, if the size of part file is changed later, the application will be displayed on JobHistory.

12.23.8.8 Why Does Spark2x Fail to Export a Table with the Same Field Name?

Question

The following code fails to be executed on spark-shell of Spark2x:

```
val acctId = List(("49562", "Amal", "Derry"), ("00000", "Fred", "Xanadu"))
val rddLeft = sc.makeRDD(acctId)
val dfLeft = rddLeft.toDF("Id", "Name", "City")
//dfLeft.show
val acctCustId = List(("Amal", "49562", "CO"), ("Dave", "99999", "ZZ"))
val rddRight = sc.makeRDD(acctCustId)
val dfRight = rddRight.toDF("Name", "CustId", "State")
//dfRight.show
val dfJoin = dfLeft.join(dfRight, dfLeft("Id") === dfRight("CustId"), "outer")
dfJoin.show
dfJoin.repartition(1).write.format("com.databricks.spark.csv").option("delimiter", "\t").option("header",
"true").option("treatEmptyValuesAsNulls", "true").option("nullValue", "").save("/tmp/outputDir")
```

Answer

In Spark2x, the duplicate field name of the **join** statement is checked. You need to modify the code to ensure that no duplicate field exists in the saved data.

12.23.8.9 Why JRE fatal error after running Spark application multiple times?

Question

Why JRE fatal error after running Spark application multiple times?

Answer

When you run Spark application multiple times, JRE fatal error occurs and this is due to the problem with the Linux Kernel.

To resolve this issue, upgrade the **kernel version to 4.13.9-2.ge7d7106-default**.

12.23.8.10 "This page can't be displayed" Is Displayed When Internet Explorer Fails to Access the Native Spark2x UI

Question

Occasionally, Internet Explorer 9, Explorer 10, or Explorer 11 fails to access the native Spark2x UI.

Symptom

Internet Explorer 9, Explorer 10, or Explorer 11 fails to access the native Spark UI, as shown in the following figure.

Cause

Some Internet Explorer 9, Explorer 10, or Explorer 11versions fail to handle SSL handshake issues, causing access failure.

Solution

Google Chrome 71 and later versions and Firefox browsers 62 and later versions are recommended.

12.23.8.11 How Does Spark2x Access External Cluster Components?

Question

There are two clusters, cluster 1 and cluster 2. How do I use Spark2x in cluster 1 to access HDFS, Hive, HBase, and Kafka components in cluster 2?

Answer

1. Components in two clusters can access each other. However, there are the following restrictions:
   - Only one Hive MetaStore can be accessed. Specifically, Hive MetaStore in cluster 1 and Hive MetaStore in cluster 2 cannot be accessed at the same time.
   - User systems in different clusters are not synchronized. When users access components in another cluster, user permission is determined by

the user configuration of the peer cluster. For example, if user A of cluster 1 does not have the permissions to access the HBase meta table in cluster 1 but user A of cluster 2 can access the HBase meta table in cluster 2, user A of cluster 1 can access the HBase meta table in cluster 2.

- To enable components in a security cluster to communicate with each other across Manager, you need to configure mutual trust.

2. The following describes how to access Hive, HBase, and Kafka components in cluster 2 as user A.

   NOTE

   The following operations are based on the scenario where a user uses the FusionInsight client to submit the Spark2x application. If the user uses the configuration file directory, the user needs to modify the corresponding file in the configuration directory of the application and upload the configuration file to the executor.

   When the HDFS and HBase clients access the server, **hostname** is used to configure the server address. Therefore, the hosts configuration of all nodes to be accessed must be saved in the **/etc/hosts** file on the client. You can add the host of the peer cluster node to the **/etc/hosts** file of the client node in advance.

   - Access Hive metastore: Replace the **hive-site.xml** file in the **conf** directory of the Spark2x client in cluster 1 with the **hive-site.xml** file in the **conf** directory of the Spark2x client in cluster 2.

     After the preceding operations are performed, you can use Spark SQL to access Hive MetaStore. To access Hive table data, you need to perform the operations in **• Access HDFS of two clusters at the same time:** and set **nameservice** of the peer cluster to **LOCATION**.

   - Access HBase of the peer cluster.

     i. Configure the IP addresses and host names of all ZooKeeper nodes and HBase nodes in cluster 2 in the **/etc/hosts** file on the client node of cluster 1.

     ii. Replace the **hbase-site.xml** file in the **conf** directory of the Spark2x client in cluster 1 with the **hbase-site.xml** file in the **conf** directory of the Spark2x client in cluster 2.

   - Access Kafka: Set the address of the Kafka Broker to be accessed to the Kafka Broker address in cluster 2.

   - Access HDFS of two clusters at the same time:

     - Two tokens with the same NameService cannot be obtained at the same time. Therefore, the NameServices of the HDFS in two clusters must be different. For example, one is **hacluster**, and the other is **test**.

       1) Obtain the following configurations from the **hdfs-site.xml** file of cluster2 and add them to the **hdfs-site.xml** file in the **conf** directory of the Spark2x client in cluster1:

          dfs.nameservices.mappings, **dfs.nameservices**, **dfs.namenode.rpc-address.test.***, **dfs.ha.namenodes.test**, and **dfs.client.failover.proxy.provider.test**

          The following is an example:

          ```
          <property>
          <name>dfs.nameservices.mappings</name>
          <value>[{"name":"hacluster","roleInstances":["14","15"]},
          ```

```
{"name":"test","roleInstances":["16","17"]}]</value>
</property>
<property>
<name>dfs.nameservices</name>
<value>hacluster,test</value>
</property>
<property>
<name>dfs.namenode.rpc-address.test.16</name>
<value>192.168.0.1:8020</value>
</property>
<property>
<name>dfs.namenode.rpc-address.test.17</name>
<value>192.168.0.2:8020</value>
</property>
<property>
<name>dfs.ha.namenodes.test</name>
<value>16,17</value>
</property>
<property>
<name>dfs.client.failover.proxy.provider.test</name>
<value>org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider
</value>
</property>
```

2) Modify **spark.yarn.extra.hadoopFileSystems = hdfs://test and spark.hadoop.hdfs.externalToken.enable = true** in the **spark-defaults.conf** configuration file under the **conf** directory on the Spark client of cluster 1.

```
spark.yarn.extra.hadoopFileSystems = hdfs://test
spark.hadoop.hdfs.externalToken.enable = true
```

3) In the application submission command, add the **--keytab** and **--principal** parameters and set them to the user who submits the task in cluster1.

4) Use the Spark client of cluster1 to submit the application. Then, the two HDFS services can be accessed at the same time.

– Access HBase of two clusters at the same time:

i. Modify **spark.hadoop.hbase.externalToken.enable = true** in the **spark-defaults.conf** configuration file under the **conf** directory on the Spark client of cluster 1.

```
spark.hadoop.hbase.externalToken.enable = true
```

ii. When accessing HBase, you need to use the configuration file of the corresponding cluster to create a **Configuration** object for creating a **Connection** object.

iii. In an MRS cluster, tokens of multiple HBase services can be obtained at the same time to solve the problem that the executor cannot access HBase. The method is as follows:

Assume that you need to access HBase of the current cluster and HBase of cluster2. Save the **hbase-site.xml** file of cluster2 in a compressed package named **external_hbase_conf*****, and use **--archives** to specify the compressed package when submitting the command.

12.23.8.12 Why Does the Foreign Table Query Fail When Multiple Foreign Tables Are Created in the Same Directory?

Question

Assume there is a data file path named **/test_data_path**. User A creates a foreign table named **tableA** for the directory, and user B creates a foreign table named **tableB** for the directory. When user B performs the insert operation on **tableB**, user A fails to query data using **tableA** and the error "Permission denied" is displayed.

Answer

After user B performs the insert operation on **tableB**, a new data file is generated in the foreign table path and the file belongs to user B. When user A queries data using **tableA**, all files in the foreign table directory are read. In this case, the query fails because user A does not have the read permissions on the file generated by user B.

This problem also occurs in other scenarios. For example, the **inset overwrite** operation will also duplicate other table files in this directory.

Due to the Spark SQL implementation mechanism, check restrictions in this scenario will lead to inconsistency and performance deterioration. Therefore, no restriction is added in this scenario, and this method is not recommended.

12.23.8.13 What Should I Do If the Native Page of an Application of Spark2x JobHistory Fails to Display During Access to the Page

Question

After a Spark application that contains a job with millions of tasks. After the application creation is complete, if you access the native page of the application in JobHistory, the native page of the application can be displayed after a long time. If the native page cannot be displayed within 10 minutes, Error information will be generated for the Proxy.

Figure 12-69 Error information example

Answer

When you switch to the native page of an application on the JobHistory page, JobHistory needs to play back the event log of the application. If the application contains a large number of event logs, the playback takes a long time and the browser takes a long time to navigate you to the native page.

The current browser uses the HTTPd as the proxy to access the JobHistory native page. The proxy timeout duration is 10 minutes. Therefore, if the JobHistory

cannot parse the event log and return the result within 10 minutes, the HTTPd automatically returns the proxy error information to the browser.

Solution

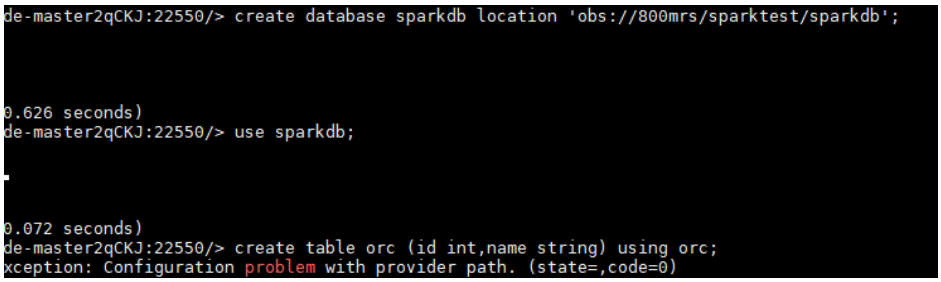
The local disk cache function is enabled on the JobHistory. When a user accesses an application, the event log of the application is cached on the local disk. In this case, the response speed can be greatly accelerated for the second access. Therefore, in this case, you only need to wait for a while and then access the link again. For the second time, you do not need to wait for a long time.

12.23.8.14 Why Do I Fail to Create a Table in the Specified Location on OBS After Logging to spark-beeline?

Question

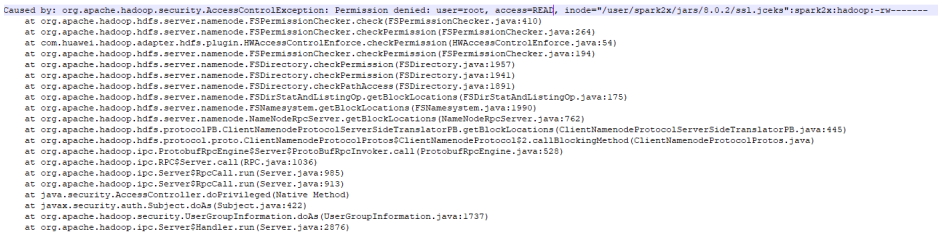
When the OBS ECS/BMS image cluster is connected, after spark-beeline is logged in, an error is reported when a location is specified to create a table on OBS.

Figure 12-70 Error message



Answer

The permission on the **ssl.jceks** file in HDFS is insufficient. As a result, the table fails to be created.



Solution

1. Log in to the node where Spark2x resides as user **omm** and run the following command:

   vi ${BIGDATA_HOME}/FusionInsight_Spark2x_8.1.0.1/install/FusionInsight-Spark2x-3.1.1/spark/sbin/fake_prestart.sh

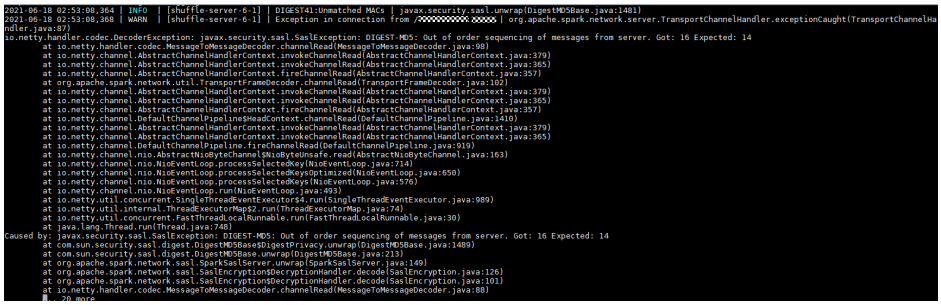
2. Change **eval "${hdfsCmd}" -chmod 600 "${InnerHdfsDir}"/ssl.jceks >> "${PRESTART_LOG}" 2>&1** to **eval "${hdfsCmd}" -chmod 644 "${InnerHdfsDir}"/ssl.jceks >> "${PRESTART_LOG}" 2>&1**.

3. Restart the SparkResource instance.

12.23.8.15 Spark Shuffle Exception Handling

Question

In some scenarios, the following exception occurs in the Spark shuffle phase:



Solution

For JDBC:

Log in to FusionInsight Manager, change the value of the JDBCServer parameter **spark.authenticate.enableSaslEncryption** to **false**, and restart the corresponding instance.

For client jobs:

When the client submits the application, change the value of **spark.authenticate.enableSaslEncryption** in the **spark-defaults.conf** file to **false**.

12.24 Using Sqoop

12.24.1 Using Sqoop from Scratch

Sqoop is an open-source tool for transferring data between Hadoop (Hive) and traditional databases (such as MySQL and PostgreSQL). It can transfer data from a relational database (such as MySQL, Oracle, and PostgreSQL) to HDFS of Hadoop and the other way around.

Prerequisites

- You have selected the Sqoop component when creating a cluster of MRS 3.1.0 or later.
- You have installed the client. For details, see **Installing a Client (Version 3.x or Later)**. For example, the installation directory of the client is **/opt/client**. The client directory in the following operations is an example. Change it to the actual installation directory.

Exporting Data From HDFS to MySQL Using the sqoop export Command

Step 1 Log in to the node where the client is located.

Step 2 Run the following command to initialize environment variables:

source /opt/client/bigdata_env

Step 3 Run the following command to operate the Sqoop client:

sqoop export --connect jdbc:mysql://10.100.231.134:3306/test --username root --password xxxxxx --table component13 -export-dir hdfs://hacluster/user/hive/warehouse/component_test3 --fields-terminated-by ',' -m 1

Table 12-430 Parameter description

Parameter	Description
-direct	Imports data to a relational database using a database import tool, for example, mysqlimport of MySQL, more efficient than the JDBC connection mode.
-export-dir <dir>	Specifies the source directory for storing data in the HDFS.
-m or -num-mappers <n>	Starts *n* (4 by default) maps to import data concurrently. The value cannot be greater than the maximum number of maps in a cluster.
-table <table-name>	Specifies the relational database table to be imported.
-update-key <col-name>	Specifies the column used for updating the existing data in a relational database.
-update-mode <mode>	Specifies how updates are performed. The value can be **updateonly** or **allowinsert**. This parameter is used only when the relational data table does not contain the data record to be imported. For example, if the HDFS data to be imported to the destination table contains a data record **id=1** and the table contains an existing data record **id=2**, the update will fail.
-input-null-string <null-string>	This parameter is optional. If it is not specified, **null** will be used.
-input-null-non-string <null-string>	This parameter is optional. If it is not specified, **null** will be used.

Parameter	Description
-staging-table <staging-table-name>	Creates a table with the same data structure as the destination table for storing data before it is imported to the destination table. This parameter ensures the transaction security when data is imported to a relational database table. Due to multiple transactions during an import, this parameter can prevent other transactions from being affected when one transaction fails. For example, the imported data is incorrect or duplicate records exist.
-clear-staging-table	Clears data in the staging table before data is imported if the staging-table is not empty.

----End

Importing Data from MySQL to Hive Using the sqoop import Command

Step 1 Log in to the node where the client is located.

Step 2 Run the following command to initialize environment variables:

source /opt/client/bigdata_env

Step 3 Run the following command to operate the Sqoop client:

sqoop import --connect jdbc:mysql://10.100.231.134:3306/test --username root --password xxxxxx --table component --hive-import --hive-table component_test2 --delete-target-dir --fields-terminated-by "," -m 1 --as-textfile

Table 12-431 Parameter description

Parameter	Description
-append	Appends data to an existing dataset in the HDFS. Once this parameter is used, Sqoop imports data to a temporary directory, renames the temporary file where the data is stored, and moves the file to a formal directory to avoid duplicate file names in the directory.
-as-avrodatafile	Imports data to a data file in the Avro format.
-as-sequencefile	Imports data to a sequence file.
-as-textfile	Import data to a text file. After the text file is generated, you can run SQL statements in Hive to query the result.

Parameter	Description
-boundary-query <statement>	Specifies the SQL statement for performing boundary query. Before importing data, use a SQL statement to obtain a result set and import the data in the result set. The data format can be **-boundary-query 'select id,creationdate from person where id = 3'** (indicating a data record whose ID is 3) or **select min(<split-by>), max(<split-by>) from <table name>**. The fields to be queried cannot contain fields whose data type is string. Otherwise, the error message "java.sql.SQLException: Invalid value for getLong()" is displayed.
-columns<col,col,col...>	Specifies the fields to be imported. The format is ***-Column id,Username***.
-direct	Imports data to a relational database using a database import tool, for example, mysqlimport of MySQL, more efficient than the JDBC connection mode.
-direct-split-size	Splits the imported streams by byte. Especially when data is imported from PostgreSQL using the direct mode, a file that reaches the specified size can be divided into several independent files.
-inline-lob-limit	Sets the maximum value of an inline LOB.
-m or -num-mappers	Starts *n* (4 by default) maps to import data concurrently. The value cannot be greater than the maximum number of maps in a cluster.
-query, -e<statement>	Imports data from the query result. To use this parameter, you must specify the **-target-dir** and **-hive-table** parameters and use the query statement containing the WHERE clause as well as $CONDITIONS. Example: **-query'select * from person where $CONDITIONS' -target-dir /user/hive/warehouse/person -hive-table person**
-split-by<column-name>	Specifies the column of a table used to split work units. Generally, the column name is followed by the primary key ID.
-table <table-name>	Specifies the relational database table from which data is obtained.
-target-dir <dir>	Specifies the HDFS path.
-warehouse-dir <dir>	Specifies the directory for storing data to be imported. This parameter is applicable when data is imported to HDFS but cannot be used when you import data to Hive directories. This parameter cannot be used together with **-target-dir**.

Parameter	Description
-where	Specifies the WHERE clause when data is imported from a relational database, for example, **-where 'id = 2'**.
-z,-compress	Compresses sequence, text, and Avro data files using the GZIP compression algorithm. Data is not compressed by default.
–compression-codec	Specifies the Hadoop compression codec. GZIP is used by default.
–null-string <null-string>	Specifies the string to be interpreted as **NULL** for string columns.
–null-non-string<null-string>	Specifies the string to be interpreted as null for non-string columns. If this parameter is not specified, **NULL** will be used.
-check-column (col)	Specifies the column for checking incremental data import, for example, **id**.
-incremental (mode) append or last modified	Incrementally imports data. **append**: appends records, for example, appending records that are greater than the value specified by **last-value**. **lastmodified**: appends data that is modified after the date specified by **last-value**.
-last-value (value)	Specifies the maximum value (greater than the specified value) of the column after the last import. This parameter can be set as required.

----End

Sqoop Usage Example

- Importing data from MySQL to HDFS using the **sqoop import** command

  sqoop import --connect jdbc:mysql://10.100.231.134:3306/test --username root --password *xxx* **--query 'SELECT * FROM component where $CONDITIONS and component_id ="MRS 1.0_002"' --target-dir /tmp/component_test --delete-target-dir --fields-terminated-by "," -m 1 --as-textfile**

- Exporting data from OBS to MySQL using the **sqoop export** command

  sqoop export --connect jdbc:mysql://10.100.231.134:3306/test --username root --password *xxx* **--table component14 -export-dir obs://obs-file-bucket/xx/part-m-00000 --fields-terminated-by ',' -m 1**

- Importing data from MySQL to OBS using the **sqoop import** command

  sqoop import --connect jdbc:mysql://10.100.231.134:3306/test --username root --password *xxx* **--table component --target-dir obs://obs-file-bucket/xx --delete-target-dir --fields-terminated-by "," -m 1 --as-textfile**

- Importing data from MySQL to OBS tables outside Hive

  sqoop import --connect jdbc:mysql://10.100.231.134:3306/test --username root --password *xxx* --table component --hive-import --hive-table component_test01 --fields-terminated-by "," -m 1 --as-textfile

12.24.2 Adapting Sqoop 1.4.7 to MRS 3.*x* Clusters

Sqoop is a tool designed for efficiently transmitting a large amount of data between Apache Hadoop and structured databases (such as relational databases). Customers need to use Sqoop to migrate data in MRS. However, MRS of an earlier version does not provide Sqoop. This section describes how to install and use Sqoop. In MRS 3.1.0 or later, you can select the Sqoop component during cluster creation.

Prerequisites

The MRS client and the JDK environment have been installed.

```
[root@node-masterlfKEj bin]# echo $JAVA_HOME
/opt/Bigdata/client/JDK/jdk1.8.0_242
```

Procedure

Step 1 Download the open-source **sqoop-1.4.7.bin__hadoop-2.6.0.tar.gz** package.

Step 2 Save the downloaded package to the **/opt/Bigdata/client** directory on the node where the MRS client is installed and decompress it.

tar zxvf sqoop-1.4.7.bin__hadoop-2.6.0.tar.gz

Step 3 Download the MySQL JDBC driver **mysql-connector-java-*xxx*.jar** from the MySQL official website. For details about how to select the MySQL JDBC driver, see the following table.

Table 12-432 Version information

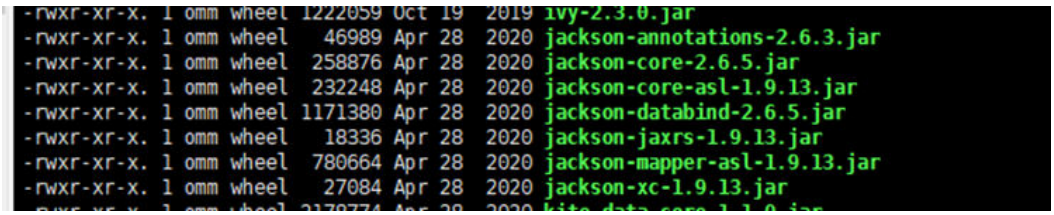
JDBC Driver Version	MySQL Version
Connector/J 5.1	MySQL 4.1, MySQL 5.0, MySQL 5.1, and MySQL 6.0 alpha
Connector/J 5.0	MySQL 4.1, MySQL 5.0 servers, and distributed transaction (XA)
Connector/J 3.1	MySQL 4.1, MySQL 5.0 servers, and MySQL 5.0 except distributed transaction (XA)
Connector/J 3.0	MySQL 3.x and MySQL 4.1

Step 4 Put the MySQL driver package in the **/opt/Bigdata/client/sqoop-1.4.7.bin__hadoop-2.6.0/lib** directory of Sqoop and modify the owner group and permission of the JAR package. For details, see the owner group and permission of **omm:wheel** and **755** in **Figure 12-71**.

Figure 12-71 Owner group and permission of the MySQL driver package

Step 5 Replace the JAR package in the **lib** directory of Sqoop with that starting with **jackson** in the **lib** directory of Hive on the MRS client, for example, **/opt/Bigdata/client/Hive/Beeline/lib**.

Figure 12-72 JAR package starting with **jackson**



Step 6 Copy the **jline** package from the **/opt/Bigdata/client/Hive/Beeline/lib** directory of the MRS Hive client to the **lib** directory of Sqoop.

Step 7 Run the **vim $JAVA_HOME/jre/lib/security/java.policy** command to add the following configuration:

permission javax.management.MBeanTrustPermission "register";

Step 8 Run the following commands to go to the **conf** directory of the Sqoop and add the configuration items of variables:

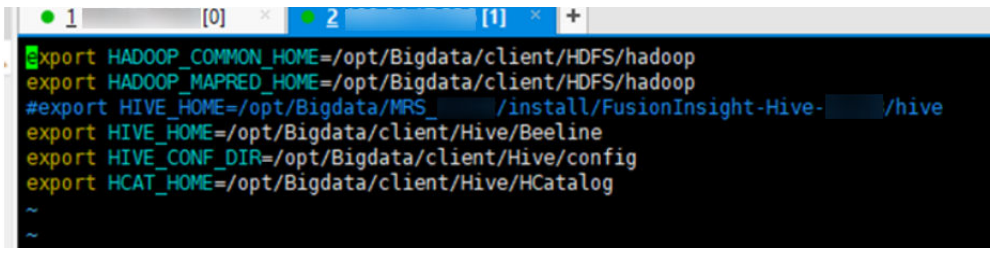
cd /opt/Bigdata/client/sqoop-1.4.7.bin__hadoop-2.6.0/conf

cp sqoop-env-template.sh sqoop-env.sh

Step 9 Run the **vim sqoop-env.sh** command to set the environment variables of Sqoop. Change the Hadoop and Hive directories as required.

```
export HADOOP_COMMON_HOME=/opt/Bigdata/client/HDFS/hadoop
export HADOOP_MAPRED_HOME=/opt/Bigdata/client/HDFS/hadoop
export HIVE_HOME=/opt/Bigdata/MRS_1.9.X/install/FusionInsight-Hive-3.1.0/hive (Enter the actual path.)
export HIVE_CONF_DIR=/opt/Bigdata/client/Hive/config
export HCAT_HOME=/opt/Bigdata/client/Hive/HCatalog
```

Figure 12-73 Setting environment variables of Sqoop



Step 10 Build the sqoop script. For example:

```
/opt/Bigdata/FusionInsight_Current/1_19_SqoopClient/install/FusionInsight-Sqoop-1.4.7/bin/sqoop import
--connect jdbc:mysql://192.168.0.183:3306/test
--driver com.mysql.jdbc.Driver
--username 'root'
--password 'xxx'
--query "SELECT id, name  FROM tbtest WHERE \$CONDITIONS"
--hcatalog-database default
```

```
--hcatalog-table test
--num-mappers 1
```

----End

12.24.3 Common Sqoop Commands and Parameters

Common Sqoop commands

Table 12-433 Common Sqoop commands

Command	Description
import	Imports data to a cluster.
export	Exports data of a cluster.
codegen	Obtains data from a table in the database to generate a Java file and compress the file.
create-hive-table	Creates a Hive table.
eval	Executes a SQL statement and view the result.
import-all-tables	Imports all tables in a database to HDFS.
job	Generates a Sqoop job.
list-databases	Lists database names.
list-tables	List table names.
merge	Merges data in different HDFS directories and saves the data to a specified directory.
metastore	Starts the metadata database to record the metadata of a Sqoop job.
help	Prints help information.
version	Prints the version information.

Common Parameters

Table 12-434 Common parameters

Category	Parameter	Description
Parameters for database connection	--connect	Specifies the URL for connecting to a relational database.
	--connection-manager	Specifies the connection manager class.

Category	Parameter	Description
	--driver jdbc	Specifies the driver package for database connection.
	--help	Prints help information.
	--password	Specifies the password for connecting to a database.
	--username	Specifies the username for connecting to a database.
	--verbose	Prints detailed information on the console.
import parameters	--fields-terminated-by	Specifies the field delimiter, which must be the same as that in a Hive table or HDFS file.
	--lines-terminated-by	Specifies the line delimiter, which must be the same as that in a Hive table or HDFS file.
	--mysql-delimiters	Specifies the default delimiter settings of MySQL.
export parameters	--input-fields-terminated-by	Specifies the field delimiter.
	--input-lines-terminated-by	Specifies the line delimiter.
Hive parameters	--hive-delims-replacement	Replaces characters such as **\r** and **\n** in data with user-defined characters.
	--hive-drop-import-delims	Removes characters such as **\r** and **\n** when data is imported to Hive.
	--map-column-hive	Specifies the data type of fields during the generation of a Hive table.
	--hive-partition-key	Creates a partition.
	--hive-partition-value	Imports data to a specified partition of a database.
	--hive-home	Specifies the installation directory for Hive.
	--hive-import	Specifies that data is imported from a relational database to Hive.
	--hive-overwrite	Overwrites existing Hive data.

Category	Parameter	Description
	--create-hive-table	Creates a Hive table. The default value is **false**. A destination table will be created if it does not exist.
	--hive-table	Specifies a Hive table to which data is to be imported.
	--table	Specifies the relational database table.
	--columns	Specifies the fields of a relational data table to be imported.
	--query	Specifies the query statement for importing the query result.
HCatalog parameters	--hcatalog-database	Specifies a Hive database and imports data to it using HCatalog.
	--hcatalog-table	Specifies a Hive table and imports data to it using HCatalog.
Others	-m or --num-mappers	Specifies the number of map tasks used by a Sqoop job.
	--split-by	Specifies the column based on which Sqoop splits work units. This parameter is used together with **-m**.
	--target-dir	Specifies the temporary directory of HDFS.
	--null-string string	Specifies the string to be written for a null value for string columns.
	--null-non-string	Specifies the string to be written for a null value for non-string columns.
	--check-column	Specifies the column for determining incremental data import.
	--incremental append or lastmodified	Incrementally imports data. **append**: appends records, for example, appending records that are greater than the value specified by **last-value**. **lastmodified**: appends data that is modified after the date specified by **last-value**.
	--last-value	Specifies the last value of the check column from the previous import.
	--input-null-string	Specifies the string to be interpreted as **NULL** for string columns.

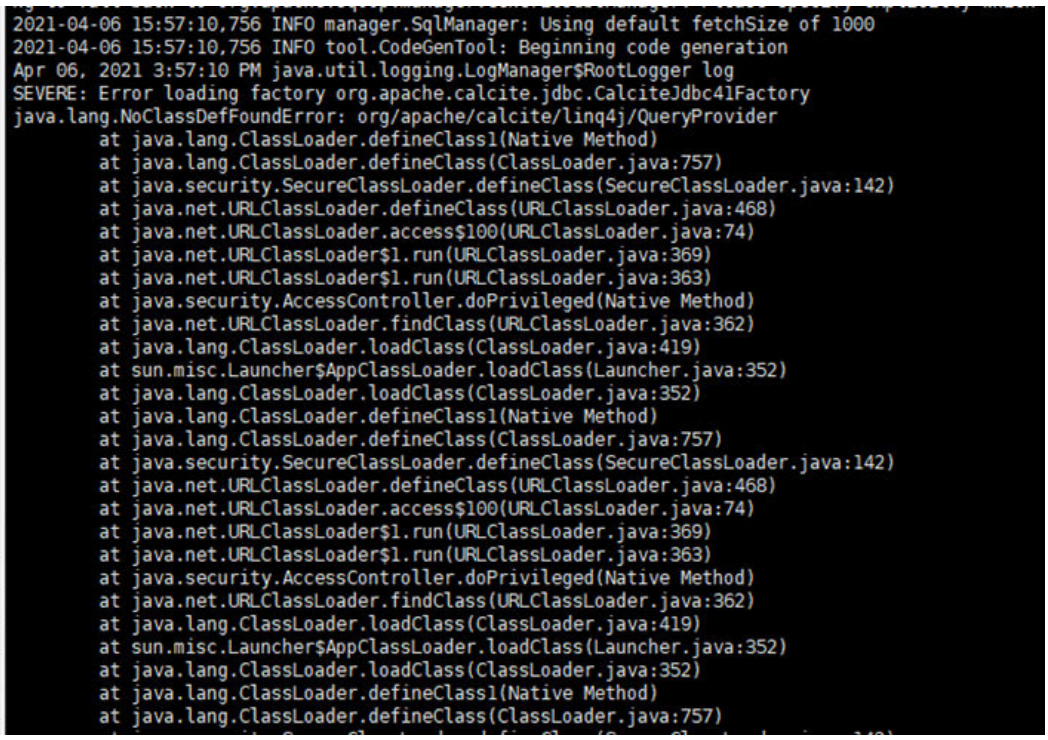
Category	Parameter	Description
	--input-null-non-string	Specifies the string to be interpreted as null for non-string columns. If this parameter is not specified, **NULL** will be used.

12.24.4 Common Issues About Sqoop

12.24.4.1 What Should I Do If Class QueryProvider Is Unavailable?

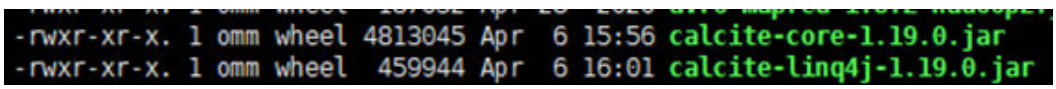
Question

What should I do if the QueryProvider class is unavailable?



Answer

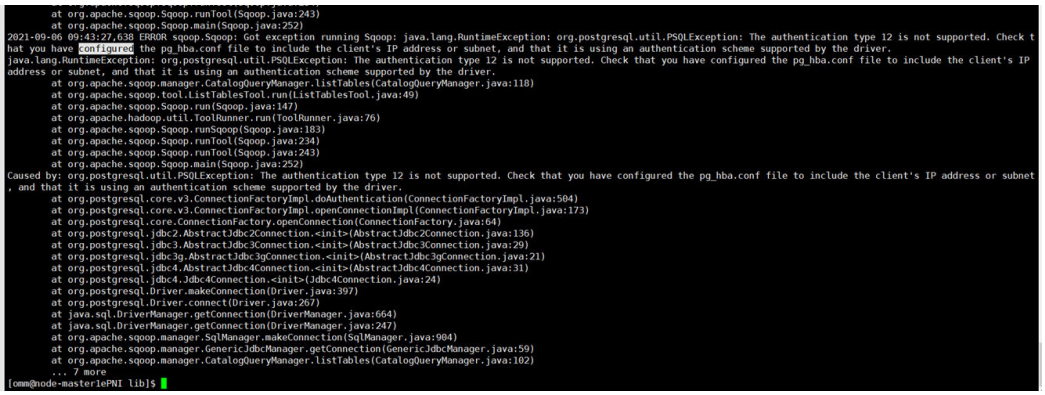
Search for the MRS client directory and save the following JAR packages to the **lib** directory of Sqoop.



12.24.4.2 What Should I Do If PostgreSQL or GaussDB Failed to Be Connected?

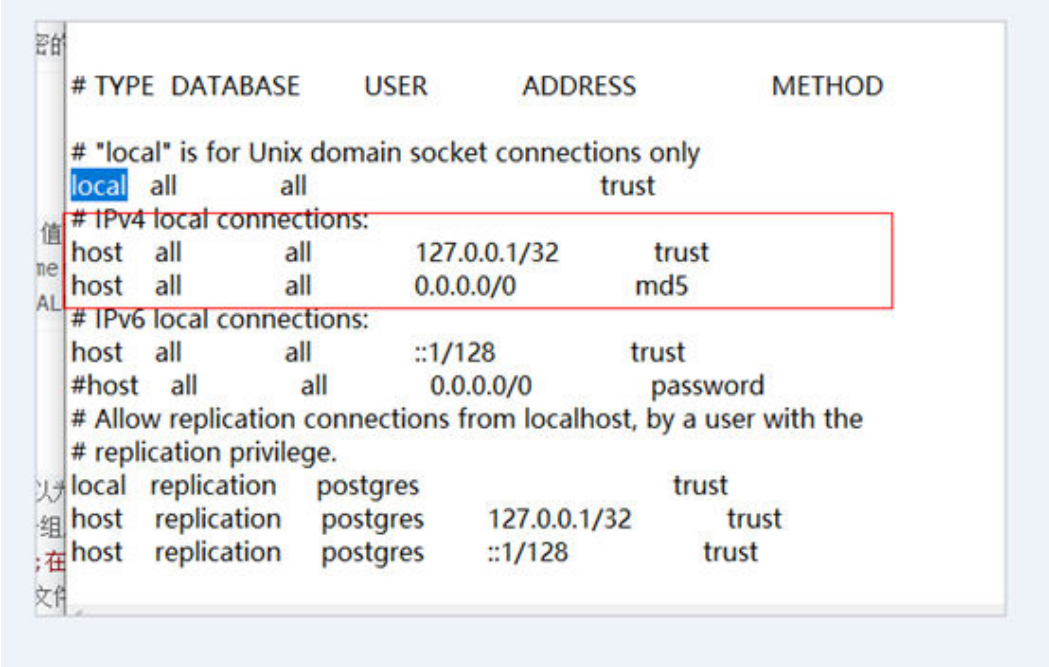
Question

What should I do if PostgreSQL or GaussDB failed to be connected?



Answer

Modify the **pg_hba.conf** file of the database and change the value of **ADDRESS** to the IP address of the node where Sqoop is located.



12.24.4.3 What Should I Do If Data Failed to Be Synchronized to a Hive Table on the OBS Using hive-table?

Question

What should I do if data failed to be synchronized to a Hive table on the OBS using hive-table?

```
2021-09-03 16:28:11,611 ERROR tools.DistCp: XAttrs not supported on at least one file system:
org.apache.hadoop.tools.CopyListing$XAttrsNotSupportedException: XAttrs not supported for file system:
obs://fdd-fs
        at org.apache.hadoop.tools.util.DistCpUtils.checkFileSystemXAttrSupport(DistCpUtils.java:555)
        at org.apache.hadoop.tools.DistCp.configureOutputFormat(DistCp.java:341)
        at org.apache.hadoop.tools.DistCp.createJob(DistCp.java:308)
        at org.apache.hadoop.tools.DistCp.createAndSubmitJob(DistCp.java:218)
        at org.apache.hadoop.tools.DistCp.execute(DistCp.java:197)
        at org.apache.hadoop.tools.DistCp.run(DistCp.java:155)
```

Answer

Change **-hive-table** to **-hcatalog-table**.

12.24.4.4 What Should I Do If Data Failed to Be Synchronized to an ORC or Parquet Table Using hive-table?

Question

What should I do if data failed to be synchronized to the ORC or parquet table using hive-table and error message that contains the **kite-sdk** package name is displayed?

Answer

Change **-hive-table** to **-hcatalog-table**.

12.24.4.5 What Should I Do If Data Failed to Be Synchronized Using hive-table?

Question

What should I do if data failed to be synchronized using hive-table?

```
        at org.apache.hadoop.hive.ql.metadata.Hive.registerAllFunctionsOnce(Hive.java:2907) [hive-exec-3.1.0-RW-ei-312001-SNAPSHOT.jar:3.1.0-RW-ei-312001-SNAPSHOT]

```

Answer

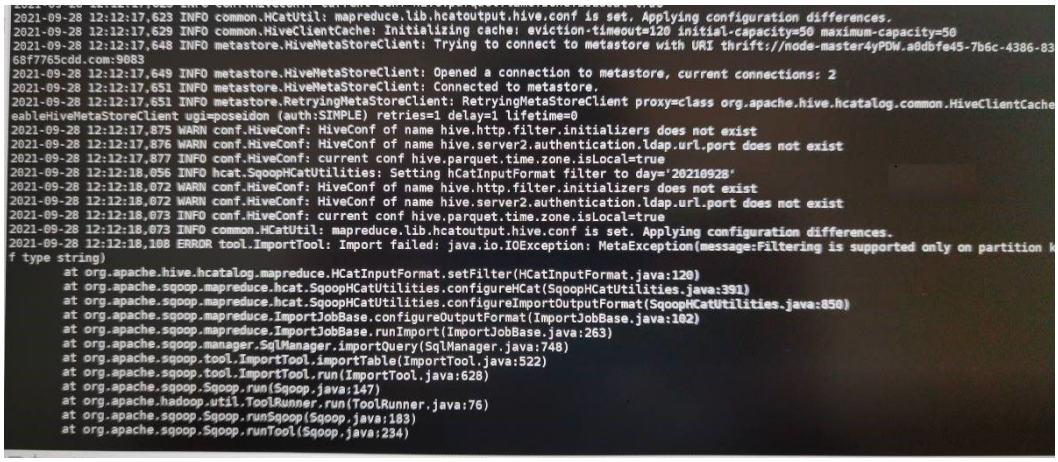
Add the following content to the **hive-site.xml** file.

```
<property>
<name>hive.metastore.schema.verification</name>
<value>false</value>
</property>
```

12.24.4.6 What Should I Do If Data Failed to Be Synchronized to a Hive Parquet Table Using HCatalog?

Question

When the partition fields in a Hive parquet table are not of the string type, data in the table can be synchronized only using HCatalog. What should I do if the following error message is displayed during data synchronization?



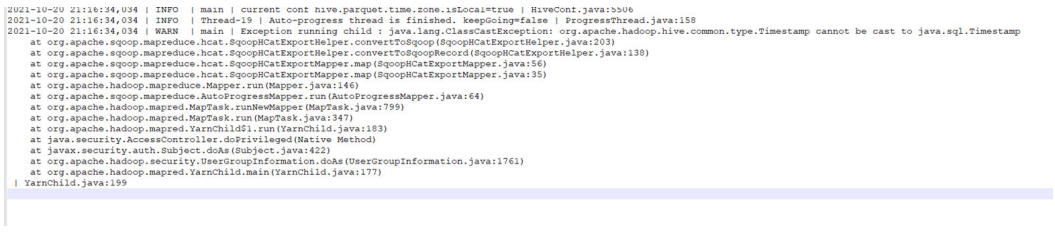
Answer

1. Delete the restricted code in the **SqoopHCatUtilities** class of Sqoop.
2. Change the value of the **hive.metastore.integral.jdo.pushdown** parameter in the **hive-site.xml** file on the Hive client to **true**.

12.24.4.7 What Should I Do If the Data Type of Fields timestamp and data Is Incorrect During Data Synchronization Between Hive and MySQL?

Question

What should I do if the data type of fields timestamp and data is incorrect during data synchronization between Hive and MySQL?



Answer

- Forcibly convert the data type of the timestamp field in the Sqoop source package to be the same as that in Hive.
- Change the data type of the timestamp field in Hive to String.

12.25 Using Storm

12.25.1 Using Storm from Scratch

You can submit and delete Storm topologies on the MRS cluster client.

Prerequisites

The MRS cluster client has been installed, for example, in the **/opt/hadoopclient** directory. The client directory in the following operations is only an example. Change it based on the actual installation directory onsite.

Procedure

Step 1 Prepare the client based on service requirements. Log in to the node where the client is installed.

Log in to the node where the client is installed. For details, see .

Step 2 Run the following command to switch to the client directory, for example, **/opt/hadoopclient**:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 For clusters with Kerberos authentication enabled, run the following command to authenticate the user. For clusters with Kerberos authentication disabled, skip this step.

kinit *Storm user*

Step 5 Run the following command to submit the Storm topology:

storm jar *Path of the topology package Class name of the topology Main method Topology name*

If the following information is displayed, the topology is submitted successfully.

```
Finished submitting topology: topo1
```

Step 6 Run the following command to query Storm topologies. For clusters with Kerberos authentication enabled, only users in the **stormadmin** or **storm** group can query all topologies.

storm list

Step 7 Run the following command to delete a Storm topology.

storm kill *Topology name*

----End

12.25.2 Using the Storm Client

Scenario

This section describes how to use the Storm client in an O&M scenario or service scenario.

Prerequisites

- You have installed the client. For example, the installation directory is **/opt/hadoopclient**.
- Service component users are created by the administrator as required. In security mode, machine-machine users have downloaded the keytab file. A human-machine user must change the password upon the first login. (Not involved in normal mode)

Procedure

Step 1 Prepare the client based on service requirements. Log in to the node where the client is installed.

Log in to the node where the client is installed. For details, see **Using an MRS Client**.

Step 2 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If multiple Storm instances are installed, run the following command to load the environment variables of a specific instance when running the Storm command to submit the topology. Otherwise, skip this step. The following command uses the instance Storm-2 as an example.

source Storm-2/component_env

Step 5 Run the following command to perform user authentication (skip this step in normal mode):

kinit *Component service user*

Step 6 Run the following command to perform operations on the client:

For example, run the following command:

- **cql**
- **storm**

NOTE

A Storm client cannot be connected to secure and non-secure ZooKeepers at the same time.

----End

12.25.3 Submitting Storm Topologies on the Client

Scenario

You can submit Storm topologies on the cluster client to continuously process stream data. For clusters with Kerberos authentication enabled, users who submit topologies must be members of the **stormadmin** or **storm** group.

Prerequisites

The client has been updated.

Procedure

Step 1 Prepare the client based on service requirements. Log in to the node where the client is installed.

Log in to the node where the client is installed. For details, see **Using an MRS Client**.

Step 2 Run the following command to set the permissions on the topology JAR file:

For example, run the following command to change the permissions on **/opt/storm/topology.jar**:

chmod 600 /opt/storm/topology.jar

Step 3 Run the following command to switch to the client directory, for example, **/opt/client**.

cd /opt/client

Step 4 Run the following command to configure environment variables:

source bigdata_env

Step 5 If multiple Storm instances are installed, run the following command to load the environment variables of a specific instance when running the Storm command to submit the topology. Otherwise, skip this step. The following command uses the instance Storm-2 as an example.

source Storm-2/component_env

Step 6 For clusters with Kerberos authentication enabled, run the following command to authenticate the user. For clusters with Kerberos authentication disabled, skip this step.

kinit *Storm user*

Step 7 For versions earlier than MRS 3.x, run the following command to submit the Storm topology:

storm jar *Path of the topology package Class name of the topology Main method Topology name*

If the following information is displayed, the topology is submitted successfully.

```
Finished submitting topology: topo1
```

NOTE

- To support sampling messages, add the **topology.debug** and **topology.eventlogger.executors** parameters.
- Data processing methods vary with topologies. The topology in the example generates characters randomly and separates character strings. To query the processing status, enable the sampling function and perform operations according to **Querying Storm Topology Logs**.

Step 8 Run the following command to submit a topology task for MRS 3.x or later:

storm jar *topology-jar-path class input parameter list*

- *topology-jar-path* indicates the path of the JAR file of the topology.
- *class* indicates the class name of the main method used by the topology.
- *Input parameter list* includes input parameters of the main method used by the topology.

If the following information is displayed, the topology is submitted successfully:

```
Finished submitting topology: topology1
```

NOTE

- The login authentication user must correspond to the loaded environment variable (**component_env**). Otherwise, an error occurs when you run the **storm** command to submit the topology task.
- After the client environment variable is loaded and the corresponding user login succeeds, the user can run the Storm command on any Storm client to submit the topology task. After the command is executed, the successfully submitted topology is still in the Storm cluster of the user.
- If cluster domain name is modified, you need to reset the domain name before submitting the topology. Run the cql statement.

Step 9 Run the following command to query Storm topologies. For clusters with Kerberos authentication enabled, only users in the **stormadmin** or **storm** group can query all topologies.

storm list

----End

12.25.4 Accessing the Storm Web UI

Scenario

The Storm web UI provides a graphical interface for using Storm.

The following information can be queried on the Storm web UI:

- Storm cluster summary
- Nimbus summary

- Topology summary
- Supervisor summary
- Nimbus configurations

Prerequisites

- The password of user **admin** has been obtained. The password of user **admin** is specified by you during the cluster creation.
- If a user other than **admin** is used to access the Storm web UI, the user must be added to the **storm** or **stormadmin** user group.

Procedure

Step 1 Access the component management page.

- For versions earlier than MRS 3.*x*, click the cluster name to go to the cluster details page and choose **Components**.

  NOTE

  If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

- For MRS 3.*x* or later, log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Choose **Cluster** > *Name of the desired cluster* > **Services**.

Step 2 Log in to the Storm WebUI.

- For versions earlier than MRS 3.x: Choose **Storm**. On the **Storm Summary** area, click any UI link on the right side of **Storm Web UI** to open the Storm web UI.

  NOTE

  When accessing the Storm web UI for the first time, you must add the address to the trusted site list.

- For MRS 3.x or later, choose **Storm** > **Overview**. In the **Basic Information** area, click any UI link on the right side of **Storm Web UI** to open the Storm web UI.

----End

Related Tasks

- Click a topology name to view details, status, Spouts information, Bolts information, and configuration information of the topology.
- In the **Topology actions** area, click **Activate**, **Deactivate**, **Rebalance**, **Kill**, **Debug**, **Stop Debug**, and **Change Log Level** to activate, deactivate, redeploy, delete, debug, and stop debugging the topology, and modify the log levels, respectively. You need to set the waiting time for the redeployment and deletion operations. The unit is second.
- In the **Topology Visualization** area, click **Show Visualization** to visualize a topology. After the topology is visualized, the WebUI displays the topology structure.

12.25.5 Managing Storm Topologies

Scenario

You can manage Storm topologies on the Storm web UI. Users in the **storm** group can manage only the topology tasks submitted by themselves, while users in the **stormadmin** group can manage all topology tasks.

Procedure

Step 1 For details about how to access the Storm WebUI, see **Accessing the Storm Web UI**.

Step 2 In the **Topology summary** area, click the desired topology.

Step 3 Use options in **Topology actions** to manage the Storm topology.

- Activating a topology

  Click **Activate** to activate the topology.

- Deactivating a topology

  Click **Deactivate** to deactivate the topology.

- Re-deploying a topology

  Click **Rebalance** and specify the wait time (in seconds) of re-deployment. Generally, if the number of nodes in a cluster changes, the topology can be re-deployed to maximize resource usage.

- Deleting a topology

  Click **Kill** and specify the wait time (in seconds) of the deletion.

- Starting or stopping sampling messages

  Click **Debug**. In the dialog box displayed, specify the percentage of the sampled data volume. For example, if the value is set to **10**, 10% of data is sampled.

  To stop sampling, click **Stop Debug**.

  NOTE

  This function is available only if the sampling function is enabled when the topology is submitted. For details about querying data processing information, see **Querying Storm Topology Logs**.

- Modifying the topology log level

  Click **Change Log Level** to specify a new log level.

Step 4 Displaying a topology

In the **Topology Visualization** area, click **Show Visualization** to visualize the topology.

----End

12.25.6 Querying Storm Topology Logs

Scenario

You can query topology logs to check the execution of a Storm topology in a worker process. To query the data processing logs of a topology, enable the **Debug** function when submitting the topology. Only streaming clusters with Kerberos authentication enabled support this function. In addition, the user who queries topology logs must be the one who submits the topology or a member of the **stormadmin** group.

Prerequisites

- The network of the working environment has been configured.
- The sampling function has been enabled for the topology.

Querying Worker Process Logs

Step 1 For details about how to access the Storm WebUI, see **Accessing the Storm Web UI**.

Step 2 In the **Topology Summary** area, click the desired topology to view details.

Step 3 Click the desired **Spouts** or **Bolts** task. In the **Executors (All time)** area, click a port in **Port** to view detailed logs.

----End

Querying Data Processing Logs of a Topology

Step 1 For details about how to access the Storm WebUI, see **Accessing the Storm Web UI**.

Step 2 In the **Topology Summary** area, click the desired topology to view details.

Step 3 Click **Debug**, specify the data sampling ratio, and click **OK**.

Step 4 Click the **Spouts** or **Bolts** task. In **Component summary**, click **events** to view data processing logs.

----End

12.25.7 Storm Common Parameters

This section applies to MRS 3.*x* or later.

Navigation Path

For details about how to set parameters, see **Modifying Cluster Service Configuration Parameters**.

Parameter Description

Table 12-435 Parameter description

Parameter	Description	Default Value
supervisor.slots.ports	Specifies the list of ports that can run workers on the supervisor. Each worker occupies a port, and each port runs only one worker. This parameter is used to set the number of workers that can run on each server. Ports range from 1024 to 65535, and ports are separated by commas (,).	6700,6701,6702,6703
WORKER_GC_OPTS	Specifies the JVM option used for supervisor to start worker. It is recommended that you set this parameter based on memory usage of a service. For simple service processing, the recommended value is **-Xmx1G**. If window cache is used, the value of this parameter is calculated based on the following formula: Size of each record x Period x 2	-Xms1G -Xmx1G -XX:+UseG1GC -XX:+PrintGCDetails -Xloggc:artifacts/gc.log -XX:+PrintGCDateStamps -XX:+PrintGCTimeStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M -XX:+HeapDumpOnOutOfMemoryError -XX:HeapDumpPath=artifacts/heapdump
default.schedule.mode	Specifies the default scheduling mode of the scheduler. Options are as follows: ● **AVERAGE**: indicates that the scheduling mechanism that uses the number of idle slots as the priority is used. ● **RATE**: indicates that the scheduling mechanism that uses the rate of idle slots as the priority is used.	AVERAGE
nimbus.thrift.threads	Set the maximum number of connection threads when the active Nimbus externally provides services. If the Storm cluster is large and the number of Supervisor instances is large, increase connection threads.	512

12.25.8 Configuring a Storm Service User Password Policy

Scenario

This section applies to MRS 3.*x* or later.

After submitting a topology task, a Storm service user must ensure that the task continuously runs. During topology running, the worker process may need to restart to ensure continuous topology work. If the password of a service user is changed or the number of days that a password is used exceeds the maximum number specified in a password policy, topology running may be affected. A system administrator must configure a separate password policy for Storm service users based on enterprise security requirements.

NOTE

If a separate password policy is not configured for Storm service users, an old topology can be deleted and then submitted again after a service user password is changed so that the topology can continuous run.

Impact on the System

- After a separate password policy is configured for a Storm service user, the user is not affected by **Password Policy** on the Manager page.
- If a separate password policy is configured for a Storm service user and cross-cluster entrusted relationships are configured, a password must be reset for the Storm service user on Manager based on the password policy.

Prerequisites

A system administrator has understood service requirements and created a **Human-Machine** user, for example, **testpol**.

Procedure

Step 1 Log in to any node in the cluster as user **omm**.

Step 2 Run the following command to disable logout upon timeout:

TMOUT=0

NOTE

After the operations in this section are complete, run the **TMOUT=***Timeout interval* command to restore the timeout interval in a timely manner. For example, **TMOUT=600** indicates that a user is logged out if the user does not perform any operation within 600 seconds.

Step 3 Run the following commands to export the environment variables:

EXECUTABLE_HOME="${CONTROLLER_HOME}/kerberos_user_specific_binay/kerberos"

LD_LIBRARY_PATH=${EXECUTABLE_HOME}/lib:$LD_LIBRARY_PATH

PATH=${EXECUTABLE_HOME}/bin:$PATH

Step 4 Run the following command and enter the Kerberos administrator password to log in to the Kerberos console:

kadmin -p kadmin/admin

NOTE

For initial use, the **kadmin/admin** password must be changed for the **kadmin/admin** user.

If the following information is displayed, you have successfully logged in to the Kerberos console.

```
kadmin:
```

Step 5 Run the following command to check details about the created **Human-Machine** user:

getprinc*Username*

Sample command for viewing details about the **testpol** user:

getprinc testpol

If the following information is displayed, the specified user has used the default password policy:

```
Principal: testpol@<System domain name>
......
Policy: default
```

Step 6 Run the following command to create a separate password policy, such as **streampol**, for the Storm service user:

addpol -maxlife 0day -minlife 0sec -history 1 -maxfailure 5 -failurecountinterval 5min -lockoutduration 5min -minlength 8 -minclasses 4 streampol

In the command, **-maxlife** indicates the maximum validity period of a password, and **0day** indicates that a password will never expire.

Step 7 Run the following command to view the newly created policy **streampol**:

getpol streampol

If the following information is displayed, the new policy specifies that the password will never expire:

```
Policy: streampol
 Maximum password life: 0 days 00:00:00
......
```

Step 8 Run the following command to apply the new policy **streampol** to the **testpol** Storm user:

modprinc -policy streampol testpol

In the command, **streampol** indicates a policy name, and **testpol** indicates a username.

If the following information is displayed, the properties of the specified user have been modified:

```
Principal "testpol@<System domain name>" modified.
```

Step 9 Run the following command to view current information about the **testpol** Storm user:

getprinc testpol

If the following information is displayed, the specified user has used the new password policy:

```
Principal: testpol@<System domain name>
.....
 Policy: streampol
```

----End

12.25.9 Migrating Storm Services to Flink

12.25.9.1 Overview

This section applies to MRS 3.*x* or later.

From 0.10.0, Flink provides a set of APIs to smoothly migrate services compiled using Storm APIs to the Flink platform. This can be used in most of the service scenarios.

Flink supports the following service migration modes:

1. Complete migration of Storm services: Convert and run a complete Storm topology developed by Storm APIs.
2. Embedded migration of Storm services: Storm code is embedded in DataStream of Flink, for example, Spout/Bolt compiled using Storm APIs.

Flink provides the flink-storm package for the preceding service migration.

12.25.9.2 Completely Migrating Storm Services

Scenarios

This section describes how to convert and run a complete Storm topology developed using Storm API.

Procedure

Step 1 Open the Storm service project, modify the POM file of the project, and add the reference of **flink-storm_2.11**, **flink-core**, and **flink-streaming-java_2.11**. The following figure shows an example.

```
<dependency>
   <groupId>org.apache.flink</groupId>
   <artifactId>flink-storm_2.11</artifactId>
   <version>1.4.0</version>
   <exclusions>
      <exclusion>
         <groupId>*</groupId>
         <artifactId>*</artifactId>
      </exclusion>
   </exclusions>
</dependency>
```

```
<dependency>
   <groupId>org.apache.flink</groupId>
   <artifactId>flink-core</artifactId>
   <version>1.4.0</version>
   <exclusions>
      <exclusion>
         <groupId>*</groupId>
         <artifactId>*</artifactId>
      </exclusion>
   </exclusions>
</dependency>
```

```
<dependency>
   <groupId>org.apache.flink</groupId>
   <artifactId>flink-streaming-java_2.11</artifactId>
   <version>1.4.0</version>
   <exclusions>
      <exclusion>
         <groupId>*</groupId>
         <artifactId>*</artifactId>
      </exclusion>
   </exclusions>
</dependency>
```

NOTE

If the project is not a non-Maven project, manually collect the preceding JAR packages and add them to the *classpath* environment variable of the project.

Step 2 Modify the code for submission of the topology. The following uses WordCount as an example:

1. Keep the structure of the Storm topology unchanged, including the Spout and Bolt developed using Storm API.

```
TopologyBuilder builder = new TopologyBuilder();
builder.setSpout("spout", new RandomSentenceSpout(), 5);
builder.setBolt("split", new SplitSentenceBolt(), 8).shuffleGrouping("spout");
builder.setBolt("count", new WordCountBolt(), 12).fieldsGrouping("split", new Fields("word"));
```

2. Modify the code for submission of the topology. An example is described as follows:

```
Config conf = new Config();
conf.setNumWorkers(3);
StormSubmitter.submitTopology("word-count", conf, builder.createTopology());
```

Perform the following operations:

```
Config conf = new Config();
 conf.setNumWorkers(3);
 //converts Storm Config to StormConfig of Flink.
 StormConfig stormConfig = new StormConfig(conf);
 //Construct FlinkTopology using TopologBuilder of Storm.
 FlinkTopology topology = FlinkTopology.createTopology(builder);
 //Obtain the Stream execution environment.
 StreamExecutionEnvironment env = topology.getExecutionEnvironment();
 //Set StormConfig to the environment variable of Job to construct Bolt and Spout.
 //If StormConfig is not required during the initialization of Bolt and Spout, you do not need to set this
parameter.
 env.getConfig().setGlobalJobParameters(stormConfig);
 //Submit the topology.
 topology.execute();
```

3. After the package is repacked, run the following command to submit the package:

   flink run -class {MainClass} WordCount.jar

----End

12.25.9.3 Performing Embedded Service Migration

Scenarios

This section describes how to embed Storm code in DataStream of Flink in embedded migration mode. For example, the code of Spout or Bolt compiled using Storm API is embedded.

Procedure

Step 1 In Flink, perform embedded conversion to Spout and Bolt in the Storm topology to convert them to Flink operators. The following is an example of the code:

```
//set up the execution environment
final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
//get input data
final DataStream<String> text = getTextDataStream(env);
final DataStream<Tuple2<String, Integer>> counts = text
  //split up the lines in pairs (2-tuples) containing: (word,1)
  //this is done by a bolt that is wrapped accordingly
  .transform("CountBolt",
    TypeExtractor.getForObject(new Tuple2<String, Integer>("", 0)),
    new BoltWrapper<String, Tuple2<String, Integer>>(new CountBolt()))
  //group by the tuple field "0" and sum up tuple field "1"
  .keyBy(0).sum(1);
// execute program
env.execute("Streaming WordCount with bolt tokenizer");
```

Step 2 After the modification, run the following command to submit the modification:

flink run -class {MainClass} WordCount.jar

----End

12.25.9.4 Migrating Services of External Security Components Interconnected with Storm

Migrating Services for Interconnecting Storm with HDFS and HBase

If the Storm services use the **storm-hdfs** or **storm-hbase** plug-in package for interconnection, you need to specify the following security parameters when migrating Storm services as instructed in **Completely Migrating Storm Services**.

```
//Initialize Storm Config.
Config conf = new Config();

//Initialize the security plug-in list.
List<String> auto_tgts = new ArrayList<String>();
//Add the AutoTGT plug-in.
auto_tgts.add("org.apache.storm.security.auth.kerberos.AutoTGT");
//Add the AutoHDFS plug-in.
//If HBase is interconnected, use auto_tgts.add("org.apache.storm.hbase.security.AutoHBase") to replace the following:
auto_tgts.add("org.apache.storm.hdfs.common.security.AutoHDFS");

//Set security parameters.
conf.put(Config.TOPOLOGY_AUTO_CREDENTIALS, auto_tgts);
//Set the number of workers.
conf.setNumWorkers(3);

//Convert Storm Config to StormConfig of Flink.
StormConfig stormConfig = new StormConfig(conf);
```

```
//Construct FlinkTopology using TopologBuilder of Storm.
FlinkTopology topology = FlinkTopology.createTopology(builder);

//Obtain the StreamExecutionEnvironment.
StreamExecutionEnvironment env = topology.getExecutionEnvironment();

//Add StormConfig to the environment variable of Job to construct Bolt and Spout.
//If Config is not required during the initialization of Bolt and Spout, do not set this parameter.
env.getConfig().setGlobalJobParameters(stormConfig);

//Submit the topology.
topology.execute();
```

After the preceding security plug-in is configured, unnecessary logins during the initialization of HDFSBolt and HBaseBolt are avoided because the security context has been configured in Flink.

Migrating Services of Storm Interconnected with Other Security Components

If the plug-in packages, such as **storm-kakfa-client** and **storm-solr** are used for interconnection between Storm and other components for service migration, the previously configured security plug-ins need to be deleted.

```
List<String> auto_tgts = new ArrayList<String>();
//keytab mode
auto_tgts.add("org.apache.storm.security.auth.kerberos.AutoTGTFromKeytab");

//Write the plug-in list configured on the client to the specified config parameter.
//Mandatory in security mode
//This configuration is not required in common mode, and you can comment out the following line.
conf.put(Config.TOPOLOGY_AUTO_CREDENTIALS, auto_tgts);
```

The AutoTGTFromKeytab plug-in must be deleted during service migration. Otherwise, the login will fail when Bolt or Spout is initialized.

12.25.10 Storm Log Introduction

This section applies to MRS 3.*x* or later.

Log Description

Log paths: The default paths of Storm log files are **/var/log/Bigdata/storm/***Role name* (run logs) and **/var/log/Bigdata/audit/storm/***Role name* (audit logs).

- Nimbus: **/var/log/Bigdata/storm/nimbus** (run logs) and **/var/log/Bigdata/audit/storm/nimbus** (audit logs)
- Supervisor: **/var/log/Bigdata/storm/supervisor** (run logs) and **/var/log/Bigdata/audit/storm/supervisor** (audit logs)
- UI: **/var/log/Bigdata/storm/ui** (run logs) and **/var/log/Bigdata/audit/storm/ui** (audit logs)
- Logviewer: **/var/log/Bigdata/storm/logviewer** (run logs) and **/var/log/Bigdata/audit/storm/logviewer** (audit logs)

Log archive rule: The automatic Storm log compression function is enabled. By default, when the size of logs exceeds 10 MB, logs are automatically compressed into a log file named in the following format: *<Original log name>***.log.***[ID]***.gz**. A

maximum of 20 latest compressed files are reserved by default. You can configure the number of compressed files and the compression threshold.

Names of compressed audit log files are in the format of **audit.log.***[yyyy-MM-dd]*.*[ID]*.**zip**. These files permanently exist.

Table 12-436 Storm log list

Log Type	Log File Name	Description
Run log	nimbus/access.log	Nimbus user access log
	nimbus/nimbus-<PID>-gc.log	GC log of the Nimbus process
	nimbus/checkavailable.log	Nimbus availability check log
	nimbus/checkService.log	Nimbus serviceability check log
	nimbus/metrics.log	Nimbus monitoring statistics log
	nimbus/nimbus.log	Run log of the Nimbus process
	nimbus/postinstall.log	Work log after Nimbus installation
	nimbus/prestart.log	Work log before Nimbus startup
	nimbus/start.log	Work log of Nimbus startup
	nimbus/stop.log	Work log of Nimbus shutdown
	supervisor/access.log	Supervisor access log
	supervisor/metrics.log	Supervisor monitoring statistics log
	supervisor/postinstall.log	Work log after supervisor installation
	supervisor/prestart.log	Work log before supervisor startup
	supervisor/start.log	Work log of supervisor startup
	supervisor/stop.log	Work log of supervisor shutdown
	supervisor/supervisor.log	Run log of the supervisor process

Log Type	Log File Name	Description
	supervisor/supervisor-<PID>-gc.log	GC log of the supervisor process
	ui/access.log	UI access log
	ui/metric.log	UI monitoring statistics log
	ui/ui-<PID>-gc.log	GC log of the UI process
	ui/postinstall.log	Work log after UI installation
	ui/prestart.log	Work log before UI startup
	ui/start.log	Work log of UI startup
	ui/stop.log	Work log of UI shutdown
	ui/ui.log	Run log of the UI process
	logviewer/access.log	Logviewer access log
	logviewer/metric.log	Logviewer monitoring statistics log
	logviewer/logviewer-<PID>-gc.log	GC log file of the logviewer process
	logviewer/logviewer.log	Run log of the logviewer process
	logviewer/postinstall.log	Work log after logviewer installation
	logviewer/prestart.log	Work log before logviewer startup
	logviewer/start.log	Work log of logviewer startup
	logviewer/stop.log	Work log of logviewer shutdown
	supervisor/[topologyId]-worker-[*Port number*].log	Run log of the Worker process. One port occupies one log file. By default, the system contains five ports: 29100, 29101, 29102, 29103 and 29304.

Log Type	Log File Name	Description
	supervisor/metadata/[topologyid]-worker-[*Port number*].yaml	Worker log metadata file, which is used by logviewer to delete logs. This file is automatically deleted by the logviewer log deletion thread based on certain conditions.
	nimbus/cleanup.log	Cleanup log of Nimbus uninstallation
	logviewer/cleanup.log	Cleanup log of logviewer uninstallation
	ui/cleanup.log	Cleanup log of UI uninstallation
	supervisor/cleanup.log	Cleanup log of supervisor uninstallation
	leader_switch.log	Run log file that records the Storm active/standby switchover
Audit log	nimbus/audit.log	Nimbus audit log
	ui/audit.log	UI audit log
	supervisor/audit.log	Supervisor audit log
	logviewer/audit	Logviewer audit log

Log Levels

Table 12-437 describes the log levels supported by Storm.

Levels of run logs and audit logs are ERROR, WARN, INFO, and DEBUG from the highest to the lowest priority. Run logs of equal or higher levels are recorded. The higher the specified log level, the fewer the logs recorded.

Table 12-437 Log levels

Level	Description
ERROR	Logs of this level record error information about system running.
WARN	Logs of this level record exception information about the current event processing.

Level	Description
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record the system information and system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of Storm by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 On the menu bar on the left, select the log menu of the target role.

Step 3 Select a desired log level.

Step 4 Save the configuration. In the displayed dialog box, click **OK** to make the configurations take effect.

----End

Log Format

The following table lists the Storm log formats:

Table 12-438 Log Formats

Log Type	Format	Example
Run log	%d{yyyy-MM-dd HH:mm:ss,SSS} | %-5p | [%t] | %m | %logger (%F:%L) %n	2015-03-11 23:04:00,241 | INFO | [RMI TCP Connection(2646)-10.0.0.2] | The baseSleepTimeMs [1000] the maxSleepTimeMs [1000] the maxRetries [1] | backtype.storm.utils.StormBoundedExponentialBackoffRetry (StormBoundedExponentialBackoffRetry.java:46)
	<yyyy-MM-dd HH:mm:ss,SSS><HostName><RoleName><logLevel><Message>	2017-03-28 02:57:52 493 10-5-146-1 storm- INFO Nimbus start normally

Log Type	Format	Example
Audit log	*<Username><User IP address><Time><Operation><Operation object><Operation result>*	UserName=storm/hadoop, UserIP=10.10.0.2, Time=Tue Mar 10 01:15:35 CST 2015, Operation=Kill, Resource=test, Result=Success

12.25.11 Performance Tuning

12.25.11.1 Storm Performance Tuning

Scenario

You can modify Storm parameters to improve Storm performance in specific service scenarios.

This section applies to MRS 3.x or later.

Modify the service configuration parameters. For details, see **Modifying Cluster Service Configuration Parameters**.

Topology Tuning

This task enables you to optimize topologies to improve efficiency for Storm to process data. It is recommended that topologies be optimized in scenarios with lower reliability requirements.

Table 12-439 Tuning parameters

Parameter	Default Value	Scenario
topology.acker.executors	null	Specifies the number of acker executors. If a service application has lower reliability requirements and certain data does not need to be processed, this parameter can be set to **null** or **0** so that you can set acker off, flow control is weakened, and message delay is not calculated. This improves performance.

Parameter	Default Value	Scenario
topology.max.spout.pending	null	Specifies the number of messages cached by spout. The parameter value takes effect only when acker is not **0** or **null**. Spout adds each message sent to downstream bolt into the pending queue. The message is removed from the queue after downstream bolt processes the message and the processing is confirmed. When the pending queue is full, spout stops sending messages. Increasing the pending value improves the message throughput of spout per second but prolongs the delay.
topology.transfer.buffer.size	32	Specifies the size of the Distuptor message queue for each worker process. It is recommended that the size be between 4 to 32. Increasing the queue size improves the throughput but may prolong the delay.
RES_CPUSET_PERCENTAGE	80	Specifies the percentage of physical CPU resources used by the supervisor role instance (including startup and management worker processes) on each node. Adjust the parameter value based on service volume requirements of the node on which the supervisor exists, to optimize CPU usage.

JVM Tuning

If an application must occupy more memory resources to process a large volume of data and the size of worker memory is greater than 2 GB, the G1 garbage collection algorithm is recommended.

Table 12-440 Tuning parameters

Parameter	Default Value	Scenario
WORKER_GC_OPTS	-Xms1G -Xmx1G -XX:+UseG1GC -XX:+PrintGCDetails -Xloggc:artifacts/gc.log -XX:+PrintGCDateStamps -XX:+PrintGCTimeStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M -XX:+HeapDumpOnOutOfMemoryError -XX:HeapDumpPath=artifacts/heapdump	If an application must occupy more memory resources to process a large volume of data and the size of worker memory is greater than 2 GB, the G1 garbage collection algorithm is recommended. In this case, change the parameter value to **-Xms2G -Xmx5G -XX:+UseG1GC**.

12.26 Using Tez

12.26.1 Precautions

This section applies to MRS 3.*x* or later.

12.26.2 Common Tez Parameters

Navigation path for setting parameters:

On Manager, choose **Cluster** > **Service** > **Tez** > **Configuration** > **All Configurations**. Enter a parameter name in the search box.

Parameter description

Table 12-441 Parameter description

Parameter	Description	Default Value
property.tez.log.dir	TezUI log directory	/var/log/Bigdata/tez/tezui
property.tez.log.level	TezUI log level	INFO

12.26.3 Accessing TezUI

Tez displays the Tez task execution process on a GUI. You can view the task execution details on the GUI.

Prerequisite

The TimelineServer instance of the Yarn service has been installed.

How to Use

Log in to Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. On Manager, choose **Cluster** > **Services** > **Tez**. Click the link on the right of **Tez WebUI** in the **Basic Information** area, and go to Tez web UI. You can view the details about Tez task execution.

12.26.4 Log Overview

Log Description

Log path: The default save path of Tez logs is **/var/log/Bigdata/tez/***role name*.

TezUI: **/var/log/Bigdata/tez/tezui** (run logs) and **/var/log/Bigdata/audit/tez/tezui** (audit logs)

Log archive rule: The automatic compression and archiving function of Tez is enabled. By default, when the size of a log file exceeds 20 MB (which is adjustable), the log file is automatically compressed. The naming rule of the compressed log file is as follows: <*Original log file name*>-<*yyyy-mm-dd_hh-mm-ss*>.[*ID*].**log.zip** A maximum of 20 latest compressed files are retained. The number of compressed files and compression threshold can be configured.

Table 12-442 Tez log list

Log Type	Name	Description
Run log	tezui.out	Log file that records TezUI running environment information

Log Type	Name	Description
	tezui.log	Run log of the TezUI process
	tezui-omm-<*Date*>-gc.log.<*No.*>	GC log of the TezUI process
	prestartDetail.log	Work logs generated before the TezUI is started
	check-serviceDetail.log	Log file that records whether the TezUI service starts successfully
	postinstallDetail.log	Work logs after the TezUI is installed
	startDetail.log	Startup log of the TezUI process
	stopDetail.log	Stop log of the TezUI process
Audit log	tezui-audit.log	TezUI audit log

Log Level

Table 12-443 describes the log levels supported by TezUI.

Levels of run logs are ERROR, WARN, INFO, and DEBUG from the highest to the lowest priority. Run logs of equal or higher levels are recorded. The higher the specified log level, the fewer the logs recorded.

Table 12-443 Log levels

Level	Description
ERROR	Logs of this level record error information about system running.
WARN	Exception information about the current event processing
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record the system information and system debugging information.

To modify log levels, perform the following operations:

Step 1 Log in to Manager.

Step 2 Choose **Cluster** > **Service** > **Tez** > **Configuration**.

Step 3 Select **All Configurations**.

Step 4 In the navigation pane, choose **TezUI** > **Log**.

Step 5 Select a desired log level.

Step 6 Click **Save**. In the dialog box that is displayed, click **OK** to save the configuration.

Step 7 Click **Instance**, select the **TezUI** role, choose **More** > **Restart Instance**, enter the user password, and click **OK** in the dialog box that is displayed.

Step 8 Wait until the instance is restarted for the configuration to take effect.

----End

Log Format

The following table lists the Tez log formats.

Table 12-444 Log formats

Log Type	Format	Example
Run log	<yyyy-MM-dd HH:mm:ss,SSS>| <LogLevel>|<Thread that generates the log>| <Message in the log>| <Location of the log event>	2020-07-31 11:44:21,378 | INFO | TezUI-health-check | Start health check | com.XXX.tez.HealthCheck.run(HealthCheck.java:30)
Audit logs	<yyyy-MM-dd HH:mm:ss,SSS>| <LogLevel>|<Thread that generates the log>|<User Name><User IP><Time><Operation><Resource><Result><Detail >|< Location of the log event >	2018-12-24 12:16:25,319 | INFO | HiveServer2-Handler-Pool: Thread-185 | UserName=hive UserIP=10.153.2.204 Time=2018/12/24 12:16:25 Operation=CloseSession Result=SUCCESS Detail= | org.apache.hive.service.cli.thrift.ThriftCLIService.logAuditEvent(ThriftCLIService.java:434)

12.26.5 Common Issues

12.26.5.1 TezUI Cannot Display Tez Task Execution Details

Question

After a user logs in to Manager and switches to the Tez web UI, the submitted Tez tasks are not displayed.

Answer

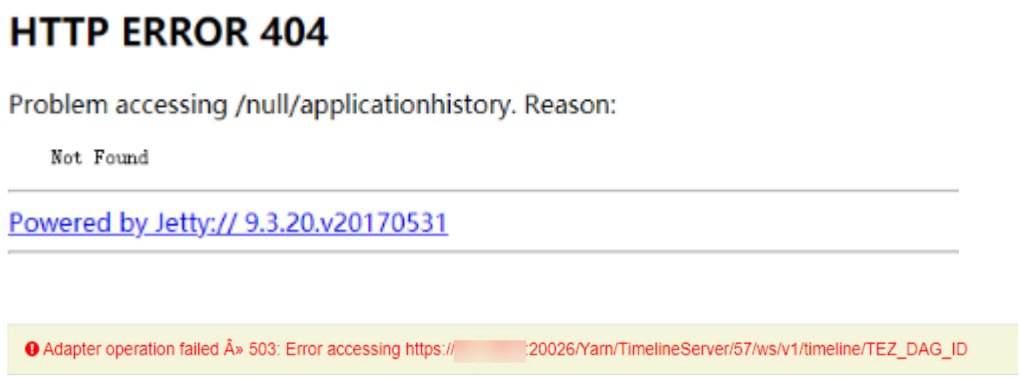
The Tez task data displayed on the Tez WebUI requires the support of TimelineServer of Yarn. Ensure that TimelineServer has been enabled and is running properly before the task is submitted.

When setting the Hive execution engine to Tez, you need to set **yarn.timeline-service.enabled** to **true**. For details, see **Switching the Hive Execution Engine to Tez**.

12.26.5.2 Error Occurs When a User Switches to the Tez Web UI

Question

When a user logs in to Manager and switches to the Tez web UI, error 404 or 503 is displayed.



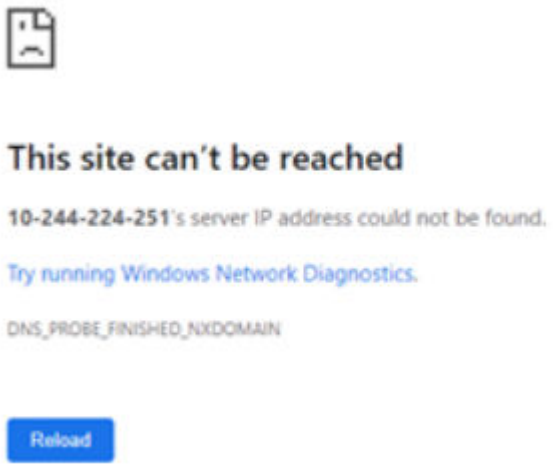
Answer

The Tez web UI depends on the TimelineServer instance of Yarn. Therefore, TimelineServer must be installed in advance and in the **Good** state.

12.26.5.3 Yarn Logs Cannot Be Viewed on the TezUI Page

Question

A user logs in to the Tez web UI and clicks **Logs**, but the Yarn log page fails to be displayed and data cannot be loaded.



Answer

Currently, the hostname is used for the access to the Yarn log page from the Tez web UI. Therefore, you need to configure the mapping between the hostname and IP address on the Windows host. Perform the following steps:

Modify the **C:\Windows\System32\drivers\etc\hosts** file on the Windows host and add a line indicating the mapping between the host name and IP address, for example, **10.244.224.45 10-044-224-45**. Save the modification and access the host again.

12.26.5.4 Table Data Is Empty on the TezUI HiveQueries Page

Question

A user logs in to Manager and switches to the Tez web UI page, but no data for the submitted task is displayed on the **Hive Queries** page.

Answer

To display task data on the **Hive Queries** page on the Tez web UI, you need to set the following parameters:

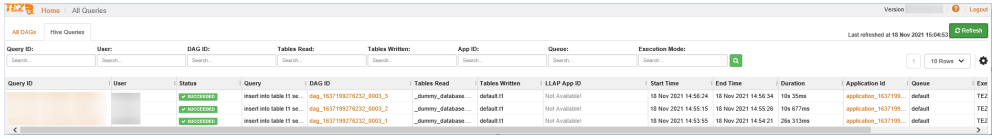
On FusionInsight Manager, choose **Cluster** > **Service** > **Hive** and click the **Configurations** tab and then **All Configurations**. In the navigation pane on the left, choose **HiveServer** > **Customization**. Add the following configuration to **hive-site.xml**:

Attribute	Attribute Value
hive.exec.pre.hooks	org.apache.hadoop.hive.ql.hooks.ATSHook
hive.exec.post.hooks	org.apache.hadoop.hive.ql.hooks.ATSHook
hive.exec.failure.hooks	org.apache.hadoop.hive.ql.hooks.ATSHook

NOTE

Data display on TezUI depends on the TimelineServer instance of Yarn. If the TimelineServer instance is faulty or not started, you need to set **yarn.timeline-service.enabled** to **false** in **yarn-site.xml**. Otherwise, the Hive task fails to be executed.

After you configure the parameters and re-execute the Hive task, data can be displayed on the **Hive Queries** page. However, data of previous tasks cannot be displayed.



12.27 Using Yarn

12.27.1 Common YARN Parameters

Allocating Queue Resources

The Yarn service provides queues for users. Users allocate system resources to each queue. After the configuration is complete, you can click **Refresh Queue** or restart the Yarn service for the configuration to take effect.

Navigation path for setting parameters:

For versions earlier than MRS 3.x, perform the following operations:

On the MRS console, choose **Tenants** > **Resource Distribution Policies**.

The following uses the **default** queue as an example. The configurations of other queues are similar. Click **Modify** to edit the parameters.

Table 12-445 Parameter description

Parameter	Description	Default Value
Capacity	Queue resource capacity (percentage). Ensure that the capacity requirement of each queue is satisfied when the system is busy. If only a few application programs are running in a queue, the remaining resource of the queue can be shared with other queues. Note that the total capacity of all queues must be smaller than 100.	20
Maximum Capacity	Maximum queue resource usage (percentage). Due to resource sharing, the resources used by a queue may exceed its capacity. The maximum resource usage can be limited using this parameter.	100

For MRS 3.*x* or later, perform the following operations:

On Manager, choose **Tenant Resources** > **Dynamic Resource Plan** > **Queue Configuration**.

The following uses the **default** tenant who modifies the Superior scheduler as an example. The configurations of other queues are similar. Click **Modify** to edit the parameters.

Table 12-446 Queue configuration parameters

Parameter	Description
Max Master Shares(%)	Indicates the maximum percentage of resources occupied by all ApplicationMasters in the current queue.
Max Allocated vCores	Indicates the maximum number of cores that can be allocated to a single YARN container in the current queue. The default value is **-1**, indicating that the number of cores is not limited within the value range.
Max Allocated Memory(MB)	Indicates the maximum memory that can be allocated to a single YARN container in the current queue. The default value is **-1**, indicating that the memory is not limited within the value range.
Max Running Apps	Maximum number of tasks that can be executed at the same time in the current queue. The default value is **-1**, indicating that the number is not limited within the value range (the meaning is the same if the value is empty). The value 0 indicates that the task cannot be executed. The value ranges from -1 to 2147483647.
Max Running Apps per User	Maximum number of tasks that can be executed by each user in the current queue at the same time. The default value is **-1**, indicating that the number is not limited within the value range. If the value is **0**, the task cannot be executed. The value ranges from -1 to 2147483647.
Max Pending Apps	Maximum number of tasks that can be suspended at the same time in the current queue. The default value is **-1**, indicating that the number is not limited within the value range (the meaning is the same if the value is empty). The value **0** indicates that tasks cannot be suspended. The value ranges from -1 to 2147483647.
Resource Allocation Rule	Indicates the rule for allocating resources to different tasks of a user. The rule can be FIFO or FAIR. If a user submits multiple tasks in the current queue and the rule is FIFO, the tasks are executed one by one in sequential order; if the rule is FAIR, resources are evenly allocated to all tasks.

Parameter	Description
Default Resource Label	Indicates that tasks are executed on a node with a specified resource label.
Active	• **ACTIVE**: indicates that the current queue can receive and execute tasks. • **INACTIVE**: indicates that the current queue can receive but cannot execute tasks. Tasks submitted to the queue are suspended.
Open	• **OPEN**: indicates that the current queue is opened. • **CLOSED**: indicates that the current queue is closed. Tasks submitted to the queue are rejected.

Displaying Container Logs on the Web UI

By default, the system collects container logs to HDFS. If you do not need to collect container logs to HDFS, configure the parameters in **Table 12-447**. For details, see **Modifying Cluster Service Configuration Parameters**.

Table 12-447 Parameter description

Parameter	Description	Default Value
yarn.log-aggregation-enable	Select whether to collect container logs to HDFS. • If the parameter is set to **true**, container logs are collected to an HDFS directory. The default directory is **{yarn.nodemanager.remote-app-log-dir}/${user}/{thisParam}**. You can set the directory by setting the **yarn.nodemanager.remote-app-log-dir-suffix** parameter on the web UI. • If this parameter is set to **false**, container logs will not be collected to HDFS. After changing the parameter value, restart the Yarn service for the setting to take effect. **NOTE** The container logs that are generated before the parameter is set to **false** and the setting takes effect cannot be obtained from the web UI. You can obtain container logs from the directory specified by the **yarn.nodemanager.remote-app-log-dir-suffix** parameter before the setting takes effect. If you want to view the logs generated before on the web UI, you are advised to set this parameter to **true**.	true

Increasing the Number of Historical Jobs to Be Displayed on the web UI

By default, the Yarn web UI supports task list pagination. A maximum of 5,000 historical jobs can be displayed on each page, and a maximum of 10,000 historical jobs can be retained. If you need to view more jobs on the WebUI, configure parameters by referring to **Table 12-448**. For details, see **Modifying Cluster Service Configuration Parameters**.

Table 12-448 Parameter description

Parameter	Description	Default Value
yarn.resourcemanager.max-completed-applications	Set the total number of historical jobs to be displayed on the web UI.	10000
yarn.resourcemanager.webapp.pagination.enable	Select whether to enable the job list background pagination function for the Yarn web UI.	true

Parameter	Description	Default Value
yarn.resourcemanager.webapp.pagination.threshold	Set the maximum number of jobs displayed on each page after the job list background pagination function of the Yarn web UI is enabled.	5000

NOTE

- If a large number of historical jobs are displayed, the performance will be affected and the time for opening the Yarn web UI will be increased. Therefore, you are advised to enable the background pagination function and modify the **yarn.resourcemanager.max-completed-applications** parameter according to the actual hardware performance.
- After changing the parameter value, restart the Yarn service for the setting to take effect.

12.27.2 Creating Yarn Roles

Scenario

This section describes how to create and configure a Yarn role. The Yarn role can be assigned with Yarn administrator permission and manage Yarn queue resources.

NOTE

If the current component uses Ranger for permission control, you need to configure permission management policies based on Ranger. Refer to **Adding a Ranger Access Permission Policy for Yarn** for clusters of MRS 3.*x* or later.

Prerequisites

- The system administrator has understood the service requirements.
- You have logged in to Manager.

Procedure

For versions earlier than MRS 3.x, perform the following operations:

Step 1 Choose **System** > **Manage Role** > **Create Role**.

Step 2 Click **Create Role** and fill in **Role Name** and **Description**.

Step 3 Set permissions. For details, see **Table 12-449**.

Yarn permissions:

- **Cluster Admin Operations**: Yarn administrator permissions.
- **Scheduler Queue**: queue resources management .

Table 12-449 Setting a role

Task	Operation
Setting the Yarn administrator permission	In the **Permission** table, click **Yarn** and select **Cluster Admin Operations**. **NOTE** The Yarn service needs to be restarted to set the Yarn administrator permission so that the saved role configuration can take effect.
Setting the permission for a user to submit tasks in a specified Yarn queue	1. In the **Permission** table, choose **Yarn** > **Scheduler Queue**. 2. In the **Permission** column of the specified queue, select **Submit**.
Setting the permission for a user to manage tasks in a specified Yarn queue	1. In the **Permission** table, choose **Yarn** > **Scheduler Queue**. 2. In the **Permission** column of the specified queue, select **Admin**.

If the Yarn role contains the **Submit** or **Manage** permission of a parent queue, the sub-queue inherits the permission by default, that is, the **Submit** or **Manage** permission is automatically added for the sub-queue. Permissions inherited by sub-queues will not be displayed as selected in the **Configure Resource Permission** table.

If you select only the **Submit** permission of a parent queue when setting the Yarn role, you need to manually specify the queue name when submitting tasks as a user with the permission of this role. Otherwise, when the parent queue has multiple sub-queues, the system does not automatically determine the queue to which the task is submitted and therefore submits the task to the **default** queue.

Step 4 Click **OK**.

----End

For MRS 3.*x* or later, perform the following operations:

Step 1 Choose System > Permission > Role.

Step 2 Click **Create Role** and set a role name and enter description.

Step 3 Refer **Table 12-450** to configure resource permissions for roles.

Yarn permissions:

- Cluster management: Yarn administrator permissions.
- Queue scheduling: queue resource management.

Table 12-450 Setting a role

Task	Operation
Setting the Yarn administrator permission	In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Yarn** > **Cluster Management**. **NOTE** The Yarn service needs to be restarted to set the Yarn administrator permission so that the saved role configuration can take effect.
Setting the permission for a user to submit tasks in a specified Yarn queue	1. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Yarn** > **Scheduling Queue** > **root**. 2. In the **Permission** column of the specified queue, select **Submit**.
Setting the permission for a user to manage tasks in a specified Yarn queue	1. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Yarn** > **Scheduling Queue** > **root**. 2. In the **Permission** column of the specified queue, select **Manage**.

If the Yarn role contains the **Submit** or **Manage** permission of a parent queue, the sub-queue inherits the permission by default, that is, the **Submit** or **Manage** permission is automatically added for the sub-queue. Permissions inherited by sub-queues will not be displayed as selected in the **Configure Resource Permission** table.

If you select only the **Submit** permission of a parent queue when setting the Yarn role, you need to manually specify the queue name when submitting tasks as a user with the permission of this role. Otherwise, when the parent queue has multiple sub-queues, the system does not automatically determine the queue to which the task is submitted and therefore submits the task to the **default** queue.

Step 4 Click **OK**.

----End

12.27.3 Using the YARN Client

Scenario

This section guides users to use a Yarn client in an O&M or service scenario.

Prerequisites

- The client has been installed.

  For example, the installation directory is **/opt/hadoopclient**. The client directory in the following operations is only an example. Change it to the actual installation directory.

- Service component users are created by the administrator as required. In security mode, machine-machine users need to download the keytab file. A human-machine user must change the password upon the first login. In common mode, you do not need to download the keytab file or change the password.

Using the Yarn Client

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, run the following command to authenticate the user. In normal mode, user authentication is not required.

kinit *Component service user*

Step 5 Run the Yarn command. The following provides an example:

yarn application -list

----End

Client-related FAQs

1. What Do I Do When the Yarn Client Exits Abnormally and Error Message "java.lang.OutOfMemoryError" Is Displayed After the Yarn Client Command Is Run?

   This problem occurs because the memory required for running the Yarn client exceeds the upper limit (128 MB by default) set on the Yarn client. For clusters of MRS 3.x or later: You can modify **CLIENT_GC_OPTS** in *<Client installation path>***/HDFS/component_env** to change the memory upper limit of the Yarn client. For example, if you want to set the maximum memory to 1 GB, run the following command:

   ```
   export CLIENT_GC_OPTS="-Xmx1G"
   ```

   For clusters earlier than MRS 3.x: You can modify **GC_OPTS_YARN** in *< Client installation path >***/HDFS/component_env** to change the memory upper limit of the Yarn client. For example, if you want to set the maximum memory to 1 GB, run the following command:

   ```
   export GC_OPTS_YARN="-Xmx1G"
   ```

   After the modification, run the following command to make the modification take effect:

   source <*Client installation path*>/**/bigdata_env**

2. How Can I Set the Log Level When the Yarn Client Is Running?

   By default, the logs generated during the running of the Yarn client are printed to the console. The default log level is INFO. To enable the DEBUG log level for fault locating, run the following command to export an environment variable:

export YARN_ROOT_LOGGER=DEBUG,console

Then run the Yarn Shell command to print DEBUG logs.

If you want to print INFO logs again, run the following command:

export YARN_ROOT_LOGGER=INFO,console

12.27.4 Configuring Resources for a NodeManager Role Instance

Scenario

If the hardware resources (such as the number of CPU cores and memory size) of the nodes for deploying NodeManagers are different but the NodeManager available hardware resources are set to the same value, the resources may be wasted or the status may be abnormal. You need to change the hardware resource configuration for each NodeManager to ensure that the hardware resources can be fully utilized.

Impact on the System

NodeManager role instances must be restarted for the new configuration to take effect, and the role instances are unavailable during restart.

Prerequisites

- For versions earlier than MRS 3.x: You have logged in to the MRS management console.
- Clusters of MRS 3.x or later: You have logged in to Manager.

Procedure

For versions earlier than MRS 3.*x*, perform the following operations:

Step 1 Choose **Clusters** > **Active Clusters**, and click a cluster name. Choose **Components** > **Yarn** > **Instances**.

Step 2 Click **NodeManager** in the **Role** column and go to the **Instance Configuration** tab page. Select **All** from the **Basic** drop-down list, and search for the required parameters.

Step 3 Enter **yarn.nodemanager.resource.cpu-vcores** in the search box, and set the number of vCPUs that can be used by NodeManager on the current node. You are advised to set this parameter to 1.5 to 2 times the number of actual logical CPUs on the node. Enter **yarn.nodemanager.resource.memory-mb** in the search box, and set the physical memory size that can be used by NodeManager on the current node. You are advised to set this parameter to 75% to 90% of the actual physical memory size of the node.

NOTE

Enter **yarn.scheduler.maximum-allocation-vcores** in the search box, and set the maximum number of available CPUs in a container. Enter **yarn.scheduler.maximum-allocation-mb** in the search box, and set the maximum available memory of a container. The instance level cannot be changed. The parameter values need to be changed in the configuration of the Yarn service, and the Yarn service needs to be restarted for the changes to take effect.

Step 4 Click **Save Configuration**, select **Restart the affected services or instances**, and click **OK** to restart the NodeManager role instance.

Operation succeeded is displayed. Click **Finish**. The NodeManager role instance is started successfully.

----End

For MRS 3.*x* or later, perform the following operations:

Step 1 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Yarn** > **Instance**.

Step 2 Click the role instance name corresponding to the node where NodeManager is deployed, switch to **Instance Configuration**, and select **All Configurations**.

Step 3 Enter **yarn.nodemanager.resource.cpu-vcores** in the search box, and set the number of vCPUs that can be used by NodeManager on the current node. You are advised to set this parameter to 1.5 to 2 times the number of actual logical CPUs on the node. Enter **yarn.nodemanager.resource.memory-mb** in the search box, and set the physical memory size that can be used by NodeManager on the current node. You are advised to set this parameter to 75% of the actual physical memory size of the node.

NOTE

Enter **yarn.scheduler.maximum-allocation-vcores** in the search box, and set the maximum number of available CPUs in a container. Enter **yarn.scheduler.maximum-allocation-mb** in the search box, and set the maximum available memory of a container. The instance level cannot be changed. The parameter values need to be changed in the configuration of the Yarn service, and the Yarn service needs to be restarted for the changes to take effect.

Step 4 Click **Save**, and then click **OK**. to restart the NodeManager role instance.

A message is displayed, indicating that the operation is successful. Click **Finish**. The NodeManager role instance is started successfully.

----End

12.27.5 Changing NodeManager Storage Directories

Scenario

If the storage directories defined by the Yarn NodeManager are incorrect or the Yarn storage plan changes, the system administrator needs to modify the NodeManager storage directories on Manager to ensure that the Yarn works properly. The storage directories of NodeManager include the local storage directory **yarn.nodemanager.local-dirs** and log directory **yarn.nodemanager.log-dirs**. Changing the ZooKeeper storage directory includes the following scenarios:

- Change the storage directory of the NodeManager role. In this way, the storage directories of all NodeManager instances are changed.
- Change the storage directory of a single NodeManager instance. In this way, only the storage directory of this instance is changed, and the storage directories of other instances remain the same.

Impact on the System

- The cluster needs to stopped and restarted during the process of changing the storage directory of the NodeManager role, and the cluster cannot provide services before started.
- The NodeManager instance needs to stopped and restarted during the process of changing the storage directory of the instance, and the instance at this node cannot provide services before it is started.
- The directory for storing service parameter configurations must also be updated.
- After the storage directories of NodeManager are changed, you need to download and install the client again.

Prerequisites

- New disks have been prepared and installed on each data node, and the disks are formatted.
- New directories have been planned for storing data in the original directories.
- The system administrator account **admin** has been prepared.

Procedure

For versions earlier than MRS 3.*x*, perform the following operations:

Step 1 Check the environment.

1. Log in to the MRS console. In the left navigation pane, choose **Clusters** > **Active Clusters**, and click a cluster name. Choose **Components** and check whether health status of Yarn is **Good**.
   - If yes, go to **Step 1.3**.
   - If no, the Yarn status is unhealthy. Go to **Step 1.2**.
2. Rectify the Yarn fault. No further action is required.
3. Determine whether to change the storage directory of the NodeManager role or that of a single NodeManager instance:
   - To change the storage directory of the NodeManager role, go to **Step 2**.
   - To change the storage directory of a single NodeManager instance, go to **Step 3**.

Step 2 Change the storage directory of the NodeManager role.

1. Choose **Clusters** > **Active Clusters**, and click a cluster name. Choose **Components** > **Yarn** > **Stop** to stop the Yarn service.
2. Log in to the ECS server and go to each node where Yarn is installed as user **root**. Perform the following operations:
   a. Create a target directory.

      For example, to create the target directory **${BIGDATA_DATA_HOME}/data2**, run the following command:

      mkdir ${BIGDATA_DATA_HOME}/data2

   b. Mount the target directory to the new disk.

      For example, mount **${BIGDATA_DATA_HOME}/data2** to the new disk.

c. Modify permissions on the new directory.

For example, to modify permissions on the **${BIGDATA_DATA_HOME}/data2** directory, run the following commands:

chmod 750 ${BIGDATA_DATA_HOME}/data2 -R and **chown omm:wheel ${BIGDATA_DATA_HOME}/data2 -R**

3. On the MRS console, choose **Clusters** > **Active Clusters** and click a cluster name. Choose **Components** > **Yarn** > **Instances**. Select the NodeManager instance of the corresponding host. Choose **Instance Configuration** > **All Configurations**.

Change the value of **yarn.nodemanager.local-dirs** or **yarn.nodemanager.log-dirs** to the new target directory.

For example, change the value of **yarn.nodemanager.local-dirs** or **yarn.nodemanager.log-dirs** to **/srv/BigData/data2/nm/containerlogs**.

4. Click **Save Configuration**, select **Restart the affected services or instances**, and click **OK** Restart the Yarn service.

Click **Finish** when the system displays "Operation successful". Yarn is successfully started. No further action is required.

Step 3 Change the storage directory of a single NodeManager instance.

1. Choose **Clusters** > **Active Clusters**, and click a cluster name. Choose **Components** > **Yarn** > **Instances**. Select the NodeManager instance whose storage directory needs to be modified, and choose **More** > **Stop Instance**.
2. Log in to the ECS and go to the NodeManager node as user **root**. Perform the following operations:

a. Create a target directory.

For example, to create the target directory **${BIGDATA_DATA_HOME}/data2**, run the following command:

mkdir ${BIGDATA_DATA_HOME}/data2

b. Mount the target directory to the new disk.

For example, mount **${BIGDATA_DATA_HOME}/data2** to the new disk.

c. Modify permissions on the new directory.

For example, to modify permissions on the **${BIGDATA_DATA_HOME}/data2** directory, run the following commands:

chmod 750 ${BIGDATA_DATA_HOME}/data2 -R and **chown omm:wheel ${BIGDATA_DATA_HOME}/data2 -R**

3. On the MRS console, click the specified NodeManager instance and switch to the **Instance Configuration** tab page.

Change the value of **yarn.nodemanager.local-dirs** or **yarn.nodemanager.log-dirs** to the new target directory.

For example, change the value of **yarn.nodemanager.local-dirs** or **yarn.nodemanager.log-dirs** to **/srv/BigData/data2/nm/containerlogs**.

4. Click **Save Configuration** and select **Restart the affected services or instances**. Click **OK** to restart the NodeManager instance.

Click **Finish** when the system displays "Operation successful". The NodeManager instance is successfully started.

----End

For MRS 3.*x* or later, perform the following operations:

Step 1 Check the environment.

1. Log in to Manager, choose **Cluster** > *Name of the desired cluster* > **Service** to check whether **Running Status** of Yarn is **Normal**.
   - If yes, go to **1.c**.
   - If no, the Yarn status is unhealthy. In this case, go to **1.b**.
2. Rectify faults of Yarn. No further action is required.
3. Determine whether to change the storage directory of the NodeManager role or that of a single NodeManager instance:
   - To change the storage directory of the NodeManager role, go to **2**.
   - To change the storage directory of a single NodeManager instance, go to **3**.

Step 2 Change the storage directory of the NodeManager role.

1. Choose **Cluster** > *Name of the desired cluster* > **Service** > **Yarn** > **Stop** to stop the Yarn service.
2. Log in to each data node where the Yarn service is installed as user **root** and perform the following operations:
   a. Create a target directory.

      For example, to create the target directory **${BIGDATA_DATA_HOME}/data2**, run the following command:

      mkdir ${BIGDATA_DATA_HOME}/data2

   b. Mount the target directory to the new disk.

      For example, mount **${BIGDATA_DATA_HOME}/data2** to the new disk.

   c. Modify permissions on the new directory.

      For example, to modify permissions on the **${BIGDATA_DATA_HOME}/data2** directory, run the following commands:

      chmod 750 ${BIGDATA_DATA_HOME}/data2 -R and **chown omm:wheel ${BIGDATA_DATA_HOME}/data2 -R**
3. On the Manager portal, choose **Cluster** > *Name of the desired cluster* > **Services** > **Yarn** > **Instance**. Select the NodeManager instance of the corresponding host, click **Instance Configuration**, and select **All Configurations**.

   Change the value of **yarn.nodemanager.local-dirs** or **yarn.nodemanager.log-dirs** to the new target directory.

   For example, change the value of **yarn.nodemanager.local-dirs** or **yarn.nodemanager.log-dirs** to **/srv/BigData/data2/nm/containerlogs**.
4. Click **Save**, and then click **OK**. Restart the Yarn service.

   Click **Finish** when the system displays "Operation successful". Yarn is successfully started. No further action is required.

Step 3 Change the storage directory of a single NodeManager instance.

1. Choose **Cluster** > *Name of the desired cluster* > **Service** > **Yarn** > **Instance**, select the NodeManager instance whose storage directory needs to be modified, and choose **More** > **Stop**.

2. Log in to the NodeManager node as user **root**, and perform the following operations:
   a. Create a target directory.
      For example, to create the target directory **${BIGDATA_DATA_HOME}/data2**, run the following command:
      mkdir ${BIGDATA_DATA_HOME}/data2
   b. Mount the target directory to the new disk.
      For example, mount **${BIGDATA_DATA_HOME}/data2** to the new disk.
   c. Modify permissions on the new directory.
      For example, to modify permissions on the **${BIGDATA_DATA_HOME}/data2** directory, run the following commands:
      chmod 750 ${BIGDATA_DATA_HOME}/data2 -R and **chown omm:wheel ${BIGDATA_DATA_HOME}/data2 -R**
3. On Manager, click the specified NodeManager instance, and switch to the **Instance Configuration** page.
   Change the value of **yarn.nodemanager.local-dirs** or **yarn.nodemanager.log-dirs** to the new target directory.
   For example, change the value of **yarn.nodemanager.local-dirs** or **yarn.nodemanager.log-dirs** to **/srv/BigData/data2/nm/containerlogs**.
4. Click **Save**, and then click **OK** to restart the NodeManager instance.
   Click **Finish** when the system displays "Operation successful". The NodeManager instance is successfully started.

----End

12.27.6 Configuring Strict Permission Control for Yarn

Scenario

In the multi-tenant scenario in security mode, a cluster can be used by multiple users, and tasks of multiple users can be submitted and executed. Users are invisible to each other. A permission control mechanism is required to prevent task information of users from being obtained by other users.

For example, if user B logs in to the system and views the application list when the application submitted by user A is running, user B should not be able to view the application information of user A.

Configuration Description

- Viewing Yarn configuration parameters
  Go to the **All Configurations** page of Yarn and enter a parameter name list in **Table 12-451** in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-451 Parameter description

Parameter	Description	Default Value
yarn.acl.enable	Whether to enable Yarn permission control	true
yarn.webapp.filter-entity-list-by-user	Whether to enable the strict view function. After this function is enabled, a login user can view only the content that the user has the permission to view. To enable this function, set **yarn.acl.enable** to **true**. **NOTE** This parameter applies to clusters of MRS 3.*x* or later.	true

- Viewing MapReduce configuration parameters

  Go to the **All Configurations** page of MapReduce and enter a parameter name in **Table 12-452** in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

  Table 12-452 Parameter description

Parameter	Description	Default Value
mapreduce.cluster.acls.enabled	Whether to enable permission control of MapReduce JobHistoryServer This parameter is a client parameter and takes effect after permission control is enabled on the JobHistoryServer server.	true
yarn.webapp.filter-entity-list-by-user	Whether to enable the strict view of MapReduce JobHistoryServer. After the strict view is enabled, a login user can view only the content that the user has the permission to view. This parameter is a server parameter of JobHistoryServer. It indicates that permission control is enabled for JHS. However, whether to control a specific application is determined by the client parameter **mapreduce.cluster.acls.enabled**. **NOTE** This parameter applies to clusters of MRS 3.*x* or later.	true

NOTICE

The preceding configurations affect the RESTful API and Shell command results. After the preceding configurations are enabled, the return results of RESTful API calls and shell commands contain only the information that the user has the permission to view.

If **yarn.acl.enable** or **mapreduce.cluster.acls.enabled** is set to **false**, the Yarn or MapReduce permission verification function is disabled. In this case, any user can submit tasks and view task information on Yarn or MapReduce, which poses security risks. Exercise caution when performing this operation.

12.27.7 Configuring Container Log Aggregation

Scenario

Yarn provides the container log aggregation function to collect logs generated by containers on each node to HDFS to release local disk space. You can collect logs in either of the following ways:

- After the application is complete, collect container logs to HDFS at a time.
- During application running, periodically collect log segments generated by containers and save them to HDFS.

Configuration Description

Navigation path for setting parameters:

Go to the **All Configurations** page of Yarn and enter a parameter name list in **Table 12-453** in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

The **yarn.nodemanager.remote-app-log-dir-suffix** parameter must be configured on the Yarn client. The configurations on the ResourceManager, NodeManager, and JobHistory nodes must be the same as those on the Yarn client.

The periodic log collection function applies only to MapReduce applications, for which rolling output of log files must be configured. **Table 12-455** describes the configurations in the **mapred-site.xml** configuration file on the MapReduce client node.

Table 12-453 Parameter description

Parameter	Description	Default Value
yarn.log-aggregation-enable	Whether to enable container log aggregation ● If this parameter is set to **true**, logs are collected to the HDFS directory. ● If this parameter is set to **false**, the function is disabled, and logs are not collected to HDFS. After changing the parameter value, restart the Yarn service for the setting to take effect. **NOTE** ● The container logs that are generated before the parameter is set to **false** and the setting takes effect cannot be obtained from the web UI. ● If you want to view the logs generated before on the web UI, you are advised to set this parameter to **true**.	true
yarn.nodemanager.log-aggregation.roll-monitoring-interval-seconds	Interval for NodeManager to periodically collect logs ● If this parameter is set to **-1** or **0**, periodic log collection is disabled. Logs are collected at a time after application running is complete. ● The minimum collection interval can be set to 3,600 seconds. If this parameter is set to a value greater than 0 and less than 3,600, the collection interval is 3,600 seconds. Interval for NodeManager to wake up and upload logs. If this parameter is set to **-1** or **0**, rolling monitoring is disabled and logs are aggregated when the application task is complete. The value must be greater than or equal to **-1**.	-1

Parameter	Description	Default Value
yarn.nodemanager.disk-health-checker.log-dirs.max-disk-utilization-per-disk-percentage	Maximum percentage of the Yarn disk quota that can be occupied by the container log directory on each disk. When the space occupied by the log directory exceeds the value of this parameter, the periodic log collection service is triggered to start a log collection activity beyond the period to release the local disk space. Maximum space for container logs that can be provided on each disk. If the disk space occupied by container logs exceeds this threshold, data aggregation in rolling mode is triggered. ● For clusters of versions earlier than MRS 3.x: The valid value range of the maximum disk quota percentage is 0 to 100. If the value is less than or equal to **0**, it is forcibly reset to **25**. If the value is greater than 100, the value is forcibly reset to **25**. ● For clusters of MRS 3.*x* or later: The valid value range of the maximum disk quota percentage is –1 to 100. If the value is less than –1, it is forcibly reset to **25**. If the value is greater than 100, the value is forcibly reset to **25**. If you set the value to **–1**, the disk capacity detection function for Container log directory is disabled. **NOTE** ● Percentage of the available disk space of the container log directory = Percentage of the available disk space of Yarn (**yarn.nodemanager.disk-health-checker.max-disk-utilization-per-disk-percentage**) x Percentage of the available disk space of the container log directory (**yarn.nodemanager.disk-health-checker.log-dirs.max-disk-utilization-per-disk-percentage**) ● Only applications with the periodic log collection function enabled can trigger log collection when the disk quota of the log directory exceeds the threshold.	25

Parameter	Description	Default Value
yarn.nodemanager.remote-app-log-dir-suffix	Name of the HDFS folder in which container logs are to be stored. This parameter and **yarn.nodemanager.remote-app-log-dir** form the full path for storing container logs. That is, **{yarn.nodemanager.remote-app-log-dir}/${user}/{yarn.nodemanager.remote-app-log-dir-suffix}**. **NOTE** *{user}* indicates the username for running the task.	logs
yarn.nodemanager.log-aggregator.on-fail.remain-log-in-sec	Duration for retaining container logs on the local host after the logs fail to be collected, in second • If this parameter is set to **0**, local logs are deleted immediately. • If this parameter is set to a positive number, local logs are retained for this period.	604800

Go to the **All Configurations** page of MapReduce and enter a parameter name in **Table 12-454** in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-454 Parameter description

Parameter	Description	Default Value
yarn.log-aggregation.retain-seconds	Duration for retaining aggregated logs, in second • If this parameter is set to **–1**, the container logs will be retained permanently in the HDFS. • If this parameter is set to **0** or a positive integer, container logs will be stored for such a period and deleted after the period expires. **NOTE** A short period may increase load of the NameNode. Therefore, you are advised to set this parameter to a proper value.	1296000

Parameter	Description	Default Value
yarn.log-aggregation.retain-check-interval-seconds	Interval for storing container logs in HDFS, in second • If this parameter is set to **-1** or **0**, the interval will be one tenth of the period specified by **yarn.log-aggregation.retain-seconds**. **NOTE** If this parameter is set to **-1** or **0**, **yarn.log-aggregation.retain-seconds** cannot be set to **0**. • If this parameter is set to a positive number, container logs in HDFS will be scanned at such an interval. **NOTE** A short interval may increase load of the NameNode. Therefore, you are advised to set this parameter to a proper value.	86400

Go to the **All Configurations** page of Yarn and enter a parameter name list in **Table 12-455** in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-455 Configuring rolling output of MapReduce application log files

Parameter	Description	Default Value
mapreduce.task.userlog.limit.kb	Maximum size of a single task log file of the MapReduce application. When the maximum size of the log file has been reached, a new log file is generated. The value **0** indicates that the size of the log file is not limited.	51200

Parameter	Description	Default Value
yarn.app.mapreduce.task.container.log.backups	Maximum number of task logs that can be retained for the MapReduce application. If this parameter is set to **0**, rolling output is disabled. Number of task log backup files when ContainerRollingLogAppender (CRLA) is used. By default, ContainerLogAppender (CLA) is used and container logs are not rolled back. When both **mapreduce.task.userlog.limit.kb** and **yarn.app.mapreduce.task.container.log.backups** are greater than 0, CRLA is enabled. The value ranges from 0 to 999.	10
yarn.app.mapreduce.am.container.log.limit.kb	Maximum size of a single ApplicationMaster log file of the MapReduce application, in KB. When the maximum size of the log file has been reached, a new log file is generated. The value **0** indicates that the size of a single ApplicationMaster log file is not limited.	51200
yarn.app.mapreduce.am.container.log.backups	Maximum number of ApplicationMaster logs that can be retained for the MapReduce application. If this parameter is set to **0**, rolling output is disabled. Number of ApplicationMaster log backup files when CRLA is used. By default, CLA is used and container logs are not rolled back. When both **yarn.app.mapreduce.am.container.log.limit.kb** and **yarn.app.mapreduce.am.container.log.backups** are greater than 0, CRLA is enabled for the ApplicationMaster. The value ranges from 0 to 999.	20
yarn.app.mapreduce.shuffle.log.backups	Maximum number of shuffle logs that can be retained for the MapReduce application. If this parameter is set to **0**, rolling output is disabled. When both **yarn.app.mapreduce.shuffle.log.limit.kb** and **yarn.app.mapreduce.shuffle.log.backups** are greater than 0, **syslog.shuffle** uses CRLA. The value ranges from 0 to 999.	10

Parameter	Description	Default Value
yarn.app.mapreduce.shuffle.log.limit.kb	Maximum size of a single shuffle log file of the MapReduce application, in KB. When the maximum size of the log file has been reached, a new log file is generated. If this parameter is set to **0**, the size of a single shuffle log file is not limited. The value must be greater than or equal to **0**.	51200

12.27.8 Using CGroups with YARN

This section applies to clusters of MRS 3.*x* or later.

Scenario

CGroups is a Linux kernel feature. In YARN this feature allows containers to be limited in their resource usage (example, CPU usage). Without CGroups, it is hard to limit the container CPU usage. Without CGroups, it is hard to limit the container CPU usage.

NOTE

Currently, CGroups is only used for limiting the CPU usage.

Configuration Description

For details about how to configure the CGroups function for CPU isolation and security, see the Hadoop official website: **http://hadoop.apache.org/docs/r3.1.1/hadoop-yarn/hadoop-yarn-site/NodeManagerCgroups.html**

CGroups is a Linux kernel feature and is enabled by using LinuxContainerExecutor. For details about how to configure the LinuxContainerExecutor for security, see the official website. You can learn the file system permissions assigned for users and user groups from documentation published on the official website. For details, see **http://hadoop.apache.org/docs/r3.1.1/hadoop-project-dist/hadoop-common/SecureMode.html#LinuxContainerExecutor**.

NOTE

- Do not modify users, user groups, and related permissions of various paths in the corresponding file system. Otherwise, functions of CGroups may become abnormal.
- If the parameter value of **yarn.nodemanager.resource.percentage-physical-cpu-limit** is too small, the number of available cores may be less than one. For example, if the parameter of a four-core node is set to 20%, the number available core is less than one. As a result, all cores will be used. The Quota mode can be used in Linux versions, for example, Cent OS, that do not support Quota mode.

The table below describes the parameter for configuring cpuset mode, that is, only configured CPUs can be used by YARN.

Table 12-456 Parameter description

Parameter	Description	Default Value
yarn.nodemanager.linux-container-executor.cgroups.cpu-set-usage	Whether to enable the cpuset mode. If this parameter is set to **true**, the cpuset mode is enabled.	false

The table below describes the parameters for configuring the strictcpuset mode, that is, only configured CPUs can be used by containers.

Table 12-457 Parameter description

Parameter	Description	Default Value
yarn.nodemanager.linux-container-executor.cgroups.cpu-set-usage	Whether to enable the cpuset mode. If this parameter is set to **true**, the cpuset mode is enabled.	false
yarn.nodemanager.linux-container-executor.cgroups.cpuset.strict.enabled	Whether containers use allocated CPUs. If this parameter is set to **true**, the container can use the allocated CPUs.	false

To switch from cpuset mode to quota mode, the following conditions must be met:

- Set the **yarn.nodemanager.linux-container-executor.cgroups.cpu-set-usage** parameter to **false**.
- Delete container folders if exists.
- Delete all the CUPs configured in the **cpuset.cpus** file.

Procedure

Step 1 Log in to Manager. Choose **Cluster** > *Name of the desired cluster* > **Services** > **Yarn** > **Configurations** and select **All Configurations**.

Step 2 In the navigation pane on the left, choose **NodeManager** > **Customization** and find the **yarn-site.xml** file.

Step 3 Add the parameters in **Table 12-456** and **Table 12-457** as user-defined parameters.

Based on the configuration files and parameter functions, locate the row where parameter **yarn-site.xml** resides. Enter the parameter name in the **Name** column and enter the parameter value in the **Value** column.

Click **+** to add a customized parameter.

Step 4 Click **Save**. In the displayed **Save Configuration** dialog box, confirm the modification and click **OK**. Click **Finish** when the system displays "Operation succeeded". The configuration is successfully saved.

After the configuration is saved, restart the Yarn service whose configuration has expired for the configuration to take effect.

----End

12.27.9 Configuring the Number of ApplicationMaster Retries

Scenario

When resources are insufficient or ApplicationMaster fails to start, a client probably encounters running errors.

Configuration Description

Go to the **All Configurations** page of Yarn and enter a parameter name list in **Table 12-458** in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-458 Parameter description

Parameter	Description	Default Value
yarn.resourcemanager.am.max-attempts	Number of retries of the ApplicationMaster. Increasing the number of retries can prevent ApplicationMaster startup failures caused by insufficient resources. This applies to global settings of all ApplicationMasters. Each ApplicationMaster can use an API to set an independent maximum number of retries. However, the number of retries cannot be greater than the global maximum number of retries. If the value is greater than the global maximum number of retries, the ResourceManager overwrites the value to allow at least one retry. The value must be greater than or equal to **1**.	5

12.27.10 Configure the ApplicationMaster to Automatically Adjust the Allocated Memory

This section applies to clusters of MRS 3.*x* or later.

Scenario

During the process of starting the configuration, when the ApplicationMaster creates a container, the allocated memory is automatically adjusted according to

the total number of tasks, which makes resource utilization more flexible and improves the fault tolerance of the client application.

Configuration Description

Navigation path for setting parameters:

On Manager, choose **Cluster** > *Name of the desired cluster* > **Service** > **Yarn** > **Configuration**. On the displayed page, select **All Configurations** and enter **mapreduce.job.am.memory.policy**.

Configuration description

If the default value of the parameter is left empty. In this case, the automatic adjustment policy is not enabled. The memory of ApplicationMaster is still affected by the value of **yarn.app.mapreduce.am.resource.mb**.

The value of **mapreduce.job.am.memory.policy** consists of five items, and they are separated by colons (:) and commas (,) in the following format: **baseTaskCount:taskStep:memoryStep,minMemory:maxMemory**. The format is strictly checked when the value is entered.

Table 12-459 Parameter description

Parameter	Description	Setting Requirement
baseTaskCount	Indicates the total number of tasks. The configuration of ApplicationMaster is valid only when the total number of tasks (on the sum of the Map and Reduce ends) is greater than or equal to the value of this parameter.	The value cannot be empty and must be greater than 0.
taskStep	Indicates the incremental step length of tasks. This parameter and **memoryStep** determine the memory adjustment amount.	The value cannot be empty and must be greater than 0.
memoryStep	Indicates the incremental memory step. The memory capacity is increased based on the value of **yarn.app.mapreduce.am.resource.mb**.	The value cannot be empty and must be greater than 0. The unit is MB.
minMemory	Indicates the lower limit of the memory that can be automatically adjusted. If the memory after the automatic adjustment is less than or equal to the value of this parameter, the value of **yarn.app.mapreduce.am.resource.mb** is used.	The value cannot be empty. It must be greater than 0 and cannot be greater than the value of **maxMemory**. Unit: MB

Parameter	Description	Setting Requirement
maxMemory	Indicates the upper limit of memory that can ve automatically adjusted. If the adjusted memory exceeds the upper limit, use this value as the final value.	The value cannot be empty. It must be greater than 0 and cannot be less than the value of **minMemory**. Unit: MB

Example Value

Configuration:

- yarn.app.mapreduce.am.resource.mb=1536
- mapreduce.job.am.memory.policy=100:10:50,1200:2000
- Total number of tasks of an application =120

The calculation process is as follows:

Memory after adjustment = 1536 + [(120 – 100)/10] x 50 = 1636. In this example, memory after adjustment 1636 is greater than the value of **minMemory 1200**, and less than the value of **maxMemory 2000**. Therefore, the ApplicationMaster memory is set to **1636 MB**.

If the value of **memStep** is changed to **250**, the calculation formula is as follows: Memory after adjustment = 1536 + [(120 – 100) / 10] x 250 = 2136. In this case, the memory after adjustment is greater than the value of **maxMemory 2000**. As a result, the value of **ApplicationMaster** is set to **2000 MB**.

NOTE

If the memory after adjustment is lower than the value of **minMemory**, the configuration does not take effect but the value is still printed on the backend server. This value is provided as the reference for adjusting the value of **minMemory**.

12.27.11 Configuring the Access Channel Protocol

Scenario

The value of the **yarn.http.policy** parameter must be consistent on both the server and clients. Web UIs on clients will be garbled if an inconsistency exists, for example, the parameter value is **HTTPS_ONLY** on the server but it is left unspecified on a client (the parameter value **HTTP_ONLY** is applied to the client by default). Set the **yarn.http.policy** parameters on the clients and server to prevent garbled characters from being displayed on the clients.

Procedure

Step 1 On Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **Yarn** > **Configurations**. On the displayed page, select **All Configurations** and enter **yarn.http.policy**.

- In security mode, set this parameter to **HTTPS_ONLY**.
- In normal mode, set this parameter to **HTTP_ONLY**.

Step 2 Log in to the node where the client is installed as the client installation user.

Step 3 Run the following command to switch to the client installation directory:

cd /opt/client

Step 4 Run the following command to edit the **yarn-site.xml** file:

vi Yarn/config/yarn-site.xml

Change the value of **yarn.http.policy**.

In security mode, set this parameter to **HTTPS_ONLY**.

In normal mode, set this parameter to **HTTP_ONLY**.

Step 5 Run the **:wq** command to save execution.

Step 6 Restart the client for the settings to take effect.

----End

12.27.12 Configuring Memory Usage Detection

Scenario

If memory usage of the submitted application cannot be estimated, you can modify the configuration on the server to determine whether to check the memory usage.

If the memory usage is not checked, the container occupies the memory until the memory overflows. If the memory usage exceeds the configured memory size, the corresponding container is killed.

Configuration Description

Go to the **All Configurations** page of Yarn and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-460 Parameter description

Parameter	Description	Default Value
yarn.nodemanager.vmem-check-enabled	Whether to enable virtual memory usage detection. If the memory used by a task exceeds the allocated memory size, the task is forcibly stopped. • If the value is **true**, the virtual memory will be checked. • If the value is **false**, the virtual memory will not be checked.	For versions earlier than MRS 3.x: false For MRS 3.x or later: true
yarn.nodemanager.pmem-check-enabled	Whether to enable physical memory usage detection. If the memory used by a task exceeds the allocated memory size, the task is forcibly stopped. • If the value is **true**, the physical memory will be checked. • If the value is **false**, the physical memory will not be checked.	true

12.27.13 Configuring the Additional Scheduler WebUI

Scenario

If the custom scheduler is set in ResourceManager, you can set the corresponding web page and other Web applications for the custom scheduler.

Configuration Description

Go to the **All Configurations** page of Yarn and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-461 Configuring the Additional Scheduler WebUI

Parameter	Description	Default Value
hadoop.http.rmwebapp.scheduler.page.classes	Load the corresponding web page for the custom scheduler on the RM WebUI. This parameter is valid only when **yarn.resourcemanager.scheduler.class** is set to a custom scheduler.	-
yarn.http.rmwebapp.external.classes	Load the custom web application in the RM Web service.	-

12.27.14 Configuring Yarn Restart

Scenario

The Yarn Restart feature includes ResourceManager Restart and NodeManager Restart.

- When ResourceManager Restart is enabled, the new active ResourceManager node loads the information of the previous active ResourceManager node, and takes over container status information on all NodeManager nodes to continue service running. In this way, status information can be saved by periodically executing checkpoint operations, avoiding data loss.
- When NodeManager Restart is enabled, NodeManager locally saves information about containers running on the node. After NodeManager is restarted, the container running progress on the node will not be lost by restoring the saved status information.

Configuration Description

Go to the **All Configurations** page of Yarn and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Configure ResourceManager Restart as follows:

Table 12-462 Parameter description of ResourceManager Restart

Parameter	Description	Default Value
yarn.resourcemanager.recovery.enabled	Whether to enable ResourceManager to restore the status after startup. If this parameter is set to **true**, **yarn.resourcemanager.store.class** must also be set.	true
yarn.resourcemanager.store.class	State-store class used to store the application and task statuses and certificate content.	For clusters of versions earlier than MRS 3.x: **org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore** For clusters of MRS 3.*x* or later: org.apache.hadoop.yarn.server.resourcemanager.recovery.AsyncZKRMStateStore
yarn.resourcemanager.zk-state-store.parent-path	Directory for storing ZKRMStateStore in ZooKeeper	/rmstore

Parameter	Description	Default Value
yarn.resourcemanager.work-preserving-recovery.enabled	Whether to enable ResourceManager work serving. This configuration is used only for Yarn feature verification.	true
yarn.resourcemanager.state-store.async.load	Whether to apply asynchronous restoration to completed applications.	For clusters of versions earlier than MRS 3.x: **false** For MRS 3.x or later: **true**
yarn.resourcemanager.zk-state-store.num-fetch-threads	If asynchronous restoration is enabled, increasing the number of working threads can speed up the restoration of task information stored in ZooKeeper. The value must be greater than 0.	For clusters of versions earlier than MRS 3.x: **1** For MRS 3.x or later: **20**

Configure NodeManager Restart as follows:

Table 12-463 Parameter description of NodeManager Restart

Parameter	Description	Default Value
yarn.nodemanager.recovery.enabled	Whether to enable the function of collecting logs upon a log collection failure when NodeManager is restarted and whether to restore the unfinished application	true
yarn.nodemanager.recovery.dir	Local directory used by NodeManager to store container status It applies to clusters of MRS 3.*x* or later.	${SRV_HOME}/tmp/yarn-nm-recovery
yarn.nodemanager.recovery.supervised	Whether NodeManager is monitored. After this parameter is enabled, NodeManager does not clear containers after exit. NodeManager assumes that it will restart and restore containers immediately.	true

12.27.15 Configuring ApplicationMaster Work Preserving

This section applies to clusters of MRS 3.*x* or later.

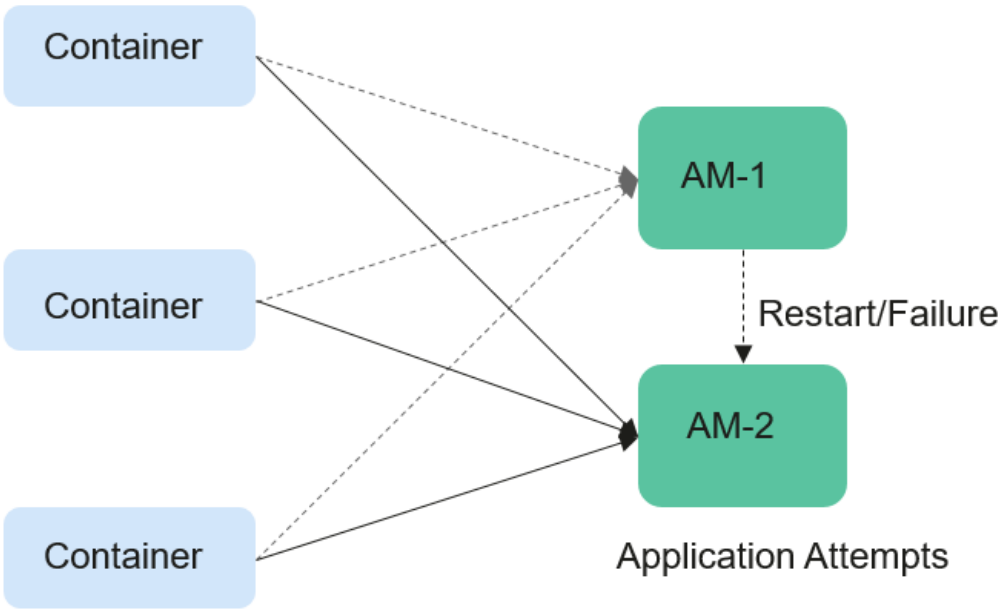
Scenario

In YARN, ApplicationMasters run on NodeManagers just like every other container (ignoring unmanaged ApplicationMasters in this context). ApplicationMasters may break down, exit, or shut down. If an ApplicationMaster node goes down, ResourceManager kills all the containers of ApplicationAttempt, including containers running on NodeManager. ResourceManager starts a new ApplicationAttempt node on another compute node.

For different types of applications, we want to handle ApplicationMaster restart events in different ways. MapReduce applications aim to prevent task loss but allow the loss of the currently running container. However, for the long-period YARN service, users may not want the service to stop due to the ApplicationMaster fault.

YARN can retain the status of the container when a new ApplicationAttempt is started. Therefore, running jobs can continue to operate without faults.

Figure 12-74 ApplicationMaster job preserving



Configuration Description

Go to the **All Configurations** page of Yarn and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Set the following parameters based on **Table 12-464**.

Table 12-464 Parameter description

Parameter	Description	Default Value
yarn.app.mapreduce.am.work-preserve	Whether to enable the ApplicationMaster job retention feature.	false
yarn.app.mapreduce.am.umbilical.max.retries	Maximum number of attempts to restore a running container in the ApplicationMaster job retention feature.	5
yarn.app.mapreduce.am.umbilical.retry.interval	Specifies the interval at which a running container attempts to recover in the ApplicationMaster job retention feature. Unit: millisecond	10000
yarn.resourcemanager.am.max-attempts	The number of retries of ApplicationMaster. Increasing the number of retries prevents ApplicationMaster startup failures caused by insufficient resources. This applies to global settings of all ApplicationMasters. Each ApplicationMaster can use an API to set an independent maximum number of retries. However, the number of retries cannot be greater than the global maximum number of retries. If the value is greater than the global maximum number of retries, the ResourceManager overwrites the value The value must be greater than or equal to **1**.	2

12.27.16 Configuring the Localized Log Levels

This section applies to clusters of MRS 3.*x* or later.

Scenarios

The default log level of localized container is **INFO**. You can change the log level by configuring **yarn.nodemanager.container-localizer.java.opts**.

Configuration Description

On Manager, choose **Cluster** > *Name of the desired cluster* > **Service** > **Yarn** > **Configuration**. Select **All Configurations** and set the following parameters in the configuration file **yarn-site.xml** of NodeManager to change the log level.

Table 12-465 Parameter description

Parameter	Description	Default Value
yarn.nodemanager.container-localizer.java.opts	The additional **jvm** parameters are provided for the localized container process.	-Xmx256m -Djava.security.krb5.conf=${KRB5_CONFIG}

The default value is **-Xmx256m -Djava.security.krb5.conf=${KRB5_CONFIG}** and the default log level is info. To change the localized log level of the container, add the following content:

```
-Dhadoop.root.logger=<LOG_LEVEL>,localizationCLA
```

Example:

To change the local log level to **DEBUG**, set the parameter as follows:

```
-Xmx256m -Dhadoop.root.logger=DEBUG,localizationCLA
```

NOTE

Allowed log levels are as follows: FATAL, ERROR, WARN, INFO, DEBUG, TRACE, and ALL.

12.27.17 Configuring Users That Run Tasks

This section applies to clusters of MRS 3.*x* or later.

Scenario

Currently, YARN allows the user that starts the NodeManager to run the task submitted by all other users, or the users to run the task submitted by themselves.

Configuration Description

On Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **Yarn** > **Configurations**. Click **All Configurations** Enter a parameter name in the search box.

Table 12-466 Parameter description

Parameter	Description	Default Value
yarn.nodemanager.linux-container-executor.user	Indicates the user who runs a task.	The value is left blank by default. **NOTE** The value is left blank by default. The user who submits a task is the actual person who runs the task.
yarn.nodemanager.container-executor.class	Indicates the executor who starts a task.	org.apache.hadoop.yarn.server.nodemanager.EnhancedLinuxContainerExecutor

NOTE

- Set **yarn.nodemanager.linux-container-executor.user** to configure the user who runs the container. This parameter is left blank by default. The user who submits the task is the person who runs the container. This parameter is valid only when **yarn.nodemanager.container-executor.class** is set to **org.apache.hadoop.yarn.server.nodemanager.EnhancedLinuxContainerExecutor**.
- In non-security mode, if **yarn.nodemanager.linux-container-executor.user** is set to **omm**, **yarn.nodemanager.linux-container-executor.nonsecure-mode.local-user** must also be set to **omm**.
- For security reasons, it is advised to retain the default values of **yarn.nodemanager.linux-container-executor.user** and **yarn.nodemanager.container-executor.class**.

12.27.18 Yarn Log Overview

Log Description

The default paths for saving Yarn logs are as follows:

- ResourceManager: **/var/log/Bigdata/yarn/rm** (run logs) and **/var/log/Bigdata/audit/yarn/rm** (audit logs)
- NodeManager: **/var/log/Bigdata/yarn/nm** (run logs) and **/var/log/Bigdata/audit/yarn/nm** (audit logs)

Log archive rule: The automatic compression and archive function is enabled for Yarn logs. By default, when the size of a log file exceeds 50 MB, the log file is automatically compressed. The naming rule of the compressed log file is as follows: *<Original log file name>-<yyyy-mm-dd_hh-mm-ss>.[ID]***.log.zip**. A maximum of 100 latest compressed files are retained. The number of compressed files can be configured on Manager.

Log archive rule:

Table 12-467 Yarn log list

Log Type	Log File Name	Description
Run log	hadoop-<SSH_USER>-<process_name>-<hostname>.log	Yarn component log file that records most of the logs generated when the Yarn component is running
	hadoop-<SSH_USER>-<process_name>-<hostname>.out	Log file that records Yarn running environment information
	<process_name>-<SSH_USER>-<DATE>-<PID>-gc.log	Garbage collection log file

Log Type	Log File Name	Description
	yarn-haCheck.log	ResourceManager active/standby status detection log file
	yarn-service-check.log	Log file that records the health check details of the Yarn service
	yarn-start-stop.log	Log file that records the startup and stop of the Yarn service
	yarn-prestart.log	Log file that records cluster operations before the Yarn service startup
	yarn-postinstall.log	Work log file after installation and before startup of the Yarn service
	hadoop-commission.log	Yarn service entry log file
	yarn-cleanup.log	Log file that records the cleanup operation during uninstallation of the Yarn service
	yarn-refreshqueue.log	Yarn queue refresh log file
	upgradeDetail.log	Upgrade log file
	stderr/stdin/syslog	Container log file of the applications running on the Yarn service
	yarn-application-check.log	Check log file of applications running on the Yarn service
	yarn-appsummary.log	Running result log file of applications running on the Yarn service
	yarn-switch-resourcemanager.log	Run log file that records the Yarn active/standby switchover
	ranger-yarn-plugin-enable.log	Log file that records the enabling of Ranger authentication for Yarn
	yarn-nodemanager-period-check.log	Periodic check log of Yarn NodeManager

Log Type	Log File Name	Description
	yarn-resourcemanager-period-check.log	Periodic check log of Yarn ResourceManager
	hadoop.log	Hadoop client logs
	env.log	Environment information log file before the instance is started or stopped.
Audit logs	yarn-audit-<process_name>.log ranger-plugin-audit.log	Yarn operation audit log file
	SecurityAuth.audit	Yarn security audit log file

Log Level

Table 12-468 describes the log levels supported by Yarn, including OFF, FATAL, ERROR, WARN, INFO, and DEBUG, from high priority to low. Logs whose levels are higher than or equal to the specified level are printed. The number of printed logs decreases as the specified log level increases.

Table 12-468 Log levels

Level	Description
FATAL	Logs of this level record critical error information about the current event processing.
ERROR	Logs of this level record error information about the current event processing.
WARN	Logs of this level record exception information about the current event processing.
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record the system as well as system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of the Yarn service by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 On the menu bar on the left, select the log menu of the target role.

Step 3 Select a desired log level.

Step 4 Click **Save Configuration**. In the dialog box that is displayed, click **OK** to make the setting take effect.

NOTE

The configurations take effect immediately without the need to restart the service.

----End

Log Format

The following table lists the Yarn log formats.

Table 12-469 Log formats

Log Type	Format	Example
Run log	<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|<*Thread that generates the log*>|<*Message in the log*>|<*Location of the log event*>	2014-09-26 14:18:59,109 | INFO | main | Client environment:java.compiler=<NA> | org.apache.zookeeper.Environment.logEnv(Environment.java:100)
Audit log	<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|<*Thread that generates the log*>|<*Message in the log*>|<*Location of the log event*>	2014-09-26 14:24:43,605 | INFO | main-EventThread | USER=omm OPERATION=refreshAdminAcls TARGET=AdminService RESULT=SUCCESS | org.apache.hadoop.yarn.server.resourcemanager.RMAuditLogger$LogLevel$6.printLog(RMAuditLogger.java:91)

12.27.19 Yarn Performance Tuning

12.27.19.1 Preempting a Task

Scenario

The capacity scheduler of ResourceManager implements job preemption to simplify job running in queues and improve resource utilization. The process is as follows:

1. Assume that there are two queues (Queue A and Queue B). The capacity of Queue A is 25%, and the capacity of Queue B is 75%.
2. In the initial state, Task 1 is distributed to Queue A for processing, requiring 75% cluster resources. Task 2 is distributed to Queue B for processing, requiring 50% cluster resources.

3. Task 1 uses 25% cluster resources provided by Queue A and 50% resources from Queue B. Queue B reserves 25% cluster resources.
4. If task preemption is enabled, the resources of Task 1 will be preempted. Queue B preempts 25% cluster resources from Queue A for Task 2.
5. Task 1 will be executed when Task 2 is complete and the cluster has sufficient resources.

Procedure

Navigation path for setting parameters:

Go to the **All Configurations** page of Yarn and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 12-470 Parameter description

Parameter	Description	Default Value
yarn.resourcemanager.scheduler.monitor.enable	Whether to start scheduler monitoring according to **yarn.resourcemanager.scheduler.monitor.policies**. If this parameter is set to **true**, scheduler monitoring is enabled based on policies specified by **yarn.resourcemanager.scheduler.monitor.policies** and task resource preemption is enabled based on the scheduler information. If this parameter is set to **false**, scheduler monitoring is disabled.	false
yarn.resourcemanager.scheduler.monitor.policies	List of the SchedulingEditPolicy class to be used with the scheduler	org.apache.hadoop.yarn.server.resourcemanager.monitor.capacity.ProportionalCapacityPreemptionPolicy
yarn.resourcemanager.monitor.capacity.preemption.observe_only	• If this parameter is set to **true**, policies will be applied but task resource preemption will not be performed. • If this parameter is set to **false**, policies will be applied and task resource preemption will be performed based on the policies.	false

Parameter	Description	Default Value
yarn.resourcemanager.monitor.capacity.preemption.monitoring_interval	Monitoring interval, in millisecond. If this parameter is set to a larger value, capacity detection will not be performed frequently.	3000
yarn.resourcemanager.monitor.capacity.preemption.max_wait_before_kill	Interval between the time when a resource preemption request is sent and the time when the container is stopped (resources are released), in millisecond. The value must be greater than or equal to **0**. By default, if ApplicationMaster does not stop the container within 15 seconds, ResourceManager will forcibly stop the container after 15 seconds.	15000
yarn.resourcemanager.monitor.capacity.preemption.total_preemption_per_round	Maximum resource preemption ratio in a period. This value can be used to limit the speed at which containers are reclaimed from the cluster. After the expected total preemption value is calculated, the policy scales the preemption ratio back to this limit.	0.1
yarn.resourcemanager.monitor.capacity.preemption.max_ignored_over_capacity	Resource preemption dead zone = Total number of resources in the cluster x Value of this configuration item + Original resources of a queue (for example, Queue A). When resources actually used by a task in Queue A exceeds the preemption dead zone, the resource beyond the preemption dead zone is preempted. The value range is 0 to 1. **NOTE** A smaller value is recommended for effective preemption.	0

Parameter	Description	Default Value
yarn.resourcemanager.monitor.capacity.preemption.natural_termination_factor	Preemption percentage. Containers preempt only this percentage of the resources. For example, a termination factor of 0.5 will reclaim almost 95% of resources within 5 times of **yarn.resourcemanager.monitor.capacity.preemption.max_wait_before_kill**, even in the absence of natural termination. That is, 5 consecutive preemptions will be performed and each time half of the target resources will be preempted. The trend is geometric convergence. The interval of each preemption is **yarn.resourcemanager.monitor.capacity.preemption.max_wait_before_kill**. The value range is 0 to 1.	1

12.27.19.2 Setting the Task Priority

Scenario

The resource contention scenarios of a cluster are as follows:

1. Submit two jobs (Job 1 and Job 2) with lower priorities.
2. Some tasks of running Job 1 and Job 2 are in the running state. However, some tasks are pending due to resource deficiency because the capacity of cluster or queue resources is limited.
3. Submit a job (Job 3) with a higher priority. In this case, after the running tasks of Job 1 and Job 2 are complete, their resources will be released and then allocated to the pending tasks of Job 3.
4. After Job 3 is complete, its resources will be released and then allocated to Job 1 and Job 2.

Users can use capacity scheduler of ResourceManager to set the task priority in Yarn because the task priority is implemented by the scheduler of ResourceManager.

Procedure

Set the **mapreduce.job.priority** parameter and use CLI or API to set the task priority.

- Through the CLI

  When submitting tasks, add the **-Dmapreduce.job.priority=***<priority>* parameter.

<priority> can be set to any of the following values:

- VERY_HIGH
- HIGH
- NORMAL
- LOW
- VERY_LOW

- Through the API

  You can also set the task priority through the API.

  Set **Configuration.set("mapreduce.job.priority", <priority>)** or **Job.setPriority(JobPriority priority)**.

12.27.19.3 Optimizing Node Configuration

Scenario

After the scheduler of a big data cluster is properly configured, you can adjust the available memory, CPU resources, and local disk of each node to optimize the performance.

The configuration items are as follows:

- Available memory
- Number of vCPUs
- Physical CPU usage
- Coordination of memory and CPU resources
- Local disk

Procedure

For details about how to adjust parameter settings, see **Modifying Cluster Service Configuration Parameters**.

- **Available memory**

  Except the memory allocated to the OS and other services, allocate as much as possible memory to Yarn. You can adjust the following parameters to improve resource utilization.

  Assume that a container uses 512 MB memory by default, then the memory usage formula is: 512 MB x Number of containers.

  By default, the Map or Reduce container uses one vCPU and 1,024 MB memory, and ApplicationMaster uses 1,536 MB memory.

Parameter	Description	Default Value
yarn.nodemanager.resource.memory-mb	Physical memory that can be allocated to containers, in MB. The value must be greater than 0. You are advised to set the parameter value to 75% to 90% of the total physical memory of nodes. If the node has permanent processes of other services, reduce this parameter value to reserve sufficient resources for the processes.	MRS 3.*x* or later: **16384** Versions earlier than MRS 3.x: **8192**

- **Number of vCPUs**

  You are advised to set this parameter to 1.5 to 2 times the number of logical CPUs. If the upper layer computing applications have low computing capability requirements, you can set the parameter to two times the number of logical CPUs.

Parameter	Description	Default Value
yarn.nodemanager.resource.cpu-vcores	Number of vCPUs that can be used by Yarn on the node. The default value is **8**. You are advised to set the value to 1.5 to 2 times the number of logical CPUs.	8

- **Physical CPU usage**

  You are advised to reserve appropriate CPUs for the OS and the processes, such as database and HBase, and allocate the remaining CPUs to Yarn. You can set the following parameters to adjust the physical CPU usage.

Parameter	Description	Default Value
yarn.nodemanager.resource.percentage-physical-cpu-limit	Physical CPU percentage that can be used by Yarn on a node. The default value is **90**, indicating that no CPU control is implemented and Yarn can use all CPU resources. You can only view the parameter. To change the value of this parameter, set the value of RES_CPUSET_PERCENTAGE of YARN. You are advised to set this parameter to the percentage of CPU resources that can be used by the YARN cluster. For example, If 20% of CPU resources are used by other services (such as HBase, HDFS, and Hive) and system processes on the node, the CPU resources can be scheduled for Yarn is 1 - 20% = 80%. Therefore, you can set this parameter to **80**.	90

- **Local disk**

  MapReduce writes the intermediate job execution results in local disks. Therefore, configure disks as much as possible and disk space as large as possible. A simple way is to configure the same number of disks as DataNode except for the last directory.

  NOTE

  Use commas (,) to separate multiple disks.

Parameter	Description	Default Value
yarn.nodemanager.log-dirs	Directories in which logs are stored. Multiple directories can be specified. Storage location of container logs. The default value is **%{@auto.detect.datapart.nm.logs}**. If there is a data partition, a path list similar to **/srv/BigData/hadoop/data1/nm/containerlogs,/srv/BigData/hadoop/data2/nm/containerlogs** is generated based on the data partition. If there is no data partition, the default path **/srv/BigData/yarn/data1/nm/containerlogs** is generated. In addition to using expressions, you can enter a complete list of paths, such as **/srv/BigData/yarn/data1/nm/containerlogs** or **/srv/BigData/yarn/data1/nm/containerlogs,/srv/BigData/yarn/data2/nm/containerlogs**. In this way, data is stored in all the configured directories, which are usually on different devices. To ensure disk I/O load balancing, you are advised to provide several paths and each path corresponds to an independent disk. The localized log directory of the application exists in the relative path **/application_%{appid}**. The log directory of an independent container, that is, **container_{$contid}**, is the subdirectory of this directory. Each container directory contains the **stderr**, **stdin**, and **syslog** files generated by the container. To add a directory, for example, **/srv/BigData/yarn/data2/nm/containerlogs**, you need to delete the files in **/srv/BigData/yarn/data2/nm/containerlogs** first. Then, assign the same read and write permissions to **/srv/BigData/yarn/data2/nm/containerlogs** as those of **/srv/**	%{@auto.detect.datapart.nm.logs}

Parameter	Description	Default Value
	BigData/yarn/data1/nm/containerlogs, and change **/srv/BigData/yarn/data1/nm/containerlogs** to **/srv/BigData/yarn/data1/nm/containerlogs,/srv/BigData/yarn/data2/nm/containerlogs**. You can add directories, but do not modify or delete existing directories. Otherwise, NodeManager data will be lost and services will be unavailable. Default value: **%{@auto.detect.datapart.nm.logs}** Exercise caution when modifying this parameter. If the configuration is incorrect, the services are unavailable. If the value of this configuration item at the role level is changed, the value of this configuration item at all instance levels will be changed. If the value of this configuration item at the instance level is changed, the value of this configuration item of other instances remains unchanged.	

Parameter	Description	Default Value
yarn.nodemanager.local-dirs	Storage location of files after localization. The default value is **%{@auto.detect.datapart.nm.localdir}**. If there is a data partition, a path list similar to **/srv/BigData/hadoop/data1/nm/localdir,/srv/BigData/hadoop/data2/nm/localdir** is generated based on the data partition. If there is no data partition, the default path **/srv/BigData/yarn/data1/nm/localdir** is generated. In addition to using expressions, you can enter a complete list of paths, such as **/srv/BigData/yarn/data1/nm/localdir** or **/srv/BigData/yarn/data1/nm/localdir,/srv/BigData/yarn/data2/nm/localdir**. In this way, data is stored in all the configured directories, which are usually on different devices. To ensure disk I/O load balancing, you are advised to provide several paths and each path corresponds to an independent disk. The localized file directory of the application is stored in the relative path **/usercache/%{user}/appcache/application_%{appid}**. The working directory of an independent container, that is, **container_%{contid}**, is the subdirectory of the directory. To add a directory, for example, **/srv/BigData/yarn/data2/nm/localdir**, you need to delete the files in **/srv/BigData/yarn/data2/nm/localdir** first. Then, assign the same read and write permissions to **/srv/BigData/hadoop/data2/nm/localdir** as those of **/srv/BigData/hadoop/data1/nm/localdir**, and change **/srv/BigData/yarn/data1/nm/localdir** to **/srv/BigData/yarn/data1/nm/localdir,/srv/BigData/yarn/data2/nm/localdir**. You can add	%{@auto.detect.datapart.nm.localdir}

Parameter	Description	Default Value
	directories, but do not modify or delete existing directories. Otherwise, NodeManager data will be lost and services will be unavailable. Default value: **%{@auto.detect.datapart.nm.localdir}** Exercise caution when modifying this parameter. If the configuration is incorrect, the services are unavailable. If the value of this configuration item at the role level is changed, the value of this configuration item at all instance levels will be changed. If the value of this configuration item at the instance level is changed, the value of this configuration item of other instances remains unchanged.	

12.27.20 Common Issues About Yarn

12.27.20.1 Why Mounted Directory for Container is Not Cleared After the Completion of the Job While Using CGroups?

Question

Why mounted directory for Container is not cleared after the completion of the job while using CGroups?

Answer

The mounted path for the Container should be cleared even if job is failed.

This happens due to the deletion timeout. Some task takes more time to complete than the deletion time.

To avoid this scenario, you can go to the **All Configurations** page of Yarn by referring to **Modifying Cluster Service Configuration Parameters**. Search for the **yarn.nodemanager.linux-container-executor.cgroups.delete-timeout-ms** configuration item in the search box to change the deletion interval. The value is in milliseconds.

12.27.20.2 Why the Job Fails with HDFS_DELEGATION_TOKEN Expired Exception?

Question

Why is the HDFS_DELEGATION_TOKEN expired exception reported when a job fails in security mode?

Answer

HDFS_DELEGATION_TOKEN expires because the token is not updated or it is accessed after max. lifetime.

Ensure the following parameter value of max. lifetime of the token is greater than the job running time.

dfs.namenode.delegation.token.max-lifetime=**604800000** (1 week by default)

Go to the **All Configurations** page of HDFS by referring to **Modifying Cluster Service Configuration Parameters** and search for this parameter in the search box.

NOTE

You are advised to set this parameter to a value that is multiple times of the number of hours within the max. lifecycle of the token.

12.27.20.3 Why Are Local Logs Not Deleted After YARN Is Restarted?

Question

If Yarn is restarted in either of the following scenarios, local logs will not be deleted as scheduled and will be retained permanently:

- When Yarn is restarted during task running, local logs are not deleted.
- When the task is complete and logs fail to be collected, restart Yarn before the logs are cleared as scheduled. In this case, local logs are not deleted.

Answer

NodeManager has a restart recovery mechanism (for details, see **https://hadoop.apache.org/docs/r3.1.1/hadoop-yarn/hadoop-yarn-site/NodeManager.html#NodeManager_Restart**). Go to the **All Configurations** page of Yarn by referring to **Modifying Cluster Service Configuration Parameters**. Set **yarn.nodemanager.recovery.enabled** of NodeManager to **true** to make the configuration take effect. The default value is **true**. In this way, redundant local logs are periodically deleted when the YARN is restarted.

12.27.20.4 Why the Task Does Not Fail Even Though AppAttempts Restarts for More Than Two Times?

Question

Why the task does not fail even though AppAttempts restarts due to failure for more than two times?

Answer

During the task execution process, if the **ContainerExitStatus** returns value **ABORTED**, **PREEMPTED**, **DISKS_FAILED**, or **KILLED_BY_RESOURCEMANAGER**, the system will not count it as a failed attempt. Therefore, the task fails only when the AppAttempts fails actually, that is, the return value is not **ABORTED**, **PREEMPTED**, **DISKS_FAILED**, or **KILLED_BY_RESOURCEMANAGER** for two times.

12.27.20.5 Why Is an Application Moved Back to the Original Queue After ResourceManager Restarts?

Question

After I moved an application from one queue to another, why is it moved back to the original queue after ResourceManager restarts?

Answer

This problem is caused by the constraints of the ResourceManager. If a running application is moved to another queue, information about the new queue will not be stored in the ResourceManager after the ResourceManager restarts.

Assume that a user submits a MapReduce application to the leaf queue test11. If the leaf queue test11 is deleted when the application is running, the application will go to the lost_and found queue and the application stops. To start the application, the user moves the application to the leaf queue test21 and the application resumes running. If the ResourceManager restarts, the displayed submission queue is lost_and_found, but not test21.

If the application is not complete, the ResourceManager only stores the queue information before the application is moved. As a result, the application is moved back to the original queue. To solve this problem, move the application again after the ResourceManager is restarted to write information about the new queue to the ResourceManager.

12.27.20.6 Why Does Yarn Not Release the Blacklist Even All Nodes Are Added to the Blacklist?

Question

Why does Yarn not release the blacklist even all nodes are added to the blacklist?

Answer

In Yarn, when the number of application nodes added to the blacklist by ApplicationMaster (AM) reaches a certain proportion (the default value is 33% of the total number of nodes), the AM automatically releases the blacklist. In this way, all available nodes are added to the blacklist and tasks can obtain node resources.

Assume that there are 8 nodes in a cluster and they are divided in to pool A and pool B by NodeLabel. There are two nodes in pool B. A user submits a task App1 to pool B, but there is not sufficient HDFS space and App1 fails to run. As a result, two nodes in pool B are added to the blacklist by the AM of App1. According to the preceding principles, 2 is less than the 33% of 8. Therefore, Yarn does not release the blacklist, and App1 cannot obtain resources and keeps running. Even if the node that is added to the blacklisted is recovered, App1 still cannot obtain resources.

The preceding principles do not apply to the resource pool scenario. Therefore, you can change the value of the client parameter **yarn.resourcemanager.am-scheduling.node-blacklisting-disable-threshold** to **(nodes number of pool / total nodes)* 33%** to solve this problem.

12.27.20.7 Why Does the Switchover of ResourceManager Occur Continuously?

Question

The switchover of ResourceManager occurs continuously when multiple, for example 2,000, tasks are running concurrently, causing the Yarn service unavailable.

Answer

The cause is that the time of full GabageCollection exceeds the interaction duration threshold between the ResourceManager and ZooKeeper duration threshold. As a result, the connection between the ResourceManager and ZooKeeper fails and the switchover of ResourceManager occurs continuously.

When there are multiple tasks, ResourceManager saves the authentication information about multiple tasks and transfers the information to NodeManagers through heartbeat, which is called heartbeat response. The lifecycle of heartbeat response is short. The default value is 1s. Normally, heartbeat response can be reclaimed during the JVM minor GabageCollection. However, if there are multiple tasks and there are a lot of nodes, for example 5000 nodes, in the cluster, the heartbeat response of multiple nodes occupy a large amount of memory. As a result, the JVM cannot completely reclaim the heartbeat response during minor GabageCollection. The heartbeat response failed to be reclaimed accumulate and the JVM full GabageCollection is triggered. The JVM GabageCollection is in a blocking mode, in other words, no jobs are performed during the GabageCollection. Therefore, if the duration of full GabageCollection exceeds the periodical interaction duration threshold between the ResourceManager and ZooKeeper, the switchover occurs.

Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Yarn**, and click the **Configurations** tab and then **All Configurations**. In the navigation pane on the

left, choose **Yarn** > **Customization**, and add the **yarn.resourcemanager.zk-timeout-ms** parameter to the **yarn.yarn-site.customized.configs** file to increase the threshold of the periodic interaction duration between ResourceManager and ZooKeeper (the value range is less than or equal to 90,000 ms). In this way, the problem of continuous active/standby ResourceManager switchover can be solved.

12.27.20.8 Why Does a New Application Fail If a NodeManager Has Been in Unhealthy Status for 10 Minutes?

Question

Why does a new application fail if a NodeManager has been in unhealthy status for 10 minutes?

Answer

When **nodeSelectPolicy** is set to **SEQUENCE** and the first NodeManager connected to the ResourceManager is unavailable, the ResourceManager attempts to assign tasks to the same NodeManager in the period specified by **yarn.nm.liveness-monitor.expiry-interval-ms**.

You can use either of the following methods to avoid the preceding problem:

- Use another nodeSelectPolicy, for example, **RANDOM**.
- Go to the **All Configurations** page of Yarn by referring to **Modifying Cluster Service Configuration Parameters**. Search for the following parameters in the search box and modify the following attributes in the **yarn-site.xml** file:

  yarn.resourcemanager.am-scheduling.node-blacklisting-enabled = **true**;

  yarn.resourcemanager.am-scheduling.node-blacklisting-disable-threshold = **0.5**.

12.27.20.9 Why Does an Error Occur When I Query the ApplicationID of a Completed or Non-existing Application Using the RESTful APIs?

Question

Why does an error occur when I query the applicationID of a completed or non-existing application using the RESTful APIs?

Answer

The Superior scheduler only stores the applicationIDs of running applications. If you view the applicationID of a completed or non-existing application by accessing the RESTful API at **https://<SS_REST_SERVER>/ws/v1/sscheduler/applications/{application_id}**. the 404 error is returned by the server. If Chrome web browser is used, the **Error Occurred** message is displayed because chrome preferentially responds in the application/xml format. If Internet Explorer is used, the **404** error code is displayed because IE web browser preferentially responds in the application/json format.

12.27.20.10 Why May A Single NodeManager Fault Cause MapReduce Task Failures in the Superior Scheduling Mode?

Question

In Superior scheduling mode, if a single NodeManager is faulty, why may the MapReduce tasks fail?

Answer

In normal cases, when the attempt of a single task of an application fails on a node for three consecutive times, the AppMaster of the application adds the node to the blacklist. Then, the AppMaster instructs the scheduler not to schedule the task to the node to avoid task failure.

However, by default, if 33% nodes in the cluster are added to the blacklist, the scheduler ignores the blacklisted nodes. Therefore, the blacklist feature is prone to become invalid in small cluster scenarios. For example, there are only three nodes in the cluster. If one node is faulty, the blacklist mechanism becomes invalid. The scheduler continues to schedule the task to the node no matter how many times the attempt of the task fails on the node. As a result, the number of attempts of the task reaches the maximum (4 times by default for MapReduce). And the MapReduce tasks failed.

Workaround:

The **yarn.resourcemanager.am-scheduling.node-blacklisting-disable-threshold** parameter indicates the threshold for ignoring blacklisted nodes, in percentage. You are advised to increase the value of this parameter based on the cluster scale. For example, you are advised to set this parameter to **50%** for a three-node cluster.

NOTE

The framework design of the Superior scheduler is time-based asynchronous scheduling. When the NodeManager is faulty, ResourceManager cannot quickly detect that the NodeManager is faulty (10 minutes by default). Therefore, the Superior scheduler still schedules tasks to the node, causing task failures.

12.27.20.11 Why Are Applications Suspended After They Are Moved From Lost_and_Found Queue to Another Queue?

Question

When a queue is deleted when there are applications running in it, these applications are moved to the "lost_and_found" queue. When these applications are moved back to another healthy queue, some tasks are suspended.

Answer

If no label expression is set for the current application, the default label expression of the queue is used as label expression for new container/resource demands requested by the application. If there is no default label expression of the queue,

then **default label** is considered as the label expression for new container/ resource demands requested by the application.

When application app1 is submitted to the queue Q1, **label1**, the default label expression of the queue, is used for the application's new resource requests/ containers. If Q1 is deleted when app1 is running, app1 is moved to the "lost_and_found" queue. Because there is no label expression of the "lost_and_found" queue, **default label** is used as the label expression of app1's new resource requests/containers. Assume that app1 is moved to another normal queue Q2. If Q2 supports **label1** and **default label**, app1 can run properly. If Q2 does not support **label1** or **default label**, the resource request with **label1** or **default label** cannot obtain resources, causing task suspension.

To solve this problem, ensure that the queue to which the application is moved from "lost_and_found" queue supports label expression of the moved application.

You are not advised to delete a queue in which there are running applications.

12.27.20.12 How Do I Limit the Size of Application Diagnostic Messages Stored in the ZKstore?

Question

How do I limit the size of application diagnostic messages stored in the ZKstore?

Answer

In some cases, it has been observed that diagnostic messages may grow infinitely. Because diagnostic messages are stored in the ZKstore, it is not recommended that you allow diagnostic messages to grow indefinitely. Therefore, a property parameter is needed to set the maximum size of the diagnostic message.

If you need to set **yarn.app.attempt.diagnostics.limit.kc**, go to the **All Configurations** page by referring to **Modifying Cluster Service Configuration Parameters** and search for the following parameters in the search box:

Table 12-471 Parameter description

Parameter	Description	Default Value
yarn.app.attempt.diagnostics.limit.kc	Data size of the diagnosis message for each application connection, in kilobytes (number of characters x 1,024). When ZooKeeper is used to store the behavior status of applications, the size of diagnosis messages needs to be limited to prevent Yarn from overloading ZooKeeper. If **yarn.resourcemanager.state-store.max-completed-applications** is set to a large value, you need to decrease the value of this property to limit the total size of stored data.	64

12.27.20.13 Why Does a MapReduce Job Fail to Run When a Non-ViewFS File System Is Configured as ViewFS?

Question

Why does a MapReduce job fail to run when a non-ViewFS file system is configured as ViewFS?

Answer

When a non-ViewFS file system is configured as a ViewFS using cluster, the user permissions on folders in the ViewFS file system are different from those of non-ViewFS folders in the default NameService. The submitted MapReduce job fails to be executed because the directory permissions are inconsistent.

When configuring the ViewFS user in the cluster, you need to check and verify the directory permissions. Before submitting a job, change the ViewFS folder permissions based on the default NameService folder permissions.

The following table lists the default permission structure of directories configured in ViewFS. If the configured directory permissions are not included in the following table, you must change the directory permissions accordingly.

Table 12-472 Default permission structure of directories configured in ViewFS

Parameter	Description	Default Value	Default value and default permissions on the parent directory
yarn.nodemanager.remote-app-log-dir	On the default file system (usually HDFS), specify the directory to which the NM aggregates logs.	logs	777
yarn.nodemanager.remote-app-log-archive-dir	Directory for archiving logs	-	777
yarn.app.mapreduce.am.staging-dir	Staging directory used when a job is submitted	/tmp/hadoop-yarn/staging	777
mapreduce.jobhistory.intermediate-done-dir	Directory for storing historical files of MapReduce jobs	${yarn.app.mapreduce.am.staging-dir}/history/done_intermediate	777

Parameter	Description	Default Value	Default value and default permissions on the parent directory
mapreduce.jobhistory.done-dir	Directory of historical files managed by the MR JobHistory Server.	${yarn.app.mapreduce.am.staging-dir}/history/done	777

12.27.20.14 Why Do Reduce Tasks Fail to Run in Some OSs After the Native Task Feature is Enabled?

Question

After the Native Task feature is enabled, Reduce tasks fail to run in some OSs.

Answer

When **-Dmapreduce.job.map.output.collector.class=org.apache.hadoop.mapred.nativetask.NativeMapOutputCollectorDelegator** is executed to enable the Native Task feature during the running of MapReduce tasks that contain Reduce tasks, the tasks fail to run in some OSs, and the error message "version 'GLIBCXX_3.4.20' not found" is displayed in logs. The cause is that the GLIBCXX version of the OSs is too early. As a result, the libnativetask.so.1.0.0 library on which the feature depends cannot be loaded, leading to task failures.

Workaround:

Set **mapreduce.job.map.output.collector.class** to **org.apache.hadoop.mapred.MapTask$MapOutputBuffer**.

12.28 Using ZooKeeper

12.28.1 Using ZooKeeper from Scratch

ZooKeeper is an open-source, highly reliable, and distributed consistency coordination service. ZooKeeper is designed to solve the problem that data consistency cannot be ensured for complex and error-prone distributed systems. There is no need to develop dedicated collaborative applications, which is suitable for high availability services to ensure data consistency.

Background Information

Before using the client, you need to download and update the client configuration file on all clients except the client of the active management node.

Procedure

For MRS 2.*x* or earlier, perform the following operations:

Step 1 Download the client configuration file.

1. Log in to the MRS console. In the left navigation pane, choose **Clusters** > **Active Clusters**, and click the cluster to be operated. This cluster is the one created in .
2. Click the **Components** tab.
3. Click **Services** and then **Download Client**.

   Set **Client Type** to **Only configuration files**, and click **OK** to generate the client configuration file. The generated file is saved in the **/tmp/MRS-client** directory on the active management node by default. You can customize the file path.

Step 2 Log in to the active management node of MRS Manager.

1. On the MRS console, choose **Clusters > Active Clusters** and click a cluster name. On the **Nodes** tab, view the node names. The node whose name contains **master1** is the Master1 node, and the node whose name contains **master2** is the Master2 node.

   The active and standby management nodes of MRS Manager are installed on Master nodes by default. Because Master1 and Master2 are switched over in active and standby mode, Master1 is not always the active management node of MRS Manager. Run a command in Master1 to check whether Master1 is active management node of MRS Manager. For details about the command, see **Step 2.4**.
2. Log in to the Master1 node using the password as user **root**. For details, see **Help Center** > **MapReduce Service** > **Connecting to Clusters** > **Logging In to a Cluster** > **Logging In to an ECS**.
3. Run the following commands to switch to user **omm**:

   sudo su - root

   su - omm
4. Run the following command to check the active management node of MRS Manager:

   sh ${BIGDATA_HOME}/om-0.0.1/sbin/status-oms.sh

   In the command output, the node whose **HAActive** is **active** is the active management node, and the node whose **HAActive** is **standby** is the standby management node. In the following example, **mgtomsdat-sh-3-01-1** is the active management node, and **mgtomsdat-sh-3-01-2** is the standby management node.

   ```
   Ha mode
   double
   NodeName            HostName                HAVersion       StartTime           HAActive
   HAAllResOK          HARunPhase
   192-168-0-30        mgtomsdat-sh-3-01-1     V100R001C01     2014-11-18 23:43:02
   active              normal                  Actived
   192-168-0-24        mgtomsdat-sh-3-01-2     V100R001C01     2014-11-21 07:14:02
   standby             normal                  Deactived
   ```
5. Log in to the active management node, for example, **192-168-0-30** of MRS Manager as user **root**, and run the following command to switch to user **omm**:

sudo su - omm

Step 3 Run the following command to go to the client installation directory, for example, **/opt/client**.

cd /opt/client

Step 4 Run the following command to update the client configuration for the active management node.

sh refreshConfig.sh /opt/client *Full path of the client configuration file package*

For example, run the following command:

sh refreshConfig.sh /opt/client/tmp/MRS-client/MRS_Services_Client.tar

If the following information is displayed, the configurations have been updated successfully:

```
ReFresh components client config is complete.
Succeed to refresh components client config.
```

NOTE

You can perform **Step 1** to **Step 4** by referring to Method 2 in **User Guide** > **Connecting to Clusters** > **Using an MRS Client** > **Updating a Client**.

Step 5 Use the client on a Master node.

1. On the active management node where the client is updated, for example, node **192-168-0-30**, run the following command to go to the client directory:

   cd /opt/client

2. Run the following command to configure environment variables:

   source bigdata_env

3. If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. If Kerberos authentication is disabled for the current cluster, skip this step:

   kinit *MRS cluster user*

   Example: **kinit zookeeperuser**.

4. Run the following Zookeeper client command:

   zkCli.sh -server *<zookeeper installation node IP>***:<port>**

   Example: ***zkCli.sh -server node-master1DGhZ:2181***

Step 6 Run the ZooKeeper client command.

1. Create a ZNode.
   ```
   create /test
   ```
2. View ZNode information.
   ```
   ls /
   ```
3. Write data to the ZNode.
   ```
   set /test "zookeeper test"
   ```
4. View the data written to the ZNode.
   ```
   get /test
   ```
5. Delete the created ZNode.
   ```
   delete /test
   ```

----End

For MRS 3.x or later, perform the following operations:

Step 1 Download the client configuration file.

1. Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**.
2. Choose **Cluster** > *Name of the desired cluster* > **Dashboard** > **More** > **Download Client**.
3. Download the cluster client.

   Set **Select Client Type** to **Configuration Files Only**, select a platform type, and click **OK** to generate the client configuration file which is then saved in the **/tmp/FusionInsight-Client/** directory on the active management node by default.

Step 2 Log in to the active management node of Manager.

1. Log in to any node where Manager is deployed as user **root**.
2. Run the following command to identify the active and standby nodes:

   sh ${BIGDATA_HOME}/om-server/om/sbin/status-oms.sh

   In the command output, the value of **HAActive** for the active management node is **active**, and that for the standby management node is **standby**. In the following example, **node-master1** is the active management node, and **node-master2** is the standby management node.

   ```
   HAMode
   double
   NodeName            HostName        HAVersion       StartTime           HAActive
   HAAllResOK          HARunPhase
   192-168-0-30        node-master1    V100R001C01     2020-05-01 23:43:02 active
   normal              Actived
   192-168-0-24        node-master2    V100R001C01     2020-05-01 07:14:02 standby
   normal              Deactived
   ```

3. Log in to the primary management node as user **root** and run the following command to switch to user **omm**:

   sudo su - omm

Step 3 Run the following command to go to the client installation directory, for example, **/opt/client**.

cd /opt/client

Step 4 Run the following command to update the client configuration for the active management node.

sh refreshConfig.sh /opt/client *Full path of the client configuration file package*

For example, run the following command:

sh refreshConfig.sh /opt/client /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Services_Client.tar

If the following information is displayed, the configurations have been updated successfully:

```
ReFresh components client config is complete.
Succeed to refresh components client config.
```

Step 5 Use the client on a Master node.

1. On the active management node where the client is updated, for example, node **192-168-0-30**, run the following command to go to the client directory:

   cd /opt/client

2. Run the following command to configure environment variables:

   source bigdata_env

3. If Kerberos authentication has been enabled for the current cluster, run the following command to authenticate the current user. For details, see to configure roles with required permissions. For details about how to bind roles with users, see . If Kerberos authentication is disabled for the current cluster, skip this step:

   kinit *MRS cluster user*

   Example: **kinit zookeeperuser**.

4. Run the following Zookeeper client command:

   zkCli.sh -server <zookeeper installation node IP>:<port>

   Example: **zkCli.sh -server node-master1DGhZ:2181**

Step 6 Run the ZooKeeper client command.

1. Create a ZNode.
   ```
   create /test
   ```
2. View ZNode information.
   ```
   ls /
   ```
3. Write data to the ZNode.
   ```
   set /test "zookeeper test"
   ```
4. View the data written to the ZNode.
   ```
   get /test
   ```
5. Delete the created ZNode.
   ```
   delete /test
   ```

----End

12.28.2 Common ZooKeeper Parameters

Navigation path for setting parameters:

Go to the **All Configurations** page of ZooKeeper by referring to **Modifying Cluster Service Configuration Parameters**. Enter a parameter name in the search box.

Table 12-473 Parameters

Parameter	Description	Default Value
skipACL	Specifies whether to skip the permission check of the ZooKeeper node.	no

Parameter	Description	Default Value
maxClientCnxns	Specifies the maximum number of connections of ZooKeeper. It is recommended this parameter is set to a larger value in scenarios with a large number of connections.	2000
LOG_LEVEL	Specifies the log level. This parameter can be set to **DEBUG** during commissioning.	INFO
acl.compare.shortName	Specifies whether to perform ACL authentication only by principal username when the Znode ACL authentication type is SASL.	true
synclimit	Specifies the interval of synchronization between the follower and leader (unit: tick). If the leader does not respond within the specified time range, the connection cannot be established.	15
tickTime	Specifies the duration of a tick (in milliseconds). It is the basic time unit used by ZooKeeper, which defines heartbeat and timeout durations.	4000

NOTE

The ZooKeeper internal time is determined by **ticktime** and **synclimit**. To increase the ZooKeeper internal timeout interval, increase the timeout interval for the client to connect to ZooKeeper.

12.28.3 Using a ZooKeeper Client

Scenario

Use a ZooKeeper client in an O&M scenario or service scenario.

Prerequisites

You have installed the client. For example, the installation directory is **/opt/client**. The client directory in the following operations is only an example. Change it based on the actual installation directory onsite.

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the following command to authenticate the user: (skip this step in common mode):

kinit *Component service user*

Step 5 Run the following command to log in to the client tool:

zkCli.sh -server *service IP address of the node where the ZooKeeper role instance locates*:*client port*

----End

12.28.4 Configuring the ZooKeeper Permissions

Scenario

Configure znode permission of ZooKeeper.

ZooKeeper uses an access control list (ACL) to implement znode access control. The ZooKeeper client specifies a znode ACL, and the ZooKeeper server determines whether a client that requests for a znode has related operation permission according to the ACL. ACL configuration involves the following four operations:

- Check znode ACLs in ZooKeeper.
- Add znode ACLs to ZooKeeper.
- Modify znode ACLs in ZooKeeper.
- Delete znode ACLs from ZooKeeper.

  The ZooKeeper ACL permission is described as follows:

  ZooKeeper supports five types of permission, create, delete, read, write, and admin. ZooKeeper permission control is of a znode level. That is, the permission configuration for a parent znode is not inherited by its child znodes. The ZooKeeper znode default permission is **world:anyone: cdrwa**. That is, any user has all permissions.

NOTE

ACL has three parts:

The first part is the authentication type. For example, **world** indicates all authentication types and **sasl** indicates the kerberos authentication type.

The second part is the account. For example, anyone indicates any user.

The third part is permission. For example, **cdrwa** indicates all permissions.

In particular, because starting the client in common mode does not need authentication, ACL with **sasl** authentication type cannot be used in common mode. Authentications of **sasl** scheme in this document are performed in clusters that have the security mode enabled.

Table 12-474 Five types of ZooKeeper ACLs

Permission Description	Permission Name	Permission Details
Create permission	create(c)	Users with this permission can create child znodes in the current znode.
Delete permission	delete(d)	Users with this permission can delete the current znode.
Read permission	read(r)	Users with this permission can obtain data of the current znode and list all the child znodes of the current znode.
Write permission	write(w)	Users with this permission can write data to the current znode and its child znodes.
Administration permission	admin(a)	Users with this permission can set permission for the current znode.

Impact on the System

NOTICE

Modifying ZooKeeper ACLs is a critical operation. If znode permission is modified in ZooKeeper, other users may have no permission to access the znode and some system functions are abnormal. In 3.5.6 and later versions, users must have the read permission for the **getAcl** operation.

Prerequisites

- The ZooKeeper client has been installed. For example, the installation directory is **/opt/client**.
- You have obtained the password of the system administrator account.

Procedure

Start the ZooKeeper client.

Step 1 Log in to the server where the ZooKeeper client is installed as user **root**.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster has the security mode enabled, run the following command for user authentication and enter the username and password (Any authorized user. **admin** is used as an example.):

kinit admin

Step 5 On the ZooKeeper client, run the following command to go to the ZooKeeper command-line interface (CLI):

sh zkCli.sh -server *ZooKeeper plane IP address of any instance*:*clientPort*

The default **clientPort** is **2181**.

Example: **sh zkCli.sh -server 192.168.0.151:2181**

Step 6 Run the **ls** command to view the znode list in ZooKeeper. For example, you can view the list of znodes in the root directory.

ls /

```
[zk: 192.168.0.151:2181(CONNECTED) 1] ls /
[hadoop-flag, hadoop-ha, test, test2, test3, test4, test5, test6, zookeeper]
```

View the ZooKeeper znode ACL.

Step 7 Start the ZooKeeper client.

Step 8 Run the **getAcl** command to view znodes. The following command can be used to view the created znode ACL named **test**:

getAcl */znode name*

```
[zk: 192.168.0.151:2181(CONNECTED) 2] getAcl /test
'world,'anyone
: cdrwa
```

Add a ZooKeeper znode ACL.

Step 9 Start the ZooKeeper client.

Step 10 View the old ACL information to check whether the current account has the permission to modify the znode ACL information (a permission). If no, use kinit to switch to a user that has the permission and restart the ZooKeeper client.

getAcl */znode name*

```
 [zk: 192.168.0.151:2181(CONNECTED) 3] getAcl /test
'world,'anyone
: cdrwa
```

Step 11 Run the **setAcl** command to add an ACL. The command for adding an ACL is as follows:

setAcl /test world:anyone:cdrwa,sasl: *username*@: *<system domain name>:ACL value*

For example, to add the ACL of the **admin** user to the test znode, run the following command:

setAcl /test world:anyone:cdrwa,sasl:admin@HADOOP.COM:cdrwa

NOTE

When adding a new ACL, reserve the existing ones. The new and old ACLs are separated by a comma. The newly added ACL has three parts:

The first part is the authentication type. For example, **sasl** indicates the kerberos authentication type.

The second part is the account. For example, **admin@HADOOP.COM** indicates user **admin**.

The third part is permission. For example, **cdrwa** indicates all permissions.

Step 12 After adding the ACL, run the **getAcl** command to check whether the permission is added successfully:

getAcl */znode name*

```
[zk: 192.168.0.151:2181(CONNECTED) 4] getAcl /test
'world,'anyone
: cdrwa
'sasl,'admin@<system domain name>
: cdrwa
```

Modify the ZooKeeper znode ACL.

Step 13 Start the ZooKeeper client.

Step 14 View the old ACL information to check whether the current account has the permission to modify the znode ACL information (a permission). If no, use kinit to switch to a user that has the permission and restart the ZooKeeper client.

getAcl */znode name*

```
[zk: 192.168.0.151:2181(CONNECTED) 5] getAcl /test
'world,'anyone
: cdrwa
'sasl,'admin@<system domain name>
: cdrwa
```

Step 15 Run the **setAcl** command to modify an ACL. The command for adding an ACL is as follows:

s**etAcl /test sasl:***Username@<System domain name>:ACL value*

For example, to reserve only **admin** user permission and delete **anyone** rw permission, run the following command:

setAcl /test sasl:admin@HADOOP.COM:cdrwa

Step 16 After modifying the ACL, run the **getAcl** command to check whether the permission is modified successfully:

getAcl */znode name*

```
[zk: 192.168.0.151:2181(CONNECTED) 6] getAcl /test
'sasl,'admin@<system domain name>
: cdrwa
```

Delete the ZooKeeper znode ACL.

Step 17 Start the ZooKeeper client.

Step 18 View the old ACL information to check whether the current account has the permission to modify the znode ACL information (a permission). If no, use kinit to switch to a user that has the permission and restart the ZooKeeper client.

getAcl */znode name*

```
[zk: 192.168.0.151:2181(CONNECTED) 5] getAcl /test
'world,'anyone
: rw
'sasl,'admin@<system domain name>
: cdrwa
```

Step 19 Run the **setAcl** command to add an ACL. The command for adding an ACL is as follows:

s**etAcl /test sasl:***Username@<System domain name>:ACL value*

For example, to reserve only **admin** user permission and delete **anyone** rw permission, run the following command:

setAcl /test sasl:admin@HADOOP.COM:cdrwa

Step 20 After modifying the ACL, run the **getAcl** command to check whether the permission is modified successfully:

getAcl */znode name*

```
[zk: 192.168.0.151:2181(CONNECTED) 6] getAcl /test
'sasl,'admin@<system domain name>
: cdrwa
```

----End

12.28.5 ZooKeeper Log Overview

Log Description

Log path: **/var/log/Bigdata/zookeeper/quorumpeer** (Run log), **/var/log/Bigdata/audit/zookeeper/quorumpeer** (Audit log)

Log archive rule: The automatic ZooKeeper log compression function is enabled. By default, when the size of logs exceeds 30 MB, logs are automatically compressed into a log file. A maximum of 20 compressed file can be reserved. The number of compressed files can be configured on Manager.

Table 12-475 ZooKeeper log list

Log Type	Log File Name	Description
Run logs	zookeeper-<SSH_USER>-<process_name>-<hostname>.log	ZooKeeper system log file, which records most of the logs generated when the ZooKeeper system is running.
	check-serviceDetail.log	Log that records whether the ZooKeeper service starts successfully.
	zookeeper-<SSH_USER>-<DATA>-<PID>-gc.log	ZooKeeper garbage collection log file
	instanceHealthDetail.log	Log that records the health check details of ZooKeeper instance
	zookeeper-omm-server-<hostname>.out	Log indicating that ZooKeeper unexpectedly quits
	zk-err-<zkpid>.log	ZooKeeper fatal error log
	java_pid<zkpid>.hprof	ZooKeeper memory overflow log
	funcDetail.log	ZooKeeper instance startup log
	zookeeper-period-check.log	Health check log of the ZooKeeper instance
	zookeeper-period-check-java.log	ZooKeeper quota monitoring period check log
Audit Log	zk-audit-quorumpeer.log	ZooKeeper operation audit log

Log levels

Table 12-476 describes the log levels supported by ZooKeeper. The priorities of log levels are FATAL, ERROR, WARN, INFO, and DEBUG in descending order. Logs whose levels are higher than or equal to the specified level are printed. The number of printed logs decreases as the specified log level increases.

Table 12-476 Log levels

Level	Description
FATAL	Logs of this level record fatal error information about the current event processing that may result in a system crash.
ERROR	Error information about the current event processing, which indicates that system running is abnormal.

Level	Description
WARN	Abnormal information about the current event processing. These abnormalities will not result in system faults.
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record the system information and system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of the ZooKeeper service by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 On the menu bar on the left, select the log menu of the target role.

Step 3 Select a desired log level.

Step 4 Click **Save**. In the displayed dialog box, click **OK** to make the configuration take effect.

NOTE

The configurations take effect immediately without the need to restart the service.

----End

Log Format

The following table lists the ZooKeeper log formats.

Table 12-477 Log Format

Log Type	Component	Format	Example
Run logs	zookeeper quorumpeer	<*yyyy-MM-dd HH:mm:ss,SSS*>|<*Log level*>|<*Name of the thread that generates the log*>|<*Message in the log*>|<*Location where the log event occurs*>	2020-01-20 16:33:43,816 | INFO | main | Defaulting to majority quorums | org.apache.zookeeper.server.quorum.QuorumPeerConfig.parseProperties(QuorumPeerConfig.java:335)

Log Type	Component	Format	Example
Audit logs	zookeeper quorumpeer	<*yyyy-MM-dd HH:mm:ss,SSS*>|<*Log level*>|<*Name of the thread that generates the log*>|<*Message in the log*>|<*Location where the log event occurs*>	2020-01-20 16:33:54,313 | INFO | CommitProcessor:13 | session=0xd4b0679daea0000 ip=10.177.112.145 operation=create znode target=ZooKeeperServer znode=/zk-write-test-2 result=success | org.apache.zookeeper.ZKAuditLogger$LogLevel$5.printLog(ZKAuditLogger.java:70)

12.28.6 Common Issues About ZooKeeper

12.28.6.1 Why Do ZooKeeper Servers Fail to Start After Many znodes Are Created?

Question

After a large number of znodes are created, ZooKeeper servers in the ZooKeeper cluster become faulty and cannot be automatically recovered or restarted.

Logs of followers:

```
2016-06-23 08:00:18,763 | WARN  | QuorumPeer[myid=26](plain=/10.16.9.138:2181)(secure=disabled) |

```

Answer

After a large number of znodes are created, a large volume of data needs to be synchronized between the follower and leader. If the data synchronization is not complete within the specified time, all ZooKeeper servers fail to start.

Go to the **All Configurations** page of the ZooKeeper service by referring to **Modifying Cluster Service Configuration Parameters**. To recover ZooKeeper servers, increase the values of **syncLimit** and **initLimit** in the ZooKeeper configuration file **zoo.cfg** until ZooKeeper servers are successfully started.

Table 12-478 Parameters

Parameter	Description	Default Value
syncLimit	Interval (unit: tick) at which data is synchronized between the follower and the leader. If the leader does not respond to the follower within the specified time, the connection between the leader and follower cannot be set up.	15
initLimit	Interval (unit: tick) within which the connection and synchronization between the follower and leader must be completed.	15

If ZooKeeper servers do not recover even after **initLimit** and **syncLimit** are set to **300** ticks, check that no other application is killing the ZooKeeper. For example, if the parameter value is **300** and the ticket duration is 2000 ms, the maximum synchronization duration is 600s (300 x 2000 ms).

There may exist the situation where an overwhelming amount of data is created in ZooKeeper and it takes long to synchronize data between the follower and the leader and to save data to the hard disk. This means that ZooKeeper needs to run for a long time. Ensure that no other monitoring application kills the ZooKeeper while ZooKeeper is running.

12.28.6.2 Why Does the ZooKeeper Server Display the java.io.IOException: Len Error Log?

Question

After a large number of znodes are created in a parent directory, the ZooKeeper client will fail to fetch all child nodes of this parent directory in a single request.

Logs of client:

```
2017-07-11 13:17:19,610 [myid:] - WARN  [New I/O worker #3:ClientCnxnSocketNetty

```

Answer

After a large number of znodes are created in a single parent directory and the client tries to fetch all the child znodes in a single request, the server will fail to return because the results exceed the data size that can be stored in a znode.

To avoid this problem, set **jute.maxbuffer** to a larger value based on the client application.

jute.maxbuffer can only be set to a Java system property without the Zookeeper prefix. To set **jute.maxbuffer** to *X*, set **Djute.maxbuffer** to *X* when starting the ZooKeeper client or the service.

For example, set the parameter to 4 MB: **-Djute.maxbuffer=0x400000**.

Table 12-479 Parameters

Parameter	Description	Default Value
jute.maxbuffer	Specifies the maximum length of data that can be stored in znode. The unit is byte. Default value: 0xfffff, which is less than 1 MB. **NOTE** If this option is changed, the system property must be set on all servers and clients, otherwise problems will arise.	0xfffff

12.28.6.3 Why Four Letter Commands Don't Work With Linux netcat Command When Secure Netty Configurations Are Enabled at Zookeeper Server?

Question

Why four letter commands do not work with linux netcat command when secure netty configurations are enabled at Zookeeper server?

For example,

echo stat /netcat host port

Answer

Linux ***netcat*** command does not have option to communicate Zookeeper server securely, so it cannot support Zookeeper four letter commands when secure netty configurations are enabled.

To avoid this problem, user can use below Java API to execute four letter commands.

```
org.apache.zookeeper.client.FourLetterWordMain
```

For example,

```
String[] args = new String[]{host, port, "stat"};
org.apache.zookeeper.client.FourLetterWordMain.main(args);
```

NOTE

netcat command should be used only with non secure netty configuration.

12.28.6.4 How Do I Check Which ZooKeeper Instance Is a Leader?

Question

How to check whether the role of a ZooKeeper instance is a leader or follower.

Answer

Log in to Manager and choose **Cluster** > *Name of the desired cluster* > **Service** > **ZooKeeper** > **Instance**. On the displayed page, click the name of the quorumpeer instance. On the displayed instance details page, view the server status of the instance.

12.28.6.5 Why Cannot the Client Connect to ZooKeeper using the IBM JDK?

Question

When the IBM JDK is used, the client fails to connect to ZooKeeper.

Answer

The possible cause is that the **jaas.conf** file format of the IBM JDK is different from that of the common JDK.

If IBM JDK is used, use the following **jaas.conf** template. The **useKeytab** file path must start with **file://**, followed by an absolute path.

```
Client {
com.ibm.security.auth.module.Krb5LoginModule required
useKeytab="file://D:/install/HbaseClientSample/conf/user.keytab"
principal="hbaseuser1"
credsType="both";
};
```

12.28.6.6 What Should I Do When the ZooKeeper Client Fails to Refresh a TGT?

Question

The ZooKeeper client fails to refresh a TGT and therefore ZooKeeper cannot be accessed. The error message is as follows:

```
Login: Could not renew TGT due to problem running shell command: '***/kinit -R'; exception
was:org.apache.zookeeper.Shell$ExitCodeException: kinit: Ticket expired while renewing credentials
```

Answer

ZooKeeper uses the system command **kinit – R** to refresh a ticket. In the current version of MRS, the function of this command is canceled. If a long-term task needs to be executed, you are advised to implement the authentication function in keytab mode.

In the **jaas.conf** configuration file, set **useTicketCache** to **false**, **useKeyTab** to **true**, and specify the keytab path.

12.28.6.7 Why Is Message "Node does not exist" Displayed when A Large Number of Znodes Are Deleted Using the deleteall Command

Question

When the client connects to a non-leader instance, run the **deleteall** command to delete a large number of znodes, the error message "Node does not exist" is displayed, but run the **stat** command, the node status can be obtained.

Answer

The leader and follower data is not synchronized due to network problems or large data volume. To solve this problem, connect the client to the leader instance and delete the instance. To delete the leader node, view the IP address of the node where the leader resides by referring to **How Do I Check Which ZooKeeper Instance Is a Leader?**, run the **zkCli.sh -server leader** *node IP address* **2181** command to connect to the client, and then run the **deleteall** command to delete the leader node. For details, see **Using a ZooKeeper Client**.

12.29 Appendix

12.29.1 Modifying Cluster Service Configuration Parameters

- You can modify service configuration parameters on the cluster management page of the MRS management console.
  a. Log in to the MRS console. In the left navigation pane, choose **Clusters** > **Active Clusters**, and click a cluster name.
  b. Choose **Components** > *Name of the desired service* > **Service Configuration**.

     The **Basic Configuration** tab page is displayed by default. To modify more parameters, click the **All Configurations** tab. The navigation tree displays all configuration parameters of the service. The level-1 nodes in the navigation tree are service names or role names. The parameter category is displayed after the level-1 node is expanded.
  c. In the navigation tree, select the specified parameter category and change the parameter values on the right.

     If you are not sure about the location of a parameter, you can enter the parameter name in search box in the upper right corner. The system searches for the parameter in real time and displays the result.
  d. Click **Save Configuration**. In the displayed dialog box, click **OK**.
  e. Wait until the message **Operation successful** is displayed. Click **Finish**.

     The configuration is modified.

     Check whether there is any service whose configuration has expired in the cluster. If yes, restart the corresponding service or role instance for the configuration to take effect. You can also select **Restart the affected services or instances** when saving the configuration. .
- For MRS 3.*x* or earlier: You can log in to MRS Manager to modify service configuration parameters.

a. Log in to MRS Manager.
b. Click **Services**.
c. Click the specified service name on the service management page.
d. Click **Service Configuration**.

   The **Basic Configuration** tab page is displayed by default. To modify more parameters, click the **All Configurations** tab. The navigation tree displays all configuration parameters of the service. The level-1 nodes in the navigation tree are service names or role names. The parameter category is displayed after the level-1 node is expanded.
e. In the navigation tree, select the specified parameter category and change the parameter values on the right.

   If you are not sure about the location of a parameter, you can enter the parameter name in search box in the upper right corner. The system searches for the parameter in real time and displays the result.
f. Click **Save**. In the confirmation dialog box, click **OK**.
g. Wait until the message **Operation successful** is displayed. Click **Finish**.

   The configuration is modified.

   Check whether there is any service whose configuration has expired in the cluster. If yes, restart the corresponding service or role instance for the configuration to take effect. You can also select **Restart the affected services or instances** when saving the configuration.

- For MRS 3.*x* or later: You can log in to FusionInsight Manager to modify service configuration parameters.
  a. You have logged in to FusionInsight Manager.
  b. Choose **Cluster** > **Service**.
  c. Click the specified service name on the service management page.
  d. Click **Configuration**.

     The **Basic Configuration** tab page is displayed by default. To modify more parameters, click the **All Configurations** tab. The navigation tree displays all configuration parameters of the service. The level-1 nodes in the navigation tree are service names or role names. The parameter category is displayed after the level-1 node is expanded.
  e. In the navigation tree, select the specified parameter category and change the parameter values on the right.

     If you are not sure about the location of a parameter, you can enter the parameter name in search box in the upper right corner. The system searches for the parameter in real time and displays the result.
  f. Click **Save**. In the confirmation dialog box, click **OK**.
  g. Wait until the message **Operation successful** is displayed. Click **Finish**.

     The configuration is modified.

     Check whether there is any service whose configuration has expired in the cluster. If yes, restart the corresponding service or role instance for the configuration to take effect.

12.29.2 Accessing Manager

12.29.2.1 Accessing MRS Manager (Versions Earlier Than MRS 3.x)

Scenario

Clusters of versions earlier than MRS 3.x use MRS Manager to monitor, configure, and manage clusters. You can open the MRS Manager page on the MRS console.

Accessing MRS manager

Step 1 Log in to the MRS management console.

Step 2 In the navigation pane, choose **Clusters** > **Active Clusters**. Click the target cluster name to access the cluster details page.

Step 3 Click **Access Manager**. The **Access MRS Manager** page is displayed.

- If you have bound an EIP when creating a cluster,
  a. Select the security group to which the security group rule to be added belongs. The security group is configured when the cluster is created.
  b. Add a security group rule. By default, your public IP address used for accessing port 9022 is filled in the rule. To enable multiple IP address segments to access MRS Manager, see **Step 6** to **Step 9**. If you want to view, modify, or delete a security group rule, click **Manage Security Group Rule**.

     NOTE

     - It is normal that the automatically generated public IP address is different from the local IP address and no action is required.
     - If port 9022 is a Knox port, you need to enable the permission of port 9022 to access Knox for accessing MRS Manager.

  c. Select the checkbox stating that **I confirm that xx.xx.xx.xx is a trusted public IP address and MRS Manager can be accessed using this IP address**.
- If you have not bound an EIP when creating a cluster,
  a. Select an available EIP from the drop-down list or click **Manage EIP** to create one.
  b. Select the security group to which the security group rule to be added belongs. The security group is configured when the cluster is created.
  c. Add a security group rule. By default, your public IP address used for accessing port 9022 is filled in the rule. To enable multiple IP address segments to access MRS Manager, see **Step 6** to **Step 9**. If you want to view, modify, or delete a security group rule, click **Manage Security Group Rule**.

     NOTE

     - It is normal that the automatically generated public IP address is different from the local IP address and no action is required.
     - If port 9022 is a Knox port, you need to enable the permission of port 9022 to access Knox for accessing MRS Manager.

d. Select the checkbox stating that **I confirm that xx.xx.xx.xx is a trusted public IP address and MRS Manager can be accessed using this IP address**.

Step 4 Click **OK**. The MRS Manager login page is displayed.

Step 5 Enter the default username **admin** and the password set during cluster creation, and click **Log In**. The MRS Manager page is displayed.

Step 6 On the MRS console, click **Clusters** and choose **Active Clusters**. Click the target cluster name to access the cluster details page.

NOTE

To assign MRS Manager access permissions to other users, follow instructions from **Step 6** to **Step 9** to add the users' public IP addresses to the trusted range.

Step 7 Click **Add Security Group Rule** on the right of **EIP**.

Step 8 On the **Add Security Group Rule** page, add the IP address segment for users to access the public network and select **I confirm that the authorized object is a trusted public IP address range. Do not use 0.0.0.0/0. Otherwise, security risks may arise**.

By default, the IP address used for accessing the public network is filled. You can change the IP address segment as required. To enable multiple IP address segments, repeat steps **Step 6** to **Step 9**. If you want to view, modify, or delete a security group rule, click **Manage Security Group Rule**.

Step 9 Click **OK**.

----End

Granting the Permission to Access MRS Manager to Other Users

Step 1 On the MRS console, click **Clusters** and choose **Active Clusters**. Click the target cluster name to access the cluster details page.

Step 2 Click **Add Security Group Rule** on the right of **EIP**.

Step 3 On the **Add Security Group Rule** page, add the IP address segment for users to access the public network and select.**I confirm that the authorized object is a trusted public IP address range. Do not use 0.0.0.0/0. Otherwise, security risks may arise.**

By default, the IP address used for accessing the public network is filled. You can change the IP address segment as required. To enable multiple IP address segments, repeat steps **Step 1** to **Step 4**. If you want to view, modify, or delete a security group rule, click **Manage Security Group Rule**.

Step 4 Click **OK**.

----End

12.29.2.2 Accessing FusionInsight Manager (MRS 3.*x* or Later)

Scenario

In MRS 3.*x* or later, FusionInsight Manager is used to monitor, configure, and manage clusters. After the cluster is installed, you can use the account to log in to FusionInsight Manager.

NOTE

If you cannot log in to the WebUI of the component, access FusionInsight Manager by referring to **Accessing FusionInsight Manager from an ECS**.

Accessing FusionInsight Manager Using EIP

Step 1 Log in to the MRS management console.

Step 2 In the navigation pane, choose **Clusters** > **Active Clusters**. Click the target cluster name to access the cluster details page.

Step 3 Click **Manager** next to **MRS Manager**. In the displayed dialog box, configure the EIP information.

1. If no EIP is bound during MRS cluster creation, select an available EIP from the drop-down list on the right of **IEP**. If you have bound an EIP when creating a cluster, go to **Step 3.2**.

   NOTE

   If no EIP is available, click **Manage EIP** to one. Then, select the d EIP from the drop-down list on the right of **EIP**.

2. Select the security group to which the security group rule to be added belongs. The security group is configured when the cluster is created.
3. Add a security group rule. By default, the filled-in rule is used to access the EIP. To enable multiple IP address segments to access Manager, see steps **Step 6** to **Step 9**. If you want to view, modify, or delete a security group rule, click **Manage Security Group Rule**.
4. Select the information to be confirmed and click **OK**.

Step 4 Click **OK**. The Manager login page is displayed.

Step 5 Enter the default username **admin** and the password set during cluster creation, and click **Log In**. The Manager page is displayed.

Step 6 On the MRS management console, choose **Clusters** > **Active Clusters**. Click the target cluster name to access the cluster details page.

NOTE

To grant other users the permission to access Manager, perform **Step 6** to **Step 9** to add the users' public IP addresses to the trusted IP address range.

Step 7 Click **Add Security Group Rule** on the right of **EIP**.

Step 8 On the **Add Security Group Rule** page, add the IP address segment for users to access the public network and select **I confirm that *public network IP*|*port* is a**

trusted public IP address. I understand that using 0.0.0.0/0. poses security risks.

By default, the IP address used for accessing the public network is filled. You can change the IP address segment as required. To enable multiple IP address segments, repeat steps **Step 6** to **Step 9**. If you want to view, modify, or delete a security group rule, click **Manage Security Group Rule**.

Step 9 Click **OK**.

----End

Accessing FusionInsight Manager from an ECS

Step 1 On the MRS management console, click **Clusters**.

Step 2 On the **Active Clusters** page, click the name of the specified cluster.

Record the **AZ**, **VPC**, **MRS ManagerSecurity Group** of the cluster.

Step 3 On the homepage of the management console, choose **Service List** > **Elastic Cloud Server** to switch to the ECS management console and create an ECS.

- The **AZ**, **VPC**, and **Security Group** of the ECS must be the same as those of the cluster to be accessed.
- Select a Windows public image. For example, a standard image **Windows Server 2012 R2 Standard 64bit(40GB)**.
- For details about other configuration parameters, see **Elastic Cloud Server > User Guide > Getting Started > Creating and Logging In to a Windows ECS**.

NOTE

If the security group of the ECS is different from **Default Security Group** of the Master node, you can modify the configuration using either of the following methods:

- Change the security group of the ECS to the default security group of the Master node. For details, see **Elastic Cloud Server** > **User Guide** > **Security Group** > **Changing a Security Group**.
- Add two security group rules to the security groups of the Master and Core nodes to enable the ECS to access the cluster. Set **Protocol** to **TCP**, **Ports** of the two security group rules to **28443** and **20009**, respectively. For details, see **Virtual Private Cloud > User Guide > Security > Security Group > Adding a Security Group Rule**.

Step 4 On the VPC management console, apply for an EIP and bind it to the ECS.

For details, see **Virtual Private Cloud** > **User Guide** > **Elastic IP** > **Assigning an EIP and Binding It to an ECS**.

Step 5 Log in to the ECS.

The Windows system account, password, EIP, and the security group rules are required for logging in to the ECS. For details, see **Elastic Cloud Server > User Guide > Instances > Logging In to a Windows ECS**.

Step 6 On the Windows remote desktop, use your browser to access Manager.

For example, you can use Internet Explorer 11 in the Windows 2012 OS.

The address for accessing Manager is the address of the **MRS Manager** page. Enter the name and password of the cluster user, for example, user **admin**.

NOTE

- If you access Manager with other cluster usernames, change the password upon your first access. The new password must meet the requirements of the current password complexity policies. For details, contact the administrator.
- By default, a user is locked after inputting an incorrect password five consecutive times. The user is automatically unlocked after 5 minutes.

----End

12.29.3 Using an MRS Client

12.29.3.1 Installing a Client (Version 3.x or Later)

Scenario

This section describes how to install clients of all services (excluding Flume) in an MRS cluster. For details about how to install the Flume client, see **Installing the Flume Client**.

A client can be installed on a node inside or outside the cluster. This section uses the installation directory **//opt/client** as an example. Replace it with the actual one.

Prerequisites

- A Linux ECS has been prepared. For details about the supported OS of the ECS, see **Table 12-480**.

  Table 12-480 Reference list

CPU Architecture	OS	Supported Version
x86 computing	Euler	Euler OS 2.5
	SuSE	SUSE Linux Enterprise Server 12 SP4 (SUSE 12.4)
	Red Hat	Red Hat-7.5-x86_64 (Red Hat 7.5)
	CentOS	CentOS 7.6
Kunpeng computing (Arm)	Euler	Euler OS 2.8
	CentOS	CentOS 7.6

  In addition, sufficient disk space is allocated for the ECS, for example, 40 GB.
- The ECS and the MRS cluster are in the same VPC.
- The security group of the ECS must be the same as that of the master node in the MRS cluster.

- The NTP service has been installed on the ECS OS and is running properly.

  If the NTP service is not installed, run the **yum install ntp -y** command to install it when the **yum** source is configured.
- A user can log in to the Linux ECS using the password (in SSH mode).

Installing a Client on a Node Inside a Cluster

1. Obtain the software package.

   Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager (MRS 3.x or Later)**. Click the name of the cluster to be operated in the **Cluster** drop-down list.

   Choose **More > Download Client**. The **Download Cluster Client** dialog box is displayed.

   NOTE

   In the scenario where only one client is to be installed, choose **Cluster > Service >** *Service name* **> More > Download Client**. The **Download Client** dialog box is displayed.

2. Set the client type to **Complete Client**.

   Configuration Files Only is to download client configuration files in the following scenario: After a complete client is downloaded and installed and administrators modify server configurations on Manager, developers need to update the configuration files during application development.

   The platform type can be set to **x86_64** or **aarch64**.

   - **x86_64**: indicates the client software package that can be deployed on the x86 servers.
   - **aarch64**: indicates the client software package that can be deployed on the TaiShan servers.

   NOTE

   The cluster supports two types of clients: **x86_64** and **aarch64**. The client type must match the architecture of the node for installing the client. Otherwise, client installation will fail.

3. Select **Save to Path** and click **OK** to generate the client file.

   The generated file is stored in the **/tmp/FusionInsight-Client** directory on the active management node by default. You can also store the client file in a directory on which user **omm** has the read, write, and execute permissions. Copy the software package to the file directory on the server where the client is to be installed as user **omm** or **root**.

   The name of the client software package is in the follow format: **FusionInsight_Cluster_***<Cluster ID>***_Services_Client.tar**.

   The following steps and sections use **FusionInsight_Cluster_1_Services_Client.tar** as an example.

NOTE

If you cannot obtain the permissions of user **root**, use user **omm**.

To install the client on another node in the cluster, run the following command to copy the client to the node where the client is to be installed:

scp -p /*tmp/FusionInsight-Client***/FusionInsight_Cluster_1_Services_Client.tar** *IP address of the node where the client is to be installed:/opt/Bigdata/client*

4. Log in to the server where the client software package is located as user **user_client**.
5. Decompress the software package.

   Go to the directory where the installation package is stored, such as **/tmp/FusionInsight-Client**. Run the following command to decompress the installation package to a local directory:

   tar -xvf FusionInsight_Cluster_1_Services_Client.tar
6. Verify the software package.

   Run the following command to verify the decompressed file and check whether the command output is consistent with the information in the **sha256** file.

   sha256sum -c FusionInsight_Cluster_1_Services_ClientConfig.tar.sha256

   ```
   FusionInsight_Cluster_1_Services_ClientConfig.tar: OK
   ```
7. Decompress the obtained installation file.

   tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar
8. Go to the directory where the installation package is stored, and run the following command to install the client to a specified directory (an absolute path), for example, **/opt/client**:

   cd /tmp/FusionInsight-ClientFusionInsight_Cluster_1_Services_ClientConfig

   Run the **./install.sh /opt/client** command to install the client. The client is successfully installed if information similar to the following is displayed:

   ```
   The component client is installed successfully
   ```

   NOTE

   - If the clients of all or some services use the **/opt/client** directory, other directories must be used when you install other service clients.
   - You must delete the client installation directory when uninstalling a client.
   - To ensure that an installed client can only be used by the installation user (for example, **user_client**), add parameter **-o** during the installation. That is, run the **./install.sh /opt/client -o** command to install the client.
   - If an HBase client is installed, it is recommended that the client installation directory contain only uppercase and lowercase letters, digits, and characters (_-?.@+=) due to the limitation of the Ruby syntax used by HBase.

Using a Client

1. On the node where the client is installed, run the **sudo su - omm** command to switch the user. Run the following command to go to the client directory:

   cd /opt/client
2. Run the following command to configure environment variables:

   source bigdata_env

3. If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user. If Kerberos authentication is disabled for the current cluster, skip this step.

   kinit *MRS cluster user*

   Example: **kinit admin**

   NOTE

   User **admin** is created by default for MRS clusters with Kerberos authentication enabled and is used for administrators to maintain the clusters.

4. Run the client command of a component directly.

   For example, run the **hdfs dfs -ls /** command to view files in the HDFS root directory.

Installing a Client on a Node Outside a Cluster

1. Create an ECS that meets the requirements in **Prerequisites**.
2. Perform NTP time synchronization to synchronize the time of nodes outside the cluster with that of the MRS cluster.

   a. Run the **vi /etc/ntp.conf** command to edit the NTP client configuration file, add the IP addresses of the master node in the MRS cluster, and comment out the IP address of other servers.

   ```
   server master1_ip prefer
   server master2_ip
   ```

   Figure 12-75 Adding the master node IP addresses

   
   b. Run the **service ntpd stop** command to stop the NTP service.

   c. Run the **/usr/sbin/ntpdate** *IP address of the active master node* command to manually synchronize time.

   d. Run the **service ntpd start** or **systemctl restart ntpd** command to start the NTP service.

   e. Run the **ntpstat** command to check the time synchronization result.

3. Perform the following steps to download the cluster client software package from FusionInsight Manager, copy the package to the ECS node, and install the client:

   a. Log in to FusionInsight Manager and download the cluster client to the specified directory on the active management node by referring to

Accessing FusionInsight Manager (MRS 3.x or Later) and **Installing a Client on a Node Inside a Cluster**.

b. Log in to the active management node as user **root** and run the following command to copy the client installation package to the target node:

scp -p /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Services_Client.tar *IP address of the node where the client is to be installed*:**/tmp**

c. Log in to the node on which the client is to be installed as the client user.

Run the following commands to install the client. If the user does not have operation permissions on the client software package and client installation directory, grant the permissions using the **root** user.

cd /tmp

tar -xvf FusionInsight_Cluster_1_Services_Client.tar

tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar

cd FusionInsight_Cluster_1_Services_ClientConfig

./install.sh /opt/client

d. Run the following commands to switch to the client directory and configure environment variables:

cd /opt/client

source bigdata_env

e. If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user. If Kerberos authentication is disabled for the current cluster, skip this step.

kinit *MRS cluster user*

Example: **kinit admin**

f. Run the client command of a component directly.

For example, run the **hdfs dfs -ls /** command to view files in the HDFS root directory.

12.29.3.2 Installing a Client (Versions Earlier Than 3.x)

Scenario

An MRS client is required. The MRS cluster client can be installed on the Master or Core node in the cluster or on a node outside the cluster.

After a cluster of versions earlier than MRS 3.x is created, a client is installed on the active Master node by default. You can directly use the client. The installation directory is **/opt/client**.

For details about how to install a client of MRS 3.x or later, see **Installing a Client (Version 3.x or Later)**.

NOTE

If a client has been installed on the node outside the MRS cluster and the client only needs to be updated, update the client using the user who installed the client, for example, user **root**.

Prerequisites

- An ECS has been prepared. For details about the OS and its version of the ECS, see **Table 12-481**.

  Table 12-481 Reference list

OS	Supported Version
EulerOS	• Available: EulerOS 2.2 • Available: EulerOS 2.3 • Available: EulerOS 2.5

  For example, a user can select an ECS running the EulerOS.

  In addition, sufficient disk space is allocated for the ECS, for example, 40 GB.
- The ECS and the MRS cluster are in the same VPC.
- The security group of the ECS is the same as that of the Master node of the MRS cluster.

  If this requirement is not met, modify the ECS security group or configure the inbound and outbound rules of the ECS security group to allow the ECS security group to be accessed by all security groups of MRS cluster nodes.
- To enable users to log in to a Linux ECS using a password (SSH), see ***Instances* > *Logging In to a Linux ECS* > *Login Using an SSH Password*** *in the Elastic Cloud Server User Guide*.

Installing a Client on the Core Node

1. Log in to MRS Manager and choose **Services** > **Download Client** to download the client installation package to the active management node.

   NOTE

   If only the client configuration file needs to be updated, see method 2 in **Updating a Client (Versions Earlier Than 3.x)**.
2. Use the IP address to search for the active management node, and log in to the active management node using VNC.
3. Log in to the active management node, and run the following command to switch the user:

   sudo su - omm
4. On the MRS management console, view the IP address on the **Nodes** tab page of the specified cluster.

   Record the IP address of the Core node where the client is to be used.
5. On the active management node, run the following command to copy the client installation package to the Core node:

   scp -p /tmp/MRS-client/MRS_Services_Client.tar *IP address of the Core node*:**/opt/client**
6. Log in to the Core node as user **root**.

Master nodes support Cloud-Init. The preset username for Cloud-Init is **root** and the password is the one you set during cluster creation.

7. Run the following commands to install the client:

   cd /opt/client

   tar -xvf MRS_Services_Client.tar

   tar -xvf MRS_Services_ClientConfig.tar

   cd /opt/client/MRS_Services_ClientConfig

   ./install.sh *Client installation directory*

   For example, run the following command:

   ./install.sh /opt/client

8. For details about how to use the client, see **Using an MRS Client**.

Using an MRS Client

1. On the node where the client is installed, run the **sudo su - omm** command to switch the user. Run the following command to go to the client directory:

   cd /opt/client

2. Run the following command to configure environment variables:

   source bigdata_env

3. If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user. If Kerberos authentication is disabled for the current cluster, skip this step.

   kinit *MRS cluster user*

   Example: **kinit admin**

   NOTE

   User **admin** is created by default for MRS clusters with Kerberos authentication enabled and is used for administrators to maintain the clusters.

4. Run the client command of a component directly.

   For example, run the **hdfs dfs -ls /** command to view files in the HDFS root directory.

Installing a Client on a Node Outside the Cluster

Step 1 Create an ECS that meets the requirements in the prerequisites.

Step 2 Log in to MRS Manager. For details, see **Accessing MRS Manager (Versions Earlier Than MRS 3.x)**. Then, choose **Services**.

Step 3 Click **Download Client**.

Step 4 In **Client Type**, select **All client files**.

Step 5 In **Download To**, select **Remote host**.

Step 6 Set **Host IP Address** to the IP address of the ECS, **Host Port** to **22**, and **Save Path** to **/tmp**.

- If the default port **22** for logging in to an ECS using SSH has been changed, set **Host Port** to the new port.

- **Save Path** contains a maximum of 256 characters.

Step 7 Set **Login User** to **root**.

If other users are used, ensure that the users have read, write, and execute permission on the save path.

Step 8 Select **Password** or **SSH Private Key** for **Login Mode**.

- **Password**: Enter the password of user **root** set during cluster creation.
- **SSH Private Key**: Select and upload the key file used for creating the cluster.

Step 9 Click **OK** to generate a client file.

If the following information is displayed, the client package is saved. Click **Close**. Obtain the client file from the save path on the remote host that is set when the client is downloaded.

```
Client files downloaded to the remote host successfully.
```

If the following information is displayed, check the username, password, and security group configurations of the remote host. Ensure that the username and password are correct and an inbound rule of the SSH (22) port has been added to the security group of the remote host. And then, go to **Step 2** to download the client again.

```
Failed to connect to the server. Please check the network connection or parameter settings.
```

NOTE

Generating a client will occupy a large number of disk I/Os. You are advised not to download a client when the cluster is being installed, started, and patched, or in other unstable states.

Step 10 Log in to the ECS using VNC. For details, see **Instance** > **Logging In to a Linux** > **Logging In to a Linux** in the *Elastic Cloud Server User Guide*

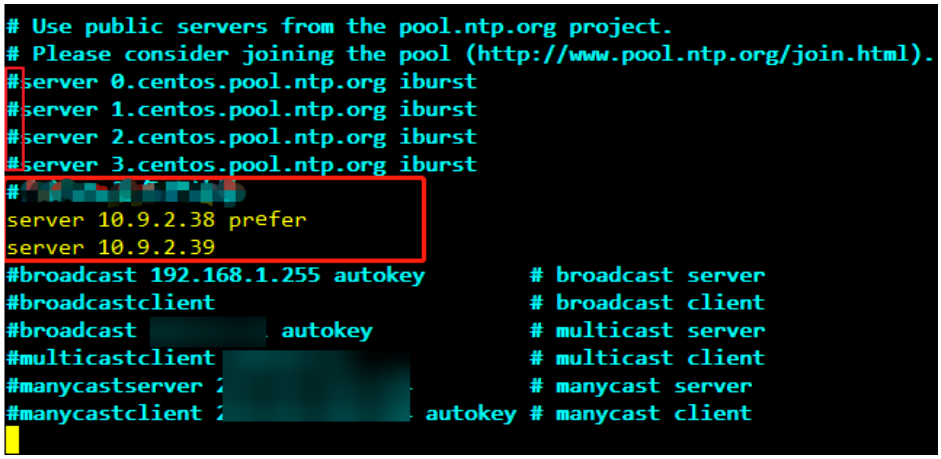
All images support Cloud-Init. The preset username for Cloud-Init is **root** and the password is the one you set during cluster creation. It is recommended that you change the password upon the first login.

Step 11 Perform NTP time synchronization to synchronize the time of nodes outside the cluster with the time of the MRS cluster.

1. Check whether the NTP service is installed. If it is not installed, run the **yum install ntp -y** command to install it.
2. Run the **vim /etc/ntp.conf** command to edit the NTP client configuration file, add the IP address of the Master node in the MRS cluster, and comment out the IP addresses of other servers.

   ```
   server master1_ip prefer
   server master2_ip
   ```

Figure 12-76 Adding the master node IP addresses



3. Run the **service ntpd stop** command to stop the NTP service.
4. Run the**/usr/sbin/ntpdate** *IP address of the active Master node* command to manually synchronize the time.
5. Run the **service ntpd start** or **systemctl restart ntpd** command to start the NTP service.
6. Run the **ntpstat** command to check the time synchronization result:

Step 12 On the ECS, switch to user **root** and copy the installation package in **Save Path** in **Step 6** to the **/opt** directory. For example, if **Save Path** is set to **/tmp**, run the following commands:

sudo su - root

cp /tmp/MRS_Services_Client.tar /opt

Step 13 Run the following command in the **/opt** directory to decompress the package and obtain the verification file and the configuration package of the client:

tar -xvf MRS_Services_Client.tar

Step 14 Run the following command to verify the configuration file package of the client:

sha256sum -c MRS_Services_ClientConfig.tar.sha256

The command output is as follows:

```
MRS_Services_ClientConfig.tar: OK
```

Step 15 Run the following command to decompress **MRS_Services_ClientConfig.tar**:

tar -xvf MRS_Services_ClientConfig.tar

Step 16 Run the following command to install the client to a new directory, for example, **/opt/Bigdata/client**. A directory is automatically generated during the client installation.

sh /opt/MRS_Services_ClientConfig/install.sh /opt/Bigdata/client

If the following information is displayed, the client has been successfully installed:

```
Components client installation is complete.
```

Step 17 Check whether the IP address of the ECS node is connected to the IP address of the cluster Master node.

For example, run the following command: **ping** *Master node IP address*.

- If yes, go to **Step 18**.
- If no, check whether the VPC and security group are correct and whether the ECS and the MRS cluster are in the same VPC and security group, and go to **Step 18**.

Step 18 Run the following command to configure environment variables:

source /opt/Bigdata/client/bigdata_env

Step 19 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user. If Kerberos authentication is disabled for the current cluster, skip this step.

kinit *MRS cluster user*

Example: **kinit admin**

Step 20 Run the client command of a component.

For example, run the following command to query the HDFS directory:

hdfs dfs -ls /

----End

12.29.3.3 Updating a Client (Version 3.x or Later)

A cluster provides a client for you to connect to a server, view task results, or manage data. If you modify service configuration parameters on Manager and restart the service, you need to download and install the client again or use the configuration file to update the client.

Updating the Client Configuration

Method 1:

Step 1 Log in to FusionInsight Manager. For details, see **Accessing MRS Manager (Versions Earlier Than MRS 3.x)**. Click the name of the cluster to be operated in the **Cluster** drop-down list.

Step 2 Choose **More** > **Download Client** > **Configuration Files Only**.

The generated compressed file contains the configuration files of all services.

Step 3 Determine whether to generate a configuration file on the cluster node.

- If yes, select **Save to Path**, and click **OK** to generate the client file. By default, the client file is generated in **/tmp/FusionInsight-Client** on the active management node. You can also store the client file in other directories, and user **omm** has the read, write, and execute permissions on the directories. Then go to **Step 4**.
- If no, click **OK**, specify a local save path, and download the complete client. Wait until the download is complete and go to **Step 4**.

Step 4 Use WinSCP to save the compressed file to the client installation directory, for example, **/opt/hadoopclient**, as the client installation user.

Step 5 Decompress the software package.

Run the following commands to go to the directory where the client is installed, and decompress the file to a local directory. For example, the downloaded client file is **FusionInsight_Cluster_1_Services_Client.tar**.

cd /opt/hadoopclient

tar -xvf FusionInsight_Cluster_1_Services_Client.tar

Step 6 Verify the software package.

Run the following command to verify the decompressed file and check whether the command output is consistent with the information in the **sha256** file.

sha256sum -c FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar.sha256

```
FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar: OK
```

Step 7 Decompress the package to obtain the configuration file.

tar -xvf FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar

Step 8 Run the following command in the client installation directory to update the client using the configuration file:

sh refreshConfig.sh *Client installation directory Directory where the configuration file is located*

For example, run the following command:

sh refreshConfig.sh /opt/hadoopclient /opt/hadoopclient/FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles

If the following information is displayed, the configurations have been updated successfully.

```
Succeed to refresh components client config.
```

----End

Method 2:

Step 1 Log in to the client installation node as user **root**.

Step 2 Go to the client installation directory, for example, **/opt/hadoopclient** and run the following commands to update the configuration file:

cd /opt/hadoopclient

sh autoRefreshConfig.sh

Step 3 Enter the username and password of the FusionInsight Manager administrator and the floating IP address of FusionInsight Manager.

Step 4 Enter the names of the components whose configuration needs to be updated. Use commas (,) to separate the component names. Press **Enter** to update the configurations of all components if necessary.

If the following information is displayed, the configurations have been updated successfully.

```
Succeed to refresh components client config.
```

----End

12.29.3.4 Updating a Client (Versions Earlier Than 3.x)

NOTE

This section applies to clusters of versions earlier than MRS 3.x. For MRS 3.x or later, see **Updating a Client (Version 3.x or Later)**.

Updating a Client Configuration File

Scenario

An MRS cluster provides a client for you to connect to a server, view task results, or manage data. Before using an MRS client, you need to download and update the client configuration file if service configuration parameters are modified and a service is restarted or the service is merely restarted on MRS Manager.

During cluster creation, the original client is stored in the **/opt/client** directory on all nodes in the cluster by default. After the cluster is created, only the client of a Master node can be directly used. To use the client of a Core node, you need to update the client configuration file first.

Procedure

Method 1:

Step 1 Log in to MRS Manager. For details, see **Accessing MRS Manager (Versions Earlier Than MRS 3.x)**. Then, choose **Services**.

Step 2 Click **Download Client**.

Set **Client Type** to **Only configuration files**, **Download To** to **Server**, and click **OK** to generate the client configuration file. The generated file is saved in the **/tmp/MRS-client** directory on the active management node by default. You can customize the file path.

Step 3 Query and log in to the active Master node.

Step 4 If you use the client in the cluster, run the following command to switch to user **omm**. If you use the client outside the cluster, switch to user **root**.

sudo su - omm

Step 5 Run the following command to switch to the client directory, for example, **/opt/Bigdata/client**:

cd /opt/Bigdata/client

Step 6 Run the following command to update client configurations:

sh refreshConfig.sh *Client installation directory Full path of the client configuration file package*

For example, run the following command:

sh refreshConfig.sh /opt/Bigdata/client /tmp/MRS-client/MRS_Services_Client.tar

If the following information is displayed, the configurations have been updated successfully.

```
ReFresh components client config is complete.
Succeed to refresh components client config.
```

----End

Method 2:

Step 1 After the cluster is installed, run the following command to switch to user **omm**. If you use the client outside the cluster, switch to user **root**.

sudo su - omm

Step 2 Run the following command to switch to the client directory, for example, **/opt/Bigdata/client**:

cd /opt/Bigdata/client

Step 3 Run the following command and enter the name of an MRS Manager user with the download permission and its password (for example, the username is **admin** and the password is the one set during cluster creation) as prompted to update client configurations.

sh autoRefreshConfig.sh

Step 4 After the command is executed, the following information is displayed, where *XXX* indicates the name of the component installed in the cluster. To update client configurations of all components, press **Enter**. To update client configurations of some components, enter the component names and separate them with commas (,).

```
Components "xxx" have been installed in the cluster. Please input the comma-separated names of the components for which you want to update client configurations. If you press Enter without inputting any component name, the client configurations of all components will be updated:
```

If the following information is displayed, the configurations have been updated successfully.

```
Succeed to refresh components client config.
```

If the following information is displayed, the username or password is incorrect.

```
login manager failed,Incorrect username or password.
```

NOTE

- This script automatically connects to the cluster and invokes the **refreshConfig.sh** script to download and update the client configuration file.
- By default, the client uses the floating IP address specified by **wsom=xxx** in the **Version** file in the installation directory to update the client configurations. To update the configuration file of another cluster, modify the value of **wsom=xxx** in the **Version** file to the floating IP address of the corresponding cluster before performing this step.

----End

Fully Updating the Original Client of the Active Master Node

Scenario

During cluster creation, the original client is stored in the **/opt/client** directory on all nodes in the cluster by default. The following uses **/opt/Bigdata/client** as an example.

- For a normal MRS cluster, you will use the pre-installed client on a Master node to submit a job on the management console page.
- You can also use the pre-installed client on the Master node to connect to a server, view task results, and manage data.

After installing the patch on the cluster, you need to update the client on the Master node to ensure that the functions of the built-in client are available.

Procedure

Step 1 Log in to MRS Manager. For details, see **Accessing MRS Manager (Versions Earlier Than MRS 3.x)**. Then, choose **Services**.

Step 2 Click **Download Client**.

Set **Client Type** to **All client files**, **Download To** to **Server**, and click **OK** to generate the client configuration file. The generated file is saved in the **/tmp/MRS-client** directory on the active management node by default. You can customize the file path.

Step 3 Query and log in to the active Master node.

Step 4 On the ECS, switch to user **root** and copy the installation package to the **/opt** directory.

sudo su - root

cp /tmp/MRS-client/MRS_Services_Client.tar /opt

Step 5 Run the following command in the **/opt** directory to decompress the package and obtain the verification file and the configuration package of the client:

tar -xvf MRS_Services_Client.tar

Step 6 Run the following command to verify the configuration file package of the client:

sha256sum -c MRS_Services_ClientConfig.tar.sha256

The command output is as follows:

```
MRS_Services_ClientConfig.tar: OK
```

Step 7 Run the following command to decompress **MRS_Services_ClientConfig.tar**:

tar -xvf MRS_Services_ClientConfig.tar

Step 8 Run the following command to move the original client to the **/opt/Bigdata/client_bak** directory:

mv /opt/Bigdata/client /opt/Bigdata/client_bak

Step 9 Run the following command to install the client in a new directory. The client path must be **/opt/Bigdata/client**.

sh /opt/MRS_Services_ClientConfig/install.sh /opt/Bigdata/client

If the following information is displayed, the client has been successfully installed:

```
Components client installation is complete.
```

Step 10 Run the following command to modify the user and user group of the **/opt/Bigdata/client** directory:

chown omm:wheel /opt/Bigdata/client -R

Step 11 Run the following command to configure environment variables:

source /opt/Bigdata/client/bigdata_env

Step 12 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user. If Kerberos authentication is disabled for the current cluster, skip this step.

kinit *MRS cluster user*

Example: **kinit admin**

Step 13 Run the client command of a component.

For example, run the following command to query the HDFS directory:

hdfs dfs -ls /

----End

Fully Updating the Original Client of the Standby Master Node

Step 1 Repeat **Step 1** to **Step 3** to log in to the standby Master node, and run the following command to switch to user **omm**:

sudo su - omm

Step 2 Run the following command on the standby master node to copy the downloaded client package from the active master node:

scp omm@*master1 nodeIP address***:/tmp/MRS-client/MRS_Services_Client.tar /tmp/MRS-client/**

NOTE

- In this command, **master1** node is the active master node.
- **/tmp/MRS-client/** is an example target directory of the standby master node.

Step 3 Repeat **Step 4** to **Step 13** to update the client of the standby Master node.

----End

13 Security Description

13.1 Security Configuration Suggestions for Clusters with Kerberos Authentication Disabled

The Hadoop community version provides two authentication modes: Kerberos authentication (security mode) and Simple authentication (normal mode). When creating a cluster, you can choose to enable or disable Kerberos authentication.

Clusters in security mode use the Kerberos protocol for security authentication.

In normal mode, MRS cluster components use a native open source authentication mechanism, which is typically Simple authentication. If Simple authentication is used, authentication is automatically performed by a client user (for example, user **root**) by default when a client connects to a server. The authentication is imperceptible to the administrator or service user. In addition, when being executed, the client may even pretend to be any user (including **superuser**) by injecting **UserGroupInformation**. Cluster resource management and data control APIs are not authenticated on the server and are easily exploited and attacked by hackers.

Therefore, in normal mode, network access permissions must be strictly controlled to ensure cluster security. You are advised to perform the following operations to ensure cluster security.

- Deploy service applications on ECSs in the same VPC and subnet and avoid accessing MRS clusters through an external network.
- Configure security group rules to strictly control the access scope. Do not configure access rules that allow **Any** or **0.0.0.0** for the inbound direction of MRS cluster ports.
- If you want to access the native pages of the components in the cluster from the external, follow instructions in **Creating an SSH Channel for Connecting to an MRS Cluster and Configuring the Browser** for configuration.

13.2 Security Authentication Principles and Mechanisms

Function

For clusters in security mode with Kerberos authentication enabled, security authentication is required during application development.

Kerberos, is now used to a concept in authentication. The Kerberos protocol adopts a client–server model and cryptographic algorithms such as AES (Advanced Encryption Standard). It provides mutual authentication, that is, both the client and the server can verify each other's identity. Kerberos is used to prevent interception and replay attacks and protect data integrity. It is a system that manages keys by using a symmetric key mechanism.

Architecture

Kerberos architecture is shown in **Figure 13-1** and module description in **Table 13-1**.

Figure 13-1 Kerberos architecture

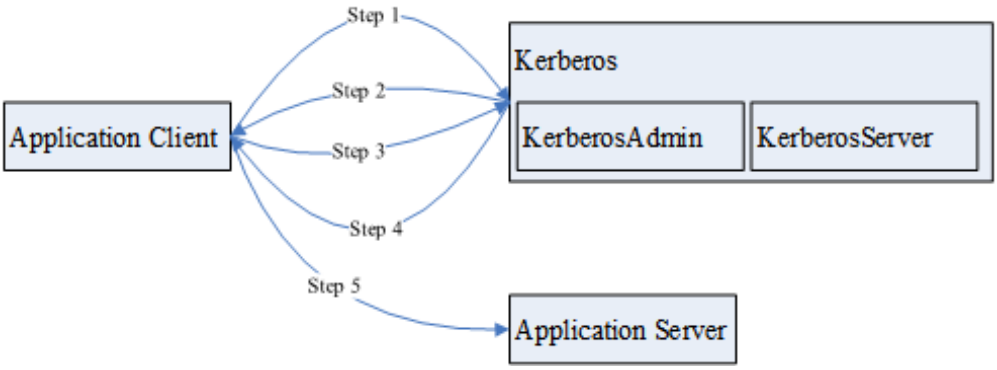


Table 13-1 Module description

Module	Description
Application Client	An application client, which is usually an application that submits tasks or jobs
Application Server	An application server, which is usually an application that an application client accesses
Kerberos	A service that provides security authentication

Module	Description
KerberosAdmin	A process that provides authentication user management
KerberosServer	A process that provides authentication ticket distribution

The process and principle are described as follows:

An application client can be a service in a cluster or a secondary development application of the customer. An application client can submit tasks or jobs to an application service.

1. Before submitting a task or job, the application client needs to apply for a ticket granting ticket (TGT) from the Kerberos service to establish a secure session with the Kerberos server.
2. After receiving the TGT request, the Kerberos service resolves parameters in the request to generate a TGT, and uses the key of the username specified by the client to encrypt the response.
3. After receiving the TGT response, the application client (based on the underlying RPC) resolves the response and obtains the TGT, and then applies for a server ticket (ST) of the application server from the Kerberos service.
4. After receiving the ST request, the Kerberos service verifies the TGT validity in the request and generates an ST of the application service, and then uses the application service key to encrypt the response.
5. After receiving the ST response, the application client packages the ST into a request and sends the request to the application server.
6. After receiving the request, the application server uses its local application service key to resolve the ST. After successful verification, the request becomes valid.

Basic Concepts

The following concepts can help users learn the Kerberos architecture quickly and understand the Kerberos service better. The following uses security authentication for HDFS as an example.

TGT

A TGT is generated by the Kerberos service and used to establish a secure session between an application and the Kerberos server. The validity period of a TGT is 24 hours. After 24 hours, the TGT expires automatically.

The following describes how to apply for a TGT (HDFS is used as an example):

1. Obtain a TGT through an API provided by HDFS.

```
/**
 * login Kerberos to get TGT, if the cluster is in security mode
 * @throws IOException if login is failed
 */
 private void login() throws IOException {
 // not security mode, just return
   if (! "kerberos".equalsIgnoreCase(conf.get("hadoop.security.authentication"))) {
```

```
        return;
    }

    //security mode
    System.setProperty("java.security.krb5.conf", PATH_TO_KRB5_CONF);

    UserGroupInformation.setConfiguration(conf);
    UserGroupInformation.loginUserFromKeytab(PRNCIPAL_NAME, PATH_TO_KEYTAB);
  }
```

2. Run shell commands on the client in kinit mode.

ST

An ST is generated by the Kerberos service and used to establish a secure session between an application and application service. An ST is valid only once.

In FusionInsight products, the generation of an ST is based on the Hadoop-RPC communication. The underlying RPC submits a request to the Kerberos server and the Kerberos server generates an ST.

Sample Authentication Code

```
package com.xxx.bigdata.hdfs.examples;

import java.io.IOException;

import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.fs.FileStatus;
import org.apache.hadoop.fs.FileSystem;
import org.apache.hadoop.fs.Path;
import org.apache.hadoop.security.UserGroupInformation;

public class KerberosTest {
    private static String PATH_TO_HDFS_SITE_XML = KerberosTest.class.getClassLoader().getResource("hdfs-
site.xml")
            .getPath();
    private static String PATH_TO_CORE_SITE_XML = KerberosTest.class.getClassLoader().getResource("core-
site.xml")
            .getPath();
    private static String PATH_TO_KEYTAB =
KerberosTest.class.getClassLoader().getResource("user.keytab").getPath();
    private static String PATH_TO_KRB5_CONF =
KerberosTest.class.getClassLoader().getResource("krb5.conf").getPath();
    private static String PRNCIPAL_NAME = "develop";
    private FileSystem fs;
    private Configuration conf;

    /**
     * initialize Configuration
     */
    private void initConf() {
        conf = new Configuration();

        // add configuration files
        conf.addResource(new Path(PATH_TO_HDFS_SITE_XML));
        conf.addResource(new Path(PATH_TO_CORE_SITE_XML));
    }

    /**
     * login Kerberos to get TGT, if the cluster is in security mode
     * @throws IOException if login is failed
     */
    private void login() throws IOException {
        // not security mode, just return
        if (! "kerberos".equalsIgnoreCase(conf.get("hadoop.security.authentication"))) {
            return;
        }
```

```
        //security mode
        System.setProperty("java.security.krb5.conf", PATH_TO_KRB5_CONF);

        UserGroupInformation.setConfiguration(conf);
        UserGroupInformation.loginUserFromKeytab(PRNCIPAL_NAME, PATH_TO_KEYTAB);
    }

    /**
     * initialize FileSystem, and get ST from Kerberos
     * @throws IOException
     */
    private void initFileSystem() throws IOException {
        fs = FileSystem.get(conf);
    }

    /**
     * An example to access the HDFS
     * @throws IOException
     */
    private void doSth() throws IOException {
        Path path = new Path("/tmp");
        FileStatus fStatus = fs.getFileStatus(path);
        System.out.println("Status of " + path + " is " + fStatus);
        //other thing
    }

    public static void main(String[] args) throws Exception {
        KerberosTest test = new KerberosTest();
        test.initConf();
        test.login();
        test.initFileSystem();
        test.doSth();
    }
}
```

NOTE

1. During Kerberos authentication, you need to configure the file parameters required for configuring the Kerberos authentication, including the keytab path, Kerberos authentication username, and the **krb5.conf** configuration file of the client for Kerberos authentication.
2. Method **login()** indicates calling the Hadoop API to perform Kerberos authentication and generating a TGT.
3. Method **doSth** indicates calling the Hadoop API to access the file system. In this situation, the underlying RPC automatically carries the TGT to Kerberos for verification and then an ST is generated.

14 High-Risk Operations Overview

Forbidden Operations

Table 14-1 lists forbidden operations during the routine cluster operation and maintenance process.

Table 14-1 Forbidden operations

Item	Risk
Delete ZooKeeper data directories.	ClickHouse, HDFS, Yarn, HBase, and Hive depend on ZooKeeper, which stores metadata. This operation has adverse impact on normal operating of related components.
Performing switchover frequently between active and standby JDBCServer nodes	This operation may interrupt services.
Delete Phoenix system tables and data (SYSTEM.CATALOG, SYSTEM.STATS, SYSTEM.SEQUENCE, and SYSTEM.FUNCTION).	This operation will cause service operation failures.
Manually modify data in the Hive metabase (hivemeta database).	This operation may cause Hive data parse errors. As a result, Hive cannot provide services.
Change permission on the Hive private file directory **hdfs:///tmp/hive-scratch**.	This operation may cause unavailable Hive services.
Modify **broker.id** in the Kafka configuration file.	This operation may cause invalid node data.
Modify the host names of nodes.	Instances and upper-layer components on the host cannot provide services properly. The fault cannot be rectified.

Item	Risk
Reinstall the OS of a node.	This operation will cause MRS cluster exceptions, leaving MRS clusters in abnormal status.
Use private images.	This operation will cause MRS cluster exceptions, leaving MRS clusters in abnormal status.

The following tables list the high-risk operations during the operation and maintenance of each component.

High-Risk Operations on a Cluster

Table 14-2 High-risk operations on a cluster

Operation	Risk	Severity	Workaround	Check Item
Modify the file directory or file permissions of user **omm** without permission.	This operation will lead to MRS service unavailability.	▲ ▲ ▲ ▲ ▲	Do not perform this operation.	Check whether the MRS cluster service is available.
Bind an EIP.	This operation exposes the Master node hosting MRS Manager of the cluster to the public network, increasing the risk of network attacks from the Internet.	▲ ▲ ▲ ▲ ▲	Ensure that the bound EIP is a trusted public IP address.	None

Operation	Risk	Severity	Workaround	Check Item
Enable security group rules for port 22 of a cluster.	This operation increases the risk of exploiting vulnerability of port 22.	▲ ▲ ▲ ▲ ▲	Configure a security group rule for port 22 to allow only trusted IP addresses to access the port. You are not advised to configure the inbound rule to allow 0.0.0.0 to access the port.	None
Delete a cluster or cluster data.	Data will get lost.	▲ ▲ ▲ ▲ ▲	Before deleting the data, confirm the necessity of the operation and ensure that the data has been backed up.	None
Scale in a cluster.	Data will get lost.	▲ ▲ ▲ ▲ ▲	Before scaling in the cluster, confirm the necessity of the operation and ensure that the data has been backed up.	None
Detach or format a data disk.	Data will get lost.	▲ ▲ ▲ ▲ ▲	Before performing this operation, confirm the necessity of the operation and ensure that the data has been backed up.	None

Manager High-Risk Operations

Table 14-3 Manager high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Change the OMS password.	This operation will restart all processes of OMSServer, which has adverse impact on cluster maintenance and management.	▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	Check whether there are uncleared alarms and whether the cluster management and maintenance are normal.
Import the certificate.	This operation will restart OMS processes and the entire cluster, which has adverse impact on cluster maintenance and management and services.	▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	Check for uncleared alarms, and check whether the cluster management and maintenance and services are normal.
Perform an upgrade.	This operation will restart Manager and the entire cluster, affecting management, maintenance, and services of the cluster. Strictly manage the user who is eligible to assign the cluster management permission to prevent security risks.	▲ ▲ ▲	Ensure that there is no other maintenance and management operations when the operation is performed.	Check for uncleared alarms, and check whether the cluster management and maintenance and services are normal.

Operation	Risk	Severity	Workaround	Check Item
Restore the OMS.	This operation will restart Manager and the entire cluster, affecting management, maintenance, and services of the cluster.	▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	Check for uncleared alarms, and check whether the cluster management and maintenance and services are normal.
Change an IP address.	This operation will restart Manager and the entire cluster, affecting management, maintenance, and services of the cluster.	▲ ▲ ▲	Ensure that there is no other maintenance and management operations when the operation is performed and that the new IP address is correct.	Check for uncleared alarms, and check whether the cluster management and maintenance and services are normal.
Change log levels.	If the log level is changed to **DEBUG**, Manager responds slowly.	▲ ▲	Before the modification, confirm the necessity of the operation and change it back to the default log level in time.	None

Operation	Risk	Severity	Workaround	Check Item
Replace a control node.	This operation will interrupt services deployed on the node. If the node is a management node, the operation will restart all OMS processes, affecting the cluster management and maintenance.	▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	Check for uncleared alarms, and check whether the cluster management and maintenance and services are normal.
Replace a management node.	This operation will interrupt services deployed on the node. As a result, OMS processes will be restarted, affecting the cluster management and maintenance.	▲ ▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	Check for uncleared alarms, and check whether the cluster management and maintenance and services are normal.
Restart the upper-layer service at the same time during the restart of a lower-layer service.	This operation will interrupt the upper-layer service, affecting the management, maintenance, and services of the cluster.	▲ ▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	Check for uncleared alarms, and check whether the cluster management and maintenance and services are normal.

Operation	Risk	Severity	Workaround	Check Item
Modify the OLDAP port.	This operation will restart the LdapServer and Kerberos services and all associated services, affecting service running.	▲ ▲ ▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	None
Delete the **supergroup** group.	Deleting the **supergroup** group decreases user rights, affecting service access.	▲ ▲ ▲ ▲ ▲	Before the change, confirm the rights to be added. Ensure that the required rights have been added before deleting the **supergroup** rights to which the user is bound, ensuring service continuity.	None
Restart a service.	Services will be interrupted during the restart. If you select and restart the upper-layer service, the upper-layer services that depend on the service will be interrupted.	▲ ▲ ▲	Confirm the necessity of restarting the system before the operation.	Check for uncleared alarms, and check whether the cluster management and maintenance and services are normal.

Operation	Risk	Severity	Workaround	Check Item
Change the default SSH port No.	After the default port (22) is changed, functions such as cluster creation, service/instance adding, host adding, and host reinstallation cannot be used, and results of cluster health check items for node mutual trust, **omm**/**ommdba** user password expiration, and others are incorrect.	▲ ▲ ▲	Before performing this operation, restore the SSH port to the default value.	None

ClickHouse High-Risk Operations

Table 14-4 ClickHouse high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Delete data directories.	This operation may cause service information loss.	▲ ▲ ▲	Do not delete data directories manually.	Check whether data directories are normal.
Remove ClickHouseServer instances.	The ClickHouseServer instance nodes in the same shard must be removed in at the same time. Otherwise, the topology information of the logical cluster is incorrect. Before performing this operation, check the database and data table information of each node in the logical cluster and perform scale-in pre-analysis to ensure that data is successfully migrated during the scale-in process to prevent data loss	▲ ▲ ▲ ▲ ▲	Before scale-in, collect information in advance to learn the status of the ClickHouse logical cluster and instance nodes.	Check the ClickHouse logical cluster topology information, database and data table information in each ClickHouseServer instance, and data volume.

Operation	Risk	Severity	Workaround	Check Item
Add ClickHouseServer instances.	When performing this operation, you must check whether a database or data table with the same name as that on the old node needs to be created on the new node. Otherwise, subsequent data migration, data balancing, scale-in, and decommissioning will fail.	▲ ▲ ▲ ▲ ▲	Before scale-out, confirm the function and purpose of new ClickHouseServer instances and determine whether to create related databases and data tables.	Check the ClickHouse logical cluster topology information, database and data table information in each ClickHouseServer instance, and data volume.
Decommission ClickHouseServer instances.	The ClickHouseServer instance nodes in the same shard must be decommissioned in at the same time. Otherwise, the topology information of the logical cluster is incorrect. Before performing this operation, check the database and data table information of each node in the logical cluster and perform decommissioning pre-analysis to ensure that data is successfully migrated during the decommissioning process to prevent data loss	▲ ▲ ▲ ▲ ▲	Before decommissioning, collect information in advance to learn the status of the ClickHouse logical cluster and instance nodes.	Check the ClickHouse logical cluster topology information, database and data table information in each ClickHouseServer instance, and data volume.
Recommission ClickHouseServer instances.	When performing this operation, you must select all nodes in the original shard. Otherwise, the topology information of the logical cluster is incorrect.	▲ ▲ ▲ ▲ ▲	Before recommissioning, you need to confirm the home information about the shards of the node to be recommissioned.	Check the ClickHouse logical cluster topology information.

Operation	Risk	Severity	Workaround	Check Item
Modify data directory content (file and folder creation).	This operation may cause the ClickHouse instance of the node faults.	▲ ▲ ▲	Do not create or modify files or folders in the data directories manually.	Check whether data directories are normal.
Start or stop basic components independently.	This operation has adverse impact on the basic functions of some services. As a result, service failures occur.	▲ ▲ ▲	Do not start or stop ZooKeeper, Kerberos, and LDAP basic components independently. Select related services when performing this operation.	Check whether the service status is normal.
Restart or stop services.	This operation may interrupt services.	▲ ▲	Restart or stop services when necessary.	Check whether the service is running properly.

DBService High-Risk Operations

Table 14-5 DBService high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Change the DBService password.	The services need to be restarted for the password change to take effect. The services are unavailable during the restart.	▲ ▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	Check whether there are uncleared alarms and whether the cluster management and maintenance are normal.
Restore DBService data.	After the data is restored, the data generated after the data backup and before the data restoration is lost. After the data is restored, the configuration of the components that depend on DBService may expire and these components need to be restarted.	▲ ▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	Check whether there are uncleared alarms and whether the cluster management and maintenance are normal.

Operation	Risk	Severity	Workaround	Check Item
Perform active/standby DBService switchover.	During the DBServer switchover, DBService is unavailable.	▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	None
Change the DBService floating IP address.	The DBService needs to be restarted for the change to take effect. The DBService is unavailable during the restart. If the floating IP address has been used, the configuration will fail, and the DBService will fail to be started.	▲ ▲ ▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.

Flink High-Risk Operations

Table 14-6 Flink high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Change log levels.	If the log level is modified to DEBUG, the task running performance is affected.	▲ ▲	Before the modification, confirm the necessity of the operation and change it back to the default log level in time.	None

Operation	Risk	Severity	Workaround	Check Item
Modify file permissions.	Tasks may fail.	▲ ▲ ▲	Confirm the necessity of the operation before the modification.	Check whether related service operations are normal.

Flume High-Risk Operations

Table 14-7 Flume high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Modify the Flume instance start parameter **GC_OPTS**.	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.
Change the default value of **dfs.replication** from **3** to **1**.	This operation will have the following impacts: 1. The storage reliability deteriorates. If the disk becomes faulty, data will be lost. 2. NameNode fails to be restarted, and the HDFS service is unavailable.	▲ ▲ ▲ ▲	When modifying related configuration items, check the parameter description carefully. Ensure that there are more than two replicas for data storage.	Check whether the default replica number is not 1 and whether the HDFS service is normal.

HBase High-Risk Operations

Table 14-8 HBase high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Modify encryption configuration. • hbase.regionserver.wal.encryption • hbase.crypto.keyprovider.parameters.uri • hbase.crypto.keyprovider.parameters.encryptedtext	Services cannot start properly.	▲ ▲ ▲ ▲	Strictly follow the prompt information when modifying related configuration items, which are associated. Ensure that new values are valid.	Check whether services can be started properly.

Operation	Risk	Severity	Workaround	Check Item
Change the value of **hbase.regionserver.wal.encryption** to **false** or switch encryption algorithm from AES to SMS4.	This operation may cause start failures and data loss.	▲ ▲ ▲ ▲	When HFile and WAL are encrypted using an encryption algorithm and a table is created, do not close or switch the encryption algorithm randomly. If an encryption table (ENCRYPTION=>AES/SMS4) is not created, you can only switch the encryption algorithm.	None
Modify HBase instance start parameter **GC_OPTS** and **HBASE_HEAPSIZE**.	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid. GC_OPTS does not conflict with HBASE_HEAPSIZE.	Check whether services can be started properly.
Use **OfflineMetaRepair** tool	Services cannot start properly.	▲ ▲ ▲ ▲	This tool can be used only when HBase is offline and cannot be used in data migration scenarios.	Check whether HBase services can be started properly.

HDFS High-Risk Operations

Table 14-9 HDFS high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Change HDFS NameNode data storage directory **dfs.namenode.name.dir** and data configuration directory **dfs.datanode.data.dir**.	Services cannot start properly.	▲ ▲ ▲ ▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.
Use the **-delete** parameter when you run the **hadoop distcp** command.	During DistCP copying, files that do not exist in the source cluster but exist in the destination cluster are deleted from the destination cluster.	▲ ▲	When using DistCP, determine whether to retain the redundant files in the destination cluster. Exercise caution when using the **-delete** parameter.	After DistCP copying is complete, check whether the data in the destination cluster is retained or deleted according to the parameter settings.

Operation	Risk	Severity	Workaround	Check Item
Modify the HDFS instance start parameter **GC_OPTS**, **HADOOP_HEAPSIZE**, and **GC_PROFILE**.	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid. GC_OPTS does not conflict with HADOOP_HEAPSIZE.	Check whether services can be started properly.
Change the default value of **dfs.replication** from **3** to **1**.	This operation will have the following impacts: 1. The storage reliability deteriorates. If the disk becomes faulty, data will be lost. 2. NameNode fails to be restarted, and the HDFS service is unavailable.	▲ ▲ ▲ ▲	When modifying related configuration items, check the parameter description carefully. Ensure that there are more than two replicas for data storage.	Check whether the default replica number is not 1 and whether the HDFS service is normal.
Change the remote procedure call (RPC) channel encryption mode (**hadoop.rpc.protection**) of each module in Hadoop.	This operation causes service faults and service exceptions.	▲ ▲ ▲ ▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether HDFS and other services that depend on HDFS can properly start and provide services.

Hive High-Risk Operations

Table 14-10 Hive high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Modify the Hive instance start parameter **GC_OPTS**.	This operation may cause Hive instance start failures.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.
Delete all MetaStore instances.	This operation may cause Hive metadata loss. As a result, Hive cannot provide services.	▲ ▲ ▲	Do not perform this operation unless ensure that Hive table information can be discarded.	Check whether services can be started properly.
Delete or modify files corresponding to Hive tables over HDFS interfaces or HBase interfaces.	This operation may cause Hive service data loss or tampering.	▲ ▲	Do not perform this operation unless ensure that the data can be discarded or that the operation meets service requirements.	Check whether Hive data is complete.

Operation	Risk	Severity	Workaround	Check Item
Delete or modify files corresponding to Hive tables or directory access permission over HDFS interfaces or HBase interfaces.	This operation may cause related service scenarios to be unavailable.	▲ ▲ ▲	Do not perform this operation.	Check whether related service operations are normal.
Delete or modify **hdfs:///apps/templeton/hive-3.1.0.tar.gz** over HDFS interfaces.	WebHCat fails to perform services due to this operation.	▲ ▲	Do not perform this operation.	Check whether related service operations are normal.
Export table data to overwrite the data at the local. For example, export the data of **t1** to **/opt/dir**. **insert overwrite local directory '/opt/dir' select * from t1;**	This operation will delete target directories. Incorrect setting may cause software or OS startup failures.	▲ ▲ ▲ ▲ ▲	Ensure that the path where the data is written does not contain any files or do not use the key word overwrite in the command.	Check whether files in the target path are lost.

Operation	Risk	Severity	Workaround	Check Item
Direct different databases, tables, or partition files to the same path, for example, default warehouse path **/user/hive/warehouse**.	The creation operation may cause disordered data. After a database, table, or partition is deleted, other object data will be lost.	▲ ▲ ▲ ▲ ▲	Do not perform this operation.	Check whether files in the target path are lost.

Kafka High-Risk Operations

Table 14-11 Kafka high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Delete Topic	This operation may delete existing topics and data.	▲ ▲ ▲	Kerberos authentication is used to ensure that authenticated users have operation permissions. Ensure that topic names are correct.	Check whether topics are processed properly.
Delete data directories.	This operation may cause service information loss.	▲ ▲ ▲	Do not delete data directories manually.	Check whether data directories are normal.

Operation	Risk	Severity	Workaround	Check Item
Modify data directory content (file and folder creation).	This operation may cause the Broker instance of the node faults.	▲ ▲ ▲	Do not create or modify files or folders in the data directories manually.	Check whether data directories are normal.
Modify the disk auto-adaptation function using the **disk.adapter.enable** parameter.	This operation adjusts the topic data retention period when the disk usage reaches the threshold. Historical data that does not fall within the storage retention may be deleted.	▲ ▲ ▲	If the retention period of some topics cannot be adjusted, add this topic to the value of **disk.adapter.topic.blacklist**.	Observe the data storage period on the Kafka topic monitoring page.
Modify data directory **log.dirs** configuration.	Incorrect operation may cause process faults.	▲ ▲ ▲	Ensure that the added or modified data directories are empty and that the directory permissions are right.	Check whether data directories are normal.
Reduce the capacity of the Kafka cluster.	This operation may cause quantity reduction of backups of some data duplicates of topic. As a result, some topics cannot be accessed.	▲ ▲	Perform backup operation and then reduce the capacity of the Kafka cluster.	Check whether backup nodes where partitions are located are activated to ensure data security.

Operation	Risk	Severity	Workaround	Check Item
Start or stop basic components independently.	This operation has adverse impact on the basic functions of some services. As a result, service failures occur.	▲ ▲ ▲	Do not start or stop ZooKeeper, Kerberos, and LDAP basic components independently. Select related services when performing this operation.	Check whether the service status is normal.
Restart or stop services.	This operation may interrupt services.	▲ ▲	Restart or stop services when necessary.	Check whether the service is running properly.
Modify configuration parameters.	This operation requires service restart for configuration to take effect.	▲ ▲	Modify configuration when necessary.	Check whether the service is running properly.
Delete or modify metadata.	Modifying or deleting Kafka metadata on ZooKeeper may cause the Kafka topic or service unavailability.	▲ ▲ ▲	Do not delete or modify Kafka metadata stored on ZooKeeper.	Check whether the Kafka topics or Kafka service is available.
Delete metadata backup files.	After Kafka metadata backup files are modified and used to restore Kafka metadata, Kafka topics or the Kafka service may be unavailable.	▲ ▲ ▲	Do not delete Kafka metadata backup files.	Check whether the Kafka topics or Kafka service is available.

KrbServer High-Risk Operations

Table 14-12 KrbServer high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Modify the **KADMIN_PORT** parameter of KrbServer.	After this parameter is modified, if the KrbServer service and its associated services are not restarted in a timely manner, the configuration of KrbClient in the cluster is abnormal and the service running is affected.	▲ ▲ ▲ ▲ ▲	After this parameter is modified, restart the KrbServer service and all its associated services.	None
Modify the **kdc_ports** parameter of KrbServer.	After this parameter is modified, if the KrbServer service and its associated services are not restarted in a timely manner, the configuration of KrbClient in the cluster is abnormal and the service running is affected.	▲ ▲ ▲ ▲ ▲	After this parameter is modified, restart the KrbServer service and all its associated services.	None
Modify the **KPASSWD_PORT** parameter of KrbServer.	After this parameter is modified, if the KrbServer service and its associated services are not restarted in a timely manner, the configuration of KrbClient in the cluster is abnormal and the service running is affected.	▲ ▲ ▲ ▲ ▲	After this parameter is modified, restart the KrbServer service and all its associated services.	None

Operation	Risk	Severity	Workaround	Check Item
Modify the domain name of Manager system.	After the domain name is modified, if the KrbServer service and its associated services are not restarted in a timely manner, the configuration of KrbClient in the cluster is abnormal and the service running is affected.	▲ ▲ ▲ ▲ ▲	After this parameter is modified, restart the KrbServer service and all its associated services.	None
Configure cross-cluster mutual trust relationships.	This operation will restart the KrbServer service and all associated services, affecting the management and maintenance and services of the cluster.	▲ ▲ ▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	Check for uncleared alarms, and check whether the cluster management and maintenance and services are normal.

LdapServer High-Risk Operations

Table 14-13 LdapServer high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Modify the **LDAP_SERVER_PORT** parameter of LdapServer.	After this parameter is modified, if the LdapServer service and its associated services are not restarted in a timely manner, the configuration of LdapClient in the cluster is abnormal and the service running is affected.	▲ ▲ ▲ ▲ ▲	After this parameter is modified, restart the LdapServer service and all its associated services.	None

Operation	Risk	Severity	Workaround	Check Item
Restore LdapServer data.	This operation will restart Manager and the entire cluster, affecting management, maintenance, and services of the cluster.	▲ ▲ ▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	Check for uncleared alarms, and check whether the cluster management and maintenance and services are normal.
Replace the Node where LdapServer is located.	This operation will interrupt services deployed on the node. If the node is a management node, the operation will restart all OMS processes, affecting the cluster management and maintenance.	▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	Check for uncleared alarms, and check whether the cluster management and maintenance and services are normal.
Change the password of LdapServer.	The LdapServer and Kerberos services need to be restarted during the password change, affecting the management, maintenance, and services of the cluster.	▲ ▲ ▲ ▲	Before performing the operation, ensure that the operation is necessary, and that no other management and maintenance operations are performed at the same time.	None

Operation	Risk	Severity	Workaround	Check Item
Restart the node where LdapServer is located.	Restarting the node without stopping the LdapServer service may cause LdapServer data damage.	▲ ▲ ▲ ▲ ▲	Restore LdapServer using LdapServer backup data	None

Loader High-Risk Operations

Table 14-14 Loader high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Change the floating IP address of a Loader instance (**loader.float.ip**).	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether the Loader UI can be connected properly.
Modify the Loader instance start parameter **LOADER_GC_OPTS**.	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.
Clear table contents when adding data to HBase.	This operation will clear original data in the target table.	▲ ▲	Ensure that the contents in the target table can be cleared before the operation.	Check whether the contents in the target table can be cleared before the operation.

Spark2x High-risk Operations

NOTE

Spark high-risk operations apply to MRS 3.x earlier versions.

Table 14-15 Spark2x high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Modify the configuration item **spark.yarn.queue**.	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.
Modify the configuration item **spark.driver.extraJavaOptions**.	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.
Modify the configuration item **spark.yarn.cluster.driver.extraJavaOptions**.	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.

Operation	Risk	Severity	Workaround	Check Item
Modify the configuration item **spark.eventLog.dir**.	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.
Modify the configuration item **SPARK_DAEMON_JAVA_OPTS**.	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.
Delete all JobHistory2x instances.	The event logs of historical applications are lost.	▲ ▲	Reserve at least one JobHistory2x instance.	Check whether historical application information is included in JobHistory2x.
Delete or modify the **/user/spark2x/jars/8.1.0.1/spark-archive-2x.zip** file in HDFS.	JDBCServer2x fails to be started and service functions are abnormal.	▲ ▲ ▲	Delete **/user/spark2x/jars/8.1.0.1/spark-archive-2x.zip**, and wait for 10-15 minutes until the .zip package is automatically restored.	Check whether services can be started properly.

Storm High-Risk Operations

Table 14-16 Storm high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Modify the following plug-in related configuration items: • storm.scheduler • nimbus.authorizer • storm.thrift.transport • nimbus.blobstore.class • nimbus.topology.validator • storm.principal.tolocal	Services cannot start properly.	▲ ▲ ▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that the class names exist and are valid.	Check whether services can be started properly.

Operation	Risk	Severity	Workaround	Check Item
Modify the Storm instance **GC_OPTS** startup parameters, including: NIMBUS_GC_OPTS SUPERVISOR_GC_OPTS UI_GC_OPTS LOGVIEWER_GC_OPTS	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.
Modify the user resource pool configuration parameter **resource.aware.scheduler.user.pools**.	Services cannot run properly.	▲ ▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that resources allocated to each user are appropriate and valid.	Check whether services can be started and run properly
Change data directories.	If this operation is not properly performed, services may be abnormal and unavailable.	▲ ▲ ▲ ▲	Do not manually change data directories.	Check whether data directories are normal.
Restart services or instances.	The service will be interrupted for a short period of time, and ongoing operations will be interrupted.	▲ ▲ ▲	Restart services or instances when necessary.	Check whether the service is running properly and whether interrupted operations are restored.

Operation	Risk	Severity	Workaround	Check Item
Synchronize configurations (by restarting the required service).	The service will be restarted, resulting in temporary service interruption. If Supervisor is restarted, ongoing operations will be interrupted for a short period of time.	▲ ▲ ▲	Modify configuration when necessary.	Check whether the service is running properly and whether interrupted operations are restored.
Stop services or instances.	The service will be stopped, and related operations will be interrupted.	▲ ▲ ▲	Stop services when necessary.	Check whether the services are properly stopped.
Delete or modify metadata.	If Nimbus metadata is deleted, services are abnormal and ongoing operations are lost.	▲ ▲ ▲ ▲ ▲	Do not manually delete Nimbus metadata files.	Check whether Nimbus metadata files are normal.
Modify file permissions.	If permissions on the metadata and log directories are incorrectly modified, service exceptions may occur.	▲ ▲ ▲ ▲	Do not manually modify file permissions.	Check whether the permissions on the data and log directories are correct.
Delete topologies.	Topologies in use will be deleted.	▲ ▲ ▲ ▲	Delete topologies when necessary.	Check whether the topologies are successfully deleted.

Yarn High-Risk Operations

Table 14-17 Yarn high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Delete or change data directories **yarn.nodemanager.local-dirs** and **yarn.nodemanager.log-dirs**	This operation may cause service information loss.	▲ ▲ ▲	Do not delete data directories manually.	Check whether data directories are normal.

ZooKeeper High-Risk Operations

Table 14-18 ZooKeeper high-risk operations

Operation	Risk	Severity	Workaround	Check Item
Delete or change ZooKeeper data directories.	This operation may cause service information loss.	▲ ▲ ▲	Follow the capacity expansion guide to change the ZooKeeper data directories.	Check whether services and associated components are started properly.
Modify the ZooKeeper instance start parameter **GC_OPTS**.	Services cannot start properly.	▲ ▲	Strictly follow the prompt information when modifying related configuration items. Ensure that new values are valid.	Check whether services can be started properly.

Operation	Risk	Severity	Workaround	Check Item
Modify the znode ACL information in ZooKeeper.	If znode permission is modified in ZooKeeper, other users may have no permission to access the znode and some system functions are abnormal.	▲ ▲ ▲ ▲	During the modification, strictly follow the ZooKeeper Configuration Guide and ensure that other components can use ZooKeeper properly after ACL information modification.	Check that other components that depend on ZooKeeper can properly start and provide services.

15 FAQs

15.1 MRS Overview

15.1.1 What Is MRS Used For?

MapReduce Service (MRS) is an enterprise-grade big data platform that allows you to quickly build and operate economical, secure, full-stack, cloud-native big data environments on the cloud. It provides engines such as ClickHouse, Spark, Flink, Kafka, and HBase, and supports convergence of data lake, data warehouse, business intelligence (BI), and artificial intelligence (AI). Fully compatible with open-source components, MRS helps you rapidly innovate and expand service growth.

15.1.2 What Types of Distributed Storage Does MRS Support?

MRS supports Hadoop 3.1.*x* and will soon support other mainstream Hadoop versions released by the community. **Table 15-1** lists the component versions supported by MRS.

Table 15-1 MRS component versions

Component	MRS 1.9.2 (Applicable to MRS 1.9.*x*)	MRS 3.1.0
Alluxio	2.0.1	N/A
CarbonData	1.6.1	2.0.1
DBService	1.0.0	2.7.0
Flink	1.7.0	1.12.0
Flume	1.6.0	1.9.0
HBase	1.3.1	2.2.3
HDFS	2.8.3	3.1.1

Component	MRS 1.9.2 (Applicable to MRS 1.9.*x*)	MRS 3.1.0
Hive	2.3.3	3.1.0
Hudi	N/A	0.7.0
Hue	3.11.0	4.7.0
Impala	N/A	3.4.0
Kafka	1.1.0	2.11-2.4.0
KafkaManager	1.3.3.1	N/A
KrbServer	1.15.2	1.17
Kudu	N/A	1.12.1
LdapServer	1.0.0	2.7.0
Loader	2.0.0	N/A
MapReduce	2.8.3	3.1.1
Oozie	N/A	5.1.0
Opentsdb	2.3.0	N/A
Presto	0.216	333
Phoenix (integrated with HBase)	N/A	5.0.0
Ranger	1.0.1	2.0.0
Spark	2.2.2	N/A
Spark2x	N/A	2.4.5
Sqoop	N/A	1.4.7
Storm	1.2.1	N/A
Tez	0.9.1	0.9.2
YARN	2.8.3	3.1.1
ZooKeeper	3.5.1	3.5.6
MRS Manager	1.9.2	N/A
FusionInsight Manager	N/A	8.1.0

15.1.3 How Do I Create an MRS Cluster Using a Custom Security Group?

If you want to use a self-defined security group when buying a cluster, you need to enable port 9022 or select **Auto create** in **Security Group** on the MRS console.

15.1.4 How Do I Use MRS?

MapReduce Service (MRS) is a service you can use to deploy and manage Hadoop-based components on the Cloud. It enables you to deploy Hadoop clusters with a few clicks. MRS provides enterprise-ready big data clusters in the cloud. Tenants can fully control the clusters and easily run big data components such as Hadoop, Spark, HBase, Kafka, and Storm in the clusters.

MRS is easy to use. You can execute various tasks and process or store PB-scale data using computers connected in a cluster. To use MRS, do as follows:

1. Upload local programs and data files to OBS.
2. Create a cluster. You need to specify the cluster type (for example, analysis or streaming), and set ECS instance specifications, number of instances, data disk type (common I/O, high I/O, and ultra-high I/O), and components to be installed, such as Hadoop, Spark, HBase, Hive, Kafka, and Storm, in a cluster. You can use a bootstrap action to install third-party software or modify the cluster running environment on a node before or after the cluster is started.
3. Use MRS to submit, execute, and monitor your programs.
4. Manage clusters on MRS Manager, an enterprise-level unified management platform of big data clusters. You can learn about the health status of services and hosts, obtain critical system information in a timely manner from graphical metric monitoring and customization, modify service attributes based on performance requirements, and start or stop clusters, services, and role instances.
5. Terminate any MRS cluster that you do not require after job execution is complete.

15.1.5 How Does MRS Ensure Security of Data and Services?

MRS is a big data management and analytic platform featuring high security. It ensures data and service security from the following aspects:

- Network isolation

  The public cloud network is divided into service plane and management plane. The two planes are physically isolated to ensure network security.

  - Service plane: provides a network plane for running cluster components. The service plane provides service channels, and implements data access and storage, job submission, and computing.
  - Management plane: provides a public cloud management console that you can use to purchase and manage MRS.

- Host security

  You can deploy third-party antivirus software based on service requirements. MRS provides the following measures to improve security of OSs and ports:

  - OS kernel security hardening
  - OS patch update
  - OS permission control
  - OS port management
  - OS protocol and port attack defense
- Data security

  MRS enables data storage on OBS, thereby ensuring data security.
- Data integrity

  MRS transmits the processed data to OBS using SSL, thereby ensuring data integrity.

15.1.6 Can I Configure a Phoenix Connection Pool?

Phoenix does not support connection pool configuration. You are advised to write code to implement a tool class for managing connections and simulate a connection pool.

15.1.7 Does MRS Support Change of the Network Segment?

You can change the network segment. On the cluster **Dashboard** page of MRS console, click **Change Subnet** to the right of **Default Subnet**, and select a subnet in the VPC of the cluster to expand subnet IP addresses. Selecting a new subnet will not change the IP addresses and subnets of existing nodes.

15.1.8 Can I Downgrade the Specifications of an MRS Cluster Node?

You cannot downgrade the specifications of an MRS cluster node by using the console. If you want to downgrade an MRS cluster node's specifications, contact technical support.

15.1.9 What Is the Relationship Between Hive and Other Components?

- Hive and HDFS

  Hive is an Apache Hadoop project. Hive uses Hadoop Distributed File System (HDFS) as its file storage system. Hive parses and processes structured data stored on HDFS. All data files in the Hive database are stored in HDFS, and all data operations on Hive are also performed using HDFS APIs.
- Hive and MapReduce

  All data computing of Hive depends on MapReduce. MapReduce, also an Apache Hadoop project, is a parallel computing framework based on HDFS. During data analysis, Hive parses HiveQL statements submitted by users into MapReduce tasks and submits the tasks for MapReduce to execute.
- Hive and DBService

  MetaStore (metadata service) of Hive processes the structure and attribute information about Hive databases, tables, and partitions that are stored in a relational database. In MRS, the relational database is maintained by DBService.

- Hive and Spark

  Hive data computing can also be implemented on Spark. Spark, also an Apache project, is an in-memory distributed computing framework. During data analysis, Hive parses HiveQL statements submitted by users into Spark tasks and submits the tasks for Spark to execute.

15.1.10 Does an MRS Cluster Support Hive on Spark?

- Clusters of MRS 1.9.*x* support Hive on Spark.
- Clusters of MRS 3.*x* or later support Hive on Spark.
- You can use Hive on Tez for the clusters of other versions.

15.1.11 What Are the Differences Between Hive Versions?

Hive 3.1 has the following differences when compared with Hive 1.2:

- String cannot be converted to int.
- The user-defined functions (UDFs) of the **Date** type are changed to Hive built-in UDFs.
- Hive 3.1 does not provide the index function anymore.
- Hive 3.1 uses the UTC time in time functions, while Hive 1.2 uses the local time zone.
- The JDBC drivers in Hive 3.1 and Hive 1.2 are incompatible.
- In Hive 3.1, column names in ORC files are case-sensitive and underscores-sensitive.
- Hive 3.1 does not allow columns named **time**.

15.1.12 Which MRS Cluster Version Supports Hive Connection and User Synchronization?

MRS cluster 2.0.5 or later supports Hive connections on DataLake Governance Center (DGC) and provides the IAM user synchronization function.

15.1.13 What Are the Differences Between OBS and HDFS in Data Storage?

The data processed by MRS is from OBS or HDFS. OBS is an object-based storage service that provides secure, reliable, and cost-effective storage of huge amounts of data. MRS can directly process data in OBS. You can view, manage, and use data by using the OBS console or OBS client. In addition, you can use REST APIs independently or integrate APIs to service applications to manage and access data.

- Data stored in OBS: Data storage is decoupled from compute. The cluster storage cost is low, and storage capacity is not limited. Clusters can be deleted at any time. However, the computing performance depends on the OBS access performance and is lower than that of HDFS. OBS is recommended for applications that do not demand a lot of computation.
- Data stored in HDFS: Data storage is not decoupled from compute. The cluster storage cost is high, and storage capacity is limited. The computing performance is high. You must export data before you delete clusters. HDFS is recommended for computing-intensive scenarios.

15.1.14 How Do I Obtain the Hadoop Pressure Test Tool?

Download it from **https://github.com/Intel-bigdata/HiBench**.

15.1.15 What Is the Relationship Between Impala and Other Components?

- Impala and HDFS

  Impala uses HDFS as its file storage system. Impala parses and processes structured data, while HDFS provides reliable underlying storage. Impala provides fast data access without moving data in HDFS.

- Impala and Hive

  Impala uses Hive metadata, Open Database Connectivity (ODBC) driver, and SQL syntax. Unlike Hive, which is over MapReduce, Impala implements a distributed architecture based on daemon and handles all query executions on the same node. Therefore, Impala is faster than Hive by reducing the latency caused by MapReduce.

- Impala and MapReduce

  None

- Impala and Spark

  None

- Impala and Kudu

  Kudu can be closely integrated with Impala to replace the combination of Impala, HDFS, and Parquet. You can insert, query, update, and delete data in Kudu tablets using Impala's SQL syntax. In addition, you can use JDBC or ODBC to connect to Kudu for data operations, using Impala as the broker.

- Impala and HBase

  The default Impala tables use data files stored in HDFS, which is ideal for batch loading and query of full table scanning. However, HBase provides convenient and efficient query of OLTP-style organization data.

15.1.16 Statement About the Public IP Addresses in the Open-Source Third-Party SDK Integrated by MRS

The open-source third-party packages on which the open-source components integrated by MRS depend contain SDK usage examples. Public IP addresses such as 12.1.2.3, 54.123.4.56, 203.0.113.0, and 203.0.113.12 are example IP addresses. MRS will not initiate a connection to the public IP address or exchange data with the public IP address.

15.1.17 What Is the Relationship Between Kudu and HBase?

Kudu is designed based on the HBase structure and can implement fast random read/write and update functions that HBase is good at. Kudu and HBase are similar in architecture. The differences are as follows:

- HBase uses ZooKeeper to ensure data consistency, whereas Kudu uses the Raft consensus algorithm to ensure consistency.

- HBase uses HDFS for resilient data storage, whereas Kudu uses TServer to ensure strong data consistency and reliability.

15.1.18 Does MRS Support Running Hive on Kudu?

MRS does not support Hive on Kudu.

Currently, MRS supports only the following two methods to access Kudu:

- Access Kudu through Impala tables.
- Access and operate Kudu tables using the client application.

15.1.19 What Are the Solutions for processing 1 Billion Data Records?

- GaussDB (for MySQL) is recommended for scenarios, such as data updates, online transaction processing (OLTP), and complex analysis of 1 billion data records.
- Impala and Kudu in MRS also meet this requirement. Impala and Kudu can load all join tables to the memory in the join operation.

15.1.20 Can I Change the IP address of DBService?

MRS does not support the change of the DBService IP address.

15.1.21 Can I Clear MRS sudo Logs?

MRS sudo log files record operations performed by user **omm** and are helpful for fault locating. You can delete the logs of the earliest date to release storage space.

1. If the log file is large, add the log file directory to **/etc/logrotate.d/syslog** to enable the system to periodically delete logs.

   Method: Run **sed -i '3 a/var/log/sudo/sudo.log' /etc/logrotate.d/syslog**.

2. Set the maximum number and size of logs in **/etc/logrotate.d/syslog**. If the number or size of logs exceeds the threshold, the logs will be automatically deleted. By default, logs are aged based on the size and number of archived logs. You can use **size** and **rotate** to limit the size and number of archived logs, respectively. If required, you can also add **daily**/**weekly**/**monthly** to specify how often the logs are cleared.

15.1.22 Is the Storm Log also limited to 20 GB in MRS cluster 2.1.0?

In MRS cluster 2.1.0, the Storm log cannot exceed 20 GB. If the Storm log exceeds 20 GB, the log files will be deleted cyclically. Logs are stored on the system disk, therefore, the log space is limited. If you want to keep the log for longer time, mount the log directory to storage media.

15.1.23 What Is Spark ThriftServer?

ThriftServer is a JDBC API. You can use JDBC to connect to ThriftServer to access SparkSQL data. Therefore, you can see JDBCServer in Spark components, but not ThriftServer.

15.1.24 What Access Protocols Are Supported by Kafka?

Kafka supports PLAINTEXT, SSL, SASL_PLAINTEXT, and SASL_SSL.

15.1.25 What Is the Compression Ratio of zstd?

Zstandard (zstd) is an open-source fast lossless compression algorithm. The compression ratio of zstd is twice that of orc. For details, see **https://github.com/L-Angel/compress-demo**. CarbonData does not support lzo, and MRS has zstd integrated.

15.1.26 Why Are the HDFS, YARN, and MapReduce Components Unavailable When an MRS Cluster Is Created?

The HDFS, YARN, and MapReduce components are integrated in Hadoop. If the three components are unavailable when are MRS cluster is created, select Hadoop instead. After an MRS cluster is created, HDFS, YARN, and MapReduce are available in the **Components** page.

15.1.27 Why Is the ZooKeeper Component Unavailable When an MRS Cluster Is Created?

If you create a cluster of a version earlier than MRS 3.*x*, ZooKeeper is installed by default and is not displayed on the GUI.

If you create a cluster of MRS 3.*x* or later, ZooKeeper is available on the GUI and is selected by default.

After the cluster is created, the ZooKeeper component is available on the **Components** page.

15.1.28 Which Python Versions Are Supported by Spark Tasks in an MRS 3.1.0 Cluster?

For MRS 3.1.0 clusters, Python 2.7 or 3.*x* is recommended for Spark tasks.

15.1.29 How Do I Enable Different Service Programs to Use Different YARN Queues?

Create a tenant on Manager.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 In the tenant list on the left, select a parent tenant and click  . On the page for adding a sub-tenant, set attributes for the sub-tenant according to **Table 15-2**.

Table 15-2 Sub-tenant parameters

Parameter	Description
Cluster	Indicates the cluster to which the parent tenant belongs.
Parent Tenant Resource	Indicates the name of the parent tenant.
Name	• Indicates the name of the current tenant. The value consists of 3 to 50 characters, including digits, letters, and underscores (_). • Plan a sub-tenant name based on service requirements. The name cannot be the same as that of a role, HDFS directory, or Yarn queue that exists in the current cluster.
Tenant Type	Specifies whether the tenant is a leaf tenant. • When **Leaf Tenant** is selected, the current tenant is a leaf tenant and no sub-tenant can be added. • When **Non-leaf Tenant** is selected, the current tenant is not a leaf tenant and sub-tenants can be added to the current tenant. However, the tenant depth cannot exceed 5 levels.
Computing Resource	Specifies the dynamic computing resources for the current tenant. • When **Yarn** is selected, the system automatically creates a queue in Yarn and the queue is named the same as the sub-tenant name. – A leaf tenant can directly submit jobs to the queue. – A non-leaf tenant cannot directly submit jobs to the queue. However, Yarn adds an extra queue (hidden) named **default** for the non-leaf tenant to record the remaining resource capacity of the tenant. Actual jobs do not run in this queue. • If **Yarn** is not selected, the system does not automatically create a queue.
Default Resource Pool Capacity (%)	Indicates the percentage of computing resources used by the current tenant. The base value is the total resources of the parent tenant.
Default Resource Pool Max Capacity (%)	Indicates the maximum percentage of computing resources used by the current tenant. The base value is the total resources of the parent tenant.

Parameter	Description
Storage Resource	Specifies storage resources for the current tenant. • When **HDFS** is selected, the system automatically creates a folder named after the sub-tenant in the HDFS parent tenant directory. • When **HDFS** is not selected, the system does not automatically allocate storage resources.
Quota	Indicates the quota for files and directories.
Space Quota	Indicates the quota for the HDFS storage space used by the current tenant. • If the unit is set to **MB**, the value ranges from **1** to **8796093022208**. If the unit is set to **GB**, the value ranges from **1** to **8589934592**. • This parameter indicates the maximum HDFS storage space that can be used by the tenant, but not the actual space used. • If its value is greater than the size of the HDFS physical disk, the maximum space available is the full space of the HDFS physical disk. • If this quota is greater than the quota of the parent tenant, the actual storage space does not exceed the quota of the parent tenant.
Storage Path	Indicates the HDFS storage directory for the tenant. • The system automatically creates a folder named after the sub-tenant name in the directory of the parent tenant by default. For example, if the sub-tenant is **ta1s** and the parent directory is **/tenant/ta1**, the storage path for the sub-tenant is then **/tenant/ta1/ta1s**. • The storage path is customizable in the parent directory.
Description	Indicates the description of the current tenant.

NOTE

Roles, computing resources, and storage resources are automatically created when tenants are created.

- The new role has permissions on the computing and storage resources. This role and its permissions are automatically controlled by the system and cannot be manually managed by choosing **System** > **Permission** > **Role**. The role name is in the format of *Tenant name_Cluster ID*. The ID of the first cluster is not displayed by default.
- When using this tenant, create a system user and bind the user to the role of the tenant.
- The sub-tenant can further allocate the resources of its parent tenant. The sum of the resource percentages of direct sub-tenants under a parent tenant at each level cannot exceed 100%. The sum of the computing resource percentages of all level-1 tenants cannot exceed 100%.

Step 3 Check whether the current tenant needs to be associated with resources of other services.

- If yes, go to **Step 4**.
- If no, go to **Step 5**.

Step 4 Click **Associate Service** to configure other service resources used by the current tenant.

1. Set **Services** to **HBase**.
2. Set **Association Type** as follows:
   - **Exclusive** indicates that the service resources are used by the tenant exclusively and cannot be associated with other tenants.
   - **Shared** indicates that the service resources can be shared with other tenants.

NOTE

- Only HBase can be associated with a new tenant. However, HDFS, HBase, and Yarn can be associated with existing tenants.
- To associate an existing tenant with service resources, click the target tenant in the tenant list, switch to the **Service Associations** page, and click **Associate Service** to configure resources to be associated with the tenant.
- To disassociate an existing tenant from service resources, click the target tenant in the tenant list, switch to the **Service Associations** page, and click **Delete** in the **Operation** column. In the displayed dialog box, select **I have read the information and understand the impact** and click **OK**.

3. Click **OK**.

Step 5 Click **OK**. Wait until the system displays a message indicating that the tenant is successfully created.

----End

15.1.30 Differences and Relationships Between the MRS Management Console and Cluster Manager

You can access Manager from the MRS management console.

Manager is classified as MRS Manager and FusionInsight Manager.

- MRS Manager is the manager page of MRS 2.*x* or earlier clusters.
- FusionInsight Manager is the manager page of MRS 3.*x* or later clusters.

The following table lists the differences and relationships between the management console and FusionInsight Manager.

Common Operation	MRS Console	FusionInsight Manager
Changing subnets, adding security group rules, controlling OBS permissions, managing agencies, and synchronizing IAM users	Supported	Not supported

Common Operation	MRS Console	FusionInsight Manager
Adding node groups, scaling out, scaling in, and upgrading specifications	Supported	Not supported
Isolating hosts, starting all roles, and stopping all roles	Supported	Supported
Downloading the client, starting services, stopping services, and perform rolling restart of services	Supported	Supported
Viewing the instance status of services, configuring parameters, and synchronizing configurations	Supported	Supported
Viewing cleared alarms and events	Supported	Supported
Viewing the alarm help	Not supported	Supported
Setting thresholds	Not supported	Supported
Adding message subscription specifications	Supported	Not supported
Managing files	Supported	Not supported
Managing jobs	Supported	Not supported
Managing tenants	Supported	Supported
Managing tags	Supported	Not supported
Managing permissions (adding and deleting users, user groups, and roles, and changing passwords)	Not supported	Supported
Performing backup and restoration	Not supported	Supported
Auditing	Not supported	Supported
Monitoring resources and logging	Supported	Supported

15.1.31 How Do I Unbind an EIP from an MRS Cluster Node?

Symptom

After an EIP is bound on the console, the EIP cannot be unbound in the EIP module of the VPC service.

A dialog box is displayed, indicating that the operation cannot be performed because the EIP is being used by MapReduce.

Procedure

Step 1 Log in to the VPC console and choose **Virtual Private Cloud** > **My VPCs**. Find the target VPC in the VPC list.

Step 2 Click the VPC name to go to the **Summary** tab page and click the number next to **Subnets** in the **Networking Components** area to find the subnet to which the cluster belongs.

Step 3 In the subnet list, click the target subnet name. Click the **IP Addresses** tab, locate the target public IP address and click **Unbind from EIP** in the **Operation** column.

----End

15.2 Account and Password

15.2.1 What Is the Account for Logging In to Manager?

The default account for logging in to Manager is **admin**, and the password is the one you set when you created the cluster.

15.2.2 How Do I Query and Change the Password Validity Period of an Account?

Querying the Password Validity Period

Querying the password validity period of a component running user (human-machine user or machine-machine user):

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to switch to the client directory, for example, **/opt/Bigdata/client**:

cd /opt/Bigdata/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the following command and enter the password of user **kadmin/admin** to log in to the kadmin console:

kadmin -p kadmin/admin

NOTE

The default password of user **kadmin/admin** is **Admin@123**. Change the password upon your first login or as prompted and keep the new password secure.

Step 5 Run the following command to view the user information:

getprinc *Internal system username*

Example: **getprinc user1**

```
kadmin:  getprinc user1
......
Expiration date: [never]
Last password change: Sun Oct 09 15:29:54 CST 2022
Password expiration date: [never]
......
```

----End

Querying the password validity period of an OS user:

Step 1 Log in to any master node in the cluster as user **root**.

Step 2 Run the following command to view the password validity period (value of **Password expires**):

chage -l *Username*

For example, to view the password validity period of user **root**, run the **chage -l root** command. The command output is as follows:

```
[root@xxx ~]#chage -l root
Last password change                                    : Sep 12, 2021
Password expires                                        : never
Password inactive                                       : never
Account expires                                         : never
Minimum number of days between password change          : 0
Maximum number of days between password change          : 99999
Number of days of warning before password expires       : 7
```

----End

Changing the Password Validity Period

- The password of a machine-machine user is randomly generated and never expires by default.
- The password validity period of a human-machine user can be changed by modifying the password policy on Manager.

15.3 Accounts and Permissions

15.3.1 Does an MRS Cluster Support Access Permission Control If Kerberos Authentication Is not Enabled?

For MRS cluster 2.1.0 or earlier, choose **System** > **Configuration** > **Permission** on MRS Manager.

For MRS cluster 3.*x* or later, choose **System** > **Permission** on FusionInsight Manager.

15.3.2 How Do I Assign Tenant Management Permission to a New Account?

You can assign tenant management permission only in analysis or hybrid clusters, but not in streaming clusters.

The operations vary depending on the MRS cluster version:

Procedure for versions earlier than MRS cluster 3.x:

Step 1 Log in to MRS Manager as user **admin**.

Step 2 Choose **System** > **Manage User**. Select the new account, and click **Modify** in the **Operation** column.

Step 3 In **Assign Rights by Role**, click **Select and Add Role**.

- If you bind the **Manager_tenant** role to the account, the account will have permission to view tenant management information.
- If you bind the **Manager_administrator** role to the account, the account will have permission to view and perform tenant management.

Step 4 Click **OK**.

----End

Procedure for MRS cluster 3.x and later versions:

Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **User**.

Step 2 Locate the user and click **Modify**.

Modify the parameters based on service requirements.

If you bind the **Manager_tenant** role to the account, the account will have permission to view tenant management information. If you bind the **Manager_administrator** role to the account, the account will have permission to perform tenant management and view related information.

NOTE

It takes about three minutes for the settings to take effect after user group or role permission are modified.

Step 3 Click **OK**.

----End

15.3.3 How Do I Customize an MRS Policy?

1. On the IAM console, choose **Permissions** in the navigation pane, and click **Create Custom Policy**.
2. Set a policy name in **Policy Name**.
3. Set **Scope** to **Project-level service** for MRS.
4. Specify **Policy View**. The following options are supported:
   - **Visual editor**: Select cloud services, actions, resources, and request conditions from the navigation pane to customize the policy. You do not require knowledge of JSON syntax.
   - **JSON**: Edit JSON policies from scratch or based on an existing policy.

   You can also click **Select Existing Policy/Role** in the **Policy Content** area to select an existing policy as the template for modification.
5. (Optional) Enter a brief description in the **Description** area.
6. Click **OK**.
7. Attach the policy to a user group. Users in the group then inherit the permissions defined in this policy.

15.3.4 Why Is the Manage User Function Unavailable on the System Page on MRS Manager?

Check whether you have the **Manager_administrator** permission. If you do not have this permission, **Manage User** will not be available on the **System** page of MRS Manager.

15.3.5 Does Hue Support Account Permission Configuration?

Hue does not provide an entry for configuring account permissions on its web UI. However, you can configure user roles and user groups for Hue accounts on the **System** tab on Manager.

15.4 Client Usage

15.4.1 How Do I Configure Environment Variables and Run Commands on a Component Client?

1. Log in to any Master node as user **root**.
2. Run the **su - omm** command to switch to user **omm**.
3. Run the **cd /opt/client** command to switch to the client.
4. Run the **source bigdata_env** command to configure environment variables.

   If Kerberos authentication is enabled for the current cluster, run the **kinit** *Component service user* command to authenticate the user. If Kerberos authentication is disabled, skip this step.
5. After the environment variables are configured, run the client command of the component. For example, to view component information, you can run the HDFS client command **hdfs dfs -ls /** to view the HDFS root directory file.

15.4.2 How Do I Disable ZooKeeper SASL Authentication?

Log in to FusionInsight Manager, choose **Cluster** > **Services** > **ZooKeeper**, click the **Configurations** tab and then **All Configurations**. In the navigation pane on the left, choose **quorumpeer(Role)** > **Customization**, add the **set zookeeper.sasl.disable** parameter, and set its value to **false**. Save the configuration and restart the ZooKeeper service.

15.4.3 An Error Is Reported When the kinit Command Is Executed on a Client Node Outside an MRS Cluster

Symptom

After the client is installed on a node outside an MRS cluster and the **kinit** command is executed, the following error information is displayed:

```
-bash kinit Permission denied
```

The following error information is displayed when the **java** command is executed:

```
-bash: /xxx/java: Permission denied
```

After running the **ll /***Java installation path***/JDK/jdk/bin/java** command, it is found that the file execution permission is correct.

Fault Locating

Run the **mount | column -t** command to check the status of the mounted partition. It is found that the partition status of the mount point where the Java execution file is located is **noexec**. In the current environment, the data disk where the MRS client is installed is set to **noexec**, that is, binary file execution is prohibited. As a result, Java commands cannot be executed.

Solution

1. Log in to the node where the MRS client is located as user **root**.
2. Remove the configuration item **noexec** of the data disk where the MRS client is located from the **/etc/fstab** file.
3. Run the **umount** command to detach the data disk, and then run the **mount -a** command to remount the data disk.

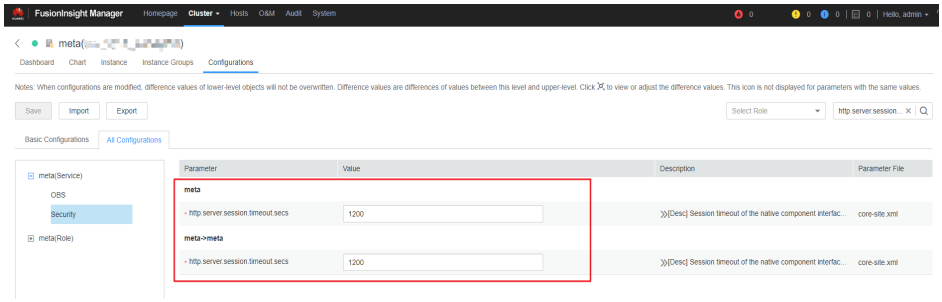
15.5 Web Page Access

15.5.1 How Do I Change the Session Timeout Duration for an Open Source Component Web UI?

You need to set a proper web session timeout duration for security purposes. To change the session timeout duration, do as follows:

Checking Whether the Cluster Supports Session Timeout Duration Adjustment

- For MRS cluster versions earlier than 3.x:
  a. On the cluster details page, choose **Components** > **meta** > **Service Configuration**.
  b. Switch **Basic** to **All**, and search for the **http.server.session.timeout.secs**.
     If **http.server.session.timeout.secs** does not exist, the cluster does not support change of the session timeout duration. If the parameter exists, perform the following steps to modify it.
- MRS 3.x and later: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **meta**. On the displayed page, click **Configurations** and select **All Configurations**. Search for the **http.server.session.timeout.secs** configuration item. If this configuration item exists, perform the following steps to modify it. If the configuration item does not exist, the version does not support dynamic adjustment of the session duration.



You are advised to set all session timeout durations to the same value. Otherwise, the settings of some parameters may not take effect due to value conflict.

Modifying the Timeout Duration on Manager and the Authentication Center Page

For clusters of versions earlier than MRS 3.*x*:

1. Log in to each master node in the cluster and perform 2 to 4.
2. Change the value of **<session-timeout>20</session-timeout>** in the **/opt/Bigdata/apache-tomcat-7.0.78/webapps/cas/WEB-INF/web.xml** file. **<session-timeout>20</session-timeout>** indicates the session timeout duration, in minutes. Change it based on service requirements. The maximum value is 480 minutes.
3. Change the value of **<session-timeout>20</session-timeout>** in the **/opt/Bigdata/apache-tomcat-7.0.78/webapps/web/WEB-INF/web.xml** file. **<session-timeout>20</session-timeout>** indicates the session timeout duration, in minutes. Change it based on service requirements. The maximum value is 480 minutes.
4. Change the values of **p:maxTimeToLiveInSeconds="${tgt.maxTimeToLiveInSeconds:1200}"** and **p:timeToKillInSeconds="${tgt.timeToKillInSeconds:1200}"** in the **/opt/Bigdata/apache-tomcat-7.0.78/webapps/cas/WEB-INF/spring-configuration/ticketExpirationPolicies.xml** file. The maximum value is 28,800 seconds.

5. Restart the Tomcat node on the active master node.
   a. On the active master node, run the **netstat -anp |grep 28443 |grep LISTEN | awk '{print $7}'** command as user **omm** to query the Tomcat process ID.
   b. Run the **kill -9** *{pid}* command, in which *{pid}* indicates the Tomcat process ID obtained in **5.a**.
   c. Wait until the process automatically restarts. You can run the **netstat -anp |grep 28443 |grep LISTEN** command to check whether the process is successfully restarted. If the process can be queried, the process is successfully restarted. If the process cannot be queried, query the process again later.

For clusters of MRS 3.*x* or later

1. Log in to each master node in the cluster and perform **2** to **3** on each master node.
2. Change the value of **<session-timeout>20</session-timeout>** in the **/opt/Bigdata/om-server_xxx/apache-tomcat-xxx/webapps/web/WEB-INF/web.xml** file. **<session-timeout>20</session-timeout>** indicates the session timeout duration, in minutes. Change it based on service requirements. The maximum value is 480 minutes.
3. Add **ticket.tgt.timeToKillInSeconds=28800** to the **/opt/Bigdata/om-server_xxx/apache-tomcat-8.5.63/webapps/cas/WEB-INF/classes/config/application.properties** file. **ticket.tgt.timeToKillInSeconds** indicates the validity period of the authentication center, in seconds. Change it based on service requirements. The maximum value is 28,800 seconds.
4. Restart the Tomcat node on the active master node.
   a. On the active master node, run the **netstat -anp |grep 28443 |grep LISTEN | awk '{print $7}'** command as user **omm** to query the Tomcat process ID.
   b. Run the **kill -9** *{pid}* command, in which *{pid}* indicates the Tomcat process ID obtained in **4.a**.
   c. Wait until the process automatically restarts.

      You can run the **netstat -anp |grep 28443 |grep LISTEN** command to check whether the process is successfully restarted. If the process is displayed, the process is successfully restarted. If the process is not displayed, query the process again later.

Modifying the Timeout Duration for an Open-Source Component Web UI

1. Access the **All Configurations** page.
   - For MRS cluster versions earlier than MRS 3.x:

     On the cluster details page, choose **Components > Meta > Service Configuration**.
   - For MRS cluster version 3.*x* or later:

     Log in to FusionInsight Manager and choose **Cluster** > **Services** > **meta**. On the displayed page, click **Configurations** and select **All Configurations**.
2. Change the value of **http.server.session.timeout.secs** under **meta** as required. The unit is second.

3. Save the settings, deselect **Restart the affected services or instances**, and click **OK**.

   You are advised to perform the restart during off-peak hours.

4. (Optional) If you need to use the Spark web UI, search for **spark.session.maxAge** on the **All Configurations** page of Spark and change the value (in seconds).

   Save the settings, deselect **Restart the affected services or instances**, and click **OK**.

5. Restart the meta service and components on web UI, or restart the cluster during off-peak hours.

   To prevent service interruption, restart the service during off-peak hours or perform a rolling restart.

15.5.2 Why Cannot I Refresh the Dynamic Resource Plan Page on MRS Tenant Tab?

Step 1 Log in to the Master1 and Master2 nodes as user **root**.

Step 2 Run the **ps -ef |grep aos** command to check the AOS process ID.

Step 3 Run the **kill -9** *AOS process ID* command to end the AOS process.

Step 4 Wait until the AOS process is automatically restarted.

You can run the **ps -ef |grep aos** command to check whether the AOS process restarts successfully. If the process exists, the restart is successful and the **Dynamic Resource Plan** page will be refreshed. If the process does not exist, retry later.

----End

15.5.3 What Do I Do If the Kafka Topic Monitoring Tab Is Unavailable on Manager?

Step 1 Log in to each Master node of the cluster and switch to user **omm**.

Step 2 Go to the **/opt/Bigdata/apache-tomcat-7.0.78/webapps/web/WEB-INF/lib/components/Kafka/** directory.

Step 3 Run the **cp /opt/share/zookeeper-3.5.1-mrs-2.0/zookeeper-3.5.1-mrs-2.0.jar ./** command to copy the ZooKeeper package.

Step 4 Restart the Tomcat process.

sh /opt/Bigdata/apache-tomcat-7.0.78/bin/shutdown.sh

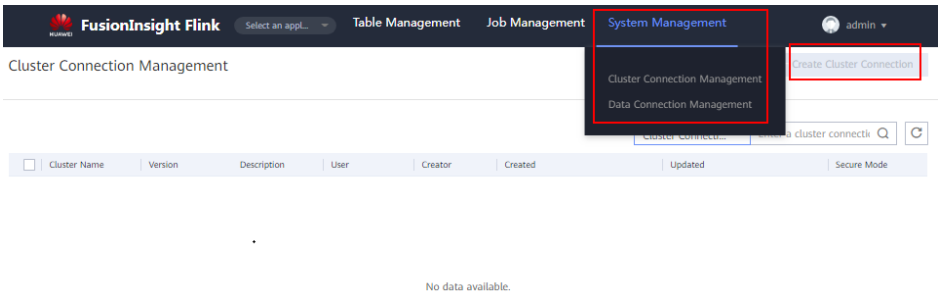
sh /opt/Bigdata/apache-tomcat-7.0.78/bin/startup.sh

----End

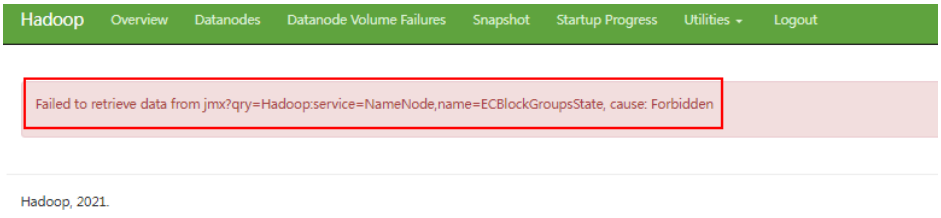
15.5.4 How Do I Do If an Error Is Reported or Some Functions Are Unavailable When I Access the Web UIs of HDFS, Hue, YARN, and Flink?

Users who access the web UIs of components such as HDFS, Hue, YARN, and Flink do not have required management permissions. As a result, an error is reported or some functions are unavailable. The following are some examples:

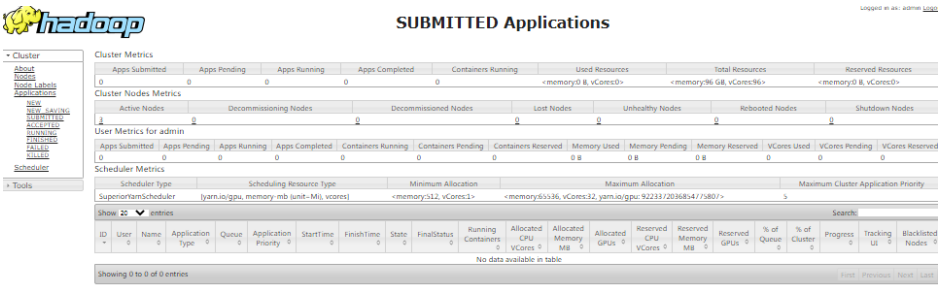
- After you log in to the web UI of Flink as the current user, some content cannot be displayed, and you do not have the permission to create applications, cluster connections, or data connections.



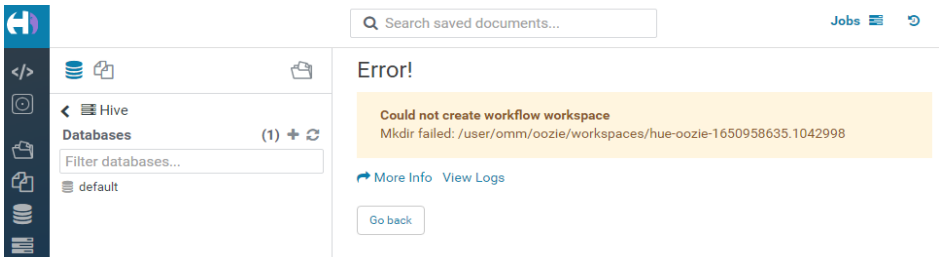
- After you log in to the web UI of HDFS as the current user, error message "Failed to retrieve data from /jmx?qry=java.lang:type=Memory, cause: Forbidden" is displayed.



- After you log in to the web UI of YARN as the current user, you cannot view job information.



- After you log in to the web UI of Hue as the current user, click  in the navigation pane on the left, and select **Workflow**, an error message is displayed.



You are advised to log in to the web UIs of the components as a user with corresponding management permissions. For example, you can create a service user who has the management permissions on HDFS and you can log in to the web UI of HDFS as the created user.

15.6 Alarm Monitoring

15.6.1 In an MRS Streaming Cluster, Can the Kafka Topic Monitoring Function Send Alarm Notifications?

The Kafka topic monitoring function cannot send alarms by email or SMS message. However, you can view alarm information on Manager.

15.6.2 Where Can I View the Running Resource Queues When the Alarm "ALM-18022 Insufficient Yarn Queue Resources" Is Reported?

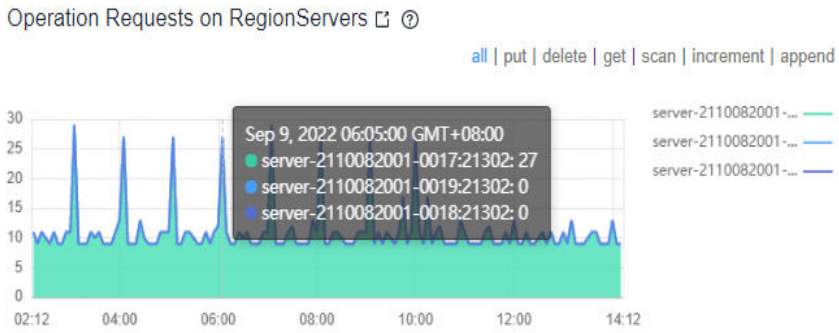
Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Yarn**. In the navigation pane on the left, choose **ResourceManager(Active)** and log in to the native Yarn page.

For details, see the online help.

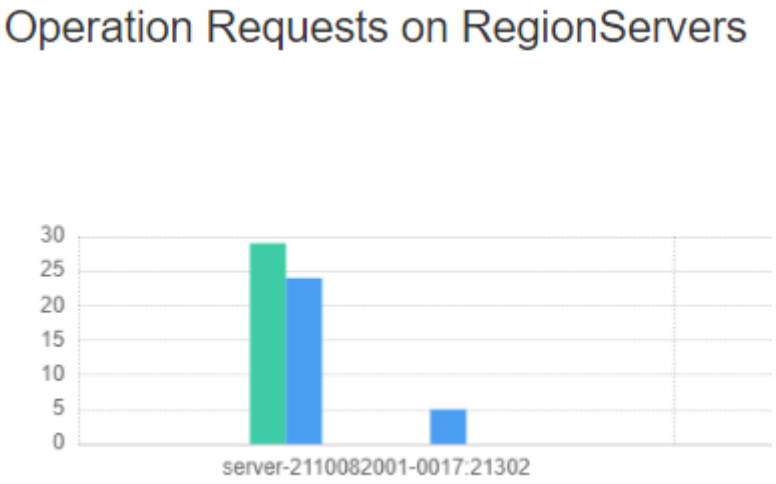
15.6.3 How Do I Understand the Multi-Level Chart Statistics in the HBase Operation Requests Metric?

The following uses the **Operation Requests on RegionServers** monitoring item as an example:

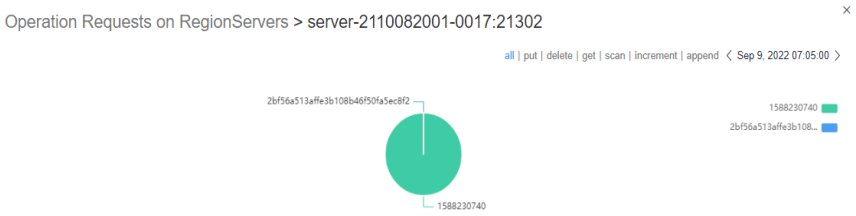
1. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HBase** > **Resource**. On the displayed page, you can view the **Operation Requests on RegionServers** chart. If you click **all**, the top 10 RegionServers ranked by the total number of operation requests in the current cluster are displayed, the statistics interval is 5 minutes.



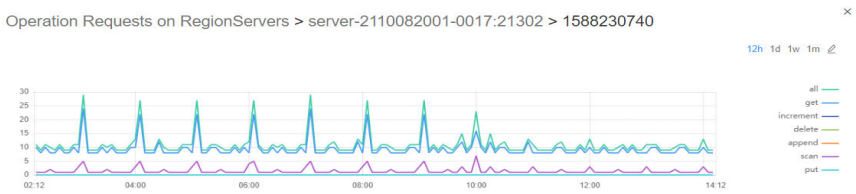
2. Click a point in the chart. A level-2 chart is displayed, showing the number of operation requests of all RegionServers in the past 5 minutes.



3. Click an operation statistics bar chart. A level-3 chart is displayed, showing the distribution of operations in each region within the period.



4. Click a region name. The distribution chart of operations performed every 5 minutes in the last 12 hours is displayed. You can view the number of operations performed in the period.



15.7 Performance Tuning

15.7.1 Does an MRS Cluster Support System Reinstallation?

An MRS cluster does not support system reinstallation.

15.7.2 Can I Change the OS of an MRS Cluster?

The OS of an MRS cluster cannot be changed.

15.7.3 How Do I Improve the Resource Utilization of Core Nodes in a Cluster?

1. Search for **yarn.nodemanager.resource.memory-mb**, and increase the value based on the actual memory of the cluster nodes.
2. Save the change and restart the affected services or instances.

15.7.4 How Do I Stop the Firewall Service?

Step 1 Log in to each node of a cluster as user **root**.

Step 2 Check whether the firewall service is started.

For example, to check the firewall status on EulerOS, run the **systemctl status firewalld.service** command.

Step 3 Stop the firewall service.

For example, to stop the firewall service on EulerOS, run the **systemctl stop firewalld.service** command.

----End

15.8 Job Development

15.8.1 How Do I Get My Data into OBS or HDFS?

MRS can process data in OBS and HDFS. You can get your data into OBS or HDFS as follows:

1. Upload local data to OBS.
   a. Log in to the OBS console.
   b. Create a parallel file system named **userdata** on OBS and create the **program**, **input**, **output**, and **log** folders in the file system.
      i. Choose **Parallel File System** > **Create Parallel File System**, and create a file system named **userdata**.
      ii. In the OBS file system list, click the file system name **userdata**, choose **Files** > **Create Folder**, and create the **program**, **input**, **output**, and **log** folders.
   c. Upload data to the **userdata** file system.
      i. Go to the **program** folder and click **Upload File**.

ii. Click **add file** and select a user program.

iii. Click **Upload**.

iv. Upload the user data file to the **input** directory using the same method.

2. Import OBS data to HDFS.

   You can import OBS data to HDFS only when **Kerberos Authentication** is disabled and the cluster is running.

   a. Log in to the MRS console.

   b. Click the name of the cluster.

   c. On the page displayed, select the **Files** tab page and click **HDFS File List**.

   d. Select a data directory, for example, **bd_app1**.

      The **bd_app1** directory is only an example. You can use any directory on the page or create a new one.

   e. Click **Import Data** and click **Browse** to select an OBS path and an HDFS path.

   f. Click **OK**.

      You can view the file upload progress on the **File Operation Records** tab page.

15.8.2 What Types of Spark Jobs Can Be Submitted in a Cluster?

MRS clusters support Spark jobs submitted in Spark, Spark Script, or Spark SQL mode.

15.8.3 Can I Run Multiple Spark Tasks at the Same Time After the Minimum Tenant Resources of an MRS Cluster Is Changed to 0?

You can run only one Spark task at a time after the minimum tenant resources of an MRS cluster is changed to 0.

15.8.4 What Are the Differences Between the Client Mode and Cluster Mode of Spark Jobs?

You need to understand the concept ApplicationMaster before understanding the essential differences between Yarn-client and Yarn-cluster.

In Yarn, each application instance has an ApplicationMaster process, which is the first container started by the application. It interacts with ResourceManager and requests resources. After obtaining resources, it instructs NodeManager to start containers. The essential difference between the Yarn-cluster and Yarn-client modes lies in the ApplicationMaster process.

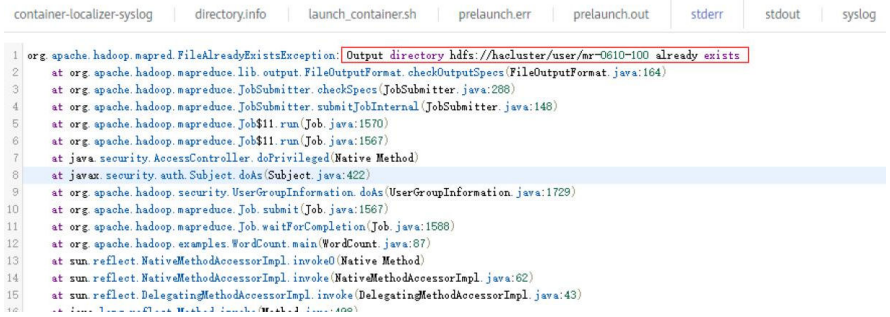
In Yarn-cluster mode, Driver runs in ApplicationMaster, which requests resources from Yarn and monitors the running status of a job. After a user submits a job, the client can be stopped and the job continues running on Yarn. Therefore, the Yarn-cluster mode is not suitable for running interactive jobs.

In Yarn-client mode, ApplicationMaster requests only Executor from Yarn. The client communicates with the requested containers to schedule tasks. Therefore, the client cannot be stopped.

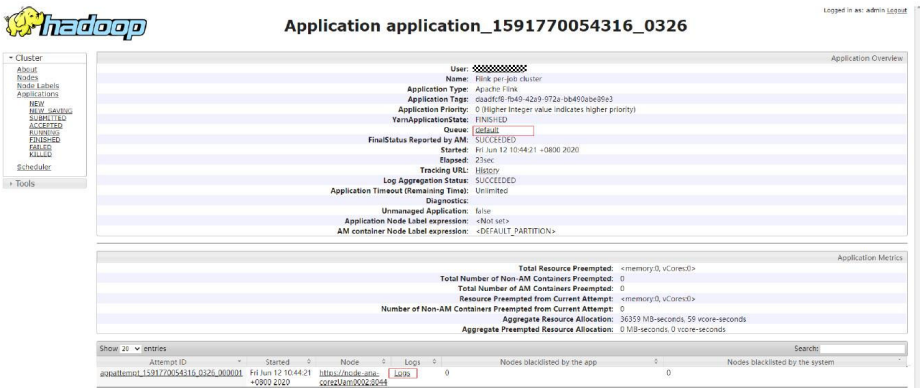
15.8.5 How Do I View MRS Job Logs?

Step 1 On the **Jobs** page of the MRS console, you can view logs of each job, including launcherJob and realJob logs.

- Generally, error logs are printed in **stderr** and **stdout** for launcherJob jobs, as shown in the following figure:



- You can view realJob logs on the ResourceManager web UI provided by the Yarn service on MRS Manager.



Step 2 Log in to the Master node of the cluster to obtain the job log files in **Step 1**. The HDFS path is **/tmp/logs/***{submit_user}*/**logs/***{application_id}*.

Step 3 After the job is submitted, if the job application ID cannot be found on the Yarn web UI, the job fails to be submitted. You can log in to the active Master node of the cluster and view the job submission process log **/var/log/executor/logs/exe.log**.

----End

15.8.6 How Do I Do If the Message "The current user does not exist on MRS Manager. Grant the user sufficient permissions on IAM and then perform IAM user synchronization on the Dashboard tab page." Is Displayed?

If IAM synchronization is not performed when a job is submitted in a security cluster, the error message "The current user does not exist on MRS Manager.

Grant the user sufficient permissions on IAM and then perform IAM user synchronization on the Dashboard tab page." is displayed.

Before submitting a job, on the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.

15.8.7 LauncherJob Job Execution Is Failed And the Error Message "jobPropertiesMap is null." Is Displayed

The cause of the launcherJob failure is that the user who submits the job does not have the write permission on the **hdfs /mrs/job-properties** directory.

This problem is fixed in the 2.1.0.6 patch. You can also grant the write permission on the **/mrs/job-properties** directory to the synchronized user who submits the job on MRS Manager.

15.8.8 How Do I Do If the Flink Job Status on the MRS Console Is Inconsistent with That on Yarn?

To save storage space, the Yarn configuration item **yarn.resourcemanager.max-completed-applications** is modified to reduce the number of historical job records stored on Yarn. Flink jobs are long-term jobs. The realJob is still running on Yarn, but the launcherJob has been deleted. As a result, the launcherJob cannot be found on Yarn, and the job status fails to be updated. This problem is fixed in the 2.1.0.6 patch.

Workaround: Terminate the job whose launcherJob cannot be found. The status of the job submitted later will be updated.

15.8.9 How Do I Do If a SparkStreaming Job Fails After Being Executed Dozens of Hours and the OBS Access 403 Error is Reported?

When a user submits a job that needs to read and write OBS, the job submission program adds the temporary access key (AK) and secret key (SK) for accessing OBS by default. However, the temporary AK and SK have expiration time.

If you want to run long-term jobs such as Flink and SparkStreaming, you can enter the AK and SK in **Service Parameter** to ensure that the jobs will not fail to be executed due to key expiration.

15.8.10 How Do I Do If an Alarm Is Reported Indicating that the Memory Is Insufficient When I Execute a SQL Statement on the ClickHouse Client?

Symptom

The ClickHouse client restricts the memory used by GROUP BY statements. When a SQL statement is executed on the ClickHouse client, the following error information is displayed:

```
Progress: 1.83 billion rows, 85.31 GB (68.80 million rows/s., 3.21 GB/s.)  6%Received exception from server:
```

```
Code: 241. DB::Exception: Received from localhost:9000, 127.0.0.1.
DB::Exception: Memory limit (for query) exceeded: would use 9.31 GiB (attempt to allocate chunk of
1048576 bytes), maximum: 9.31 GiB:
(while reading column hits):
```

Solution

- Run the following command before executing an SQL statement on condition that the cluster has sufficient memory:
  ```
  SET max_memory_usage = 128000000000; #128G
  ```
- If no sufficient memory is available, ClickHouse enables you to overflow data to disk to free up the memory: You are advised to set the value of **max_memory_usage** to twice the size of **max_bytes_before_external_group_by**.
  ```
  set max_bytes_before_external_group_by=20000000000; #20G
  set max_memory_usage=40000000000; #40G
  ```

15.8.11 How Do I Do If Error Message "java.io.IOException: Connection reset by peer" Is Displayed During the Execution of a Spark Job?

Symptom

The Spark job keeps running and error message "java.io.IOException: Connection reset by peer" is displayed.

Solution

Add the **executor.memory Overhead** parameter to the parameters for submitting a job.

15.8.12 How Do I Do If Error Message "requestId=49718838510717737250" Is Displayed When a Spark Job Accesses OBS?

Symptom

Error message "requestId=4971883851071737250" is displayed when a Spark job accesses OBS.

Solution

Log in to the node where the Spark client is located, go to the **conf** directory, and change the value of the **fs.obs.metrics.switch** parameter in the **core-site.xml** configuration file to **false**.

15.8.13 Why DataArtsStudio Occasionally Fail to Schedule Spark Jobs and the Rescheduling also Fails?

Symptom

DataArtsStudio occasionally fails to schedule Spark jobs and the rescheduling also fails. The following error information is displayed:

```
Caused by: org.apache.spark.SparkException: Application application_1619511926396_2586346 finished with failed status
```

Solution

Log in to the node where the Spark client is located as user **root** and increase the value of the **spark.driver.memory** parameter in the **spark-defaults.conf** file.

15.8.14 How Do I Do If a Flink Job Fails to Execute and the Error Message "java.lang.NoSuchFieldError: SECURITY_SSL_ENCRYPT_ENABLED" Is Displayed?

Symptom

A Flink job fails to be executed and the following error message is displayed:

```
Caused by: java.lang.NoSuchFieldError: SECURITY_SSL_ENCRYPT_ENABLED
```

Solution

The third-party dependency package in the customer code conflicts with the cluster package. As a result, the job fails to be submitted to the MRS cluster. You need to modify the dependency package, set the scope of the open source Hadoop package and Flink package in the POM file to **provide**, and pack and execute the job again.

15.8.15 Why Submitted Yarn Job Cannot Be Viewed on the Web UI?

After a Yarn job is created, it cannot be viewed if you log in to the web UI as the **admin** user.

- The **admin** user is a user on the cluster management page. Check whether the user has the **supergroup** permission. Generally, only the user with the **supergroup** permission can view jobs.
- Log in to Yarn as the user who submits jobs to view jobs on Yarn. Do not view the jobs using the **admin** user.

15.8.16 How Do I Modify the HDFS NameSpace (fs.defaultFS) of an Existing Cluster?

You can modify or add the HDFS NameSpace (fs.defaultFS) of the cluster by modifying the **core-site.xml** and **hdfs-site.xml** files on the client. However, you are not advised to perform this operation on the server.

15.8.17 How Do I Do If the launcher-job Queue Is Stopped by YARN due to Insufficient Heap Size When I Submit a Flink Job on the Management Plane?

Symptom

The launcher-job queue is stopped by YARN when a Flink job is submitted on the management plane.

Solution

Increase the heap size of the launcher-job queue.

1. Log in to the active OMS node as user **omm**.
2. Change the value of **job.launcher.resource.memory.mb** in **/opt/executor/webapps/executor/WEB-INF/classes/servicebroker.xml** to **2048**.
3. Run the **sh /opt/executor/bin/restart-executor.sh** command to restart the executor process.

15.8.18 How Do I Do If the Error Message "slot request timeout" Is Displayed When I Submit a Flink Job?

Symptom

When a Flink job is submitted, JobManager is started successfully. However, TaskManager remains in the starting state until timeout. The following error information is displayed:

```
org.apache.flink.runtime.jobmanager.scheduler.NoResourceAvailableException: Could not allocate the required slot within slot request timeout. Please make sure that the cluster has enough resources
```

Possible Causes

1. The resources in the YARN queue are insufficient. As a result, TaskManager fails to start.
2. Your JAR files conflict with those in the environment. You can execute the WordCount program to determine whether the issue occurs.
3. If the cluster is in security mode, the SSL certificate of Flink may be incorrectly configured or has expired.

Solution

1. Add resources to the YARN queue.

2. Exclude the Flink and Hadoop dependencies in your JAR files so that Flink and Hadoop can depend only on the JAR files in the environment.
3. Reconfigure the SSL certificate of Flink..

15.8.19 Data Import and Export of DistCP Jobs

- Does a DistCP job compare data consistency during data import and export?

  No. DistCP jobs only copy data but do not modify it.
- When data is exported from a DistCP job, if some files already exist in OBS, how will the job process the files?

  DistCP jobs will overwrite the files in OBS.

15.9 Cluster Upgrade/Patching

15.9.1 Can I Upgrade an MRS Cluster?

You cannot upgrade an MRS cluster. However, you can create a cluster of the target version and migrate data from the old cluster to the new cluster.

15.9.2 Can I Change the MRS Cluster Version?

You cannot change the version of an MRS cluster. However, you can terminate the current cluster and create an MRS cluster of the version you require.

15.10 Cluster Access

15.10.1 Can I Switch Between the Two Login Modes of MRS?

No. You can select the login mode when creating the cluster. You cannot change the login mode after you created the cluster.

15.10.2 How Can I Obtain the IP Address and Port Number of a ZooKeeper Instance?

You can obtain the IP address and port number of a ZooKeeper instance through the MRS console or FusionInsight Manager.

Method 1: Obtaining the IP address and port number of a ZooKeeper through the MRS console

1. On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.
2. Click the **Components** tab and choose **ZooKeeper**. On the displayed page, click **Instances** to view the business IP address of a ZooKeeper instance.
3. Click the **Service Configuration** tab. On the displayed page, search for the **clientPort** parameter to view the port number of the ZooKeeper instance.

Method 2: Obtaining the IP address and port number of a ZooKeeper through FusionInsight Manager

1. Log in to FusionInsight Manager. For details, see .
2. Perform the following operations to obtain the IP address and port number of a ZooKeeper instance.
   - For clusters of MRS 3.*x* or earlier
     i. Choose **Services** > **ZooKeeper**. On the displayed page, click the **Instance** tab to view the business IP address of a ZooKeeper instance.
     ii. Click the **Service Configuration** tab. On the displayed page, search for the **clientPort** parameter to view the port number of the ZooKeeper instance.
   - For clusters of MRS 3.*x* or later
     i. Choose **Cluster** > **Services** > **ZooKeeper**. On the displayed page, click the **Instance** tab to view the business IP address of a ZooKeeper instance.
     ii. Click the **Configurations** tab. On the displayed page, search for the **clientPort** parameter to view the port number of the ZooKeeper instance.

15.10.3 How Do I Access an MRS Cluster from a Node Outside the Cluster?

Creating a Linux ECS Outside the Cluster to Access the MRS Cluster

Step 1 Create an ECS outside the cluster.

Set **AZ**, **VPC**, and **Security Group** of the ECS to the same values as those of the cluster to be accessed.

Step 2 On the VPC management console, apply for an EIP and bind it to the ECS.

Step 3 Configure security group rules for the cluster.

1. On the **Dashboard** tab page, click **Add Security Group Rule**. In the **Add Security Group Rule** dialog box that is displayed, click **Manage Security Group Rule**.
2. Click the **Inbound Rules** tab, and click **Add Rule**. In the **Add Inbound Rule** dialog box, configure the IP address of the ECS and enable all ports.
3. After the security group rule is added, you can download and install the client on the ECS..
4. Use the client.

   Log in to the client node as the client installation user and run the following command to switch to the client directory:

   cd /opt/hadoopclient

   Run the following command to load environment variables:

   source bigdata_env

   If Kerberos authentication is enabled for the cluster, run the following command to authenticate the user. If Kerberos authentication is disabled for the current cluster, authentication is not required.

kinit *MRS cluster user*

Example:

kinit admin

Run the client command of a component.

Example:

Run the following command to view files in the HDFS root directory:

hdfs dfs -ls /

```
Found 15 items
drwxrwx--x   - hive       hive              0 2021-10-26 16:30 /apps
drwxr-xr-x   - hdfs       hadoop            0 2021-10-18 20:54 /datasets
drwxr-xr-x   - hdfs       hadoop            0 2021-10-18 20:54 /datastore
drwxrwx---+  - flink      hadoop            0 2021-10-18 21:10 /flink
drwxr-x---   - flume      hadoop            0 2021-10-18 20:54 /flume
drwxrwx--x   - hbase      hadoop            0 2021-10-30 07:31 /hbase
...
```

----End

15.11 Big Data Service Development

15.11.1 Can MRS Run Multiple Flume Tasks at a Time?

The Flume client supports multiple independent data flows. You can configure and link multiple sources, channels, and sinks in the **properties.properties** configuration file. These components can be linked to form multiple flows.

The following is an example of configuring two data flows in a configuration file:

```
server.sources = source1 source2
server.sinks = sink1 sink2
server.channels = channel1 channel2

#dataflow1
server.sources.source1.channels = channel1
server.sinks.sink1.channel = channel1

#dataflow2
server.sources.source2.channels = channel2
server.sinks.sink2.channel = channel2
```

15.11.2 How Do I Change FlumeClient Logs to Standard Logs?

1. Log in to the node where FlumeClient is running.
2. Go to the FlumeClient installation directory.

   For example, if the FlumeClient installation directory is **/opt/FlumeClient**, run the following command:

   cd /opt/FlumeClient/fusioninsight-flume-1.9.0/bin
3. Run the **./flume-manage.sh stop** command to stop FlumeClient.
4. Run the **vi /log4j.properties** command to open the **log4j.properties** file and change the value of **flume.root.logger** to **${flume.log.level},console**.
5. Run the **vim /flume-manager.sh** command to open the **flume-manager.sh** script in the **bin** directory in the Flume installation directory.

6. Comment out the following information in the **flume-manager.sh** script:

   >/dev/null 2>&1 &

7. Run the **./flume-manage.sh start** command to restart FlumeClient.
8. After the modification, check whether the Docker configuration is correct.

15.11.3 Where Are the .jar Files and Environment Variables of Hadoop Located?

- The **hadoopstreaming.jar** file is stored in the **/opt/share/hadoop-streaming-*** directory. ***** indicates the Hadoop version.
- The JDK environment variables are stored in **/opt/client/JDK/component_env**.
- The Hadoop environment variables are stored in **/opt/client/HDFS/component_env**.
- The Hadoop client path is **/opt/client/HDFS/hadoop**.

15.11.4 What Compression Algorithms Does HBase Support?

HBase supports the Snappy, LZ4, and gzip compression algorithms.

15.11.5 Can MRS Write Data to HBase Through the HBase External Table of Hive?

No. Hive on HBase supports only data query.

15.11.6 How Do I View HBase Logs?

1. Log in to the Master node in the cluster as user **root**.
2. Run the **su - omm** command to switch to user **omm**.
3. Run the **cd /var/log/Bigdata/hbase/** command to go to the **/var/log/Bigdata/hbase/** directory and view HBase logs.

15.11.7 How Do I Set the TTL for an HBase Table?

- Set the time to live (TTL) when creating a table:

  Create the **t_task_log** table, set the column family to **f**, and set the TTL to **86400** seconds.

  ```
  create 't_task_log',{NAME => 'f', TTL=>'86400'}
  ```

- Set the TTL for an existing table:

  ```
  disable "t_task_log" #Disable the table (services must be stopped).
  alter "t_task_log",NAME=>'data',TTL=>'86400' # Set the TTL value for the column family data.
  enable "t_task_log" #Restore the table.
  ```

15.11.8 How Do I Balance HDFS Data?

1. Log in to the master node of the cluster and run the corresponding command to configure environment variables. **/opt/client** indicates the client installation directory. Replace it with the actual one.

   source /opt/client/bigdata_env

kinit Component service user (If Kerberos authentication is enabled for the cluster, run this command to authenticate the user. Skip this step if the Kerberos authentication is disabled.)

2. Run the following command to start the balancer:

   /opt/client/HDFS/hadoop/sbin/start-balancer.sh -threshold 5

3. View the log.

   After you execute the balance task, the **hadoop-root-balancer-***Host name*.**log** log file will be generated in the client installation directory **/opt/client/HDFS/hadoop/logs**.

4. (Optional) If you do not want to perform data balancing, run the following commands to stop the balancer:

   source /opt/client/bigdata_env

   kinit Component service user (If Kerberos authentication is enabled for the cluster, run this command to authenticate the user. Skip this step if the Kerberos authentication is disabled.)

   /opt/client/HDFS/hadoop/sbin/stop-balancer.sh -threshold 5

15.11.9 How Do I Change the Number of HDFS Replicas?

1. Search for **dfs.replication**, change the value (value range: 1 to 16), and restart the HDFS instance.

15.11.10 What Is the Port for Accessing HDFS Using Python?

The default port of open source HDFS is **50070** for versions earlier than MRS 3.0.0, and **9870** for MRS 3.0.0 or later. **Common HDFS Ports** describes the common ports of HDFS.

Common HDFS Ports

The protocol type of all ports in the table is TCP.

Parameter	Default Port	Port Description
dfs.namenode.rpc.port	• 9820 (versions earlier than MRS 3.*x*) • 8020 (MRS 3.*x* and later)	NameNode RPC port This port is used for: 1. Communication between the HDFS client and NameNode 2. Connection between the DataNode and NameNode **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. • Is the port enabled by default during the installation: Yes • Is the port enabled after security hardening: Yes

Parameter	Default Port	Port Description
dfs.namenode.http.port	9870	HDFS HTTP port (NameNode) This port is used for: 1. Point-to-point NameNode checkpoint operations. 2. Connecting the remote web client to the NameNode UI **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.namenode.https.port	9871	HDFS HTTPS port (NameNode) This port is used for: 1. Point-to-point NameNode checkpoint operations 2. Connecting the remote web client to the NameNode UI **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.datanode.ipc.port	9867	IPC server port of DataNode This port is used for: Connection between the client and DataNode to perform RPC operations. **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Parameter	Default Port	Port Description
dfs.datanode.port	9866	DataNode data transmission port This port is used for: 1. Transmitting data from HDFS client from or to the DataNode 2. Point-to-point DataNode data transmission **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.datanode.http.port	9864	DataNode HTTP port This port is used for: Connecting to the DataNode from the remote web client in security mode **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.datanode.https.port	9865	HTTPS port of DataNode This port is used for: Connecting to the DataNode from the remote web client in security mode **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Parameter	Default Port	Port Description
dfs.JournalNode.rpc.port	8485	RPC port of JournalNode This port is used for: Client communication to access multiple types of information **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.journalnode.http.port	8480	JournalNode HTTP port This port is used for: Connecting to the JournalNode from the remote web client in security mode **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes
dfs.journalnode.https.port	8481	HTTPS port of JournalNode This port is used for: Connecting to the JournalNode from the remote web client in security mode **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. ● Is the port enabled by default during the installation: Yes ● Is the port enabled after security hardening: Yes

Parameter	Default Port	Port Description
httpfs.http.port	14000	Listening port of the HttpFS HTTP server This port is used for: Connecting to the HttpFS from the remote REST API **NOTE** The port ID is a recommended value and is specified based on the product. The port range is not restricted in the code. • Is the port enabled by default during the installation: Yes • Is the port enabled after security hardening: Yes

15.11.11 How Do I Modify the HDFS Active/Standby Switchover Class?

If the **org.apache.hadoop.hdfs.server.namenode.ha.AdaptiveFailoverProxyProvider** class is unavailable when a cluster of MRS 3.*x* connects to NameNodes using HDFS, the cause is that the HDFS active/standby switchover class of the cluster is configured improperly. To solve the problem, perform the following operations:

- Method 1: Add the **hadoop-plugins-*xxx*.jar** package to the **classpath** or **lib** directory of your program.

  The **hadoop-plugins-*xxx*.jar** package is stored in the HDFS client directory, for example, **$HADOOP_HOME/share/hadoop/common/lib/hadoop-plugins-8.0.2-302023.jar**.
- Method 2: Change the configuration item of HDFS to the corresponding open source class, as shown in the follows:

  dfs.client.failover.proxy.provider.hacluster=org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider

15.11.12 What Is the Recommended Number Type of DynamoDB in Hive Tables?

smallint is recommended.

15.11.13 Can the Hive Driver Be Interconnected with DBCP2?

The Hive driver cannot be interconnected with the DBCP2 database connection pool. The DBCP2 database connection pool invokes the **isValid** method to check whether a connection is available. However, Hive directly throws an exception when implementing this method.

15.11.14 How Do I View the Hive Table Created by Another User?

Versions earlier than MRS 3.*x*:

1. Log in to MRS Manager and choose **System** > **Permission** > **Manage Role**.
2. Click **Create Role**, and set **Role Name** and **Description**.
3. In the **Permission** table, choose **Hive** > **Hive Read Write Privileges**.
4. In the database list, click the name of the database where the table created by user B is stored. The table is displayed.
5. In the **Permission** column of the table created by user B, select **SELECT**.
6. Click **OK**, and return to the **Role** page.
7. Choose **System** > **Manage User**. Locate the row containing user A, click **Modify** to bind the new role to user A, and click **OK**. After about 5 minutes, user A can access the table created by user B.

MRS 3.*x* or later:

1. Log in to FusionInsight Manager and choose **Cluster** > **Services**. On the page that is displayed, choose **Hive**. On the displayed page, choose **More**, and check whether **Enable Ranger** is grayed out.
   - If yes, go to **9**.
   - If no, perform **2** to **8**.
2. Log in to FusionInsight Manager and choose **System** > **Permission** > **Role**.
3. Click **Create Role**, and set **Role Name** and **Description**.
4. In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Hive** > **Hive Read Write Privileges**.
5. In the database list, click the name of the database where the table created by user B is stored. The table is displayed.
6. In the **Permission** column of the table created by user B, select **Select**.
7. Click **OK**, and return to the **Role** page.
8. Choose **Permission** > **User**. On the **Local User** page that is displayed, locate the row containing user A, click **Modify** in the **Operation** column to bind the new role to user A, and click **OK**. After about 5 minutes, user A can access the table created by user B.
9. Perform the following steps to add the Ranger access permission policy of Hive:
   a. Log in to FusionInsight Manager as a Hive administrator and choose **Cluster** > **Services**. On the page that is displayed, choose **Ranger**. On the displayed page, click the URL next to **Ranger WebUI** to go to the Ranger management page.
   b. On the home page, click the component plug-in name in the **HADOOP SQL** area, for example, **Hive**.
   c. On the **Access** tab page, click **Add New Policy** to add a Hive permission control policy.
   d. In the **Create Policy** dialog box that is displayed, set the following parameters:

- **Policy Name**: Enter a policy name, for example, **table_test_hive**.
- **database**: Enter or select the database where the table created by user B is stored, for example, **default**.
- **table**: Enter or select the table created by user B, for example, **test**.
- **column**: Enter and select a column, for example, *****.
- In the **Allow Conditions** area, click **Select User**, select user A, click **Add Permissions**, and select **select**.
- Click **Add**.

10. Perform the following steps to add the Ranger access permission policy of HDFS:
    a. Log in to FusionInsight Manager as user **rangeradmin** and choose **Cluster** > **Services**. On the page that is displayed, choose **Ranger**. On the displayed page, click the URL next to **Ranger WebUI** to go to the Ranger management page.
    b. On the home page, click the component plug-in name in the **HDFS** area, for example, **hacluster**.
    c. Click **Add New Policy** to add a HDFS permission control policy.
    d. In the **Create Policy** dialog box that is displayed, set the following parameters:
        - **Policy Name**: Enter a policy name, for example, **tablehdfs_test**.
        - **Resource Path**: Set this parameter to the HDFS path where the table created by user B is stored, for example, **/user/hive/warehouse/***Database name***/***Table name*.
        - In the **Allow Conditions** area, select user A for **Select User**, click **Add Permissions** in the **Permissions** column, and select **Read** and **Execute**.
        - Click **Add**.
11. View basic information about the policy in the policy list. After the policy takes effect, user A can view the table created by user B.

15.11.15 Can I Export the Query Result of Hive Data?

Run the following statement to export the query result of Hive data:

```
insert overwrite local directory "/tmp/out/" row format delimited fields terminated by "\t" select * from table;
```

15.11.16 How Do I Do If an Error Occurs When Hive Runs the beeline -e Command to Execute Multiple Statements?

When Hive of MRS 3.*x* runs the **beeline -e " use default;show tables;"** command, the following error message is displayed: Error while compiling statement: FAILED: ParseException line 1:11 missing EOF at ';' near 'default' (state=42000,code=40000).

Solutions:

- Method 1: Replace the **beeline -e " use default;show tables;"** command with **beeline --entirelineascommand=false -e "use default;show tables;"**.
- Method 2:
  a. In the **/opt/Bigdata/client/Hive** directory on the Hive client, change **export CLIENT_HIVE_ENTIRELINEASCOMMAND=true** in the **component_env** file to **export CLIENT_HIVE_ENTIRELINEASCOMMAND=false**.

  Figure 15-1 Changing the **component_env** file

  b. Run the following command to verify the configuration:

  source /opt/Bigdata/client/bigdata_env

  beeline -e " use default;show tables;"

15.11.17 How Do I Do If a "hivesql/hivescript" Job Fails to Submit After Hive Is Added?

This issue occurs because the **MRS CommonOperations** permission bound to the user group to which the user who submits the job belongs does not include the Hive permission after being synchronized to Manager. To solve this issue, perform the following operations:

1. Add the Hive service.
2. Log in to the IAM console and create a user group. The policy bound to the user group is the same as that of the user group to which the user who submits the job belongs.
3. Add the user who submits the job to the new user group.
4. Refresh the cluster details page on the MRS console. The status of IAM user synchronization is **Not synchronized**.
5. Click **Synchronize** on the right of **IAM User Sync**. Go back to the previous page. In the navigation pane on the left, choose **Operation Logs** and check whether the user is changed.
   - If yes, submit the Hive job again.
   - If no, check whether all the preceding operations are complete.
     - If yes, contact the O&M personnel.
     - If no, submit the Hive job after the preceding operations are complete.

15.11.18 What If an Excel File Downloaded on Hue Failed to Open?

1. Log in to a Master node as user **root** and switch to user **omm**.

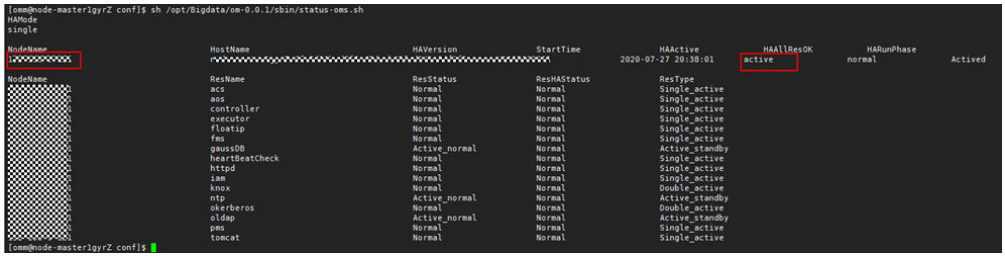
su - omm

2. Check whether the current node is the active OMS node.

   sh ${BIGDATA_HOME}/om-0.0.1/sbin/status-oms.sh

   If **active** is displayed in the command output, the node is the active node. Otherwise, log in to the other Master node.

Figure 15-2 Active OMS node



3. Go to the **${BIGDATA_HOME}/Apache-httpd-*/conf** directory.

   cd ${BIGDATA_HOME}/Apache-httpd-*/conf

4. Open the **httpd.conf** file.

   vim httpd.conf

5. Search for **21201** in the file and delete the following content from the file (The values of *proxy_ip* and *proxy_port* in **Figure 15-3** are examples only):

   ProxyHTMLEnable On
   SetEnv PROXY_PREFIX=https://[proxy_ip]:[proxy_port]
   ProxyHTMLURLMap (https?:\/\/[^:]*:[0-9]*.*) ${PROXY_PREFIX}/proxyRedirect=$1 RV

Figure 15-3 Content to be deleted

6. Save the modification and exit.
7. Open the **httpd.conf** file again, search for **proxy_hue_port**, and delete the following content:

   ProxyHTMLEnable On
   SetEnv PROXY_PREFIX=https://[proxy_ip]:[proxy_port]
   ProxyHTMLURLMap (https?:\/\/[^:]*:[0-9]*.*) ${PROXY_PREFIX}/proxyRedirect=$1 RV

Figure 15-4 Content to be deleted

8. Save the modification and exit.
9. Run the following command to restart the **httpd** process:

   sh ${BIGDATA_HOME}/Apache-httpd-*/setup/restarthttpd.sh
10. Check whether the **httpd.conf** file on the standby Master node is modified. If the file is modified, no further action is required. If the file is not modified, modify the **httpd.conf** file on the standby Master node in the same way. You do not need to restart the **httpd** process.
11. Download the Excel file again. You can open the file successfully.

15.11.19 How Do I Do If Sessions Are Not Released After Hue Connects to HiveServer and the Error Message "over max user connections" Is Displayed?

Applicable versions: MRS 3.1.0 and earlier

1. Modify the following file on the two Hue nodes:

   /opt/Bigdata/FusionInsight_Porter_8.*/install/FusionInsight-Hue-*/hue/apps/beeswax/src/beeswax/models.py
2. Change the configurations in lines 396 and 404.

   Change **q Changed = self.filter(owner=user, application=application).exclude(guid='').exclude(secret='')** to **q = self.filter(owner=user, application=application).exclude(guid=None).exclude(secret=None)**.

15.11.20 How Do I Reset Kafka Data?

You can reset Kafka data by deleting Kafka topics.

- Delete a topic: **kafka-topics.sh --delete --zookeeper** *ZooKeeper Cluster service IP address*:**2181/kafka --topic** ***topicname***
- Query all topics: **kafka-topics.sh --zookeeper** *ZooKeeper cluster service IP address*:**2181/kafka --list**

After the deletion command is executed, empty topics will be deleted immediately. If a topic has data, the topic will be marked for deletion and will be deleted by Kafka later.

15.11.21 How Do I Obtain the Client Version of MRS Kafka?

Run the **--bootstrap-server** command to query the information about the client.

15.11.22 What Access Protocols Are Supported by Kafka?

Kafka supports PLAINTEXT, SSL, SASL_PLAINTEXT, and SASL_SSL.

15.11.23 How Do I Do If Error Message "Not Authorized to access group xxx" Is Displayed When a Kafka Topic Is Consumed?

This issue is caused by the conflict between the Ranger authentication and ACL authentication of a cluster. If a Kafka cluster uses ACL for permission access control and Ranger authentication is enabled for the Kafka component, all authentications of the component are managed by Ranger. The permissions set by the original authentication plug-in are invalid. As a result, ACL authorization does not take effect. You can disable Ranger authentication of Kafka and restart the Kafka service to rectify the fault. The procedure is as follows:

1. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**.
2. In the upper right corner of the **Dashboard** page, click **More** and choose **Disable Ranger**. In the displayed dialog box, enter the password and click **OK**. After the operation is successful, click **Finish**.
3. In the upper right corner of the **Dashboard** page, click **More** and choose **Restart Service** to restart the Kafka service.

15.11.24 What Compression Algorithms Does Kudu Support?

Kudu supports **Snappy**, **LZ4**, and **zlib**. **LZ4** is used by default.

15.11.25 How Do I View Kudu Logs?

1. Log in to the Master node in the cluster.
2. Run the **su - omm** command to switch to user **omm**.
3. Run the **cd /var/log/Bigdata/kudu/** command to go to the **/var/log/Bigdata/kudu/** directory and view Kudu logs.

15.11.26 How Do I Handle the Kudu Service Exceptions Generated During Cluster Creation?

Viewing the Kudu Service Exception Logs

1. Log in to the MRS console.
2. Click the name of the cluster.
3. On the page displayed, choose **Components** > **Kudu** > **Instances** and locate the IP address of the abnormal instance.

   If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)
4. Log in to the node where the abnormal instance resides, and view the Kudu log.

   ```
   cd /var/log/Bigdata/Kudu
   [root@node-master1AERu kudu]# ls
   healthchecklog  runninglog  startlog
   ```

   You can find the Kudu health check logs in the **healthchecklog** directory, the startup logs in the **startlog** directory, and the Kudu process run logs in the **runninglog** directory.

```
[root@node-master1AERu logs]# pwd
/var/log/Bigdata/kudu/runninglog/master/logs
[root@node-master1AERu logs]# ls -al
kudu-master.ERROR   kudu-master.INFO   kudu-master.WARNING
```

Run logs are classified into three types: ERROR, INFO, and WARNING. Each type of run logs is recorded in the corresponding file. You can run the **cat** command to view run logs of each type.

Handling Kudu Service Exceptions

The **/var/log/Bigdata/kudu/runninglog/master/logs/kudu-master.INFO** file contains the following error information:

```
"Unable to init master catalog manager: not found: Unable to initialize catalog manager: Failed to initialize sys tables async: Unable to load consensus metadata for tablet 00000000000000000000000000: xxx"
```

If this exception occurs when the Kudu service is installed for the first time, the KuduMaster service is not started. The data inconsistency causes the startup failure. To solve the problem, perform the following steps to clear the data directories and restart the Kudu service. If the Kudu service is not installed for the first time, clearing the data directories will cause data loss. In this case, migrate data and clear the data directory.

1. Search for the data directories **fs_data_dir**, **fs_wal_dir**, and **fs_meta_dir**.

   find /opt -name master.gflagfile

   cat /opt/Bigdata/FusionInsight_Kudu_*/*_KuduMaster/etc/master.gflagfile | grep fs_

2. On the cluster details page, choose **Components** > **Kudu** and click **Stop Service**.
3. Clear the Kudu data directories on all KuduMaster and KuduTserver nodes. The following command uses two data disks as an example.

   rm -Rvf /srv/Bigdata/data1/kudu, rm -Rvf /srv/Bigdata/data2/kudu

4. On the cluster details page, choose **Components** > **Kudu** and choose **More** > **Restart Service**.
5. Check the Kudu service status and logs.

15.11.27 Does OpenTSDB Support Python APIs?

OpenTSDB supports Python APIs. OpenTSDB provides HTTP-based RESTful APIs that are language-independent. Any language that supports HTTP requests can interconnect to OpenTSDB.

15.11.28 How Do I Configure Other Data Sources on Presto?

In this section, MySQL is used as an example.

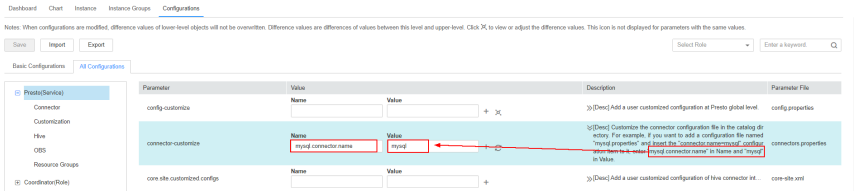
- For MRS 1.*x* and 3.*x* clusters, do the following:
  a. Log in to the MRS management console.
  b. Click the name of the cluster to go to its details page.
  c. Click the **Components** tab and then **Presto** in the component list. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab.

d. On the Presto configuration page that is displayed, find **connector-customize**.

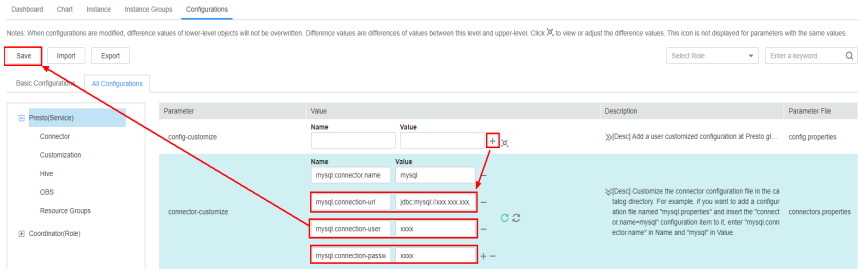
e. Set **Name** and **Value** as follows:

Name: **mysql.connector.name**

Value: **mysql**



f. Click the plus sign (+) to add three more fields and set **Name** and **Value** according to the table below. Then click **Save**.



Name	Value	Description
mysql.connection-url	jdbc:mysql://xxx.xxx.xxx.xxx:3306	Database connection pool
mysql.connection-user	xxxx	Database username
mysql.connection-password	xxxx	Database password

g. Restart the Presto service.

h. Run the following command to connect to the Presto Server of the cluster:

presto_cli.sh **--***krb5-config-path* {krb5.conf path} --*krb5-principal* {User principal} --*krb5-keytab-path* {user.keytab path} --*user* {presto username}

i. Log in to Presto and run the **show catalogs** command to check whether the data source list mysql of Presto can be queried.

```
[root@node-master2uoHG bin]# ./presto_cli.sh
--server http://10.[redacted]20
       show catalogs;
 Catalog
---------
 hive
 jmx
 mysql
 system
 tpcds
 tpch
(6 rows)

Query 20220422_121338_00002_ra2vb, FINISHED, 3 nodes
Splits: 53 total, 53 done (100.00%)
0:00 [0 rows, 0B] [0 rows/s, 0B/s]
```

Run the **show schemas from mysql** command to query the MySQL database.

- For MRS 2.*x* clusters, do the following:
  a. Create the **mysql.properties** configuration file containing the following content:

     connector.name=mysql

     connection-url=jdbc:mysql://mysqlIp:3306

     connection-user=Username

     connection-password=Password

     NOTE

     - **mysqlIp** indicates the IP address of the MySQL instance, which must be able to communicate with the MRS network.
     - The username and password are those used to log in to the MySQL database.

  b. Upload the configuration file to the **/opt/Bigdata/MRS_Current/1_14_Coordinator/etc/catalog/** directory on the master node (where the Coordinator instance resides) and the **/opt/Bigdata/MRS_Current/1_14_Worker/etc/catalog/** directory on the core node (depending on the actual directory in the cluster), and change the file owner group to **omm:wheel**.
  c. Restart the Presto service.

15.11.29 How Do I Connect to Spark Shell from MRS?

1. Log in to the Master node in the cluster as user **root**.
2. Run the following command to configure environment variables:

   source /opt/client/bigdata_env
3. If Kerberos authentication is enabled for the cluster, authenticate the user. If Kerberos authentication is disabled, skip this step.

   Command: **kinit** *MRS cluster user*

   Example:

   – If the user is a machine-machine user, run **kinit -kt user.keytab sparkuser**.
   – If the user is a human-machine user, run **kinit sparkuser**.
4. Run the following command to connect to Spark shell:

   spark-shell

15.11.30 How Do I Connect to Spark Beeline from MRS?

1. Log in to the master node in the cluster as user **root**.
2. Run the following command to configure environment variables:

   source /opt/client/bigdata_env
3. If Kerberos authentication is enabled for the cluster, authenticate the user. If Kerberos authentication is disabled, skip this step.

   Command: **kinit** *MRS cluster user*

   Example:

- If the user is a machine-machine user, run **kinit -kt user.keytab sparkuser**.
- If the user is a human-machine user, run **kinit sparkuser**.

4. Run the following command to connect to Spark Beeline:

   spark-beeline

5. Run commands on Spark Beeline. For example, create the table **test** in the **obs://mrs-word001/table/** directory.

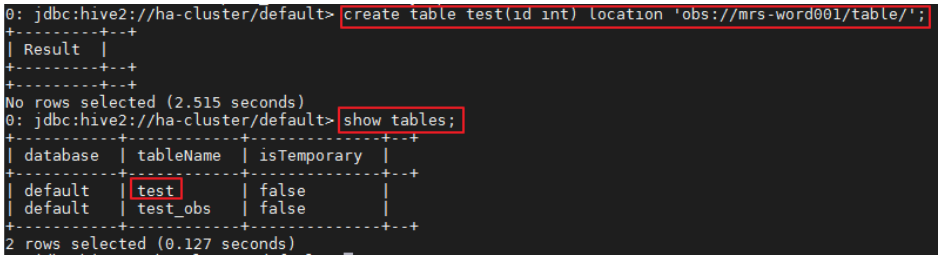
   create table test(id int) location 'obs://mrs-word001/table/';

6. Query all tables.

   show tables;

   If the table **test** is displayed in the command output, OBS is successfully accessed.

   Figure 15-5 Returned table name

7. Press **Ctrl+C** to exit the Spark Beeline.

15.11.31 Where Are the Execution Logs of Spark Jobs Stored?

- Logs of unfinished Spark jobs are stored in the **/srv/BigData/hadoop/data1/nm/containerlogs/** directory on the Core node.
- Logs of finished Spark jobs are stored in the **/tmp/logs/***username*/**logs** directory of HDFS.

15.11.32 How Do I Specify a Log Path When Submitting a Task in an MRS Storm Cluster?

You can modify the **/opt/Bigdata/MRS_***XXX* **/1_***XX* **_Supervisor/etc/worker.xml** file on the streaming Core node of MRS, set the value of **filename** to the path, and restart the corresponding instance on Manager.

You are advised not to modify the default log configuration of MRS. Otherwise, the log system may become abnormal.

15.11.33 How Do I Check Whether the ResourceManager Configuration of Yarn Is Correct?

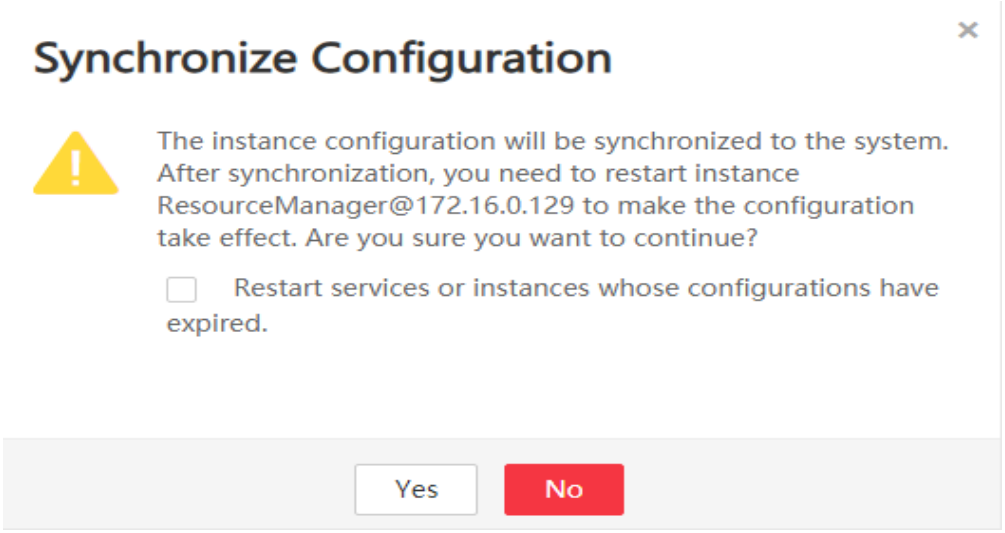
Step 1 Log in to MRS Manager and choose **Services** > **Yarn** > **Instance**.

Step 2 Synchronize the configuration between the two ResourceManager nodes.

Perform the following steps on each ResourceManager node:

1. Click the name of the ResourceManager node, and choose **More** > **Synchronize Configuration**.
2. In the dialog box displayed, deselect **Restart services or instances whose configurations have expired** and click **Yes**.

Figure 15-6 Synchronization configurations



Step 3 Log in to the Master nodes as user **root**.

Step 4 Run the **cd /opt/Bigdata/MRS_Current/*_*_ResourceManager/etc_UPDATED/** command to go to the **etc_UPDATED** directory.

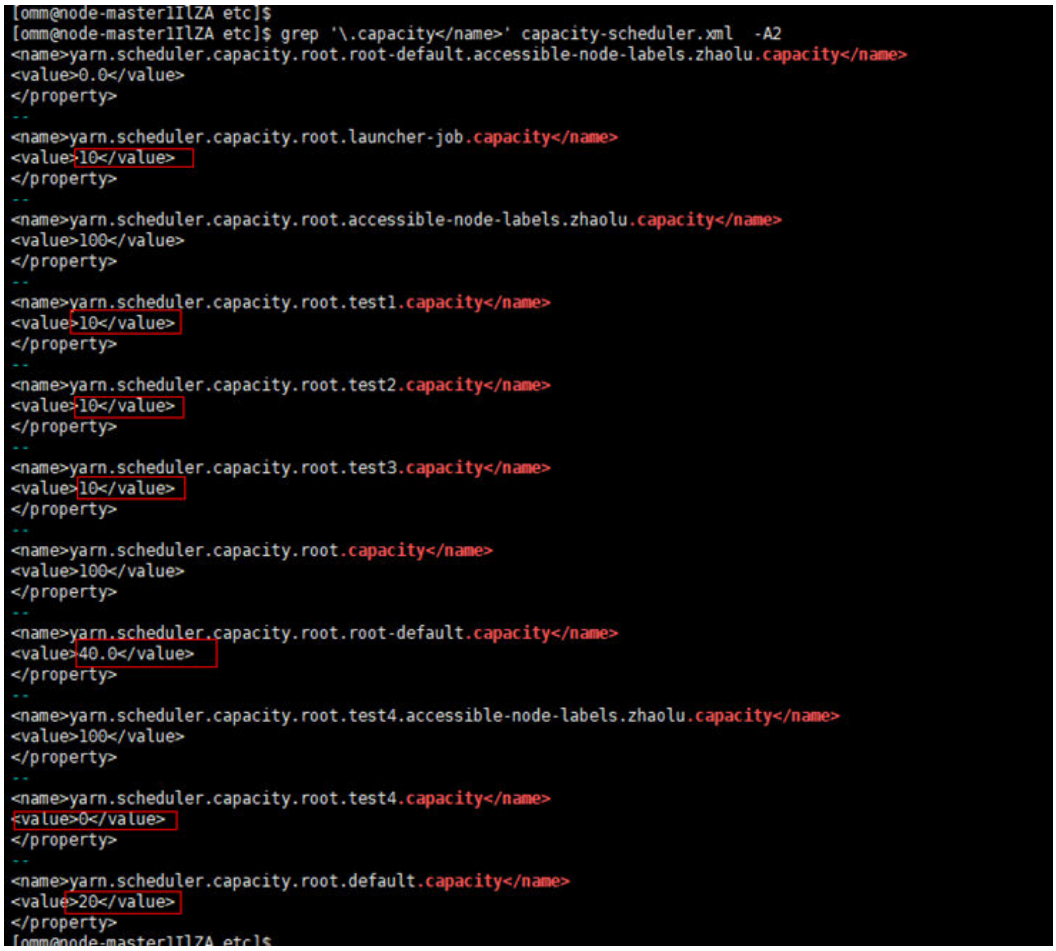
Step 5 Run the **grep '\.queues' capacity-scheduler.xml -A2** command to display all configured queues and check whether the queues are consistent with those displayed on Manager.

root-default is hidden on the Manager page.

```
[omm@node-master1IlZA etc]$
[omm@node-master1IlZA etc]$ grep '\.queues' capacity-scheduler.xml  -A2
<name>yarn.scheduler.capacity.root.queues</name>
<value>default,root-default,launcher-job,test1,test2,test3,test4</value>
</property>
[omm@node-master1IlZA etc]$
[omm@node-master1IlZA etc]$
```

Step 6 Run the **grep '\.capacity</name>' capacity-scheduler.xml -A2** command to display the value of each queue and check whether the value of each queue is the same as that displayed on Manager. Check whether the sum of the values configured for all queues is **100**.

- If the sum is **100**, the configuration is correct.
- If the sum is not **100**, the configuration is incorrect. Perform the following steps to rectify the fault.



Step 7 Log in to MRS Manager, and select **Hosts**.

Step 8 Determine the active Master node. The host name of the active Master node starts with a solid pentagon.

Step 9 Log in to the active Master node as user **root**.

Step 10 Run the **su - omm** command to switch to user **omm**.

Step 11 Run the **sh /opt/Bigdata/om-0.0.1/sbin/restart-controller.sh** command to restart the controller when no operation is being performed on Manager.

Restarting the controller will not affect the big data component services.

Step 12 Repeat **Step 1** to **Step 6** to synchronize ResourceManager configurations and check whether the configurations are correct.

If the latest configuration has not been loaded after the configuration synchronization is complete, a message will be displayed on the Manager page indicating that the configuration has expired. However, this will not affect services. The latest configuration will be automatically loaded when the component restarts.

----End

15.11.34 How Do I Modify the allow_drop_detached Parameter of ClickHouse?

Step 1 Log in to the node where the ClickHouse client is located as user **root**.

Step 2 Run the following commands to go to the client installation directory and set the environment variables:

cd /opt/*Client installation directory*

source bigdata_env

Step 3 If Kerberos authentication is enabled for the cluster, run the following command to authenticate the user. If Kerberos authentication is disabled, skip this step.

kinit *MRS cluster user*

NOTE

The user must have the ClickHouse administrator permissions.

Step 4 Run the **clickhouse client --host** *192.168.42.90* **--secure -m** command, in which *192.168.42.90* indicates the IP address of the ClickHouseServer instance node. The command output is as follows:

```
[root@server-2110082001-0017 hadoopclient]# clickhouse client --host 192.168.42.90 --secure -m
ClickHouse client version 21.3.4.25.
Connecting to 192.168.42.90:21427.
Connected to ClickHouse server version 21.3.4 revision 54447.
```

Step 5 Run the following command to set the value of the **allow_drop_detached** parameter, for example, **1**:

set allow_drop_detached=1;

Step 6 Run the following command to query the value of the **allow_drop_detached** parameter:

SELECT * FROM system.settings WHERE name = 'allow_drop_detached';

Step 7 Run the **q;** command to exit the ClickHouse client.

----End

15.11.35 How Do I Do If an Alarm Indicating Insufficient Memory Is Reported During Spark Task Execution?

Symptom

When a Spark task is executed, an alarm indicating insufficient memory is reported. The alarm ID is 18022. As a result, no available memory can be used.

Procedure

Set the executor parameters in the SQL script to limit the number of cores and memory of an executor.

For example, the configuration is as follows:

```
set hive.execution.engine=spark;
set spark.executor.cores=2;
set spark.executor.memory=4G;
set spark.executor.instances=10;
```

Change the values of the parameters as required.

15.11.36 How Do I Do If ClickHouse Consumes Excessive CPU Resources?

Symptom

A user performs a large number of update operations using ClickHouse. This operation on a ClickHouse consumes a large number of resources. In addition, the operation will be executed again if it fails. As a result, retries of those failed operations occupy too many CPU resources.

Procedure

Delete existing data from ZooKeeper and release delete the update statement.

15.11.37 How Do I Enable the Map Type on ClickHouse?

Step 1 Log in to the active Master node as user **root**.

Step 2 Run the following command to modify the **/opt/Bigdata/components/current/ClickHouse/configurations.xml** configuration file to enable user parameter customization:

vim /opt/Bigdata/components/current/ClickHouse/configurations.xml

Change **hidden** to **advanced**, as shown in the following information in bold. Then save the configuration and exit.

```
<property type="hidden" scope="all" classification="Customization"
classdesc="RESID_CLICKHOUSE_CONF_0056">
       <name>_clickhouse.custom_content.key</name>
       <value>_user-xml-content</value>
</property>
<property type="advanced" scope="all" classification="Customization"
classdesc="RESID_CLICKHOUSE_CONF_0056">
      <name>_user-xml-content</name>
      <value vType="text" checker="clickhouse.xmlformat">&lt;yandex&gt;&lt;/yandex&gt;</value>
      <description>RESID_CLICKHOUSE_CONF_0025</description>
</property>
```

Step 3 Run the following commands to switch to user **omm** and restart the controller service:

su - omm

sh /opt/Bigdata/om-server/om/sbin/restart-controller.sh

Step 4 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. Click **ClickHouseServer(Role)** > **Customization**, and add the following content to the **_user-xml-content** configuration item in the right pane:

```
<yandex>
  <profiles>
    <default>
   <allow_experimental_map_type>1</allow_experimental_map_type>
    </default>
  </profiles>
</yandex>
```

Step 5 Click **Save**.

Step 6 Choose **Cluster** > **Services** > **ClickHouse**. In the upper right corner, choose **More** > **Restart Service** to restart the ClickHouse service.

----End

15.11.38 A Large Number of OBS APIs Are Called When Spark SQL Accesses Hive Partitioned Tables

Symptom

When Spark SQL is used to access Hive partitioned tables stored in OBS, the acces speed is slow and a large number of OBS query APIs are called.

Example SQL:

```
select a,b,c from test where b=xxx
```

Fault Locating

According to the configuration, the task should scan only the partition whose b is *xxx*. However, the task logs show that the task scans all partitions and then calculates the data whose b is *xxx*. As a result, the task calculation is slow. In addition, a large number of OBS requests are sent because all files need to be scanned.

By default, the execution plan optimization based on partition statistics is enabled on MRS, which is equivalent to automatic execution of Analyze Table. (The default configuration method is to set **spark.sql.statistics.fallBackToHdfs** to **true**. You can set this parameter to **false**.) After this function is enabled, table partition statistics are scanned during SQL execution and used as cost estimation in the execution plan. For example, small tables identified during cost evaluation are broadcast to each node in the memory for join operations, significantly reducing shuffle time. This function greatly optimizes performance in join scenarios, but increases the number of OBS calls.

Procedure

Set the following parameter in Spark SQL and then run the SQL statement:

```
set spark.sql.statistics.fallBackToHdfs=false;
```

Alternatively, run the **--conf** command to set this parameter to **false** before startup.

```
--conf spark.sql.statistics.fallBackToHdfs=false
```

15.12 API

15.12.1 How Do I Configure the node_id Parameter When Using the API for Adjusting Cluster Nodes?

When you use the API for adjusting cluster nodes, the value of **node_id** is fixed to **node_orderadd**.

15.13 Cluster Management

15.13.1 How Do I View All Clusters?

You can view all MRS clusters on the **Clusters** page. You can view clusters in different status.

- **Active Clusters**: all clusters except clusters in **Failed** and **Terminated** states.
- **Cluster History**: clusters in the **Terminated** state. Only the clusters terminated within the last six months are displayed. If you want to view clusters terminated more than six months ago, contact technical support engineers.
- **Failed Tasks**: tasks in **Failed** state. The failed tasks include the following:
  - Tasks failed to create clusters
  - Tasks failed to terminate clusters
  - Tasks failed to scale out clusters
  - Tasks failed to scale in clusters

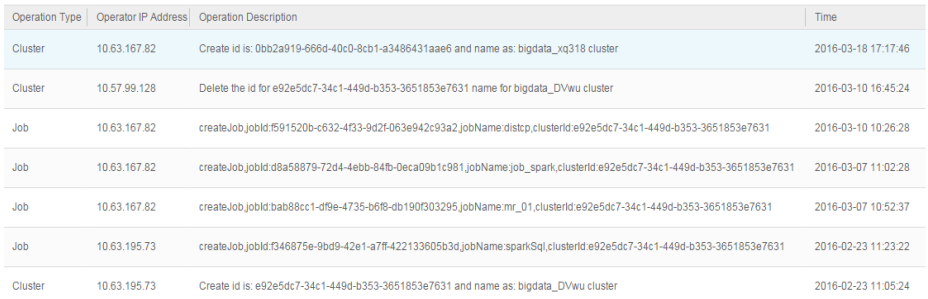
15.13.2 How Do I View Log Information?

You can view operation logs of clusters and jobs on the **Operation Logs** page. The MRS operation logs record the following operations:

- Cluster operations
  - Create, terminate, and scale out or in clusters
  - Create directories and delete directories or files
- Job operations: Create, stop, and delete jobs
- Data operations: IAM user tasks, add users, and add user groups

Figure 15-7 shows the operation logs.

Figure 15-7 Log information



Operation Type	Operator IP Address	Operation Description	Time
Cluster	10.63.167.82	Create id is: 0bb2a919-666d-40c0-8cb1-a3486431aae6 and name as: bigdata_xq318 cluster	2016-03-18 17:17:46
Cluster	10.57.99.128	Delete the id for e92e5dc7-34c1-449d-b353-3651853e7631 name for bigdata_DVwu cluster	2016-03-10 16:45:24
Job	10.63.167.82	createJob,jobId:f591520b-c632-4f33-9d2f-063e942c93a2,jobName:distcp,clusterId:e92e5dc7-34c1-449d-b353-3651853e7631	2016-03-10 10:26:28

Cluster	10.63.195.73	Create id is: e92e5dc7-34c1-449d-b353-3651853e7631 and name as: bigdata_DVwu cluster	2016-02-23 11:05:24

15.13.3 How Do I View Cluster Configuration Information?

- After a cluster is created, click the cluster name on the MRS console. On the page displayed, you can view basic configuration information about the cluster. The instance specifications and node capacity determine the data analysis and processing capability. Higher instance specifications and larger capacity enable faster data processing at a higher cost.
- On the basic information page, click **Access Manager** to access the MRS cluster management page. On MRS Manager, you can view and handle alarms, and modify cluster configuration.

15.13.4 How Do I Install Kafka and Flume in an MRS Cluster?

You cannot install the Kafka and Flume components for a created cluster of MRS 3.1.0 or earlier. Kafka and Flume are components for a streaming cluster. To install Kafka and Flume, create a streaming or hybrid cluster, and install Kafka and Flume.

15.13.5 How Do I Stop an MRS Cluster?

To stop an MRS cluster, stop each node in the cluster on the ECS. Click the name of each node on the **Nodes** tab page to go to the **Elastic Cloud Server** page and click **Stop**.

15.13.6 Can I Expand Data Disk Capacity for MRS?

You can expand data disk capacity for MRS during off-peak hours.

Expand the EVS disk capacity, and then log in to the ECS and expand the partitions and file system. MRS nodes are installed using public images and support the capacity expansion of in-use EVS disks.

15.13.7 Can I Add Components to an Existing Cluster?

You cannot add or remove any component to and from a created cluster of MRS 3.1.0. However, you can create an MRS cluster that contains the required components.

15.13.8 Can I Delete Components Installed in an MRS Cluster?

You cannot delete any component from a created MRS cluster of MRS 3.1.0. If a component is not required, log in to MRS Manager and stop the component on the **Services** page.

15.13.9 Can I Change MRS Cluster Nodes on the MRS Console?

You cannot change MRS cluster nodes on the MRS console. You are also advised not to change MRS cluster nodes on the ECS console. Manually stopping or deleting an ECS, modifying or reinstalling the ECS OS, or modifying ECS specifications for a cluster node on the ECS console will affect the cluster stability.

If an ECS is deleted, the ECS OS is modified or reinstalled, or the ECS specifications are modified on the ECS console, MRS will automatically identify and delete the node. You can log in to the MRS console and restore the deleted node through scale-out. Do not perform operations on the nodes that are being scaled out.

15.13.10 How Do I Shield Cluster Alarm/Event Notifications?

1. Log in to the MRS console.
2. Click the name of the cluster.
3. On the page displayed, choose **Alarms** > **Notification Rules**.
4. Locate the row that contains the rule you want to modify, click **Edit** in the **Operation** column, and deselect the alarm or event severity levels.
5. Click **OK**.

15.13.11 Why Is the Resource Pool Memory Displayed in the MRS Cluster Smaller Than the Actual Cluster Memory?

In an MRS cluster, MRS allocates 50% of the cluster memory to Yarn by default. You manage Yarn nodes logically by resource pool. Therefore, the total memory of the resource pool displayed in the cluster is only 50% of the total memory of the cluster.

15.13.12 How Do I Configure the knox Memory?

Step 1 Log in to a Master node of the cluster as user **root**.

Step 2 Run the following command on the Master node to open the **gateway.sh** file:

su omm

vim /opt/knox/bin/gateway.sh

Step 3 Change **APP_MEM_OPTS=""** to **APP_MEM_OPTS="-Xms256m -Xmx768m"**, save the file, and exit.

Step 4 Run the following command on the Master node to restart the knox process:

sh /opt/knox/bin/gateway.sh stop

sh /opt/knox/bin/gateway.sh start

Step 5 Repeat the preceding steps on each Master node.

Step 6 Run the **ps -ef |grep knox** command to check the configured memory.

Figure 15-8 knox memory

----End

15.13.13 What Is the Python Version Installed for an MRS Cluster?

Log in to a Master node as user **root** and run the **Python3** command to query the Python version.

15.13.14 How Do I View the Configuration File Directory of Each Component?

The configuration file paths of commonly used components are as follows:

Component	Configuration File Directory
ClickHouse	*Client installation directory*/**ClickHouse/clickhouse/config**
Flink	*Client installation directory*/**Flink/flink/conf**
Flume	*Client installation directory*/**fusioninsight-flume-***xxx*/**conf**
HBase	*Client installation directory*/**HBase/hbase/conf**
HDFS	*Client installation directory*/**HDFS/hadoop/logs/hadoop.log**
Hive	*Client installation directory*/**Hive/config**
Hudi	*Client installation directory*/**Hudi/hudi/conf**
Kafka	*Client installation directory*/**Kafka/kafka/config**
Loader	• *Client installation directory*/**Loader/loader-tools-xxx/loader-tool/conf** • *Client installation directory*/**Loader/loader-tools-xxx/schedule-tool/conf** • *Client installation directory*/**Loader/loader-tools-xxx/shell-client/conf** • *Client installation directory*/**Loader/loader-tools-xxx/sqoop-shell/conf**
Oozie	*Client installation directory*/**Oozie/oozie-client-***xxx*/**conf**

Component	Configuration File Directory
Spark2x	*Client installation directory/Spark2x/spark/conf*
Yarn	*Client installation directory/Yarn/config*
ZooKeeper	*Client installation directory/Zookeeper/zookeeper/conf*

15.13.15 How Do I Do If the Time on MRS Nodes Is Incorrect?

- If the time on a node inside the cluster is incorrect, log in to the node and rectify the fault from 2.
- If the time on a node inside the cluster is different from that on a node outside the cluster, log in to the node and rectify the fault from 1.

1. Run the **vi /etc/ntp.conf** command to edit the NTP client configuration file, add the IP addresses of the master node in the MRS cluster, and comment out the IP address of other servers.

   ```
   server master1_ip prefer
   server master2_ip
   ```

   Figure 15-9 Adding the master node IP addresses

   ```
   # For more information about this file, see the man pages
   # ntp.conf(5), ntp_acc(5), ntp_auth(5), ntp_clock(5), ntp_misc(5), ntp_mon(5).

   driftfile /var/lib/ntp/drift

   # Permit time synchronization with our time source, but do not
   # permit the source to query or modify the service on this system.
   restrict default nomodify notrap nopeer noquery

   # Permit all access over the loopback interface.  This could
   # be tightened as well, but to do so would effect some of
   # the administrative functions.
   restrict 127.0.0.1
   restrict ::1

   # Hosts on local network are less restricted.
   #restrict 192.168.1.0 mask 255.255.255.0 nomodify notrap

   # Use public servers from the pool.ntp.org project.
   # Please consider joining the pool (http://www.pool.ntp.org/join.html).
   #server 0.centos.pool.ntp.org iburst
   #server 1.centos.pool.ntp.org iburst
   #server 2.centos.pool.ntp.org iburst
   #server 3.centos.pool.ntp.org iburst
   #
   server 10.9.2.38 prefer
   server 10.9.2.39
   #broadcast 192.168.1.255 autokey        # broadcast server
   #broadcastclient                        # broadcast client
   #broadcast 224.0.1.1 autokey            # multicast server
   #multicastclient 224.0.1.1              # multicast client
   #manycastserver 239.255.254.254         # manycast server
   #manycastclient 239.255.254.254 autokey # manycast client

   # Enable public key cryptography.
   #crypto
   ```

2. Run the **service ntpd stop** command to stop the NTP service.
3. Run the **/usr/sbin/ntpdate** *IP address of the active master node* command to manually synchronize time.

4. Run the **service ntpd start** or **systemctl restart ntpd** command to start the NTP service.
5. Run the **ntpstat** command to check the time synchronization result:

15.13.16 How Do I Query the Startup Time of an MRS Node?

Log in to the target node and run the following command to query the startup time:

date -d "$(awk -F. '{print $1}' /proc/uptime) second ago" +"%Y-%m-%d %H:%M:%S"

```
[root@server-2110082001-0018 ~]#date -d "$(awk -F. '{print $1}' /proc/uptime) second ago" +"%Y-%m-%d %H:%M:%S"
2021-12-13 15:56:23
```

15.13.17 How Do I Do If Trust Relationships Between Nodes Are Abnormal?

If "ALM-12066 Inter-Node Mutual Trust Fails" is reported on Manager or there is no SSH trust relationship between nodes, rectify the fault by performing the following operations:

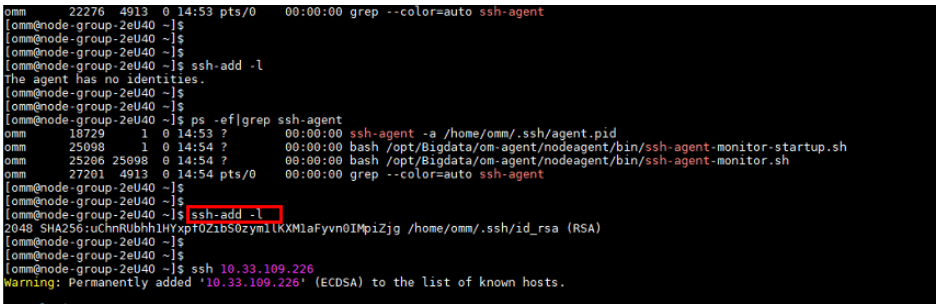
1. Run the **ssh-add -l** command on both nodes of the trusted cluster to check whether there are identities.

```
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$ ll .ssh/
total 32
srw-------. 1 omm wheel     0 Dec 29 14:17 agent.pid
-rw-------. 1 omm wheel 12901 Mar  9 14:48 authorized_keys
-rw-------. 1 omm wheel    54 Sep 24 11:42 config
-rw-------. 1 omm wheel  1766 Sep 24 11:43 id_rsa
-rw-------. 1 omm wheel   402 Sep 24 11:42 id_rsa.pub
-rw-------. 1 omm wheel    88 Jun  8  2020 id_rsa.sha256
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$ ssh-add -l
The agent has no identities.
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$ vim /var/log/Bigdata/nodeagent/
agentlog/   alarmlog/   monitorlog/ scriptlog/
[omm@node-group-2eU40 ~]$ vim /var/log/Bigdata/nodeagent/scriptlog/
agent_alarm_py.log                      install.log
agent_alarm_py.log.1                    installntp.log
```

2. If no identities are displayed, run the **ps -ef|grep ssh-agent** command to find the ssh-agent process, kill the process, and wait for the process to automatically restart.

```
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$ ssh-add -l
The agent has no identities.
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$ ps -ef|grep ssh-agent
omm      18729     1  0 14:53 ?        00:00:00 ssh-agent -a /home/omm/.ssh/agent.pid
omm      25098     1  0 14:54 ?        00:00:00 bash /opt/Bigdata/om-agent/nodeagent/bin/ssh-agent-monitor-startup.sh
omm      25206 25098  0 14:54 ?        00:00:00 bash /opt/Bigdata/om-agent/nodeagent/bin/ssh-agent-monitor.sh
omm      27201  4913  0 14:54 pts/0    00:00:00 grep --color=auto ssh-agent
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$
[omm@node-group-2eU40 ~]$ ssh-add -l
```

3. Run the **ssh-add -l** command to check whether the identities have been added. If yes, manually run the **ssh** command to check whether the trust relationship is normal.



4. If identities exist, check whether the **authorized_keys** file in the **/home/omm/.ssh** directory contains the information in the **id_rsa.pub** file in the **/home/omm/.ssh** of the peer node. If no, manually add the information about the peer node.
5. Check whether the permissions on the files in **/home/omm/.ssh** directory are correct.
6. Check the **/var/log/Bigdata/nodeagent/scriptlog/ssh-agent-monitor.log** file.
7. If the **home** directory of user **omm** is deleted, contact MRS support personnel.

15.13.18 How Do I Adjust the Memory Size of the manager-executor Process?

Symptom

The **manager-executor** process runs either on the Master1 or Master2 node in the MRS cluster in active/standby mode. This process is used to encapsulate the MRS management and control plane's operations on the MRS cluster, such as job submission, heartbeat reporting, certain alarm reporting, as well as cluster creation, scale-out, and scale-in. When you submit jobs on the MRS management and control plane, the Executor memory may become insufficient as the tasks increase or the number of concurrent tasks increases. As a result, the CPU usage is high and the Executor process experiences out-of-memory (OOM) errors.

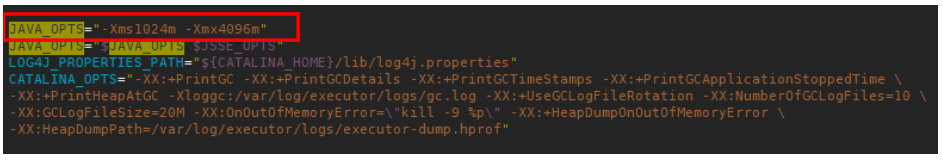
Procedure

1. Log in to either the Master1 or Master2 node as user **root** and run the following command to switch to user **omm**:

   su - omm

2. Run the following command to modify the **catalina.sh** script. Specifically, search for **JAVA_OPTS** in the script, find the configuration items similar to **JAVA_OPTS="-Xms1024m -Xmx4096m**, and change the values of the items to desired ones, and save the modification.

   vim /opt/executor/bin/catalina.sh



3. The **manager-executor** process only runs on either the Master1 or Master2 node in active/standby mode. Check whether it exists on the node before restarting it.

   a. Log in to the Master1 and Master2 nodes and run the following command to check whether the process exists. If any command output is displayed, the process exists.

      ps -ef | grep "/opt/executor" | grep -v grep

   b. Run the following command to restart the process:

      sh /opt/executor/bin/shutdown.shsh /opt/executor/bin/startup.sh

15.14 Kerberos Usage

15.14.1 How Do I Change the Kerberos Authentication Status of a Created MRS Cluster?

You cannot change the Kerberos service after an MRS cluster is created.

15.14.2 What Are the Ports of the Kerberos Authentication Service?

The Kerberos authentication service uses ports 21730 (TCP), 21731 (TCP/UDP), and 21732 (TCP/UDP).

15.14.3 How Do I Deploy the Kerberos Service in a Running Cluster?

The MRS cluster does not support customized Kerberos installation and deployment, and the Kerberos authentication cannot be set up between components. To enable Kerberos authentication, you need to create a cluster with Kerberos enabled and migrate data.

15.14.4 How Do I Access Hive in a Cluster with Kerberos Authentication Enabled?

1. Log in to the master node in the cluster as user **root**.
2. Run the following command to configure environment variables:

   source /opt/client/bigdata_env

3. If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user:

   kinit *MRS cluster user*

   Example: **kinit hiveuser**

   The current user must have the permission to create Hive tables..

4. Run the client command of the Hive component.

beeline

5. Run the Hive command in Beeline, for example:

   create table test_obs(a int, b string) row format delimited fields terminated by "," stored as textfile location "obs://test_obs";

6. Press **Ctrl+C** to exit the Hive Beeline.

15.14.5 How Do I Access Presto in a Cluster with Kerberos Authentication Enabled?

1. Log in to the Master node in the cluster as user **root**.
2. Run the following command to configure environment variables:

   source /opt/client/bigdata_env

3. Access Presto in a cluster with Kerberos authentication enabled.
   a. Log in to MRS Manager and create a role with the **Hive Admin Privilege** permission, for example, **prestorerole**.
   b. Create a user, for example, **presto001**, who belongs to the **Presto** and **Hive** groups, and bind the user to the role created in **3.a**.
   c. Authenticate user **presto001**.

      kinit presto001

   d. Download the user authentication credential.

      - Operations on MRS Manager:

        Log in to MRS Manager, choose **System** > **Manage User**. Locate the user, and choose **More** > **Download authentication credential**.

        Figure 15-10 Downloading the Presto user authentication credential

        
      - Operations on FusionInsight Manager:

        Log in to FusionInsight Manager, choose **System** > **Permission** > **User**. On the displayed page, locate the row that contains the user, choose **More** > **Download Authentication Credential**.

   e. Decompress the downloaded user credential file, and save the obtained **krb5.conf** and **user.keytab** files to the client directory, for example, /opt/**client/Presto/**.
   f. Run the following command to obtain the user principal:

      klist -kt /opt/client/Presto/user.keytab

   g. Run the following command to connect to the Presto Server of the cluster:

presto_cli.sh --krb5-config-path *{krb5.conf file path}* **--krb5-principal** *{User's principal}* **--krb5-keytab-path** *{user.keytab file path}* **--user** *{presto username}*

- **krb5.conf** *file path*: file path set in **3.e**, for example, **/opt/client/Presto/krb5.conf**.
- **user.keytab** *file path*: file path set in **3.e**, for example, **/opt/client/Presto/user.keytab**.
- *User's principal*: principal obtained in **3.f**.
- *presto username*: user created in **3.b**, for example, **presto001**.

Example: **presto_cli.sh --krb5-config-path /opt/client/Presto/krb5.conf --krb5-principal prest001@xxx_xxx_xxx_xxx.COM --krb5-keytab-path /opt/client/Presto/user.keytab --user presto001**

h. On the Presto client, run the following statement to create a schema:

CREATE SCHEMA hive.demo01 WITH (location = 'obs://presto-demo002/');

i. Create a table in the schema. The table data is stored in the OBS bucket, as shown in the following example:

CREATE TABLE hive.demo01.demo_table WITH (format = 'ORC') AS SELECT * FROM tpch.sf1.customer;

Figure 15-11 Return result

j. Run **exit** to exit the client.

15.14.6 How Do I Access Spark in a Cluster with Kerberos Authentication Enabled?

1. Log in to the master node in the cluster as user **root**.
2. Run the following command to configure environment variables:

   source /opt/client/bigdata_env
3. If the Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user.

   kinit *MRS cluster user*

   Example:

   If the development user is a machine-machine user, run **kinit -kt user.keytab sparkuser**.

   If the development user is a human-machine user, run **kinit sparkuser**.
4. Run the following command to connect to Spark Beeline:

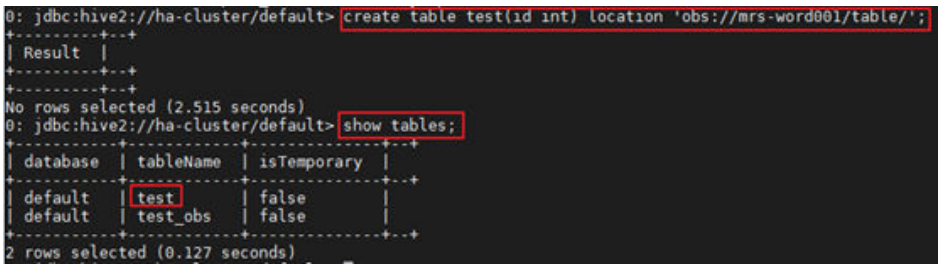
   spark-beeline
5. Run commands on Spark Beeline. For example, create the table **test** in the **obs://mrs-word001/table/** directory.

   create table test(id int) location 'obs://mrs-word001/table/';

6. Run the following command to query all tables. If table **test** is displayed in the command output, OBS access is successful.

   show tables;

   Figure 15-12 Returned table name



7. Press **Ctrl+C** to exit Spark Beeline.

15.14.7 How Do I Prevent Kerberos Authentication Expiration?

- Java applications:

  Before connecting to HBase, HDFS, or other big data components, call loginUserFromKeytab() to create a UGI. Then, start a scheduled thread to periodically check whether the Kerberos Authentication expires. Log in to the system again before the Kerberos Authentication expires.

```
private static void startCheckKeytabTgtAndReloginJob() {
//The credential is checked every 10 minutes, and updated before the expiration time.
      ThreadPool.updateConfigThread.scheduleWithFixedDelay(() -> {
         try {
            UserGroupInformation.getLoginUser().checkTGTAndReloginFromKeytab();
            logger.warn("get tgt:{}", UserGroupInformation.getLoginUser().getTGT());
            logger.warn("Check Kerberos Tgt And Relogin From Keytab Finish.");
         } catch (IOException e) {
            logger.error("Check Kerberos Tgt And Relogin From Keytab Error", e);
         }
      }, 0, 10, TimeUnit.MINUTES);
      logger.warn("Start Check Keytab TGT And Relogin Job Success.");
   }
```

- Tasks executed in shell mode:

  a. Run the **kinit** command to authenticate the user.

  b. Create a scheduled task of the operating system or any other scheduled task to run the **kinit** command to authenticate the user periodically.

  c. Submit jobs to execute big data tasks.

- Spark jobs:

  If you submit jobs using spark-shell, spark-submit, or spark-sql, you can specify **Keytab** and **Principal** in the command to perform authentication and periodically update the login credential and authorization tokens to prevent authentication expiration.

  Example:

  spark-shell --principal spark2x/hadoop.<*System domain name*>@<*System domain name*> **--keytab ${BIGDATA_HOME}/FusionInsight_Spark2x_8.1.0.1/install/FusionInsight-Spark2x-2.4.5/keytab/spark2x/SparkResource/spark2x.keytab --master yarn**

15.15 Metadata Management

15.15.1 Where Can I View Hive Metadata?

- If Hive metadata is stored in GaussDB of an MRS cluster, log in to the master DBServer node of the cluster, switch to user **omm**, and run the **gsql -p 20051 -U {USER} -W {PASSWD} -d hivemeta** command to view the metadata.
- If Hive metadata is stored in an external relational database, perform the following steps:
  a. On the cluster **Dashboard** page, click **Manage** on the right of **Data Connection**.
  b. On the displayed page, obtain the value of **Data Connection ID**.
  c. On the MRS console, click **Data Connections**.
  d. In the data connection list, locate the data connection based on the data connection ID obtained in **b**.
  e. Click **Edit** in the **Operation** column of the data connection.

     The **RDS Instance** and **Database** indicate the relational database in which the Hive metadata is stored.

16 Troubleshooting

16.1 Accessing the Web Pages

16.1.1 Failed to Access MRS Manager

Symptom

The MRS Manager is not accessible after a cluster is created.

Possible Cause

- MRS can be accessed from an external network only after an EIP is bound to an MRS node.
- Port 9022 is disabled. Add a security group rule to enable the port.

Procedure

Step 1 Log in to the MRS management console, locate the cluster to be accessed in the active cluster list, and click the cluster name.

Step 2 On the node information page, click the name of the node to be accessed, and choose **EIPs** > **Bind EIP**.

Step 3 On the **Bind EIP** page, select a NIC from the **Select NIC** drop-down list, select an EIP from the **Select EIP** list, and click **OK**.

Step 4 After the EIP is bound, enable port 9022 in a security group rule.

Click the **Security Groups** tab. Then, click **Change Security Group**.

You can select an existing security group, or click **Create Security Group** to add a security group rule to enable port 9022 for accessing through the public IP address.

Step 5 After the EIP is added, you can access MRS through **https://***Elastic IP address*:**9022/mrsmanager/**. If the fault still persists, contact technical support for assistance.

----End

16.1.2 Failed to Log In to MRS Manager After the Python Upgrade

Issue

Failed to log in to MRS Manager after Python is upgraded.

Symptom

After Python is upgraded, MRS Manager fails to be accessed using the **admin** account and the correct password.

Possible Cause

When upgrading Python to Python 3.*x*, the user modifies the file directory permission of **openssl**. As a result, the LdapServer service cannot be started, causing a login authentication failure.

Procedure

Step 1 Log in to the Master node in the cluster as user **root**.

Step 2 Run the **chmod 755 /usr/bin/openssl** command to modify the file directory permission of **/usr/bin/openssl** to **755**.

Step 3 Run the **su omm** command to switch to user **omm**.

Step 4 Run the **openssl** command to check whether the **openssl** mode can be entered.

If it can be entered, the permission has been modified successfully. If it cannot be entered, the permission fails to be modified.

If the permission fails to be modified, check whether the command is correct or contact O&M personnel.

Step 5 After the permission is modified, the LdapServer service will be restarted. After the LdapServer service is restarted, log in to MRS Manager again.

----End

Summary and Suggestions

It is recommended that software installed by the user be separated from system software. A system software upgrade may cause compatibility problems.

16.1.3 Failed to Log In to MRS Manager After Changing the Domain Name

Symptom

After changing the domain name, the user cannot log in to MRS Manager through the console, or fails to log in to MRS Manager.

Possible Causes

After the domain name is changed, the **keytab** file of user **executor** is not updated. As a result, the executor process repeatedly performs authentication after the authentication fails, causing memory overflow of the ACS process.

Solution

Step 1 Restart the acs process.

1. Log in to the active management node (master node marked a solid star on the **Nodes** tab of the MRS cluster) as user **root**.
2. Run the following commands to restart the acs process:

   su - omm

   ps -ef|grep =acs (Query the PID of the acs process.)

   kill -9 *PID* (Replace *PID* with the acs process ID to kill the acs process.)
3. Wait for several minutes and run the **ps -ef|grep =acs** command to check whether the acs process is automatically started.

Step 2 Replace the **keytab** file of user **executor**.

1. Log in to MRS Manager and choose **System** > **User**. In the **Operation** column where user **executor** resides, click **Download Authentication Credential**. Decompress the package to obtain the **keytab** file.
2. Log in to the active management node as user **root** and replace the **/opt/executor/webapps/executor/WEB-INF/classes/user.keytab** file with the file obtained in **Step 2.1**.

Step 3 Replace the **keytab** and **conf** files of user **knox**.

1. Log in to MRS Manager and choose **System** > **User**. In the **Operation** column where user **knox** resides, click **Download Authentication Credential**. Decompress the package to obtain the **keytab** and **conf** files.
2. Log in to the active management node as user **root** and replace the **/opt/knox/conf/user.keytab** with the file obtained in **Step 3.1**.
3. Change the **principal** value in the **/opt/knox/conf/krb5JAASLogin.conf** file to the new domain name.
4. Replace the **/opt/knox/conf/krb5.conf** file with the **krb5.conf** file obtained in **Step 3.1**.

Step 4 Back up the original client directory.

mv *{Client directory}* **/opt/client_init**

Step 5 Reinstall the client.

Step 6 Log in to the active and standby management nodes as user **root** and run the following commands to restart the knox process:

su - omm

ps -ef | grep gateway | grep -v grep (Search for the PID of the knox process.)

kill -9 *PID* (Replace *PID* with the ID of the knox process to kill the knox process.)

/opt/knox/bin/restart-knox.sh (Start the knox process.)

Step 7 Log in to the active and standby management nodes as user **root** and run the following commands to restart the executor process:

su - omm

netstat -anp |grep 8181 |grep LISTEN (Search for the PID of the executor process.)

kill -9 *PID* (Replace *PID* with the ID of the executor process to kill the executor process.)

/opt/executor/bin/startup.sh (Start the executor process.)

----End

16.1.4 A Blank Page Is Displayed Upon Login to Manager

Issue

After a user logs in to FusionInsight Manager, the page displayed is blank.

Symptom

After a user logs in to FusionInsight Manager, the page displayed is blank.

Cause Analysis

Login to FusionInsight Manager fails, and the browser cache needs to be cleared.

Procedure

Step 1 Open the browser (using Google Chrome as an example), and press **Ctrl+Shift +Delete**. The dialog box for clearing browsing data is displayed.

Step 2 Select the browsing records to be cleared and click **Clear Data**.

----End

16.1.5 Failed to Download Authentication Credentials When the Username Is Too Long

Issue

In MRS clusters 3.0.2 to 3.1.0, a maximum of 32 characters are allowed in the username when a user is added. However, if the username contains more than 20

characters, the user fails to download the Keytab file, and status code "400 Bad Request" is displayed.

Symptom

In MRS clusters 3.0.2 to 3.1.0, a maximum of 32 characters are allowed in the username when a user is added. However, if the username contains more than 20 characters, the user fails to download the Keytab file, and status code "400 Bad Request" is displayed.

Cause Analysis

The **validate-common-config.xml**, **validate-rule-session.xml**, and **validate-rule-user.xml** configuration files in the **/opt/Bigdata/om-server_*/apache-tomcat-*/webapps/web/WEB-INF/validate** directory of the master node are incorrect and need to be modified.

Procedure

Step 1 Log in to the master node as user **omm** and switch to the **/opt/Bigdata/om-server_*/apache-tomcat-*/webapps/web/WEB-INF/validate** directory.

cd /opt/Bigdata/om-server_*/apache-tomcat-*/webapps/web/WEB-INF/validate

Step 2 Modify the **validate-common-config.xml** file.

vi validate-common-config.xml

Change the **maxLength** value of the username from **32** to **64**.

```
<!-- Username -->
<validators alias="USER_NAME">
      <validator name="RANGE_LENGTH_VALIDATOR" minLength="3"
         maxLength="64" />
      <validator name="REGEXP_VALIDATOR" rule="^[_a-zA-Z0-9\- ]+$"
</validators>
```

Step 3 Modify the **validate-rule-session.xml** file.

vi validate-rule-session.xml

Change the **rule** value from **20** to **64**.

```
 <!-- Download the credentials of the current user -->
 <param_validator url="/api/v2/session/user/keytab/download" method="get"
errorHandler="com.xxx.bigdata.om.web.api.validate.SpecialValidatorErrorHandler" dataPattern="form">
            <!-- Parameter name: File name -->
            <!--Validation rule: userName_13-digit number_keytab.tar; case sensitive-->
            <parameter name="file_name" required="true" errorKey="13-4000005"
errorMessage="RESID_OM_API_SESSION_0013">
                  <validator name="REGEXP_VALIDATOR" rule="[\-\w ]{3,64}_\d{13}_keytab\.tar"
caseSensitive="true" />
 </parameter>
```

Step 4 Modify the **validate-rule-user.xml** file.

vi validate-rule-user.xml

Change the **rule** value from **20** to **64**.

```
<!--Download the user credentials  -->
  <param_validator url="/api/v2/permission/users/keytab/download" method="get"
```

```
errorHandler="com.xxx.bigdata.om.web.api.validate.SpecialValidatorErrorHandler" dataPattern="form">
            <!--Mandatory; userName_13-digit number_keytab.tar; case sensitive-->
            <parameter name="file_name" required="true" errorKey="12-4000005"
errorMessage="RESID_OM_API_AUTHORITY_0005">
                    <validator name="REGEXP_VALIDATOR" rule="[\-\w ]{3,64}_\d{13}_keytab\.tar"
caseSensitive="true" />
            </parameter>
    </param_validator>
```

Step 5 Restart Tomcat and wait until the startup is successful.

1. Run the following command as user **omm** to query the PID of the Tomcat process:

   ps -ef|grep apache-tomcat

2. Run the **kill -9** *PID* command to forcibly stop the specified Tomcat process. For example:

   kill -9 1203

3. Run the following command to restart Tomcat:

   sh ${BIGDATA_HOME}/om-server/tomcat/bin/startup.sh

Step 6 Download the authentication credentials again.

----End

16.2 Cluster Management

16.2.1 Failed to Reduce Task Nodes

Issue

A user fails to scale in an MRS 2.*x* cluster by reducing the number of task nodes to **0** on the MRS console.

Symptom

When the number of task nodes in an MRS cluster is reduced on the MRS console, the following information is displayed:

This operation is not allowed because the number of instances of NodeManager will be less than the minimum configuration after scale-in, which may cause data loss.

Cause Analysis

The NodeManager service of the core node is stopped. If the number of task nodes is changed to **0**, there will be no NodeManager in the cluster and the Yarn service will be unavailable. Therefore, MRS allows the reduction of task nodes only when the number of NodeManagers is greater than or equal to **1**.

Procedure

Step 1 Select the NodeManager instance of the core node, click **More**, and select **Start Instance**.

Step 2 Reduce the number of task nodes on the cluster details page.

1. Click the cluster name, and select the **Nodes** tab.
2. Locate the row that contains the task node group and click **Scale In** in the **Operation** column.
3. Click **OK**. In the displayed dialog box, click **Yes**.

Step 3 After the scale-in is successful, stop NodeManager of the core node if you do not need it.

----End

Summary and Suggestions

You are advised not to stop NodeManager of the core node.

16.2.2 Adding a New Disk to an MRS Cluster

Issue

MRS HBase is unavailable.

Symptom

A high disk usage of the user's host causes service faults.

Cause Analysis

The service becomes unavailable due to insufficient disk capacity of the core node.

Procedure

Step 1 Purchase an EVS disk.

Step 2 Attach the EVS disk.

- If the EVS disk has been attached, go to **Step 6**.
- If an ECS cannot be selected when you attach the EVS disk on the EVS console, go to **Step 3**.

Step 3 Log in to the ECS console and click the name of the ECS to which the new disk is to be attached.

Step 4 On the **Disks** tab, click **Attach Disk**.

Step 5 Select the new disk to be attached and click **OK**.

Step 6 Initialize a Linux data disk.

NOTE

- The mount point directory is the existing DataNode instance ID plus one. For example, if you run the **df –h** command and find that the existing ID is **/srv/BigData/hadoop/data1**, the new mount point is then **/srv/BigData/hadoop/data2**. When initializing a Linux data disk to create a mount point, name the mount point **/srv/BigData/hadoop/data2** and mount a new partition to the mount point. For example:
  ```
  mkdir /srv/BigData/hadoop/data2
  mount /dev/xvdb1 /srv/BigData/hadoop/data2
  ```

About the **/srv/BigData/hadoop/data2** path: Change **/srv/BigData/hadoop/data2** mentioned below according to the following scenarios:

- In 3.*x*: Change it to **/srv/BigData/data2**.
- In versions earlier than 3.*x* : Change it to **/srv/BigData/hadoop/data2**.

Step 7 Run the following command to grant user **omm** the permissions to access the new disk:

chown omm:wheel *New mount point*

Example: **chown omm:wheel /srv/BigData/hadoop/data2**

Step 8 Run the following command to grant the execution permission on the new mount point directory:

chmod 701 *New mount point*

Example: **chmod 701 /srv/BigData/hadoop/data2**

NOTE

In this command, **701** is only an example. Replace it with the value of the existing data disk **data1**.

Step 9 Log in to Manager and add data disks to DataNode and NodeManager instances.

Step 10 Modify the DataNode instance configuration.

MRS Manager: Log in to MRS Manager, choose **Services** > **HDFS** > **Instance**, click the target DataNode instance, and click **Instance Configuration**. On the displayed page, set **Type** to **All**.

FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster**. Click the name of the desired cluster and choose **Service** > **HDFS** > **Instance**. Click the target DataNode instance, click **Instance Configuration**, and select **All Configurations**.

- Method 1: Manually modify the DataNode instance configuration on the current node.
  - Enter **dfs.datanode.fsdataset.volume.choosing.policy** in the search box and change the parameter value to **org.apache.hadoop.hdfs.server.datanode.fsdataset.AvailableSpaceVolumeChoosingPolicy**.
  - Enter **dfs.datanode.data.dir** in the search box and change the parameter value to **/srv/BigData/hadoop/data1/dn,/srv/BigData/hadoop/data2/dn**.

  If the values of the two parameters have been changed, click **Save Configuration** and select **Restart role instance** to restart the DataNode instance.

- Method 2: Automatically synchronize the DataNode instance configuration on the current node.
  a. Click **Synchronize Configuration** to enable the new configuration for the HDFS service.
  b. After the synchronization is complete, restart the instance for the configuration to take effect.

NOTE

- If HDFS is not used and you want to quickly restart the instance, select **Restart role instance**.
- If a task is using HDFS, you must select rolling restart to prevent data exceptions or task failures.

Step 11 Modify the Yarn NodeManager instance configuration.

MRS Manager: Log in to MRS Manager, choose **Services** > **Yarn** > **Instance**, click the target NodeManager instance, and click **Instance Configuration**. On the displayed page, set **Type** to **All**.

FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster**. Click the name of the desired cluster and choose **Service** > **Yarn** > **Instance**. Click the target NodeManager instance, click **Instance Configuration**, and select **All Configurations**.

- Method 1: Manually modify the Yarn NodeManager instance configuration on the current node.
  - Enter **yarn.nodemanager.local-dirs** in the search box and change the parameter value to **/srv/BigData/hadoop/data1/nm/localdir,/srv/BigData/hadoop/data2/nm/localdir**.
  - Enter **yarn.nodemanager.log-dirs** in the search box and change the parameter value to **/srv/BigData/hadoop/data1/nm/containerlogs,/srv/BigData/hadoop/data2/nm/containerlogs**.

    If the values of the two parameters have been changed, click **Save Configuration** and select **Restart role instance** to restart the NodeManager instance.
- Method 2: Automatically synchronize the Yarn NodeManager instance configuration on the current node.
  a. Click **Synchronize Configuration** to enable the new configuration for the Yarn service.
  b. After the synchronization is complete, restart the instance for the configuration to take effect.

NOTE

- If Yarn is not used and you want to quickly restart the instance, select **Restart role instance**.
- If a task is using Yarn, you must select rolling restart to prevent data exceptions or task failures.

Step 12 Check whether the capacity expansion is successful.

MRS Manager: Log in to MRS Manager, choose **Services** > **HDFS** > **Instance**, and click the target DataNode instance.

FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster**. Click the name of the desired cluster, choose **Service** > **HDFS** > **Instance**, and click the target DataNode instance.

In the **Chart** area, check whether the total disk capacity in real-time monitoring item **DataNode Storage** is increased. If **DataNode Storage** does not exist in the **Chart** area, click **Customize** to add it.

- If the total disk capacity has been increased, the capacity expansion is complete.
- If the total disk capacity does not increase, contact technical support.

Step 13 (Optional) Add data disks to a Kafka instance.

Modify the Kafka instance configuration.

1. Navigate to the parameter settings of the target Kafka Broker node.

   MRS Manager: Log in to MRS Manager, choose **Services** > **Kafka** > **Instance**, click the target Broker instance, and click **Instance Configuration**. On the displayed page, set **Type** to **All**.

   FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster**. Click the name of the desired cluster and choose **Service** > **Kafka** > **Instance**. Click the target Broker instance, click **Instance Configuration**, and select **All Configurations**.
2. Enter **log.dirs** in the search box, add information about the disks to be added, and use commas (,) to separate them.

   For example, if there is only one existing Kafka data disk and a new one is added, change **/srv/BigData/kafka/data1/kafka-logs** to **/srv/BigData/kafka/data1/kafka-logs,/srv/BigData/kafka/data2/kafka-logs**.
3. Save the configuration and select **Restart role instance** to restart the instance as prompted.
4. Check whether the capacity expansion is successful.

   MRS Manager: Log in to MRS Manager, choose **Services** > **Kafka** > **Instance**, and click the target Broker instance.

   FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster**. Click the name of the desired cluster, choose **Service** > **Kafka** > **Instance**, and click the target Broker instance.

   Check whether the total disk capacity in real-time monitoring item **Capacity of Broker Disks** is increased.

----End

NOTICE

After the disk capacity of a cluster node is expanded, if a new node is added to the cluster, you need to add disks to the new node by referring to the preceding procedure. Otherwise, data may be lost.

Summary and Suggestions

- If the disk usage exceeds 85%, you are advised to expand disk capacity and attach the newly purchased disks to ECSs to associate with the cluster.

- The procedure for attaching disks and setting parameters may vary depending on the site environment.

16.2.3 Replacing a Disk in an MRS Cluster (Applicable to 2.x and Earlier)

Issue

A disk is not accessible.

Symptom

A user created an MRS cluster with local disks. A disk of a core node in this cluster is damaged, resulting in file read failures.

Cause Analysis

The disk hardware is faulty.

Procedure

NOTE

This procedure is applicable to analysis clusters earlier than MRS 3.*x*. If you need to replace disks for a streaming cluster or hybrid cluster, contact technical support.

Step 1 Log in to .

Step 2 Choose **Hosts**, click the name of the host to be decommissioned, click **RegionServer** in the **Roles** list, click **More**, and select **Decommission**.

Step 3 Choose **Hosts**, click the name of the host to be decommissioned, click **DataNode** in the **Roles** list, click **More**, and select **Decommission**.

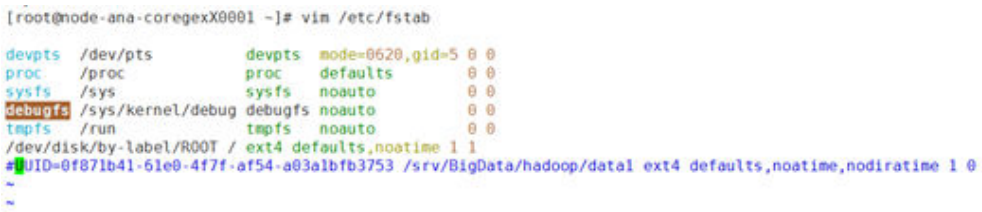
Step 4 Choose **Hosts**, click the name of the host to be decommissioned, click **NodeManager** in the **Roles** list, click **More**, and select **Decommission**.

NOTE

If this host still runs other instances, perform the similar operation to decommission the instances.

Step 5 Run the **vim /etc/fstab** command to comment out the mount point of the faulty disk.

Figure 16-1 Commenting out the mount point of the faulty disk



Step 6 Migrate the user data on the faulty disk (for example, **/srv/BigData/hadoop/data1/**).

Step 7 Log in to the MRS console.

Step 8 On the cluster details page, click the **Nodes** tab.

Step 9 Click the node whose disk is to be replaced to go to the ECS console. Click **Stop** to stop the node.

Step 10 Contact technical support to replace the disk in the background.

Step 11 On the ECS console, click **Start** to start the node where the disk has been replaced.

Step 12 Run the **fdisk -l** command to view the new disk.

Step 13 Run the **cat /etc/fstab** command to obtain the drive letter.

Figure 16-2 Obtaining the drive letter

```
[omm@node-master1dGom ~]$ cat /etc/fstab

#
# /etc/fstab
# Created by anaconda on Wed Feb 27 06:58:49 2019
#
# Accessible filesystems, by reference, are maintained under '/dev/disk'
# See man pages fstab(5), findfs(8), mount(8) and/or blkid(8) for more info
#
UUID=b13ee9c8-0ef0-4159-9b90-fc47bde0d464 /                       ext4    defaults,noatime        1 1
UUID=029408e0-71a6-4f73-b817-42d7049b7595 /srv/BigData ext4 defaults,noatime,nodiratime 1 0
UUID=f9cb8844-dabf-4a69-aff4-587de2fc4d7c /srv/BigData1 ext4 defaults,noatime,nodiratime 1 0
UUID=876e73be-1f80-4466-92b7-01d7c68bbb1b /srv/BigData2 ext4 defaults,noatime,nodiratime 1 0
UUID=0d5fce7f-afd0-420a-b1bb-e5500a1851cd /srv/BigData3 ext4 defaults,noatime,nodiratime 1 0
```

Step 14 Use the corresponding drive letter to format the new disk.

Example: **mkfs.ext4 /dev/sdh**

Step 15 Run the following command to attach the new disk.

mount *New disk Mount point*

Example: **mount /dev/sdh /srv/BigData/hadoop/data1**

Step 16 Run the following command to grant the **omm** user permission to the new disk:

chown omm:wheel *Mount point*

Example: **chown -R omm:wheel /srv/BigData/hadoop/data1**

Step 17 Add the UUID of the new disk to the **fstab** file.

1. Run the **blkid** command to check the UUID of the new disk.

   ```
   [root@node-ana-coreKpoT0003 ~]# blkid
   /dev/vda1: LABEL="ROOT" UUID="2aa97872-11ec-422e-9513-0f28b925ad5e" TYPE="ext4"
   /dev/vdb: UUID="e5f652c3-f9af-427f-89da-f2545618688d" TYPE="ext4"
   [root@node-ana-coreKpoT0003 ~]#
   ```

2. Open the **/etc/fstab** file and add the following information:
   UUID=*New disk UUID* **/srv/BigData/hadoop/data1 ext4 defaults,noatime,nodiratime 1 0**

Step 18 (Optional) Create a log directory.

mkdir -p /srv/BigData/Bigdata

chown omm:ficommon /srv/BigData/Bigdata

chmod 770 /srv/BigData/Bigdata

NOTE

Run the following command to check whether symbolic links to **Bigdata** logs exist. If yes, skip this step.

ll /var/log

Step 19 Log in to .

Step 20 Choose **Hosts**, click the name of the host to be recommissioned, click **RegionServer** in the **Roles** list, click **More**, and select **Recommission**.

Step 21 Choose **Hosts**, click the name of the host to be recommissioned, click **DataNode** in the **Roles** list, click **More**, and select **Recommission**.

Step 22 Choose **Hosts**, click the name of the host to be recommissioned, click **NodeManager** in the **Roles** list, click **More**, and select **Recommission**.

NOTE

If this host still runs other instances, perform the similar operation to recommission the instances.

Step 23 Choose **Services** > **HDFS**. In the **HDFS Summary** area on the **Service Status** page, check whether **Missing Blocks** is **0**.

- If **Missing Blocks** is **0**, no further action is required.
- If **Missing Blocks** is not **0**, contact technical support.

----End

16.2.4 Replacing a Disk in an MRS Cluster (Applicable to 3.x)

Issue

A disk is not accessible.

Symptom

A user created an MRS cluster with local disks. A disk of a core node in this cluster is damaged, resulting in file read failures.

Cause Analysis

The disk hardware is faulty.

Procedure

NOTE

This procedure is applicable to troubleshooting disk hardware faults of core and task nodes in MRS clusters using local disks (ECSs of D, I, IR, and KI series).

Kafka does not support disk replacement. If the node that stores Kafka data is faulty, contact technical support.

Step 1 Log in to .

Step 2 Choose **Hosts** and click the name of the faulty host. In the **Instance** area, click **DataNode**. Then on the page that is displayed, click **More** and select **Decommission**.

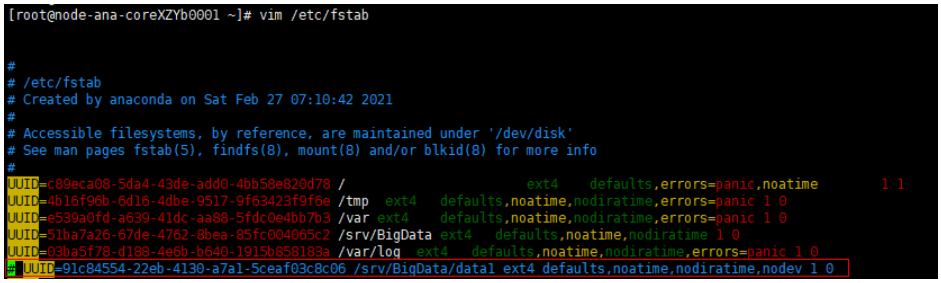
NOTE

- If this host accommodates DataNode, NodeManager, RegionServer, and ClickHouseServer instances, decommission these instances by referring to this step.
- In versions later than MRS 3.1.2, the ClickHouseServer role instance can be decommissioned.

Step 3 Choose **Hosts**, select the faulty host, click **More**, and select **Stop All Instances**.

Step 4 Run the **vim /etc/fstab** command to comment out the mount point of the faulty disk.

Figure 16-3 Commenting out the mount point of the faulty disk



Step 5 If the old disk is still accessible, migrate user data on the old disk (for example, **/srv/BigData/data1/**).

cp -r *Mount point of the old disk Temporary data storage directory*

Example: **cp -r /srv/BigData/data1 /tmp/**

Step 6 Log in to the MRS console.

Step 7 On the cluster details page, click the **Nodes** tab.

Step 8 Click the node whose disk is to be replaced to go to the ECS console. Click **Stop** to stop the node.

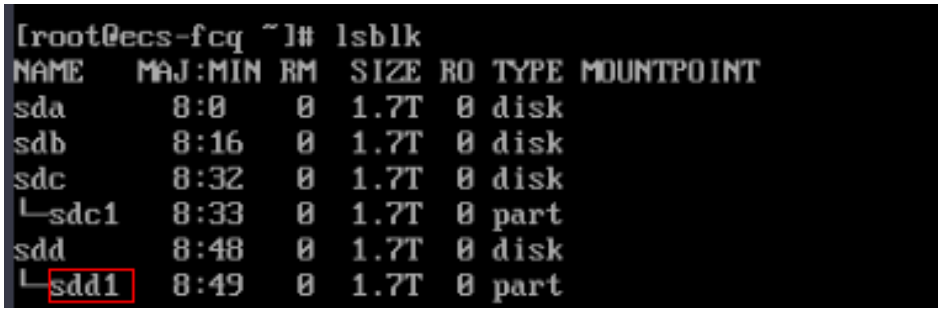
Step 9 Contact technical support to replace the disk in the background.

Step 10 On the ECS console, click **Start** to start the node where the disk has been replaced.

Step 11 Initialize the Linux data disk.

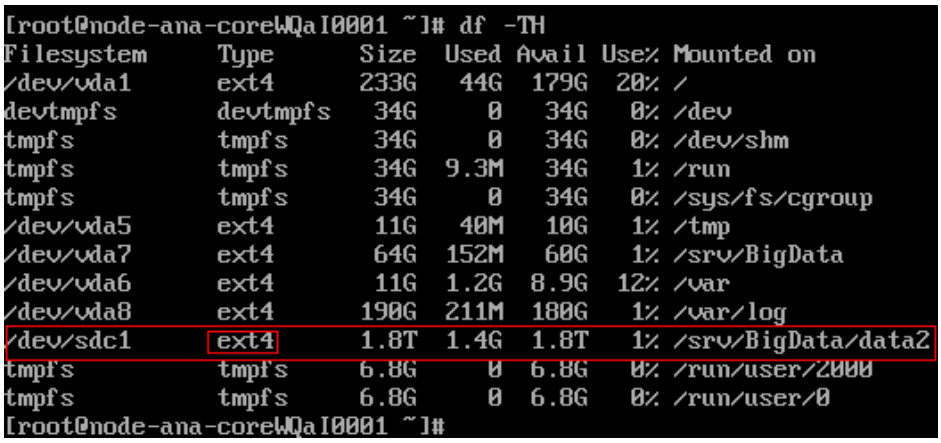
Step 12 Run the **lsblk** command to view information about the new disk partition.

Figure 16-4 Viewing the new disk partition



Step 13 Run the **df -TH** command to obtain the file system type.

Figure 16-5 Obtaining the file system type



Step 14 Format the new disk partition based on the obtained file system type.

Example: **mkfs.ext4 /dev/sdd1**

Step 15 Run the following command to mount the new disk:

mount *New disk Mount point*

Example: **mount /dev/sdd1 /srv/BigData/data1**

NOTE

If the disk cannot be mounted, run the following command to reload the configuration and mount it again:

systemctl daemon-reload

Step 16 Run the following command to grant the **omm** user permission to the new disk:

chown omm:wheel *Mount point*

Example: **chown -R omm:wheel /srv/BigData/data1**

Step 17 Migrate user data from the old disk (for example, **/srv/BigData/data1/**) to the new disk.

cp -r *Temporary data storage directory Mount point of the new disk*

Example: **cp -r /tmp/data1/* /srv/BigData/data1/**

Step 18 Add the UUID of the new disk to the **fstab** file.

1. Run the **blkid** command to check the UUID of the new disk.

2. Open the **/etc/fstab** file and add the following information:
   UUID=*UUID of the new disk* /srv/BigData/data1 ext4 defaults,noatime,nodiratime,nodev 1 0

Step 19 Log in to .

Step 20 Choose **Hosts** and click the name of the host to be recommissioned. In the **Instance** area, click **DataNode**. Then on the page that is displayed, click **More** and select **Recommission**.

NOTE

- If this host accommodates DataNode, NodeManager, RegionServer, and ClickHouseServer instances, recommission these instances by referring to this step.
- In versions later than MRS 3.1.2, the ClickHouseServer role instance can be recommissioned.

Step 21 Choose **Hosts**, select the faulty host, click **More**, and select **Start All Instances**.

Step 22 Choose **Cluster** > **HDFS**. In the **Basic Information** area on the **Dashboard** page, check whether **Missing Blocks** is **0**.

- If **Missing Blocks** is **0**, no further action is required.
- If **Missing Blocks** is not **0**, contact technical support.

----End

16.2.5 MRS Backup Failure

Issue

MRS backup keeps failing.

Symptom

MRS backup keeps failing.

Cause Analysis

The backup directory is connected to the system disk using a soft link. As a result, if the system disk is full, the backup fails.

Procedure

Step 1 Check whether the backup directory is connected to the system disk using a soft disk.

1. Log in to the active and standby Master nodes in the cluster as user **root**.
2. Run the **df -h** command to check the storage usage of the system disk.
3. Run the **ll /srv/BigData/LocalBackup** command to check whether the backup directory is connected to **/opt/Bigdata/LocalBackup** using a soft link.

   Check whether the backup file is connected to the system disk using a soft link and whether the system disk has sufficient space. If the soft link is used for connecting to the system disk and the system disk space is insufficient, go to **Step 2**. If the soft link is not used, the failure is not caused by insufficient system disk space. Contact technical support for troubleshooting.

Step 2 Move historical backup data to a new directory on the data disk.

1. Log in to the Master node as user **root**.
2. Run the **su - omm** command to switch to user **omm**.
3. Run the **rm -rf /srv/BigData/LocalBackup** command to delete the soft link of the backup directory.
4. Run the **mkdir -p /srv/BigData/LocalBackup** command to create a backup directory.
5. Run the **mv /opt/Bigdata/LocalBackup/* /srv/BigData/LocalBackup/** command to move the historical backup data to the new directory.

----End

16.2.6 Inconsistency Between df and du Command Output on the Core Node

Issue

The capacity displayed in the **df** command output on the Core node is inconsistent with that displayed in the **du** command output.

Symptom

After the **df** and **du** commands are executed, the values of the Core node capacity displayed are different.

The disk usage of the **/srv/BigData/hadoop/data1/** directory queried by running the **df -h** command differs greatly from that queried by running the **du -sh /srv/BigData/hadoop/data1/** command. The difference is greater than 10 GB.

Cause Analysis

The **lsof |grep deleted** command output indicates that a large number of log files in the directory are in the deleted state.

When some Spark tasks are running for a long time, some containers in the tasks keep running and logs are continuously generated. When printing logs, the executor of Spark uses the log4j log scrolling function to output logs to the **stdout** file. The container also monitors this file. As a result, the file is monitored by two processes at the same time. When one process scrolls according to the configuration, the earliest log file is deleted, but the other process still occupies the file handle. As a result, a file in the deleted state is generated.

Procedure

Change the output directory name for executor logs of Spark.

1. Open the log configuration file. By default, the configuration file is located in *<Client address>***/Spark/spark/conf/log4j-executor.properties**.
2. Change the name of the log output file.

   For example, change **log4j.appender.sparklog.File = ${spark.yarn.app.container.log.dir}/stdout** to **log4j.appender.sparklog.File = ${spark.yarn.app.container.log.dir}/stdout.log**.

3. Save the configuration and exit.
4. Submit the tasks again.

16.2.7 Disassociating a Subnet from the ACL Network

Scenarios

You can disassociate a subnet from the ACL network when necessary.

Procedure

Step 1 Log in to the management console.

Step 2 On the console homepage, under **Network**, click **Virtual Private Cloud**.

Step 3 In the navigation tree on the left, choose **Network ACL**.

Step 4 Locate the target network ACL in the right pane, and click the network ACL name to switch to the network ACL details page.

Step 5 On the displayed page, click the **Associated Subnets** tab.

Step 6 On the **Associated Subnets** page, locate the target network ACL and click **Disassociate** in the **Operation** column.

Step 7 Click **OK**.

----End

16.2.8 MRS Becomes Abnormal After hostname Modification

Issue

What should I do if MRS becomes abnormal after **hostname** is modified?

Symptom

MRS becomes abnormal after **hostname** is modified.

Possible Cause

The **hostname** modification causes compatibility problems and faults.

Procedure

Step 1 Log in to any node in the cluster as user **root**.

Step 2 Run the **cat /etc/hosts** command on the node to check the value of **hostname** of each node and set the **newhostname** variable based on the value.

Step 3 Run the **sudo hostnamectl set-hostname ${newhostname}** command on the node where **hostname** is modified to restore the correct hostname.

NOTE

${newhostname}: new value of **hostname**

Step 4 After the modification, log in to the node where **hostname** is modified, and check whether the new hostname takes effect.

----End

16.2.9 DataNode Restarts Unexpectedly

Symptom

A DataNode is restarted unexpectedly, but no manual restart operation is performed for the DataNode.

Cause Analysis

Possible causes:

- **OOM of the Java process is killed.**

  In general, the OMM Killer is configured for Java processes to detect and kill OOM. The OOM log is printed in the out log. In this case, you can view the run log (for example, the DataNode's log path is **/var/log/Bigdata/hdfs/dn/hadoop-omm-datanode-***hostname***.log**) to check whether OutOfMemory is printed.

- **DataNode is manually killed or killed by another process.**

  Check the DataNode run log file **/var/log/Bigdata/hdfs/dn/hadoop-omm-datanode-***hostname***.log**. It is found that the health check fails after "RECEIVED SIGNAL 15" is received. In the following example, the DataNode is killed at 11:04:48 and then started at 11:06:52 two minutes later.

  ```
  2018-12-06 11:04:48,433 | ERROR | SIGTERM handler | RECEIVED SIGNAL 15: SIGTERM | LogAdapter.java:69
  2018-12-06 11:04:48,436 | INFO  | Thread-1 | SHUTDOWN_MSG:
  /************************************************************
  SHUTDOWN_MSG: Shutting down DataNode at 192-168-235-85/192.168.235.85
  ************************************************************/ | LogAdapter.java:45
  2018-12-06 11:06:52,744 | INFO  | main | STARTUP_MSG:
  ```

  According to the logs, DataNode was closed and then the health check reported the exception. After 2 minutes, NodeAgent started the DataNode process.

Procedure

Add the rule for recording the kill command in the audit log of the operating system. The process that delivers the kill command will be recorded in the audit log.

Operation impact

- Printing audit logs affects operating system performance. However, analysis result shows that the impact is less than 1%.
- Printing audit log occupies some disk space. The logs to be printed are within megabytes. By default, the aging mechanism and the mechanism for checking the remaining disk space are configured. Therefore, the disk space will not be used up.

Locating Method

Perform the following operations on nodes that may restart the DataNode process:

Step 1 Log in to the node as the **root** user and run the **service auditd status** command to check the service status.

```
Checking for service auditd  running
```

If the service is not started, run the **service auditd restart** command to restart the service. The command execution takes less than 1 second and has no impact on the system.

```
Shutting down auditd done
Starting auditd done
```

Step 2 The audit rule of the **kill** command is temporarily added to audit logs.

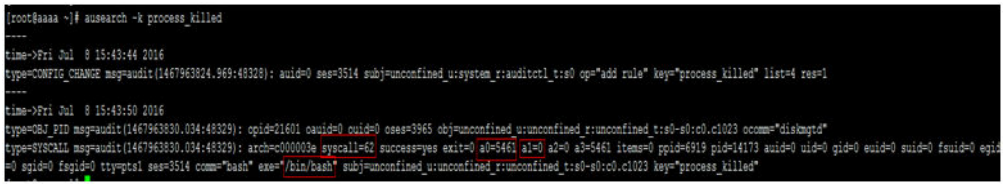
Add an audit rule:

auditctl -a exit,always -F arch=b64 -S kill -S tkill -S tgkill -F a1!=0 -k process_killed

View the rule:

auditctl -l

Step 3 If a process is killed due to an exception, you can run the **ausearch -k process_killed** command to query the kill history.



NOTE

a0 is the PID (hexadecimal) of the process that is killed, and **a1** is the semaphore of the kill command.

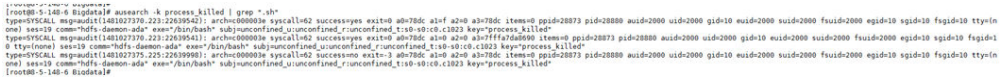
----End

Verification

Step 1 Restart an instance of the node on MRS Manager, for example, DataNode.

Step 2 Run the **ausearch -k process_killed** command to check whether logs are printed.

The following is an example of the **ausearch -k process_killed |grep ".sh"** command. The command output indicates that the **hdfs-daemon-ada*** script closed the DataNode process.



----End

Stop auditing the **kill** command.

Step 1 Run the **service auditd restart** command. The temporarily added kill command audit logs are cleared automatically.

Step 2 Run the **auditctl -l** command. If no information about killing a process is returned, the rule is cleared successfully.

----End

16.2.10 Network Is Unreachable When Using pip3 to Install the Python Package in an MRS Cluster

Issue

When the Python package is installed using pip3, an error message is displayed, indicating that the network is unreachable.

Symptom

When a user runs the pip3 install command to install the Python package, an error message is displayed, indicating that the network is unreachable. For details, see the following figure:

Cause Analysis

The customer does not bind an EIP to the Master node.

Procedure

Step 1 Log in to the MRS management console.

Step 2 Choose **Clusters** > **Active Clusters**, select the faulty cluster, and click its name to check the **Basic Information** on the **Dashboard** tab page.

Step 3 On the **Nodes** tab page, click the name of a Master node in the Master node group to log in to the ECS management console.

Step 4 Click the **EIPs** tab and click **Bind EIP** to bind an EIP to the ECS.

Step 5 Log in to the Master node and run the **pip3 install** command to install the Python package.

----End

16.2.11 Failed to Download the MRS Cluster Client

Issue

On the local Master host, a user attempts to download an MRS cluster client for another remote host. However, the system displays a message indicating that the network or parameter is abnormal.

Symptom

On the local Master host, a user attempts to download an MRS cluster client for another remote host. However, the system displays a message indicating that the network or parameter is abnormal.

Cause Analysis

- The two hosts are in different VPCs.
- The password is incorrect.
- The firewall is enabled on the remote host.

Procedure

- The two hosts are in different VPCs.

  Enable port 22 of the remote host.
- The password is incorrect.

  Check whether the password is correct. The password cannot contain special characters.
- The firewall is enabled on the remote host.

  Download the MRS cluster client to the server and run the **scp** command provided by Linux to remotely send the client to the remote host.

16.2.12 Failed to Scale Out an MRS Cluster

Issue

The MRS console is accessible and functions properly, but the MRS cluster fails to be scaled out.

Symptom

The MRS console is normal, and no alarm or error message is displayed on MRS Manager. However, an error message is displayed during cluster scale-out, indicating that the MRS cluster contains nodes that are not running.

Cause Analysis

An MRS cluster can be scaled in or out only when it is running properly. According to the error message, the possible cause is that the cluster status in the database is abnormal or is not updated. As a result, the nodes in the cluster are not in the running state.

Procedure

Step 1 Log in to the MRS console and click the cluster name to go to the cluster details page. Check that the cluster is in the **Running** state.

Step 2 Click **Nodes** to view the status of all nodes. Ensure that all nodes are in the **Running** state.

Step 3 Log in to the podMaster node in the cluster, switch to the MRS deployer node, and view the **api-gateway.log** file.

1. Run the **kubectl get pod -n mrs** command to view the **pod** of the MRS deployer node.
2. Run the **kubectl exec -ti ${***Pod of the deployer node***} -n mrs /bin/bash** command to log in to the pod. For example, run the **kubectl exec -ti mrsdeployer-78bc8c76cf-mn9ss -n mrs /bin/bash** command to access the deployer container of MRS.
3. In the **/opt/cloud/logs/apigateway** directory, view the latest **api-gateway.log** file and search for the required keyword (such as **ERROR**, **scaling**, **clusterScaling**, **HostState**, **state-check**, or the cluster ID) in the file to check the error type.
4. Rectify the fault based on the error information and perform the scale-out again.
   - If the scale-out is successful, no further action is required.
   - If the scale-out fails, go to **Step 4**.

Step 4 Run the **/opt/cloud/mysql -u${***Username***} -P${***Port***} -h${***Address***} -p${***Password***}** command to log in to the database.

Step 5 Run the **select cluster_state from cluster_detail where cluster_id=***Cluster ID***";** command to check the value of **cluster_state**.

- If the value of **cluster_state** is **2**, the cluster status is normal. Go to **Step 6**.
- If the value of **cluster_state** is not **2**, the cluster status in the database is abnormal. You can run the **update cluster_detail set cluster_state=2 where cluster_id="***Cluster ID***";** command to update the cluster status and then check the value of **cluster_state**.
  - If the value of **cluster_state** is **2**, the cluster status is normal. Go to **Step 6**.
  - If the value of **cluster_state** is not **2**, contact technical support.

Step 6 Run the **select host_status from host where cluster_di="***Cluster ID***";** command to query the cluster host status.

- If the host is in the started state, no further action is required.
- If the host is not in the started state, run the **update host set host_status='started' where cluster_id="***Cluster ID***";** command to update the host status to the database.
  - If the host is in the started state, no further action is required.
  - If the host is not in the started state, contact technical support.

----End

16.2.13 Error Occurs When MRS Executes the Insert Command Using Beeline

Issue

An error occurs when MRS executes the insert command using Beeline.

Symptom

When the **insert into** statement is executed in Beeline of Hive, the following error is reported:

```
Mapping run in Tez on Hive transactional table fails when data volume is high with error: "org.apache.hadoop.hive.ql.lockmgr.LockException Reason: Transaction... already aborted, Hive SQL state [42000]."
```

Cause Analysis

This problem is caused by improper cluster configuration and Tez resource setting.

Procedure

This problem can be solved by setting configuration parameters on Beeline.

Step 1 Set the following properties to optimize performance (you are advised to change them at the cluster level):

- Set **hive.auto.convert.sortmerge.join** to **true**.
- Set **hive.optimize.bucketmapjoin** to **true**.
- Set **hive.optimize.bucketmapjoin.sortedmerge** to **true**.

Step 2 Modify the following content to adjust the resources of Tez:

- Set **hive.tez.container.size** to the size of the Yarn container.
- Set **hive.tez.container.size** to the Yarn container size **yarn.scheduler.minimum-allocation-mb** or a smaller value (for example, a half or quarter of the Yarn container size). Ensure that the value does not exceed **yarn.scheduler.maximum-allocation-mb**.

----End

16.2.14 How Do I Upgrade EulerOS to Fix Vulnerabilities in an MRS Cluster?

Issue

EulerOS has vulnerabilities at the underlying layer. This section describes how to upgrade the OS to fix vulnerabilities for an MRS cluster.

Symptom

When the NSFOCUS software is used to test the cluster, vulnerabilities are found at the underlying layer in the EulerOS.

Cause Analysis

When the NSFOCUS software is used to test the cluster, it is found that vulnerabilities exist at the underlying layer in the EulerOS. The MRS service is deployed in the EulerOS. Therefore, the system needs to be upgraded to fix the vulnerabilities.

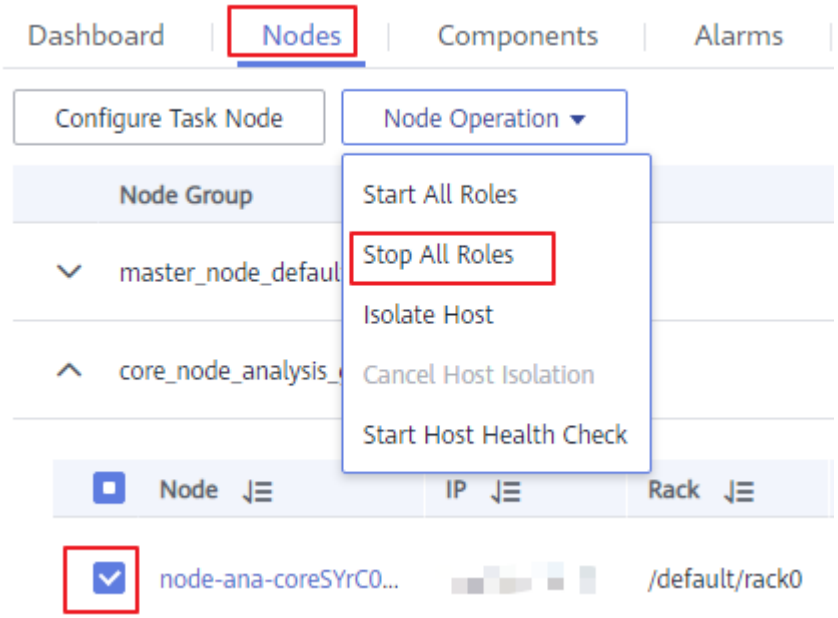
Procedure

> **NOTE**
>
> Before fixing the vulnerability, check whether Host Security Service (HSS) is enabled. If yes, disable HSS from monitoring the MRS cluster. After the vulnerability is fixed, enable HSS again.

Step 1 Log in to the MRS console.

Step 2 Click the cluster name. On the cluster details page, click the **Nodes** tab.

Step 3 In the core node group, select a core node, click **Node Operation**, and select **Stop All Roles**.



Step 4 Remotely log in to the core node and configure the yum repository.

Step 5 Run the **uname –r** or **rpm –qa |grep kernel** command to query and record the kernel version of the current node.

Step 6 Run the **yum update –y --skip-broken --setopt=protected_multilib=false** command to update the patch.

Step 7 After the update is complete, query the kernel version and run the **rpm -e** *Old kernel version* command to delete the old kernel version.

Step 8 On the cluster details page, click the **Nodes** tab.

Step 9 In the core node group, click the name of the core node whose patch has been updated. The ECS console is displayed.

Step 10 In the upper right corner of the page, click **Restart** to restart the core node.

Step 11 On the **Nodes** tab of the cluster details page, select the core node, click **Node Operation**, and select **Start All Roles**.

Step 12 Repeat **Step 1** to **Step 11** to upgrade other core nodes.

Step 13 After all core nodes are upgraded, upgrade the standby master node and then the active master node. For details, see **Step 1** to **Step 11**.

----End

16.2.15 Using CDM to Migrate Data to HDFS

Issue

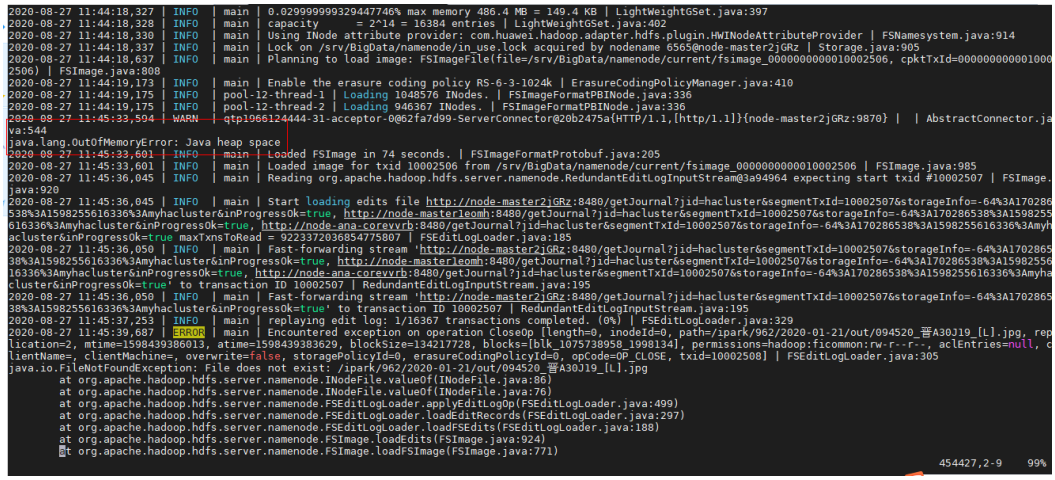
A user failed to use CDM to migrate data from an old cluster to HDFS of a new cluster.

Symptom

When CDM is used to import data from the source HDFS to the destination HDFS, the destination MRS cluster is faulty and the NameNode cannot be started.

The logs show that the **Java heap space** error is reported during the startup. The JVM parameter of the NameNode needs to be modified.

Figure 16-6 Fault logs



Cause Analysis

When the user uses CDM to migrate data, the HDFS data volume is too large. As a result, a stack exception occurs when metadata is merged.

Procedure

Step 1 Search for the **GC_OPTS** parameter in **HDFS->NameNode** and increase the values of **-Xms512M** and **-Xmx512M** based on service requirements.

Step 2 Save the configuration and restart the affected services or instances.

----End

16.2.16 Alarms Are Frequently Generated in the MRS Cluster

Issue

The cluster frequently reports alarms indicating that the heartbeat between the active and standby Manager nodes is interrupted, the heartbeat between the active and standby DBService nodes is interrupted, and the node is faulty. As a result, Hive is occasionally unavailable.

Symptom

The cluster frequently reports alarms indicating that the heartbeat between the active and standby Manager nodes is interrupted, the heartbeat between the active and standby DBService nodes is interrupted, and the node is faulty. As a result, Hive is occasionally unavailable, affecting customer services

Cause Analysis

1. When the alarm is generated, the VM is restarted. The alarm is generated because the VM is restarted.

```

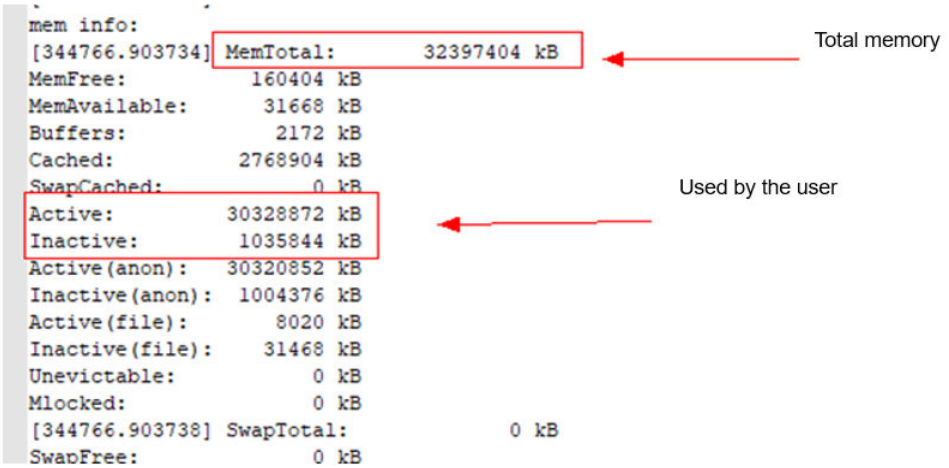
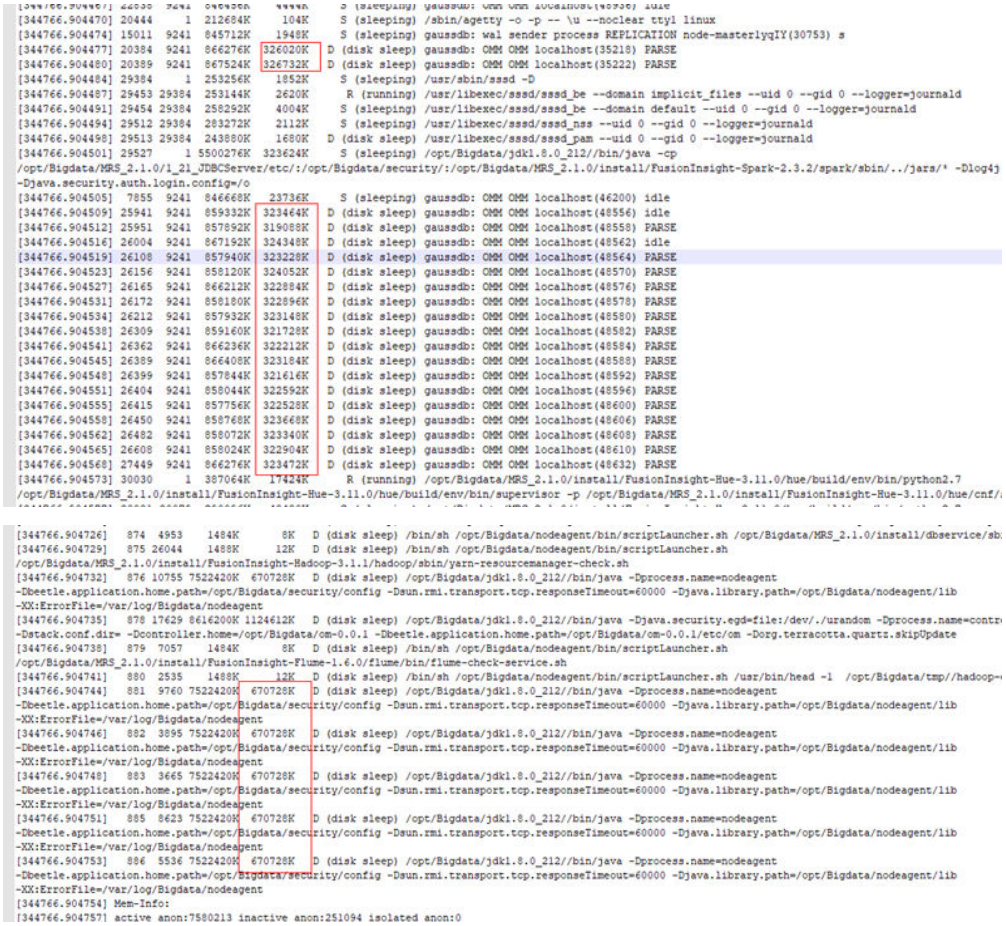
2. According to the OS analysis, the cause of the VM restart is that the node does not have available memory. Memory overflow triggers oom-killer. When the process is invoked, the process enters the **disk sleep** state. As a result, the VM restarts.





3. Check the processes that occupy the memory. It is found that the processes that occupy the memory are normal service processes.

Conclusion: The VM memory cannot meet service requirements.

Procedure

- You are advised to expand the node memory.
- You are advised to disable unnecessary services to avoid this problem.

16.2.17 Memory Usage of the PMS Process Is High

Issue

What can I do if the memory usage of the active Master node is high?

Symptom

The memory usage of the active Master node is high. The **top -c** command output shows that the following idle processes occupy a large amount of memory:

```
12180 ommdba    20   0 1395492 1.180g 1.082g S   0.0  3.8  23:14.29 gaussdb: OMM OMM localhost(60598) idle
14828 ommdba    20   0 1395904 1.180g 1.081g S   0.0  3.8  23:17.08 gaussdb: OMM OMM localhost(60698) idle
15016 ommdba    20   0 1395840 1.180g 1.081g S   0.0  3.8  23:11.19 gaussdb: OMM OMM localhost(60824) idle
14943 ommdba    20   0 1395900 1.180g 1.081g S   0.0  3.8  23:14.76 gaussdb: OMM OMM localhost(60764) idle
14908 ommdba    20   0 1395840 1.180g 1.081g S   0.0  3.8  23:15.18 gaussdb: OMM OMM localhost(60738) idle
14953 ommdba    20   0 1395824 1.180g 1.081g S   0.0  3.8  23:15.96 gaussdb: OMM OMM localhost(60770) idle
14995 ommdba    20   0 1395560 1.180g 1.081g S   0.0  3.8  23:13.28 gaussdb: OMM OMM localhost(60812) idle
15062 ommdba    20   0 1395820 1.180g 1.081g S   0.0  3.8  23:16.12 gaussdb: OMM OMM localhost(60868) idle
15064 ommdba    20   0 1395512 1.180g 1.081g S   0.0  3.8  23:13.33 gaussdb: OMM OMM localhost(60870) idle
14973 ommdba    20   0 1395528 1.180g 1.081g S   0.0  3.8  23:12.74 gaussdb: OMM OMM localhost(60790) idle
14835 ommdba    20   0 1395536 1.180g 1.081g S   0.0  3.8  23:17.39 gaussdb: OMM OMM localhost(60704) idle

14977 ommdba    20   0 1395496 1.180g 1.081g S   0.0  3.8  23:16.90 gaussdb: OMM OMM localhost(60794) idle
15028 ommdba    20   0 1395800 1.180g 1.081g S   0.0  3.8  23:09.35 gaussdb: OMM OMM localhost(60836) idle
```

Cause Analysis

- PostgreSQL cache: In addition to common execution plan cache and data cache, PostgreSQL provides cache mechanisms such as **catalog** and **relation** to improve the efficiency of generating execution plans. In the persistent connection scenario, some of the caches are not released. As a result, the persistent connection may occupy a large amount of memory.
- PMS is a monitoring process of MRS. This process frequently creates table partitions or new tables. The PostgreSQL caches the metadata of the objects accessed by the current session, and the connections in the database connection pool of the PMS exist for a long time. Therefore, the memory occupied by the connections gradually increases.

Procedure

Step 1 Log in to the active Master node as user **root**.

Step 2 Run the following command to query the PMS process ID:

ps -ef | grep =pmsd |grep -v grep

Step 3 Run the following command to stop the PMS process. In the command, **PID** indicates the PMS process ID obtained in **Step 2**.

kill -9 PID

Step 4 Wait for the PMS process to automatically start.

It takes 2 to 3 minutes to start PMS. PMS is a monitoring process. Restarting PMS does not affect big data services.

----End

16.2.18 High Memory Usage of the Knox Process

Issue

The memory usage of the knox process is high.

Symptom

The memory usage of the active Master node is high. The **top -c** command output shows that the memory usage of the knox process exceeds 4 GB.

Cause Analysis

The memory is not separately configured for the knox process. The process automatically allocates available memory based on the system memory size. As a result, the knox process occupies a large amount of memory.

Procedure

Step 1 Log in to the Master nodes as user **root**.

Step 2 Open the **/opt/knox/bin/gateway.sh** file. Search for **APP_MEM_OPTS**, and set its value to **-Xms3072m -Xmx4096m**.

Step 3 Log in to Manager and click **Hosts**. Find the IP address of the active Master node (that is, the node with a solid star before the hostname), and log in to the background of the node.

Step 4 Run the following commands to restart the process:

su - omm

sh /opt/knox/bin/restart-knox.sh

----End

16.2.19 It Takes a Long Time to Access HBase from a Client Installed on a Node Outside the Security Cluster

Issue

The cluster client is installed on a node outside the security cluster. When a user runs the **hbase shell** command on the client to access HBase, it is found that the access is very slow.

Symptom

A user creates a security cluster, installs a cluster client on a node outside the cluster, and runs the **hbase shell** command to access HBase. It is found that the access to HBase is very slow.

Cause Analysis

Kerberos authentication is required for a security cluster. You need to configure the **hosts** file on the client node to ensure that the access speed is not affected. An example of the **hosts** configuration is as follows:

```
1.1.1.1 hadoop.782670e3_1364_47e2_8c70_1b61bb80479c.com
1.1.1.1 hadoop.hadoop.com
1.1.1.1 hacluster
1.1.1.1 haclusterX
1.1.1.1 haclusterX1
```

```
1.1.1.1 haclusterX2
1.1.1.1 haclusterX3
1.1.1.1 haclusterX4
1.1.1.1 ClusterX
1.1.1.1 manager
ip1 hostname1
ip2 hostname2
ip3 hostname3
ip4 hostname4
```

Procedure

Copy the content of the **hosts** file on the cluster node to the **hosts** file on the node where the client is installed.

16.2.20 How Do I Locate a Job Submission Failure?

Symptom

A user cannot submit jobs through DGC or on the MRS console.

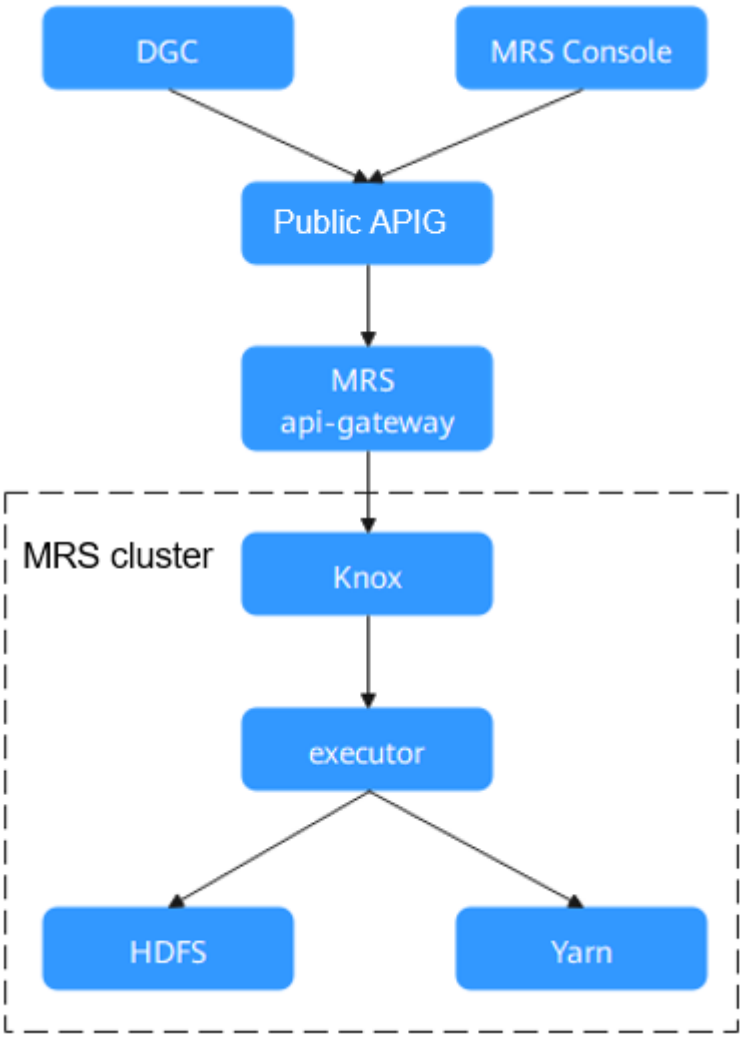
Impact

Jobs cannot be submitted, and services are interrupted.

Introduction to the Operation Process

1. All requests pass through APIG gateway and are restricted by the flow control configured on APIG.
2. APIG forwards the request to the api-gateway of the MRS management plane.
3. The API node on the MRS management plane polls the Knox of the active and standby OMS nodes to determine the Knox of the active OMS node.
4. MRS management-plane API submits a task to Knox of the active OMS.
5. Knox forwards requests to the Executor process on the current node.
6. The executor process submits a task to Yarn.

Figure 16-7 Job process



Procedure

Make preparations:

- Check whether the job is submitted through DGC or on the MRS console.
- Prepare the information listed in **Table 16-1**.

Table 16-1 Items to be prepared before the rectification

No.	Projects	Operation Mode
1	Cluster account information	Apply for **password** of user **admin** in the cluster.
2	Node account information	Apply for the passwords of users **omm** and **root** of cluster nodes.

No.	Projects	Operation Mode
3	Secure Shell (SSH) remote login tool	Prepare such tools as PuTTY or SecureCRT.
4	Client	Install the client.

Step 1 Locate the cause of the exception.

View the error code received in the job log and check whether the error code belongs to APIG or MRS.

- If the error code is a public APIG error code (starting with "APIGW"), contact public APIG maintenance personnel.
- If an error occurs on MRS, go to the next step.

Step 2 Check the running status of services and processes.

1. Log in to Manager and check whether a service fault occurs. If a job-related service fault or an underlying basic service fault occurs, rectify the fault.
2. Check whether a critical alarm is generated.
3. Log in to the active Master node.
4. Run the following command to check whether the OMS status is normal and whether the executor and knox processes on the active OMS node are normal: The knox is in active-active mode, and the executor is in single-active mode.

   /opt/Bigdata/om-0.0.1/sbin/status-oms.sh

5. Run the **jmap -heap** *PID* command as user **omm** to check the memory usage of the Knox and Executor processes. If the old-generation memory usage is 99.9%, the memory overflow occurs.

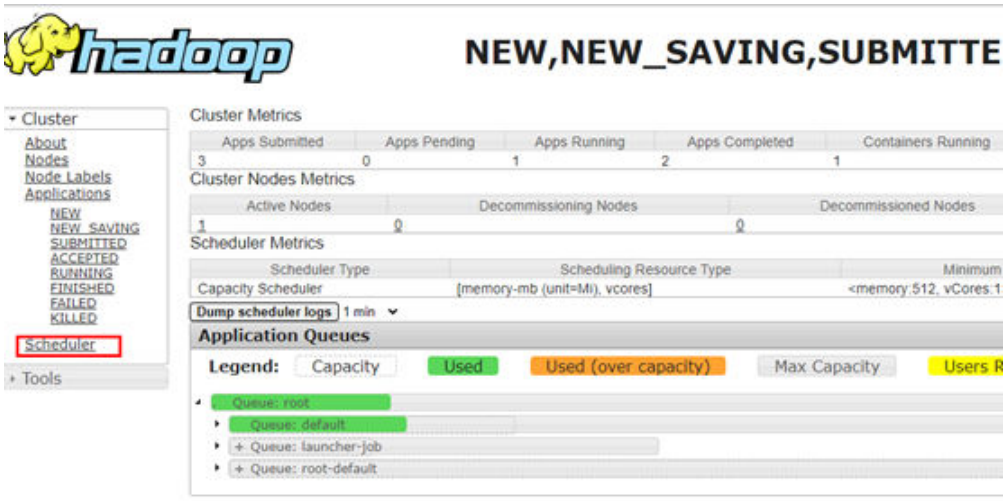
   Run the **netstat -anp | grep 8181 | grep LISTEN** command to query the PID of the executor process.

   Run the **ps -ef|grep knox | grep -v grep** command to query the PID of the knox process.

   If the memory overflows, run the **jmap -dump:format=b,file=/home/omm/temp.bin** *PID* command to export the memory information and restart the process.
6. View the native Yarn page to check the queue resource usage and whether the task is submitted to Yarn.

   On the native Yarn page: choose **Components** > **Yarn** > **ResourceManager WebUI** > **ResourceManager (Active)**.

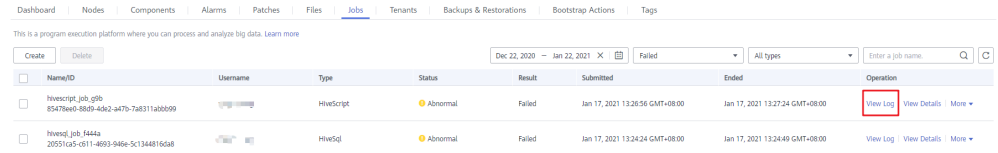
Figure 16-8 Queue resource usage on the Yarn page



Step 3 Locate the fault causing the task submission failure.

1. Log in to the MRS management console and click the cluster name to go to the cluster details page.
2. On the **Jobs** tab page, locate the row that contains the target job and click **View Log** in the **Operation** column.

   Figure 16-9 View the logs

3. If there is no log or the log information is not detailed, copy the job ID in the **Name/ID** column.
4. Run the following command on the active OMS node to check whether the task request is sent to the KNOX. If the request is not sent to the KNOX, the KNOX may be faulty. In this case, restart the KNOX to rectify the fault.

   grep "mrsjob" /var/log/Bigdata/knox/logs/gateway-audit.log | tail -10
5. Search for the job ID in the Executor log and view the error information.

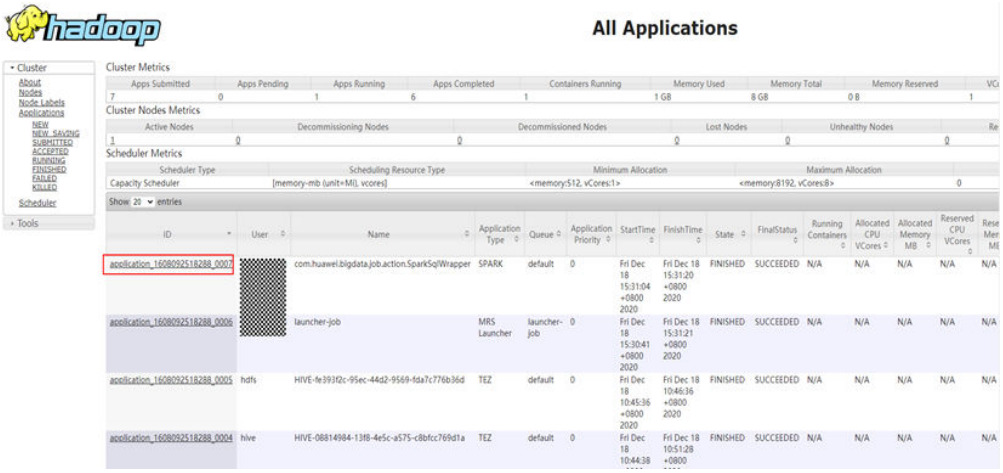
   Log file path: **/var/log/Bigdata/executor/logs/exe.log**
6. Modify the **/opt/executor/webapps/executor/WEB-INF/classes/log4j.properties** file to enable the debug log of the executor. Submit the test task and view the executor log. Confirm the error reported during job submission.

   Log file path: **/var/log/Bigdata/executor/logs/exe.log**
7. If an error occurs in the executor, run the following command to print the jstack information of the executor and check the current execution status of the thread:

   jstack PID > xxx.log
8. On the cluster details page, click the **Jobs** tab. Locate the row that contains the target job, and click **View Details** in the **Operation** column to obtain the actual job ID (**applicationID**).

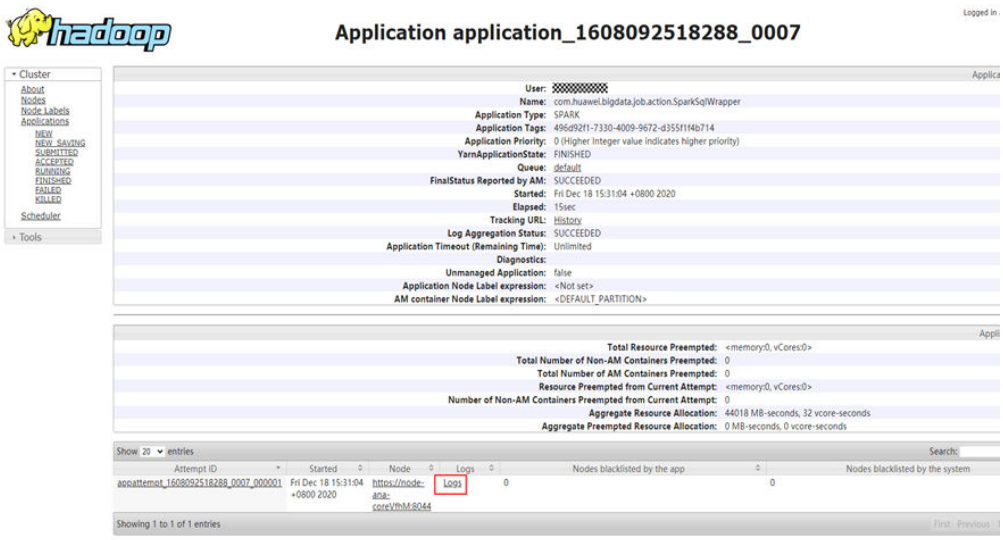
9. On the cluster details page, choose **Components** > **Yarn** > **ResourceManager WebUI** > **ResourceManager (Active)**. On the native Yarn page that is displayed, click **applicationID**.

Figure 16-10 Yarn applications



10. View logs on the task details page.

Figure 16-11 Task logs



----End

16.2.21 OS Disk Space Is Insufficient Due to Oversized HBase Log Files

Issue

The space of the **/var/log** partition on the system disk is insufficient.

Symptom

The **/var/log/Bigdata/hbase/*/hbase-omm-*.out** log file is too large, causing insufficient space of the **/var/log** partition on the system disk.

Cause Analysis

During the long-term running of HBase, the OS periodically deletes the **/tmp/.java_pid*** files created by the JVM. The HBase memory monitoring uses the **jinfo** command, which depends on the **/tmp/.java_pid*** file. If the file does not exist, the **jinfo** command runs **kill -3** to print the jstack information to the **.out** log file. As a result, the **.out** log file becomes oversize as time goes by.

Procedure

On each node hosting the HBase instance, deploy a scheduled task to periodically clear the **.out** log file. For example, log in to the HBase instance node and run the **crontab -e** command to add a scheduled task to clear the **.out** log file at 00:00:00 every day.

crontab -e

00 00 * * * for file in `ls /var/log/Bigdata/hbase/*/hbase-omm-*.out`; do echo "" > $file; done

NOTE

If large **.out** files are generated frequently, you can clear the files multiple times every day or adjust the automatic clearing policy of the OS.

16.2.22 Failed to Delete a New Tenant on FusionInsight Manager

Symptom

A user fails to delete a tenant created on the **Tenant Resources** page of FusionInsight Manager, and an error message is displayed.

Cause Analysis

When a tenant is created, its role is generated. The role will be deleted first when the tenant is deleted. If the component that supports permission configuration is abnormal, the resource permission of the role fails to be deleted.

Procedure

Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **Role**.

Step 2 Click **Create Role**. In the **Configure Resource Permission** area, click the cluster name to check the components available for resource permission configuration.

Step 3 Choose **Cluster** > **Services** and check that the running status of these components is **Normal**.

Step 4 (Optional) If the running status is not **Normal**, start or repair the component until its running status becomes **Normal**.

Step 5 Delete the tenant again.

----End

16.3 Using Alluixo

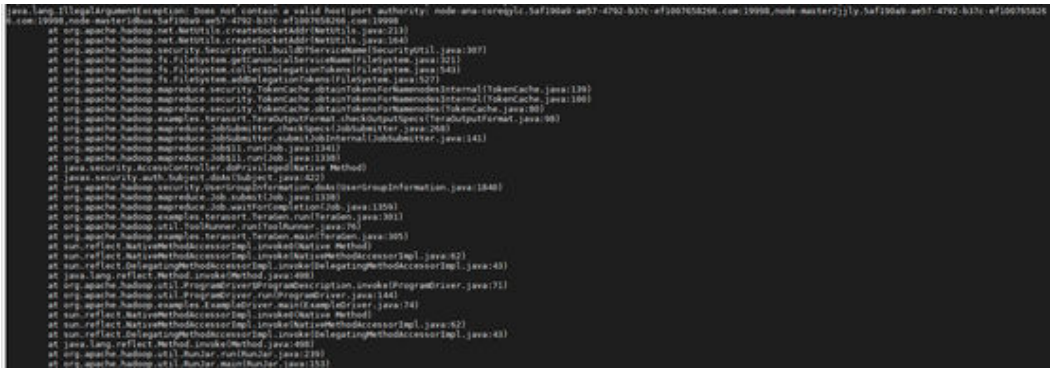
16.3.1 Error Message "Does not contain a valid host:port authority" Is Reported When Alluixo Is in HA Mode

Issue

Error message "Does not contain a valid host:port authority" is reported for Alluixo in HA mode in a security cluster.

Symptom

Error message "Does not contain a valid host:port authority" is reported for Alluixo in HA mode in a security cluster.



Cause Analysis

org.apache.hadoop.security.SecurityUtil.buildDTServiceName does not support multiple alluxiomaster addresses in the URI.

Procedure

Use **alluxio:///** or **alluxio://**<*IP address or hostname of the active AlluxioMaster*>**:19998/** for access.

16.4 Using ClickHouse

16.4.1 ClickHouse Fails to Start Due to Incorrect Data in ZooKeeper

Symptom

An instance node in the ClickHouse cluster fails to start. The startup log of the instance node contains error information similar to the following:

```
2021.03.15 21:01:19.816593 [ 11111 ] {} <Error> Application: DB::Exception:
The local set of parts of table DEFAULT.lineorder doesn't look like the set ofdoesn't look like the set of
parts in ZooKeeper: 59.99 million rows of 59.99 million total rows in
filesystem are suspicious. There are 30 unexpected parts with 59986052 rows
(14 of them is not just-written with 59986052 rows), 0 missing parts (with 0
blocks).: Cannot attach table `DEFAULT`.`lineorder` from metadata file
...
: while loading database
```

Cause Analysis

When a ClickHouse instance is abnormal, the ReplicatedMergeTree engine table is repeatedly created in the cluster, and then deleted. The creation and deletion of the ReplicatedMergeTree engine table causes data error in ZooKeeper, which causes a start failure of ClickHouse.

Solution

Step 1 Back up all data tables in the database of the faulty node to another directory.

- Back up table data:

  cd /srv/BigData/data*1*/**clickhouse/data/***Database name*

  mv *Table name Directory to be backed up/***data***1*

  NOTE

  If there are multiple disks, back up data of **data1** to **dataN**.

- Back up metadata information:

  cd /srv/BigData/data1/clickhouse_path/metadata

  mv *Table name***.sql** *Directory to be backed up*

For example, to back up the lineorder table in the default database to the **/home/backup** directory, run the following command.

cd /srv/BigData/data1/clickhouse/data/default

mv lineorder /home/backup/data1

cd /srv/BigData/data1/clickhouse_path/metadata

mv lineorder.sql /home/backup

Step 2 Log in to MRS Manager, choose **Cluster** > **Services** > **ClickHouse** > **Instance**, select the target instance node, and click **Start Instance**.

Step 3 After the instance is started, use the ClickHouse client to log in to the faulty node.

clickhouse client --host *Clickhouse instance IP address* **--user** *User name* **--password** *Password*

Step 4 Run the following command to obtain the ZooKeeper path **zookeeper_path** of the current table and **replica_num** of the corresponding node.

SELECT zookeeper_path FROM system.replicas WHERE database = '*Database name*' **AND table = '***Table name*'**;**

SELECT replica_num,host_name FROM system.clusters;

Step 5 Run the following command to access the ZooKeeper command line interface:

zkCli.sh -server *IP address of the ZooKeeper node*:**2181**

Step 6 Locate the ZooKeeper path corresponding to the table data of the faulty node.

ls *zookeeper_path*/**replicas/***replica_num*

NOTE

zookeeper_path indicates the value of **zookeeper_path** obtained in **Step 4**.

replica_num indicates the value of **replica_num** corresponding to the host in **Step 4**.

Step 7 Run the following command to delete the replica data from ZooKeeper:

deleteall *zookeeper_path*/**replicas/***replica_num*

Step 8 Use the ClickHouse client to log in to the node and create the ReplicatedMergeTree engine table of the cluster.

clickhouse client --host *Clickhouse instance IP address* **--multiline --user** *Username* **--password** *Password*

CREATE TABLE *Database name.Table name* **ON CLUSTER** *Cluster name*

...

ENGINE = ReplicatedMergeTree ...

The following error message is displayed on other replica nodes, which is normal and can be ignored.

```
Received exception from server (version 20.8.7):
Code: 57. DB::Exception: Received from x.x.x.x:9000. DB::Exception:
There was an error on [x.x.x.x:9000]: Code: 57, e.displayText() =
DB::Exception: Table DEFAULT.lineorder already exists. (version 20.8.11.17
(official build)).
```

After the table is successfully created, the table data on the faulty node will be automatically synchronized. The data restoration is complete.

----End

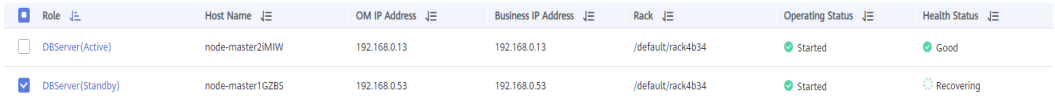
16.5 Using DBService

16.5.1 DBServer Instance Is in Abnormal Status

Symptom

A DBServer instance is in the **Concerning** state for a long period of time.

Figure 16-12 DBServer instance status



Role	Host Name	OM IP Address	Business IP Address	Rack	Operating Status	Health Status
DBServer(Active)	node-master2iMIW	192.168.0.13	192.168.0.13	/default/rack4b34	Started	Good
DBServer(Standby)	node-master1GZB5	192.168.0.53	192.168.0.53	/default/rack4b34	Started	Recovering

Cause Analysis

The permission for files or directories in the data directory is incorrect. GaussDB requires that the file permission be at least 600 and directory permission be at least 700.

Figure 16-13 Directory permission list

```
omm@192-168-234-176:/srv/BigData/dbdata_service> ll
total 4
drwx------ 19 omm wheel 4096 Dec 14 10:15 data
```

Figure 16-14 File permission list

```
omm@192-168-234-176:/srv/BigData/dbdata_service/data> ll

drwx------ 3 omm wheel   4096 Dec  9 15:39 pg_xlog
-rw------- 1 omm wheel  13309 Dec 14 10:15 postgresql.conf
-rw------- 1 omm wheel   1024 Dec  9 15:34 postgresql.conf.lock
-rw------- 1 omm wheel    105 Dec 14 10:15 postmaster.opts
-rw------- 1 omm wheel     96 Dec 14 10:15 postmaster.pid
```

Solution

Step 1 Modify the permissions on the files and directories based on the permission list in **Figure 16-13** and **Figure 16-14**.

Step 2 Restart the DBServer instance.

----End

16.5.2 DBServer Instance Remains in the Restoring State

Symptom

A DBServer instance remains in the **Restoring** state. The status cannot be recovered even after a restart.

Cause Analysis

1. DBService monitors the **${BIGDATA_HOME}/MRS_*XXX*/install/dbservice/ha/module/harm/plugin/script/gsDB/.startGS.fail** file. *XXX* indicates the product version.
2. If the value in the file is greater than 3, the startup fails. The NodeAgent keeps trying to restart the instance. In this case, the startup still fails and the value is incremented by 1 each time the startup fails.

Solution

Step 1 Log in to MRS Manager.

Step 2 Stop the DBServer instance.

Step 3 Log in to the node where the DBServer instance is abnormal as user **omm**.

Step 4 Change the value of in the **${BIGDATA_HOME}/MRS_*XXX*/install/dbservice/ha/module/harm/plugin/script/gsDB/.startGS.fail** file to **0**. *XXX* indicates the product version.

Step 5 Start the DBServer instance.

----End

16.5.3 Default Port 20050 or 20051 Is Occupied

Symptom

DBService restart fails, and information indicating that port 20050 or 20051 is occupied is displayed in the printed fault log.

Cause Analysis

1. The default port 20050 or 20051 used by DBService is occupied by another process.
2. The DBService process is not stopped, and the port used by DBService is not released.

Solution

This solution uses port 20051 as an example. The solution to the problem that port 20050 is occupied is similar.

Step 1 Log in to the node where the error is reported as user **root**, and run the **netstat -nap | grep 20051** command to check the process that occupies port 20051.

Step 2 Run the **kill** command to forcibly stop the process that uses port 20051.

Step 3 About 2 minutes later, run the **netstat -nap | grep 20051** command again to check whether any process uses the port.

Step 4 Check the service to which the process belongs and change the port for the service.

Step 5 Run the **find . -name "*20051*"** command in the **/tmp** and **/var/run/MRS-DBService/** directories, and delete all files found.

Step 6 Log in to Manager and restart DBService.

----End

16.5.4 DBServer Instance Is Always in the Restoring State Because the Incorrect /tmp Directory Permission

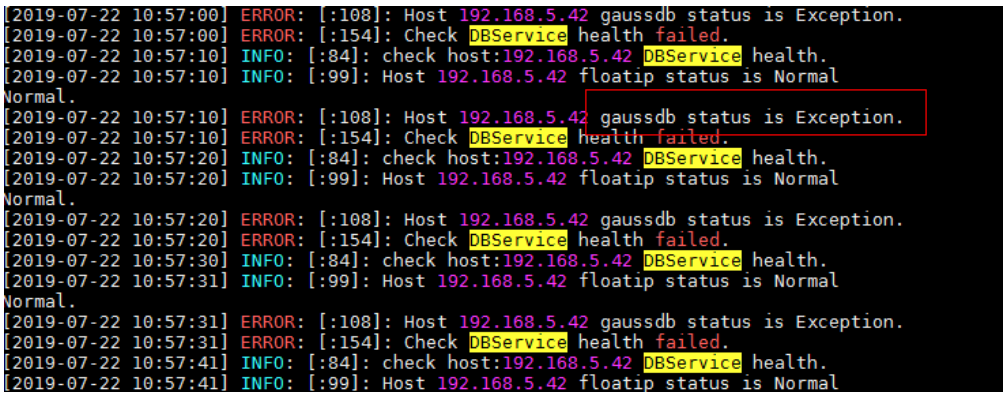
Symptom

A DBServer instance remains in the **Restoring** state. The status cannot be recovered even after a restart.

Cause Analysis

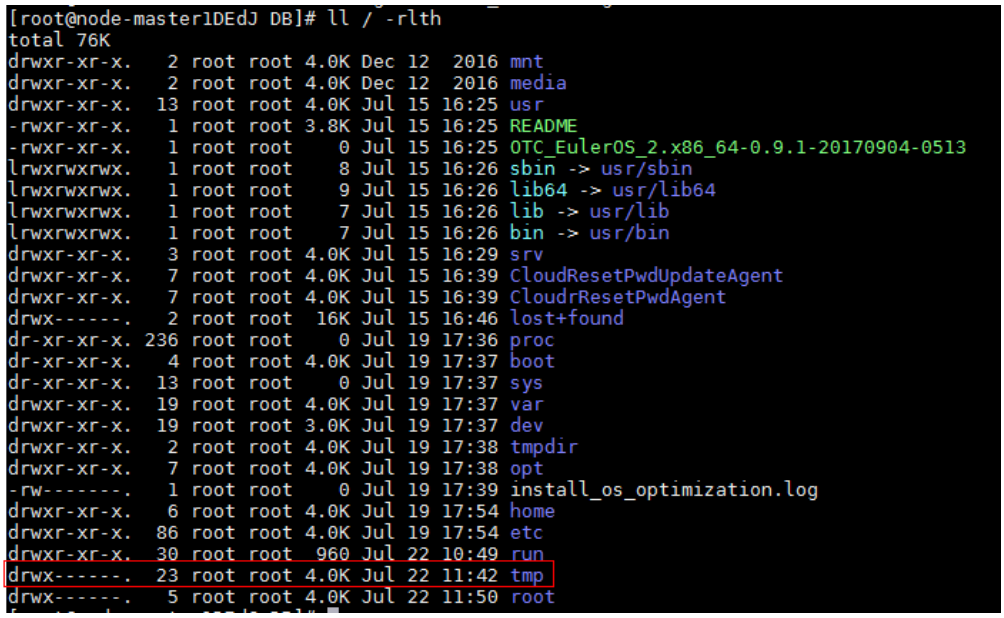
1. Check **/var/log/Bigdata/dbservice/healthCheck/dbservice_processCheck.log**. It is found that GaussDB is abnormal.

   Figure 16-15 GaussDB exception

2. The check result shows that the permission on the **/tmp** directory is incorrect.

Figure 16-16 /tmp permission



Solution

Step 1 Run the following command to modify the **/tmp** permission:

chmod 1777 /tmp

Step 2 Wait until the instance status recovers.

----End

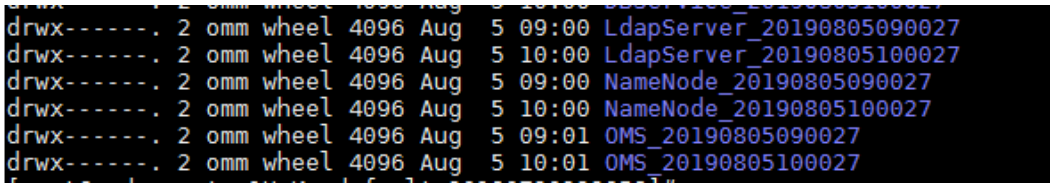
16.5.5 DBService Backup Failure

Symptom

ls /srv/BigData/LocalBackup/default_20190720222358/ -rlth

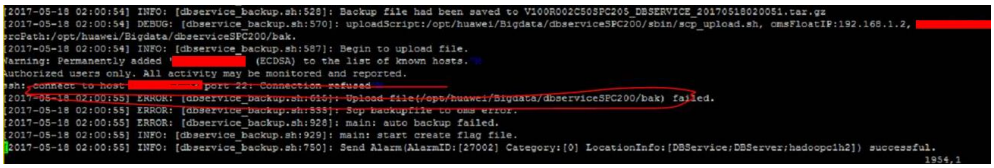
No DBService backup file exists in the backup file path.

Figure 16-17 Checking the backup file



Cause Analysis

- Check the backup log of DBService in **/var/log/Bigdata/dbservice/scriptlog/backup.log**. It is found that the backup is successful but fails to be uploaded to the OMS node.



- The failure is caused by the SSH failure.

Solution

Step 1 If the network is faulty, contact network engineers.

Step 2 Perform backup operations again after the network fault is rectified.

----End

16.5.6 Components Failed to Connect to DBService in Normal State

Symptom

Upper-layer components fail to connect to DBService. The DBService component and two instances are normal.

Figure 16-18 DBService status

Cause Analysis

1. The upper-layer component is DBService connected through **dbservice.floatip**.
2. Run the **netstat -anp | grep 20051** command on the node where DBServer resides. It is found that the Gauss process of DBService is not bound to the floating IP address during startup, and only the local IP address 127.0.0.1 is listened.

Solution

Step 1 Restart the DBService service.

Step 2 Run the **netstat -anp | grep 20051** command on the active DBServer node to check whether **dbservice.floatip** is bound.

----End

16.5.7 DBServer Failed to Start

Symptom

DBService fails to be started and restarts also fail. The instance keeps in the **Recovering** state.

Figure 16-19 DBService status

Role	Host Name	OM IP Address	Business IP Address	Rack	Operating Status	Health Status
DBServer(Active)	node-master2iMIW	192.168.0.13	192.168.0.13	/default/rack4b34	Started	Good
DBServer(Standby)	node-master1GZBS	192.168.0.53	192.168.0.53	/default/rack4b34	Started	Recovering

Cause Analysis

1. Check the DBService logs in **/var/log/Bigdata/dbservice/DB/gs_ctl-current.log**. The following error message is displayed:

```
OCATION:  PostmasterMain, postmaster.c:798
OG:  Starting SelectConfigFiles (postmaster.c:1049)

drwxr-xr-x  13 root  root     4096 Apr 22  2014 usr
```

Solution

Step 1 Modify the **/tmp** permission by changing the value to **777**.

Step 2 Restart DBService.

----End

16.5.8 DBService Backup Failed Because the Floating IP Address Is Unreachable

Symptom

The default DBService backup fails, but backups of NameNode, LdapServer, and OMS are successful.

Cause Analysis

1. Check the error information on the DBService backup page:
   Clear temporary files at backup checkpoint DBService_test_DBService_DBService_20180326155921 that fialed last time.
   Temporyary files at backup checkpoint DBService_test_DBService_DBService20180326155921 that failed last time are cleared successfully.

```
Start executing the backup task.
The backup of configuration DBService is started.
Check the backup available disk space.
Backup initialization succeeded for configuration DBService.
Clear temporary files at backup checkpoint DBService_test_DBService_DBService_20180326155921 that failed last time.
Temporary files at backup checkpoint DBService_test_DBService_DBService_20180326155921 that failed last time are cleared successfully.
Checkpoint DBService_test_DBService_DBService_20180326162235 is verified successfully before backup.
Temporary files are cleared successfully before backup checkpoint DBService_test_DBService_DBService_20180326162235.
Prestart backup succeeded for checkpoint DBService_test_DBService_DBService_20180326162235.
The snapshot is created successfully for checkpoint DBService_test_DBService_DBService_20180326162235 before backup.
Backup is being performed for checkpoint DBService_test_DBService_DBService_20180326162235.
Backup execution failed. Task ID: 2
Detail: DBService backup task failed, please view details in logs.
Temporary files are cleared successfully after backup checkpoint DBService_test_DBService_DBService_20180326162235.
checkpoint DBService_test_DBService_DBService_20180326162235 is deleted successfully after backup failure.
Failed to backup configuration DBService.
```

2. Check the **/var/log/Bigdata/dbservice/scriptlog/backup.log** file. It is found that the log printing stops and no related backup information is found.
3. Check the **/var/log/Bigdata/controller/backupplugin.log** file on the active OMS node. The following error information is found:
   result error is ssh:connect to host 172.16.4.200 port 22: Connection refused (172.16.4.200 is the floating IP address of DBService)
   DBService backup failed.

```

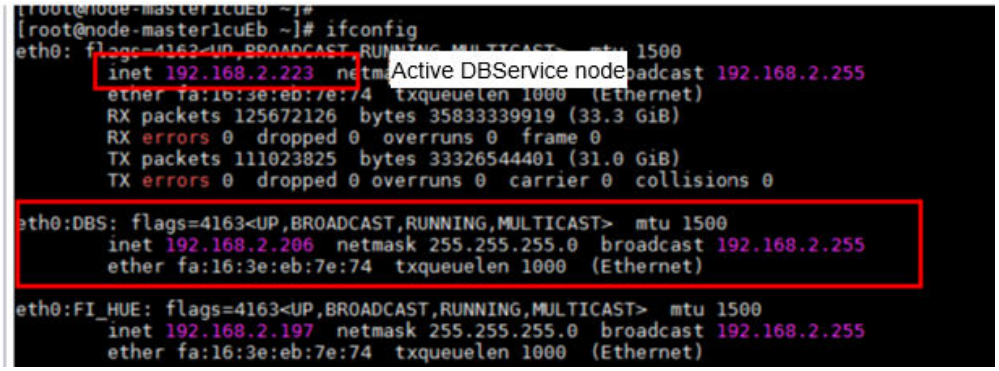
```

Solution

Step 1 Log in to the active DBService node (the Master node bound with the DBService floating IP address).



Step 2 Add the DBService floating IP address to **ListenAddress** or comment out **ListenAddress** in the **/etc/ssh/sshd_config** file.

Step 3 Run the following command to restart the SSHD service:

service sshd restart

Step 4 Check whether the next DBServie backup is successful.

----End

16.5.9 DBService Failed to Start Due to the Loss of the DBService Configuration File

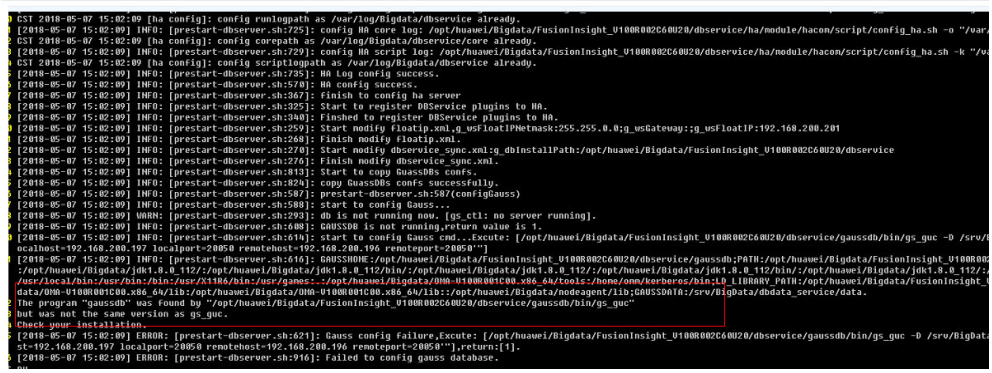
Symptom

The nodes are powered off unexpectedly, and the standby DBService node fails to be restarted.

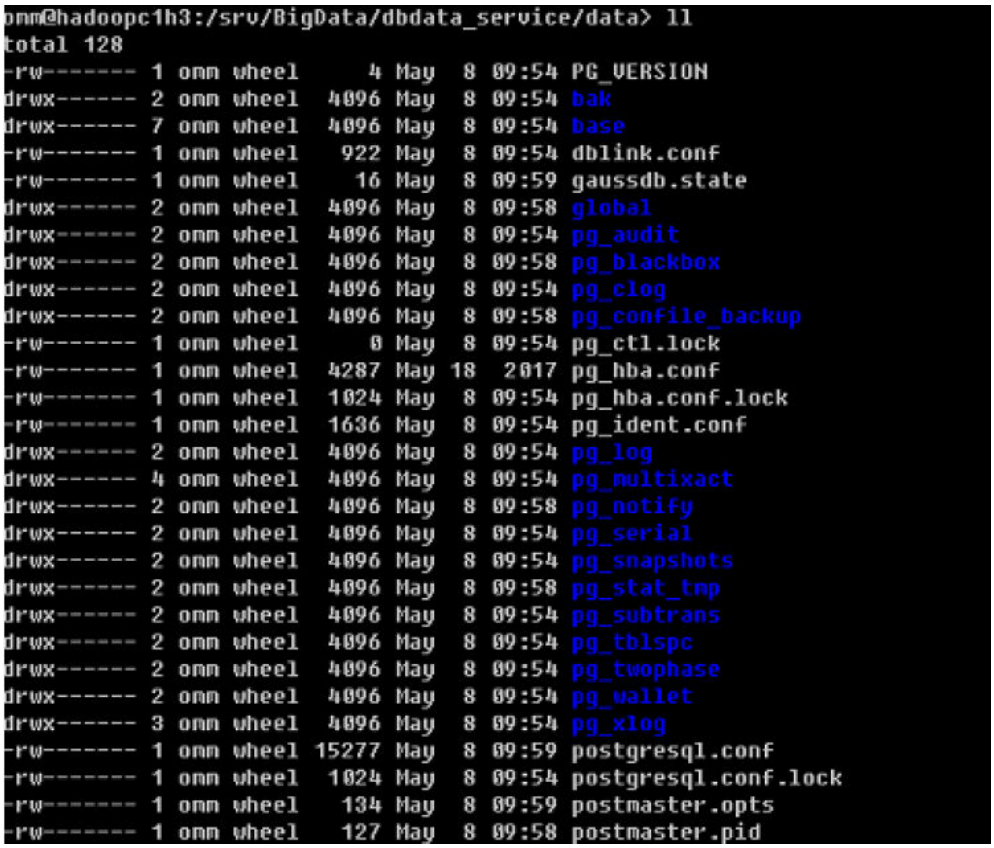
Cause Analysis

1. The **/var/log/Bigdata/dbservice/DB/gaussdb.log** file is viewed, which contains no information.
2. The **/var/log/Bigdata/dbservice/scriptlog/preStartDBService.log** file is viewed. This file contains the following information, indicating that the configuration information is lost:

```
The program "gaussdb" was found by "
/opt/Bigdata/MRS_xxx/install/dbservice/gaussdb/bin/gs_guc)
But not was not the same version as gs_guc.
Check your installation.
```



3. The configuration file in the **/srv/BigData/dbdata_service/data** directory on the active DBServer node is compared with the configuration file in the **/srv/BigData/dbdata_service/data** directory on the standby DBServer node, which shows major difference.



```
nm@hadoopc1h3:/srv/BigData/dbdata_service> cd data_bak/
nm@hadoopc1h3:/srv/BigData/dbdata_service/data_bak> ll
otal 64
rw------- 1 onm wheel   202 Feb 11 10:43 backup_label
rw------- 1 onm wheel     0 Feb 11 10:42 build_completed.start
rw------- 1 onm wheel    16 Apr 28 17:32 gaussdb.state

rw------- 1 onm wheel     0 Apr 28 17:32 pg_ctl.lock
rw------- 1 onm wheel  4287 May 18  2017 pg_hba.conf
rwx------ 2 onm wheel  4096 Feb 11 10:43 pg_notify
rwx------ 2 onm wheel  4096 Feb 11 10:43 pg_xlog
rw------- 1 onm wheel 15155 May  7 15:33 postgresql.conf
rw------- 1 onm wheel  1024 May  7 15:33 postgresql.conf.lock
rw------- 1 onm wheel   134 Feb 11 10:42 postmaster.opts
```

Solution

Step 1 Copy the content in the **/srv/BigData/dbdata_service/data** directory on the active node to the standby node and ensure that the file permission and owner group are the same as those on the active node.

Step 2 Modify configuration in **postgresql.conf**. Set **localhost** to the IP of the local node and **remotehost** to the IP of the peer node.

```
#------------------------------------------------------------------------------
# CUSTOMIZED OPTIONS
#------------------------------------------------------------------------------

# Add settings for extensions here
max_files_per_process = 300
unix_socket_directory = '/var/run/FusionInsight-DBService'
replconninfo1 = 'localhost=192.168.200.197 localport=20050 remotehost=192.168.200.196 remoteport=20050'
"postgresql.conf" 382L, 15277C
```

Step 3 Log in to Manager and restart the standby DBServer node.

----End

16.6 Using Flink

16.6.1 "IllegalConfigurationException: Error while parsing YAML configuration file: "security.kerberos.login.keytab" Is Displayed When a Command Is Executed on an Installed Client

Symptom

After the client is successfully installed, an error message "IllegalConfigurationException: Error while parsing YAML configuration file:"security.kerberos.login.keytab" is displayed when the command (for example, **yarn-session.sh**) on the client is executed.

```
[root@8-5-131-10 bin]# yarn-session.sh
2018-10-25 01:22:06,454 | ERROR | [main] | Error while trying to split key and value in configuration file /opt/flinkclient/Flink/flink/conf/flink-conf.yaml:80: "security.kerberos.login.keytab: " | org.apache.flink.configuration.GlobalConfiguration (GlobalConfiguration.java:160)
Exception in thread "main" org.apache.flink.configuration.IllegalConfigurationException: Error while parsing YAML configuration file :80: "security.kerberos.login.keytab: "
```

```
        at org.apache.flink.configuration.GlobalConfiguration.loadYAMLResource(GlobalConfiguration.java:161)
        at org.apache.flink.configuration.GlobalConfiguration.loadConfiguration(GlobalConfiguration.java:112)
        at org.apache.flink.configuration.GlobalConfiguration.loadConfiguration(GlobalConfiguration.java:79)
        at org.apache.flink.yarn.cli.FlinkYarnSessionCli.main(FlinkYarnSessionCli.java:482)
[root@8-5-131-10 bin]#
```

Cause Analysis

In a secure cluster environment, Flink requires security authentication. The security authentication is not configured on the current client.

1. The following two authentication modes are available for Flink.
   - Kerberos authentication: Flink Yarn client, Yarn ResourceManager, JobManager, HDFS, TaskManager, Kafka, and ZooKeeper
   - Internal authentication mechanism of Yarn: The internal authentication used between YarnResource Manager and Application Master (AM).
2. If a security cluster is required, the Kerberos authentication and security cookie authentication are mandatory. As shown in the logs, it is found that the **security.kerberos.login.keytab** setting in the configuration file is incorrect and the security configuration is not performed.

Solution

Step 1 Download the keytab file from MRS and save it in a folder on a host where the Flink client resides.

Step 2 Configure following parameters in the **flink-conf.yaml** file:

1. Keytab path
   ```
   security.kerberos.login.keytab: /home/flinkuser/keytab/abc222.keytab
   ```

   NOTE

   - **/home/flinkuser/keytab/abc222.keytab** indicates the user directory, which is the directory saves the keytab file in **Step 1**.
   - Ensure that the client user has the permission on the corresponding directory.

2. Principal name
   ```
   security.kerberos.login.principal: abc222
   ```
3. In HA mode, if Zookeeper is configured, the ZooKeeper Kerberos authentication configuration items must be configured as follows:
   ```
   zookeeper.sasl.disable: false
   security.kerberos.login.contexts: Client
   ```
4. If Kerberos authentication is required between the Kafka client and Kafka broker, configure it as follows:
   ```
   security.kerberos.login.contexts: Client,KafkaClient
   ```

----End

16.6.2 "IllegalConfigurationException: Error while parsing YAML configuration file" Is Displayed When a Command Is Executed After Configurations of the Installed Client Are Changed

Symptom

After the client is successfully installed, an error message "IllegalConfigurationException: Error while parsing YAML configuration file: 81: "security.kerberos.login.principal:pippo " is displayed when the command (for example, **yarn-session.sh**) on the client is executed.

```
[root@8-5-131-10 bin]# yarn-session.sh
2018-10-25 19:27:01,397 | ERROR | [main] | Error while trying to split key and value in configuration file /opt/flinkclient/Flink/flink/conf/flink-conf.yaml:81: "security.kerberos.login.principal:pippo " | org.apache.flink.configuration.GlobalConfiguration (GlobalConfiguration.java:160)
Exception in thread "main" org.apache.flink.configuration.IllegalConfigurationException: Error while parsing YAML configuration file :81: "security.kerberos.login.principal:pippo "
        at org.apache.flink.configuration.GlobalConfiguration.loadYAMLResource(GlobalConfiguration.java:161)
        at org.apache.flink.configuration.GlobalConfiguration.loadConfiguration(GlobalConfiguration.java:112)
        at org.apache.flink.configuration.GlobalConfiguration.loadConfiguration(GlobalConfiguration.java:79)
        at org.apache.flink.yarn.cli.FlinkYarnSessionCli.main(FlinkYarnSessionCli.java:482)
```

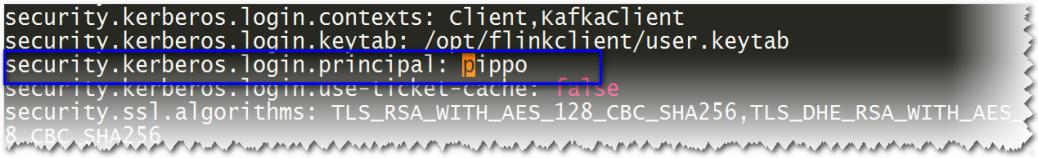
Cause Analysis

The **security.kerberos.login.principal:pippo** item in the **flink-conf.yaml** configuration file was faulty.

Solution

Modify the configuration in the **flink-conf.yaml** file.

Note: The configuration item name and value must be separated by a space.



16.6.3 The yarn-session.sh Command Fails to Be Executed When the Flink Cluster Is Created

Symptom

During the creation of the Flink cluster, an error message is displayed after the **yarn-session.sh** command execution is suspended.

```
2018-09-20 22:51:16,842 | WARN  | [main] | Unable to get ClusterClient status from Application Client | org.apache.flink.yarn.YarnClusterClient (YarnClusterClient.java:253)
```

```

    at org.apache.flink.runtime.util.LeaderRetrievalUtils.retrieveLeaderGateway(LeaderRetrievalUtils.java:79)
    at org.apache.flink.client.program.ClusterClient.getJobManagerGateway(ClusterClient.java:856)
    ... 10 common frames omitted
Caused by: java.util.concurrent.TimeoutException: Futures timed out after [10000 milliseconds]
```

Possible Causes

The SSL communication encryption is enabled for Flink, but no correct SSL certificate is configured.

Solution

For MRS 2.*x* or earlier, perform the following operations:

Method 1:

Run the following command to disable the Flink SSL communication encryption, and modify the client configuration file **conf/flink-conf.yaml**.

```
security.ssl.internal.enabled: false
```

Method 2:

Enable the Flink SSL communication encryption and retain the default value of **security.ssl.internal.enabled**. Configure the SSL as follows:

- If the KeyStore or TrustStore file is a relative path, and the Flink client directory where the command is executed can directly access this relative path.

  ```
  security.ssl.internal.keystore: ssl/flink.keystore
  security.ssl.internal.truststore: ssl/flink.truststore
  ```

  Add **-t** option to the CLI **yarn-session.sh** command of Flink to transmit the KeyStore and TrustStore files to each execution node. Example:

  ```
  yarn-session.sh -t ssl/ 2
  ```

- If the keystore or truststore file path is an absolute path, the keystore or truststore files must exist in the absolute path on Flink Client and all nodes.

  ```
  security.ssl.internal.keystore: /opt/client/Flink/flink/conf/flink.keystore
  security.ssl.internal.truststore: /opt/client/Flink/flink/conf/flink.truststore
  ```

For MRS 3.*x* or later, perform the following operations:

Method 1:

Run the following command to disable the Flink SSL communication encryption, and modify the client configuration file **conf/flink-conf.yaml**.

```
security.ssl.enabled: false
```

Method 2:

Enable the Flink SSL communication encryption and retain the default value of **security.ssl.enabled**. Configure the SSL as follows:

- If the KeyStore or TrustStore file is a relative path, and the Flink client directory where the command is executed can directly access this relative path.

  ```
  security.ssl.keystore: ssl/flink.keystore
  security.ssl.truststore: ssl/flink.truststore
  ```

  Add **-t** option to the CLI **yarn-session.sh** command of Flink to transmit the KeyStore and TrustStore files to each execution node. Example:

  ```
  yarn-session.sh -t ssl/ 2
  ```

- If the keystore or truststore file path is an absolute path, the keystore or truststore files must exist in the absolute path on Flink Client and all nodes.

  ```
  security.ssl.keystore: /opt/Bigdata/client/Flink/flink/conf/flink.keystore
  security.ssl.truststore: /opt/Bigdata/client/Flink/flink/conf/flink.truststore
  ```

16.6.4 Failed to Create a Cluster by Executing the yarn-session Command When a Different User Is Used

Symptom

Two users **testuser** and **bdpuser** with the same rights are used to create the Flink cluster.

When user **testuser** is used to create a Flink cluster, no error message is displayed. While user **bdpuser** is used to create a Flink cluster, an error message is displayed during the **yarn-session.sh** command execution:

```
2019-01-02 14:28:09,098 | ERROR | [main] | Ensure path threw exception |
org.apache.flink.shaded.curator.org.apache.curator.framework.imps.CuratorFrameworkImpl
(CuratorFrameworkImpl.java:566)
org.apache.flink.shaded.zookeeper.org.apache.zookeeper.KeeperException$NoAuthException:
KeeperErrorCode = NoAuth for /flink/application_1545397824912_0022
```

Possible Causes

The HA configuration item is not modified. In the Flink configuration file, the default value of **high-availability.zookeeper.client.acl** is **creator**, indicating that only the creator has the access permission. A new user cannot access the directory on ZooKeeper. As a result, the **yarn-session.sh** command execution fails.

Solution

Step 1 Modify the value of **high-availability.zookeeper.path.root** in the **conf/flink-conf.yaml** file. For example, run the following command:

```
high-availability.zookeeper.path.root: flink2
```

Step 2 Submit the tasks again.

----End

16.6.5 Flink Service Program Fails to Read Files on the NFS Disk

Issue

The Flink service program cannot read files on the NFS disk mounted to the cluster node.

Symptom

The Flink service program developed by a user needs to read the user-defined configuration file. The configuration file is stored on the NFS disk. The NFS disk is mounted to the cluster node and can be accessed by all nodes in the cluster. After the user submits the Flink program, the service code cannot access the user-defined configuration file. As a result, the service program fails to be started.

Cause Analysis

The root cause is that the permission on the root directory of the NFS disk is insufficient. As a result, the Flink program cannot access the directory after being started.

Flink tasks of MRS are running on Yarn. If the cluster is a common cluster, the user who runs the tasks on Yarn is **yarn_user**. If the user-defined configuration file is used after the tasks are started, **yarn_user** must be allowed to access the file and the parent directory of the file (parent directory of the file on the NFS, not the soft link on the cluster node). Otherwise, the program cannot obtain the file content. If the cluster is a cluster with Kerberos authentication enabled, the file permission must allow the user who submits the program to access the file.

Procedure

Step 1 Log in to the Master node in the cluster as user **root**.

Step 2 Run the following command to check the permission on the parent directory of the user-defined configuration file:

ll <*Parent directory of the file path***>**

Step 3 Go to the directory of the file to be accessed on the NFS disk and change the permission of the parent directory of the user-defined configuration file to 755.

chmod 755 -R /<*Path of the parent directory of the file***>**

Step 4 Check whether the Core or Task node can access the configuration file.

1. Log in to the Core or Task node as the **root** user.

   If Kerberos authentication is enabled for the current cluster, log in to the Core node as user **root**.

2. Run **su - yarn_user** to switch to user **yarn_user**.

   If Kerberos authentication is enabled for the cluster, run the **su -** *User who submits the job* command to switch the user.

3. Run the following command to check the user permission. The file path must be the absolute path of the file.

ll <*File path*>

----End

Summary and Suggestions

When a user-defined configuration file needs to be accessed in the submitted task, especially when the NFS disk is mounted, you need to check whether the permission of the parent directory of the file is correct in addition to the file permission. When an NFS disk is mounted to an MRS cluster node, a soft link is created to the NFS directory. In this case, you need to check whether the directory permission on the NFS is correct.

16.6.6 Failed to Customize the Flink Log4j Log Level

Issue

The customized level for Flink Log4j logs of an MRS 3.1.0 cluster does not take effect.

Symptom

1. When analyzing data using Flink of an MRS 3.1.0 cluster, a user changes the log level in the **log4j.properties** file in the **$Flink_HOME/conf** directory to **INFO**.
2. However, after the task is submitted successfully, the log level displayed on the console is still **ERROR**, rather than **INFO**.

Cause Analysis

The **log4j.properties** file in the **$Flink_HOME/conf** directory controls the log output of in JobManager and TaskManager operators, and the logs are printed to the corresponding Yarn containers. You can view the logs on the Yarn web UI. In MRS 3.1.0 and later versions, the default log framework of Flink 1.12.0 is Log4j2. The configuration method is different from that of Log4j. For example, Log4j log rules do not take effect.

Procedure

For details about configuring Log4j2 log specifications, see the official open-source document at **http://logging.apache.org/log4j/2.x/manual/configuration.html#Properties**.

16.7 Using Flume

16.7.1 Class Cannot Be Found After Flume Submits Jobs to Spark Streaming

Issue

After Flume submits jobs to Spark Streaming, the class cannot be found.

Symptom

After the Spark Streaming code is packed into a JAR file and submitted to the cluster, an error message is displayed indicating that the class cannot be found. The following two methods are not useful:

1. When submitting a Spark job, run the **--jars** command to reference the JAR file of the class.
2. Import the JAR file where the class resides to the JAR file of Spark Streaming.

Cause Analysis

Some JAR files cannot be loaded during Spark job execution, resulting that the class cannot be found.

Procedure

Step 1 Run the **--jars** command to load the **flume-ng-sdk-{version} .jar** dependency package.

Step 2 Modify the two configuration items in the **spark-default.conf** file:

spark.driver.extraClassPath=$PWD/*: {Add the original value}

spark.executor.extraClassPath =$PWD/*

Step 3 Run the job successfully. If an error is reported, check which JAR is not loaded and perform step 1 and step 2 again.

----End

16.7.2 Failed to Install a Flume Client

Symptom

A Flume client fails to be installed, and "JAVA_HOME is null" or "flume has been installed" is displayed.

```
CST 2016-08-31 17:02:51 [flume-client install]: JAVA_HOME is null in current user,please install the JDK and set the JAVA_HOME
CST 2016-08-31 17:02:51 [flume-client install]: check environment failed.
CST 2016-08-31 17:02:51 [flume-client install]: check param failed.
CST 2016-08-31 17:02:51 [flume-client install]: install flume client failed.
```

```
CST 2016-08-31 17:03:58 [flume-client install]: flume has been installed
CST 2016-08-31 17:03:58 [flume-client install]: check path failed.
CST 2016-08-31 17:03:58 [flume-client install]: check param failed.
CST 2016-08-31 17:03:58 [flume-client install]: install flume client failed.
```

Cause Analysis

- Environment variables are checked during Flume client installation. If no Java is available, an error message is displayed stating "JAVA_HOME is null" and the installation quits.
- If Flume has been installed in the specified directory, an error message is displayed stating "flume has been installed" during client installation and the installation quits.

Solution

Step 1 Run the following command if an error message is displayed stating "JAVA_HOME is null":

export JAVA_HOME=*Java path*

Set **JAVA_HOME** and execute the installation script again.

Step 2 If a Flume client has been installed under the specified directory, uninstall the client and use another directory.

----End

16.7.3 A Flume Client Cannot Connect to the Server

Symptom

A user installs a Flume client and sets an Avro sink to communicate with the server. However, the Flume server cannot be connected.

Cause Analysis

1. The server is incorrectly configured and the monitoring port fails to be started up. For example, an incorrect IP address or an occupied port is configured for the Avro source of the server. View Flume run logs.

```
2016-08-31 17:28:42,092 | ERROR | [lifecycleSupervisor-1-9] |  Unable to start EventDrivenSourceRunner: { source:Avro source avro_source: { bindAddress: 10.120.205.7, port: 21154 } } - Exception follows.  | org.apache.flume.lifecycle.LifecycleSupervisor $MonitorRunnable.run(LifecycleSupervisor.java:253)
java.lang.RuntimeException: org.jboss.netty.channel.ChannelException: Failed to bind to: /192.168.205.7:21154
```

2. If encrypted transmission is used, the certificate or password is incorrect.

```
2016-08-31 17:15:59,593 | ERROR | [conf-file-poller-0] |  Source avro_source has been removed due to an error during configuration  | org.apache.flume.node.AbstractConfigurationProvider.loadSources(AbstractConfigurationProvider.java:388)
org.apache.flume.FlumeException: Avro source configured with invalid keystore: /opt/Bigdata/MRS_XXX/install/FusionInsight-Flume-1.9.0/flume/conf/flume_sChat.jks
```

3. The network connection between the client and the server is abnormal.

```
PING 192.168.85.55 (10.120.85.55) 56(84) bytes of data.
From 192.168.85.50 icmp_seq=1 Destination Host Unreachable
From 192.168.85.50 icmp_seq=2 Destination Host Unreachable
From 192.168.85.50 icmp_seq=3 Destination Host Unreachable
From 192.168.85.50 icmp_seq=4 Destination Host Unreachable
```

Solution

Step 1 Set a correct IP address (an IP address of the local host). If the port has been occupied, configure another free port.

Step 2 Configure a correct certificate path.

Step 3 Contact the network administrator to restore the network.

----End

16.7.4 Flume Data Fails to Be Written to the Component

Symptom

After the Flume process is started, Flume data cannot be written to the corresponding component. (The following uses writing data from the server to HDFS as an example.)

Cause Analysis

1. HDFS is not started or is faulty. View Flume run logs.

```
2019-02-26 11:16:33,564 | ERROR | [SinkRunner-PollingRunner-DefaultSinkProcessor] |  opreation the hdfs file errors.  | org.apache.flume.sink.hdfs.HDFSEventSink.process(HDFSEventSink.java:414)
2019-02-26 11:16:33,747 | WARN  | [hdfs-CCCC-call-runner-4] |  A failover has occurred since the start of call #32795 ClientNamenodeProtocolTranslatorPB.getFileInfo over 192-168-13-88/192.168.13.88:25000  | org.apache.hadoop.io.retry.RetryInvocationHandler$ProxyDescriptor.failover(RetryInvocationHandler.java:220)
2019-02-26 11:16:33,748 | ERROR | [hdfs-CCCC-call-runner-4] |  execute hdfs error. {}  | org.apache.flume.sink.hdfs.HDFSEventSink$3.call(HDFSEventSink.java:744)
java.net.ConnectException: Call From 192-168-12-221/192.168.12.221 to 192-168-13-88:25000 failed on connection exception: java.net.ConnectException: Connection refused; For more details see:  http://wiki.apache.org/hadoop/ConnectionRefused
```

2. The HDFS sink is not started. Check the Flume run log. It is found that the Flume current metrics file does not contain sink information.

```
2019-02-26 11:46:05,501 | INFO  | [pool-22-thread-1] |  flume current metrics:{"CHANNEL.BBBB":{"ChannelCapacity":"10000","ChannelFillPercentage":"0.0","Type":"CHANNEL","ChannelStoreSize":"0","EventProcessTimedelta":"0","EventTakeSuccessCount":"0","ChannelSize":"0","EventTakeAttemptCount":"0","StartTime":"1551152734999","EventPutAttemptCount":"0","EventPutSuccessCount":"0","StopTime":"0"},"SOURCE.AAAA":{"AppendBatchAcceptedCount":"0","EventAcceptedCount":"0","AppendReceivedCount":"0","MonTime":"0","StartTime":"1551152735503","AppendBatchReceivedCount":"0","EventReceivedCount":"0","Type":"SOURCE","TotalFilesCount":"1001","SizeAcceptedCount":"0","UpdateTime":"605410241202740","AppendAcceptedCount":"0","OpenConnectionCount":"0","MovedFilesCount":"1001","StopTime":"0"}}  | org.apache.flume.node.Application.getRestartComps(Application.java:467)
```

Solution

Step 1 If the component to which Flume writes data is not started, start the component. If the component is abnormal, contact technical support.

Step 2 If the sink is not started, check whether the configuration file is correctly configured. If the configuration file is incorrectly configured, modify the configuration file and restart the Flume process. If the configuration file is correctly configured, view the error information in the log and rectify the fault based on the error information.

----End

16.7.5 Flume Server Process Fault

Symptom

After Flume runs for a period of time, the Flume instance is in the faulty state on Manager.

Cause Analysis

If the Flume file or folder permission is abnormal, the following information is displayed on MRS Manager after the restart:

```
[2019-02-26 13:38:02]RoleInstance prepare to start failure [{ScriptExecutionResult=ScriptExecutionResult [exitCode=126, output=, errMsg=sh: line 1: /opt/Bigdata/MRS_XXX/install/FusionInsight-Flume-1.9.0/flume/bin/flume-manage.sh: Permission denied
```

Solution

Compare the file and folder permissions with those for the Flume node that is running properly and correct the file or folder permissions.

16.7.6 Flume Data Collection Is Slow

Symptom

After Flume is started, it takes a long time for Flume to collect data.

Cause Analysis

1. The heap memory of Flume is not properly set. As a result, the Flume process keeps in the GC state. View Flume run logs.
   ```
   2019-02-26T13:06:20.666+0800: 1085673.512: [Full GC:[CMS: 3849339k->3843458K(3853568K), 2.5817610 secs] 4153654K->3843458K(4160256K), [CMS Perm : 27335K->27335K(45592K),2.5820080 SECS] [Times: user=2.63, sys0.00, real=2.59 secs]
   ```
2. The **deletePolicy** policy configured for the Spooldir source is **immediate**.

Solution

Step 1 Increase the size of the heap memory (**xmx**).

Step 2 Change the **deletePolicy** policy of the Spooldir source to **never**.

----End

16.7.7 Failed to Start Flume

Symptom

The Flume service fails to be installed or restarted.

Cause Analysis

1. The heap memory of Flume is greater than the remaining memory of the server. The Flume startup log shows the following information:

```
[CST 2019-02-26 13:31:43][INFO] [[checkMemoryValidity:124]] [GC_OPTS is invalid:
Xmx(40960000MB) is bigger than the free memory(56118MB) in system.] [9928]
```

2. The permission on the Flume file or folder is abnormal. The following information is displayed on the GUI or in the background:

```
[2019-02-26 13:38:02]RoleInstance prepare to start failure
[{ScriptExecutionResult=ScriptExecutionResult [exitCode=126, output=, errMsg=sh: line 1: /opt/Bigdata/
MRS_XXX/install/FusionInsight-Flume-1.9.0/flume/bin/flume-manage.sh: Permission denied
```

3. The **JAVA_HOME** is incorrectly configured. The Flume agent startup log shows the following information:

```
Info: Sourcing environment configuration script /opt/FlumeClient/fusioninsight-flume-1.9.0/conf/
flume-env.sh
+ '[' -n '' ']'
+ exec /tmp/MRS-Client/MRS_Flume_ClientConfig/JDK/jdk-8u18/bin/java '-
XX:OnOutOfMemoryError=bash /opt/FlumeClient/fusioninsight-flume-1.9.0/bin/
out_memory_error.sh /opt/FlumeClient/fusioninsight-flume-1.9.0/conf %p' -Xms2G -Xmx4G -

fusioninsight-flume-1.9.0/conf:/opt/FlumeClient/fusioninsight-flume-1.9.0/lib/*:/opt/FlumeClient/
fusioninsight-flume-1.9.0/conf/service/' -Djava.library.path=/opt/FlumeClient/fusioninsight-flume-1.9.0/
plugins.d/native/native org.apache.flume.node.Application --conf-file /opt/FlumeClient/fusioninsight-
flume-1.9.0/conf/properties.properties --name client
/opt/FlumeClient/fusioninsight-flume-1.9.0/bin/flume-ng: line 233: /tmp/FusionInsight-Client/Flume/
FusionInsight_Flume_ClientConfig/JDK/jdk-8u18/bin/java: No such file or directory
```

Solution

Step 1 Increase the size of the heap memory (**xmx**).

Step 2 Compare the file and folder permissions with those for node where Flume is started properly and change the incorrect file or folder permissions.

Step 3 Reconfigure **JAVA_HOME**. On the client, replace the value of **JAVA_HOME** in the **${install_home}/fusioninsight-flume-***Flume version***/conf/ENV_VARS** file. On the server, replace the value of **JAVA_HOME** in the **ENV_VARS** file in the **etc** directory.

To obtain the value of **JAVA_HOME**, log in to the node where Flume is properly started and run the **echo ${JAVA_HOME}** command.

NOTE

${install_home} is the installation path of the Flume client.

----End

16.8 Using HBase

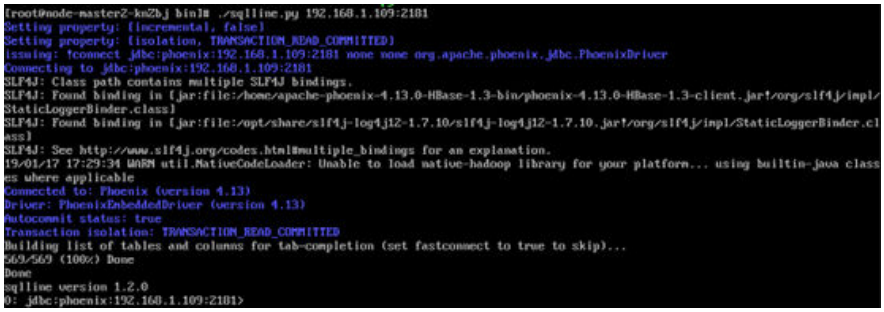
16.8.1 Slow Response to HBase Connection

Issue

Under the same VPC network, response is slow when an external cluster connects to HBase through Phoenix.

Symptom

Under the same VPC network, response is slow when an external cluster connects to HBase through Phoenix.



Possible Cause

DNS has been configured. When a client connects to HBase, DNS resolves the server first, causing slow response.

Procedure

Step 1 Log in to the Master node as user **root**.

Step 2 Run the **vi /etc/resolv.conf** command to open the **resolv.conf** file and comment out the address of the DNS server, for example, #1.1.1.1.

----End

16.8.2 Failed to Authenticate the HBase User

Issue

Failed to authenticate the HBase user.

Symptom

Failed to authenticate the HBase user on the client. The following error information is displayed:

```
2019-05-13 10:53:09,975 ERROR [localhost-startStop-1] xxxConfig.LoginUtil: login failed with hbaseuser and /usr/local/linoseyc/hbase-tomcat/webapps/bigdata_hbase/WEB-INF/classes/user.keytab.
2019-05-13 10:53:09,975 ERROR [localhost-startStop-1] xxxConfig.LoginUtil: perhaps cause 1 is (wrong password) keytab file and user not match, you can kinit -k -t keytab user in client server to check.
2019-05-13 10:53:09,975 ERROR [localhost-startStop-1] xxxConfig.LoginUtil: perhaps cause 2 is (clock skew) time of local server and remote server not match, please check ntp to remote server.
2019-05-13 10:53:09,975 ERROR [localhost-startStop-1] xxxConfig.LoginUtil: perhaps cause 3 is (aes256 not support) aes256 not support by default jdk/jre, need copy local_policy.jar and US_export_policy.jar from remote server in path ${BIGDATA_HOME}/jdk/jre/lib/security.
```

Cause Analysis

The version of the JAR file in the JDK used by the user is different from that of the JAR file authenticated by MRS.

Procedure

Step 1 Log in to the Master1 node as user **root**.

Step 2 Run the following command to check the JAR file authenticated by MRS:

ll /opt/share/local_policy/local_policy.jar

ll /opt/Bigdata/jdk{version}/jre/lib/security/local_policy.jar

Step 3 Download the JAR package queried in step 2 to the local host.

Step 4 Copy the downloaded JAR package to the local JDK directory **/opt/Bigdata/jdk/jre/lib/security**.

Step 5 Run the **cd /opt/client/HBase/hbase/bin** command to go to the **bin** directory of HBase.

Step 6 Run the **sh start-hbase.sh** command to restart HBase.

----End

16.8.3 RegionServer Failed to Start Because the Port Is Occupied

Symptom

RegionServer is in the **Restoring** state on Manager.

Cause Analysis

1. View the RegionServer log (**/var/log/Bigdata/hbase/rs/hbase-omm-xxx.log**).
2. Run the **lsof -i:21302** command (the port number of MRS 1.7.X and later versions is 16020) to view the PID. Based on the PID, check the process. It is found that the RegionServer port is occupied by DFSZkFailoverController.
3. The value of **/proc/sys/net/ipv4/ip_local_port_range** is **9000 65500**. The temporary port range and the MRS port range overlap. This is because the preinstall operation is not performed during installation.

Solution

Step 1 Run the **kill -9** *DFSZkFailoverController pid* command to ensure that another port is bound with after a restart and restart the RegionServer in the **Restoring** state.

----End

16.8.4 HBase Failed to Start Due to Insufficient Node Memory

Symptom

The RegionServer service of HBase is always in the **Restoring** state.

Cause Analysis

1. Check the RegionServer log (**/var/log/Bigdata/hbase/rs/hbase-omm-XXX.out**). It is found that the following information is printed:
   ```
   There is insufficient memory for the Java Runtime Environment to continue.
   ```
2. Run the **free** command to check the memory. It is found that the available memory of the node is insufficient.

Solution

Step 1 Locate why the memory is insufficient. It is found that some processes occupy too much memory or the server does not have sufficient memory.

----End

16.8.5 HBase Service Unavailable Due to Poor HDFS Performance

Symptom

The HBase component intermittently reports alarms indicating that the service is unavailable.

Cause Analysis

HDFS performance is low, causing health check timeout and the alarm is generated accordingly. You can perform the following operations:

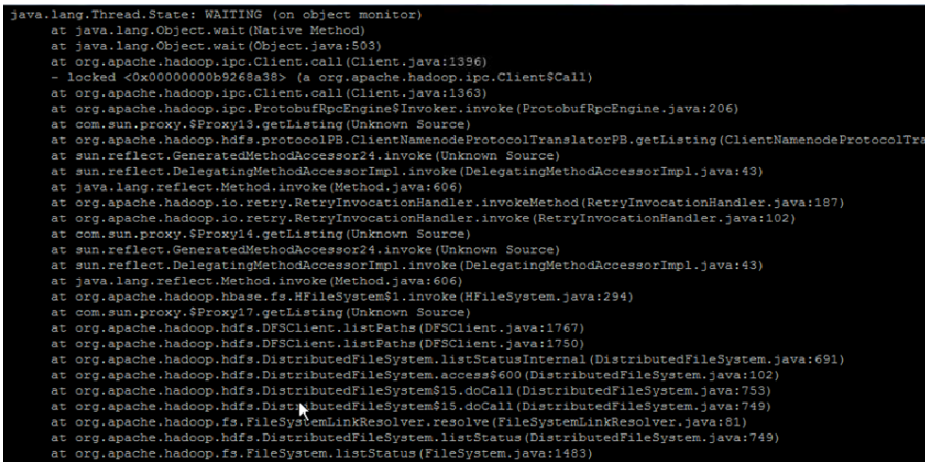
1. View the HMaster log (**/var/log/Bigdata/hbase/hm/hbase-omm-xxx.log**) and check that **system pause**, **jvm**, and other GC-related information is not frequently printed in the log.
2. Determine whether the fault is caused by poor HDFS performance using either of the following methods:
   a. Run **hbase shell** to access the HBase shell, and run the **list** command to check whether it takes a long period of time to list all tables in HBase.
   b. Enable printing of the debug logs of HDFS, and check whether it takes a long period of time to list the content of a large number of directories by running the **hadoop fs –ls** */XXX/XXX* command.
   c. Print the Java stack information about a specified HMaster process.

      su - omm

      jps

      jstack pid
3. Check the jstack information. The following figure shows that the process is stuck at the **DFSClient.listPaths** state.

Figure 16-20 Exception



Solution

Step 1 If this alarm is caused by poor HDFS performance, check whether Impala is of an earlier version or JournalNode was incorrectly deployed during the initial deployment (more than three JournalNode nodes are deployed).

----End

16.8.6 HBase Failed to Start Due to Inappropriate Parameter Settings

Symptom

After some parameters are modified, HBase cannot be started.

Cause Analysis

1. Check the HMaster log (**/var/log/Bigdata/hbase/hm/hbase-omm-*xxx*.log**). It is found that the total of **hbase.regionserver.global.memstore.size** and **hfile.block.cache.size** is greater than 0.8, which causes the startup failure. Therefore, adjust the parameter values to make sure that the total value is less than 0.8.

2. Check the HMaster and RegionServer out logs (**/var/log/Bigdata/hbase/hm/hbase-omm-*xxx*.out/var/log/Bigdata/hbase/rs/hbase-omm-*xxx*.out**). It is found that **Unrecognized VM option** is displayed.

```
Unrecognized VM option
Error: Could not create the Java Virtual Machine.
Error: A fatal exception has occurred. Program will exit.
```

Check the **GC_OPTS** parameters. It is found that the parameters contain unnecessary spaces, for example, **-D sun.rmi.dgc.server.gcInterval=0x7FFFFFFFFFFFFE**.

Solution

Step 1 After the **MemStore** and **cache** parameters are modified, the HBase service is restarted successfully.

Step 2 After the **GC_OPTS** parameters are modified, the HBase service is restarted successfully.

----End

16.8.7 RegionServer Failed to Start Due to Residual Processes

Symptom

The HBase service fails to start, and an error is reported during the health check.

Cause Analysis

Check detailed information about HBase startup on the MRS Manager page. It is found that **the previous process is not quit** is displayed.

Solution

Step 1 Log in to the node and run the **ps -ef | grep HRegionServer** command in the background. A residual process is found.

Step 2 After confirming that the process can be killed, kill the process. If the process cannot be stopped by running the **kill** command, run the **kill -9** command to forcibly stop the process.

Step 3 Restart the HBase service.

----End

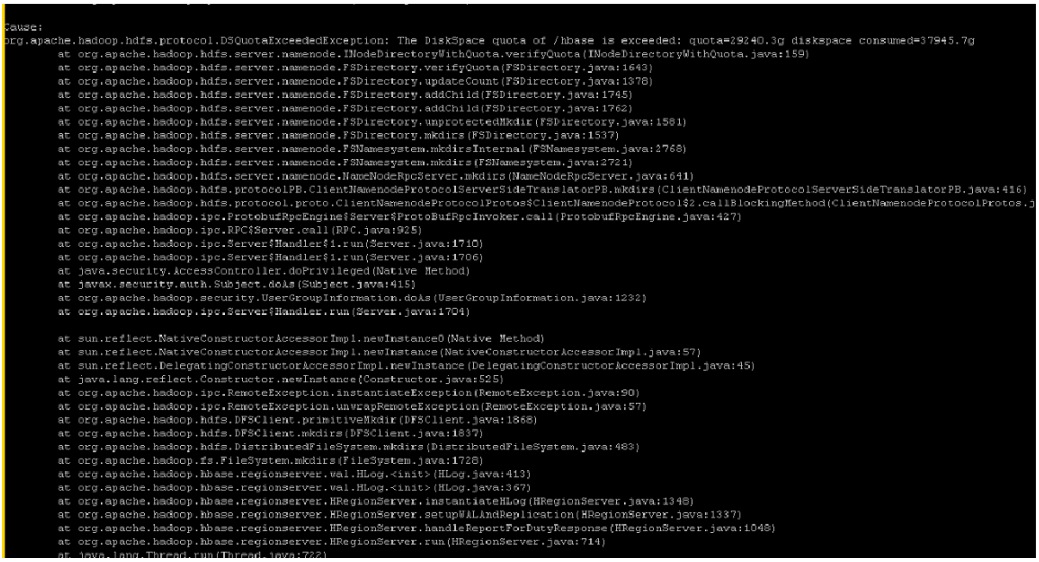
16.8.8 HBase Failed to Start Due to a Quota Set on HDFS

Symptom

HBase fails to start.

Cause Analysis

Check the HMaster log (**/var/log/Bigdata/hbase/hm/hbase-omm-*xxx*.log**). It is found that "The DiskSpace quota of /hbase is exceeded" is displayed.



Solution

Step 1 Run the **df -h** command to check data directory space. It is found that the directory space is full. Delete unnecessary data to free up space.

Step 2 Expand the node to ensure that the data directory space is sufficient.

----End

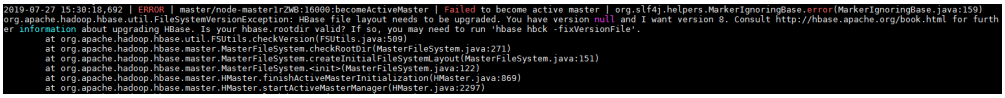
16.8.9 HBase Failed to Start Due to Corrupted Version Files

Symptom

HBase fails to start.

Cause Analysis

1. The **hbase.version** file is read during HBase startup. However, the log indicates that a reading exception occurs.



2. The file cannot be viewed by running the **hadoop fs -cat /hbase/hbase.version** command. The file is corrupted.

Solution

Step 1 Run the **hbase hbck -fixVersionFile** command to restore the file.

Step 2 If the problem persists after performing **Step 1**, obtain the **hbase.version** file from another cluster of the same version and upload the file to replace the original one.

Step 3 Restart the HBase service.

----End

16.8.10 High CPU Usage Caused by Zero-Loaded RegionServer

Symptom

The CPU usage of RegionServer is high, but there is no service running on RegionServer.

Cause Analysis

1. Run the **top** command to obtain the CPU usage of RegionServer processes and check the IDs of processes with high CPU usage.
2. Obtain the CPU usage of threads under these processes based on the RegionServer process IDs.

   Run the **top -H -p** *<PID>* (replace it with the actual RegionServer process ID). As shown in the following figure, the CPU usage of some threads reaches 80%.

   ```
   PID USER      PR  NI    VIRT    RES    SHR S %CPU %MEM     TIME+ COMMAND
   75706 omm     20   0 6879444   1.0g  25612 S  90.4  1.6   0:00.00 java
   75716 omm     20   0 6879444   1.0g  25612 S  90.4  1.6   0:04.74 java
   75720 omm     20   0 6879444   1.0g  25612 S  88.6  1.6   0:01.93 java
   75721 omm     20   0 6879444   1.0g  25612 S  86.8  1.6   0:01.99 java
   75722 omm     20   0 6879444   1.0g  25612 S  86.8  1.6   0:01.94 java
   75723 omm     20   0 6879444   1.0g  25612 S  86.8  1.6   0:01.96 java
   75724 omm     20   0 6879444   1.0g  25612 S  86.8  1.6   0:01.97 java
   75725 omm     20   0 6879444   1.0g  25612 S  81.5  1.6   0:02.06 java
   75726 omm     20   0 6879444   1.0g  25612 S  79.7  1.6   0:02.01 java
   75727 omm     20   0 6879444   1.0g  25612 S  79.7  1.6   0:01.95 java
   75728 omm     20   0 6879444   1.0g  25612 S  78.0  1.6   0:01.99 java
   ```

3. Obtain the thread stack information based on the ID of the RegionServer process.

   jstack 12345 >allstack.txt (Replace it with the actual RegionServer process ID.)

4. Convert the thread ID into the hexadecimal format:

   printf "%x\n" 30648

   In the command output, the TID is **77b8**.

5. Search the thread stack based on the hexadecimal TID. It is found that the compaction operation is performed.

   ```
   "regionserver/ahbd-hbase-dat1/12.2.168.1:21302-longCompactions-1482676601478" #1641 prio=5 os_prio=0 tid=0x00007fa614563000 nid=0x77b8 runnable [0x0

       at java.io.DataOutputStream.write(DataOutputStream.java:107)
       - locked <0x00000004de9535c8> (a org.apache.hadoop.hdfs.client.HdfsDataOutputStream)
       at java.io.FilterOutputStream.write(FilterOutputStream.java:97)
   ```

Solution

This is a normal phenomenon.

The threads that consume a large number of CPU resources are compaction threads. Some threads invoke the Snappy compression algorithm, and some threads invoke HDFS data writing and reading. Each region has massive sets of data and numerous data files and uses the Snappy compression algorithm. For this reason, the compaction operations consume a large number of CPU resources.

Fault Locating Methods

Step 1 Run the **top** command to check the process with high CPU usage.

Step 2 Check the threads with high CPU usage in the process.

Run the **top -H -p** *<PID>* command to print CPU usage of threads under the process.

Obtain the thread with the highest CPU usage from the query result. You can also obtain the thread by running the following command:

Or run the **ps -mp** *<PID>* **-o THREAD,tid,time | sort -rn** command.

View the command output to obtain the ID of the thread with the highest CPU usage.

Step 3 Obtain the stack of the faulty thread.

The jstack tool is the most effective and reliable tool for locating Java problems.

You can obtain the jstack tool from the **java/bin** directory.

jstack <PID> > allstack.txt

Obtain the process stack and output it to a local file.

Step 4 Convert the thread ID into the hexadecimal format:

printf "%x\n" <PID>

The process ID in the command output is the TID.

Step 5 Run the following command to obtain the TID and output it to a local file:

jstack <PID> | grep <TID> > Onestack.txt

If you want to view the TID in the CLI only, run the following command:

jstack <PID> | grep <TID> -A 30

-A 30 indicates that 30 lines are displayed.

----End

16.8.11 HBase Failed to Started with "FileNotFoundException" in RegionServer Logs

Symptom

HBase fails to start, and the RegionServer stays in the **Restoring** state.

Cause Analysis

1. Check the RegionServer log (**/var/log/Bigdata/hbase/rs/hbase-omm-*XXX*.out**). It is found that the following information is printed:

```
| ERROR | RS_OPEN_REGION-ab-dn01:21302-2 | ABORTING region server ab-dn01,21302,1487663269375: The coprocessor org.apache.kylin.storage.hbase.cube.v2.coprocessor.endpoint.CubeVisitService threw java.io.FileNotFoundException: File does not exist: hdfs://hacluster/kylin/kylin_metadata/coprocessor/kylin-coprocessor-1.6.0-SNAPSHOT-0.jar |

at java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:617)
at java.lang.Thread.run(Thread.java:745)
```

2. Run the **hdfs** command on the client. It is found that the following file does not exist:

   hdfs://hacluster/kylin/kylin_metadata/coprocessor/kylin-coprocessor-1.6.0-SNAPSHOT-0.jar

3. When configuring the coprocessor for HBase, make sure that the path of the corresponding JAR package is correct. Otherwise, HBase cannot be started.

Solution

Use the Apache Kylin engine to interconnect with MRS and make sure that the JAR file of the Kylin engine exists.

16.8.12 The Number of RegionServers Displayed on the Native Page Is Greater Than the Actual Number After HBase Is Started

Symptom

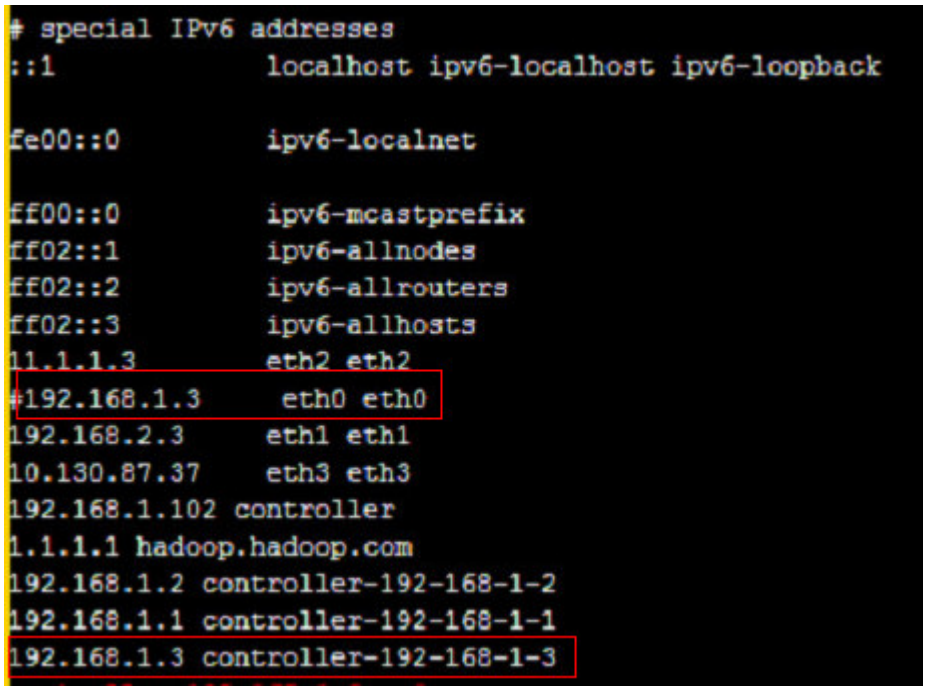
After HBase is started, the number of RegionServers displayed on the HMaster native page is greater than the actual number.

The HMaster native page shows that four RegionServers are online, as shown in the following figure.

ServerName	Start time	Requests Per Second	Num. Regions
controller-192-168-1-1,21302,1494933959261	Tue May 16 19:25:59 CST 2017	0	19
controller-192-168-1-2,21302,1494933957536	Tue May 16 19:25:57 CST 2017	0	24
controller-192-168-1-3,21302,1494933958592	Tue May 16 19:25:58 CST 2017	0	16
eth0,21302,1494933958592	Tue May 16 19:25:58 CST 2017	0	0
Total:4		0	59

Cause Analysis

As shown in the following figure, the hostname of the node in the third row is **controller-192-168-1-3** and that of the fourth row is **eth0**. The two carry the same information reported by RegionServer. Then, log in to the corresponding nodes to check the **/etc/hosts** file. It is found that the same IP address is configured for the two hostnames. For details, see the following figure:



Solution

Log in to the node where RegionServer resides, and modify the **/etc/hosts** file. Make sure that the same IP address can correspond to only one hostname.

16.8.13 RegionServer Instance Is in the Restoring State

Symptom

HBase fails to start, and the RegionServer stays in the **Restoring** state.

Cause Analysis

Check the running log (**/var/log/Bigdata/hbase/rs/hbase-omm-*XXX*.log**) of the abnormal RegionServer instance. It is found that the following information is displayed: **ClockOutOfSyncException..., Reported time is too far out of sync with master**.

```
2017-09-18 11:16:23,636 | FATAL | regionserver21302 | Master rejected startup because clock is out of sync |
org.apache.hadoop.hbase.regionserver.HRegionServer.reportForDuty(HRegionServer.java:2059)
org.apache.hadoop.hbase.ClockOutOfSyncException: org.apache.hadoop.hbase.ClockOutOfSyncException:
Server nl-bi-fi-datanode-24-65,21302,1505726180086 has been rejected; Reported time is too far out of
sync with master.  Time difference of 152109ms > max allowed of 30000ms
at org.apache.hadoop.hbase.master.ServerManager.checkClockSkew(ServerManager.java:354)
...

...
2017-09-18 11:16:23,858 | ERROR | main | Region server exiting |
org.apache.hadoop.hbase.regionserver.HRegionServerCommandLine.start(HRegionServerCommandLine.java:
70)
java.lang.RuntimeException: HRegionServer Aborted
```

This log indicates that the time difference between the abnormal RegionServer instance and the HMaster instance is greater than the allowed time difference 30s (specified by the **hbase.regionserver.maxclockskew** parameter and the default value is **30000 ms**). As a result, the RegionServer instance is abnormal.

Solution

Adjust the node time to ensure that the time difference between nodes is less than 30s.

16.8.14 HBase Failed to Start in a Newly Installed Cluster

Symptom

HBase of a newly installed cluster fails to start. The RegionServer log contains the following error information:

```
2018-02-24 16:53:03,863 | ERROR | regionserver/host3/187.6.71.69:21302 | Master passed us a different hostname to use; was=host3, but now=187-6-71-69 | org.apache.hadoop.hbase.regionserver.HRegionServer.handleReportForDutyResponse(HRegionServer.java:1386)
```

Cause Analysis

In the **/etc/hosts** file, an IP address maps multiple hostnames.

Solution

Step 1 Modify the mapping between the IP address and hostnames in the **/etc/host** file.

Step 2 Restart HBase.

----End

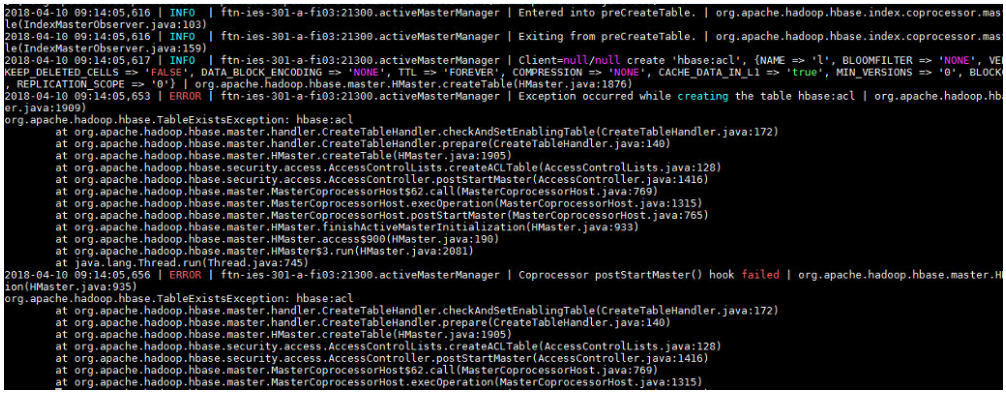
16.8.15 HBase Failed to Start Due to the Loss of the ACL Table Directory

Symptom

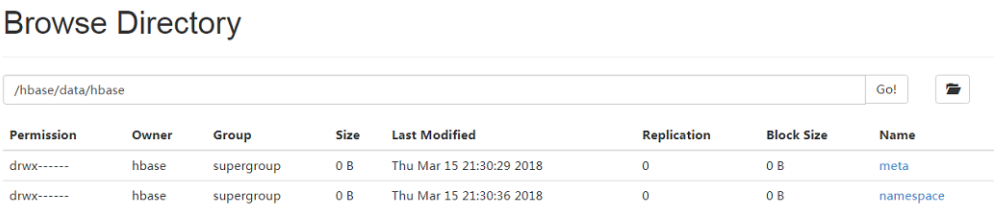
The HBase cluster fails to start.

Cause Analysis

1. Check the HMaster log of HBase. The following error information is displayed:



2. The HBase directory in HDFS is checked, which shows that the ACL table directory is lost.



Solution

Step 1 Stop HBase.

Step 2 Log in to the HBase client as the **hbase** user and run the following command.

Example:

```
hadoop03:~ # source /opt/client/bigdata_env
hadoop03:~ # kinit hbase
Password for hbase@HADOOP.COM:
hadoop03:~ # hbase zkcli
```

Step 3 Delete the ACL table information from the ZooKeeper.

Example:

```
[zk: hadoop01:24002,hadoop02:24002,hadoop03:24002(CONNECTED) 0] deleteall /hbase/table/hbase:acl
[zk: hadoop01:24002,hadoop02:24002,hadoop03:24002(CONNECTED) 0] deleteall /hbase/table-lock/
hbase:acl
```

Step 4 Start HBase.

----End

16.8.16 HBase Failed to Start After the Cluster Is Powered Off and On

Symptom

After the ECS in the cluster is stopped and restarted, HBase fails to start.

Cause Analysis

Check the HMaster run logs. A large number of errors are reported, as shown below:

```
2018-03-26 11:10:54,185 | INFO  | hadoopc1h3,21300,1522031630949_splitLogManager__ChoreService_1 |

| org.apache.hadoop.hbase.master.SplitLogManager$TimeoutMonitor.chore
(SplitLogManager.java:745)
```

The WAL splitting of RegionServer fails when the node is powered on and off.

Solution

Step 1 Stop HBase.

Step 2 Run the **hdfs fsck** command to check the health status of the **/hbase/WALs** file.

hdfs fsck /hbase/WALs

If the following command output is displayed, all files are normal. If any file is abnormal, rectify the fault, and then perform the subsequent operations.

```
The filesystem under path '/hbase/WALs' is HEALTHY
```

Step 3 Back up the **/hbase/WALs** file.

hdfs dfs -mv /hbase/WALs /hbase/WALs_old

Step 4 Run the following command to create the **/hbase/WALs** directory.

hdfs dfs -mkdir /hbase/WALs

Make sure that the permission on the directory is **hbase:hadoop**.

Step 5 Start HBase.

----End

16.8.17 Failed to Import HBase Data Due to Oversized File Blocks

Symptom

Error Message "NotServingRegionException" is displayed when data is imported to HBase.

Cause Analysis

When a block is greater than 2 GB, a read exception occurs during the seek operation of the HDFS. A full GC occurs when data is frequently written to the RegionServer. As a result, the heartbeat between the HMaster and RegionServer becomes abnormal, and the HMaster marks the RegionServer as dead, and the RegionServer is forcibly restarted. After the restart, the servercrash mechanism is triggered to roll back WALs. Currently, the **splitwal** file has reached 2.1 GB and has only one block. As a result, the HDFS seek operation becomes abnormal and the WAL file splitting fails. However, the RegionServer detects that the WAL needs to be split and triggers the splitwal mechanism, causing a loop between WAL splitting and the splitting failure. In this case, the regions on the RegionServer node cannot be brought online, and an exception is thrown indicating that the region is not online when a region on the RegionServer is queried.

Procedure

Step 1 On the right of **HMaster Web UI**, click **HMaster (Active)** to go to the HBase Web UI page.

Step 2 On the **Procedures** page, view the node where the problem occurs.

Step 3 Log in to the faulty node as user **root** and run the **hdfs dfs -ls** command to view all block information.

Step 4 Run the **hdfs dfs -mkdir** command to create a directory for storing faulty blocks.

Step 5 Run the **hdfs dfs -mv** command to move the faulty block to the new directory.

----End

Summary and Suggestions

The following is provided for your reference:

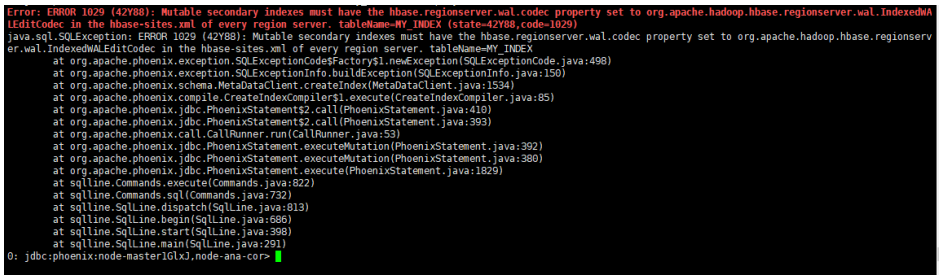
- If data blocks are corrupted, run the **hdfs fsck /tmp -files -blocks -racks** command to check the health information about data blocks.
- If you perform data operations when a region is being split, **NotServingRegionException** is thrown.

16.8.18 Failed to Load Data to the Index Table After an HBase Table Is Created Using Phoenix

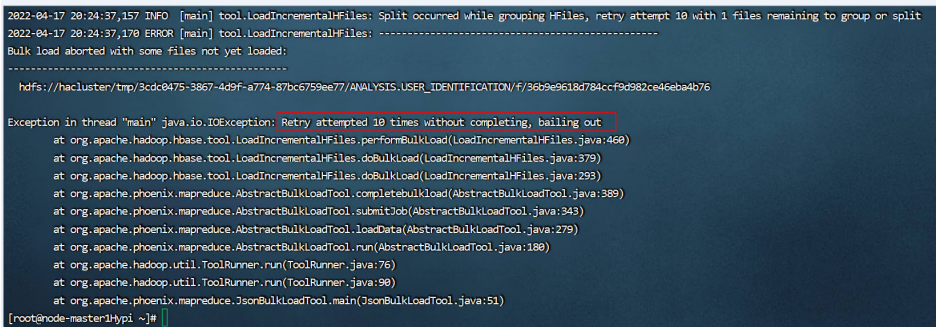
Symptom

A user fails to run commands to load data to the index table after creating an HBase table using Phoenix. The following error information is displayed:

- MRS 2.x or earlier: Mutable secondary indexes must have the hbase.regionserver.wal.codec property set to org.apache.hadoop.hbase.regionserver.wal.IndexedWALEditCodec in the hbase-sites.xml of every region server. tableName=MY_INDEX (state=42Y88,code=1029)



- MRS 3. x or later: Exception in thread "main" java.io.IOException: Retry attempted 10 times without completing, bailing out



Procedure

Step 1 For MRS 2.x or earlier, perform the following operations:

1. Log in to MRS Manager as user **admin**, choose **Services**, and click **HBase**. On the **Service Configuration** tab, select **All** from the **Type** drop-down list, choose **HMaster** > **Customization**, and add a configuration item for parameter **hbase.hmaster.config.expandor** with name **hbase.regionserver.wal.codec** and value **org.apache.hadoop.hbase.regionserver.wal.IndexedWALEditCodec**.
2. Choose **RegionServer** > **Customization**, add a configuration item for parameter **hbase.regionserver.config.expandor** with name **hbase.regionserver.wal.codec** and value **org.apache.hadoop.hbase.regionserver.wal.IndexedWALEditCodec**, and click **Save Configuration**. Then enter the password of the current user and click **OK**.
3. On the **Service Status** page, click **More** and select **Restart Service**. Enter the password of the current user and click **OK** to restart the HBase service.

Step 2 For MRS 3.x or later, perform the following operations:

1. Log in to FusionInsight Manager as user **admin** and choose **Cluster** > **Services** > **HBase**. On the HBase page, choose **Configurations** > **All Configurations** > **RegionServer** > **Customization**. In the right pane, add a configuration item for parameter **hbase.regionserver.config.expandor** with name **hbase.regionserver.wal.codec** and value **org.apache.hadoop.hbase.regionserver.wal.IndexedWALEditCodec**.
2. Choose **HMaster** > **Customization**, and add a configuration item for parameter **hbase.hmaster.config.expandor** with name **hbase.regionserver.wal.codec** and value **org.apache.hadoop.hbase.regionserver.wal.IndexedWALEditCodec**.
3. Click **Save**. In the dialog box that is displayed, click **OK** to save the configuration.
4. On the **Dashboard** page, click **More** and select **Restart Service**. Enter the password of the current user and click **OK** to restart the HBase service.

----End

16.8.19 Failed to Run the hbase shell Command on the MRS Cluster Client

Issue

A user fails to run the **hbase shell** command on the MRS cluster client.

Cause Analysis

- Environment variables have not been configured before the **hbase shell** command is executed.
- The HBase client is not installed in the MRS cluster.

Procedure

Step 1 Log in to the node where the client is installed as user **root**, switch to the client installation directory, and check whether the HBase client is installed.

- If yes, go to **Step 2**.
- If no, download and install the client.

Step 2 Run the following command to set environment variables:

source bigdata_env

Step 3 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. The current user must have the permission to create HBase tables. If Kerberos authentication is disabled for the current cluster, skip this step.

kinit *MRS cluster user*

Step 4 Run the HBase client command.

hbase shell

----End

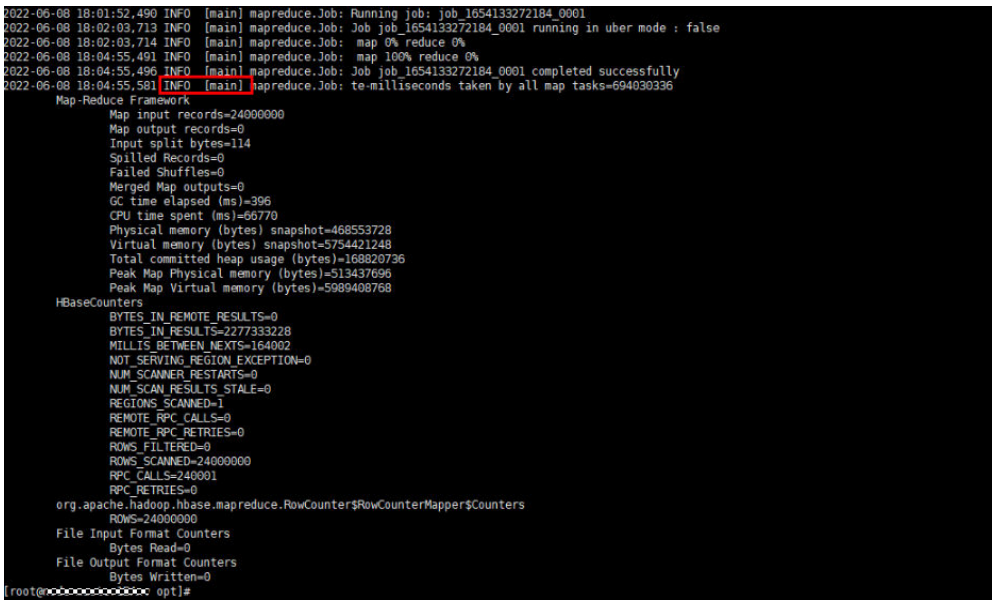
16.8.20 Disordered Information Display on the HBase Shell Client Console Due to Printing of the INFO Information

Issue

When the HBase shell is used, INFO information is printed on the console, causing disordered information display. Before entering a command, the user has to press **Enter** to clean the console. The following figure provides an example.

Cause Analysis

- By default, the log printing function of the HBase client is set to **INFO,console**. Therefore, INFO logs will be printed to the console, affecting the information display on the HBase shell console.
- The HBase client supports many commands, such as **hbase shell**, **hbase hbck**, and **hbase org.apache.hadoop.hbase.mapreduce.RowCounter**, and will support more in the future. The output type of some commands is **INFO**. If **INFO** is disabled, the output of these commands will be lost. For example, the output of **RowCounter** is of the **INFO** type.



Procedure

Step 1 Log in to the node where the HBase client is installed as user **root**.

Step 2 Add the following information to the *HBase client installation directory*/**HBase/component_env** file:

export HBASE_ROOT_LOGGER=INFO,RFA

Logs are exported to log files. If you run the **hbase org.apache.hadoop.hbase.mapreduce.RowCounter** command, you can view the execution result in the *HBase client installation directory*/**HBase/hbase/logs/hbase.log** file.

Step 3 Switch to the HBase client installation directory and run the following commands for the configuration to take effect:

cd *HBase client installation directory*

source HBase/component_env

----End

16.8.21 HBase Failed to Start Due to Insufficient RegionServer Memory

Issue

The HBase service fails to start because the remaining RegionServer memory is insufficient.

Cause Analysis

The troubleshooting process is as follows:

1. Log in to the master node, go to the **/var/log/Bigdata** directory, and search for the HBase log. The log contains error message "connect regionserver timeout".
2. Log in to the RegionServer node in **1** that cannot be connected to HMaster and go to the **/var/log/Bigdata** directory to search for the HBase log. The RegionServer reports error message "error='Cannot allocate memory'(errno=12)".
3. According to the error message in **2**, the startup failure is caused by insufficient RegionServer memory.

Procedure

Step 1 Log in to the RegionServer node where the error is reported and run the following command to check the remaining memory of the node:

free -g

Step 2 Run the **top** command to check the memory usage of the node.

Step 3 Stop the memory-consuming processes (not the processes of the MRS components) as prompted and restart the HBase service.

NOTE

Besides MRS components, jobs on Yarn are allocated to core nodes in the cluster, thereby occupying node memory. If the startup failure is caused by memory-consuming Yarn jobs, you are advised to expand the capacity of core nodes.

----End

16.9 Using HDFS

16.9.1 All NameNodes Become the Standby State After the NameNode RPC Port of HDFS Is Changed

Issue

After the NameNode RPC port is changed on the page and HDFS is restarted, all NameNodes are in the standby state, causing a cluster exception.

Symptom

All NameNodes are in the standby state, causing a cluster exception.

Cause Analysis

After the cluster is installed and started, if the NameNode RPC port is changed, the Zkfc service must be formatted to update node information on ZooKeeper.

Procedure

Step 1 Log in to Manager and stop the HDFS service.

NOTE

Do not stop related services when stopping HDFS.

Step 2 After the services are stopped, log in to the Master node whose RPC port is changed.

NOTE

If the RPC port is changed on both Master nodes, you can log in to either of the Master nodes.

Step 3 Run the **su - omm** command to switch to user **omm**.

NOTE

For a security cluster, run the **kinit hdfs** command for authentication.

Step 4 Run the following command to load the environment variable script to the environment:

cd ${BIGDATA_HOME}/*MRS_X.X.X*_*1_8*_**Zkfc/etc**

source ${BIGDATA_HOME}/*MRS_X.X.X***/install/FusionInsight-Hadoop-3.1.1/hadoop/sbin/exportENV_VARS.sh**

NOTE

In the preceding command, *MRS_X.X.X* and *1_8* vary depending on the actual version.

Step 5 After the loading is complete, run the following command to format the Zkfc:

cd ${HADOOP_HOME}/bin

./hdfs zkfc -formatZK

Step 6 After the formatting is successful, restart HDFS on Manager.

NOTE

If the RPC port of the NameNode is changed, the configuration file must be updated for all clients that have been installed.

----End

16.9.2 An Error Is Reported When the HDFS Client Is Used After the Host Is Connected Using a Public Network IP Address

Issue

When the host is connected using a public network IP address, the HDFS client cannot be used and the message "**-bash: hdfs: command not found**" is displayed when the HDFS is running.

Symptom

When the host is connected using a public network IP address, the HDFS client cannot be used and the message "**-bash: hdfs: command not found**" is displayed when the HDFS is running.

Possible Causes

The environment variables are not set before the user logs in to the Master node and runs the command.

Procedure

Step 1 Log in to any Master node as user **root**.

Step 2 Run the **source /opt/client/bigdata_env** command to configure environment variables.

Step 3 Run the **hdfs** command to use the HDFS client.

----End

16.9.3 Failed to Use Python to Remotely Connect to the Port of HDFS

Issue

Failed to use Python to remotely connect to the port of HDFS.

Symptom

Failed to use Python to remotely connect to port 50070 of HDFS.

Cause Analysis

The default port of open source HDFS is 50070 for versions earlier than 3.0.0 and is 9870 for version 3.0.0 or later. The port used by the user does not match the HDFS version.

Step 1 Log in to the active Master node in the cluster.

Step 2 Run the **su - omm** command to switch to user **omm**.

Step 3 Run the **/opt/Bigdata/om-0.0.1/sbin/queryVersion.sh** command to check the HDFS version in the cluster.

Determine the port number of the open-source component based on the version number.

Step 4 Run the **netstat -anp|grep ${port}** command to check whether the default port number of the component exists.

If it does not exist, the default port number is changed. Change the port to the default port and reconnect to HDFS.

If it exists, contact technical support.

NOTE

- **${port}**: indicates the default port number corresponding to the component version.
- If you have changed the default port number, use the new port number to connect to HDFS. You are advised not to change the default port number.

----End

16.9.4 HDFS Capacity Usage Reaches 100%, Causing Unavailable Upper-layer Services Such as HBase and Spark

Issue

The HDFS capacity usage of the cluster reaches 100%, and the HDFS service status is read-only. As a result, upper-layer services such as HBase and Spark are unavailable.

Symptom

The HDFS capacity usage is 100%, the disk capacity usage is only about 85%, and the HDFS service status is read-only. As a result, upper-layer services such as HBase and Spark are unavailable.

Cause Analysis

Currently, NodeManager and DataNode share data disks. By default, MRS reserves 15% of data disk space for non-HDFS. You can change the percentage of data disk space by setting the HDFS parameter **dfs.datanode.du.reserved.percentage**.

If the HDFS disk usage is 100%, you can set **dfs.datanode.du.reserved.percentage** to a smaller value to restore services and then expand disk capacity.

Procedure

Step 1 Log in to any Master node in the cluster.

Step 2 Run the **source /opt/client/bigdata_env** command to initialize environment variables.

NOTE

If it is a security cluster, run the **kinit -kt <keytab file> <pricipal name>** command for authentication.

Step 3 Run the **hdfs dfs –put ./startDetail.log /tmp** command to check whether HDFS fails to write files.

```
19/05/12 10:07:32 WARN hdfs.DataStreamer: DataStreamer Exception
org.apache.hadoop.ipc.RemoteException(java.io.IOException): File /tmp/startDetail.log._COPYING_ could only be replicated to 0 nodes instead of minReplication (=1).  There are 3 datanode(s) running and no node(s) are excluded in this operation.
```

Step 4 Run the **hdfs dfsadmin -report** command to check the used HDFS capacity. The command output shows that the HDFS capacity usage has reached 100%.

```
Configured Capacity: 5389790579100 (4.90 TB)
Present Capacity: 5067618628404 (4.61 TB)
DFS Remaining: 133350196 (127.17 MB)
DFS Used: 5067485278208 (4.61 TB)
DFS Used%: 100.00%
Under replicated blocks: 10
Blocks with corrupt replicas: 0
Missing blocks: 0
Missing blocks (with replication factor 1): 0
Pending deletion blocks: 0
```

Step 5 When the HDFS capacity usage reaches 100%, change the percentage of data disk space by setting the HDFS parameter **dfs.datanode.du.reserved.percentage**.

1. Go to the service configuration page.
   - MRS Manager: Log in to MRS Manager and choose **Services** > **HDFS** > **Configuration**.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **HDFS** > **Configurations**.
2. Select **All Configurations** and search for **dfs.datanode.du.reserved.percentage** in the search box.
3. Change the value of this parameter to **10**.

Step 6 After the modification, increase the number of disks of the Core node.

----End

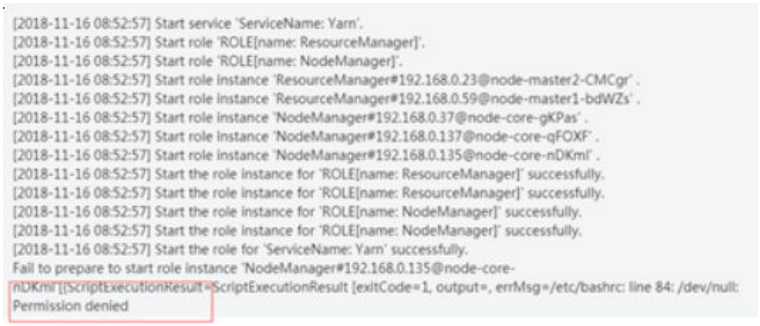
16.9.5 An Error Is Reported During HDFS and Yarn Startup

Issue

An error is reported during HDFS and Yarn startup.

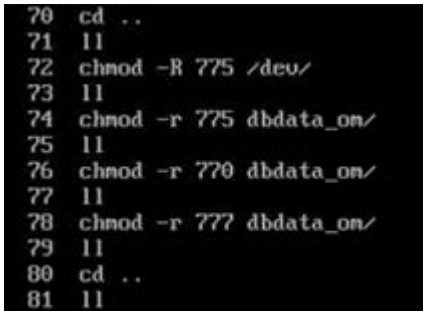
Symptom

HDFS and Yarn fail to be started. The following error information is displayed: **/dev/null Permission denied**



Cause Analysis

The customer changed the permission value of **/dev/null** of the VM system to **775**.



Procedure

Step 1 Log in to any Master node in the cluster as user **root**.

Step 2 After successful login, run the **chmod 666 /dev/null** command to modify the permission value of **/dev/null** to **666**.

Step 3 Run the **ls -al /dev/null** command to check whether the new permission value of **/dev/null** is **666**. If it is not, change the value to **666**.

Step 4 After the modification is successful, restart HDFS and Yarn.

----End

16.9.6 HDFS Permission Setting Error

Issue

When using MRS, a user has the permission to delete or create files in another user's HDFS directory.

Symptom

When using MRS, a user has the permission to delete or create files in another user's HDFS directory.

Cause Analysis

The user has the permission for the **ficommon** group and therefore can perform any operations on the HDFS. You need to remove the user's **ficommon** group permission.

Procedure

Step 1 Log in to the master node in the cluster as user **root**.

Step 2 Run the **id ${Username}** command to check whether the user has the **ficommon** group permission.

If the user has the **ficommon** group permission, go to **Step 3**. If the user does not have the **ficommon** group permission, contact technical support.

NOTE

${Username} indicates the name of the user whose HDFS permission is incorrectly set.

Step 3 Run the **gpasswd -d ${Username} ficommon** command to delete the user's **ficommon** group permission.

NOTE

${Username} indicates the name of the user whose HDFS permission is incorrectly set.

Step 4 Modify parameters on Manager.

MRS Manager (applicable to versions earlier than MRS 3.*x*):

1. Log in to MRS Manager and choose **Services** > **HDFS** > **Service Configuration**.
2. Set **Type** to **All**, enter **dfs.permissions.enabled** in the search box, and change the parameter value to **true**.
3. Click **Save Configuration** and restart the HDFS service.

FusionInsight Manager (applicable to MRS 3.*x* or later):

1. Log in to FusionInsight Manager. Choose **Cluster** > **Services** > **HDFS** > **Configurations** > **All Configurations**.
2. Enter **dfs.permissions.enabled** in the search box and change the value to **true**.
3. After the modification is complete, click **Save** and restart the HDFS service.

MRS console :

1. Log in to the MRS console and choose **Components** > **HDFS** > **Service Configuration**.
2. Set **Type** to **All**, enter **dfs.permissions.enabled** in the search box, and change the parameter value to **true**.

3. Click **Save Configuration** and restart the HDFS service.

----End

16.9.7 A DataNode of HDFS Is Always in the Decommissioning State

Issue

A DataNode of HDFS is in the **Decommissioning** state for a long period of time.

Symptom

A DataNode of HDFS fails to be decommissioned (or the Core node fails to be scaled in), but the DataNode remains in the Decommissioning state.

Cause Analysis

During the decommissioning of a DataNode (or scale-in of the Core node) in HDFS, the decommissioning or scale-in task fails and the blacklist is not cleared because the Master node is restarted or the NodeAgent process exits unexpectedly. In this case, the DataNode remains in the **Decommissioning** state. The blacklist needs to be cleared manually.

Procedure

Step 1 Go to the service instance page.

MRS Manager:

Log in to MRS Manager and choose **Services** > **HDFS** > **Instance**.

FusionInsight Manager:

MRS 3.x or later: Log in to FusionInsight Manager and choose **Cluster** > **Service** > **HDFS** > **Instance**.

Log in to the MRS console and choose **Components** > **HDFS** > **Instances**.

Step 2 Check the HDFS service instance status, locate the DataNode that is in the decommissioning state, and copy the IP address of the DataNode.

Step 3 Log in to the Master1 node and run the **cd ${BIGDATA_HOME}/MRS_*/1_*_NameNode/etc/** command to go to the blacklist directory.

Step 4 Run the **sed -i "/^*IP*$/d" excludeHosts** command to clear the faulty DataNode information from the blacklist. Replace the IP address in the command with the IP address of the faulty DataNode queried in **Step 2**. The IP address cannot contain spaces.

Step 5 If there are two Master nodes, perform **Step 3** and **Step 4** on Master2.

Step 6 Run the following command on the Master1 node to initialize environment variables:

source /opt/client/bigdata_env

Step 7 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user. If Kerberos authentication is disabled for the current cluster, skip this step:

kinit *MRS cluster user*

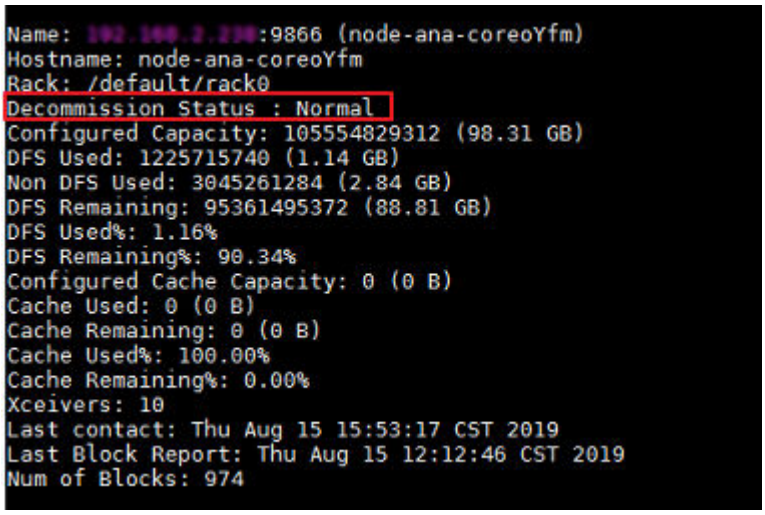
Example: **kinit admin**

Step 8 Run the following command on the Master1 node to update the HDFS blacklist:

hdfs dfsadmin -refreshNodes

Step 9 Run the **hdfs dfsadmin -report** command to check the status of each DataNode. Ensure that the DataNode corresponding to the IP address obtained in has been restored to the **Normal** state.

Figure 16-21 DataNode status



Step 10 Go to the service instance page.

MRS Manager:

Log in to MRS Manager and choose **Services** > **HDFS** > **Instances**.

FusionInsight Manager:

MRS 3.x or later: Log in to FusionInsight Manager and choose **Cluster** > **Service** > **HDFS** > **Instance**.

Log in to the MRS console and choose **Components** > **HDFS** > **Instances**.

Step 11 Select the DataNode instance that is in the decommissioning state and choose **More** > **Restart Instance**.

Step 12 Wait until the restart is complete and check whether the DataNode is restored.

----End

Summary and Suggestions

Do not perform high-risk operations, such as restarting nodes, during decommissioning (or scale-in).

Related Information

None

16.9.8 HDFS Failed to Start Due to Insufficient Memory

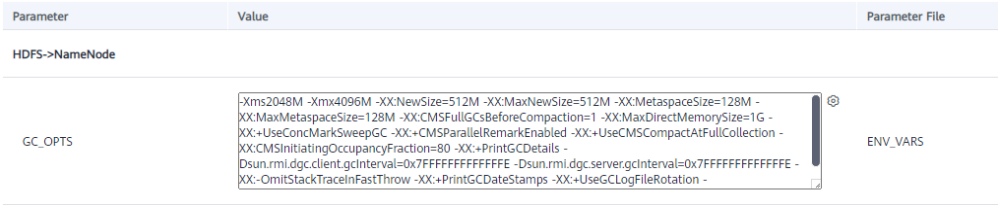
Symptom

After the HDFS service is restarted, HDFS is in the Bad state, the NameNode instance status is abnormal, and the system cannot exit the security mode for a long time.

Cause Analysis

1. In the NameNode run log (**/var/log/Bigdata/hdfs/nn/hadoop-omm-namendoe-XXX.log**), search for **WARN**. It is found that GC takes 63 seconds.
   ```
   2017-01-22 14:52:32,641 | WARN  | org.apache.hadoop.util.JvmPauseMonitor$Monitor@1b39fd82 |
   Detected pause in JVM or host machine (eg GC): pause of approximately 63750ms
   GC pool 'ParNew' had collection(s): count=1 time=0ms
   GC pool 'ConcurrentMarkSweep' had collection(s): count=1 time=63924ms | JvmPauseMonitor.java:189
   ```
2. Analyze the NameNode log **/var/log/Bigdata/hdfs/nn/hadoop-omm-namendoe-XXX.log**. It is found that the NameNode is waiting for block reporting and the total number of blocks is too large. In the following example, the total number of blocks is 36.29 million.
   ```
   2017-01-22 14:52:32,641 | INFO  | IPC Server handler 8 on 25000 | STATE* Safe mode ON.
   The reported blocks 29715437 needs additional 6542184 blocks to reach the threshold 0.9990 of total blocks 36293915.
   ```
3. On Manager, check the **GC_OPTS** parameter of the NameNode:

   Figure 16-22 Checking the GC_OPTS parameter of the NameNode

4. For details about the mapping between the NameNode memory configuration and data volume, see **Table 16-2**.

   Table 16-2 Mapping between NameNode memory configuration and data volume

Number of File Objects	Reference Value
10,000,000	-Xms6G -Xmx6G -XX:NewSize=512M -XX:MaxNewSize=512M
20,000,000	-Xms12G -Xmx12G -XX:NewSize=1G -XX:MaxNewSize=1G
50,000,000	-Xms32G -Xmx32G -XX:NewSize=2G -XX:MaxNewSize=3G
100,000,000	-Xms64G -Xmx64G -XX:NewSize=4G -XX:MaxNewSize=6G

Number of File Objects	Reference Value
200,000,000	-Xms96G -Xmx96G -XX:NewSize=8G -XX:MaxNewSize=9G
300,000,000	-Xms164G -Xmx164G -XX:NewSize=12G -XX:MaxNewSize=12G

Solution

Step 1 Modify the NameNode memory parameter based on the specifications. If the number of blocks is 36 million, change the parameter value to **-Xms32G -Xmx32G -XX:NewSize=2G -XX:MaxNewSize=3G**.

Step 2 Restart a NameNode and check that the NameNode can be started normally.

Step 3 Restart the other NameNode and check that the page status is restored.

----End

16.9.9 A Large Number of Blocks Are Lost in HDFS due to the Time Change Using ntpdate

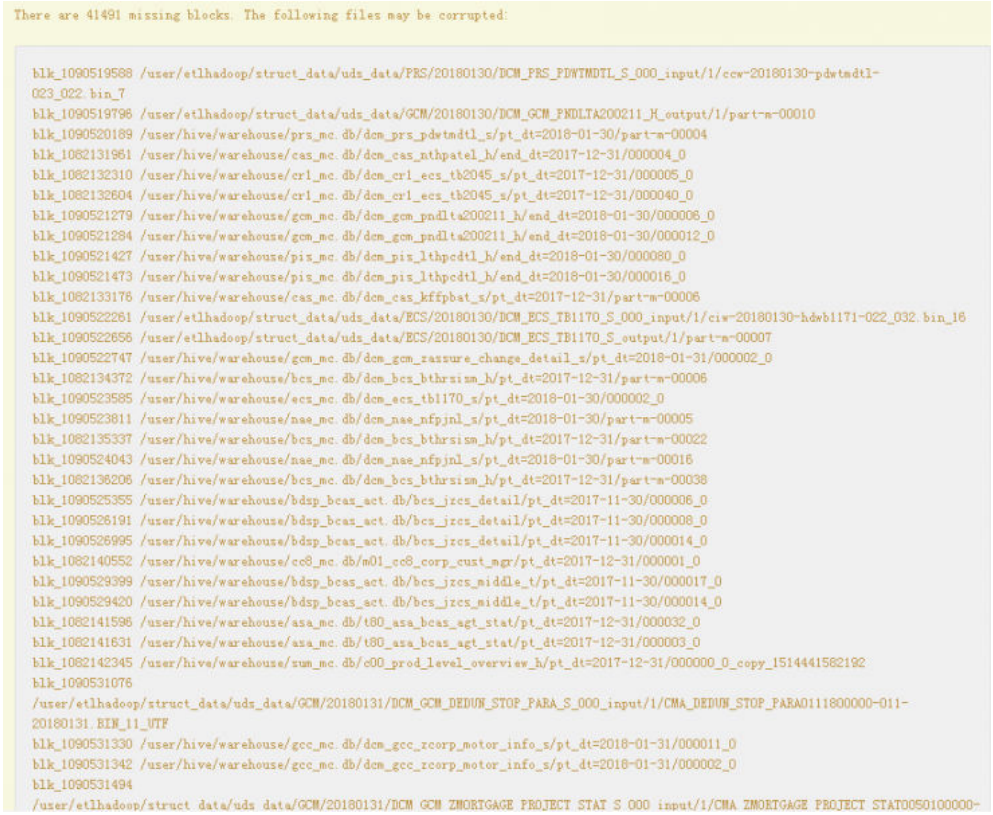
Symptom

1. A user uses **ntpdate** to change the time for a cluster that is not stopped. After the time is changed, HDFS enters the safe mode and cannot be started.
2. After the system exits the safe mode and starts, about 1 TB data is lost during the **hfck** check.

Cause Analysis

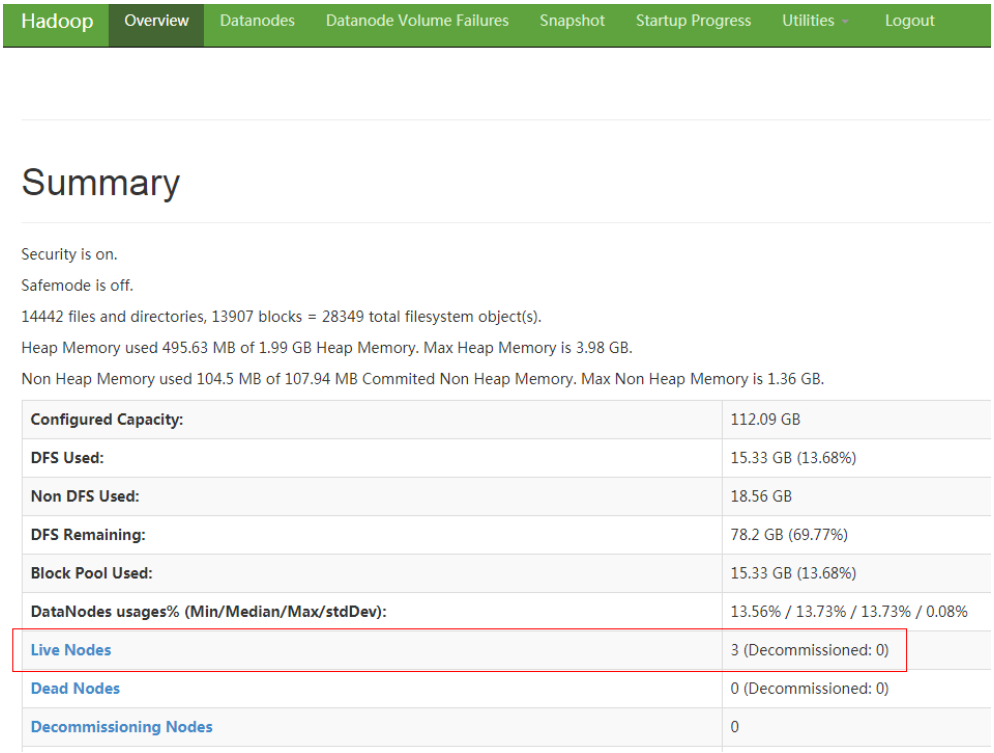
1. A large number of blocks are lost on the native NameNode page.

Figure 16-23 Block loss



2. DataNode information on the native page shows that the number of displayed DataNode nodes is 10 less than that of actual DataNode nodes.

Figure 16-24 Checking the number of DataNodes



3. Check the DataNode run log file **/var/log/Bigdata/hdfs/dn/hadoop-omm-datanode-*hostname*.log**. The following error information is displayed:

   Major error information: Clock skew too great

```

Solution

Step 1 Check DataNode memory configuration and whether the remaining server memory is sufficient.

Step 2 Increase DataNode memory and restart the DataNode.

----End

16.9.11 Manually Performing Checkpoints When a NameNode Is Faulty for a Long Time

Symptom

If the standby NameNode is faulty for a long time, a large amount of editlog will be accumulated. In this case, if the HDFS or active NameNode is restarted, the active NameNode reads a large amount of unmerged editlog. As a result, the HDFS or active NameNode takes a long time to restart and even fails to restart.

Cause Analysis

The standby NameNode periodically combines editlog files and generates the fsimage file. This process is called checkpoint. After the fsimage file is generated, the standby NameNode transfers it to the active NameNode.

NOTE

As the standby NameNode periodically combines editlog files, it cannot combine them when it becomes abnormal. As a result, the active NameNode needs to load many editlog files during its next startup, which occupies much memory and takes a long time.

The period of metadata combination is determined by the following parameters. If the NameNode runs for 30 minutes or one million counts of operations are performed on HDFS, the checkpoint is implemented.

- **dfs.namenode.checkpoint.period**: specifies the checkpoint period. The default value is **1800s**.
- dfs.namenode.checkpoint.txns: specifies the times of operations for triggering the checkpoint execution. The default value is **1000000**.

Solution

Before restarting the HDFS or active NameNode, perform checkpoint manually to merge metadata of the active NameNode.

Step 1 Stop workloads.

Step 2 Obtain the hostname of the active NameNode.

Step 3 Run the following commands on the client:

source /opt/client/bigdata_env

kinit *Component user*

Note: Replace **/opt/client** with the actual installation path of the client.

Step 4 Run the following command to enable the safe mode for the active NameNode (replace **linux22** with the hostname of the active NameNode):

hdfs dfsadmin -fs linux22:25000 -safemode enter

```
linux16:/opt/fi_client #  hdfs dfsadmin -fs linux22:25000   -safemode enter
17/04/26 18:38:30 WARN fs.FileSystem: "linux22:25000" is a deprecated filesystem name. Use "hdfs://linux22:25000/" instead.
17/04/26 18:38:32 INFO hdfs.PeerCache: SocketCache disabled.
Safe mode is ON
```

Step 5 Run the following command to merge editlog on the active NameNode:

hdfs dfsadmin -fs linux22:25000 -saveNamespace

```
linux16:/opt/fi_client #  hdfs dfsadmin -fs linux22:25000   -saveNamespace
17/04/26 18:38:54 WARN fs.FileSystem: "linux22:25000" is a deprecated filesystem name. Use "hdfs://linux22:25000/" instead.
17/04/26 18:38:56 INFO hdfs.PeerCache: SocketCache disabled.
Save namespace successful
```

Step 6 Run the following command to make the active NameNode exit the safe mode:

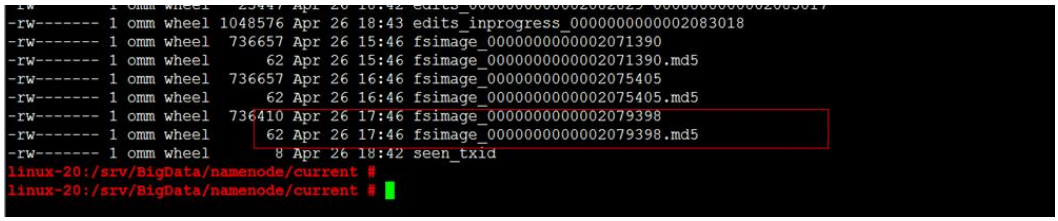
hdfs dfsadmin -fs linux22:25000 -safemode leave

```
linux16:/opt/fi_client #  hdfs dfsadmin -fs linux22:25000  -safemode leave
17/04/26 18:39:07 WARN fs.FileSystem: "linux22:25000" is a deprecated filesystem name. Use "hdfs://linux22:25000/" instead.
17/04/26 18:39:09 INFO hdfs.PeerCache: SocketCache disabled.
Safe mode is OFF
```

Step 7 Check whether the combination is complete.

cd /srv/BigData/namenode/current

Check whether the time of the first generated fsimage is the current time. If yes, the combination is complete.



----End

16.9.12 Common File Read/Write Faults

Symptom

When a user performs a write operation on HDFS, the message "Failed to place enough replicas:expected…" is displayed.

Cause Analysis

- The data receiver of the DataNode is unavailable.

  The DataNode log is as follows:

  ```
  2016-03-17 18:51:44,721 | WARN |
  org.apache.hadoop.hdfs.server.datanode.DataXceiverServer@5386659f |
  hadoopc1h2:25009:DataXceiverServer: | DataXceiverServer.java:158
  java.io.IOException: Xceiver count 4097 exceeds the limit of concurrent xcievers: 4096
  at org.apache.hadoop.hdfs.server.datanode.DataXceiverServer.run(DataXceiverServer.java:140)
  at java.lang.Thread.run(Thread.java:745)
  ```

- The disk space configured for the DataNode is insufficient.
- DataNode heartbeats are delayed.

Solution

- If the DataNode data receiver is unavailable, add the value of the HDFS parameter **dfs.datanode.max.transfer.threads** on Manager.
- If disk space or CPU resources are insufficient, add DataNodes or ensure that disk space and CPU resources are available.
- If the network is faulty, ensure that the network is available.

16.9.13 Maximum Number of File Handles Is Set to a Too Small Value, Causing File Reading and Writing Exceptions

Symptom

The maximum number of file handles is set to a too small value, causing insufficient file handles. Writing files to HDFS is slow or file writing fails.

Cause Analysis

1. The DataNode log **/var/log/Bigdata/hdfs/dn/hadoop-omm-datanode-XXX.log** contains exception information "java.io.IOException: Too many open files."

   ```
   2016-05-19 17:18:59,126 | WARN |
   org.apache.hadoop.hdfs.server.datanode.DataXceiverServer@142ff9fa |
   YSDN12:25009:DataXceiverServer: |
   ```

```
org.apache.hadoop.hdfs.server.datanode.DataXceiverServer.run(DataXceiverServer.java:160)
java.io.IOException: Too many open files
at sun.nio.ch.ServerSocketChannelImpl.accept0(Native Method)
at sun.nio.ch.ServerSocketChannelImpl.accept(ServerSocketChannelImpl.java:241)
at sun.nio.ch.ServerSocketAdaptor.accept(ServerSocketAdaptor.java:100)
at org.apache.hadoop.hdfs.net.TcpPeerServer.accept(TcpPeerServer.java:134)
at org.apache.hadoop.hdfs.server.datanode.DataXceiverServer.run(DataXceiverServer.java:137)
at java.lang.Thread.run(Thread.java:745)
```

2. The error indicates insufficient file handles. File handles cannot be opened and data is written to other DataNodes. As a result, writing files is slow or fails.

Solution

Step 1 Run the **ulimit -a** command to check the maximum number of file handles set for the involved node. If the value is small, change it to **640000**.

Figure 16-29 Check the number of file handles.

```
[omm@189-39-150-167 ~]$ ulimit -a
core file size          (blocks, -c) 0
data seg size           (kbytes, -d) unlimited
scheduling priority             (-e) 0
file size               (blocks, -f) unlimited
pending signals                 (-i) 256551
max locked memory       (kbytes, -l) 64
max memory size         (kbytes, -m) unlimited
open files                      (-n) 640000
pipe size            (512 bytes, -p) 8
POSIX message queues     (bytes, -q) 819200
real-time priority              (-r) 0
stack size              (kbytes, -s) 10240
cpu time               (seconds, -t) unlimited
max user processes              (-u) 60000
virtual memory          (kbytes, -v) unlimited
file locks                      (-x) unlimited
```

Step 2 Run the **vi /etc/security/limits.d/90-nofile.conf** command to edit this file. Set the number of file handles to **64000**. If the file does not exist, create one and modify the file as follows:

Figure 16-30 Changing the number of file handles

```
*          hard    nofile    640000
*          soft    nofile    640000
~
```

Step 3 Open another terminal. Run the **ulimit -a** command to check whether the modification is successful. If the modification fails, perform the preceding operations again.

Step 4 Restart the DataNode instance on Manager.

----End

16.9.14 A Client File Fails to Be Closed After Data Writing

Symptom

A client file fails to be closed after data is written to the file. A message is displayed indicating that the data block does not have enough replicas.

Client log:

```
2015-05-27 19:00:52.811 [pool-2-thread-3] ERROR: /tsp/nedata/collect/UGW/ugwufdr/
20150527/10/6_20150527105000_20150527105500_SR5S14_1432723806338_128_11.pkg.tmp143272380633
8 close hdfs sequence file fail (SequenceFileInfoChannel.java:444)

at java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:615)
at java.lang.Thread.run(Thread.java:745)
```

Cause Analysis

1. The HDFS client starts to write blocks.

   For example, the HDFS client starts to write **/20150527/10/6_20150527105000_20150527105500_SR5S14_1432723806338_128_11.pkg.tmp1432723806338 at 2015-05-27 18:50:24,232**. The allocated block is **blk_1099105501_25370893**:

   ```
   2015-05-27 18:50:24,232 | INFO  | IPC Server handler 30 on 25000 | BLOCK* allocateBlock: /
   20150527/10/6_20150527105000_20150527105500_SR5S14_1432723806338_128_11.pkg.tmp1432723
   806338. BP-1803470917-192.168.57.33-1428597734132
   blk_1099105501_25370893{blockUCState=UNDER_CONSTRUCTION, primaryNodeIndex=-1,
   replicas=[ReplicaUnderConstruction[[DISK]DS-b2d7b7d0-f410-4958-8eba-6deecbca2f87:NORMAL|
   RBW], ReplicaUnderConstruction[[DISK]DS-76bd80e7-ad58-49c6-bf2c-03f91caf750f:NORMAL|RBW]]}
   |
   org.apache.hadoop.hdfs.server.namenode.FSNamesystem.saveAllocatedBlock(FSNamesystem.java:3166
   )
   ```

2. After the writing is complete, the HDFS client invokes **fsync**:

   ```
   2015-05-27 19:00:22,717 | INFO  | IPC Server handler 22 on 25000 | BLOCK* fsync:
   20150527/10/6_20150527105000_20150527105500_SR5S14_1432723806338_128_11.pkg.tmp1432723
   806338 for DFSClient_NONMAPREDUCE_-120525246_15 |
   org.apache.hadoop.hdfs.server.namenode.FSNamesystem.fsync(FSNamesystem.java:3805)
   ```

3. The HDFS client invokes **close** to close the file. After receiving the close request from the client, the NameNode uses the checkFileProgress function to check the completion status of the last block and closes the file only when enough DataNodes report that the last block is complete:

   ```
   2015-05-27 19:00:27,603 | INFO  | IPC Server handler 44 on 25000 | BLOCK* checkFileProgress:
   blk_1099105501_25370893{blockUCState=COMMITTED, primaryNodeIndex=-1,
   replicas=[ReplicaUnderConstruction[[DISK]DS-ef5fd3c9-5088-4813-ae9a-34a0714ec3a3:NORMAL|
   RBW], ReplicaUnderConstruction[[DISK]DS-f863e30f-ce5b-48cc-9cca-72f64c558adc:NORMAL|RBW]]}
   has not reached minimal replication 1 |
   org.apache.hadoop.hdfs.server.namenode.FSNamesystem.checkFileProgress(FSNamesystem.java:3197)

RBW], ReplicaUnderConstruction[[DISK]DS-f863e30f-ce5b-48cc-9cca-72f64c558adc:NORMAL|RBW]]}
has not reached minimal replication 1 |
org.apache.hadoop.hdfs.server.namenode.FSNamesystem.checkFileProgress(FSNamesystem.java:3197)
```

4. The NameNode prints **CheckFileProgress** multiple times because the HDFS client retries to close the file for several times. The file closing fails because the block status is not complete. The number of retries is determined by the **dfs.client.block.write.locateFollowingBlock.retries** parameter. The default value is **5**. Therefore, **CheckFileProgress** is printed six times in the NameNode log.
5. After 0.5 seconds, the DataNodes report that the block has been successfully written.

   ```
   2015-05-27 19:00:40,608 | INFO  | IPC Server handler 60 on 25000 | BLOCK* addStoredBlock:
   blockMap updated: 192.168.10.21:25009 is added to
   blk_1099105501_25370893{blockUCState=COMMITTED, primaryNodeIndex=-1,
   replicas=[ReplicaUnderConstruction[[DISK]DS-ef5fd3c9-5088-4813-ae9a-34a0714ec3a3:NORMAL|
   RBW], ReplicaUnderConstruction[[DISK]DS-f863e30f-ce5b-48cc-9cca-72f64c558adc:NORMAL|RBW]]}
   size 11837530 |
   org.apache.hadoop.hdfs.server.blockmanagement.BlockManager.logAddStoredBlock(BlockManager.java
   :2393)
   2015-05-27 19:00:48,297 | INFO  | IPC Server handler 37 on 25000 | BLOCK* addStoredBlock:
   blockMap updated: 192.168.10.10:25009 is added to blk_1099105501_25370893 size 11837530 |
   org.apache.hadoop.hdfs.server.blockmanagement.BlockManager.logAddStoredBlock(BlockManager.java
   :2393)
   ```

6. The block write success notification is delayed because of network bottlenecks or CPU bottlenecks.
7. If close is invoked again or the number of file closing retries increases, a closing success message will be displayed. You are advised to increase the value of **dfs.client.block.write.locateFollowingBlock.retries**. The default parameter value is 5 and retry intervals are 400 ms, 800 ms, 1600 ms, 3200 ms, 6400 ms, and 12800 ms. Therefore, the result of the close function can be returned after a maximum of 25.2 seconds.

Solution

Step 1 Solution:

Set the value of **dfs.client.block.write.locateFollowingBlock.retries** to **6**. The retry intervals are 400 ms, 800 ms, 1600 ms, 3200 ms, 6400 ms, and 12800 ms.

Therefore, the result of the close function can be returned after a maximum of 50.8 seconds.

----End

Remarks

Generally, this fault occurs when the cluster workload is heavy. Adjusting the parameter can only temporarily avoid the fault. You are advised to reduce the cluster workload, for example, do not allocate all CPU resources to MapReduce.

16.9.15 File Fails to Be Uploaded to HDFS Due to File Errors

Symptom

The **hadoop dfs -put** command is used to copy local files to HDFS.

After some files are uploaded, an error occurs. The size of the temporary files no long changes on the native NameNode page.

Cause Analysis

1. Check the NameNode log **/var/log/Bigdata/hdfs/nn/hadoop-omm-namenode-*hostname*.log**. It is found that the file is being written until a failure occurs.

   ```
   2015-07-13 10:05:07,847 | WARN  | org.apache.hadoop.hdfs.server.namenode.LeaseManager
   $Monitor@36fea922 | DIR* NameSystem.internalReleaseLease: Failed to release lease for file /hive/
   order/OS_ORDER._8.txt._COPYING_. Committed blocks are waiting to be minimally replicated. Try
   again later. | FSNamesystem.java:3936
   2015-07-13 10:05:07,847 | ERROR | org.apache.hadoop.hdfs.server.namenode.LeaseManager
   $Monitor@36fea922 | Cannot release the path /hive/order/OS_ORDER._8.txt._COPYING_ in the lease
   [Lease.  Holder: DFSClient_NONMAPREDUCE_-1872896146_1, pendingcreates: 1] |
   LeaseManager.java:459
   org.apache.hadoop.hdfs.protocol.AlreadyBeingCreatedException: DIR*
   NameSystem.internalReleaseLease: Failed to release lease for file /hive/order/
   OS_ORDER._8.txt._COPYING_. Committed blocks are waiting to be minimally replicated. Try again
   later.
   at FSNamesystem.internalReleaseLease(FSNamesystem.java:3937)
   ```

2. Root cause: The uploaded files are damaged.
3. Verification: The cp or scp operation fails to be performed for the copied files. Therefore, the files are damaged.

Solution

Step 1 Upload normal files.

----End

16.9.16 After dfs.blocksize Is Configured and Data Is Put, Block Size Remains Unchanged

Symptom

After **dfs.blocksize** is set to **268435456** on the interface and data is put, the original block size keeps unchanged.

Cause Analysis

The **dfs.blocksize** value in the **hdfs-site.xml** file of the client is not changed, and the value prevails.

Solution

Step 1 Ensure that the **dfs.blocksize** value is a multiple of 512.

Step 2 Download a client or modify the client configuration.

Step 3 **dfs.blocksize** is configured on the client and is subject to the client. Otherwise, the value configured on the server prevails.

----End

16.9.17 Failed to Read Files, and "FileNotFoundException" Is Displayed

Symptom

In MapReduce tasks, all Map tasks are successfully executed, but Reduce tasks fail. The error message "FileNotFoundException...No lease on...File does not exist" is displayed in the logs.

```
Error: org.apache.hadoop.ipc.RemoteException(java.io.FileNotFoundException): No lease on /user/sparkhive/warehouse/daas/dsp/output/_temporary/1/_temporary/attempt_1479799053892_17075_r_000007_0/part-r-00007 (inode 6501287): File does not exist. Holder DFSClient_attempt_1479799053892_17075_r_000007_0_-1463597952_1 does not have any open files.
at org.apache.hadoop.hdfs.server.namenode.FSNamesystem.checkLease(FSNamesystem.java:3350)
at org.apache.hadoop.hdfs.server.namenode.FSNamesystem.completeFileInternal(FSNamesystem.java:3442)
at org.apache.hadoop.hdfs.server.namenode.FSNamesystem.completeFile(FSNamesystem.java:3409)
at org.apache.hadoop.hdfs.server.namenode.NameNodeRpcServer.complete(NameNodeRpcServer.java:789)
```

Cause Analysis

"FileNotFoundException...No lease on...File does not exist" indicates that the file is deleted during the operation.

1. Search for the file name in the NameNode audit log of HDFS (**/var/log/Bigdata/audit/hdfs/nn/hdfs-audit-namenode.log** of the active NameNode) to confirm the creation time of the file.
2. Search the NameNode audit logs that are generated within the time range from the file creation to the time of exception occurrence and determine whether the file is deleted or moved to another directory.
3. If the file is not deleted or moved, the parent directory of the file may be deleted or moved. You need to search the upper-layer directory. In this example, the parent directory of the file's parent directory is deleted.

   ```
   2017-05-31 02:04:08,286 | INFO  | IPC Server handler 30 on 25000 | allowed=true ugi=appUser@HADOOP.COM (auth:TOKEN) ip=/192.168.1.22 cmd=delete src=/user/sparkhive/warehouse/daas/dsp/output/_temporary dst=null perm=null proto=rpc | FSNamesystem.java:8189
   ```

NOTE

- The preceding log indicates that the **appUser** user of the 192.168.1.22 node deletes **/user/sparkhive/warehouse/daas/dsp/output/_temporary**.
- Run the **zgrep "***file name***" *.zip** command to search for the contents of the .zip package.

Solution

Step 1 Check the service to find out why the file or the parent directory of the file is deleted.

----End

16.9.18 Failed to Write Files to HDFS, and "item limit of / is exceeded" Is Displayed

Symptom

The client or upper-layer component logs indicate that a file fails to be written to a directory on HDFS. The error information is as follows:

The directory item limit of /tmp is exceeded: limit=5 items=5.

Cause Analysis

1. The run log file **/var/log/Bigdata/hdfs/nn/hadoop-omm-namenode-XXX.log** of the client or NameNode contains error information "The directory item limit of /tmp is exceeded:." The error message indicates that the number of files in the **/tmp** directory exceeds 1048576.
   2018-03-14 11:18:21,625 | WARN | IPC Server handler 62 on 25000 | DIR* NameSystem.startFile: /tmp/test.txt The directory item limit of /tmp is exceeded: limit=1048576 items=1048577 | FSNamesystem.java:2334
2. The **dfs.namenode.fs-limits.max-directory-items** parameter specifies the maximum number of directories or files that are not in recursion relationship in a single directory. The default value is **1048576**. The value ranges from 1 to 6400000.

Solution

Step 1 Check whether it is normal that the directory contains more than one million files that are not in recursion relationship. If it is normal, increase the value of the HDFS parameter **dfs.namenode.fs-limits.max-directory-items** and restart the HDFS NameNode for the modification to take effect.

Step 2 If it is abnormal, delete unnecessary files.

----End

16.9.19 Adjusting the Log Level of the Shell Client

- **Temporary adjustment**: After the Shell client window is closed, the log is restored to the default value.

a. Run the **export HADOOP_ROOT_LOGGER** command to adjust the log level of the client.

b. Run the **export HADOOP_ROOT_LOGGER=***log level***,console** command to adjust the log level of the Shell client.

   Run the **export HADOOP_ROOT_LOGGER=DEBUG,console** command to adjust the log level to **Debug**.

   Run the **export HADOOP_ROOT_LOGGER=ERROR,console** command to adjust the log level to **Error**.

- **Permanent adjustment**

  a. Add **export HADOOP_ROOT_LOGGER**=*log level***,console** to the HDFS client's environment variable configuration file **/opt/client/HDFS/component_env** (replace **/opt/client** with the actual client path).

  b. Run the **source /opt/client/bigdata_env** command.

  c. Run the command on the client again.

16.9.20 File Read Fails, and "No common protection layer" Is Displayed

Symptom

HDFS fails to be operated on the Shell client or other clients, and the error message "No common protection layer between client and server" is displayed.

Running any **hadoop** command, such as **hadoop fs -ls /**, on a node outside the cluster fails. The bottom-layer error message is displayed stating "No common protection layer between client and server."

```

        ... 28 more
Caused by: javax.security.sasl.SaslException: No common protection layer between client and server
        at com.sun.security.sasl.gsskerb.GssKrb5Client.doFinalHandshake(GssKrb5Client.java:251)
...
        at org.apache.hadoop.ipc.Client$Connection.setupIOstreams(Client.java:720)
```

Cause Analysis

1. The RPC protocol is used for data transmission between the client and server of HDFS. The protocol has multiple encryption modes and the hadoop.rpc.protection parameter specifies the mode to use.

2. If the value of the **hadoop.rpc.protection** parameter on the client is different from that on the server, the "No common protection layer between client and server" error is reported.

   NOTE

   hadoop.rpc.protection indicates that data can be transmitted between nodes in any of the following modes:

   - **privacy**: Data is transmitted after authentication and encryption. This mode reduces the performance.
   - **authentication**: Data is transmitted after authentication without encryption. This mode ensures performance but has security risks.
   - **integrity**: Data is transmitted without encryption or authentication. To ensure data security, exercise caution when using this mode.

Solution

Step 1 Download the client again. If the client is an application, update the configuration file in the application.

----End

16.9.21 Failed to Write Files Because the HDFS Directory Quota Is Insufficient

Symptom

After quota is set for a directory, writing files to the directory fails. The "The DiskSpace quota of /tmp/tquota2 is exceeded" error message is displayed.

```
[omm@189-39-150-115 client]$ hdfs dfs -put switchuser.py  /tmp/tquota2
put: The DiskSpace quota of /tmp/tquota2 is exceeded: quota = 157286400 B = 150 MB but diskspace consumed = 402653184 B = 384 MB
```

Possible Causes

The remaining space configured for the directory is less than the space required for writing files.

Cause Analysis

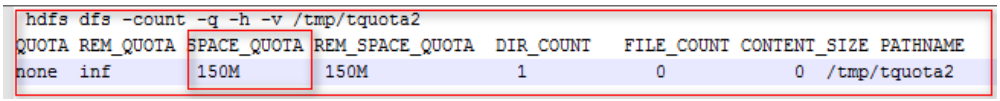
1. The HDFS supports setting the quota for a specific directory, that is, the maximum space occupied by files in a directory can be set. For example, the following command is used to set a maximum of 150 MB files to be written to the **/tmp/tquota** directory. (Space = Block size x Number of copies)

   hadoop dfsadmin -setSpaceQuota 150M /tmp/tquota2

2. Run the following command to check the configured quota for the directory. **SPACE_QUOTA** is the configured space quota, and **REM_SPACE_QUOTA** is the remaining space.

   hdfs dfs -count -q -h -v /tmp/tquota2

   Figure 16-31 Viewing the quota set for a directory



3. Analyze logs. The following log indicates that writing the file requires 384 MB space, but the current space quota is only 150 MB. Therefore, the space is insufficient. Before a file is written, the required remaining space is as follows: Block size x Number of copies. 128 MB x 3 copies = 384 MB.

```
[omm@189-39-150-115 client]$
[omm@189-39-150-115 client]$ hdfs dfs -put switchuser.py  /tmp/tquota2
put: The DiskSpace quota of /tmp/tquota2 is exceeded: quota = 157286400 B = 150 MB but diskspace consumed = 402653184 B = 384 MB
```

Solution

Step 1 Set a proper quota for the directory.

hadoop dfsadmin -setSpaceQuota 150G /*directory name*

Step 2 Run the following command to clear the quota:

hdfs dfsadmin -clrSpaceQuota /*directory name*

----End

16.9.22 Balancing Fails, and "Source and target differ in block-size" Is Displayed

Symptom

When the **distcp** command is executed to copy files across clusters, the message "Source and target differ in block-size." is displayed, indicating that some files fail to be copied. Use -pb to preserve block-sizes during copy. "

```
 Caused by: java.io.IOException: Check-sum mismatch between hdfs://10.180.144.7:25000/kylin/kylin_default_instance_prod/parquet/f2e72874-f01c-45ff-b219-207f3a5b3fcb/c769cd2d-575a-4459-837b-a19dd7b20c27/339114721280/0.parquettar and hdfs://10.180.180.194:25000/kylin/kylin_default_instance_prod/parquet/f2e72874-f01c-45ff-b219-207f3a5b3fcb/.distcp.tmp.attempt_1523424430246_0004_m_000019_2. Source and target differ in block-size. Use -pb to preserve block-sizes during copy. Alternatively, skip checksum-checks altogether, using -skipCrc. (NOTE: By skipping checksums, one runs the risk of masking data-corruption during file-transfer.)        at org.apache.hadoop.tools.mapred.RetriableFileCopyCommand.compareCheckSums(RetriableFileCopyCommand.java:214)
```

Possible Causes

This is not a version-related problem. When you run the **distcp** command to copy files, the block size of the source file is not recorded by default. As a result, the verification fails when the block size of the source file is not 128 MB. In this case, you need to add parameter **-pb** to the **distcp** command.

Cause Analysis

1. The block size is set when data is written to HDFS. The default block size is 128 MB. The size of files written by some components or service programs may not be 128 MB, for example, 8 MB.

```
<name>dfs.blocksize</name>
<value>134217728</value>
```

Figure 16-32 Size of files written by some components or service programs

2. DistCp reads the file from a source cluster and writes it to a destination cluster. By default, the value of dfs.blocksize in the MapReduce task is used as the block size, whose default value is 128 MB.
3. After DistCp finishes writing a file, the system performs verification based on the physical size of the block. Because the block size of the file in the source cluster is different from that of the file in the destination cluster, the splitting sizes are different. As a result, the verification fails.

   For example, in the preceding file, there are three blocks (17.9/8 MB = 3 blocks) in the old cluster and one block (17.9/128 MB = 1 block) in the new cluster. Therefore, the verification fails because the physical size of the disk is divided.

Solution

Add parameter **-pb** in the **distcp** command. This parameter is used to reserve the block size when **distcp** is used to ensure that the block size of the new cluster is the same as that of the old cluster.

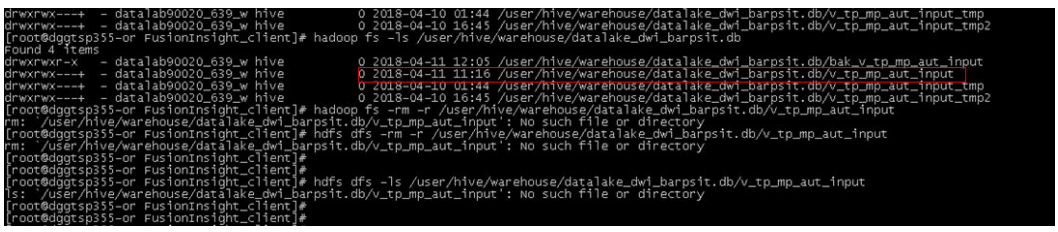
Figure 16-33 Size of the reserved block during **distcp** command execution

16.9.23 A File Fails to Be Queried or Deleted, and the File Can Be Viewed in the Parent Directory (Invisible Characters)

Symptom

A file fails to be queried or deleted using the HDFS Shell client. The file can be viewed in the parent directory.

Figure 16-34 List of files in the parent directory



Cause Analysis

The possible cause is that invisible characters are written to the file. You can write the file name to the local text and run the **vi** command to open the file.

hdfs dfs -ls *parent directory* **> /tmp/t.txt**

vi /tmp/t.txt

Run the **:set list** command to display invisible characters in the file name. For example, the file name contains **^M**, which is invisible.

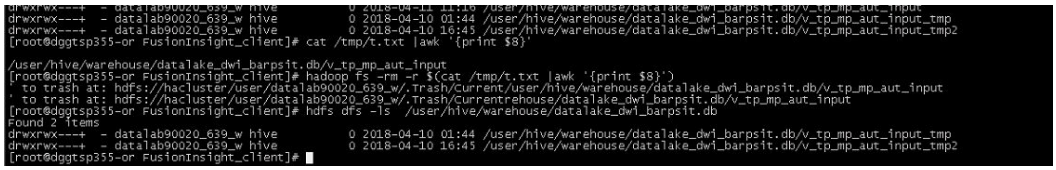
Figure 16-35 Displaying invisible characters

Solution

Step 1 Run the Shell command to read the file name recorded in the text. Ensure that the following command output contains the full path of the file in HDFS.

cat /tmp/t.txt |awk '{print $8}'

Figure 16-36 File path



Step 2 Run the following command to delete the file:

hdfs dfs -rm $(cat /tmp/t.txt |awk '{print $8}')

Step 3 Verify that the file has been deleted.

hdfs dfs -ls *parent directory*

----End

16.9.24 Uneven Data Distribution Due to Non-HDFS Data Residuals

Symptom

Data distribution is uneven. A disk is full while other disks have sufficient space.

The data storage directory of HDFS DataNode is set to **/export/data1/dfs--/export/data12/dfs**. A large volume of data is stored to **/export/data1/dfs** but data is evenly distributed to other disks.

Cause Analysis

The customer's disk is reinstalled. However, a directory is not thoroughly deleted during disk uninstallation, that is, the added disk is unformatted and historical junk data remains.

Solution

Manually delete data residuals.

16.9.25 Uneven Data Distribution Due to the Client Installation on the DataNode

Symptom

Data is unevenly distributed on HDFS DataNodes. Disk usage of a node is high or even reaches 100% while disks on other nodes have sufficient idle space.

Cause Analysis

In the HDFS data replica mechanism, the first replica is stored to the local node where the client is stored. As a result, disks of the node run out while disks of other nodes have sufficient idle space.

Solution

Step 1 For the existing data unevenly distributed, run the following command to balance data:

/opt/client/HDFS/hadoop/sbin/start-balancer.sh -threshold 10

/opt/client indicates the actual client installation directory.

Step 2 For new data, install the client on the node without DataNode.

----End

16.9.26 Handling Unbalanced DataNode Disk Usage on Nodes

Symptom

The disk usage of each DataNode on a node is uneven.

Example:

```
189-39-235-71:~ # df -h
Filesystem  Size  Used Avail Use% Mounted on
/dev/xvda  360G  92G   250G  28% /
/dev/xvdb  700G  900G   200G  78% /srv/BigData/hadoop/data1
/dev/xvdc  700G  900G   200G  78% /srv/BigData/hadoop/data2
/dev/xvdd  700G  900G   200G  78% /srv/BigData/hadoop/data3
/dev/xvde  700G  900G   200G  78% /srv/BigData/hadoop/data4
/dev/xvdf  10G   900G   890G  2% /srv/BigData/hadoop/data5
189-39-235-71:~ #
```

Possible Causes

Some disks are faulty and are replaced with new ones. The new disk usage is low.

Disks are added. For example, the original four data disks are expanded to five disks.

Cause Analysis

There are two policies for writing data to Block disks on DataNodes: 1. Round Robin (default value) and 2. Preferentially writing data to the disk with the more available space.

Description of the **dfs.datanode.fsdataset.volume.choosing.policy** parameter

Possible values:

- Polling: **org.apache.hadoop.hdfs.server.datanode.fsdataset.RoundRobinVolumeChoosingPolicy**
- Preferentially writing data to the disk with more available space: **org.apache.hadoop.hdfs.server.datanode.fsdataset.AvailableSpaceVolumeChoosingPolicy**

Solution

Change the value of **dfs.datanode.fsdataset.volume.choosing.policy** to **org.apache.hadoop.hdfs.server.datanode.fsdataset.AvailableSpaceVolumeChoosingPolicy**, save the settings, and restart the affected services or instances.

In this way, the DataNode preferentially selects a node with the most available disk space to store data copies.

NOTE

- Data written to the DataNode will be preferentially written to the disk with more available disk space.
- The high usage of some disks can be relieved with the gradual deletion of aging data from the HDFS.

16.9.27 Locating Common Balance Problems

Problem 1: Lack of Permission to Execute the balance Task (Access denied).

Problem details: After the **start-balancer.sh** command is executed, the " hadoop-root-balancer-hostname.out" log displays "Access denied for user test1. Superuser privilege is required."

```
cat /opt/client/HDFS/hadoop/logs/hadoop-root-balancer-host2.out
Time Stamp               Iteration#  Bytes Already Moved  Bytes Left To Move  Bytes Being Moved
INFO: Watching file:/opt/client/HDFS/hadoop/etc/hadoop/log4j.properties for changes with interval : 60000
org.apache.hadoop.ipc.RemoteException(org.apache.hadoop.security.AccessControlException): Access denied for user test1.
Superuser privilege is required
at
org.apache.hadoop.hdfs.server.namenode.FSPermissionChecker.checkSuperuserPrivilege(FSPermissionChecker.java:122)
at
org.apache.hadoop.hdfs.server.namenode.FSNamesystem.checkSuperuserPrivilege(FSNamesystem.java:5916)
```

Cause analysis:

The administrator account is required for executing the balance task.

Solution

- Secure version

  Perform authentication for user **hdfs** or a user in the **supergroup** group and then execute the balance task.
- General version

Run the **su - hdfs** command on the client before running the **balance** command on HDFS.

Problem 2: The balance command fails to be executed, and the /system/balancer.id file is abnormal.

Problem details:

A user starts a balance process on the HDFS client. After the process is stopped unexpectedly, the user performs the balance operation again. The operation fails.

```
org.apache.hadoop.ipc.RemoteException(org.apache.hadoop.protocol.RecoveryInProgressException): Failed to APPEND_FILE /system/balancer.id for DFSClient because lease recovery is in progress. Try again later.
```

Cause analysis:

Generally, after the balance operation is complete in HDFS, the **/system/balancer.id** file is automatically released and the balance operation can be performed again.

In the preceding scenario, the first balance operation is stopped abnormally. Therefore, when the balance operation is performed for the second time, the **/system/balancer.id** file still exists. As a result, the **append /system/balancer.id** operation is triggered and the balance operation fails.

Solution

Method 1: After the hard lease period exceeds one hour, release the lease on the original client and perform the balance operation again.

Method 2: Delete the **/system/balancer.id** file from HDFS and perform the balance operation again.

16.9.28 HDFS Displays Insufficient Disk Space But 10% Disk Space Remains

Symptom

1. The alarm "HDFS Disk Usage Exceeds the Threshold" is reported.
2. On the HDFS page, high disk space usage is displayed.

Cause Analysis

The **dfs.datanode.du.reserved.percentage** parameter is set in HDFS, indicating the percentage of the reserved space of each disk to the total disk space. The DataNode reserves space you set for NodeManager running and computing of other components, for example, Yarn, or for upgrades.

As 10% disk space is reserved, the HDFS DataNode regards that there is no available disk space when the disk usage reaches 90%.

Solution

Step 1 Expand the HDFS DataNode disk capacity when its usage reaches 80%.

Step 2 If the disk capacity cannot be expanded in time, delete useless data in HDFS to release disk space.

----End

16.9.29 An Error Is Reported When the HDFS Client Is Installed on the Core Node in a Common Cluster

Issue

In a common cluster, an error message is displayed when a user is created on the Core node to install the client.

Symptom

In a common cluster, the following error message is displayed when a user is created on the Core node to install the client:

```
2020-03-14 19:16:17,166 WARN shortcircuit.DomainSocketFactory: error creating DomainSocket
java.net.ConnectException: connect(2) error: Permission denied when trying to connect to '/var/run/MRS-HDFS/dn_socket'
at org.apache.hadoop.net.unix.DomainSocket.connect0(Native Method)
at org.apache.hadoop.net.unix.DomainSocket.connect(DomainSocket.java:256)
at org.apache.hadoop.hdfs.shortcircuit.DomainSocketFactory.createSocket(DomainSocketFactory.java:168)
at org.apache.hadoop.hdfs.client.impl.BlockReaderFactory.nextDomainPeer(BlockReaderFactory.java:799)
...
```

Cause Analysis

A user runs the **useradd** command to create a user. The default user group of the user does not contain the **ficommmon** user group. As a result, the preceding error is reported when the **get** command of HDFS is executed.

Procedure

Run the **usermod -a -G ficommon username** command to add the user to the **ficommon** user group.

16.9.30 Client Installed on a Node Outside the Cluster Fails to Upload Files Using hdfs

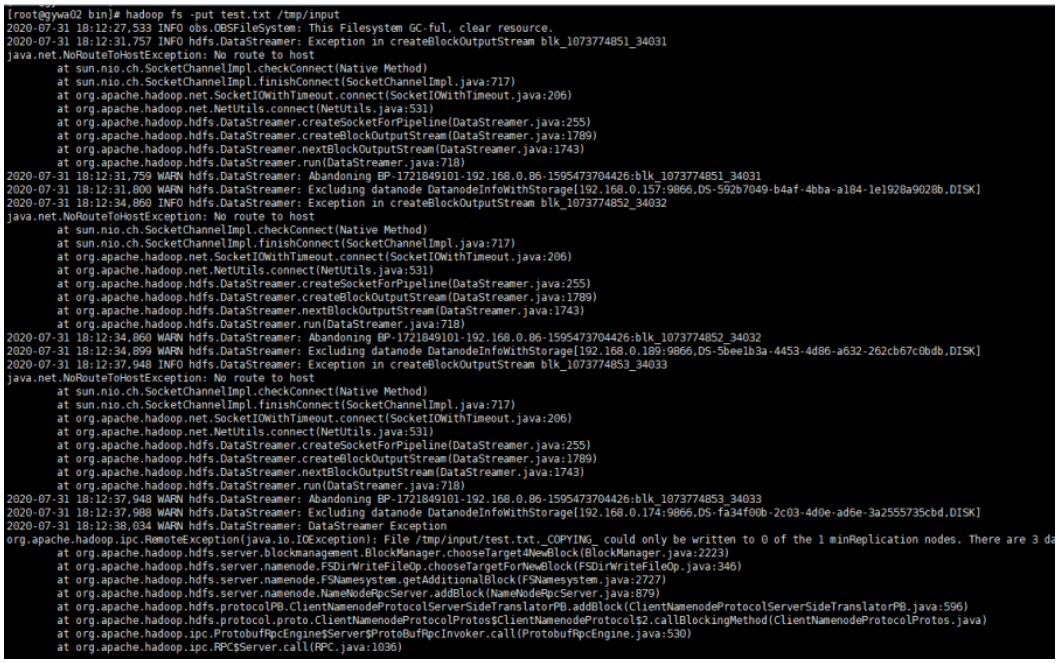
Issue

A client installed on a node outside the cluster fails to upload files using hdfs.

Symptom

After a client is installed on a cluster node and a file is uploaded using the **hdfs** command, the following error is reported:

Figure 16-37 An error is reported during file upload.



Cause Analysis

The error message "no route to host" is displayed, and the IP address 192.168 is contained in the error message. That is, the internal network route from the client node to the DataNode in the cluster is unreachable. As a result, the file fails to be uploaded.

Procedure

In the client directory of the client node, find the **hdfs-site.xml** file in the HDFS client configuration directory. Add the **dfs.client.use.datanode.hostname** configuration item to the configuration file, and set the value to **true**.

16.9.31 Insufficient Number of Replicas Is Reported During High Concurrent HDFS Writes

Symptom

File writes to HDFS fail occasionally.

The operation log is as follows:

105 | INFO | IPC Server handler 23 on 25000 | IPC Server handler 23 on 25000, call org.apache.hadoop.hdfs.protocol.ClientProtocol.addBlock from 192.168.1.96:47728 Call#1461167 Retry#0 | Server.java:2278
java.io.IOException: File /hive/warehouse/000000_0.835bf64f-4103 could only be replicated to 0 nodes instead of minReplication (=1). **There are 3 datanode(s) running and 3 node(s) are excluded in this operation.**

Cause Analysis

- HDFS has a reservation mechanism for file writing: each block to be written is 128 MB no matter whether the file is 10 MB or 1 GB. If a 10 MB file needs to

be written, the file occupies 10 MB of the first block and about 118 MB space will be released. If a 1 GB file needs to be written, HDFS writes the file block by block and releases unused space after the file is written.

- If there are a large number of files to be written concurrently, the disk space for reserved write blocks is insufficient. As a result, the file fails to be written.

Solution

Step 1 Log in to the HDFS WebUI and go to the JMX page of the DataNode.

1. On the native HDFS page, choose **Datanodes**.
2. Locate the target DataNode and click the HTTP address to go to the DataNode details page.
3. Change **datanode.html** in **url** to **jmx**.

Step 2 Search for the **XceiverCount** indicator. If the value of this indicator multiplied by the block size exceeds the DataNode disk capacity, the disk space reserved for block write is insufficient.

Step 3 You can use either of the following methods to solve the problem:

Method 1: Reduce the service concurrency.

Method 2: Combine multiple files into one file to reduce the number of files to be written.

----End

16.9.32 HDFS Client Failed to Delete Overlong Directories

Symptom

When a user runs the **hadoop fs -rm -r -f obs://***<obs_path>* command to delete an OBS directory with an overlong path name, the following error message is displayed:

```
2022-02-28 17:12:45,605 INFO internal.RestStorageService: OkHttp cost 19 ms to apply http request

```

Cause Analysis

When you run the **rm** command to delete some content from the HDFS, the files or directories are not deleted immediately. Instead, they are moved to the **current** directory (**/user/*${Username}*/.Trash/current**) in the recycle bin.

Solution

You can run the **skipTrash** command to skip the HDFS recycle bin and directly delete the data. Set the **dfs.client.skipTrash.enabled=true** configuration item of the HDFS client.

Step 1 Log in to any master node in the cluster as user **root**.

Step 2 Run the following command to edit the **hdfs-site.xml** file used by HDFS:

vim *Client installation directory*/**HDFS/hadoop/etc/hadoop/hdfs-site.xml**

Step 3 Add the following content to the **hdfs-site.xml** file:

```
<property>
<name>dfs.client.skipTrash.enabled</name>
<value>true</value>
</property>
```

Step 4 Run the following command to delete the overlong OBS directory:

hadoop fs -rm -r -f –skipTrash obs://*<obs_path>*

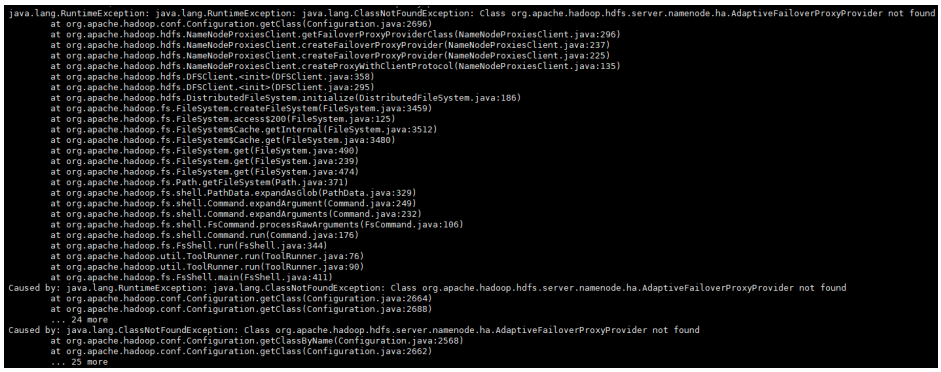
Step 5 Log in to the other master nodes in the cluster and repeat **Step 2** to **Step 4** one by one until the operations are complete on all master nodes.

----End

16.9.33 An Error Is Reported When a Node Outside the Cluster Accesses MRS HDFS

Symptom

When a node outside the MRS cluster accesses HDFS in the cluster, the following error message is reported: Class org.apache.hadoop.hdfs.server.namenode.ha.AdaptiveFailoverProxyProvider not found



Cause Analysis

The possible causes are as follows:

- An error is reported when an open-source HDFS client accesses HDFS of an MRS cluster.
- An error is reported when the JAR package is used to connect to HDFS of the MRS cluster (including connection to HDFS during task submission).

Procedure

Method 1:

Step 1 Locate the HDFS configuration file **hdfs-site.xml** used by the command or JAR package.

Step 2 Modify the **dfs.client.failover.proxy.provider.hacluster** configuration as follows:

```
<property>
<name>dfs.client.failover.proxy.provider.hacluster</name>
<value>org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider</value>
</property>
```

NOTE

You can also delete the preceding configuration items.

Step 3 Save the file and access MRS HDFS again.

----End

Method 2:

Step 1 Download the hadoop-plugins matching the MRS cluster version from the Maven repository.

Step 2 Add the downloaded JAR package to the dependency of the command or JAR package.

----End

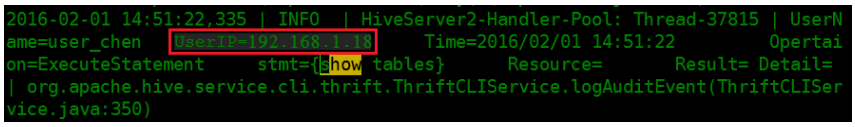
16.10 Using Hive

16.10.1 Content Recorded in Hive Logs

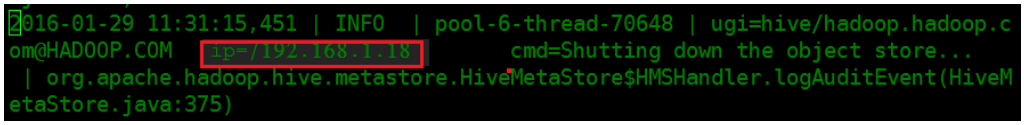
Audit log

An audit log records at what time a user sends a request to HiveServer and MetaStore from which IP address with what statement.

The following HiveServer audit log shows that at 14:51:22 on February 1, 2016, **user_chen** sent a **show tables** request to HiveServer from the 192.168.1.18 IP address.



The following MetaStore audit log shows that user **hive** sent a **shutdown** request to MetaStore from the 192.168.1.18 IP address at 11:31:15 on January 29, 2016.



Generally, the audit log does not play a role in actual error location. However, the audit log must be checked to solve the following problems:

1. There is no response after a client sends a request. The audit log can be used to check whether the task suspends on the client or server. If the audit log has no related information, the task suspends on the client. If the audit log has related information, view the run log to locate where the program suspends.
2. The audit log can be used to check the number of requests in a specified period of time. You can view the number of requests in a specified period in audit logs.

HiveServer Run Log

HiveServer receives requests from a client (SQL statement), compile and execute the statement (submitted to Yarn or local MapReduce), and interact with MetaStore to obtain metadata information. The HiveServer run log records a complete SQL execution process.

Generally, if SQL statement running fails, check the HiveServer run log first.

MetaStore Run Log

Typically, if the HiveServer run log contains MetaException or MetaStore connection failure, check the MetaStore run log.

GC Log

Both HiveServer and MetaStore have GC logs. If GC-related problems occur, view the GC logs to quickly locate the cause. For example, if HiveServer or MetaStore frequently restarts, check its GC log.

16.10.2 Causes of Hive Startup Failure

The most common cause of the Hive startup failure is that the MetaStore instance cannot connect to DBService. You can view the detailed error information in the MetaStore logs. The reasons for the failure to connect to DBService are as follows:

Possible Cause 1

DBService does not properly initialize the Hive metabase hivemeta.

Procedure 1

Step 1 Run the following commands:

source /opt/Bigdata/MRS_*XXX*/install/dbservice/.dbservice_profile

gsql -h *DBservice floating IP* **-p 20051 -d hivemeta -U hive -W HiveUser@**

Step 2 If the interaction interface cannot be properly displayed, database initialization fails. If the following error information is displayed, the hivemeta configuration may be lost in the configuration file of the node where DBService is located.

```
org.postgresql.util.PSQLException: FATAL: no pg_hba.conf entry for host "192.168.0.146", database "HIVEMETA"
```

Step 3 Edit **/srv/BigData/dbdata_service/data/pg_hba.conf** by adding **host hivemeta hive 0.0.0.0/0 sha256** to the file.

Step 4 Run the **source /opt/Bigdata/MRS_*XXX*/install/dbservice/.dbservice_profile** command to configure environment variables.

Step 5 Run **gs_ctl -D $GAUSSDATA reload #** to make new configurations take effect.

----End

Possible Cause 2

The floating IP address of DBService is incorrect. As a result, the IP address of the MetaStore node fails to connect to or build mutual trust with the floating IP address, causing MetaStore startup failure.

Procedure 2

The floating IP address of DBService must be an IP address that is not used in the same network segment and cannot be pinged before configuration. Modify the floating IP address of DBService.

16.10.3 "Cannot modify *xxx* at runtime" Is Reported When the set Command Is Executed in a Security Cluster

Symptom

The following error is reported when running the **set** command:

```
0: jdbc:hive2://192.168.1.18:21066/> set mapred.job.queue.name=QueueA;
 Error: Error while processing statement: Cannot modify mapred.job.queue.name at list of params that are allowed to be modified at runtime (state=42000,code=1)
```

Procedure

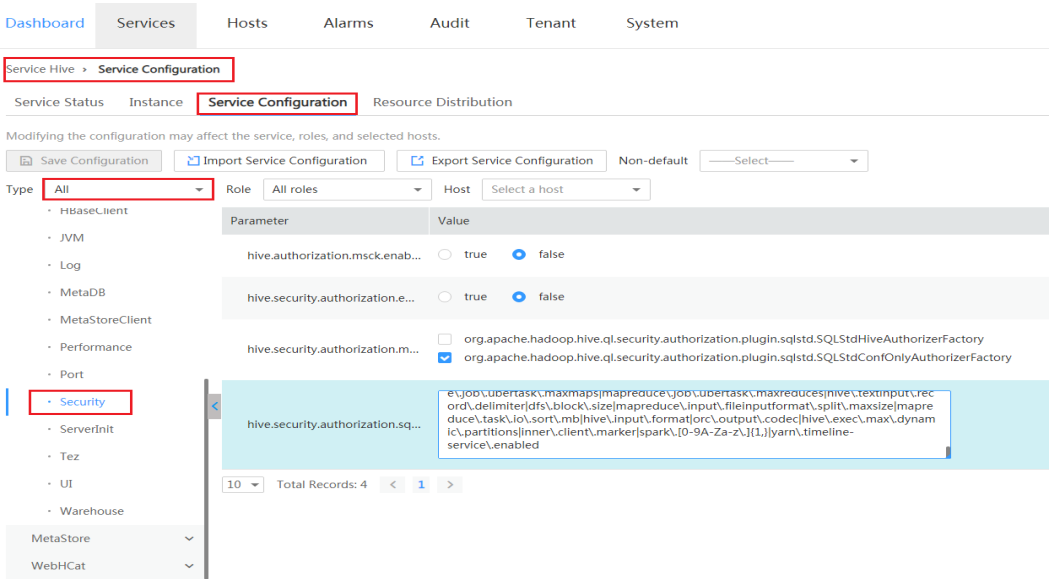
Solution 1:

Step 1 Log in to Manager and modify Hive parameters.

- MRS Manager: Log in to MRS Manager and choose **Services** > **Hive** > **Service Configuration**. Set **Type** to **All** and choose **HiveServer** > **Security**.
- FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Services** > **Hive** > **Configurations** > **All Configurations** > **HiveServer** > **Security**.

Step 2 Add the command parameters to be executed to the **hive.security.authorization.sqlstd.confwhitelist.append** configuration item.

Step 3 Click **Save** and restart **HiveServer**.



----End

Solution 2:

Step 1 Log in to Manager and modify Hive parameters.

- MRS Manager: Log in to MRS Manager and choose **Services** > **Hive** > **Service Configuration**. Set **Type** to **All** and choose **HiveServer** > **Security**.
- FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Services** > **Hive** > **Configurations** > **All Configurations** > **HiveServer** > **Security**.

Step 2 Locate **hive.security.whitelist.switch** and select **OFF**. Click **Save** and restart HiveServer.

----End

16.10.4 How to Specify a Queue When Hive Submits a Job

Symptom

How do I specify a queue when Hive submits a job?

Procedure

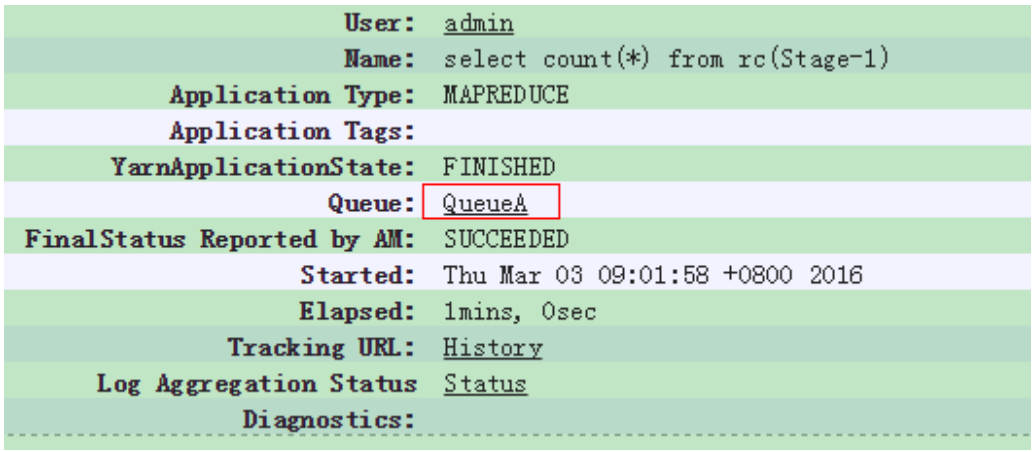
Step 1 Before submitting the job, set the job queue, for example, submitting the job to QueueA.

```
set mapred.job.queue.name=QueueA;
select count(*) from rc;
```

NOTE

The queue name is case sensitive. For example, in this example, **queueA** and **Queuea** are invalid. In addition, the queue must be a leaf queue, and jobs cannot be submitted to a non-leaf queue.

Step 2 After job submission, go to the Yarn page to check the job. The job has been submitted to QueueA.



----End

16.10.5 How to Set Map and Reduce Memory on the Client

Symptom

How do I set Map and Reduce memory on the client?

Procedure

Before SQL statement execution, run the set command to set parameters of clients related to Map/Reduce.

The following parameters are related to Map and Reduce memory:

```
set mapreduce.map.memory.mb=4096; //Memory required by each Map task
set mapreduce.map.java.opts=-Xmx3276M; //Maximum memory used by the JVM of each Map task
set mapreduce.reduce.memory.mb=4096; //Memory required by each Reduce task
set mapreduce.reduce.java.opts=-Xmx3276M; //Maximum memory used by the JVM of each Reduce task
set mapred.child.java.opts=-Xms1024M -Xmx3584M; // This parameter is a global parameter, which is used to set Map and Reduce in a unified manner.
```

NOTE

Parameter settings take effect for the current session only.

16.10.6 Specifying the Output File Compression Format When Importing a Table

Question

How do I specify an output file compression format when importing a table?

Procedure

Hive supports the following compression formats:

```
org.apache.hadoop.io.compress.BZip2Codec
org.apache.hadoop.io.compress.Lz4Codec
org.apache.hadoop.io.compress.DeflateCodec
org.apache.hadoop.io.compress.SnappyCodec
org.apache.hadoop.io.compress.GzipCodec
```

- If global settings are required, that is, all tables need to be compressed, you can perform the following global settings for Hive service configuration parameters on the Manager page:
  - Set **hive.exec.compress.output** to **true**.
  - Set **mapreduce.output.fileoutputformat.compress.codec** to **org.apache.hadoop.io.compress.BZip2Codec**.

    NOTE

    The following parameters take effect only when **hive.exec.compress.output** is set to **true**.
- If it needs to be set at the session level, configure the parameters as follows before command execution:

```
set hive.exec.compress.output=true;
set mapreduce.output.fileoutputformat.compress.codec=org.apache.hadoop.io.compress.SnappyCodec;
```

16.10.7 desc Table Cannot Be Completely Displayed

Symptom

How do I make sure that the description is completely displayed when the desc table is too long?

Procedure

Step 1 When starting Beeline of Hive, set **maxWidth** to **20000**.

```
[root@192-168-1-18 logs]# beeline --maxWidth=20000
scan complete in 3ms
Connecting to
...
Beeline version 1.1.0 by Apache Hive
```

Step 2 (Optional) Run the **beeline -help** command to view the client display settings.

```
 -u <database url>               the JDBC URL to connect to
 -n <username>                   the username to connect as
 -p <password>                   the password to connect as
 -d <driver class>               the driver class to use
 -i <init file>                  script file for initialization
 -e <query>                      query that should be executed
 -f <exec file>                  script file that should be executed
```

```
 --hiveconf property=value       Use value for given property
 --color=[true/false]             control whether color is used for display
 --showHeader=[true/false]        show column names in query results
 --headerInterval=ROWS;           the interval between which heades are displayed
 --fastConnect=[true/false]       skip building table/column list for tab-completion
 --autoCommit=[true/false]        enable/disable automatic transaction commit
 --verbose=[true/false]           show verbose error messages and debug info
 --showWarnings=[true/false]      display connection warnings
 --showNestedErrs=[true/false]    display nested errors
 --numberFormat=[pattern]         format numbers using DecimalFormat pattern
 --force=[true/false]             continue running script even after errors
 --maxWidth=MAXWIDTH              the maximum width of the terminal
 --maxColumnWidth=MAXCOLWIDTH     the maximum width to use when displaying columns
 --silent=[true/false]            be more silent
 --autosave=[true/false]          automatically save preferences
 --outputformat=[table/vertical/csv2/tsv2/dsv/csv/tsv]  format mode for result display
                                Note that csv, and tsv are deprecated - use csv2, tsv2 instead
 --truncateTable=[true/false]     truncate table column when it exceeds length
 --delimiterForDSV=DELIMITER      specify the delimiter for delimiter-separated values output format
(default: |)
 --isolation=LEVEL                set the transaction isolation level
 --nullemptystring=[true/false]  set to true to get historic behavior of printing null as empty string
 --socketTimeOut=n                socket connection timeout interval, in second. The default value is 300.
```

----End

16.10.8 NULL Is Displayed When Data Is Inserted After the Partition Column Is Added

Symptom

1. Run the following command to create a table:
   ```
   create table test_table(
   col1 string,
   col2 string
   )
   PARTITIONED BY(p1 string)
   STORED AS orc tblproperties('orc.compress'='SNAPPY');
   ```
2. Modify the table structure, add partitions, and insert data.
   ```
   alter table test_table add partition(p1='a');
   insert into test_table partition(p1='a') select col1,col2 from temp_table;
   ```
3. Modify the table structure, add columns, and insert data.
   ```
   alter table test_table add columns(col3 string);
   insert into test_table partition(p1='a') select col1,col2,col3 from temp_table;
   ```
4. Query data in the **test_table** table. In the returned result, the values in the **col3** column are all NULL.
   ```
   select * from test_table where p1='a'
   ```
5. Add a table partition and insert data.
   ```
   alter table test_table add partition(p1='b');
   insert into test_table partition(p1='b') select col1,col2,col3 from temp_table;
   ```
6. Query data in the **test_table** table. In the returned result, the value of **col3** is not all NULL.
   ```
   select * from test_table where p1='b'
   ```

Cause Analysis

RESTRICT is the default option for altering a table. In the RESTRICT mode, only the metadata is changed, while the table's partition structure created before the altering operation remains unchanged. However, new partitions created after the altering operation are changed. Therefore, when values of the old partitions are queried, they are all NULL.

Procedure

Add the **cascade** keyword when adding columns, for example:

```
alter table test_table add columns(col3 string) cascade;
```

16.10.9 A Newly Created User Has No Query Permissions

Symptom

When a user is created, an error message is displayed indicating that the user does not have permissions to query data.

```
Error: Error while compiling statement: FAILED: HiveAccessControlException Permission denied: Principal [name=hive, type=USER] does not have following privileges for operation QUERY [[SELECT] on Object [type=TABLE_OR_VIEW, name=default.t1]] (state=42000,code=40000)
```

Cause Analysis

The newly created user does not have the permission to operate the Hive component.

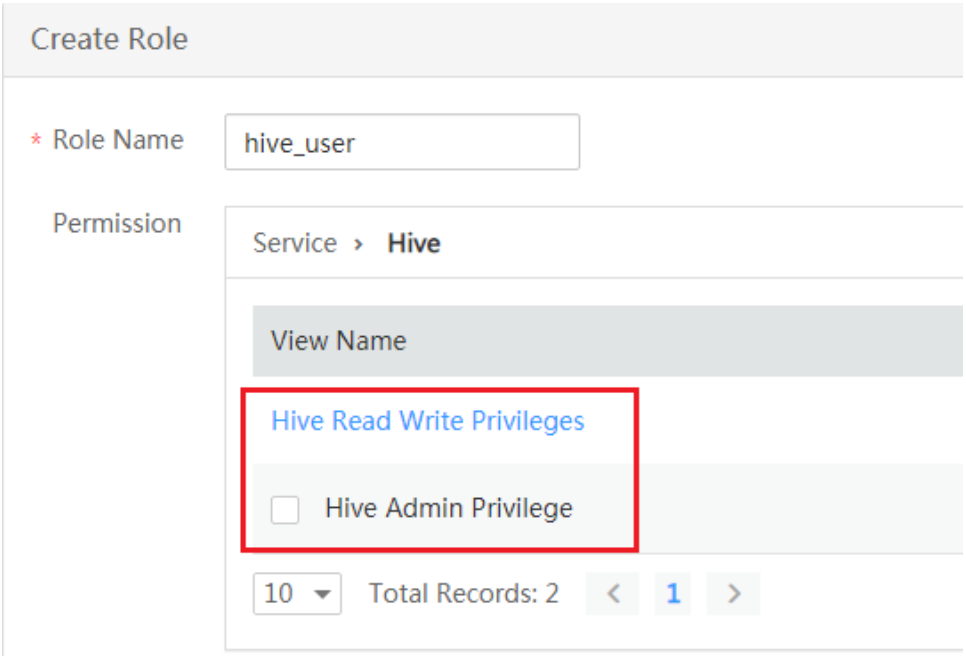
Solution

MRS Manager:

Step 1 Log in to MRS Manager and choose **System** > **Manage Role** > **Create Role**.

Step 2 Enter a role name.

Step 3 In the **Permission** area, select **Hive**. The Hive administrator permission and the read and write permission for Hive tables are displayed.



Step 4 Select **Hive Read Write Privileges**. All databases in the Hive column are displayed.

Step 5 Select the permissions required by the role and click **OK**.

Step 6 On MRS Manager, choose **System** > **Manage User**.

Step 7 Locate the row that contains the created user, and click **Modify** in the **Operation** column.

Step 8 Click **Select and Join User Group**. To use the Hive service, you must add a Hive group.

Step 9 Click **Select and Add Role** and select the role created in **Step 5**.

Step 10 Click **OK**.

----End

FusionInsight Manager:

Step 1 Log in to FusionInsight Manager. Choose **System** > **Permission** > **Role**.

Step 2 Click **Create Role**, and set **Role name** and **Description**.

Step 3 Set **Configure Resource Permission** for the role and select **Hive Read and Write Permission** for the Hive table. All databases in the Hive column are displayed.

Step 4 Select the permissions required by the role and click **OK**.

Step 5 On FusionInsight Manager, choose **System** > **Permission** > **User**.

Step 6 Locate the row that contains the created user, and click **Modify** in the **Operation** column.

Step 7 Click **Add** on the right of **User Group**. To use the Hive service, you must add a Hive group.

Step 8 Click **Add** on the right of **Role** and select the role created in **4**.

Step 9 Click **OK**.

----End

16.10.10 An Error Is Reported When SQL Is Executed to Submit a Task to a Specified Queue

Symptom

The following error is reported when executing SQL to submit a task to Yarn:

```
Failed to submit application_1475400939788_0033 to YARN :
org.apache.hadoop.security.AccessControlException: User newtest cannot submit applications to queue
root.QueueA
```

Cause Analysis

The current login user does not have the permission to submit the YARN queue.

Solution

Grant the submission permission of the specified Yarn queue to the user. On Manager, choose **System** > **Permission** > **User** and bind a role with the queue submission permission to the user.

16.10.11 An Error Is Reported When the "load data inpath" Command Is Executed

Symptom

The following errors are reported when the **load data inpath** command is executed:

- Error 1:
  ```
  HiveAccessControlException Permission denied. Principal [name=user1, type=USER] does not have following privileges on Object [type=DFS_URI, name=hdfs://hacluster/tmp/input/mapdata] for operation LOAD : [OBJECT OWNERSHIP]
  ```
- Error 2:
  ```
  HiveAccessControlException Permission denied. Principal [name=user1, type=USER] does not have following privileges on Object [type=DFS_URI, name=hdfs://hacluster/tmp/input/mapdata] for operation LOAD : [INSERT, DELETE]
  ```
- Error 3:
  ```
  SemanticException [Error 10028]: Line 1:17 Path is not legal ''file:///tmp/input/mapdata'': Move from: file:/tmp/input/mapdata to: hdfs://hacluster/user/hive/warehouse/tmp1 is not valid. Please check that values for params "default.fs.name" and "hive.metastore.warehouse.dir" do not conflict.
  ```

Cause Analysis

The current login user does not have the permission to operate the directory or the file directory format is incorrect.

Solution

Hive has the following requirements on the **load data inpath** command:

- The file owner must be the user who executes the command.
- The current user must have read and write permissions for the file.
- The current user must have permissions to execute the directory of the file.
- The current user must have the write permission on the directory of the table, because the load operation moves the file to the directory.
- The file format must be the same as the storage format specified by the table. For example, if **stored as rcfile** is specified during table creation but the file format is TXT, it is unsatisfied.
- The file must be stored in HDFS. Files in the local file system cannot be specified using the **file://** form.
- The file name cannot start with an underscore (_) or period (.). A file whose name starts with an underscore (_) or period (.) will be ignored.

  The following shows permissions required when user **test_hive** loads data.

  ```
  [root@192-168-1-18 duan]# hdfs dfs -ls /tmp/input2
  16/03/21 14:45:07 INFO hdfs.PeerCache: SocketCache disabled.
  Found 1 items
  -rw-r--r--   3 test_hive hive          6 2016-03-21 14:44 /tmp/input2/input.txt
  ```

16.10.12 An Error Is Reported When the "load data local inpath" Command Is Executed

Symptom

The following errors are reported when the **load data local inpath** command is executed:

- Error 1:
  ```
  HiveAccessControlException Permission denied. Principal [name=user1, type=USER] does not have following privileges on Object [type=LOCAL_URI, name=file:/tmp/input/mapdata] for operation LOAD : [SELECT, INSERT, DELETE]
  ```
- Error 2:
  ```
  HiveAccessControlException Permission denied. Principal [name=user1, type=USER] does not have following privileges on Object [type=LOCAL_URI, name=file:/tmp/input/mapdata] for operation LOAD : [OBJECT OWNERSHIP]
  ```
- Error 3:
  ```
  SemanticException Line 1:23 Invalid path ''/tmp/input/mapdata'': No files matching path file:/tmp/input/mapdata
  ```

Cause Analysis

The current user does not have the permission to operate the directory or the directory does not exist on the node where HiveServer is located.

Solution

NOTE

Generally, you are not advised to use local files to load data to Hive tables. You are advised to store local files in HDFS and then load data from the cluster.

Hive has the following requirements on the **load data local inpath** command:

- The file must be stored on the HiveServer node, because all commands are sent to the active HiveServer for execution.
- User **omm** must have the read permission for the file and read and execution permissions for the directory where the file is located, because the HiveServer process is started by user **omm** in the OS.
- The file owner must be the user who executes the command.
- The current user must have read and write permissions for the file.
- The file format must be the same as the storage format specified by the table. For example, if **stored as rcfile** is specified during table creation but the file format is TXT, it is unsatisfied.
- The file name cannot start with an underscore (_) or period (.). A file whose name starts with an underscore (_) or period (.) will be ignored.

16.10.13 An Error Is Reported When the "create external table" Command Is Executed

Symptom

The following error is reported when the **create external table** *xx(xx int)* **stored as textfile location '/tmp/aaa/aaa'** command is executed.

```
Permission denied. Principal [name=fantasy, type=USER] does not have following privileges on Object [type=DFS_URI, name=/tmp/aaa/aaa] for operation CREATETABLE : [SELECT, INSERT, DELETE, OBJECT OWNERSHIP] (state=42000,code=40000)
```

Cause Analysis

The current login user does not have the read and write permissions for the directory or its parent directory. When an external table is created, whether the current user is checked for its read and write permissions for the specified directory and its subdirectories and subfiles. If the specified directory does not exist, permissions for the parent directory are checked, and so on. If the check results show that the user has no permissions on any directory, "insufficient permission" is reported instead of "The specified directory does not exist".

Solution

Check whether the current user has read and write permissions for the **/tmp/aaa/aaa** path. If the path does not exist, check whether the user has read and write permissions for its parent directory.

16.10.14 An Error Is Reported When the dfs -put Command Is Executed on the Beeline Client

Symptom

Run the following command:

dfs -put /opt/kv1.txt /tmp/kv1.txt

The following error is reported:

```
Permission denied. Principal [name=admin, type=USER] does not have following privileges onObject[type=COMMAND_PARAMS,name=[-put, /opt/kv1.txt, /tmp/kv1.txt]] for operation DFS : [ADMIN PRIVILEGE] (state=,code=1)
```

Cause Analysis

The current login user does not have the permissions to run the command.

Solution

If the current user has the **admin** role, run the **set role admin** command to switch to the **admin** role. If the user does not have the admin role, bind the user with the permissions of the corresponding role on the Manager page.

16.10.15 Insufficient Permissions to Execute the set role admin Command

Symptom

When a user runs the following command:

set role admin

The following error is reported:

```
0: jdbc:hive2://192.168.42.26:21066/> set role admin;
Error: Error while processing statement: FAILED: Execution Error, return code 1 from
org.apache.hadoop.hive.ql.exec.DDLTask. dmp_B doesn't belong to role admin (state=08S01,code=1)
```

Cause Analysis

The current user does not have the permissions of the **admin** role of Hive.

Solution

Step 1 Log in to Manager.

- For versions earlier than MRS 3.x, go to **Step 7**.
- For MRS 3.x or later, choose **Cluster** > **Services** > **Hive**. In the upper right corner of the **Dashboard** page, click **More** and check whether **Enable Ranger** is unavailable.
  - If yes, go to **Step 2**.
  - If no, go to **Step 7**.

Step 2 Choose **Cluster** > **Services** > **Ranger** and click **RangerAdmin** in the **Basic Information** area. The Ranger web UI is displayed.

Step 3 Click the username in the upper right corner, select **Log Out** to log out of the system, and log in to the system as user **rangeradmin**.

Step 4 On the homepage, click **Settings** and choose **Roles**.

Step 5 Click the role with **Role Name** set to **admin**. In the **Users** area, click **Select User** and select a username.

Step 6 Click **Add Users**, select **Is Role Admin** in the row where the username is located, and click **Save**.

Step 7 Choose **System** > **Permission** > **Role** and add a role with the Hive administrator permission.

Step 8 On FusionInsight Manager, choose **System** > **Permission** > **User**.

Step 9 In the **Operation** column of the user, click **Modify**.

Step 10 Bind a role that has the Hive administrator permissions to the user and click **OK**.

----End

16.10.16 An Error Is Reported When UDF Is Created Using Beeline

Symptom

Run the following command:

create function fn_test3 as 'test.MyUDF' using jar 'hdfs:///tmp/udf2/MyUDF.jar'

The following error is reported:

```
Error: Error while compiling statement: FAILED: HiveAccessControlException Permission denied: Principal [name=admin, type=USER] does not have following privileges for operation CREATEFUNCTION [[ADMIN PRIVILEGE] on Object [type=DATABASE, name=default], [ADMIN PRIVILEGE] on Object [type=FUNCTION, name=default.fn_test3]] (state=42000,code=40000)
```

Cause Analysis

To create a permanent function in Hive, role **admin** is required.

Solution

Run the **set role admin** command before running the statement.

16.10.17 Difference Between Hive Service Health Status and Hive Instance Health Status

Question

What is the difference between Hive service health status and Hive instance health status?

Solution

The Hive service health status is displayed on the **Services** page and has four values: **Good**, **Bad**, **Partially Healthy**, and **Unknown**. It depends not only on Hive service availability but also the service status of other related components. Simple SQL is used to check Hive service availability.

Hive instances consist of HiveServer and MetaStore. Their health status is determined by communications between instances and JMX and can be **Good** (normal communications), **Concerning** (abnormal communications), or **Unknown** (no communications).

16.10.18 Hive Alarms and Triggering Conditions

Hive Alarms

Alarm ID	Alarm Severity	Auto Clear	Alarm Name	Alarm Type
16000	Minor	TRUE	Percentage of Sessions Connected to the HiveServer to Maximum Number Allowed Exceeds the Threshold	Fault alarm
16001	Minor	TRUE	Hive Warehouse Space Usage Exceeds the Threshold	Fault alarm
16002	Minor	TRUE	The Successful Hive SQL Operations Lower than The Threshold	Fault alarm
16004	Critical	TRUE	Hive Service Unavailable	Fault alarm

Alarm Triggering Scenarios

- 16000: An alarm is triggered when the ratio of the number of sessions connected to HiveServer to the allowed total number of sessions exceeds the threshold. For example, if the number of connected sessions is 9, the allowed total number of sessions is 12, and the threshold is 70%, an alarm is triggered, because 9/12 > 70%.
- 16001: An alarm is triggered when the ratio of HDFS capacities used by Hive to total HDFS capacities allocated to Hive exceeds the threshold. For example, if 500 GB is allocated to Hive, Hive uses 400 GB, and the threshold is 75%, an alarm is triggered, because 400/500 > 75%.
- 16002: An alarm is triggered when SQL execution success rate is lower than the threshold. If two out of four SQL statements are executed successfully and the threshold is 60%, an alarm is triggered, because 2/4 < 60%.
- 16004: An alarm is triggered when the health status of the Hive service changes to Bad.

NOTE

- MRS Manager: To set the alarm threshold, alarm severity, and alarm triggering time segment, choose **System > Configure Alarm Threshold** on MRS Manager.FusionInsight Manager: Choose **O&M** > **Alarm** > **Thresholds** to set the alarm threshold, alarm severity, and alarm triggering time range.
- Metrics related to Hive running can be viewed on the Hive monitoring interface.

16.10.19 "authentication failed" Is Displayed During an Attempt to Connect to the Shell Client

Symptom

In clusters in security mode, the **beeline** command fails to be executed on the Shell client when the HiveServer service is normal, and the system prompts "authentication failed". The following information is displayed.

```
Debug is true storeKey false useTicketCache true useKeyTab false doNotPrompt false ticketCache is null isInitiator true KeyTab is null refreshKrb5Config is false principal is null tryFirstPass is false useFirstPass is false storePass is false clearPass is false
Acquire TGT from Cache
Credentials are no longer valid
Principal is null
null credentials from Ticket Cache
[Krb5LoginModule] authentication failed
No password provided
```

Cause Analysis

- The client user does not perform security authentication.
- Kerberos authentication expired.

Solution

Step 1 Log in to the node where the Hive client is installed.

Step 2 Run the **source** *Cluster client installation directory*/**bigdata_env** command.

Run the **klist** command to check whether there is a valid ticket in the local end. The following information shows that the ticket became valid at 14:11:42 on December 24, 2016, and expired at 14:11:40 on December 25, 2016. In the period of time, the ticket was available.

```
klist
Ticket cache: FILE:/tmp/krb5cc_0
Default principal: xxx@HADOOP.COM
Valid starting     Expires            Service principal
12/24/16 14:11:42  12/25/16 14:11:40  krbtgt/HADOOP.COM@HADOOP.COM
```

Step 3 Run the **kinit** ***username*** command for authentication and log in to the client again.

----End

16.10.20 Failed to Access ZooKeeper from the Client

Symptom

In clusters in security mode, when the HiveServer service is normal and SQL is executed by using the JDBC interface to connect to HiveServer, "The ZooKeeper client is AuthFailed" is reported.

```
14/05/19 10:52:00 WARN utils.HAClientUtilDummyWatcher: The ZooKeeper client is AuthFailed
 14/05/19 10:52:00 INFO utils.HiveHAClientUtil: Exception thrown while reading data from znode.The possible reason may be connectionless. This is recoverable. Retrying..
 14/05/19 10:52:16 WARN utils.HAClientUtilDummyWatcher: The ZooKeeper client is AuthFailed
 14/05/19 10:52:32 WARN utils.HAClientUtilDummyWatcher: The ZooKeeper client is AuthFailed
 14/05/19 10:52:32 ERROR st.BasicTestCase: Exception: Could not establish connection to active hiveserver
 java.sql.SQLException: Could not establish connection to active hiveserver
```

Or an error is reported stating "Unable to read HiveServer2 configs from ZooKeeper":

```
Exception in thread "main" java.sql.SQLException: org.apache.hive.jdbc.ZooKeeperHiveClientException: Unable to read HiveServer2 configs from ZooKeeper

at org.apache.curator.framework.imps.GetChildrenBuilderImpl.forPath(GetChildrenBuilderImpl.java:38)
```

Cause Analysis

- When the client connects to HiveServer, the HiveServer address is automatically obtained from ZooKeeper. If ZooKeeper connection authentication is abnormal, the HiveServer address cannot be obtained from ZooKeeper correctly.
- During ZooKeeper connection authentication, **krb5.conf**, **principal**, **keytab**, and related information must be loaded to the client. Authentication failure causes are as follows:
  - The **user.keytab** path is incorrectly entered.
  - **user.principal** is incorrectly entered.
  - The cluster has switched the domain name. However, the old principal is used when the client combines the URL.

- The client cannot pass Kerberos authentication due to firewall settings. Ports 21730 (TCP), 21731 (TCP/UDP), and 21732 (TCP/UDP) need to be opened for Kerberos.

Solution

Step 1 Ensure that the user can properly access the **user.keytab** file in related paths on the client node.

Step 2 Ensure that the user's **user.principal** corresponds to the specified **keytab** file.

Run the **klist -kt keytabpath/user.keytab** command to check the file.

Step 3 If the cluster has switched the domain name, the **principal** field used in the URL must be the new domain name.

For example, the default value is **hive/hadoop.hadoop.com@HADOOP.COM**. If the cluster has switched the domain name, the field must be changed accordingly. For example, if the domain name is **abc.com**, enter **hive/hadoop.abc.com@ABC.COM**.

Step 4 Ensure that authentication is normal and HiveServer can be connected.

Run the following commands on the client:

source *Client installation directory*/**bigdata_env**

kinit *username*

Run the **beeline** command on the client to ensure normal running.

----End

16.10.21 "Invalid function" Is Displayed When a UDF Is Used

Symptom

When a UDF is created on the Hive client using Spark, "Error 10011" indicating "invalid function" is reported:

```
Error: Error while compiling statement: FAILED: SemanticException [Error 10011]: Line 1:7 Invalid function 'test_udf' (state=42000,code=10011)
```

The preceding problem occurs when multiple HiveServers use a UDF. For example, if metadata is not synchronized in time when the UDF created on HiveServer2 is used on HiveServer1, the preceding error is reported when clients on HiveServer1 are connected.

Cause Analysis

Metadata shared by multiple HiveServers or Hive and Spark is not synchronized, causing memory data inconsistency between different HiveServer instances and invalid UDF.

Solution

Synchronize new UDF information to HiveServer and reload the function.

16.10.22 Hive Service Status Is Unknown

Cause Analysis

The Hive service stops.

Solution

Restart the Hive service.

16.10.23 Health Status of a HiveServer or MetaStore Instance Is Unknown

Symptom

The health status of a HiveServer or MetaStore instance is unknown.

Cause Analysis

The HiveServer or MetaStore instance is stopped.

Solution

Restart the HiveServer or MetaStore instance.

16.10.24 Health Status of a HiveServer or MetaStore Instance Is Concerning

Symptom

The health status of the HiveServer or MetaStore instance is **Concerning**.

Cause Analysis

The HiveServer or MetaStore instance cannot be normally started. For example, when modifying the MetaStore/HiveServer GC parameter, you can view the startup log of the corresponding process, for example, the **hiveserver.out(hadoop-omm-jar-192-168-1-18.out)** file. The following exception occurs:

Error: Could not find or load main class Xmx2048M

The preceding information indicates that **Xmx2048M** is used as the startup parameter of the Java process instead of the JVM during the startup of the Java virtual machine. As shown in the following information, the hyphen (-) is deleted mistakenly.

```
METASTORE_GC_OPTS=Xms1024M Xmx2048M -DIgnoreReplayReqDetect
-XX\:CMSFullGCsBeforeCompaction\=1 -XX\:+UseConcMarkSweepGC
-XX\:+CMSParallelRemarkEnabled -XX\:+UseCMSCompactAtFullCollection
-XX\:+ExplicitGCInvokesConcurrent -server -XX\:MetaspaceSize\=128M
-XX\:MaxMetaspaceSize\=256M
```

Solution

Check the latest changes to detect incorrect settings.

```
METASTORE_GC_OPTS=Xms1024M -Xmx2048M -DIgnoreReplayReqDetect
-XX\:CMSFullGCsBeforeCompaction\=1 -XX\:+UseConcMarkSweepGC
-XX\:+CMSParallelRemarkEnabled -XX\:+UseCMSCompactAtFullCollection
-XX\:+ExplicitGCInvokesConcurrent -server -XX\:MetaspaceSize\=128M
-XX\:MaxMetaspaceSize\=256M
```

16.10.25 Garbled Characters Returned upon a select Query If Text Files Are Compressed Using ARC4

Symptom

If a Hive query result table is compressed and stored using the ARC4 algorithm, garbled characters are returned after the select * query is conducted in the result table.

Cause Analysis

The default Hive compression format is not ARC4 or output compression is disabled.

Solution

Step 1 If garbled characters are returned after the SETECT query, set the following in Beeline:

set mapreduce.output.fileoutputformat.compress.codec=org.apache.hadoop.io.encryption.arc4.ARC4BlockCodec;

set hive.exec.compress.output=true;

Step 2 Import the table to a new table using block decompression.

insert overwrite table tbl_result select * from tbl_source;

Step 3 Perform the query again.

select * from tbl_result;

----End

16.10.26 Hive Task Failed to Run on the Client But Successful on Yarn

Symptom

When Hive task running fails, an error similar to the following is reported on the client:

```
Error:Invalid OperationHandler:OperationHander [opType=EXECUTE_STATEMENT,getHandleIdentifier()=XXX]
(state=,code=0)
```

However, the MapReduce task that is submitted by the task to Yarn is successfully executed.

```
0: jdbc:hive2://189.120.204.104:21066/> select count(*) from test1;
INFO  : Number of reduce tasks determined at compile time: 1

 85 ce e4 8a 01 59 ce 92 52 e4 8e 07 d8 0c
INFO  : The url to track the job: https://189-120-204-104:26001/proxy/application_1484563934624_0003/
INFO  : Starting Job = job_1484563934624_0003, Tracking URL = https://189-120-204-104:26001/proxy/application_1484563934624_0003/
INFO  : Kill Command = /opt/huawei/Bigdata/FusionInsight-Hive-1.1.0/hadoop/bin/hadoop job  -kill job_1484563934624_0003
INFO  : Hadoop job information for Stage-1: number of mappers: 1; number of reducers: 1
INFO  : 2017-01-17 11:46:12,579 Stage-1 map = 0%,  reduce = 0%
INFO  : 2017-01-17 11:46:23,243 Stage-1 map = 100%,  reduce = 0%, Cumulative CPU 2.32 sec
Error: Invalid OperationHandle: OperationHandle [opType=EXECUTE_STATEMENT, getHandleIdentifier()=386323de-dfla-4299-826e-96368d4baf80] (state=,code=0)
0: jdbc:hive2://189.120.204.215:21066/>
```

Cause Analysis

The cluster where the error occurs has two HiveServer instances. The error in the log of one HiveServer instance is the same as the error (Error: Invalid OperationHandler) reported on the client. In the log of the other HiveServer instance, **START_UP** information similar to the following is printed when the error occurs, which indicates that the process is killed and restarted during that time. Because the HiveServer instance the task process plans to connect to is killed, it connects to the other healthy one, causing the error.

```
2017-02-15 14:40:11,309 | INFO  | main | STARTUP_MSG:
/************************************************************
STARTUP_MSG: Starting HiveServer2
STARTUP_MSG:   host = XXX-120-85-154/XXX.120.85.154
STARTUP_MSG:   args = []
STARTUP_MSG:   version = 1.3.0
```

Solution

Submit the task again and ensure that the HiveServer process is not manually restarted during task execution.

16.10.27 An Error Is Reported When the select Statement Is Executed

Symptom

When the **select count(*) from XXX** statement is executed, the client reports the error "Error:Error while processing statement :FAILED:Execution Error,return code 2 from...".

return code 2 indicates that the task fails because an error is reported during the execution of the MapReduce task.

```
0: jdbc:hive2://134.160.37.21:21066/> select count(*) from src.gn_data_info_gz where day_id='18' and timenap='10';

INFO  : MapReduce Total cumulative CPU time: 0 days 1 hours 41 minutes 18 seconds 400 msec
ERROR : Ended Job = job_1482323187492_57815 with errors
Error: Error while processing statement: FAILED: Execution Error, return code 2 from org.apache.hadoop.hive.ql.exec.mr.MapRedTask (state=08S01,code=2)
0: jdbc:hive2://134.160.37.21:21066/>
```

Cause Analysis

1. Go to the native Yarn page to check the MapReduce task logs. The check result shows that the error occurs due to unidentified compression mode. The file name suffix is **.gzip** but the stack reports **.zlib**.

```
2017-01-18 16:22:07,566 INFO [main] org.apache.hadoop.hive.ql.exec.MapOperator: 4 Close done

at org.apache.thrift.transport.TSaslTransport.readLength(TSaslTransport.java:376)
at org.apache.thrift.transport.TSaslTransport.readFrame(TSaslTransport.java:453)
at org.apache.thrift.transport.TSaslTransport.read(TSaslTransport.java:435)
...
```

As indicated by the MetaStore log, StackOverFlow occurs.

```
2017-04-22 01:00:58,834 | ERROR | pool-6-thread-208 | java.lang.StackOverflowError
at org.datanucleus.store.rdbms.sql.SQLText.toSQL(SQLText.java:330)
at org.datanucleus.store.rdbms.sql.SQLText.toSQL(SQLText.java:339)
at org.datanucleus.store.rdbms.sql.SQLText.toSQL(SQLText.java:339)
at org.datanucleus.store.rdbms.sql.SQLText.toSQL(SQLText.java:339)
at org.datanucleus.store.rdbms.sql.SQLText.toSQL(SQLText.java:339)
```

Cause Analysis

The processing logic of the drop partition operation is to find all the partitions that meet the conditions, combine them, and delete them together. However, because the number of partitions is too large and the data stack for deleting metadata is deep, StackOverFlow errors occur.

Solution

Delete partitions in batches.

16.10.29 Failed to Start a Local Task

Symptom

1. When operations such as JOIN are performed for a small amount of data, a local task will be started. However, the execution fails and reports the following error:

```
jdbc:hive2://10.*.*.*:21066/> select a.name ,b.sex from student a join student1 b on (a.name = b.name);
ERROR : Execution failed with exit status: 1
ERROR : Obtaining error information
ERROR :
Task failed!
Task ID:
  Stage-4
...
Error: Error while processing statement: FAILED: Execution Error, return code 1 from
org.apache.hadoop.hive.ql.exec.mr.MapredLocalTask (state=08S01,code=1)
...
```

2. The HiveServer log shows that the local task fails to start.

```
2018-04-25 16:37:19,296 | ERROR | HiveServer2-Background-Pool: Thread-79 | Execution failed with exit status: 1 | org.apache.hadoop.hive.ql.session.SessionState $LogHelper.printError(SessionState.java:1016)

        at java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:617)
        at java.lang.Thread.run(Thread.java:745)
```

3. The **hs_err_pid_*****.log** file in the HiveServer log directory **/var/log/Bigdata/hive/hiveserver** contains an error about insufficient memory.

```
# There is insufficient memory for the Java Runtime Environment to continue.
# Native memory allocation (mmap) failed to map 20776943616 bytes for committing reserved memory.
  ...
```

Cause Analysis

When Hive executes JOIN for a small amount of data, MapJoin is generated. During MapJoin execution, a local task is started. JVM memory launched by the local task inherits the memory of the parent process.

When multiple JOIN operations are executed, multiple local tasks are started. If the host is out of memory, the local tasks fail to start.

Solution

Step 1 Search for the **hive.auto.convert.join** parameter and change the value of **hive.auto.convert.join** in Hive to **false**. Save the configuration and restart the service.

The value change may deteriorate service performance. You can perform the next step to avoid adverse impacts on the performance.

Step 2 Search for the **HIVE_GC_OPTS** parameter and decrease the value of **Xms** based on service requirements. The minimum value is half that of **Xmx**. After the modification, save the configuration and restart the service.

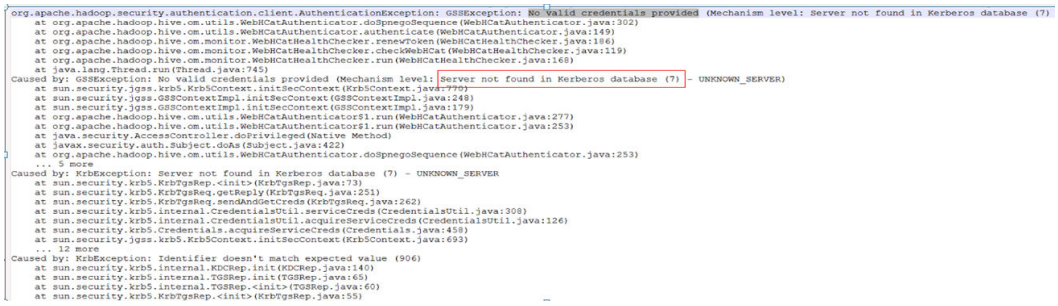
----End

16.10.30 Failed to Start WebHCat

Symptom

WebHCat fails to be started after the hostname is changed.

The following error is reported in the WebHCat startup log (**/var/log/Bigdata/hive/webhcat/hive.log**) of the corresponding node:



Cause Analysis

1. The server account of the MRS WebHCat role involves the hostname. If you change the hostname after the installation, WebHCat fails to start.
2. The one-to-many or many-to-one association between IP addresses and hostnames is configured in the **/etc/hosts** file. As a result, the IP address and hostname cannot be obtained correctly after the **hostname** and **hostname -i** commands are executed.

Solution

Step 1 Change the hostname of the modified node to the hostname before the cluster is installed.

Step 2 Check whether the **/etc/hosts** of the node where WebHCat is located is correctly configured.

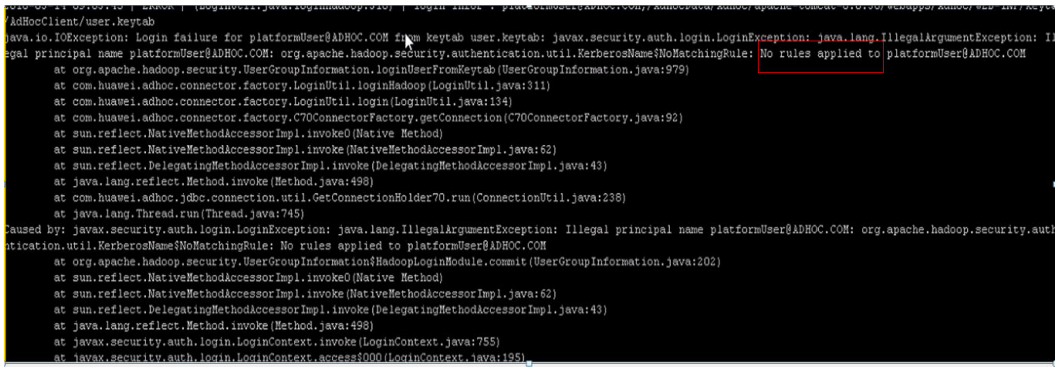
Step 3 Restart WebHCat.

----End

16.10.31 Sample Code Error for Hive Secondary Development After Domain Switching

Symptom

In the sample code for Hive secondary development, an error "No rules applied to ****" is reported:



Cause Analysis

1. The sample code for Hive secondary development loads **core-site.xml** file that is loaded through classload by default. Therefore, you need to put the configuration file to the **classpath** directory of the startup program.
2. If the domain name of the cluster is changed, the **core-site.xml** file will change. You need to download the latest **core-site.xml** file and save it to the **classpath** directory where the sample code for Hive secondary development is located.

Solution

Step 1 Download the latest client of the Hive cluster to obtain the latest **core-site.xml** file.

Step 2 Save the **core-site.xml** file to the **classpath** directory where the sample code process for Hive secondary development is located.

----End

16.10.32 MetaStore Exception Occurs When the Number of DBService Connections Exceeds the Upper Limit

Symptom

By default, the maximum number of connections to DBService is 300. If the number of connections is greater than 300 due to heavy traffic, an exception occurs in MetaStore and error "slots are reserved for non-replication superuser connections" is reported.

```
2018-04-26 14:58:55,657 | ERROR | BoneCP-pool-watch-thread | Failed to acquire connection to jdbc:postgresql://10.*.*.*:20051/hivemeta?socketTimeout=60. Sleeping for 1000 ms. Attempts left: 9 | com.jolbox.bonecp.BoneCP.obtainInternalConnection(BoneCP.java:292)

at java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:617)
at java.lang.Thread.run(Thread.java:745)
```

Cause Analysis

Heavy service traffic causes more than 300 connections to DBService, and the maximum number of connections to DBService needs to be increased.

Solution

Step 1 Search for **dbservice.database.max.connections** and set it to a proper value not greater than **1000**.

Step 2 Save the configuration and restart the affected services or instances.

Step 3 If the fault persists, check the service code for any connection leaks.

----End

16.10.33 "Failed to execute session hooks: over max connections" Reported by Beeline

Symptom

The default maximum connections to HiveServer are 200. When the number of connections exceeds 200, Beeline reports error "Failed to execute session hooks: over max connections."

```
beeline> [root@172-27-16-38 c70client]# beeline

    at org.apache.hive.jdbc.HiveQueryResultSet.next(HiveQueryResultSet.java:358)
Error: Error retrieving next row (state=,code=0)
```

Cause Analysis

- The data volume is excessively large.
- Users use the **select * from table_name;** statement for query in the whole table. There is a large amount of data in the table.
- The default startup memory of Beeline is 128 MB. The returned result set is too large during query, overloading Beeline.

Solution

Step 1 Before running **select count(*) from table_name;**, check the amount of data to be queried and determine whether to display data of this magnitude in Beeline.

Step 2 If a certain amount of data needs to be displayed, adjust the JVM parameter of the Hive client. Add **export HIVE_OPTS=-Xmx1024M** (change the value based on service requirements) to **component_env** in the **/Hive** directory of the Hive client. Run the **source** command to obtain the **/bigdata_env** directory on the client.

----End

16.10.35 Task Execution Fails Because the Input File Number Exceeds the Threshold

Symptom

When Hive performs a query operation, error message "Job Submission failed with exception 'java.lang.RuntimeException(input file number exceeded the limits in the conf;input file num is: 2380435,max heap memory is: 16892035072,the limit conf

is: 500000/4)'" is displayed. The value in the error message varies depending on the actual situation. The error details are as follows:

```
ERROR : Job Submission failed with exception 'java.lang.RuntimeException(input file numbers exceeded the limits in the conf;
 input file num is: 2380435 ,
 max heap memory is: 16892035072 ,
 the limit conf is: 500000/4)'
java.lang.RuntimeException: input file numbers exceeded the limits in the conf;

    at java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:617)
    at java.lang.Thread.run(Thread.java:745)

Error: Error while processing statement: FAILED: Execution Error, return code 1 from
org.apache.hadoop.hive.ql.exec.mr.MapRedTask (state=08S01,code=1)
```

Cause Analysis

MRS uses the ratio of maximum files to the maximum HiveServer heap memory to determine the number of input files allowed in a MapReduce job submission. Default value **500000/4** indicates that each 4 GB of heap memory allows a maximum of 500,000 input files. An error occurs if the number of input files exceeds this limit.

Solution

Step 1 Search for **hive.mapreduce.input.files2memory** and set it to a proper value based on the actual memory and task.

Step 2 Save the configuration and restart the affected services or instances.

Step 3 If the fault persists, adjust the GC parameter of the HiveServer based on service requirements.

----End

16.10.36 Task Execution Fails Because of Stack Memory Overflow

Symptom

When Hive performs a query operation, error "Error running child: java.lang.StackOverflowError" is reported. The error details are as follows:

```
FATAL [main] org.apache.hadoop.mapred.YarnChild: Error running child : java.lang.StackOverflowError
at org.apache.hive.come.esotericsoftware.kryo.io.Input.readVarInt(Input.java:355)
at

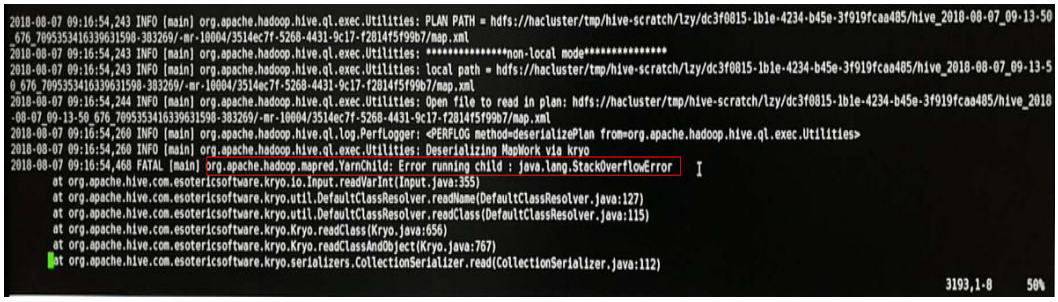
at org.apache.hive.come.esotericsoftware.kryo.Kryo.readClass(Kryo.java.656)
at org.apache.hive.come.esotericsoftware.kryo.kryo.readClassAnd0bject(Kryo.java:767)
at
org.apache.hive.come.esotericsoftware.kryo.serializers.collectionSerializer.read(CollectionSerializer.java:112)
```



Cause Analysis

Error "java.lang.StackOverflowError" indicates the memory overflow of the thread stack. It may occur if there are multiple levels of calls (for example, infinite recursive calls) or the thread stack is too small.

Solution

Adjust the stack memory in the JVM parameters of the Map and Reduce stages during execution of a MapReduce job, that is, **mapreduce.map.java.opts** (adjusting the stack memory of Map) and **mapreduce.reduce.java.opts** (adjusting the stack memory of Reduce). The following uses the **mapreduce.map.java.opts** parameter as an example.

- To increase the Map memory temporarily (only valid for Beeline):

  Run the **set mapreduce.map.java.opts=-Xss8G;** command on the Beeline client. (Change the value as required.)

- To permanently increase the Map memory specified by the **mapreduce.map.memory.mb** and **mapreduce.map.java.opts** parameters:

  a. Add custom parameter **mapreduce.map.java.opts** and set it to a proper value.

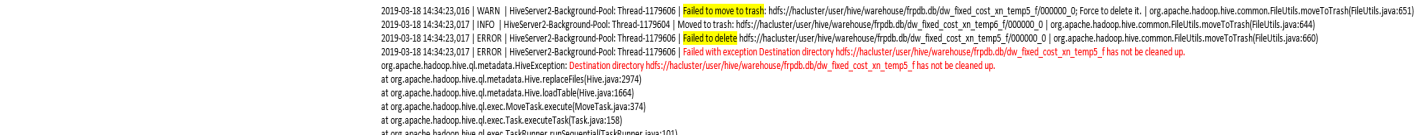
  b. Save the configuration and restart the affected services or instances.

  Note that the modification takes effect after a service restart. During the restart, the Hive service is unavailable.

16.10.37 Task Failed Due to Concurrent Writes to One Table or Partition

Symptom

When Hive executes an INSERT statement, an error is reported indicating that a file or directory already exists or is cleared in HDFS. The error details are as follows:



Cause Analysis

1. Check the start time and end time of the task based on the HiveServer audit logs.
2. Check whether data is inserted into the same table or partition in the time segment.
3. Hive does not support concurrent data insertion for a table or partition. As a result, multiple tasks perform operations on the same temporary data directory, and one task moves the data of another task, causing task failure.

Solution

The service logic is modified so that data is inserted to the same table or partition in single thread mode.

16.10.38 Hive Task Failed Due to a Lack of HDFS Directory Permission

Symptom

An error message is displayed, indicating that the user does not have the permission to access the HDFS directory.

```
2019-04-09 17:49:19,845 | ERROR | HiveServer2-Background-Pool: Thread-3160445 | Job Submission failed with exception 'org.apache.hadoop.security.AccessControlException(Permission denied: user=hive_quanxian, access=READ_EXECUTE, inode="/user/hive/warehouse/bigdata.db/gd_ga_wa_swryswjl":zhongao:hive:drwx------

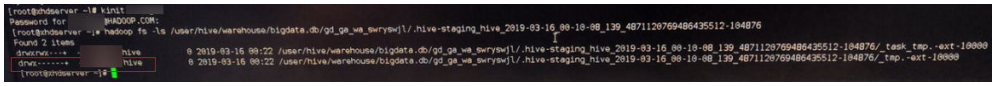
at org.apache.hadoop.security.UserGroupInformation.doAs(UserGroupInformation.java:1781)
at org.apache.hadoop.ipc.Server$Handler.run(Server.java:2254)
)'
```

Cause Analysis

1. According to the stack information, the permission on the subdirectory fails to be checked.
   ```
   org.apache.hadoop.hdfs.server.namenode.FSPermissionChecker.checkSubAccess(FSPermissionChecker.ja
   va:300)
   ```
2. Check the permission of all files and directories in HDFS. The permission of a directory is 700 (only the file owner can access the directory). It is confirmed that an abnormal directory exists.



Solution

1. Check whether the file is imported manually. If not, delete the file or directory.
2. If the file or directory cannot be deleted, change the file or directory permission to 770.

16.10.39 Failed to Load Data to Hive Tables

Symptom

After creating a table, a user runs the **LOAD** command to import data to the table. However, the following problem occurs during the import:

```
.....
> LOAD DATA INPATH '/user/tester1/hive-data/data.txt' INTO TABLE employees_info;
Error: Error while compiling statement: FAILED: SemanticException Unable to load data to destination table.
Error: The file that you are trying to load does not match the file format of the destination table.
(state=42000,code=40000)
.....
```

Cause Analysis

1. The storage format is not specified during table creation, and the default format RCFile is used.
2. However, the data to be imported is in TEXTFILE format.

Solution

This problem is caused by an application defect. You can use a proper method based on site requirements only by ensuring that the storage format specified by the table is the same as the format of the data to be imported.

- Method 1:

  Specify the storage format when creating a table as a user who has the Hive table operation permission. For example:

  CREATE TABLE IF NOT EXISTS employees_info(name STRING,age INT) ROW FORMAT DELIMITED FIELDS TERMINATED BY ',' STORED AS TEXTFILE;

  Specify the format of the data to be imported as TEXTFILE.
- Method 2:

  Import RCFile data, but not TEXTFILE data.

16.10.40 HiveServer and HiveHCat Process Faults

Issue

The HiveServer and WebHCat processes in the customer cluster are faulty.

Symptom

The HiveServer and WebHCat processes on the Master2 node in the MRS cluster are faulty. After the restart, the processes are still faulty.

Cause Analysis

On Manager, start the faulty HiveServer process. Log in to the background and search for the error information at the corresponding time point in the **hiveserver.out** log file. The error information is as follows: **error parsing conf mapred-site.xml** and **Premature end of file**. Restart WebHCat. The same error is reported because the **mapred-site.xml** file fails to be parsed.

Procedure

1. Log in to the Master2 node as user **root**.
2. Run the **find / -name 'mapred-site.xml'** command to obtain the location of the **mapred-site.xml** file.
   - The path of HiveServer is **/opt/Bigdata/***Cluster version***/1_13_HiveServer/etc/mapred-site.xml**.
   - The path of WebHCat is **/opt/Bigdata/***Cluster version***/1_13_WebHCat/etc/mapred-site.xml**.

3. Check whether the **mapred-site.xml** file is normal. In this case, the configuration file is empty. As a result, the parsing fails.
4. Restore the **mapred-site.xml** file. Run the **scp** command to copy the configuration file in the corresponding directory on the Master1 node to the corresponding directory on the Master2 node to replace the original file.
5. Run the **chown omm:wheel mapred-site.xml** command to change the owner group and user.
6. On Manager, restart the faulty HiveServer and WebHCat processes.

16.10.41 An Error Occurs When the INSERT INTO Statement Is Executed on Hive But the Error Message Is Unclear

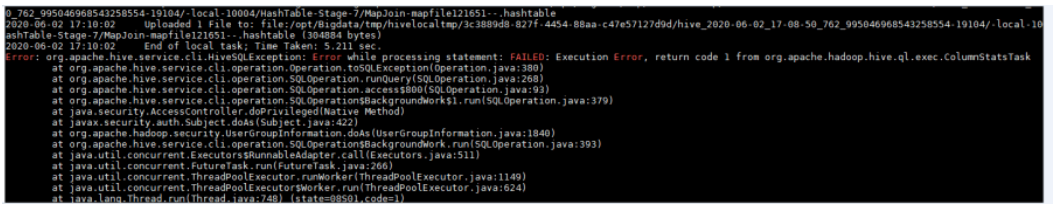
Issue

An error is reported when a user uses MRS Hive to execute a SQL statement.

Symptom

When a user uses MRS Hive to execute a SQL statement, the following error message is displayed.

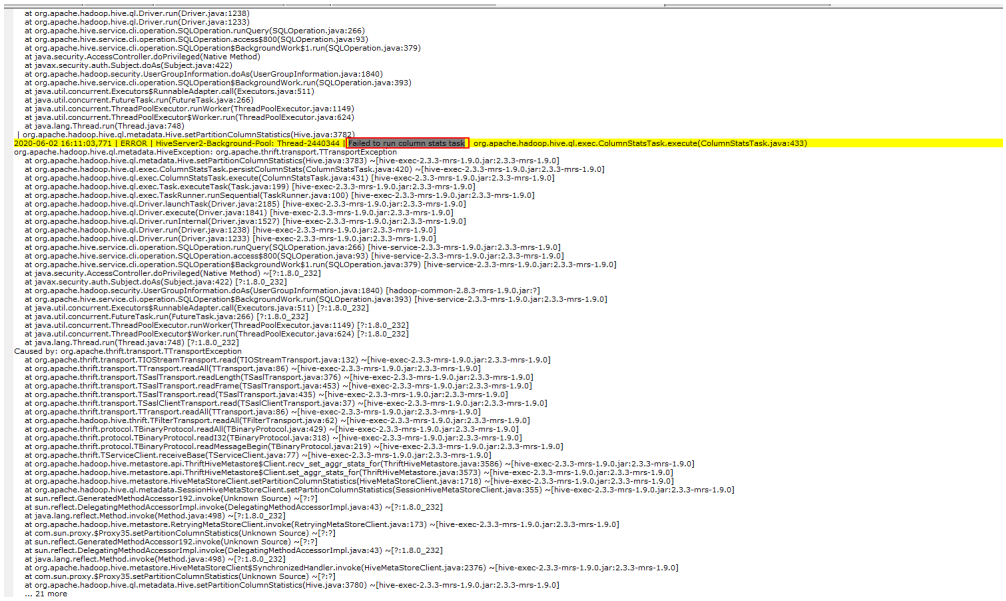
Figure 16-38 Error reported when MRS Hive executes a SQL statement



Cause Analysis

1. The HiveServer log shows the following message at the time when the error is reported.

Figure 16-39 HiveServer log



2. No important information is found in that log, but the **metadata** field is found in the stack. Therefore, the error may be related to MetaStore.

Figure 16-40 Metadata in the stack

3. The MetaStore log shows the following error information.

Figure 16-41 MetaStore log

The error context indicates that an error occurs during SQL statement execution, and the following information is displayed in the error message:

```
Caused by: org.postgresql.util.PSQLException: ERROR: value too long for type character varying(4000)
```

The SQL statement fails because the length of all columns exceeds 4000 bytes. The restriction needs to be modified.

Procedure

Step 1 Log in to any master node in the cluster as user **root** and run the **su - omm** command to switch to user **omm**.

Step 2 Run the following command to log in to GaussDB:

gsql -p 20051 -d hivemeta -U *username* -W *password*

Step 3 Run the following command to modify the restriction:

alter table PARTITION_PARAMS alter column PARAM_VALUE type varchar(6000);

----End

16.10.42 Timeout Reported When Adding the Hive Table Field

Issue

An error message is reported when adding the Hive table fields.

Symptom

Hive executes **ALTER TABLE table_name ADD COLUMNS(column_name string) CASCADE** on tables that contain more than 10,000 partitions. The error information is as follows:

```
Timeout when executing method: alter_table_with_environment_context; 600525ms exceeds 600000ms
```

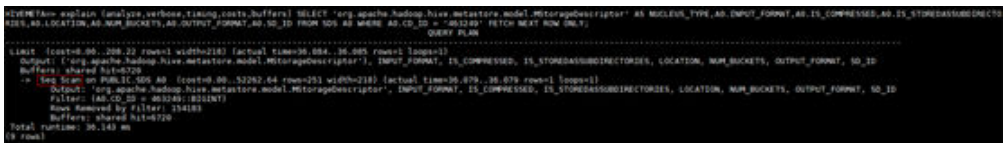
Cause Analysis

1. The MetaStore client connection times out. The default timeout interval for the connection between the MetaStore client and server is 600 seconds. On FusionInsight Manager, increase the value of **hive.metastore.client.socket.timeout** to **3600s**.
2. Another error is reported:
   ```
   Error: org.apache.hive.service.cli.HiveSQLException: Error while processing statement: FAILED: Execution Error, return code 1 from org.apache.hadoop.hive.ql.exec.DDLTask. Unable to alter table. java.net.SocketTimeoutException: Read timed out
   ```
   JDBC connection timeout interval of the MetaStore metadata. The default value is 60 ms.
3. Increase the value of **socketTimeout** in **javax.jdo.option.ConnectionURL** to **60000**. The initial error is still reported.
   ```
   Timeout when executing method: alter_table_with_environment_context;3600556ms exceeds 3600000ms
   ```
4. Increase the values of parameters such as **hive.metastore.batch.retrieve.max**, **hive.metastore.batch.retrieve.table.partition.max**, and **dbservice.database.max.connections**. The problem persists.
5. It is suspected that the problem is caused by the GaussDB because adding a field will traverse each partition to execute **getPartitionColumnStatistics** and **alterPartition**.
6. Run the **gsql -p 20051 -U omm -W dbserverAdmin@123 -d hivemeta** command as user **omm** to log in to the Hive metabase.

7. Run **select * from pg_locks**. No lock wait is found.
8. Run **select * from pg_stat_activity;**. It is found that the process execution takes a long time.

```
SELECT 'org.apache.hadoop.hive.metastore.model.MPartitionColumnStatistics'AS
NUCLEUS_TYPE,A0.AVG_COL_LEN,A0."COLUMN_NAME",A0.COLUMN_TYPE,A0.DB_NAME,A0.BIG_DECI
MAL_HIGH_VALUE,A0.BIG_DECIMAL_LOW_VALUE,A0.DOUBLE_HIGH_VALUE,A0.DOUBLE_LOW_VALUE,
A0.LAST_ANALYZED,A0.LONG_HIGH_VALUE,A0.LONG_LOW_VALUE,A0.MAX_COL_LEN,A0.NUM_DISTIN
CTS,A0.NUM_FALSES,A0.NUM_NULLS,A0.NUM_TRUES,A0.PARTITION_NAME,A0."TABLE_NAME",A0.CS_
ID,A0.PARTITION_NAMEAS NUCORDER0 FROM PART_COL_STATS A0 WHERE A0."TABLE_NAME" =
'$1' ANDA0.DB_NAME = '$2' AND A0.PARTITION_NAME = '$3' AND((((((A0."COLUMN_NAME" = '$4')
OR (A0."COLUMN_NAME" ='$5')) OR (A0."COLUMN_NAME" = '$6')) OR (A0."COLUMN_NAME"
='$7')) OR (A0."COLUMN_NAME" = '$8')) OR (A0."COLUMN_NAME" ='$9')) ORDER BY NUCORDER0;
```

9. Run the **gs_guc reload -c log_min_duration_statement=100 -D /srv/BigData/dbdata_service/data/** command to start SQL recording. It is found that the execution duration of the **Run select * from pg_sta...** statement is **700 ms**, and more than 10,000 commands are executed because there are more than 10,000 partitions.
10. Add explain (analyze, verbose, timing, costs, buffers) before the SQL statement to analyze the execution plan. It is found that the entire table needs to be scanned during execution.



11. Check the index. It is found that the index does not meet the leftmost match rule.

```
HIVEMETA=# \d+ PART_COL_STATS
                                    Table "PUBLIC.PART_COL_STATS"
        Column         |          Type          |          Modifiers          | Storage  | Stats target | Description
-----------------------+------------------------+-----------------------------+----------+--------------+-------------

 PART_ID               | BIGINT                 | not null                    | plain    |              |
 LONG_LOW_VALUE        | BIGINT                 |                             | plain    |              |
 LONG_HIGH_VALUE       | BIGINT                 |                             | plain    |              |
 DOUBLE_LOW_VALUE      | DOUBLE PRECISION       |                             | plain    |              |
 DOUBLE_HIGH_VALUE     | DOUBLE PRECISION       |                             | plain    |              |
 BIG_DECIMAL_LOW_VALUE | CHARACTER VARYING(4000) | default NULL::CHARACTER VARYING | extended |              |
 BIG_DECIMAL_HIGH_VALUE | CHARACTER VARYING(4000) | default NULL::CHARACTER VARYING | extended |              |
 NUM_NULLS             | BIGINT                 | not null                    | plain    |              |
 NUM_DISTINCTS         | BIGINT                 |                             | plain    |              |
 BIT_VECTOR            | BYTEA                  |                             | extended |              |
 AVG_COL_LEN           | DOUBLE PRECISION       |                             | plain    |              |
 MAX_COL_LEN           | BIGINT                 |                             | plain    |              |
 NUM_TRUES             | BIGINT                 |                             | plain    |              |
 NUM_FALSES            | BIGINT                 |                             | plain    |              |
 LAST_ANALYZED         | BIGINT                 | not null                    | plain    |              |
Indexes:
    "PART_COL_STATS_pkey" PRIMARY KEY, BTREE (CS_ID)
    "PART_COL_STATS_N49" BTREE (PART_ID)
    "PCS_STATS_IDX" BTREE (CAT_NAME, DB_NAME, TABLE_NAME, COLUMN_NAME, PARTITION_NAME)
Foreign-key constraints:
    "PART_COL_STATS_fkey" FOREIGN KEY (PART_ID) REFERENCES PARTITIONS(PART_ID) DEFERRABLE
Has OIDs: no
```

Procedure

1. Rebuild an index.

   ```
   su – omm
   gsql -p 20051 -U omm -W dbserverAdmin@123 -d hivemeta
   DROP INDEX PCS_STATS_IDX;
   CREATE INDEX PCS_STATS_IDX ON PART_COL_STATS(DB_NAME, TABLE_NAME, COLUMN_NAME, PARTITION_NAME);
   CREATE INDEX SDS_N50 ON SDS(CD_ID);
   ```

2. Check the execution plan again. It is found that the statement can be indexed and executed within 5 ms (the original execution time is 700 ms). Add fields to the Hive table again. The fields can be added successfully.

   

16.10.43 Failed to Restart the Hive Service

Issue

After the Hive service configuration is modified, the configuration fails to be saved. The configuration status of the Hive service on Manager is **Failed**.

Symptom

User A opens the Hive configuration file in the background of the MRS node and does not close the file. User B modifies the Hive configuration item in **Service Management** on the MRS Manager page, saves the configuration, and restarts the Hive service. However, the configuration fails to be saved and the Hive service fails to be started.

Cause Analysis

When user B modifies the configuration on the MRS Manager page, the configuration file is opened by user A in the background of an MRS node. As a

result, the configuration file cannot be replaced and the Hive service fails to be started.

Procedure

Step 1 Manually close the Hive configuration file opened in the background of the cluster node.

Step 2 Modify the Hive configuration on MRS Manager and save the configuration.

Step 3 Restart the Hive service.

----End

16.10.44 Hive Failed to Delete a Table

Issue

Hive fails to delete a table.

Symptom

Partitioning a Hive table by two columns may eventually generate over 20,000 partition files. As a result, the user fails to execute the **truncate table ${TableName}** or **drop table ${TableName}** statement to delete table data.

Cause Analysis

The file deletion operations are executed by a single thread serially. If the Hive partitioned tables have too many partition files, a large amount of metadata is stored in the metadata database. It takes a long time to delete metadata when a statement is executed to delete table data. As a result, the deletion cannot be complete within the specified timeout period, and the operation fails.

NOTE

You can log in to FusionInsight Manager and choose **Cluster** > **Services** > **Hive**. On the Hive page, choose **Configuration** > **All Configurations**, choose **ServerInit** under **MetaStore(Role)** in the navigation tree, and view the **hive.metastore.client.socket.timeout** parameter value in the right pane. This value is the timeout period. You can view the default value in the **Description** column.

Procedure

Step 1 (Optional, perform this step for an internal table) Use **alter table ${TableName} set TBLPROPERTIES('EXTERNAL'='true')** to convert it into an external table. In this way, only its metadata but not data stored on the HDFS is deleted, saving the table deletion time.

Step 2 (Optional, perform this step to use the same table name) Run the **show create table ${TableName}** command to export the table structure, and then run the **ALTER TABLE ${TableName} RENAME TO ${new_table_name};** command to rename the table. In this way, you can create a table that is the same as the original one.

Step 3 Run the **hdfs dfs –rm –r –f ${hdfs_path}** command to delete table data from the HDFS.

Step 4 Use **alter table ${Table_Name} drop partition (${PartitionName}<'XXXX', ${PartitionName}>'XXXX');** in Hive to delete partitions and reduce the number of files. The deletion conditions can be flexibly configured.

Step 5 When the number of rest partitions is smaller than 1,000, run the **drop table ${TableName}** command to delete the table.

----End

Summary and Suggestions

Hive partitioning can improve query efficiency. However, you should properly plan the partitioning policies to prevent a large number of small files from being generated.

16.10.45 An Error Is Reported When msck repair table table_name Is Run on Hive

Symptom

When **msck repair table table_name** is run on Hive, the error message "FAILED: Execution Error, return code 1 from org.apache.hadoop.hive.ql.exec.DDLTask (state=08S01,code=1)" is displayed.

Possible Causes

A directory in the HiveServer log file **/var/log/Bigdata/hive/hiveserver/hive.log** does not comply with the partition format.

```
2020-07-15 15:38:10,427 | WARN  | HiveServer2-Background-Pool: Thread-10905216 | Failed to run metacheck: | org.apache.hadoop.hive.ql.exec.DDLTask.msck(DDLTask.java:2023)

```

Procedure

- Method 1: Delete the incorrect file or directory.
- Method 2: Run the **set hive.msck.path.validation=skip** command to skip invalid directories.

16.10.46 How Do I Release Disk Space After Dropping a Table in Hive?

Issue

After a user runs the **drop** command on the Hive CLI to drop a table and then uses the **hdfs dfsadmin -report** command to check the disk space, the command output shows that the table is not deleted.

Cause Analysis

The **drop** command executed on the Hive CLI deletes only the table structure of the external table, but not the table data stored in HDFS.

Procedure

Step 1 Log in to the node where the client is installed as user **root** and authenticate the component user.

cd *Client installation directory*

source bigdata_env

kinit *Component service user* (Skip this step for clusters with Kerberos authentication disabled.)

Step 2 Run the following command to delete the table stored in HDFS:

hadoop fs -rm hdfs://hacluster/*Path of the table*

----End

16.10.47 Connection Timeout During SQL Statement Execution on the Client

Symptom

The SQL statement fails to be executed on the client, and the error message "Timed out waiting for a free available connection" is displayed.

Possible Causes

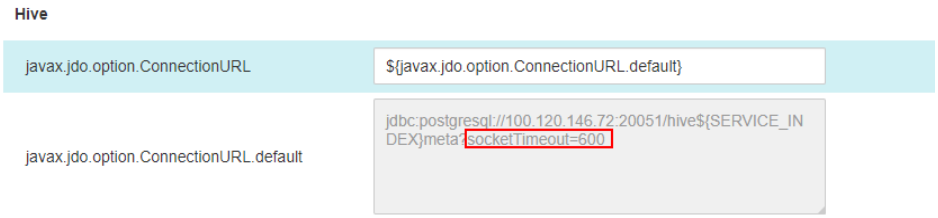
A large number of DBService connections exist, and obtaining connections times out.

Procedure

Step 1 Check whether the client uses the Spark-SQL client to execute SQL statements.

- If yes, check the timeout parameter in the URL, change the value to **600**, and go to **Step 7**.
- If the alarm is not cleared, go to **Step 2**.

Step 2 Log in to FusionInsight Manager, choose **Cluster > Services > Hive > Configuration > All Configurations**, search for **javax.jdo.option.ConnectionURL**, and check whether the value of the timeout parameter is less than **600**.



NOTE

This parameter exists in Hive, HiveServer, MetaStore, and WebHCat. Ensure that the parameter values are the same.

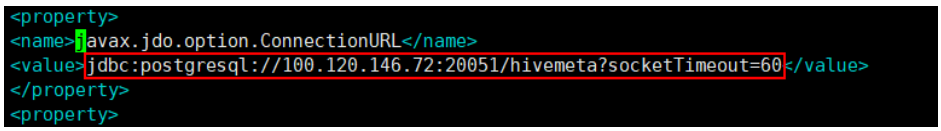
- If yes, go to **Step 3**.
- If no, go to **Step 7**.

Step 3 Check whether the value of **javax.jdo.option.ConnectionURL** is **${javax.jdo.option.ConnectionURL.default}**.

- If yes, go to **Step 4**.
- If no, change the timeout parameter in the URL to **600**, click **Save**, and go to **Step 7**.

Step 4 Click **Instance**, select any HiveServer instance, and log in to the instance node as user **root**.

Step 5 Open the **${BIGDATA_HOME}/FusionInsight_Current/*HiveServer/etc/hivemetastore-site.xml** configuration file, find the **javax.jdo.option.ConnectionURL** parameter, and copy its value.



Step 6 Log in to FusionInsight Manager, choose **Cluster > Services > Hive > Configuration > All Configurations**, search for **javax.jdo.option.ConnectionURL**, change its value to the URL copied in **Step 5**, change the timeout parameter to **600**, and click **Save**.

NOTE

This parameter exists in Hive, HiveServer, MetaStore, and WebHCat. Ensure that the parameter values are the same.

Step 7 Choose **Cluster > Services > Hive > Configuration > All Configurations**, search for **maxConnectionsPerPartition**, and check whether its value is less than **100**.

- If yes, change the value to **100**, click **Save**, and go to **Step 8**.
- If no, go to **Step 8**.

Step 8 If parameters are modified in the preceding steps, choose **Cluster > Services > Hive > Dashboard** and choose **More > Service Rolling Restart**. If the parameters are not modified, skip this step.

----End

16.10.48 WebHCat Failed to Start Due to Abnormal Health Status

Issue

The WebHCat instance fails to be started.

Symptom

On Manager, the health status of the WebHCat instance is **Faulty**, and alarm **ALM-12007 Process Fault** is generated for the WebHCat instance of the Hive service. An error is reported when the Hive service is restarted.

Error messages "Service not found in Kerberos database" and "Address already in use" are contained in the **/var/log/Bigdata/hive/webhcat/webhcat.log** file of the WebHCat instance.

Procedure

Step 1 Log in to each node where the WebHCat instance resides and check whether the mapping between IP addresses and hostnames in the **/etc/hosts** file is correct. The WebHCat configurations in the **/etc/hostname** and **/etc/HOSTNAME** files must be the same as those in the **/etc/hosts** file. If they are different, manually modify them.

NOTE

To view the mapping between the IP addresses and hostnames of the WebHCat instance, log in to FusionInsight Manager and choose **Cluster** > **Services** > **Hive** > **Instance**.

Step 2 Log in to any node where the WebHCat instance resides and run the following command to switch to user **omm**:

su - omm

Step 3 Run the following command to check whether the WebHCat process exists:

ps -ef|grep webhcat|grep -v grep

If it does, run the following command to kill it:

kill -9 ${webhcat_pid}

Step 4 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Hive** . On the page that is displayed, click the **Instance** tab. The select all WebHCat instances, click **More**, and select **Restart Instance**. Wait until WebHCat is restarted successfully.

----End

16.10.49 WebHCat Failed to Start Because the mapred-default.xml File Cannot Be Parsed

Issue

The Hive service of MRS is faulty. After the Hive service is restarted, the HiveServer and WebHCat processes on the Master2 node fail to start, but the processes on the Master1 node are normal.

Cause Analysis

Log in to the Master2 node and check the **/var/log/Bigdata/hive/hiveserver/hive.log** file. It is found that HiveServer keeps loading **/opt/Bigdata/*/*_HiveServer/etc/hive-site.xml**. Check the **/var/log/Bigdata/hive/hiveserver/hiveserver.out** log generated when HiveServer exits. It is found that an exception occurs when the **mapred-default.xml** file is parsed.

Procedure

Step 1 Log in to the Master2 node and run the following command to query the path of **mapred-default.xml**:

find /opt/ -name 'mapred-default.xml'

The configuration file is in the **/opt/Bigdata/*/*_WebHCat/etc/** directory but is empty.

Step 2 Log in to the Master1 node, copy the **/opt/Bigdata/*/*_WebHCat/etc/mapred-default.xml** file to the Master2 node, and change the owner group of the file to **omm:wheel**.

Step 3 Log in to Manager and restart the abnormal HiveServer and WebHCat instances.

----End

16.11 Using Hue

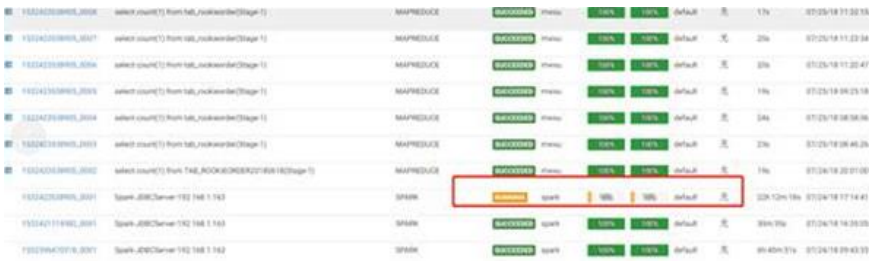
16.11.1 A Job Is Running on Hue

Issue

The customer finds that a job is running on Hue.

Symptom

After the customer's MRS is installed, the job is running on Hue but the running job is not operated by the customer.



Cause Analysis

This job is a permanent job generated when the system connects to JDBC after Spark is started.

Procedure

This is not a problem. No handling is required.

16.11.2 HQL Fails to Be Executed on Hue Using Internet Explorer

Symptom

Using Internet Explorer to access Hive Editor and execute all HQL statements on Hue fails and the system prompts "There was an error with your query".

Cause Analysis

Internet Explorer has functional problems and cannot process AJAX POST requests containing form data in 307 redirection. Use a compatible browser.

Solution

Use Google Chrome 21 or later.

16.11.3 Hue (Active) Cannot Open Web Pages

Symptom

The following information is displayed on the web UI of Hue (active):

Service Unavailable
The server is temporarily unable to service your request due to maintenance downtime or capacity problems. Please try again later.

Cause Analysis

- The Hue configuration has expired.
- The configuration of the Hue service needs to be modified manually in a single-master cluster.

Solution

- If the Hue configuration has expired, restart the Hue service.
- Manually modify the Hue service configuration for a single-master cluster.
  a. Log in to the Master node.
  b. Run the **hostname -i** command to obtain the IP address of the local host.
  c. Run the following command to obtain the value of **HUE_FLOAT_IP**:

     grep "HUE_FLOAT_IP" ${BIGDATA_HOME}/*MRS*_Current/1_*/etc*/ENV_VARS,

     Replace *MRS* with the actual file name.
  d. Check whether the local IP address is the same as the value of **HUE_FLOAT_IP**. If they are different, change the value of **HUE_FLOAT_IP** to the local IP address.
  e. Restart the Hue service.

16.11.4 Failed to Access the Hue Web UI

Issue

An error page is displayed when the Hue web UI is accessed.

Symptom

The following error information is displayed on the Hue web UI:

```
503 Service Unavailable
The server is temporarily unable to service your requster due to maintenance downtime or capacity problems.Please try again later.
```

Cause Analysis

- The Hue configuration has expired.
- The configuration of the Hue service needs to be modified manually in a single-master cluster.

Procedure

Step 1 Log in to the Master node.

Step 2 Run the **hostname -i** command to obtain the IP address of the local host.

Step 3 Run the following command to obtain the value of **HUE_FLOAT_IP**:

grep "HUE_FLOAT_IP" ${BIGDATA_HOME}/*MRS*_Current/1_*/etc*/ENV_VARS, where *MRS* is subject to the actual file name.

Step 4 Check whether the local IP address is the same as the value of **HUE_FLOAT_IP**. If they are different, change the value of **HUE_FLOAT_IP** to the local IP address.

Step 5 Restart the Hue service.

----End

16.11.5 HBase Tables Cannot Be Loaded on the Hue Web UI

Issue

After Hive data is imported to HBase on the Hue page, an error message is displayed, indicating that the HBase table cannot be detected.

Symptom

In the Kerberos cluster, the IAM sub-account does not have sufficient permissions. As a result, the HBase table cannot be loaded.

Cause Analysis

The IAM subaccount does not have sufficient permissions.

Procedure

MRS Manager:

Step 1 Log in to MRS Manager.

Step 2 Choose **System** > **Manage User**.

Step 3 Locate the row that contains the target user, and click **Modify**.

Step 4 Add the user to the **supergroup** group.

Step 5 Click **OK**. The modification is complete.

----End

FusionInsight Manager:

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User**.

Step 3 Locate the row that contains the target user, and click **Modify**.

Step 4 Add the user to the **supergroup** group.

Step 5 Click **OK**. The modification is complete.

----End

Summary and Suggestions

If Kerberos authentication is enabled for a cluster, "No data available" is displayed on the page. In this case, check the permission first.

16.12 Using Impala

16.12.1 Failed to Connect to impala-shell

Issue

A user fails to connect to impala-shell.

Symptom

After a user modifies the configuration of any component on the component management page and restarts the service, the connection to impala-shell fails, and the error message "no such file/directory" is displayed.

```
[root@node-master1emdj etc]# pwd
/opt/Bigdata/MRS_2.1.0/1_7_KuduMaster/etc
[root@node-master1emdj etc]# impala-shell -i 192.168.0.73
shell-init: error retrieving current directory: getcwd: cannot access parent directories: No such file or directory
chdir: error retrieving current directory: getcwd: cannot access parent directories: No such file or directory

  File "/usr/lib64/python2.7/posixpath.py", line 356, in abspath
    cwd = os.getcwd()
OSError: [Errno 2] No such file or directory
```

Cause Analysis

After the service configuration is modified and the service is restarted, some directory structures of the service, such as the etc directory, are deleted and recreated. If the directory is etc or its subdirectory before the service is restarted, some system variables or parameters cannot be found when impala-shell is executed in the original directory because the directory is recreated after the service is restarted. As a result, impala-shell fails to be connected.

Procedure

Switch to any existing directory and reconnect to impala-shell.

16.12.2 Failed to Create a Kudu Table

Issue

An error occurs when a user creates a Kudu table.

Symptom

When a user creates table in a new cluster, the following error message is displayed: [Cloudera]ImpalaJDBCDriver ERROR processing query/statement. Error

Code: 0, SQL state: TStatus(statusCode:ERROR_STATUS, sqlState:HY000, errorMessage:AnalysisException: Table property 'kudu.master_addresses' is required when the impalad startup flag -kudu_master_hosts is not used.

Cause Analysis

The user does not specify **kudu.master_addresses** in the Impala SQL statement.

Procedure

Specify **kudu.master_addresses** when creating a Kudu table.

16.12.3 Failed to Log In to the Impala Client

Issue

Error information similar to the following is displayed when a user runs the Impala client.

```
[root@node-master1avIy ~]# impala-shell -i 192.168.128.49:21000
  File "/opt/client/Impala/impala/shell/impala_shell.py", line 1675
    except Exception, e:
                    ^
SyntaxError: invalid syntax
[root@node-master1avIy ~]#
```

Cause Analysis

The latest MRS cluster uses EulerOS 2.9 or later, which provides only Python 3. However, the Impala client is implemented based on Python 2 and is incompatible with some syntax of Python 3. As a result, an error occurs when the Impala client is running. You can manually install Python 2 to solve this problem.

Procedure

Step 1 Log in to the Impala node as user **root** and run the following command to check its Python version:

python --version

```
[root@node-master2JgOY ~]# python --version
Python 3.7.4
```

Step 2 Run the **yum install make** command to check whether yum is available.

- If the following error is reported, the yum configuration is incorrect. Go to **Step 3**.

  ```
  [root@node-master2JgOY ~]# yum install make
  Error: There are no enabled repositories in "/etc/yum.repos.d", "/etc/yum/repos.d", "/etc/distro.repos.d".
  ```

- If no error is reported, go to **Step 4**.

Step 3 Run the **cat /etc/yum.repos.d/EulerOS-base.repo** command to check whether the yum source matches the system version. If they do not match, modify them.

Before modification

```
[root@node-master1avIy ~]# cat /etc/yum.repos.d/EulerOS-base.repo
[base]
name=EulerOS-2.0SP2 base
baseurl=http://mirrors.myhuaweicloud.com/euler/ict/site-euleros/euleros/repo/yum/2.2/os/x86_64/
enabled=1
gpgcheck=1
gpgkey=http://mirrors.myhuaweicloud.com/euler/ict/site-euleros/euleros/repo/yum/2.2/os/RPM-GPG-KEY-EulerOS
[root@node-master1avIy ~]# uname -a
Linux node-master1avIy.mrs-mq7v.com 4.18.0-147.5.1.6.h541.eulerosv2r9.x86_64 #1 SMP Wed Aug 4 02:30:13 UTC
 x86_64 GNU/Linux
```

After modification

```
[base]
name=EulerOS-2.0SP9 base
baseurl=http://mirrors.myhuaweicloud.com/euler/ict/site-euleros/euleros/repo/yum/2.9/os/x86_64/
enabled=1
gpgcheck=1
gpgkey=http://mirrors.myhuaweicloud.com/euler/ict/site-euleros/euleros/repo/yum/2.9/os/RPM-GPG-KEY-EulerOS
```

Step 4 Run the following command to check for the software whose name starts with **python2** in the yum source:

yum list python2*

```
[root@node-master2JgOY ~]# yum list python2*

16.13 Using Kafka

16.13.1 An Error Is Reported When Kafka Is Run to Obtain a Topic

Issue

An Error is reported when Kafka is run to obtain a topic.

Symptom

An error is reported when the Kafka is run to obtain topics. The error information is as follows:

```
ERROR org.apache.kafka.common.errors.InvalidReplicationFactorException: Replication factor: 2 larger than available brokers: 0.
```

Possible Cause

The variable for obtaining the ZooKeeper address is incorrect due to special characters.

Procedure

Step 1 Log in to any Master node.

Step 2 Run the **cat /opt/client/Kafka/kafka/config/server.properties |grep '^zookeeper.connect ='** command to check the variable of the Zookeeper address.

Step 3 Run Kafka again to obtain the topic. Do not add any character to the variables obtained in **Step 2**.

----End

16.13.2 Flume Normally Connects to Kafka But Fails to Send Messages

Symptom

An MRS cluster is installed, and ZooKeeper, Flume, and Kafka are installed in the cluster.

Flume fails to send data to Kafka.

Possible Causes

1. The Kafka service is abnormal.
2. The IP address for Flume to connect to Kafka is incorrect.
3. The size of the message sent from Flume to Kafka exceeds the upper limit.

Cause Analysis

The possible reasons why Flume fails to send data to Kafka may be related to Flume or Kafka.

1. Check the Kafka service status and monitoring metrics on Manager.
   - MRS Manager: Log in to MRS Manager and choose **Services** > **Kafka**. Check the Kafka status. The status is **Good**, and the monitoring metrics are correctly displayed.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka**.

     Check the Kafka status. It is found that the status is good and the monitoring metrics are correctly displayed.

2. Check the Flume log. The log contains **MessageSizeTooLargeException** information, as shown in the following:

```
2016-02-26 14:55:19,126 | WARN  | [SinkRunner-PollingRunner-DefaultSinkProcessor] |  Produce request with correlation id 349829 failed due to [LOG,7]: kafka.common.MessageSizeTooLargeException  | kafka.utils.Logging$class.warn(Logging.scala:83)
```

   The exception shows that the size of data written to Kafka by Flume exceeds the maximum message size specified by Kafka.

3. Check the maximum message size specified by Kafka on Manager.
   - MRS Manager portal: Log in to MRS Manager and choose **Services** > **Kafka** > **Configuration**.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka** > **Configuration**.

   On the page that is displayed, set **Type** to **All**. All Kafka configurations are displayed. Enter **message.max.bytes** in the **Search** text box to search.

   In MRS, the maximum size of a message that can be received by the Kafka server is 1000012 bytes = 977 KB by default.

Solution

After confirmation with the customer, data sent by Flume contains messages over 1 MB. Adjust parameters on Kafka to enable the messages to be written to Kafka.

Step 1 Set **message.max.bytes** to a value that is larger than the current maximum size of the message to be written so that Kafka can receive all messages.

Step 2 Set **replica.fetch.max.bytes** to a value that is equal to or larger than the value of **message.max.bytes** so that replicas of partitions on different Brokers can be synchronized to all messages.

- MRS Manager portal: Log in to MRS Manager and choose **Services** > **Kafka** > **Configuration**.
- FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka** > **Configuration**.

On the page that is displayed, set **Type** to **All**. All Kafka configurations are displayed. Enter **replica.fetch.max.bytes** in the **Search** text box to search.

Step 3 Click **Save** and restart the Kafka service to make Kafka configurations take effect.

Step 4 Set **fetch.message.max.bytes** to a value that is equal to or larger than the value of **message.max.bytes** for Consumer service applications to ensure that Consumers can consume all messages.

----End

16.13.3 Producer Failed to Send Data and Threw "NullPointerException"

Symptom

An MRS cluster has ZooKeeper and Kafka installed.

When the Producer client sends data to Kafka, it fails and throws "NullPointerException".

Possible Causes

1. The Kafka service is abnormal.
2. The **jass** and **keytab** files configured on the Producer client are incorrect.

Cause Analysis

The possible causes may be related to Producer or Kafka.

1. Check the Kafka service status and monitoring metrics on Manager.
   - MRS Manager: Log in to MRS Manager and choose **Services** > **Kafka**. Check the Kafka status. The status is **Good**, and the monitoring metrics are correctly displayed.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster**. Click the name of the target cluster and choose **Service** > **Kafka**.

     Check the Kafka status. The status is good, and the monitoring metrics are correctly displayed.
2. Check the Producer client log. The log contains "NullPointerException", as shown in **Figure 16-42**.

   Figure 16-42 Producer client log

   ```
   [2016-12-06 02:04:05,906]-[schedule-C50D0717-4643-4D4E-9D6E-B940E4BD7159]-[kafka-producer-network-thread |
   SZX1000161910-10.21.219.222-bigdata-producer-5]-[1005]-[org.apache.kafka.clients.producer.internals.Sender.run
   thread:
   java.lang.NullPointerException

       at org.apache.kafka.clients.producer.internals.Sender.run(Sender.java:229)
       at org.apache.kafka.clients.producer.internals.Sender.run(Sender.java:134)
       at java.lang.Thread.run(Thread.java:745)
   [2016-12-06 02:04:05,921]-[schedule-C50D0717-4643-4D4E-9D6E-B940E4BD7159]-[kafka-producer-network-thread |
   SZX1000161910-10.21.219.222-bigdata-producer-3]-[1005]-[org.apache.kafka.clients.producer.internals.Sender.run
   thread:
   java.lang.NullPointerException
       at org.apache.kafka.common.network.Selector.pollSelectionKeys(Selector.java:302)
       at org.apache.kafka.common.network.Selector.poll(Selector.java:283)
       at org.apache.kafka.clients.NetworkClient.poll(NetworkClient.java:260)
       at org.apache.kafka.clients.producer.internals.Sender.run(Sender.java:229)
       at org.apache.kafka.clients.producer.internals.Sender.run(Sender.java:134)
       at java.lang.Thread.run(Thread.java:745)
   ```

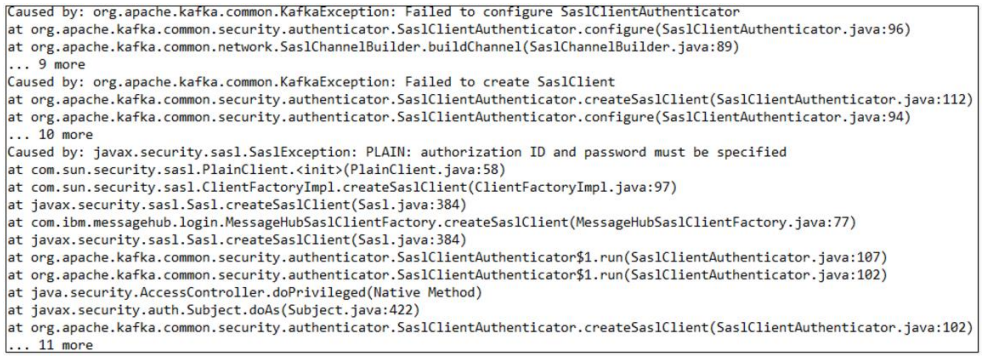
   Alternatively, the log contains only "NullPointerException" but no stack information. The problem is caused by JDK self-protection. If much information is printed for the same stack, the JDK self-protection is triggered and stack information is no longer printed, as shown in **Figure 16-43**.

   Figure 16-43 Error information

   ```
   [2016-11-23 04:06:53,973] [kafka-producer-network-thread | producer-1] [ERROR] [org.apache.kafka.clients.producer.internals.Sender] (run:130)- Uncaught error in kafka producer I/O thread:
   java.lang.NullPointerException
   [2016-11-23 04:06:53,973] [kafka-producer-network-thread | producer-1] [ERROR] [org.apache.kafka.clients.producer.internals.Sender] (run:130)- Uncaught error in kafka producer I/O thread:
   java.lang.NullPointerException
   [2016-11-23 04:06:53,973] [kafka-producer-network-thread | producer-1] [ERROR] [org.apache.kafka.clients.producer.internals.Sender] (run:130)- Uncaught error in kafka producer I/O thread:
   java.lang.NullPointerException
   [2016-11-23 04:06:53,973] [kafka-producer-network-thread | producer-1] [ERROR] [org.apache.kafka.clients.producer.internals.Sender] (run:130)- Uncaught error in kafka producer I/O thread:
   java.lang.NullPointerException
   ```

3. Check the Producer client log. Error information "Failed to configure SaslClientAuthenticator" is displayed, as shown in **Figure 16-44**.

Figure 16-44 Error log

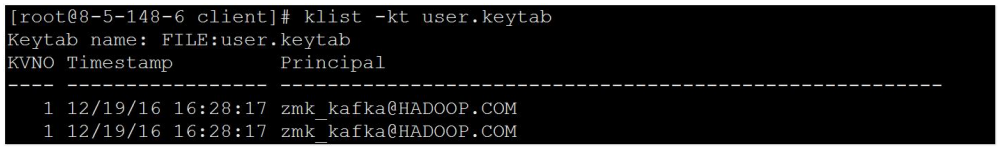


4. The authentication failure causes the failure to create the KafkaChannel. The KafkaChannel obtained through the **channel(key)** method is empty and "NullPointerException" is excessively printed. According to the preceding log, the authentication fails due to an incorrect password which does not match the username.
5. Check the **jaas** and **keytab** files. The **principal** is set to **stream** in the **jaas** file.

Figure 16-45 Checking the jaas file

The **principal** is set to **zmk_kafka** in the **user.keytab** file.

Figure 16-46 Checking the user.keytab file



The **principal** in the **jaas** file is inconsistent with that in the **user.keytab** file.

The application automatically and periodically updates the **jaas** file. However, when two processes of the application update the **jaas** file, one process writes a correct **principal** whereas the other process writes an incorrect one. As a result, the application is abnormal sometimes.

Procedure

Step 1 Modify the **jaas** file to ensure that its **principal** exists in the **keytab** file.

----End

16.13.4 Producer Fails to Send Data and "TOPIC_AUTHORIZATION_FAILED" Is Thrown

Symptom

An MRS cluster is installed, and ZooKeeper and Kafka are installed in the cluster.

When Producer sends data to Kafka, the client throws "TOPIC_AUTHORIZATION_FAILED."

Possible Causes

1. The Kafka service is abnormal.
2. The Producer client adopts non-security access and access is disabled on the server.
3. The Producer client adopts non-security access and ACL is set for Kafka topics.

Cause Analysis

The possible reasons why Producer fails to send data to Kafka may be related to Producer or Kafka.

1. Check the Kafka service status:
   - MRS Manager: Log in to MRS Manager and choose **Services** > **Kafka**. Check the Kafka status. The status is **Good**, and the monitoring metrics are correctly displayed.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka**.

     Check the Kafka status. It is found that the status is good and the monitoring metrics are correctly displayed.
2. Check the Producer client logs. The logs contain the error information "TOPIC_AUTHORIZATION_FAILED."

   ```
   [root@10-10-144-2 client]# kafka-console-producer.sh --broker-list 10.5.144.2:9092 --topic test
   1
   [2017-01-24 16:58:36,671] WARN Error while fetching metadata with correlation id 0 :
   {test=TOPIC_AUTHORIZATION_FAILED} (org.apache.kafka.clients.NetworkClient)
   [2017-01-24 16:58:36,672] ERROR Error when sending message to topic test with key: null, value: 1
   bytes with error: Not authorized to access topics: [test]
   (org.apache.kafka.clients.producer.internals.ErrorLoggingCallback)
   ```

   Producer accesses Kafka using port 9092, which is a non-security port.
3. On Manager, check the current Kafka cluster configuration. It is found that the customized configuration **allow.everyone.if.no.acl.found**=**false** is not configured.
   - MRS Manager portal: Log in to MRS Manager and choose **Services** > **Kafka** > **Configuration**.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka** > **Configuration**.
4. If ACL is set to **false**, port 9092 cannot be used for access.
5. Check the Producer client logs. The logs contain the error information "TOPIC_AUTHORIZATION_FAILED."

   ```
   [root@10-10-144-2 client]# kafka-console-producer.sh --broker-list 10.5.144.2:21005 --topic test_acl
   1
   ```

```
[2017-01-25 11:09:40,012] WARN Error while fetching metadata with correlation id 0 :
{test_acl=TOPIC_AUTHORIZATION_FAILED} (org.apache.kafka.clients.NetworkClient)
[2017-01-25 11:09:40,013] ERROR Error when sending message to topic test_acl with key: null, value:
1 bytes with error: Not authorized to access topics: [test_acl]
(org.apache.kafka.clients.producer.internals.ErrorLoggingCallback)
[2017-01-25 11:14:40,010] WARN Error while fetching metadata with correlation id 1 :
{test_acl=TOPIC_AUTHORIZATION_FAILED} (org.apache.kafka.clients.NetworkClient)
```

Producer accesses Kafka using port 21005, which is a non-security port.

6. Run the client command to check the ACL permission of the topic.

```
[root@10-10-144-2 client]# kafka-acls.sh --authorizer-properties zookeeper.connect=10.5.144.2:24002/
kafka --list --topic topic_acl
Current ACLs for resource `Topic:topic_acl`:
 User:test_user has Allow permission for operations: Describe from hosts: *
User:test_user has Allow permission for operations: Write from hosts: *
```

If ACL is set for the topic, port 9092 cannot be used for access.

7. Check the Producer client logs. The logs contain the error information "TOPIC_AUTHORIZATION_FAILED."

```
[root@10-10-144-2 client]# kafka-console-producer.sh --broker-list 10.5.144.2:21007 --topic topic_acl
--producer.config /opt/client/Kafka/kafka/config/producer.properties
1
[2017-01-25 12:43:58,506] WARN Error while fetching metadata with correlation id 0 :
{topic_acl=TOPIC_AUTHORIZATION_FAILED} (org.apache.kafka.clients.NetworkClient)
[2017-01-25 12:43:58,507] ERROR Error when sending message to topic topic_acl with key: null,
value: 1 bytes with error: Not authorized to access topics: [topic_acl]
(org.apache.kafka.clients.producer.internals.ErrorLoggingCallback)
```

Producer uses port 21007 to access Kafka.

8. Run the client command **klist** to query the current authenticated user.

```
[root@10-10-144-2 client]# klist
Ticket cache: FILE:/tmp/krb5cc_0
Default principal: test@HADOOP.COM

Valid starting     Expires            Service principal
01/25/17 11:06:48  01/26/17 11:06:45  krbtgt/HADOOP.COM@HADOOP.COM
```

The **test** user is used in this example.

9. Run the client command to check the ACL permission of the topic.

```
[root@10-10-144-2 client]# kafka-acls.sh --authorizer-properties zookeeper.connect=10.5.144.2:2181/
kafka --list --topic topic_acl
Current ACLs for resource `Topic:topic_acl`:
 User:test_user has Allow permission for operations: Describe from hosts: *
User:test_user has Allow permission for operations: Write from hosts: *
```

After ACL is set for the topic, user **test_user** has Producer permission. User **test** has no permission to perform Producer operations.

For details about the solution, see **2**.

10. Log in to Kafka Broker using SSH.

Run the **cd /var/log/Bigdata/kafka/broker** command to go to the log directory.

Check the **kafka-authorizer.log** file. It shows that the user does not belong to the **kafka** or **kafkaadmin** group.

```
2017-01-25 13:26:33,648 | INFO  | [kafka-request-handler-0] | The principal is test, belongs to Group :
[hadoop, ficommon] | kafka.authorizer.logger (SimpleAclAuthorizer.scala:169)
2017-01-25 13:26:33,648 | WARN  | [kafka-request-handler-0] | The user is not belongs to kafka or
kafkaadmin group, authorize failed! | kafka.authorizer.logger (SimpleAclAuthorizer.scala:170)
```

For details about the solution, see **3**.

Solution

Step 1 Set **allow.everyone.if.no.acl.found** to **true** and restart the Kafka service.

Step 2 Use the account with permission for login.

Example:

kinit test_user

Alternatively, grant the user with related permission.

NOTICE

This operation must be performed by the Kafka administrator (belonging to the **kafkaadmin** group).

Example:

kafka-acls.sh --authorizer-properties zookeeper.connect=10.5.144.2:2181/kafka --topic topic_acl --producer --add --allow-principal User:test

```
[root@10-10-144-2 client]# kafka-acls.sh --authorizer-properties zookeeper.connect=8.5.144.2:2181/kafka --list --topic topic_acl
Current ACLs for resource `Topic:topic_acl`:
 User:test_user has Allow permission for operations: Describe from hosts: *
 User:test_user has Allow permission for operations: Write from hosts: *
  User:test has Allow permission for operations: Describe from hosts: *
  User:test has Allow permission for operations: Write from hosts: *
```

Step 3 Add the user to the **kafka** or **kafkaadmin** group.

----End

16.13.5 Producer Occasionally Fails to Send Data and the Log Displays "Too many open files in system"

Symptom

When Producer sends data to Kafka, it is found that the client fails to send data.

Figure 16-47 Producer fails to send data.

Possible Causes

1. The Kafka service is abnormal.
2. The network is abnormal.
3. The Kafka topic is abnormal.

Cause Analysis

1. Check the Kafka service status:
   - MRS Manager: Log in to MRS Manager and choose **Services** > **Kafka**. Check the Kafka status. The status is **Good**, and the monitoring metrics are correctly displayed.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka**.

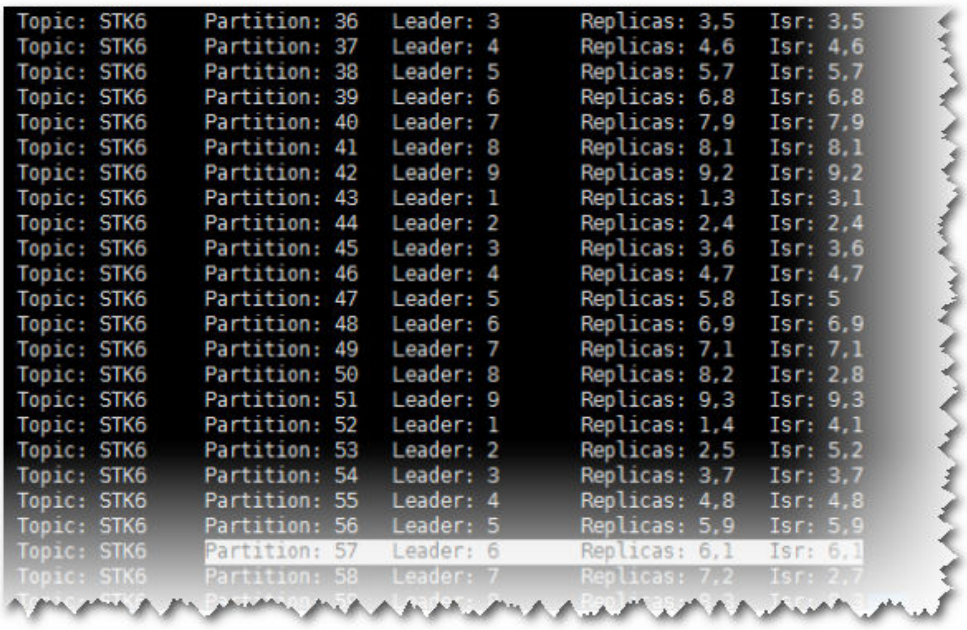
     Check the Kafka status. It is found that the status is good and the monitoring metrics are correctly displayed.
2. View the error topic information in the SparkStreaming log.

   Run the Kafka commands to obtain the topic assignment information and copy synchronization information, and check the return result.

   kafka-topics.sh --describe --zookeeper <zk_host:port/chroot>

   As shown in **Figure 16-48**, the topic status is normal. All partitions have normal leader information.

   Figure 16-48 Topic status

3. Run the **telnet** command to check whether the Kafka can be connected.

   telnet *Kafka service IP address Kafka service port*

   If telnet fails, check the network security group and ACL.
4. Log in to Kafka Broker using SSH.

   Run the **cd /var/log/Bigdata/kafka/broker** command to go to the log directory.

   Check on **server.log** indicates that the error message is displayed in the log shown in the following figure.

Figure 16-49 Log exception

5. Output of the **lsof** command used to check the handle usage of the Kafka process on the current node shows that the number of handles used by the Kafka process reaches 470,000.

Figure 16-50 Handles

6. Check the service code. It is found that the Producer object is frequently created and is not closed normally.

Solution

Step 1 Stop the current application to ensure that the number of handles on the server does not increase sharply, which affects the normal running of services.

Step 2 Optimize the application code to resolve the handle leakage problem.

Suggestion: Use one Producer object globally. After the use is complete, call the Close interface to close the handle.

----End

16.13.6 Consumer Is Initialized Successfully, But the Specified Topic Message Cannot Be Obtained from Kafka

Symptom

An MRS cluster is installed, and ZooKeeper, Flume, Kafka, Storm, and Spark are installed in the cluster.

The customer cannot consume any data using Storm, Spark, Flume or self-programmed Consumer code to consume messages of the specified Kafka topic.

Possible Causes

1. The Kafka service is abnormal.
2. The IP address for ZooKeeper connection is incorrectly set.
3. "ConsumerRebalanceFailedException" is thrown.

4. "ClosedChannelException" caused by network problems is thrown.

Cause Analysis

Storm, Spark, Flume or user-defined Consumer code can be called Consumer.

1. Check the Kafka service status:
   - MRS Manager: Log in to MRS Manager and choose **Services** > **Kafka**. Check the Kafka status. The status is **Good**, and the monitoring metrics are correctly displayed.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka**.

     Check the Kafka status. It is found that the status is good and the monitoring metrics are correctly displayed.
2. Check whether data can be normally consumed through the Kafka client.

   Suppose the client has been installed in the **/opt/client** directory, **test** is the topic name to be consumed, and the IP address of ZooKeeper is 192.168.234.231.

   ```
   cd /opt/client
   source bigdata_env
   kinit admin
   kafka-topics.sh --zookeeper 192.168.234.231:2181/kafka --describe --topic testkafka-console-consumer.sh --topic test --zookeeper 192.168.234.231:2181/kafka --from-beginning
   ```

   If data can be consumed, the cluster service is running properly.
3. Check Consumer configurations. The IP address for connecting to ZooKeeper is incorrect.
   - Flume

     ```
     server.sources.Source02.type=org.apache.flume.source.kafka.KafkaSource

     server.sources.Source02.zookeeperConnect=192.168.234.231:2181
     server.sources.Source02.topic = test
     server.sources.Source02.groupId = test_01
     ```
   - Spark

     ```
     val zkQuorum = "192.168.234.231:2181"
     ```
   - Storm

     ```
     BrokerHosts brokerHosts = new ZKHosts("192.168.234.231:2181");
     ```
   - Consumer API

     ```
     zookeeper.connect="192.168.234.231:2181"
     ```

   On MRS Manager, the root path of ZNode where Kafka is stored on ZooKeeper is **/kafka**, which is differentiated from the open source. The address for Kafka to connect to ZooKeeper is **192.168.234.231:2181/kafka**.

   However, the address for Consumer to connect to ZooKeeper is **192.168.234.231:2181**. Therefore, topic information about Kafka cannot be correctly obtained.

   For details about the solution, see **Step 1**.
4. Check Consumer logs. The logs contain "ConsumerRebalanceFailedException".

   ```
   2016-02-03 15:55:32,557 | ERROR | [ZkClient-EventThread-75- 192.168.234.231:2181/kafka] |  Error handling event ZkEvent[New session event sent to kafka.consumer.ZookeeperConsumerConnector$ZKSessionExpireListener@34b41dfe]  | org.I0Itec.zkclient.ZkEventThread.run(ZkEventThread.java:77)
   kafka.common.ConsumerRebalanceFailedException: pc-zjqbetl86-1454482884879-2ec95ed3 can't rebalance after 4 retries
   at kafka.consumer.ZookeeperConsumerConnector$ZKRebalancerListener.syncedRebalance(ZookeeperConsumerConnector.scala:633)
   ```

```
at kafka.consumer.ZookeeperConsumerConnector
$ZKSessionExpireListener.handleNewSession(ZookeeperConsumerConnector.scala:487)
at org.I0Itec.zkclient.ZkClient$4.run(ZkClient.java:472)
at org.I0Itec.zkclient.ZkEventThread.run(ZkEventThread.java:71)
```

The exception shows that the current Consumer does not complete rebalance within the specified retry times. As a result, Kafka Topic-Partition is not allocated to Consumer and Consumer cannot consume messages.

For details about the solution, see **Step 3**.

5. Check Consumer logs. The logs contain "Fetching topic metadata with correlation id 0 for topics [Set(test)] from broker [id:26,host:192-168-234-231,port:9092] failed" and "ClosedChannelException".

```
[2016-03-04 03:33:53,047] INFO Fetching metadata from broker id:26,host:
192-168-234-231,port:9092 with correlation id 0 for 1 topic(s) Set(test) (kafka.client.ClientUtils$)

at kafka.client.ClientUtils$.fetchTopicMetadata(ClientUtils.scala:93)
at kafka.consumer.ConsumerFetcherManager
$LeaderFinderThread.doWork(ConsumerFetcherManager.scala:66)
at kafka.utils.ShutdownableThread.run(ShutdownableThread.scala:60)
[2016-03-04 03:33:55,615] INFO Disconnecting from 192-168-234-231:21005
(kafka.producer.SyncProducer)
```

The exception shows that the current Consumer cannot obtain metadata from the Kafka Broker 192-168-234-231 node and cannot connect to the correct Broker for obtaining messages.

6. Check the network conditions. If the network is normal, check whether mapping between the host and the IP address is configured.
   - Linux

     Run the **cat /etc/hosts** command.

     Figure 16-51 Example 1

     
   - Windows

     Open **C:\Windows\System32\drivers\etc\hosts**.

Figure 16-52 Example 2

```
# For example:
#
#      192.168.94.97     rhino.acme.com          # source server
#      192.168.63.10     x.acme.com              # x client host

# localhost name resolution is handled within DNS itself.
#       127.0.0.1       localhost
#       ::1             localhost
10.82.129.120 rms.huawei.com # modified by IrmTool at 2015-01-18 17:55:13
```

For details about the solution, see **Step 4**.

Solution

Step 1 The IP address for connecting to ZooKeeper is incorrectly configured.

Step 2 Change the IP address for connecting to ZooKeeper in the Consumer configuration and make it consistent with MRS configuration.

- Flume
  ```
  server.sources.Source02.type=org.apache.flume.source.kafka.KafkaSource
  server.sources.Source02.zookeeperConnect=192.168.234.231:2181/kafka
  server.sources.Source02.topic = test
  server.sources.Source02.groupId = test_01
  ```
- Spark
  ```
  val zkQuorum = "192.168.234.231:2181/kafka"
  ```
- Storm
  ```
  BrokerHosts brokerHosts = new ZKHosts("192.168.234.231:2181/kafka");
  ```
- Consumer API
  ```
  zookeeper.connect="192.168.234.231:2181/kafka"
  ```

Step 3 Rebalance is abnormal.

Multiple Consumers in the same consumer group are successively started and consume data of multiple partitions at the same time, load balancing is performed for Consumers when consumers are fewer than partitions.

The temporary node where the Consumer is stored on ZooKeeper determines read/write permission of which partition of which topic the Consumer has. The path is **/consumers/consumer-group-xxx/owners/topic-xxx/x**.

After the load balancing is triggered, the original Consumer will be recalculated and release occupied partitions, which takes a while. Therefore, new Consumers may fail to preempt the partitions.

Table 16-3 Parameters

Name	Function	Default Value
rebalance.max.retries	Maximum number of rebalance retries	4
rebalance.backoff.ms	Interval for each rebalance retry	2000

Name	Function	Default Value
zookeeper.session.timeout.ms	Maximum time allowed to create a session with ZooKeeper	15000

Set the preceding parameters to higher values. The following is for your reference:

```
zookeeper.session.timeout.ms = 45000
rebalance.max.retries = 10
rebalance.backoff.ms = 5000
```

Parameter setting must comply with the following rule:

rebalance.max.retries * rebalance.backoff.ms > zookeeper.session.timeout.ms

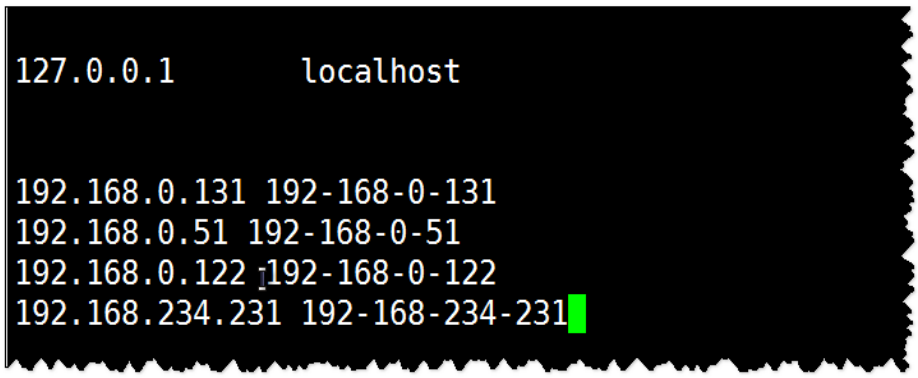
Step 4 The network is abnormal.

In the **hosts** file, mapping between the hostname and IP address is not configured. As a result, information cannot be obtained when using the hostname for access.

Step 5 Add the hostname to the **hosts** file and make it correspond to the IP address.

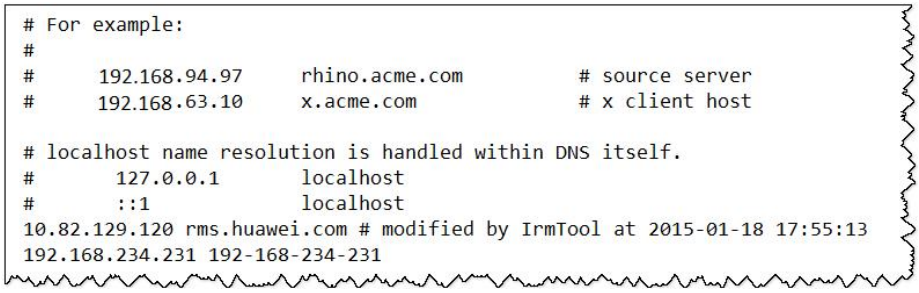
- Linux

  Figure 16-53 Example 3

- Windows

  Figure 16-54 Example 4

----End

16.13.7 Consumer Fails to Consume Data and Remains in the Waiting State

Symptom

An MRS cluster is installed, and ZooKeeper and Kafka are installed in the cluster.

When the Consumer consumes data from Kafka, the client stays in the Waiting state.

Possible Causes

1. The Kafka service is abnormal.
2. The Consumer client adopts non-security access and access is disabled on the server.
3. The Consumer client adopts non-security access and ACL is set for Kafka topics.

Cause Analysis

The possible reasons why the Consumer fails to consume data from Kafka may be related to the Consumer or Kafka.

1. Check the Kafka service status:
   - MRS Manager: Log in to MRS Manager and choose **Services** > **Kafka**. Check the Kafka status. The status is **Good**, and the monitoring metrics are correctly displayed.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka**.

     Check the Kafka status. It is found that the status is good and the monitoring metrics are correctly displayed.
2. Check the Consumer client log. It is found that the information about the frequent connections and disconnections to the Broker node is printed, as shown in the following output.

   ```
   [root@10-10-144-2 client]# kafka-console-consumer.sh --topic test --zookeeper 10.5.144.2:2181/kafka
   --from-beginning

   [2017-03-07 09:22:00,658] INFO Fetching metadata from broker BrokerEndPoint(1,10.5.144.2,9092)
   with correlation id 26 for 1 topic(s) Set(test) (kafka.client.ClientUtils$)
   [2017-03-07 09:22:00,659] INFO Connected to 10.5.144.2:9092 for producing
   (kafka.producer.SyncProducer)
   [2017-03-07 09:22:00,659] INFO Disconnecting from 10.5.144.2:9092 (kafka.producer.SyncProducer)
   ```

   Consumer accesses Kafka using port 9092, which is a non-security port.
3. On Manager, check the current Kafka cluster configuration. It is found that the customized configuration **allow.everyone.if.no.acl.found**=**false** is not configured.
   - MRS Manager portal: Log in to MRS Manager and choose **Services** > **Kafka** > **Configuration**.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka** > **Configuration**.

4. If ACL is set to **false**, port 9092 cannot be used for access.
5. Check the Consumer client log. It is found that the information about the frequent connections and disconnections to the Broker node is printed, as shown in the following output.

```
[root@10-10-144-2 client]# kafka-console-consumer.sh --topic test_acl --zookeeper 10.5.144.2:2181/kafka --from-beginning

[2017-03-07 09:49:16,992] INFO Fetching metadata from broker BrokerEndPoint(2,10.5.144.3,9092) with correlation id 16 for 1 topic(s) Set(topic_acl) (kafka.client.ClientUtils$)
[2017-03-07 09:49:16,993] INFO Connected to 10.5.144.3:9092 for producing (kafka.producer.SyncProducer)
[2017-03-07 09:49:16,994] INFO Disconnecting from 10.5.144.3:9092 (kafka.producer.SyncProducer)
```

   The Consumer accesses Kafka using port 21005, which is a non-security port.
6. Run the client command to check the ACL permission of the topic.

```
[root@10-10-144-2 client]# kafka-acls.sh --authorizer-properties zookeeper.connect=10.5.144.2:2181/kafka --list --topic topic_acl
Current ACLs for resource `Topic:topic_acl`:
 User:test_user has Allow permission for operations: Describe from hosts: *
User:test_user has Allow permission for operations: Write from hosts: *
```

   If ACL is set for the topic, port 9092 cannot be used for access.
7. The following information is printed in the Consumer client log:

```
[root@10-10-144-2 client]# kafka-console-consumer.sh --topic topic_acl --bootstrap-server 10.5.144.2:21007 --consumer.config /opt/client/Kafka/kafka/config/consumer.properties --from-beginning --new-consumer

[2017-03-07 10:19:18,478] INFO Kafka version : 0.9.0.0 (org.apache.kafka.common.utils.AppInfoParser)
[2017-03-07 10:19:18,478] INFO Kafka commitId : unknown (org.apache.kafka.common.utils.AppInfoParser)
```

   The Consumer uses port 21007 to access Kafka.
8. Run the client command **klist** to query the current authenticated user.

```
[root@10-10-144-2 client]# klist
Ticket cache: FILE:/tmp/krb5cc_0
Default principal: test@HADOOP.COM

Valid starting     Expires            Service principal
01/25/17 11:06:48  01/26/17 11:06:45  krbtgt/HADOOP.COM@HADOOP.COM
```

   The **test** user is used in this example.
9. Run the client command to check the ACL permission of the topic.

```
[root@10-10-144-2 client]# kafka-acls.sh --authorizer-properties zookeeper.connect=10.5.144.2:24002/kafka --list --topic topic_acl
Current ACLs for resource `Topic:topic_acl`:
 User:test_user has Allow permission for operations: Describe from hosts: *
 User:test_user has Allow permission for operations: Write from hosts: *
 User:ttest_user has Allow permission for operations: Read from hosts: *
```

   If ACL is set for the topic, user **test** does not have the permission to perform the Consumer operation.

   For details about the solution, see **Step 2**.
10. Log in to Kafka Broker using SSH.

    Run the **cd /var/log/Bigdata/kafka/broker** command to go to the log directory.

    Check the **kafka-authorizer.log** file. It shows that the user does not belong to the **kafka** or **kafkaadmin** group.

```
2017-01-25 13:26:33,648 | INFO  | [kafka-request-handler-0] | The principal is test, belongs to Group : [hadoop, ficommon] | kafka.authorizer.logger (SimpleAclAuthorizer.scala:169)
2017-01-25 13:26:33,648 | WARN  | [kafka-request-handler-0] | The user is not belongs to kafka or kafkaadmin group, authorize failed! | kafka.authorizer.logger (SimpleAclAuthorizer.scala:170)
```

For details about the solution, see **Step 3**.

Solution

Step 1 Set **allow.everyone.if.no.acl.found** to **true** and restart the Kafka service.

Step 2 Use the account with permission for login.

Example:

kinit test_user

Alternatively, grant the user with related permission.

NOTICE

This operation must be performed by the Kafka administrator (belonging to the **kafkaadmin** group).

Example:

kafka-acls.sh --authorizer-properties zookeeper.connect=10.5.144.2:2181/kafka --topic topic_acl --consumer --add --allow-principal User:test --group test

```
[root@10-10-144-2 client]# kafka-acls.sh --authorizer-properties zookeeper.connect=8.5.144.2:2181/kafka --list --topic topic_acl
Current ACLs for resource `Topic:topic_acl`:
 User:test_user has Allow permission for operations: Describe from hosts: *
 User:test_user has Allow permission for operations: Write from hosts: *
  User:test has Allow permission for operations: Describe from hosts: *
  User:test has Allow permission for operations: Write from hosts: *
  User:test has Allow permission for operations: Read from hosts: *
```

Step 3 Add the user to the **kafka** or **kafkaadmin** group.

----End

16.13.8 SparkStreaming Fails to Consume Kafka Messages, and "Error getting partition metadata" Is Displayed

Symptom

When SparkStreaming is used to consume messages of a specified topic in Kafka, data cannot be obtained from Kafka. The message "Error getting partition metadata" is displayed.

```
Exception in thread "main" org.apache.spark.SparkException:  Error getting partition metadata for 'testtopic'. Does the topic exist?
org.apache.spark.streaming.kafka.KafkaCluster$$anonfun$checkErrors$1.apply(KafkaCluster.scala:366)
org.apache.spark.streaming.kafka.KafkaCluster$$anonfun$checkErrors$1.apply(KafkaCluster.scala:366)
scala.util.Either.fold(Either.scala:97)
org.apache.spark.streaming.kafka.KafkaCluster$.checkErrors(KafkaCluster.scala:365)
org.apache.spark.streaming.kafka.KafkaUtils$.createDirectStream(KafkaUtils.scala:422)
com.xxxxxx.bigdata.spark.examples.FemaleInfoCollectionPrint$.main(FemaleInfoCollectionPrint.scala:45)
com.xxxxxx.bigdata.spark.examples.FemaleInfoCollectionPrint.main(FemaleInfoCollectionPrint.scala)

sun.reflect.NativeMethodAccessorImpl.invoke(NativeMethodAccessorImpl.java:62)
sun.reflect.DelegatingMethodAccessorImpl.invoke(DelegatingMethodAccessorImpl.java:43)
```

```
java.lang.reflect.Method.invoke(Method.java:498)
org.apache.spark.deploy.SparkSubmit$.org$apache$spark$deploy$SparkSubmit$
$runMain(SparkSubmit.scala:762)
org.apache.spark.deploy.SparkSubmit$.doRunMain$1(SparkSubmit.scala:183)
org.apache.spark.deploy.SparkSubmit$.submit(SparkSubmit.scala:208)
org.apache.spark.deploy.SparkSubmit$.main(SparkSubmit.scala:123)
org.apache.spark.deploy.SparkSubmit.main(SparkSubmit.scala)
```

Possible Causes

1. The Kafka service is abnormal.
2. The Consumer client adopts non-security access and access is disabled on the server.
3. The Consumer client adopts non-security access and ACL is set for Kafka topics.

Cause Analysis

1. Check the Kafka service status:
   - MRS Manager: Log in to MRS Manager and choose **Services** > **Kafka**. Check the Kafka status. The status is **Good**, and the monitoring metrics are correctly displayed.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka**.

     Check the Kafka status. It is found that the status is good and the monitoring metrics are correctly displayed.
2. On Manager, check the current Kafka cluster configuration. It is found that **allow.everyone.if.no.acl.found** is not configured or is set to **false**.
   - MRS Manager portal: Log in to MRS Manager and choose **Services** > **Kafka** > **Configuration**.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka** > **Configuration**.
3. If it is set to **false**, the Kafka non-secure port 21005 cannot be used for access.
4. Run the client command to check the ACL permission of the topic.

   ```
   [root@10-10-144-2 client]# kafka-acls.sh --authorizer-properties zookeeper.connect=10.5.144.2:2181/
   kafka --list --topic topic_acl
   Current ACLs for resource `Topic:topic_acl`:
    User:test_user has Allow permission for operations: Describe from hosts: *
   User:test_user has Allow permission for operations: Write from hosts: *
   ```

   If an ACL is configured for a topic, the Kafka non-secure port 21005 cannot be used to access the topic.

Solution

Step 1 Add the customized configuration **allow.everyone.if.no.acl.found** or change its value to **true** and restart the Kafka service.

Step 2 Delete the ACL configured for the topic.

Example:

kinit test_user

NOTICE

This operation must be performed by the Kafka administrator (belonging to the **kafkaadmin** group).

Example:

kafka-acls.sh --authorizer-properties zookeeper.connect=10.5.144.2:2181/kafka --remove --allow-principal User:test_user --producer --topic topic_acl

kafka-acls.sh --authorizer-properties zookeeper.connect=10.5.144.2:2181/kafka --remove --allow-principal User:test_user --consumer --topic topic_acl --group test

----End

16.13.9 Consumer Fails to Consume Data in a Newly Created Cluster, and the Message " GROUP_COORDINATOR_NOT_AVAILABLE" Is Displayed

Symptom

A Kafka cluster is created, and two Broker nodes are deployed. The Kafka client can be used for production but cannot be used for consumption. The Consumer fails to consume data, and the message "GROUP_COORDINATOR_NOT_AVAILABLE" is displayed. The key log is as follows:

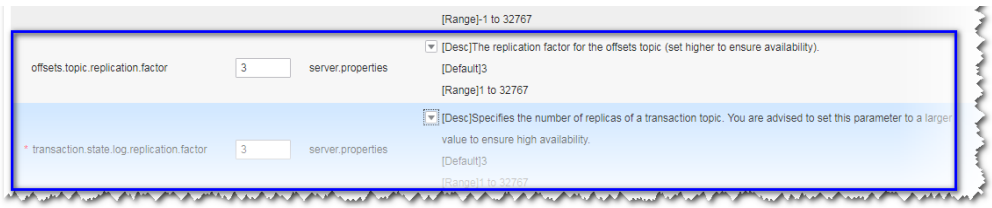
```
2018-05-12 10:58:42,561 | INFO | [kafka-request-handler-3] | [GroupCoordinator 2]: Preparing to restabilize group DemoConsumer with old generation 118 | kafka.coordinator.GroupCoordinator (Logging.scala:68)
2018-05-12 10:59:13,562 | INFO | [executor-Heartbeat] | [GroupCoordinator 2]: Preparing to restabilize group DemoConsumer with old generation 119 | kafka.coordinator.GroupCoordinator (Logging.scala:68)
```

Possible Causes

The **__consumer_offsets** cannot be created.

Cause Analysis

1. As indicated by the log, a large number of **_consumer_offset** creation operations failed.
2. The number of Brokers for the cluster is 2.
3. However, the number of replicas for the **_consumer_offset** topic is 3. Therefore, the creation fails.



Solution

Expand the cluster to at least three streaming core nodes or perform the following steps to modify service configuration parameters:

Step 1 Go to the service configuration page.

- MRS Manager: Log in to MRS Manager, choose **Services** > **Kafka** > **Service Configuration**, and select **All** from **Type**.
- FusionInsight Manager: Log in to FusionInsight Manager. Choose **Cluster** > **Services** > **Kafka**. Click **Configurations** and select **All Configurations**.

Step 2 Search for **offsets.topic.replication.factor** and **transaction.state.log.replication.factor** and change their values to **2**.

Step 3 Click **Save Configuration** and select **Restart the affected services or instances**. Click **OK** to restart the services.

----End

16.13.10 SparkStreaming Fails to Consume Kafka Messages, and the Message "Couldn't find leader offsets" Is Displayed

Symptom

When SparkStreaming is used to consume messages of a specified topic in Kafka, data cannot be obtained from Kafka. The following error message is displayed: Couldn't find leader offsets.

```
2018-05-30 12:01:17,816 | INFO  | [Driver] | Reconnect due to socket error: java.net.SocketTimeoutException | kafka.utils.Logging$class.info(Logging.scala:68)

```

Possible Causes

- The Kafka service is abnormal.
- The network is abnormal.
- The Kafka topic is abnormal.

Cause Analysis

Step 1 On Manager, check the status of the Kafka cluster. The status is **Good**, and the monitoring metrics are correctly displayed.

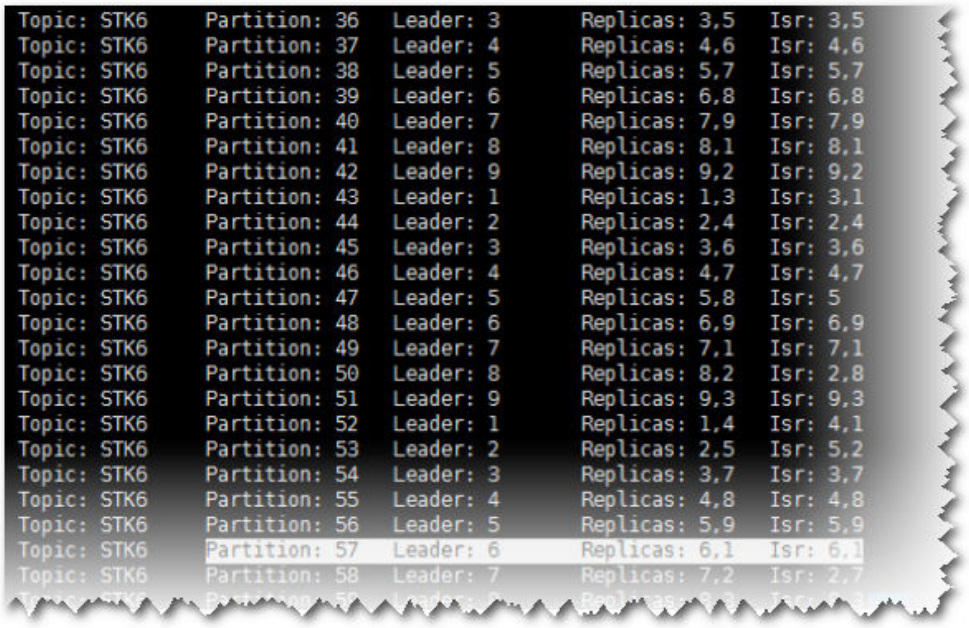
Step 2 View the error topic information in the SparkStreaming log.

Run the Kafka commands to obtain the topic assignment information and copy synchronization information, and check the return result.

kafka-topics.sh --describe --zookeeper <zk_host:port/chroot> --topic <topic name>

If information in the following figure is displayed, the topic is normal. All partitions have normal leader information.

Figure 16-55 Topic distribution information and copy synchronization information



Step 3 Check whether the network connection between the client and Kafka cluster is normal. If no, contact the network team to rectify the fault.

Step 4 Log in to Kafka Broker using SSH.

Run the **cd /var/log/Bigdata/kafka/broker** command to go to the log directory.

Check on **server.log** indicates that the error message is displayed in the log shown in the following figure.

```
2018-05-30 12:02:00,246 | ERROR | [kafka-network-thread-6-PLAINTEXT-3] | Processor got uncaught exception. | kafka.network.Processor (Logging.scala:103)

 java.lang.OutOfMemoryError: Direct buffer memory
 at java.nio.Bits.reserveMemory(Bits.java:694)
 at java.nio.DirectByteBuffer.<init>(DirectByteBuffer.java:123)
 at java.nio.ByteBuffer.allocateDirect(ByteBuffer.java:311)
 at sun.nio.ch.Util.getTemporaryDirectBuffer(Util.java:241)
 at sun.nio.ch.IOUtil.read(IOUtil.java:195)
 at sun.nio.ch.SocketChannelImpl.read(SocketChannelImpl.java:380)
```

at org.apache.kafka.common.network.PlaintextTransportLayer.read(PlaintextTransportLayer.java:110)

Step 5 On Manager, check the configuration of the current Kafka cluster.

- MRS Manager: Log in to MRS Manager and choose **Services** > **Kafka** > **Service Configuration**. Set **Type** to **All**. The value of **-XX:MaxDirectMemorySize** in **KAFKA_JVM_PERFORMANCE_OPTS** is **1G**.
- FusionInsight Manager: Log in to FusionInsight Manager. Choose **Cluster** > **Services** > **Kafka** > **Configurations** > **All Configurations**. The value of **-XX:MaxDirectMemorySize** in **KAFKA_JVM_PERFORMANCE_OPTS** is **1G**.

Step 6 If the direct memory is too small, an error is reported. Once the direct memory overflows, the node cannot process new requests. As a result, other nodes or clients fail to access the node due to timeout.

----End

Solution

Step 1 Log in to FusionInsight Manager and go to the Kafka configuration page.

- MRS Manager portal: Log in to MRS Manager and choose **Services** > **Kafka** > **Configuration**.
- FusionInsight Manager: Log in to FusionInsight Manager. Choose Cluster > **Services** > **Kafka** > **Configurations**.

Step 2 Set **Type** to **All**, and search for and change the value of **KAFKA_JVM_PERFORMANCE_OPTS**.

Step 3 Click **Save Configuration** and select **Restart the affected services or instances**. Click **OK** to restart the services.

----End

16.13.11 Consumer Fails to Consume Data and the Message " SchemaException: Error reading field 'brokers'" Is Displayed

Symptom

When a Consumer consumes messages of a specified topic in Kafka, the Consumer cannot obtain data from Kafka. The following error message is displayed: org.apache.kafka.common.protocol.types.SchemaException: Error reading field 'brokers': Error reading field 'host': Error reading string of length 28271, only 593 bytes available.

```
Exception in thread "Thread-0" org.apache.kafka.common.protocol.types.SchemaException: Error reading field 'brokers': Error reading field 'host': Error reading string of length 28271, only 593 bytes available

at
org.apache.kafka.clients.consumer.internals.ConsumerNetworkClient.poll(ConsumerNetworkClient.java:163)
atorg.apache.kafka.clients.consumer.internals.AbstractCoordinator.ensureCoordinatorReady(AbstractCoordinator.java:179)
at org.apache.kafka.clients.consumer.KafkaConsumer.pollOnce(KafkaConsumer.java:973)
```

```
at org.apache.kafka.clients.consumer.KafkaConsumer.poll(KafkaConsumer.java:937)
at KafkaNew.Consumer$ConsumerThread.run(Consumer.java:40)
```

Possible Causes

The JAR versions of the client and server are inconsistent.

Solution

Modify the Kafka JAR package in the Consumer application to ensure that it is the same as that on the server.

16.13.12 Checking Whether Data Consumed by a Customer Is Lost

Symptom

A Customer saves the consumed data to the database and finds that the data is inconsistent with the production data. Therefore, it is suspected that some of Kafka's consumed data is lost.

Possible Causes

- The customer code is incorrect.
- An exception occurs when Kafka production data is written.
- The Kafka consumption data is abnormal.

Solution

Check Kafka.

Step 1 Observe the changes of the written and consumed offset through **consumer-groups.sh**. (Produce a certain number of messages, and consume these messages on the client to observe the changes of the offset.)

Step 2 Create a consumption group, use the client to consume messages, and view the consumed messages.

new-consumer:

kafka-console-consumer.sh --topic <topic name> --bootstrap-server <IP1:PORT, IP2:PORT,...> --new-consumer --consumer.config <config file>

----End

Check the customer code.

Step 1 Check whether an error is reported when the offset is submitted on the client.

Step 2 If no error is reported, add a printing message to the API that is consumed, and print only the key to view the lost data.

----End

16.13.13 Failed to Start a Component Due to Account Lock

Symptom

In a new cluster, Kafka fails to be started. Authentication failure causes startup failure.

```
/home/omm/kerberos/bin/kinit -k -t /opt/xxxxxx/Bigdata/etc/2_15_ Broker /kafka.keytab kafka/
hadoop.hadoop.com -c /opt/xxxxxx/Bigdata/etc/2_15_ Broker /11846 failed.
export key tab file for kafka/hadoop.hadoop.com failed.export and check keytab file failed, errMsg=]}] for
Broker #192.168.1.92@192-168-1-92.
[2015-07-11 02:34:33] RoleInstance started failure for ROLE[name: Broker].
[2015-07-11 02:34:34] Failed to complete the instances start operation. Current operation entities: [Broker
#192.168.1.92@192-168-1-92], Failure entites : [Broker #192.168.1.92@192-168-1-92].Operation
Failed.Failed to complete the instances start operation. Current operation entities:
[Broker#192.168.1.92@192-168-1-92], Failure entites: [Broker #192.168.1.92@192-168-1-92].
```

Cause Analysis

Check the Kerberos log **/var/log/Bigdata/kerberos/krb5kdc.log**. It is found that IP addresses outside of the cluster uses the **kafka** account for connections, causing multiple authentication failures. As a result, the **kafka** account is locked.

```
Jul 11 02:49:16 192-168-1-91 krb5kdc[1863](info): AS_REQ (2 etypes {18 17}) 192.168.1.93:
NEEDED_PREAUTH: kafka/hadoop.hadoop.com@HADOOP.COM for krbtgt/HADOOP.COM@HADOOP.COM,
Additional pre-authentication required
Jul 11 02:49:16 192-168-1-91 krb5kdc[1863](info): preauth (encrypted_timestamp) verify failure: Decrypt
integrity check failed
Jul 11 02:49:16 192-168-1-91 krb5kdc[1863](info): AS_REQ (2 etypes {18 17}) 192.168.1.93:
PREAUTH_FAILED: kafka/hadoop.hadoop.com@HADOOP.COM for krbtgt/HADOOP.COM@HADOOP.COM,
Decrypt integrity check failed
```

Solution

Log in to a node outside the cluster (for example, 192.168.1.93 in the cause analysis example) and disable Kafka authentication. Wait 5 minutes for the account to be unlocked.

16.13.14 Kafka Broker Reports Abnormal Processes and the Log Shows "IllegalArgumentException"

Symptom

The Process Fault alarm is reported on Manager. Check whether the faulty process is Kafka Broker.

Possible Causes

Broker configuration is abnormal.

Cause Analysis

1. On Manager, obtain the host information on the alarm page.
2. Log in to Kafka Broker using SSH. Run the **cd /var/log/Bigdata/kafka/broker** command to go to the log directory.

   Check the **server.log** file. It is found that the "IllegalArgumentException" exception is thrown in the following log stating "java.lang.IllegalArgumentException: requirement failed: replica.fetch.max.bytes should be equal or greater than message.max.bytes."

   ```
   2017-01-25 09:09:14,930 | FATAL | [main] |  | kafka.Kafka$ (Logging.scala:113)
   java.lang.IllegalArgumentException: requirement failed: replica.fetch.max.bytes should be equal or greater than message.max.bytes
       at scala.Predef$.require(Predef.scala:233)
       at kafka.server.KafkaConfig.validateValues(KafkaConfig.scala:959)
       at kafka.server.KafkaConfig.<init>(KafkaConfig.scala:944)
       at kafka.server.KafkaConfig$.fromProps(KafkaConfig.scala:701)
       at kafka.server.KafkaConfig$.fromProps(KafkaConfig.scala:698)
       at kafka.server.KafkaServerStartable$.fromProps(KafkaServerStartable.scala:28)
       at kafka.Kafka$.main(Kafka.scala:60)
       at kafka.Kafka.main(Kafka.scala)
   ```

   Kafka requires that **replica.fetch.max.bytes** be greater than or equal to **message.max.bytes**.
3. On the Kafka configuration page, select **All Configurations**. All Kafka configurations are displayed. Search for **message.max.bytes** and

   replica.fetch.max.bytes. It is found that the value of **replica.fetch.max.bytes** is less than that of **message.max.bytes**.

Solution

Step 1 Go to the Kafka configuration page.

- For versions earlier than MRS 3.*x*: Log in to MRS Manager and choose **Services** > **Kafka** > **Service Configuration** > **All Configurations**.
- For MRS 3.*x* or later: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka** > **Configurations** > **All Configurations**.

Step 2 Search for and modify the **replica.fetch.max.bytes** parameter to ensure that its value is greater than or equal to that of **message.max.bytes**. In this way, replicas of partitions on different brokers can be synchronized to all messages.

Step 3 Save the configuration and check whether there is any service whose configuration has expired in the cluster. If yes, restart the corresponding service or role instance for the configuration to take effect.

Step 4 Modify **fetch.message.max.bytes** in the Consumer service application to ensure that the value of **fetch.message.max.bytes** is greater than or equal to that of **message.max.bytes**.

----End

16.13.15 Kafka Topics Cannot Be Deleted

Symptom

When running the following command on the Kafka client to delete topics, it is found that the topics cannot be deleted.

```
kafka-topics.sh --delete --topic test --zookeeper 192.168.234.231:2181/kafka
```

Possible Causes

- The command for connecting the client to ZooKeeper is incorrect.
- Kafka is abnormal and some Kafka nodes are stopped.
- Perform the following operations when Kafka server configurations cannot be deleted.
- Perform the following operations when Kafka configurations are automatically created and the Producer is not stopped.

Cause Analysis

1. After the client command is run, the "ZkTimeoutException" exception is reported.

   ```
   [2016-03-09 10:41:45,773] WARN Can not get the principle name from server 192.168.234.231 (org.apache.zookeeper.ClientCnxn)
   Exception in thread "main" org.I0Itec.zkclient.exception.ZkTimeoutException: Unable to connect to zookeeper server within timeout: 30000
   at org.I0Itec.zkclient.ZkClient.connect(ZkClient.java:880)
   at org.I0Itec.zkclient.ZkClient.<init>(ZkClient.java:98)
   at org.I0Itec.zkclient.ZkClient.<init>(ZkClient.java:84)
   at kafka.admin.TopicCommand$.main(TopicCommand.scala:51)
   at kafka.admin.TopicCommand.main(TopicCommand.scala)
   ```

   For details about the solution, see **Step 1**.

2. Run the following query command on the client:

   kafka-topics.sh --list --zookeeper 192.168.0.122:2181/kafka

   ```
   test - marked for deletion
   ```

   On Manager, check the running status of Kafka Broker instances.

   Run the **cd /var/log/Bigdata/kafka/broker** command to go to the log directory of node **RunningAsController**. Locate **ineligible for deletion: test** in the **controller.log** file.

   ```
   2016-03-09 11:11:26,228 | INFO  | [main] | [Controller 1]: List of topics to be deleted:  | kafka.controller.KafkaController (Logging.scala:68)
   2016-03-09 11:11:26,229 | INFO  | [main] | [Controller 1]: List of topics ineligible for deletion: test | kafka.controller.KafkaController (Logging.scala:68)
   ```

3. On Manager, view the **delete.topic.enable** status of Broker.

   For details about the solution, see **Step 2**.

4. Run the following query command on the client:

   ```
   kafka-topics.sh --describe –topic test --zookeeper 192.168.0.122:2181/kafka
   ```

   Go to the log directory of node **RunningAsController**. Locate **marked ineligible for deletion** in the **controller.log** file.

   ```
   2016-03-10 11:11:17,989 | INFO  | [delete-topics-thread-3] | [delete-topics-thread-3], Handling deletion for topics test | kafka.controller.TopicDeletionManager$DeleteTopicsThread (Logging.scala:68)
   2016-03-10 11:11:17,990 | INFO  | [delete-topics-thread-3] | [delete-topics-thread-3], Not retrying deletion of topic test at this time since it is marked ineligible for deletion | kafka.controller.TopicDeletionManager$DeleteTopicsThread (Logging.scala:68)
   ```

5. On Manager, query the Broker status.

   It can be seen that a Broker is in the Stopped state. In this case, delete the topic and ensure that Brokers where partitions of the topic reside must be in the Good state.

   For details about the solution, see **Step 3**.

6. Go to the log directory of node **RunningAsController**. Locate **Deletion successfully** in the **controller.log** file. If **New topics:[Set(test)]** is displayed again, it indicates that the topic is created again.

```
2016-03-10 11:33:35,208 | INFO  | [delete-topics-thread-3] | [delete-topics-thread-3], Deletion of topic test successfully completed | kafka.controller.TopicDeletionManager$DeleteTopicsThread (Logging.scala:68)

2016-03-10 11:33:38,501 | INFO  | [ZkClient-EventThread-19-192.168.0.122:2181,160.172.0.52:2181,160.172.0.51:2181/kafka] | [TopicChangeListener on Controller 3]: New topics: [Set(test)], deleted topics: [Set()], new partition replica assignment
```

7. Use Manager to query the topic creation configuration of Broker.

   It is confirmed that the application that performs operations on the topic is not stopped.

   For details about the solution, see **Step 4**.

Solution

Step 1 Perform the following operations when connection to ZooKeeper fails.

When the connection between the Kafka client and ZooKeeper times out, run the ping command to check whether the Kafka client can connect to ZooKeeper. Check the network connection between the client and ZooKeeper.

If the network connection fails, check the ZooKeeper service information on Manager.

If ZooKeeper is improperly configured, change the ZooKeeper IP address in the client command.

Step 2 Perform the following operations when Kafka server configurations cannot be deleted.

On Manager, change the value of **delete.topic.enable** to **true**. Save the configurations and restart the service.

The client query command does not contain **Topic:test**.

```
kafka-topics.sh --list --zookeeper 192.168.0.122:24002/kafka
```

Go to the log directory of node **RunningAsController**. Locate **Deletion of topic test successfully** in the **controller.log** file.

```
2016-03-10 10:39:40,665 | INFO  | [delete-topics-thread-3] | [Partition state machine on Controller 3]: Invoking state change to OfflinePartition for partitions [test,2],[test,15],[test,6],[test,16],[test,12],[test,7],[test,10],[test,13],[test,9],[test,19],[test,3],[test,5],[test,1],[test,0],[test,17],[test,8],[test,4],[test,11],[test,14],[test,18] | kafka.controller.PartitionStateMachine (Logging.scala:68)
2016-03-10 10:39:40,668 | INFO  | [delete-topics-thread-3] | [Partition state machine on Controller 3]: Invoking state change to NonExistentPartition for partitions [test,2],[test,15],[test,6],[test,16],[test,12],[test,7],[test,10],[test,13],[test,9],[test,19],[test,3],[test,5],[test,1],[test,0],[test,17],[test,8],[test,4],[test,11],[test,14],[test,18] | kafka.controller.PartitionStateMachine (Logging.scala:68)
2016-03-10 10:39:40,977 | INFO  | [delete-topics-thread-3] | [delete-topics-thread-3], Deletion of topic test successfully completed | kafka.controller.TopicDeletionManager$DeleteTopicsThread (Logging.scala:68)
```

Step 3 Some Kafka nodes are stopped or faulty.

Start the stopped Broker instances.

The client query command does not contain **Topic:test**.

```
kafka-topics.sh --list --zookeeper 192.168.0.122:24002/kafka
```

Go to the log directory of node **RunningAsController**. Locate **Deletion of topic test successfully** in the **controller.log** file.

```
2016-03-10 11:17:56,463 | INFO  | [delete-topics-thread-3] | [Partition state machine on Controller 3]: Invoking state change to NonExistentPartition for partitions [test,4],[test,1],[test,8],[test,2],[test,5],[test,9],[test,7],[test,6],[test,0],[test,3] | kafka.controller.PartitionStateMachine (Logging.scala:68)
2016-03-10 11:17:56,726 | INFO  | [delete-topics-thread-3] | [delete-topics-thread-3], Deletion of topic test successfully completed | kafka.controller.TopicDeletionManager$DeleteTopicsThread (Logging.scala:68)
```

Step 4 Perform the following operations when Kafka configurations are automatically created and the Producer is not stopped.

Stop related applications, change the value of **auto.create.topics.enable** to **false** on Manager. Save the configuration and restart the service.

Step 5 Perform the delete operation again.

----End

16.13.16 Error "AdminOperationException" Is Displayed When a Kafka Topic Is Deleted

Symptom

When running the following command on the Kafka client to set the ACL for a topic, it is found that the ACL cannot be set.

```
kafka-topics.sh --delete --topic test4 --zookeeper 10.5.144.2:2181/kafka
```

The error message "ERROR kafka.admin.AdminOperationException: Error while deleting topic test4" is displayed.

Details are as follows:

```
Error while executing topic command : Error while deleting topic test4
[2017-01-25 14:00:20,750] ERROR kafka.admin.AdminOperationException: Error while deleting topic test4

at kafka.admin.TopicCommand$$anonfun$deleteTopic$1.apply(TopicCommand.scala:162)
at scala.collection.mutable.ResizableArray$class.foreach(ResizableArray.scala:59)
at scala.collection.mutable.ArrayBuffer.foreach(ArrayBuffer.scala:47)
at kafka.admin.TopicCommand$.deleteTopic(TopicCommand.scala:162)
at kafka.admin.TopicCommand$.main(TopicCommand.scala:68)
at kafka.admin.TopicCommand.main(TopicCommand.scala)
 (kafka.admin.TopicCommand$)
```

Possible Causes

The user does not belong to the **kafkaadmin** group. Kafka provides a secure access interface. Only users in the **kafkaadmin** group can delete topics.

Cause Analysis

1. After the client command is run, the "AdminOperationException" exception is reported.
2. Run the client command **klist** to query the current authenticated user.

   ```
   [root@10-10-144-2 client]# klist
   Ticket cache: FILE:/tmp/krb5cc_0
   Default principal: test@HADOOP.COM

   Valid starting     Expires            Service principal
   01/25/17 11:06:48  01/26/17 11:06:45  krbtgt/HADOOP.COM@HADOOP.COM
   ```

The **test** user is used in this example.

3. Run the **id** command to query the user group information.
   ```
   [root@10-10-144-2 client]# id test
   uid=20032(test) gid=10001(hadoop) groups=10001(hadoop),9998(ficommon),10003(kafka)
   ```

Solution

MRS Manager:

Step 1 Log in to MRS Manager.

Step 2 Choose **System** > **Manage User**.

Step 3 In the **Operation** column of the user, click **Modify**.

Step 4 Add the user to the **kafkaadmin** group. Click **OK**.

Step 5 Run the **id** command to query the user group information.

```
[root@10-10-144-2 client]# id test
uid=20032(test) gid=10001(hadoop)
groups=10001(hadoop),9998(ficommon),10002(kafkaadmin),10003(kafka)
```

----End

FusionInsight Manager:

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User**.

Step 3 Locate the row that contains the target user, and click **Modify**.

Step 4 Add the user to the **kafkaadmin** group. Click **OK**.

Step 5 Run the **id** command to query the user group information.

```
[root@10-10-144-2 client]# id test
uid=20032(test) gid=10001(hadoop)
groups=10001(hadoop),9998(ficommon),10002(kafkaadmin),10003(kafka)
```

----End

16.13.17 When a Kafka Topic Fails to Be Created, "NoAuthException" Is Displayed

Symptom

When running the following command on the Kafka client to create topics, it is found that the topics cannot be created.

```
kafka-topics.sh --create --zookeeper 192.168.234.231:2181/kafka --replication-factor 1 --partitions 2 --topic test
```

Error messages "NoAuthException" and "KeeperErrorCode = NoAuth for /config/topics" are displayed.

Details are as follows:

```

    at org.I0Itec.zkclient.ZkClient.retryUntilConnected(ZkClient.java:985)
    ... 8 more
 (kafka.admin.TopicCommand$)
```

Possible Causes

- The Kafka service is not running.
- The ZooKeeper address parameter in the client command is incorrectly configured.

Cause Analysis

1. After the client command is run, the "NoNodeException" exception is reported.

   ```
   Error while executing topic command : org.apache.zookeeper.KeeperException$NoNodeException: KeeperErrorCode = NoNode for /brokers/ids
   [2017-09-17 16:35:28,520] ERROR org.I0Itec.zkclient.exception.ZkNoNodeException: org.apache.zookeeper.KeeperException$NoNodeException: KeeperErrorCode = NoNode for /brokers/ids
       at org.I0Itec.zkclient.exception.ZkException.create(ZkException.java:47)
       at org.I0Itec.zkclient.ZkClient.retryUntilConnected(ZkClient.java:995)
       at org.I0Itec.zkclient.ZkClient.getChildren(ZkClient.java:675)
       at org.I0Itec.zkclient.ZkClient.getChildren(ZkClient.java:671)
       at kafka.utils.ZkUtils.getChildren(ZkUtils.scala:541)
       at kafka.utils.ZkUtils.getSortedBrokerList(ZkUtils.scala:176)
   ```

```
    at kafka.admin.AdminUtils$.createTopic(AdminUtils.scala:235)
    at kafka.admin.TopicCommand$.createTopic(TopicCommand.scala:105)
    at kafka.admin.TopicCommand$.main(TopicCommand.scala:60)
    at kafka.admin.TopicCommand.main(TopicCommand.scala)
```

2. Check whether the Kafka service is in the normal state on Manager.
3. Check whether the ZooKeeper address in the client command is correct. Check the Kafka information stored in ZooKeeper. The path (Znode) should be suffixed with **/kafka**. It is found that **/kafka** is missing in the configuration.

```
[root@10-10-144-2 client]#
kafka-topics.sh --create  --replication-factor 1 --partitions 2 --topic test --zookeeper
192.168.234.231:2181
```

Solution

Step 1 Ensure that the Kafka service is normal.

Step 2 Add **/kafka** to the ZooKeeper address in the command.

```
[root@10-10-144-2 client]#
kafka-topics.sh --create  --replication-factor 1 --partitions 2 --topic test --zookeeper
192.168.234.231:2181/kafka
```

----End

16.13.20 When a Kafka Topic Fails to Be Created, "replication factor larger than available brokers" Is Displayed

Symptom

When running the following command on the Kafka client to create topics, it is found that the topics cannot be created.

```
kafka-topics.sh --create  --replication-factor 2 --partitions 2 --topic test --zookeeper
192.168.234.231:2181
```

The error message "replication factor larger than available brokers" is displayed.

See the following:

```
Error while executing topic command : replication factor: 2 larger than available brokers: 0
[2017-09-17 16:44:12,396] ERROR kafka.admin.AdminOperationException: replication factor: 2 larger than
available brokers: 0
    at kafka.admin.AdminUtils$.assignReplicasToBrokers(AdminUtils.scala:117)
    at kafka.admin.AdminUtils$.createTopic(AdminUtils.scala:403)
    at kafka.admin.TopicCommand$.createTopic(TopicCommand.scala:110)
    at kafka.admin.TopicCommand$.main(TopicCommand.scala:61)
    at kafka.admin.TopicCommand.main(TopicCommand.scala)
 (kafka.admin.TopicCommand$)
```

Possible Causes

- The Kafka service is not running.
- The available Broker of the Kafka service is smaller than the configured **replication-factor**.
- The ZooKeeper address parameter in the client command is incorrectly configured.

Cause Analysis

1. After the client command is run, "replication factor larger than available brokers" is reported.

```
Error while executing topic command : replication factor: 2 larger than available brokers: 0
[2017-09-17 16:44:12,396] ERROR kafka.admin.AdminOperationException: replication factor: 2 larger than available brokers: 0
    at kafka.admin.AdminUtils$.assignReplicasToBrokers(AdminUtils.scala:117)
    at kafka.admin.AdminUtils$.createTopic(AdminUtils.scala:403)
    at kafka.admin.TopicCommand$.createTopic(TopicCommand.scala:110)
    at kafka.admin.TopicCommand$.main(TopicCommand.scala:61)
    at kafka.admin.TopicCommand.main(TopicCommand.scala)
 (kafka.admin.TopicCommand$)
```

2. Check whether the Kafka service is in the normal state on Manager and whether the current available Broker is smaller than the configured **replication-factor**.
3. Check whether the ZooKeeper address in the client command is correct. Check the Kafka information stored in ZooKeeper. The path (Znode) should be suffixed with **/kafka**. It is found that **/kafka** is missing in the configuration.

```
[root@10-10-144-2 client]#
kafka-topics.sh --create  --replication-factor 2 --partitions 2 --topic test --zookeeper 192.168.234.231:2181
```

Solution

Step 1 Ensure that the Kafka service is in the normal state and the available Broker is not less than the configured **replication-factor**.

Step 2 Add **/kafka** to the ZooKeeper address in the command.

```
[root@10-10-144-2 client]#
kafka-topics.sh --create  --replication-factor 1 --partitions 2 --topic test --zookeeper 192.168.234.231:2181/kafka
```

----End

16.13.21 Consumer Repeatedly Consumes Data

Symptom

When the data volume is large, rebalance occurs frequently, causing repeated consumption. The key logs are as follows:

```
2018-05-12 10:58:42,561 | INFO | [kafka-request-handler-3] | [GroupCoordinator 2]: Preparing to restabilize group DemoConsumer with old generation 118 | kafka.coordinator.GroupCoordinator (Logging.scala:68)

(Logging.scala:68)
2018-05-12 11:02:49,913 | INFO | [kafka-request-handler-6] | Rolled new log segment for
'__consumer_offsets-17' in 2 ms. | kafka.log.Log (Logging.scala:68)
```

In the logs, "Preparing to restabilize group DemoConsumer with old generation" indicates that rebalance occurs.

Possible Causes

The parameter settings are improper.

Cause Analysis

Cause: Due to improper parameter settings, the data processing time is too long when the data volume is large. Balance frequently occurs, and the offset cannot be submitted normally. As a result, the data is repeatedly consumed.

Principle: The offset is submitted only after the poll data is processed. If the processing duration after the poll data is processed exceeds the duration specified by **session.timeout.ms**, the rebalance occurs. As a result, the consumption fails and the offset of the consumed data cannot be submitted. Therefore, the data is consumed at the old offset next time. As a result, the data is repeatedly consumed.

Solution

Adjust the following service parameters on Manager:

request.timeout.ms=100000

session.timeout.ms=90000

max.poll.records=50

heartbeat.interval.ms=3000

Among the preceding parameters:

The value of **request.timeout.ms** is 10s greater than that of **session.timeout.ms**.

The value of **session.timeout.ms** must be within the values of **group.min.session.timeout.ms** and **group.max.session.timeout.ms** on the server.

Set the parameters as required. The **max.poll.records** parameter specifies the number of records for each poll. The purpose is to ensure that the processing time of poll data does not exceed the value of **session.timeout.ms**.

Related Information

- The post-poll data processing must be efficient and do not block the next poll.
- The poll method and data processing suggestion are processed asynchronously.

16.13.22 Leader for the Created Kafka Topic Partition Is Displayed as none

Symptom

When a user creates a topic using the Kafka client command, the leader for the created topic partition is displayed as **none**.

```
[root@10-10-144-2 client]#
kafka-topics.sh --create  --replication-factor 1 --partitions 2 --topic test --zookeeper 10.6.92.36:2181/
kafka

Created topic "test".
```

```
[root@10-10-144-2 client]#
kafka-topics.sh --describe --zookeeper 10.6.92.36:2181/kafka

Topic:test      PartitionCount:2        ReplicationFactor:2     Configs:
        Topic: test     Partition: 0    Leader: none       Replicas: 2,3   Isr:
        Topic: test     Partition: 1    Leader: none       Replicas: 3,1   Isr:
```

Possible Causes

- The Kafka service is not running.
- The user group information cannot be found.

Cause Analysis

1. Check the Kafka service status and monitoring metrics.
   - MRS Manager: Log in to MRS Manager and choose **Services** > **Kafka**. Check the Kafka status. The status is **Good**, and the monitoring metrics are correctly displayed.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Kafka**. Check the Kafka status. The status is **Good**, and the monitoring metrics are correctly displayed.
2. Obtain the Controller node information on the Kafka overview page.
3. Log in to the node where the Controller resides, and run the **cd /var/log/Bigdata/kafka/broker** command to go to the node log directory. The **state-change.log** contains "NoAuthException", which indicates that the ZooKeeper permission is incorrect.

   ```
   2018-05-31 09:20:42,436 | ERROR | [ZkClient-
   EventThread-34-10.6.92.36:24002,10.6.92.37:24002,10.6.92.38:24002/kafka] | Controller 4 epoch 6
   initiated state change for partition [test,1] from NewPartition to OnlinePartition failed |
   state.change.logger (Logging.scala:103)
   ```

```
 org.I0Itec.zkclient.exception.ZkException: org.apache.zookeeper.KeeperException$NoAuthException:
KeeperErrorCode = NoAuth for /brokers/topics/test/partitions
 at org.I0Itec.zkclient.exception.ZkException.create(ZkException.java:68)
 at org.I0Itec.zkclient.ZkClient.retryUntilConnected(ZkClient.java:1000)
 at org.I0Itec.zkclient.ZkClient.create(ZkClient.java:527)
 at org.I0Itec.zkclient.ZkClient.createPersistent(ZkClient.java:293)
```

4. Check on ZooKeeper audit logs recorded in the specified period also indicates that the permission is abnormal.

```
2018-05-31 09:20:42,421 | ERROR | CommitProcWorkThread-1 | session=0xc3000007015d5a18
user=10.6.92.39,kafka/hadoop.hadoop.com@HADOOP.COM,kafka/

hadoop.hadoop.com@HADOOP.COM    ip=10.6.92.39    operation=create znode
target=ZooKeeperServer    znode=/kafka/brokers/topics/test/partitions    result=failure
```

5. Run the **id -Gn kafka** command on each ZooKeeper instance node. It is found that user group information cannot be queried on a node.

```
[root @bdpsit3ap03 ~]# id -Gn kafka
id:  kafka: No such user
[root @bdpsit3ap03 ~]#
```

6. In an MRS cluster, user management is provided by the LDAP service and depends on the SSSD (Red Hat) and NSCD (SUSE) services of OSs. The process from creating a user to synchronizing the user to the SSSD service takes some time. If the user does not take effect or the SSSD version has bugs, the user may be invalid on the ZooKeeper node in some cases, which causes topic creation failures.

Solution

Step 1 Restart the SSD/NSCD service.

- Red Hat

  ```
  service sssd restart
  ```

- SUSE

  ```
  sevice nscd restart
  ```

Step 2 After restarting related services, run the **id username** command on the active ResourceManager node to check whether the user information is valid.

----End

16.13.23 Safety Instructions on Using Kafka

Brief Introduction to API for Kafka

- New Producer API

  Indicates the API defined in org.apache.kafka.clients.producer.KafkaProducer. When kafka-console-producer.sh is used, the API is used by default.

- Old Producer API

  Indicates the API defined in kafka.producer.Producer. When kafka-console-producer.sh is used, the API is invoked to add --old-producer.

- New Consumer API

  Indicates the API defined in org.apache.kafka.clients.consumer.KafkaConsumer. When kafka-console-consumer.sh is used, the API is invoked to add --new-consumer.

- Old Consumer API

  Indicates the API defined in kafka.consumer.ConsumerConnector. When **kafka-console-consumer.sh** is used, the API is used by default.

NOTE

New Producer API and new Consumer API are called new API in general in the document.

Protocol Description for Accessing Kafka

The protocols used to access Kafka are as follows: PLAINTEXT, SSL, SASL_PLAINTEXT, and SASL_SSL.

When Kafka service is started, the listeners using the PLAINTEXT and SASL_PLAINTEXT protocols are started. You can set **ssl.mode.enable** to **true** in Kafka service configuration to start listeners using SSL and SASL_SSL protocols.

The following table describes the four protocols:

Protocol Type	Description	Supported API	Default Port
PLAINTEXT	Supports plaintext access without authentication.	New and old APIs	9092
SASL_PLAINTEXT	Supports plaintext access with Kerberos authentication.	New API	21007
SSL	Supports SSL-encrypted access without authentication.	New API	9093
SASL_SSL	Supports SSL-encrypted access with Kerberos authentication.	New API	21009

ACL Settings for Topic

Kafka supports secure access. Therefore, users can set the ACL for topics to control that different users access different topics. To view and set the permission information about a topic, run the kafka-acls.sh script on the Linux client.

- Scenarios

  Assign Kafka users with specific permissions for related topics based on service requirements.

  The following table describes default Kafka user groups.

User Group	Description
kafkaadmin	Kafka administrator group. Users added to this group have the permissions to create, delete, authorize, as well as read from and write data to all topics.
kafkasuperuser	Users added to this group have permissions to read data from and write data to all topics.
kafka	Kafka common user group. If users in this group want to read data from and write data to a specific topic, the users in the kafkaadmin group must grant permissions to users in this group.

- Prerequisites
  a. The system administrator has understood service requirements and prepared a Kafka administrator (belonging to the kafkaadmin group).
  b. The Kafka client has been installed.
- Procedure
  a. Log in to the node where the Kafka client is installed as the client installation user.
  b. Switch to the Kafka client installation directory, for example, **/opt/kafkaclient**.

     cd /opt/kafkaclient
  c. Run the following command to configure environment variables:

     source bigdata_env
  d. Run the following command to perform user authentication (skip this step for a cluster in common mode):

     kinit *Component service user*
  e. Run the following command to switch to the Kafka client installation directory:

     cd Kafka/kafka/bin
  f. The following describes the commands commonly used for user authorization when **kafka-acl.sh** is used:

- View the permission control list of a topic:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=<ZooKeeper cluster service IP:2181/kafka > --list --topic <Topic name>

- Add the Producer permission for a user:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=<ZooKeeper cluster service IP:2181/kafka > --add --allow-principal User:<username> --producer --topic <Topic name>

- Remove the Producer permission from a user:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=<ZooKeeper cluster service IP:2181/kafka > --remove --allow-principal User:<username> --producer --topic <Topic name>

- Add the Consumer permission for a user:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=<ZooKeeper cluster service IP:2181/kafka > --add --allow-principal User:<username> --consumer --topic <Topic name> --group <consumer group name>

- Remove the Consumer permission from a user:

  ./kafka-acls.sh --authorizer-properties zookeeper.connect=<ZooKeeper cluster service IP:2181/kafka > --remove --allow-principal User:<username> --consumer --topic <Topic name> --group <consumer group name>

Use of New and Old Kafka APIs in Different Scenarios

- Scenario 1: accessing the topic with an ACL

Used API	User Group	Client Parameter	Server Parameter	Access Port
New API	Users need to meet one of the following conditions: • In the administrator group • In the **kafkaadmin** group • In the **kafkasuperuser** group • In the **kafka** group and be authorized	security.protocol=SASL_PLAINTEXT sasl.kerberos.service.name = kafka	-	sasl.port (The default number is 21007.)
		security.protocol=SASL_SSL sasl.kerberos.service.name = kafka	Set ssl.mode.enable to true.	sasl-ssl.port (The default port number is 21009.)
Old API	N/A	N/A	N/A	N/A

- Scenario 2: accessing the topic without an ACL

Used API	User Group	Client Parameter	Server Parameter	Access Port
New API	Users need to meet one of the following conditions: • In the administrator group • In the **kafkaadmin** group • In the **kafkasuperuser** group	security.protocol=SASL_PLAINTEXT sasl.kerberos.service.name = kafka	-	sasl.port (The default number is 21007.)
	Users are in the **kafka** group.		Set **allow.everyone.if.no.acl.found** to **true**.	sasl.port (The default number is 21007.)
	Users need to meet one of the following conditions: • In the administrator group • In the **kafkaadmin** group • In the **kafkasuperuser** group	security.protocol=SASL_SSLsasl.kerberos.service.name = kafka	Set **ssl-enable** to **true**.	sasl-ssl.port (The default port number is 21009.)
	Users are in the **kafka** group.		Set **allow.everyone.if.no.acl.found** to **true**. Set **ssl-enable** to **true**.	sasl-ssl.port (The default port number is 21009.)

Used API	User Group	Client Parameter	Server Parameter	Access Port
	-	security.protocol=PLAINTEXT	Set **allow.everyone.if.no.acl.found** to **true**.	port (The default number is 21005.)
	-	security.protocol=SSL	Set **allow.everyone.if.no.acl.found** to **true**. Set **ssl-enable** to **true**.	ssl.port (The default number is 21008.)
Old Producer	-	-	Set **allow.everyone.if.no.acl.found** to **true**.	port (The default number is 21005.)
Old Consumer	-	-	Set **allow.everyone.if.no.acl.found** to **true**.	ZooKeeper service port: clientPort (The default number is 24002.)

16.13.24 Obtaining Kafka Consumer Offset Information

Symptom

How do I obtain Kafka Consumer offset information when using Kafka Consumer to consume data?

Kafka APIs

- New Producer API

  Indicates the API defined in **org.apache.kafka.clients.producer.KafkaProducer**. When **kafka-console-producer.sh** is used, the API is used by default.

- Old Producer API

  Indicates the API defined in **kafka.producer.Producer**. When **kafka-console-producer.sh** is used, the API is invoked to add **--old-producer**.

- New Consumer API

  Indicates the API defined in **org.apache.kafka.clients.consumer.KafkaConsumer**. When **kafka-console-consumer.sh** is used, the API is invoked to add **--new-consumer**.

- Old Consumer API

Indicates the API defined in **kafka.consumer.ConsumerConnector**. When **kafka-console-consumer.sh** is used, the API is used by default.

NOTE

New Producer API and new Consumer API are called new API in general in the document.

Procedure

Old Consumer API

- Prerequisites
  a. The system administrator has understood service requirements and prepared a Kafka administrator (belonging to the kafkaadmin group).
  b. The Kafka client has been installed.
- Procedure
  a. Log in to the node where the Kafka client is installed as the client installation user.
  b. Switch to the Kafka client installation directory, for example, **/opt/kafkaclient**.

     cd /opt/kafkaclient
  c. Run the following command to configure environment variables:

     source bigdata_env
  d. Run the following command to perform user authentication (skip this step for a cluster in common mode):

     kinit *Component service user*
  e. Run the following command to switch to the Kafka client installation directory:

     cd Kafka/kafka/bin
  f. Run the following command to obtain Consumer offset metric information:

     ```
     bin/kafka-consumer-groups.sh --zookeeper <zookeeper_host:port>/kafka --list
     ```

     ```
     bin/kafka-consumer-groups.sh --zookeeper <zookeeper_host:port>/kafka --describe --group test-consumer-group
     ```

     Example:

     ```
     kafka-consumer-groups.sh --zookeeper 192.168.100.100:2181/kafka --list
     kafka-consumer-groups.sh --zookeeper 192.168.100.100:2181/kafka --describe --group test-consumer-group
     ```

New Consumer API

- Prerequisites
  a. The system administrator has understood service requirements and prepared a Kafka administrator (belonging to the kafkaadmin group).
  b. The Kafka client has been installed.
- Procedure
  a. Log in to the node where the Kafka client is installed as the client installation user.

b. Switch to the Kafka client installation directory, for example, **/opt/client**.

cd /opt/client

c. Run the following command to configure environment variables:

source bigdata_env

d. Run the following command to perform user authentication (skip this step for a cluster in common mode):

kinit *Component service user*

e. Run the following command to switch to the Kafka client installation directory:

cd Kafka/kafka/bin

f. Run the following command to obtain Consumer offset metric information:

kafka-consumer-groups.sh --bootstrap-server <broker_host:port> --describe --group my-group

Example:

kafka-consumer-groups.sh --bootstrap-server 192.168.100.100:9092 --describe --group my-group

16.13.25 Adding or Deleting Configurations for a Topic

Symptom

Configure or modify a specific topic when using Kafka.

Parameters that can be modified at the topic level:

```
cleanup.policy
compression.type
delete.retention.ms
file.delete.delay.ms
flush.messages
flush.ms
index.interval.bytes
max.message.bytes
min.cleanable.dirty.ratio
min.insync.replicas
preallocate
retention.bytes
retention.ms
segment.bytes
segment.index.bytes
segment.jitter.ms
segment.ms
unclean.leader.election.enable
```

Procedure

- Prerequisites

  The Kafka client has been installed.

- Procedure

  a. Log in to the node where the Kafka client is installed as the client installation user.

  b. Switch to the Kafka client installation directory, for example, **/opt/client**.

cd /opt/client

c. Run the following command to configure environment variables:

source bigdata_env

d. Run the following command to perform user authentication (skip this step for a cluster in common mode):

kinit *Component service user*

e. Run the following command to switch to the Kafka client installation directory:

cd Kafka/kafka/bin

f. Run the following commands to configure and delete a topic:

kafka-topics.sh --alter --topic <topic_name> --zookeeper <zookeeper_host:port>/kafka --config <name=value>

kafka-topics.sh --alter --topic <topic_name> --zookeeper <zookeeper_host:port>/kafka --delete-config <name>

Example:

kafka-topics.sh --alter --topic test1 --zookeeper 192.168.100.100:2181/kafka --config retention.ms=86400000

kafka-topics.sh --alter --topic test1 --zookeeper 192.168.100.100:2181/kafka --delete-config retention.ms

g. Run the following command to query topic information:

kafka-topics.sh --describe -topic <topic_name> --zookeeper <zookeeper_host:port>/kafka

16.13.26 Reading the Content of the __consumer_offsets Internal Topic

Issue

How does Kafka save the offset of a Consumer to the **__consumer_offsets** of internal topics?

Procedure

Step 1 Log in to the node where the Kafka client is installed as the client installation user.

Step 2 Switch to the Kafka client installation directory, for example, **/opt/client**.

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the following command to perform user authentication (skip this step for a cluster in common mode):

kinit *Component service user*

Step 5 Run the following command to switch to the Kafka client installation directory:

cd Kafka/kafka/bin

Step 6 Run the following command to obtain Consumer offset metric information:

kafka-console-consumer.sh --topic __consumer_offsets --zookeeper <zk_host:port>/kafka --formatter "kafka.coordinator.group.GroupMetadataManager\$OffsetsMessageFormatter" --consumer.config <property file> --from-beginning

Add the following content to the <*property file*> configuration file:

```
exclude.internal.topics = false
```

Example:

kafka-console-consumer.sh --topic __consumer_offsets --zookeeper 10.5.144.2:2181/kafka --formatter "kafka.coordinator.group.GroupMetadataManager\$OffsetsMessageFormatter" --consumer.config ../config/consumer.properties --from-beginning

```
[example-group1,test2,0]::[OffsetMetadata[0,NO_METADATA],CommitTime 1487121209218,ExpirationTime 148720760
9218]
[example-group1,test2,1]::[OffsetMetadata[0,NO_METADATA],CommitTime 1487121209218,ExpirationTime 148720760
9218]
[example-group1,test2,0]::[OffsetMetadata[2,NO_METADATA],CommitTime 1487121269208,ExpirationTime 148720760
9208]
[example-group1,test2,1]::[OffsetMetadata[1,NO_METADATA],CommitTime 1487121269208,ExpirationTime 148720760
```

----End

16.13.27 Configuring Logs for Shell Commands on the Client

Issue

How do I set the log level for shell commands on the client?

Procedure

Step 1 Log in to the node where the Kafka client is installed as the client installation user.

Step 2 Switch to the Kafka client installation directory, for example, **/opt/client**.

cd /opt/client

Step 3 Run the following command to switch to the Kafka client configuration directory:

cd Kafka/kafka/config

Step 4 Open the **tools-log4j.properties** file, change **WARN** to **INFO**, and save the file.

```
log4j.rootLogger=WARN, stderr

log4j.appender.stderr=org.apache.log4j.ConsoleAppender
log4j.appender.stderr.layout=org.apache.log4j.PatternLayout
log4j.appender.stderr.layout.ConversionPattern=[%d] %p %m (%c)%n
log4j.appender.stderr.Target=System.err
```

```
log4j.rootLogger=INFO, stderr

log4j.appender.stderr=org.apache.log4j.ConsoleAppender
log4j.appender.stderr.layout=org.apache.log4j.PatternLayout
log4j.appender.stderr.layout.ConversionPattern=[%d] %p %m (%c)%n
log4j.appender.stderr.Target=System.err
```

Step 5 Switch to the Kafka client installation directory, for example, **/opt/client**.

cd /opt/client

Step 6 Run the following command to configure environment variables:

source bigdata_env

Step 7 Run the following command to perform user authentication (skip this step for a cluster in common mode):

kinit *Component service user*

Step 8 Run the following command to switch to the Kafka client installation directory:

cd Kafka/kafka/bin

Step 9 Run the following command to obtain the topic information. The log information can be viewed on the console.

```
kafka-topics.sh --list --zookeeper 10.5.144.2:2181/kafka
[2017-02-17 14:34:27,005] INFO JAAS File name: /opt/client/Kafka/./kafka/config/jaas.conf

16.13.28 Obtaining Topic Distribution Information

Issue

How do I obtain topic distribution information in a Broker instance?

Preparations

- Prerequisites

  The Kafka and ZooKeeper clients have been installed.

- Procedure

  a. Log in to the node where the Kafka client is installed as the client installation user.

  b. Switch to the Kafka client installation directory, for example, **/opt/client**.

  cd /opt/client

  c. Run the following command to configure environment variables:

source bigdata_env

d. Run the following command to perform user authentication (skip this step for a cluster in common mode):

kinit *Component service user*

e. Run the following command to switch to the Kafka client installation directory:

cd Kafka/kafka/bin

f. Run the Kafka commands to obtain the topic assignment information and copy synchronization information, and check the return result.

kafka-topics.sh --describe --zookeeper <zk_host:port/chroot>

Example:

```
[root@mgtdat-sh-3-01-3 client]#kafka-topics.sh --describe --zookeeper 10.149.0.90:2181/
kafka
Topic:topic1   PartitionCount:2  ReplicationFactor:2     Configs:
Topic: topic1  Partition: 0 Leader: 26 Replicas: 23,25 Isr: 26
Topic: topic1  Partition: 1 Leader: 24 Replicas: 24,23 Isr: 24,23
```

In the preceding information, **Replicas** indicates the replica assignment information and **Isr** indicates the replica synchronization information.

Solution 1

1. Query the Broker ID mapping in ZooKeeper.

   sh zkCli.sh -server <zk_host:port>

2. Run the following command on the ZooKeeper client:

   ls /kafka/brokers/ids

   get/kafka/brokers/ids/<queried Broker ID>

   Example:

```
[root@node-master1gAMQ kafka]# zkCli.sh -server node-master1gAMQ:2181
Connecting to node-master1gAMQ:2181
Welcome to ZooKeeper!
JLine support is enabled

WATCHER::

WatchedEvent state:SyncConnected type:None path:null
[zk: node-master1gAMQ:2181(CONNECTED) 0] ls /kafka/brokers/
ids     seqid    topics
[zk: node-master1gAMQ:2181(CONNECTED) 0] ls /kafka/brokers/ids
[1]
[zk: node-master1gAMQ:2181(CONNECTED) 1] get /kafka/brokers/ids/1
{"listener_security_protocol_map":{"PLAINTEXT":"PLAINTEXT","SSL":"SSL"},"endpoints":["PLAINTEXT://
192.168.2.242:9092","SSL://192.168.2.242:9093"],"rack":"/default/
rack0","jmx_port":21006,"host":"192.168.2.242","timestamp":"1580886124398","port":9092,"version":4}
[zk: node-master1gAMQ:2181(CONNECTED) 2]
```

Solution 2

Obtain the mapping between nodes and Broker IDs.

kafka-broker-info.sh --zookeeper <zk_host:port/chroot>

Example:

```
[root@node-master1gAMQ kafka]# bin/kafka-broker-info.sh --zookeeper 192.168.2.70:2181/kafka
Broker_ID     IP_Address
```

```
---------------------------
1          192.168.2.242
```

16.13.29 Kafka HA Usage Description

Kafka High Reliability and Availability

Kafka message transmission assurance mechanism ensures message transmission after required parameters are set to meet different performance and reliability requirements.

- **Kafka high availability and high performance**

  If HA and high performance are required, configure parameters listed in the following table.

Parameter	Default Value	Description
unclean.leader.election.enable	true	Specifies whether a replica that is not in the ISR can be selected as the leader. If this parameter is set to **true**, data may be lost.
auto.leader.rebalance.enable	true	Specifies whether the leader automated balancing function is used. If this parameter is set to **true**, the controller periodically balances the leader of each partition on all nodes and assigns the leader to a replica with a higher priority.

Parameter	Default Value	Description
acks	1	The leader needs to check whether the message has been received and determine whether the required operation has been processed. This parameter affects message reliability and performance. • If this parameter is set to **0**, the Producer does not wait for any response from the server and the message is considered successful. • If this parameter is set to **1**, when the leader of the copy verifies that data has been written into the cluster, the leader makes repose quickly without waiting until all the copies are written. In this case, if the leader is abnormal when the leader makes the confirmation but replica synchronization is not complete, data will be lost. • If this parameter is set to **-1** (all), the synchronization is successful only after all synchronization copies are confirmed. If **min.insync.replicas** is also configured, multiple copies can be written successfully. In this case, as long as one copy remains active, the record is not lost. **NOTE** This parameter is configured in the Kafka client configuration file.
min.insync.replicas	1	Specifies the minimum number of replicas to which data is written when **acks** is set to **-1** for the Producer.

Impact of HA and high performance configurations:

NOTICE

After HA and high performance are configured, the data reliability decreases. Specifically, data may be lost of disks or nodes are faulty.

- **Kafka high reliability configuration**

  If high data reliability is required, configure parameters listed in the following table.

Parameter	Recommended Value	Description
unclean.leader.election.enable	false	Indicates whether a replica that is not in the ISR list can be elected as a leader.
acks	-1	The leader needs to check whether the message has been received and determine whether the required operation has been processed. If this parameter is set to **-1**, the message is successfully received only when all replicas in the ISR list have confirmed to receive the message. The **min.insync.replicas** parameter must also be set to ensure that multiple copies can be written successfully. As long as one copy is active, the record is not lost. **NOTE** This parameter is configured in the Kafka client configuration file.
min.insync.replicas	2	Specifies the minimum number of replicas to which data is written when **acks** is set to **-1** for the Producer. Ensure that the value of **Min.insync.replicas** is equal to or less than that of **replication.factor**.

Impact of high reliability configurations:

- Deteriorated performance

  All copies in the ISR list are required, and the writing of the minimum number of copies has been verified successful. As a result, the delay of a single message increases and the processing capability of the client decreases. The actual performance depends on the onsite test data.

- Reduced availability

  A replica that is not in the ISR list cannot be elected as a leader. If the leader goes offline and other replicas are not in the ISR list, the partition remains unavailable until the leader node recovers.

  All copies in the ISR list are required, and the writing of the minimum number of copies has been verified successful. When the node where a copy of a partition is located is faulty, the minimum number of successful copies cannot be met. As a result, service writing fails.

Configuration Impact

Evaluate reliability and performance requirements based on service scenarios and use proper parameter configuration.

NOTE

- For valuable data, you are advised to configure raid1 or raid5 for Kafka data directory disks to improve data reliability in case disk fault of a single disk.
- The **acks** parameter is named different for different Producer APIs.
  - New Producer API

    Indicates the interface defined in **org.apache.kafka.clients.producer.KafkaProducer**. The **acks** parameter name remains unchanged for this API.
  - Old Producer API

    Indicates the interface defined in **kafka.producer.Producer**. The **acks** parameter is named as **request.required.acks** for this API.
- For parameters that can be modified at the topic level, the service level configurations are used by default. These parameters can be separately configured based on topic reliability requirements.

  For example, you can configure the reliability parameters of the topic named **test**.

  kafka-topics.sh --zookeeper 192.168.1.205:2181/kafka --alter --topic test --config unclean.leader.election.enable=false --config min.insync.replicas=2

  192.168.1.205 indicates the ZooKeeper service IP address.
- If modification of the service-level requires the restart of Kafka, you are advised to modify the service-level configuration on the change page.

16.13.30 Kafka Producer Writes Oversized Records

Symptom

When a user develops a Kafka application and invokes the new interface (**org.apache.kafka.clients.producer.***) as a Producer to write data to Kafka, the size of a single record is 1100055, which exceeds the value (**1000012**) of **message.max.bytes** in the Kafka configuration file **server.properties**. After the values of **message.max.bytes** and **replica.fetch.max.bytes** in the Kafka service configuration are changed to **5242880**, the exception persists. The error information is as follows:

```
.....
14749 [Thread-0] INFO  com.xxxxxx.bigdata.kafka.example.NewProducer  - The ExecutionException occured : {}.
java.util.concurrent.ExecutionException: org.apache.kafka.common.errors.RecordTooLargeException: The message is 1100093 bytes when serialized which is larger than the maximum request size you have configured with the max.request.size configuration.
at org.apache.kafka.clients.producer.KafkaProducer$FutureFailure.<init>(KafkaProducer.java:739)
at org.apache.kafka.clients.producer.KafkaProducer.doSend(KafkaProducer.java:483)
at org.apache.kafka.clients.producer.KafkaProducer.send(KafkaProducer.java:430)
at org.apache.kafka.clients.producer.KafkaProducer.send(KafkaProducer.java:353)
at com.xxxxxx.bigdata.kafka.example.NewProducer.run(NewProducer.java:150)
Caused by: org.apache.kafka.common.errors.RecordTooLargeException: The message is **** bytes when serialized which is larger than the maximum request size you have configured with the max.request.size configuration.
.....
```

Cause Analysis

When data is written to Kafka, the Kafka client compares the value of **max.request.size** with the size of the data to be written. If the size of the data to be written exceeds the default value of **max.request.size**, the preceding exception is reported.

Solution

Step 1 You can set the value of **max.request.size** when initializing the Kafka Producer instance.

For example, you can set this parameter to **5252880** as follows:

```
// Protocol type: Currently, the SASL_PLAINTEXT or PLAINTEXT protocol types can be used.
props.put(securityProtocol, kafkaProc.getValues(securityProtocol, "SASL_PLAINTEXT"));
 // Service name
props.put(saslKerberosServiceName, "kafka");
props.put("max.request.size", "5252880");
.....
```

----End

16.13.31 Kafka Consumer Reads Oversized Records

Symptom

After data is written to Kafka, a user develops an application and invokes the interface (**org.apache.kafka.clients.consumer.***) to read data from Kafka as a Consumer. However, the reading fails and the following error is reported:

```
.....
1687 [KafkaConsumerExample] INFO  org.apache.kafka.clients.consumer.internals.AbstractCoordinator  - Successfully joined group DemoConsumer with generation 1
1688 [KafkaConsumerExample] INFO  org.apache.kafka.clients.consumer.internals.ConsumerCoordinator  - Setting newly assigned partitions [default-0, default-1, default-2] for group DemoConsumer
2053 [KafkaConsumerExample] ERROR com.xxxxxx.bigdata.kafka.example.NewConsumer  - [KafkaConsumerExample], Error due to
org.apache.kafka.common.errors.RecordTooLargeException: There are some messages at [Partition=Offset]: {default-0=177} whose size is larger than the fetch size 1048576 and hence cannot be ever returned. Increase the fetch size on the client (using max.partition.fetch.bytes), or decrease the maximum message size the broker will allow (using message.max.bytes).
2059 [KafkaConsumerExample] INFO  com.xxxxxx.bigdata.kafka.example.NewConsumer  - [KafkaConsumerExample], Stopped
.....
```

Cause Analysis

When reading data, the Kafka client compares the size of the data to be read with the value of **max.partition.fetch.bytes**. If the size exceeds the value of **max.partition.fetch.bytes**, the preceding exception is reported.

Solution

Step 1 When creating a Kafka Consumer instance during initialization, set **max.partition.fetch.bytes**.

For example, you can set this parameter to **5252880** as follows:

```
.....
// Security protocol type
props.put(securityProtocol, kafkaProc.getValues(securityProtocol, "SASL_PLAINTEXT"));
// Service name
props.put(saslKerberosServiceName, "kafka");

props.put("max.partition.fetch.bytes","5252880");
.....
```

----End

16.13.32 High Usage of Multiple Disks on a Kafka Cluster Node

Issue

The usage of multiple disks on a node in the Kafka streaming cluster is high. The Kafka service will become unavailable if the usage reaches 100%.

Symptom

A node in the MRS Kafka streaming cluster by the customer has multiple disks. Due to improper partitioning and service reasons, the usage of some disks is high. When the usage reaches 100%, Kafka becomes unavailable.

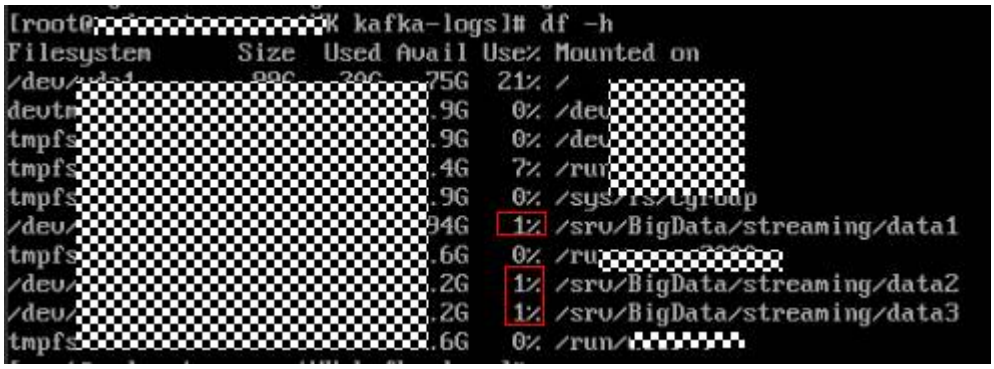
Cause Analysis

The disk data needs to be processed in a timely manner. After the value of **log.retention.hours** is changed, the service needs to be restarted. To ensure service continuity, you can shorten the aging time of a single data-intensive topic as required.

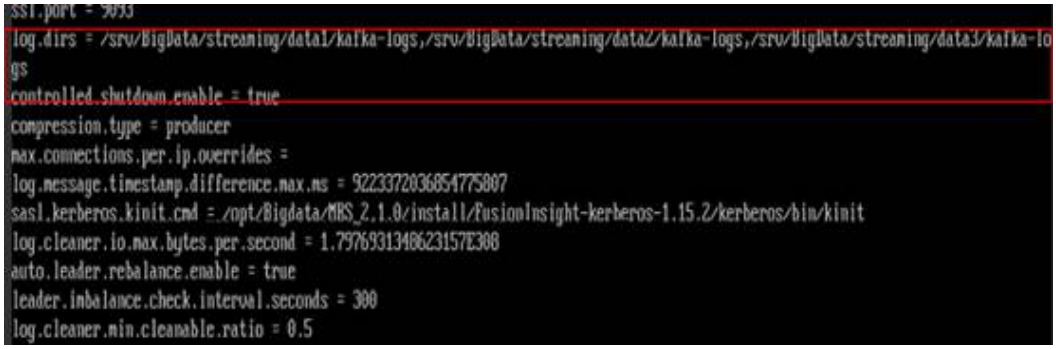
Procedure

Step 1 Log in to the core node of the Kafka streaming cluster.

Step 2 Run the **df –h** command to check the disk usage.

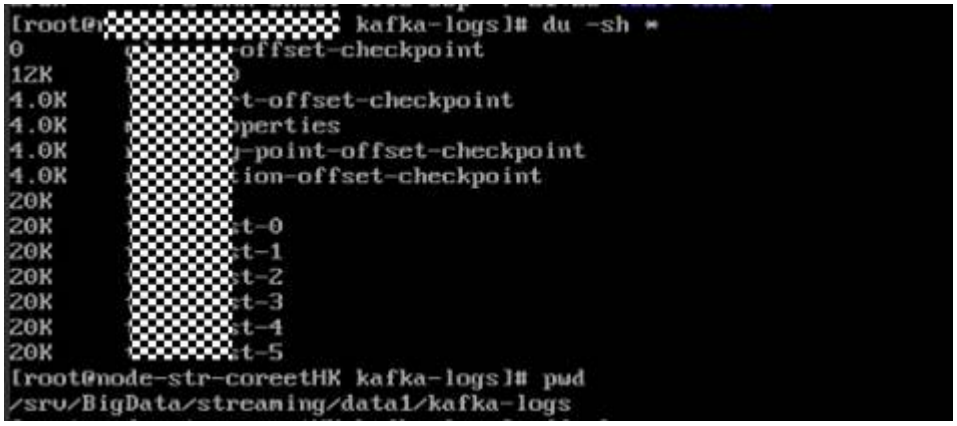


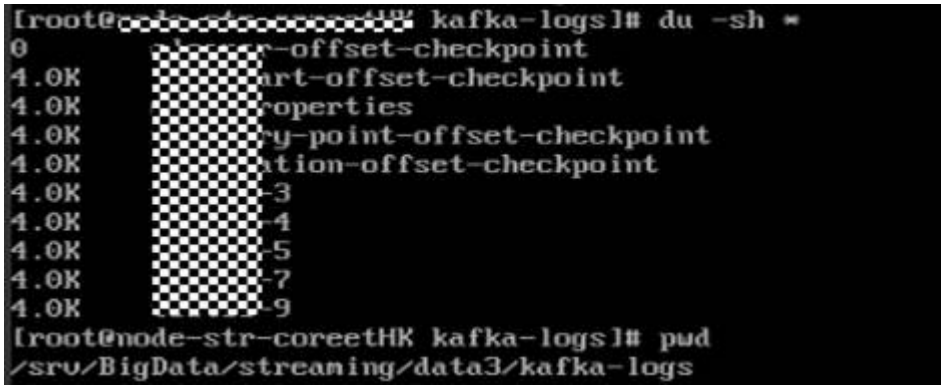
Step 3 Obtain the data storage directory from the **log.dirs** configuration item in the Kafka configuration file **opt/Bigdata/MRS_2.1.0/1_11_Broker/etc/server.properties**. Change the configuration file path based on the cluster version in the environment. If there are multiple disks, use commas (,) to separate multiple configuration items.



Step 4 Run the **cd** command to go to the data storage directory obtained in **Step 3** of the disk with high usage.

Step 5 Run the **du -sh *** command to print the name and size of the current topic.





Step 6 Determine the method of changing the data retention period. The default global data retention period of Kafka is seven days. A large amount of data may be written to some topics, and these topics reside on the partitions on the disk with high usage.

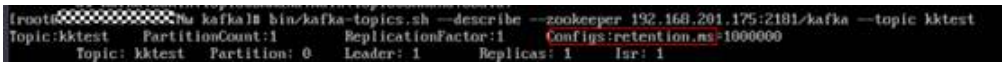
- You can change the global data retention period to a smaller value to release disk space. This method requires a Kafka service restart, which may affect service running. For details, see **Step 7**.
- You can change the data retention period of a single topic to a smaller value to release disk space. This configuration takes effect without a Kafka service restart. For details, see **Step 8**.

Step 7 Log in to Manager. On the Kafka service configuration page, switch to **All Configurations** and search for the **log.retention.hours** configuration item. The default value is 7 days. Change it based on the site requirements.

Step 8 Change the data retention time of the topics on these disks.

1. Check the retention time of the topic data.

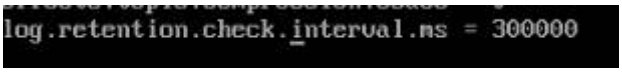
   bin/kafka-topics.sh --describe --zookeeper *<ZooKeeper cluster service IP address>*:2181/kafka --topic kktest

2. Set the topic data retention time. **--topic** indicates the topic name, and **retention.ms** indicates the data retention time, in milliseconds.

   kafka-topics.sh --zookeeper *<ZooKeeper cluster service IP address>*:2181/kafka --alter --topic kktest --config retention.ms=1000000

   
   After the data retention time is set, the deletion operation may not be performed immediately. The deletion operation starts after the time specified by **log.retention.check.interval.ms**. You can check whether the **delete** field exists in the **server.log** file of Kafka to determine whether the deletion operation takes effect. If the **delete** field exists, the deletion operation has taken effect. You can also run the **df –h** command to check the disk usage and determine whether the setting takes effect.

----End

16.14 Using Oozie

16.14.1 Oozie Jobs Do Not Run When a Large Number of Jobs Are Submitted Concurrently

Issue

When a large number of Oozie jobs are submitted concurrently, the jobs do not run.

Symptom

When a large number of Oozie jobs are submitted concurrently, the jobs do not run.

Cause Analysis

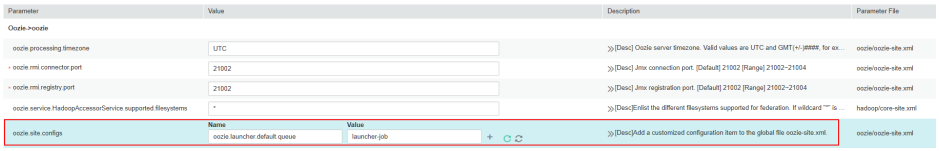
When Oozie submits a job, an oozie-launcher job is started first, and then the oozie-launcher job submits the real job for execution. By default, the oozie-launcher job and the real job are in the same queue.

When a large number of Oozie jobs are submitted concurrently, a large number of oozie-launcher jobs may be started, exhausting the resources of the queue. As a result, no more resources are available to start real jobs, and the jobs are not executed.

Procedure

Step 1 Create a queue for Oozie. For details, see **User Guide** > **Managing an Existing Cluster** > **Tenant Management** > **Creating a Tenant**. You can also use the launcher-job queue generated during MRS cluster creation.

Step 2 On Manager, choose **Cluster** > **Services** > **Oozie** > **Configurations**, search for **oozie.site.configs**, and add **oozie.launcher.default.queue** as the parameter name and **launcher-job** as the value.



----End

16.15 Using Presto

16.15.1 During sql-standard-with-group Configuration, a Schema Fails to Be Created and the Error Message "Access Denied" Is Displayed

Issue

A schema fails to be created during sql-standard-with-group configuration and the error message "Access Denied" is displayed.

Symptom

```
CREATE SCHEMA hive.sf2 WITH (location = 'obs://obs-zy1234/sf2');Query 20200224_031203_00002_g6gzy failed: Access Denied: Cannot create schema sf2
```

Cause Analysis

To create a schema in Presto, you must have the administrator permission of Hive.

Procedure

MRS Manager:

- Method 1:
  a. Log in to MRS Manager and choose **System** > **Manage User**.
  b. Locate the row that contains the target user, and click **Modify** in the **Operation** column.

c. Click **Select and Add Role** to assign the **System_administrator** permission to the user.

d. Click **OK**.

- Method 2:

a. Log in to MRS Manager and choose **System** > **Manage Role**.

b. Click **Create Role** and set the following parameters:

- Enter a role name, for example, **hive_admin**.
- Set **Permission** to **Hive** and select **Hive Admin Privilege**.

c. Click **OK** to save the role.

d. Choose **System** > **Manage User**.

e. Locate the row that contains the target user, and click **Modify** in the **Operation** column.

f. Click **Select and Add Role** to add the newly created hive_admin permission to the user.

g. Click **OK**.

FusionInsight Manager:

- Method 1:

a. Log in to FusionInsight Manager and choose **System** > **Permission** > **User**.

b. Locate the row that contains the target user, and click **Modify** in the **Operation** column.

c. Click **Add** next to the role to assign the **System_administrator** permission to the user.

d. Click **OK**.

- Method 2:

a. Log in to FusionInsight Manager and choose **System** > **Permission** > **Role**.

b. Click **Create Role** and set the following parameters:

- Enter a role name, for example, **hive_admin**.
- To configure resource permissions, select **Hive** and **Hive Admin Permissions**.

c. Click **OK** to save the role.

d. Choose **System** > **Permission** > **User**.

e. Locate the row that contains the target user, and click **Modify** in the **Operation** column.

f. Click **Add** next to the role to add the **hive_admin** permission for the user.

g. Click **OK**.

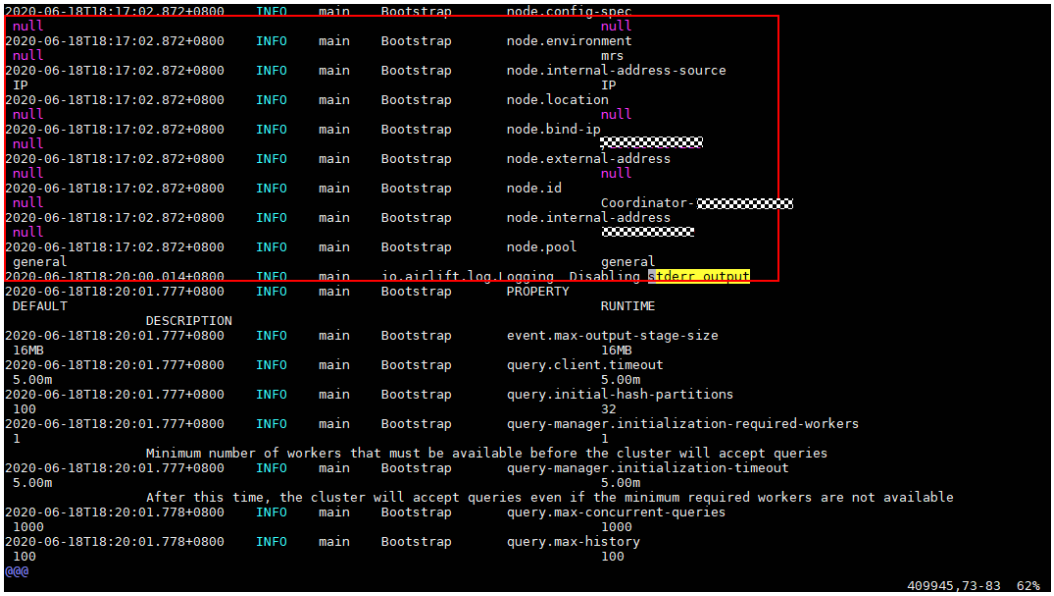
16.15.2 The Presto coordinator cannot be started properly.

Issue

The coordinator process of Presto is killed due to an unknown reason, or the coordinator process of Presto cannot be started.

Symptom

The Presto coordinator process cannot be started properly. On the Manager page, it is shown that the presto coordinator process is started properly and its status is normal. However, the background log shows that the coordinator process is not started. Only the following log is displayed:



The Presto coordinator is killed before being started, and no other logs are printed. Other Presto logs do not indicate the reason why the presto coordinator is killed.

Cause Analysis

The port check logic of the presto health check script does not distinguish ports.

Procedure

Step 1 Use a tool to log in to the master nodes of the cluster and perform the following operations:

Step 2 Run the following command to edit the file:

vim /opt/Bigdata/MRS_xxx/install/FusionInsight-Presto-*/ha/module/harm/plugin/script/pcd.sh

Change line 31 in the file to **http_port_exists=$(netstat -apn | awk '{print $4, $6}' | grep :${HTTP_PORT} | grep LISTEN | wc -l)**.

```
25
26 check_status()
27 {
28         proc_exists=$(ps -ef | grep com.facebook.presto.server.PrestoServer | grep -v grep | wc -l)
29         param="-u $PRESTO_SERVER/v1/cluster"
30         if [[ ${proc_exists} == 1 ]]; then
31             http_port_exists=$(netstat -apn | awk '{print $4, $6}' | grep :${HTTP_PORT} | grep LISTEN | wc -l)
32
33             if [[ ${http_port_exists} == 1 ]] ;then
34                 log ${PCD_LOG_FILE} "INFO" "return [ normal ]"
35                 return 0
36             else
37                 log ${PCD_LOG_FILE} "ERROR" "HTTP PORT does not exist, return [ abnormal ]"
38                 return 2
39             fi
40         else
41             log ${PCD_LOG_FILE} "INFO" " coordinator process not exists, return [ abnormal ]"
42             return 2
43         fi
44 }
45
```

Step 3 Save the modification. On FusionInsight Manager, choose **Services** > **Presto** > **Instances** to restart the Coordinator process.

----End

16.15.3 An Error Is Reported When Presto Is Used to Query a Kudu Table

Issue

An error is reported when Presto is used to query a Kudu table.

Symptom

When Presto is used to query a Kudu table, the following error message is displayed.

```
presto:default> show tables;
          Table

 impala::default.kudu_taobao
 impala::default.kudu_tt
 impala::default.kudutest
(3 rows)

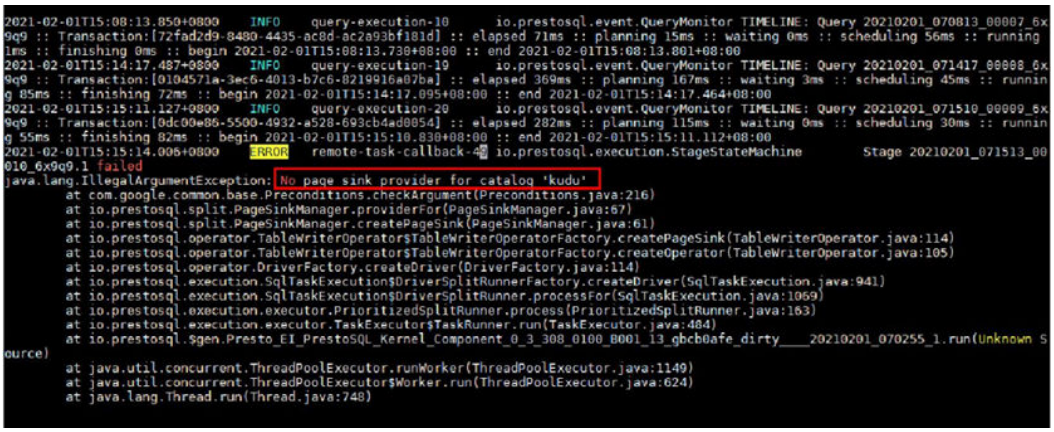
Query 20210201_030636_00026_95mzd, FINISHED, 4 nodes
Splits: 53 total, 53 done (100.00%)
0:00 [3 rows, 125B] [18 rows/s, 766B/s]

presto:default> select count(*) from kudu.default.kudu_taobao;
Query 20210201_030653_00027_95mzd failed: line 1:22: Table kudu.default.kudu_taobao does not exist
select count(*) from kudu.default.kudu_taobao

presto:default> select count(*) from kudu_taobao;
Query 20210201_030939_00028_95mzd failed: line 1:22: Table kudu.default.kudu_taobao does not exist
select count(*) from kudu_taobao

presto:default>
```

Error information



Cause Analysis

There are no Kudu configurations on the actually running node (node where the worker instance is located).

Procedure

Step 1 Add configuration file **kudu.properties** to all worker instance nodes in the Presto cluster.

Path for storing the configuration file: **/opt/Bigdata/MRS_xxx/1_x_Worker/etc/catalog/** (Change the path based on the actual cluster version.)

Configuration file content:

```
connector.name=kudu
kudu.client.master-addresses=KuduMasterIP1:port,KuduMasterIP2:port,KuduMasterIP3:port
```

NOTE

- Set the IP address and port number of the KuduMaster node based on the site requirements.
- Add the file permission and owner group that are the same as those of other files in the file save path to the configuration file.

Step 2 After the modification, choose **Components** > **Kudu** on the cluster details page, click **More**, and select **Restart Service**.

----End

16.15.4 No Data is Found in the Hive Table Using Presto

Issue

When Presto is used to query the Hive table, no data is found.

Symptom

Presto cannot query the data written by **union** statements executed by the Tez engine.

Cause Analysis

When Hive uses the Tez engine to execute the **union** statements, the output file is stored in the **HIVE_UNION_SUBDIR** directory. However, Presto does not access files in child directories by default. Therefore, data in the **HIVE_UNION_SUBDIR** directory is not read.

Procedure

Step 1 On the MRS console, click the cluster name, and choose **Components** > **Presto** > **Service Configuration**.

Step 2 Change **Basic** to **All**.

Step 3 In the navigation tree on the left, choose **Presto** > **Hive**. In the **catalog/hive.properties** file, add the **hive.recursive-directories** parameter and set it to **true**.

Step 4 Click **Save Configuration** and select **Restart the affected services or instances**.

----End

16.16 Using Spark

16.16.1 An Error Occurs When the Split Size Is Changed in a Spark Application

Issue

An error occurs when the split size is changed in a Spark application.

Symptom

A user needs to implement multiple mappers by changing the maximum split size to make the Spark application run faster. However, an error occurs when the user runs the **set $Parameter** command to modify the Hive configuration.

```
0: jdbc:hive2://192.168.1.18:21066/> set mapred.max.split.size=1000000;
Error: Error while processing statement: Cannot nodify mapred.max.split.size at runtime. It is not in list of params that are allowed to be modified at runtime( state=42000,code=1)
```

Cause Analysis

- Before the **hive.security.whitelist.switch** parameter is set to enable or disable the whitelist in security mode, the allowed parameters must have been configured in **hive.security.authorization.sqlstd.confwhitelist**.
- The default whitelist does not contain the **mapred.max.split.size** parameter. Therefore, the system displays a message indicating that the maximum split size cannot be changed.

Procedure

Step 1 Search for **hive.security.authorization.sqlstd.confwhitelist.append**, and add **mapred.max.split.size** to **hive.security.authorization.sqlstd.confwhitelist.append**. For details, see **Component Operation Guide** > **Using Hive** > **Using Hive from Scratch**.

Step 2 Save the configuration and restart the Hive component.

Step 3 Run the **set mapred.max.split.size=1000000;** command. If no error occurs, the modification is successful.

----End

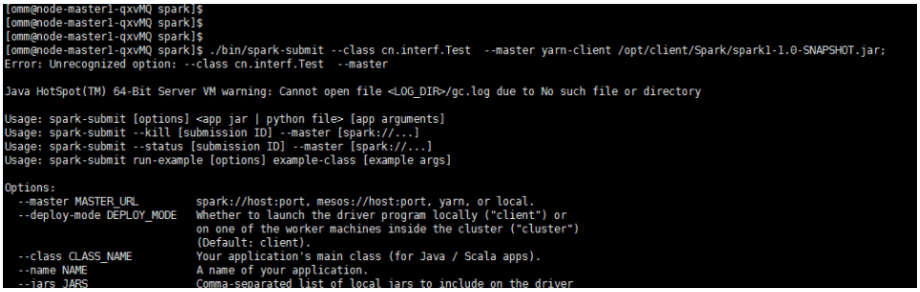
16.16.2 An Error Is Reported When Spark Is Used

Issue

When Spark is used, the cluster fails to run.

Symptom

When Spark is used, the cluster fails to run.



Cause Analysis

- Invalid characters are added during command execution.
- The owner and owner group of the uploaded JAR file is incorrect.

Procedure

Step 1 Run **./bin/spark-submit --class cn.interf.Test --master yarn-client /opt/client/Spark/spark1-1.0-SNAPSHOT.jar;** to check whether invalid characters are imported.

Step 2 If they are imported, modify the invalid characters and run the command again.

Step 3 After the command is executed again, other errors occur. Both the owner and the owner group of the JAR file are **root**.

Step 4 Change the owner and the owner group of the JAR file to **omm:wheel**.

----End

16.16.3 A Spark Job Fails to Run Due to Incorrect JAR File Import

Issue

A Spark job fails to be executed.

Symptom

A Spark job fails to be executed.

Cause Analysis

The imported JAR file is incorrect when the Spark job is executed. As a result, the Spark job fails to be executed.

Procedure

Step 1 Log in to any Master node.

Step 2 Run the **cd /opt/Bigdata/MRS_*/install/FusionInsight-Spark-*/spark/examples/jars** command to view the JAR file of the sample program.

NOTE

A JAR file name contains a maximum of 1023 characters and cannot include special characters (;|&>,<'$). In addition, it cannot be left blank or full of spaces.

Step 3 Check the executable programs in the OBS bucket. The executable programs can be stored in HDFS or OBS. The paths vary according to file systems.

NOTE

- OBS storage path: starts with **obs://**, for example, **obs://wordcount/program/hadoop-mapreduce-examples-2.7.x.jar**.
- HDFS storage path: starts with **/user**. Spark Script must end with **.sql**, and MR and Spark must end with **.jar**. The **.sql** and **.jar** are case-insensitive.

----End

16.16.4 A Spark Job Is Pending Due to Insufficient Memory

Issue

Memory is insufficient to submit a Spark job. As a result, the job is in the pending state for a long time or out of memory (OMM) occurs during job running.

Symptom

The job is pending for a long time after being submitted. The following error information is displayed after the job is executed repeatedly:

```
Exception in thread "main" org.apache.spark.SparkException: Job aborted due to stage failure:
Aborting TaskSet 3.0 because task 0 (partition 0) cannot run anywhere due to node and executor blacklist.
Blacklisting behavior can be configured via spark.blacklist.*.
```

Cause Analysis

The memory is insufficient. As a result, the submitted Spark job is in the pending state for a long time.

Procedure

Step 1 Log in to the MRS console, click a cluster name on the **Active Clusters** page and view the node specifications of the cluster on the **Nodes** tab page.

Step 2 Add cluster resources owned by the **nodemanager** process.

MRS Manager:

1. Log in to MRS Manager and choose **Services** > **Yarn** > **Service Configuration**.
2. Set **Type** to **All**, and then search for **yarn.nodemanager.resource.memory-mb** in the search box to view the value of this parameter. You are advised to set the parameter value to 75% to 90% of the total physical memory of nodes.

FusionInsight Manager:

1. Log in to FusionInsight Manager. Choose **Cluster** > **Service** > **Yarn**.
2. Choose **Configurations** > **All Configurations**. Search for **yarn.nodemanager.resource.memory-mb** in the search box and check the parameter value. You are advised to set the parameter value to 75% to 90% of the total physical memory of nodes.

Step 3 Modify the Spark service configuration.

MRS Manager:

1. Log in to MRS Manager and choose **Services** > **Spark** > **Service Configuration**.
2. Set **Type** to **All**, and then search for **spark.driver.memory** and **spark.executor.memory** in the search box.

   Set these parameters to a larger or smaller value based on the complexity and memory requirements of the submitted Spark job. (Generally, the values need to be increased.)

FusionInsight Manager:

1. Log in to FusionInsight Manager. Choose **Cluster** > **Service** > **Spark**.
2. Choose **Configurations** > **All Configurations**. Search for **spark.driver.memory** and **spark.executor.memory** in the search box and increase or decrease the values based on actual requirements. Generally, increase the values based on the complexity and memory of the submitted Spark job.

NOTE

- If a SparkJDBC job is used, search for **SPARK_EXECUTOR_MEMORY** and **SPARK_DRIVER_MEMORY** and modify their values based on the complexity and memory requirements of the submitted Spark job. (Generally, the values need to be increased.)
- If the number of cores needs to be specified, you can search for **spark.driver.cores** and **spark.executor.cores** and modify their values.

Step 4 Scale out the cluster if the preceding requirements still cannot be met because Spark depends on the memory for computing.

----End

16.16.5 An Error Is Reported During Spark Running

Issue

The specified class cannot be found when a Spark job is running.

Symptom

The specified class cannot be found when a Spark job is running. The error message is as follows:

```
Exception encountered | org.apache.spark.internal.Logging$class.logError(Logging.scala:91)
org.apache.hadoop.hbase.DoNotRetryIOException: java.lang.ClassNotFoundException:
org.apache.phoenix.filter.SingleCQKeyValueComparisonFilter
```

Cause Analysis

The default path configured by the user is incorrect.

Procedure

Step 1 Log in to any Master node.

Step 2 Modify the configuration file in the Spark client directory.

Run the **vim /opt/client/Spark/spark/conf/spark-defaults.conf** command to open the **spark-defaults.conf** file and set **spark.executor.extraClassPath** to **${PWD}/***.

----End

16.16.6 Executor Memory Reaches the Threshold Is Displayed in Driver

Symptom

A Spark task fails to be submitted due to excessive memory usage.

Cause Analysis

The Driver log prints that the applied Executor memory exceeds the cluster limit.

```
16/02/06 14:11:25 INFO Client: Verifying our application has not requested more than the maximum
memory capability of the cluster (6144 MB per container)
16/02/06 14:11:29 ERROR SparkContext: Error initializing SparkContext.
java.lang.IllegalArgumentException: Required executor memory (10240+1024 MB) is above the max
threshold (6144 MB) of this cluster!
```

Spark tasks are submitted to Yarn and the resources used by the Executor to run tasks are managed by Yarn. From the error message, you can see that when a user starts the Executor, 10 GB memory is specified, which exceeds the upper memory limit of each Container set by Yarn. As a result, the task cannot be started.

Solution

Modify the Yarn configuration to increase the restriction on containers. For example, you can adjust parameter **yarn.scheduler.maximum-allocation-mb** to control the resources for starting the Executor. Restart the Yarn service after the modification.

You can modify the configuration as follows:

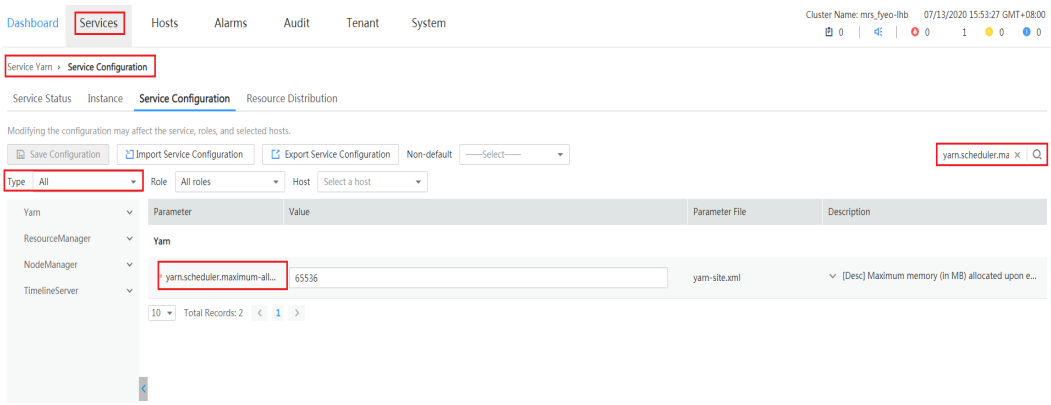
MRS Manager:

Step 1 Log in to MRS Manager.

Step 2 Choose **Services** > **Yarn** > **Service Configuration** and set **Type** to **All**.

Step 3 In **Search**, enter **yarn.scheduler.maximum-allocation-mb** to modify the parameter, save the configuration, and then restart the service. See the following figure.

Figure 16-56 Modifying Yarn service parameters



----End

FusionInsight Manager:

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Service** > **Yarn**. Click **Configurations** and select **All Configurations**.

Step 3 In **Search**, enter **yarn.scheduler.maximum-allocation-mb** to modify the parameter, save the configuration, and then restart the service.

----End

16.16.7 Message "Can't get the Kerberos realm" Is Displayed in Yarn-cluster Mode

Symptom

A Spark task fails to be submitted due to an authentication failure.

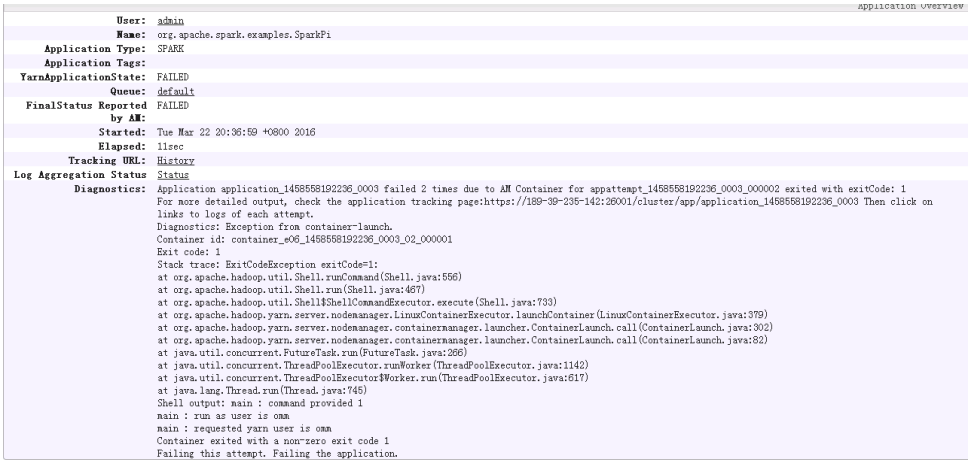
Cause Analysis

1. According to the exception printed in the driver log, the token used to connect to HDFS cannot be found.

```
16/03/22 20:37:10 WARN Client: Exception encountered while connecting to the server :
org.apache.hadoop.ipc.RemoteException(org.apache.hadoop.security.token.SecretManager
$InvalidToken): token (HDFS_DELEGATION_TOKEN token 192 for admin) can't be found in cache
16/03/22 20:37:10 WARN Client: Failed to cleanup staging dir .sparkStaging/
application_1458558192236_0003
org.apache.hadoop.ipc.RemoteException(org.apache.hadoop.security.token.SecretManager
$InvalidToken): token (HDFS_DELEGATION_TOKEN token 192 for admin) can't be found in cache
```

2. The native Yarn web UI shows that ApplicationMaster fails to be started twice and the task exits.

   Figure 16-57 ApplicationMaster start failure



3. The ApplicationMaster log shows the following error information:

```
Exception in thread "main" java.lang.ExceptionInInitializerError
Caused by: org.apache.spark.SparkException: Unable to load YARN support
Caused by: java.lang.IllegalArgumentException: Can't get Kerberos realm
Caused by: java.lang.reflect.InvocationTargetException
Caused by: KrbException: Cannot locate default realm
Caused by: KrbException: Generic error (description in e-text) (60) - Unable to locate Kerberos realm
org.apache.hadoop.hive.metastore.MetaStoreUtils.newInstance(MetaStoreUtils.java:1410)
... 86 more
Caused by: javax.jdo.JDOFatalInternalException: Unexpected exception caught.
NestedThrowables:java.lang.reflect.InvocationTargetException
... 110 more
```

4. When you execute **./spark-submit --class yourclassname --master yarn-cluster /yourdependencyjars** to submit a task in Yarn-cluster mode, the driver is enabled in the cluster. Because the client's **spark.driver.extraJavaOptions** is loaded, you cannot find the **kdc.conf** file in the target path on the cluster node and cannot obtain information required for Kerberos authentication. As a result, the ApplicationMaster fails to be started.

Solution

When submitting a task on the client, configure the **spark.driver.extraJavaOptions** parameter in the CLI. In this way, the **spark.driver.extraJavaOptions** parameter in the **spark-defaults.conf** file is not automatically loaded from the client path. When starting a Spark task, use **--conf** to specify the driver configuration as follows (note that the quotation mark after **spark.driver.extraJavaOptions=** is mandatory):

./spark-submit -class yourclassname --master yarn-cluster --conf spark.driver.extraJavaOptions="

-Dlog4j.configuration=file:/opt/client/Spark/spark/conf/log4j.properties -Djetty.version=x.y.z -Dzookeeper.server.principal=zookeeper/hadoop.794bbab6_9505_44cc_8515_b4eddc84e6c1.com -Djava.security.krb5.conf=/opt/client/KrbClient/kerberos/var/krb5kdc/krb5.conf -Djava.security.auth.login.config=/opt/client/Spark/spark/conf/jaas.conf -Dorg.xerial.snappy.tempdir=/opt/client/Spark/tmp -Dcarbon.properties.filepath=/opt/client/Spark/spark/conf/carbon.properties" ../yourdependencyjars

16.16.8 Failed to Start spark-sql and spark-shell Due to JDK Version Mismatch

Symptom

The JDK version does not match. As a result, the client fails to start spark-sql and spark-shell.

Cause Analysis

1. The following error information is displayed on the Driver:
   Exception Occurs: BadPadding 16/02/22 14:25:38 ERROR Schema: Failed initialising database. Unable to open a test connection to the given database. JDBC url = jdbc:postgresql://ip:port/sparkhivemeta, username = spark. Terminating connection pool (set lazyInit to true if you expect to start your database after your app).
2. When a SparkSQL task is used, DBService needs to be accessed to obtain metadata information. On the client, the ciphertext needs to be decrypted for access. During the use, the user does not follow the process or configure environment variables, and the default JDK version exists in the environment variables of the client. As a result, the decryption program invoked during decryption is abnormal, and the user is locked.

Solution

Step 1 Run the **which java** command to check whether the default Java command is the Java command of the client.

Step 2 If it is not, go to the next step.

source ${client_path}/bigdata_env

Run the **kinit** *username* command and enter the password corresponding to the username to start the task.

----End

16.16.9 ApplicationMaster Failed to Start Twice in Yarn-client Mode

Symptom

In Yarn-client mode, ApplicationMaster fails to start twice.

Cause Analysis

1. Driver exception:

```
16/05/11 18:10:56 INFO Client:
client token: N/A
diagnostics: Application application_1462441251516_0024 failed 2 times due to AM Container for
appattempt_1462441251516_0024_000002 exited with  exitCode: 10
For more detailed output, check the application tracking page:https://hdnode5:26001/cluster/app/
application_1462441251516_0024 Then click on links to logs of each attempt.
Diagnostics: Exception from container-launch.
Container id: container_1462441251516_0024_02_000001
```

2. The ApplicationMaster log file contains the following error information:

```
2016-05-12 10:21:23,715 | ERROR | [main] | Failed to connect to driver at 192.168.30.57:23867,
retrying ... | org.apache.spark.Logging$class.logError(Logging.scala:75)
2016-05-12 10:21:24,817 | ERROR | [main] | Failed to connect to driver at 192.168.30.57:23867,
retrying ... | org.apache.spark.Logging$class.logError(Logging.scala:75)
2016-05-12 10:21:24,918 | ERROR | [main] | Uncaught exception:  | org.apache.spark.Logging
$class.logError(Logging.scala:96)
org.apache.spark.SparkException: Failed to connect to driver!
at org.apache.spark.deploy.yarn.ApplicationMaster.waitForSparkDriver(ApplicationMaster.scala:426)
at org.apache.spark.deploy.yarn.ApplicationMaster.runExecutorLauncher(ApplicationMaster.scala:292)
...
2016-05-12 10:21:24,925 | INFO  | [Thread-1] | Unregistering ApplicationMaster with FAILED (diag
message: Uncaught exception: org.apache.spark.SparkException: Failed to connect to driver!) |
org.apache.spark.Logging$class.logInfo(Logging.scala:59)
```

In Spark-client mode, the task Driver runs on a client node (usually a node outside the cluster). During the startup, the ApplicationMaster process is started in the cluster. After the process is started, information needs to be registered with the Driver process. The task can be continued only after the registration is successful. According to the ApplicationMaster log, the connection to the Driver fails, which causes the task failure.

Solution

Step 1 Check whether the IP address of the Driver process can be pinged.

Step 2 Start a SparkPI task. Information similar to the following is displayed on the console:

```
16/05/11 18:07:20 INFO Remoting: Remoting started; listening on addresses :[akka.tcp://
sparkDriver@192.168.1.100:23662]
16/05/11 18:07:20 INFO Utils: Successfully started service 'sparkDriver' on port 23662.
```

Step 3 Run the **netstat - anp | grep 23662** command on the node (192.168.1.100 in **Step 2**) to check whether the port is enabled. The following information indicates that the port is enabled.

```
tcp       0      0  ip:port    :::*                    LISTEN      107274/java
tcp       0      0  ip:port    ip:port                 ESTABLISHED 107274/java
```

Step 4 Run the **telnet 192.168.1.100 23662** command on the node where ApplicationMaster is started to check whether the port can be connected. Perform this operation as both the **root** and **omm** users. If information similar to **Escape character is '^]'** is displayed, the connection is normal. If **connection refused** is displayed, the connection fails and the related port cannot be connected.

If the port is enabled but cannot be connected from other nodes, check the network configuration.

NOTE

The port (port 23662 in this example) is randomly selected each time. Therefore, you need to test the port enabled by the task.

----End

16.16.10 Failed to Connect to ResourceManager When a Spark Task Is Submitted

Symptom

The connection to ResourceManager is abnormal. As a result, Spark tasks fail to be submitted.

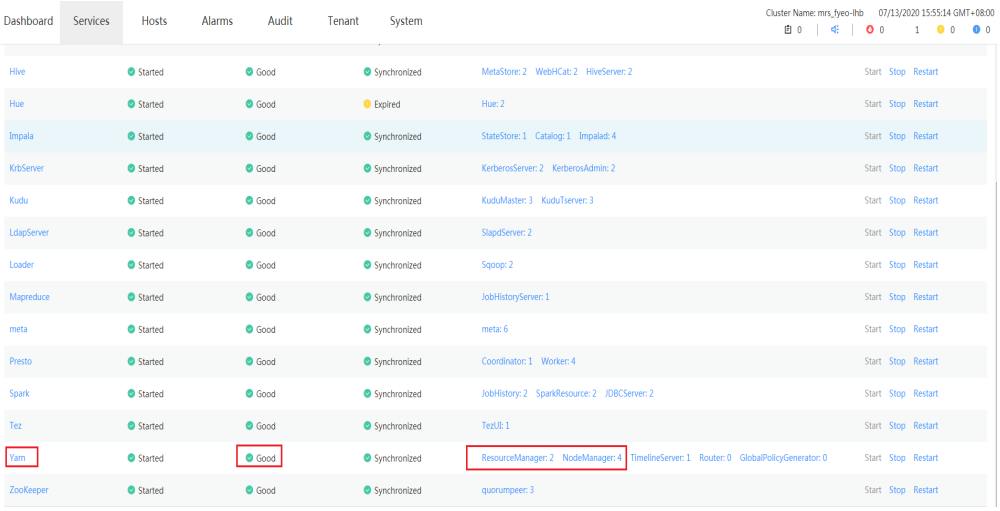
Cause Analysis

1. The following error information is displayed on the Driver, indicating that port 26004 connecting to the active and standby ResourceManager nodes is rejected:

```
15/08/19 18:36:16 INFO RetryInvocationHandler: Exception while invoking getClusterMetrics of class ApplicationClientProtocolPBClientImpl over 33 after 1 fail over attempts. Trying to fail over after sleeping for 17448ms.
 java.net.ConnectException: Call From ip0 to ip1:26004 failed on connection exception: java.net.ConnectException: Connection refused.
INFO RetryInvocationHandler: Exception while invoking getClusterMetrics of class ApplicationClientProtocolPBClientImpl over 32 after 2 fail over attempts. Trying to fail over after sleeping for 16233ms.
 java.net.ConnectException: Call From ip0 to ip2:26004 failed on connection exception: java.net.ConnectException: Connection refused;
```

2. On MRS Manager, check whether ResourceManager is running properly, as shown in **Figure 16-58**. If Yarn is faulty or an unknown exception occurs on a Yarn service instance, ResourceManager of the cluster may be abnormal.

Figure 16-58 Service status



3. Check whether the client is the latest one in the cluster.

   Check whether the ResourceManager instance has been migrated in the cluster. (Uninstall a ResourceManager instance and add it back to other nodes.)

4. On MRS Manager, click **Audit** to view audit logs and check whether related operations are recorded.

   Run the **ping** command to check whether the IP address can be pinged.

Solution

- If ResourceManager is abnormal, see the Yarn-related sections to rectify the fault.
- If the client is not the latest, download the client again.
- If the IP address cannot be pinged, contact network management personnel to check the network.

16.16.11 DataArts Studio Failed to Schedule Spark Jobs

Issue

DataArts Studio fails to schedule jobs, and a message is displayed indicating that data in the **/thriftserver/active_thriftserver** directory cannot be read.

Symptom

DataArts Studio fails to schedule jobs, and the following error is reported indicating that data in the **/thriftserver/active_thriftserver** directory cannot be read:

Can not get JDBC Connection, due to KeeperErrorCode = NoNode for /thriftserver/active_thriftserver

Cause Analysis

When DataArts Studio submits a Spark job, Spark JDBC is invoked. Spark starts a ThriftServer process for the client to provide JDBC connections. During the startup, JDBCServer creates the **active_thriftserver** subdirectory in the **/thriftserver** directory of ZooKeeper, and registers related connection information. If the connection information cannot be read, the JDBC connection is abnormal.

Procedure

Check whether the ZooKeeper directory contains the target directory and registration information.

Step 1 Log in to any master node as user **root** and initialize environment variables.

source /opt/client/bigdata_env

Step 2 Run the **zkCli.sh -server 'ZookeeperIp:2181'** command to log in to ZooKeeper.

Step 3 Run the **ls /thriftserver** command to check whether the **active_thriftserver** directory exists.

- If the **active_thriftserver** directory exists, run the **get /thriftserver/active_thriftserver** command to check whether it contains the registered configuration information.
  - If yes, contact technical support.

  - If no, go to **Step 4**.
- If the **active_thriftserver** directory does not exist, go to **Step 4**.

Step 4 Log in to Manager and check whether the active/standby status of the Spark JDBCServer instance is unknown.

- If yes, go to **Step 5**.
- If no, contact O&M personnel.

Step 5 Restart the two JDBCServer instances. Check whether the status of the active and standby instances is normal and whether the target directory and data exist in ZooKeeper. If yes, the job is restored. If the instance status is not restored, contact technical support.

----End

16.16.12 Submission Status of the Spark Job API Is Error

Issue

After a Spark job is submitted using an API, the job status is displayed as **error**.

Issue Type

Job management

Symptom

After the log level in **/opt/client/Spark/spark/conf/log4j.properties** is changed and a job is submitted using API V1.1, the job status is displayed as error.

Cause Analysis

The executor monitors the job log output and determines the job execution result. After the execution result is changed to **error**, the output result cannot be detected. Therefore, the executor determines that the job status is abnormal after the job expires.

Procedure

Change the log level in the **/opt/client/Spark/spark/conf/log4j.properties** file to **info**.

Summary and Suggestions

You are advised to use the V2 API to submit jobs.

16.16.13 Alarm 43006 Is Repeatedly Generated in the Cluster

Issue

The alarm "ALM-43006 Heap Memory Usage of the JobHistory Process Exceeds the Threshold" is repeatedly generated in the cluster, and the setting according to the alarm reference is invalid.

Symptom

Alarm **ALM-43006 Heap Memory Usage of the JobHistory Process Exceeds the Threshold** is generated in the cluster. The same alarm is generated again a period of time after handling measures are taken.

Cause Analysis

The JobHistory memory leakage may occur. You need to install the corresponding patch to rectify the fault.

Procedure

- Increase the heap memory of the JobHistory process.
- If the heap memory has been increased, restart the JobHistory instance.

16.16.14 Failed to Create or Delete a Table in Spark Beeline

Issue

When the customer frequently creates or deletes a large number of users in Spark Beeline, some users occasionally fail to create or delete tables.

Symptom

The procedure for creating a table is as follows:

```
CREATE TABLE wlg_test001 (start_time STRING,value INT);
```

The following error message is displayed:

```
Error: org.apache.spark.sql.AnalysisException:
org.apache.hadoop.hive.ql.metadata.HiveException: MetaException(message:Failed to grant permission on
HDFSjava.lang.reflect.UndeclaredThrowableException); (state=,code=0)
```

Cause Analysis

1. View metastore logs.

2. View HDFS logs.

```
2020-08-31 14:41:38,568 | INFO  | Socket Reader #1 for port 9820 | Authorization successful for hive/hadoop.036a3461_d09b_494f_a32c_af273307d943.com@036A3461_D09B_494F_A32C_AF273307D943.COM (auth:KERBEROS) for protocol=interface org.apache.hadoop.hdfs.protocol.ClientProtocol | ServiceAuthorizationManager.java:135

```

5. Analyze the cause.

   The default user created during cluster creation uses the same UID, causing user disorder. This problem is triggered when a large number of users are created. As a result, the Hive user does not have the permission to create tables occasionally.

```

```

Procedure

Restart the **sssd** process of the cluster.

Run the **service sssd restart** command as the **root** user to restart the **sssd** process and run the **ps -ef | grep sssd** command to check whether the **sssd** process is running properly.

In normal cases, the **/usr/sbin/sssd** process and three sub-processes **/usr/libexec/sssd/sssd_be**, **/usr/libexec/sssd/sssd_nss** and **/usr/libexec/sssd/sssd_pam** exist.

16.16.15 Failed to Connect to the Driver When a Node Outside the Cluster Submits a Spark Job to Yarn

Issue

When a node outside the cluster uses the client mode to submit a Spark task to Yarn, the task fails and an error message is displayed, indicating that the driver cannot be connected.

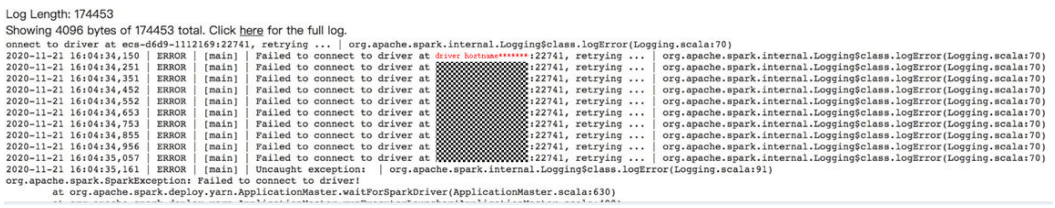
Symptom

Nodes outside the cluster can communicate with each node in the cluster. When a node outside the cluster submits a Spark task to Yarn in client mode, the task fails and an error message is displayed, indicating that the driver cannot be connected.

Cause Analysis

When a Spark task is submitted in the client mode, the driver process of Spark is on the client side, and the executor needs to interact with the driver to run the job.

If the NodeManager fails to connect to the node where the client is located, the following error is reported:



Procedure

Specify the IP address of the driver in the Spark configuration of the client.

Add **spark.driver.host=driverIP** to *<Client installation path>***/Spark/spark/conf/spark-defaults.conf** and run the Spark task again.

Summary and Suggestions

You are advised to submit jobs in cluster mode.

16.16.16 Large Number of Shuffle Results Are Lost During Spark Task Execution

Issue

Spark tasks fail to be executed. The task log shows that a large number of **shuffle** files are lost.

Symptom

Spark tasks fail to be executed. The task log shows that a large number of **shuffle** files are lost.

Cause Analysis

When Spark is running, the **shuffle** file generated temporarily is stored in the temporary directory of the executor for later use.

When an executor exits abnormally, NodeManager deletes the temporary directory of the container where the executor is located. When other executors apply for the shuffle result of the executor, a message is displayed indicating that the file cannot be found.

Therefore, you need to check whether the executor exits abnormally. You can check whether there are executors in the **dead** state on the executors tab page on the Spark task page and view the executor logs of each **dead** state, determine the cause of abnormal exit. Some executors may exit because the **shuffle** file cannot be found. You need to find the earliest executor that exits abnormally.

Common abnormal exit causes:

- OOM occurs on the executor.
- Multiple tasks fail when the executor is running.
- The node where the executor is located is cleared.

Procedure

Adjust or modify the task parameters or code based on the actual cause of the abnormal exit of the executor, and run the Spark task again.

16.16.17 Disk Space Is Insufficient Due to Long-Term Running of JDBCServer

Issue

When the JDBCServer service connected to Spark submits a spark-sql task to the Yarn cluster, the data disk of the Core node is fully occupied after the task runs for a period of time.

Symptom

When the JDBCServer service of a customer connected to Spark submits a spark-sql task to the Yarn cluster, the data disk of the Core node is fully occupied after the task runs for a period of time.

After checking the disk usage in the background, it is found that there are too many APP temporary files (files generated by shuffle) of the JDBCServer service, and the files are not cleared, occupying a large amount of memory.

Cause Analysis

After checking the directories that contain a large number of files on the Core node, it is found that most of the directories are similar to **blockmgr-033707b6-fbbb-45b4-8e3a-128c9bcfa4bf**, which stores temporary shuffle files generated during computing.

The dynamic resource allocation function of Spark is enabled on JDBCServer, and shuffle is hosted by NodeManager. NodeManager only manages these files based on the running period of the application, and does not check whether the container where a single executor is located exists. Therefore, the temporary files are deleted only when the app is stopped. When a task runs for a long time, a large number of temporary files occupy a large amount of disk space.

Procedure

Start a scheduled task to delete shuffle files that have been stored for a specified period of time. For example, delete shuffle files that have been stored for more than 6 hours each hour.

Step 1 Create the **clean_appcache.sh** script. If there are multiple data disks, change the value of **data1** in **BASE_LOC** based on the actual situation.

- Security cluster

```
#!/bin/bash
BASE_LOC=/srv/BigData/hadoop/data1/nm/localdir/usercache/spark/appcache/application_*/blockmgr*
find $BASE_LOC/ -mmin +360 -exec rmdir {} \;
find $BASE_LOC/ -mmin +360 -exec rm {} \;
```

- Common cluster

```
#!/bin/bash
BASE_LOC=/srv/BigData/hadoop/data1/nm/localdir/usercache/omm/appcache/application_*/blockmgr*
find $BASE_LOC/ -mmin +360 -exec rmdir {} \;
find $BASE_LOC/ -mmin +360 -exec rm {} \;
```

Step 2 Run the following commands to change the permission to the script:

chmod 755 clean_appcache.sh

Step 3 Add a scheduled task to start the clearance script. Change the script path to the actual path.

Run the **crontab -l** command to view the scheduled task.

Run the **crontab -e** command to edit the scheduled task.

```
0 * * * * sh /root/clean_appcache.sh > /dev/null 2>&1
```

----End

16.16.18 Failed to Load Data to a Hive Table Across File Systems by Running SQL Statements Using Spark Shell

Issue

When the **spark-shell** command is used to execute SQL statements or the **spark-submit** command is used to submit Spark tasks, the **load** command of SQL statements exists, and the source data and target table are not stored in the same file system. An error is reported when the MapReduce task is started in the preceding two modes.

Cause Analysis

When the **load** command is used to import data to the Hive table across file systems (for example, the original data is stored in the HDFS but the Hive table data is stored in the OBS), and the file length is greater than the threshold (32 MB by default). In this case, the MapReduce job that uses DistCp is triggered to migrate data. The MapReduce task configuration is directly extracted from the Spark task configuration. However, the **net.topology.node.switch.mapping.impl** configuration item of the Spark task does not retain the default value of the Hadoop. Therefore, the JAR package of the Spark needs to be used. As a result, the MapReduce reports an error indicating that the class cannot be found.

Procedure

Solution 1:

If the file size is small, set the default file size to a value greater than the maximum file size. For example, if the maximum file size is 95 MB, run the following command:

```
hive.exec.copyfile.maxsize=104857600
```

Solution 2:

If the file size is large, use DistCp to improve the data migration efficiency. Add the following parameters when starting the Spark task:

```
--conf spark.hadoop.net.topology.node.switch.mapping.impl=org.apache.hadoop.net.ScriptBasedMapping
```

16.16.19 Spark Task Submission Failure

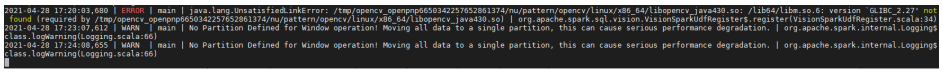
Symptom

- A Spark task fails to be submitted.
- Spark displays a message indicating that the Yarn JAR package cannot be obtained.
- A file is submitted for multiple times.

Cause Analysis

- Symptom 1:

  The most common cause for task submission failure is authentication failure.



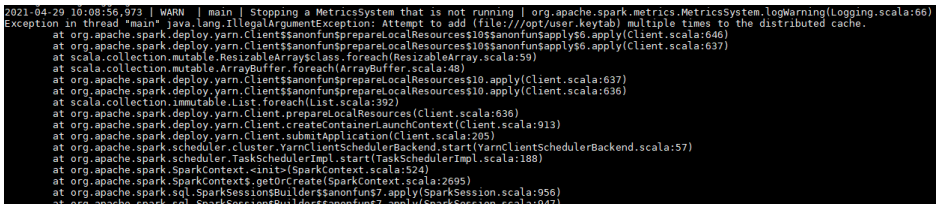
The parameter settings may be incorrect.

- Symptom 2:

  By default, the cluster adds the Hadoop JAR package of the analysis node to the classpath of the task. If the system displays a message indicating that Yarn packages cannot be found, the Hadoop configuration is not set.

- Symptom 3:

  The common scenario is as follows: The **--files** option is used to upload the **user.keytab** file, and then the **--keytab** option is used to specify the same file. As a result, the same file is uploaded for multiple times.



Procedure

- Symptom 1:

  Run **kinit** *[user]* again and modify the corresponding configuration items.

- Symptom 2:

  Check that the Hadoop configuration items are correct and the **core-site.xml**, **hdfs-site.xml**, **yarn-site.xml**, and **mapred-site.xml** configuration files in the **conf** directory of Spark are correct.

- Symptom 3:

  Copy a new **user.keytab** file, for example:

  cp user.keytab user2.keytab

  spark-submit --master yarn --files user.keytab --keytab user2.keytab .....

16.16.20 Spark Task Execution Failure

Symptom

- An executor out of memory (OOM) error occurs.
- The information about the failed task shows that the failure cause is "lost task xxx."

Cause Analysis

- Symptom 1: The data volume is too large or too many tasks are running on the same executor at the same time.
- Symptom 2: Some tasks fail to be executed. When the error is reported, determine the node where the lost task is running. Generally, the error is caused by the abnormal exit of the lost task.

Procedure

- Symptom 1:
  - If the data volume is too large, adjust the memory size of the executor and use **--executor-memory** to specify the memory size.
  - If too many tasks are running at the same time, check the number of vcores specified by **--executor-cores**.
- Symptom 2: Locate the cause in the corresponding task log. If an OOM error occurs, see the solutions to symptom 1.

16.16.21 JDBCServer Connection Failure

Symptom

- The ha-cluster cannot be identified (unknowHost or port required).
- Failed to connect to JDBCServer.

Cause Analysis

- Symptom 1: The **spark-beeline** command is used to connect to JDBCServer. JDBCServer in versions earlier than MRS_3.0 adopts HA mode. Therefore, a specific URL and the JAR package provided by MRS Spark is required to connect to JDBCServer.
- Symptom 2: The JDBCServer service is not running properly or port listening is abnormal.

Procedure

- Symptom 1: Use a specific URL and the JAR package provided by MRS Spark to connect to JDBCServer.
- Symptom 2: Check that the JDBCServer service is running properly and port listening is normal, and try again.

16.16.22 Failed to View Spark Task Logs

Symptom

- A user fails to view logs when a task is running.
- A user fails to view logs when a task is complete.

Cause Analysis

- Symptom 1: The MapReduce component is abnormal.
- Symptom 2:
  - The JobHistory service of Spark is abnormal.
  - The log size is too large, and NodeManager times out during log aggregation.
  - The permission on the HDFS log storage directory (**/tmp/logs/Username/logs** by default) is abnormal.

- Logs have been deleted. By default, Spark JobHistory stores event logs for seven days (specified by **spark.history.fs.cleaner.maxAge**). MapReduce stores task logs for 15 days (specified by **mapreduce.jobhistory.max-age-ms**).
- If the task cannot be found on the Yarn page, it may have been cleared by Yarn. By default, Yarn stores 10,000 historical tasks (specified by **yarn.resourcemanager.max-completed-applications**).

Procedure

- Symptom 1: Check whether the MapReduce component is running properly. If it is abnormal, restart it. If the fault persists, check the JobhistoryServer log file in the background.
- Symptom 2: Perform the following checks in sequence:
  a. Check whether JobHistory of Spark is running properly.
  b. On the app details page of Yarn, check whether the log file is too large. If log aggregation fails, the value of **Log Aggregation Status** should be **Failed** or **Timeout**.
  c. Check whether the permission on the corresponding directory is normal.
  d. Check whether the corresponding **appid** file exists in the directory. In MRS 3.x or later, the event log files are stored in the **hdfs://hacluster/spark2xJobHistory2x** directory. In versions earlier than MRS 3.x, the event log files are stored in the **hdfs://hacluster/sparkJobHistory** directory. The task run logs are stored in the **hdfs://hacluster/tmp/logs/*Username*/logs** directory.
  e. Check whether **appid** or the current job ID exceeds the maximum value in the historical records.

16.16.23 Authentication Fails When Spark Connects to Other Services

Symptom

- When Spark connects to HBase, an authentication failure message is displayed or the HBase table cannot be connected.
- When Spark connects to HBase, a message is displayed indicating that the JAR package cannot be found.

Cause Analysis

- Symptom 1: HBase does not obtain the authentication information of the current task. As a result, the authentication fails when HBase is connected, and the corresponding data cannot be read
- Symptom 2: By default, Spark does not load the HBase JAR package. You need to use **--jars** to add the JAR package to the task.

Procedure

- Symptom 1: Enable the HBase authentication function by running the **spark.yarn.security.credentials.hbase.enabled=true** command. However, do

not replace **hbase-site.xml** on the Spark client with **hbase-site.xml** on the HBase client because they are not completely consistent.

- Symptom 2: Use **--jars** to upload the HBase JAR package.

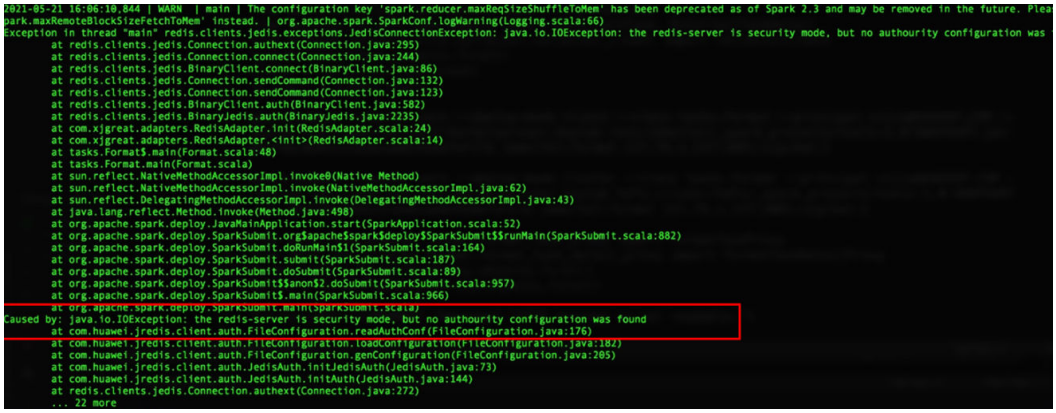
16.16.24 An Error Occurs When Spark Connects to Redis

Issue

An error occurs when the Spark component of the MRS 3.x security cluster is used to access Redis.

Symptom

When Spark of the MRS 3.0 security cluster is used to access Redis, the following error message is displayed.



Cause Analysis

The **jars** directory of Spark contains a **jredisclient-xxx.jar** package provided by the MRS cluster. This package is loaded when a Spark task connects to Redis, thereby causing this error. You can manually remove this package to rectify the fault.

Procedure

Step 1 Delete JAR packages from the Spark client.

cd $SPARK_HOME/jars

mv jredisclient-*.jar /tmp

Step 2 Delete JAR packages from the Spark server.

Log in to the nodes (generally two) where SparkResource2x is located.

mkdir /tmp/SparkResource2x

cd /opt/Bigdata/FusionInsight_Current/1_*_SparkResource2x/install/spark/jars/

mv jredisclient-*.jar /tmp/SparkResource2x

Step 3 Delete the **jredisclient** file from the HDFS.

1. Check configuration item **spark.yarn.archive** in the **$SPARK_HOME/conf/spark-defaults.conf** file to obtain the address of the **spark-archive-2x.zip** package.

   cat $SPARK_HOME/conf/spark-defaults.conf | grep "spark.yarn.archive"

2. Download the **spark-archive-2x.zip** package. (This section uses MRS 3.0.5 as an example. Modify the command based on the actual cluster version.)

   cd /opt

   mkdir sparkTmp

   cd sparkTmp

   hdfs dfs -get hdfs://hacluster/user/spark2x/jars/8.0.2.1/spark-archive-2x.zip

3. Decompress **spark-archive-2x.zip** and remove the package file.

   unzip spark-archive-2x.zip

   rm -f spark-archive-2x.zip

4. Remove the **jredisclient** package.

   rm -f jredisclient-*.jar

5. Compress the **spark-archive-2x.zip** package again.

   zip spark-archive-2x.zip ./*

6. Back up the original package from the HDFS to **tmp** and upload the newly compressed package to the HDFS.

   hdfs dfs -mv hdfs://hacluster/user/spark2x/jars/8.0.2.1/spark-archive-2x.zip /tmp

   hdfs dfs -put spark-archive-2x.zip hdfs://hacluster/user/spark2x/jars/8.0.2.1/spark-archive-2x.zip

7. Restart the JDBCServer service to prevent JDBCServer exceptions. The **jredisclient** file has been deleted from the **spark-archive-2x.zip** package.

8. Delete temporary files.

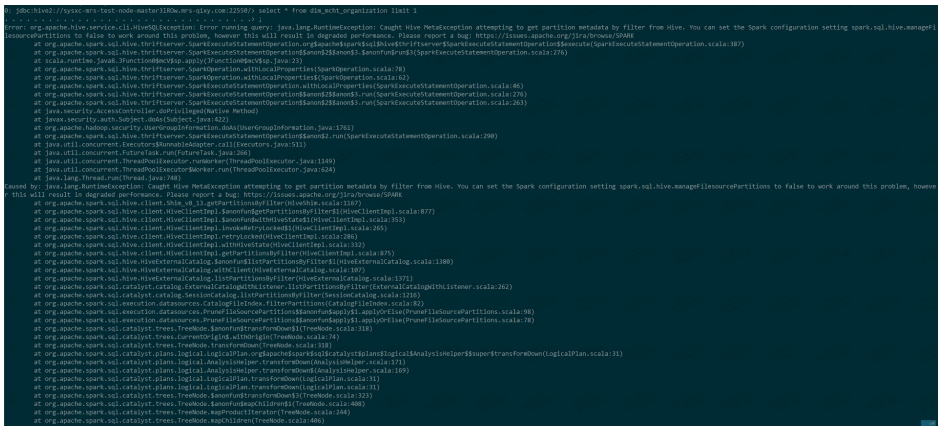
   rm -rf /opt/sparkTmp

----End

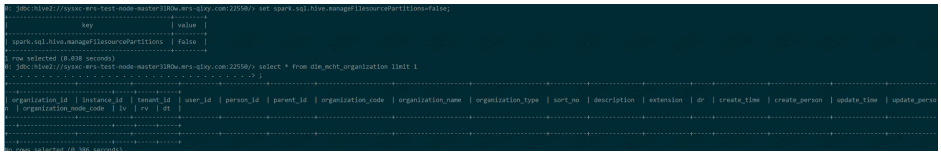
16.16.25 An Error Is Reported When spark-beeline Is Used to Query a Hive View

Issue

In MRS 3.1.2, an error is reported when spark-beeline is used to query a Hive view. The error information is as follows.



After **spark.sql.hive.manageFilesourcePartitions=false** is set as prompted, no data can be found. However, data can be queried in Hive.



Cause Analysis

Failed to convert the format. Spark SQL uses its built-in Metastore instead of Hive Metastore. As a result, metadata fails to be read. Spark SQL reads data in Parquet format, but Hive reads data in ORC format by default.

Procedure

Step 1 Log in to the Spark client node and run the following commands to access Spark SQL:

cd *Client installation directory*

source bigdata_env

source Spark2x/component_env

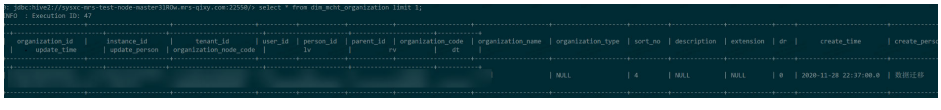
kinit *Component service user* (**kinit** is not required in a normal cluster.)

spark-sql

Step 2 Run the following command to set **spark.sql.hive.convertMetastoreOrc** to **false**:

set spark.sql.hive.convertMetastoreOrc=false;

Step 3 Query the Hive view again.



----End

16.17 Using Sqoop

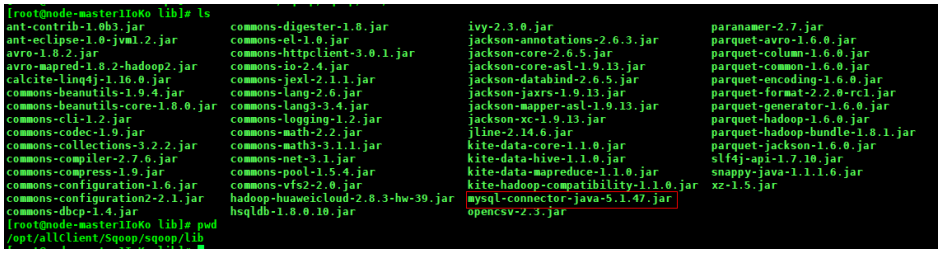
16.17.1 Connecting Sqoop to MySQL

Issue

The user does not know how to connect Sqoop to MySQL.

Procedure

Step 1 Install the client in the cluster and check whether the MySQL driver package exists in the **sqoop/lib** directory of the client.



Step 2 Load environment variables in the client directory.

source bigdata_env

Step 3 Perform the Kerberos authentication.

If Kerberos authentication is not enabled for the cluster, skip this step. If it is enabled, run the following command to authenticate the current user:

kinit *MRS cluster user*

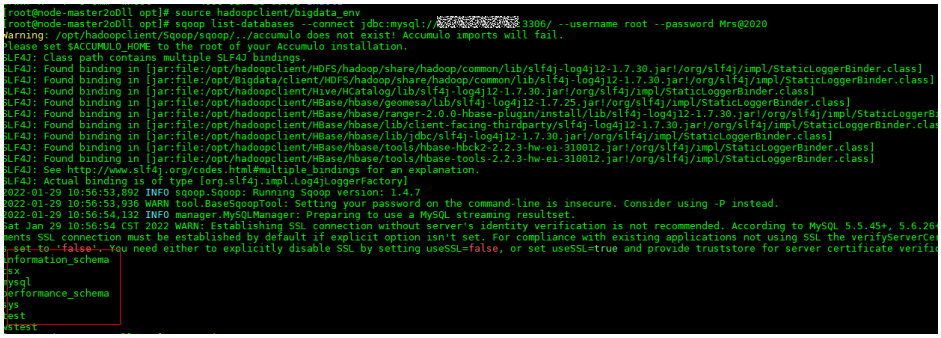
For example:

kinit admin

Step 4 Connect to the database.

sqoop list-databases --connect jdbc:mysql://IP:3306/ --username ***Username*** **--password** ***Password***

An example is as follows.



The command output shows that Sqoop is successfully connected to the MySQL database.

----End

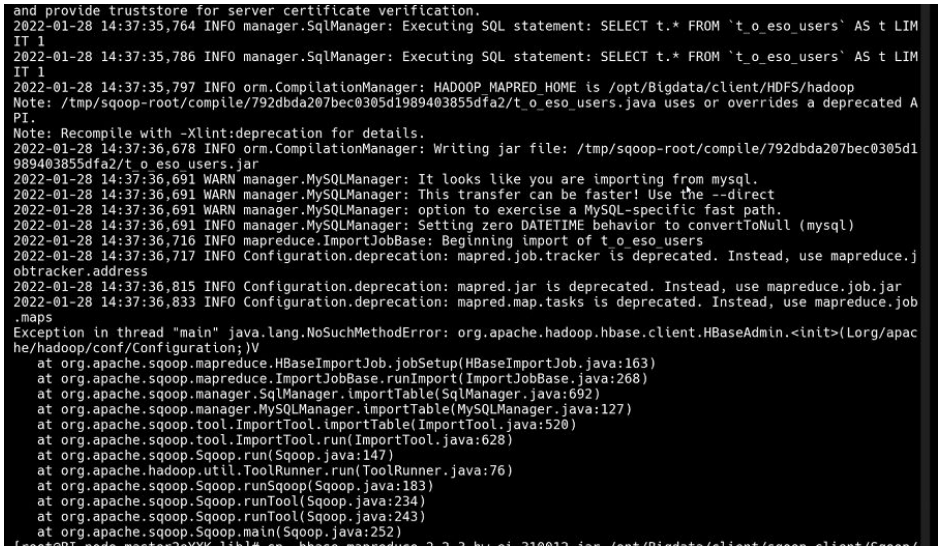
16.17.2 Failed to Find the HBaseAdmin.<init> Method When Sqoop Reads Data from the MySQL Database to HBase

Issue

If the Sqoop client (version 1.4.7) of MRS is used to extract data from a specified table in the MySQL database to a table in HBase 2.2.3, the following exception is reported:

```
Trying to load data into HBASE through Sqoop getting below error.
Exception in thread "main" java.lang.NoSuchMethodError:
org.apache.hadoop.hbase.client.HBaseAdmin.<init>(Lorg/apache/hadoop/conf/Configuration;)V
```

The following figure shows the complete exception information.



The following is an example of running the Sqoop command to extract data:

```
sqoop import \
--connect jdbc:mysql://mysql<i>Server address:Port number</i>/database1 \
--username admin \
--password <i>xxx</i> \
--table table1 \
--hbase-table table2 \
--column-family info \
--hbase-row-key id \
--hbase-create-table --m 1
```

Procedure

After the Sqoop client is installed, the JAR packages on which HBase depends are not imported. You need to manually import the JAR packages on which HBase of an earlier version depends.

Step 1 Check whether the Sqoop and HBase clients are in the same path.

- If yes, go to **Step 2**.
- If no, delete the original Sqoop and HBase client files, download the complete clients from FusionInsight Manager, and install them in the same path. Then go to **Step 2**.

Step 2 Log in to the node where the Sqoop client is installed as user **root**.

Step 3 Download JAR packages of HBase 1.6.0 and upload them to the **lib** directory on the Sqoop client:

Step 4 After the packages are uploaded, run the following command to change the permission on the packages to **755**:

chmod 755 *Package name*

Step 5 Run the following command in the client directory to refresh the Sqoop client:

source bigdata_env

Run the target Sqoop command again.

----End

16.17.3 Failed to Export HBase Data to HDFS Through Hue's Sqoop Task

This section applies only to MRS 1.9.2 clusters.

Issue

An error is reported when a Sqoop operation is performed on Hue to export data from HBase to HDFS.

Caused by: java.lang.ClassNotFoundException: org.apache.htrace.Trace

```
2022-03-02 15:09:00,264 [main] ERROR org.apache.sqoop.connector.hbase.HBaseExtractor  - An exceptional condition has occurred.

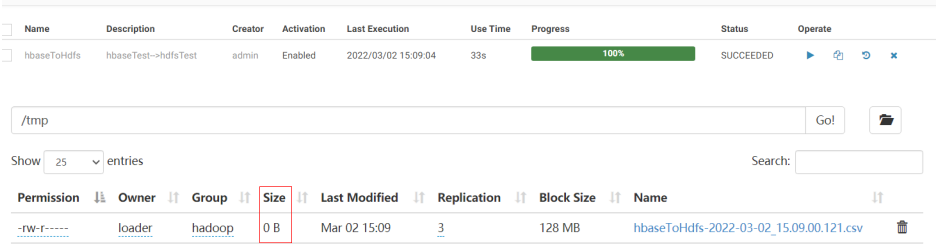
        at org.apache.hadoop.security.UserGroupInformation.doAs(UserGroupInformation.java:1840)
        at org.apache.hadoop.mapred.YarnChild.main(YarnChild.java:182)
Caused by: java.lang.reflect.InvocationTargetException
```

Symptom

The Sqoop task is executed successfully, but the CSV file in HDFS is empty.



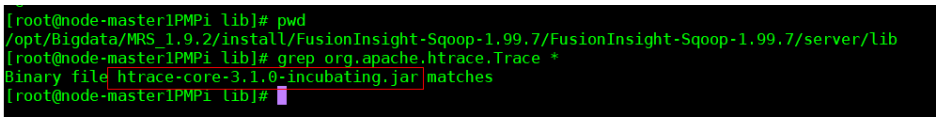
Cause Analysis

The JAR package conflicts or is missing.

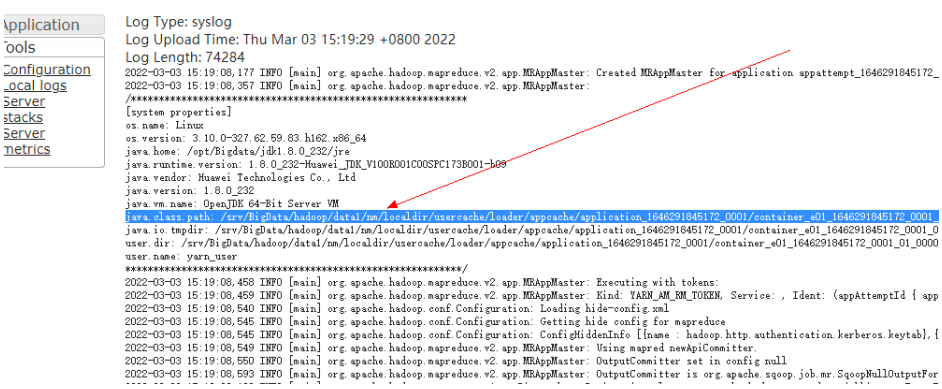
Procedure

Step 1 Use the **grep** command in the **lib** directory of Sqoop.

1. Go to the **lib** directory of Sqoop and run the **grep** command.

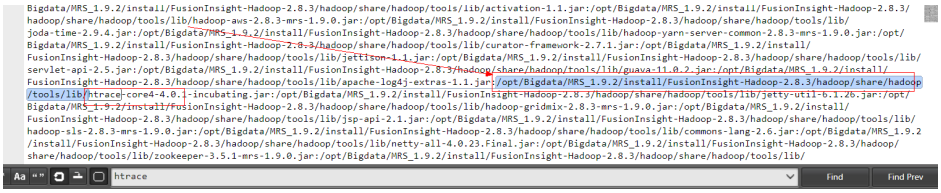


2. Go to the native Yarn page and view the error information about the running task.



Step 1 Use the **grep** command in the **lib** directory of Sqoop.

3. Copy **java.class.path** and search for **htrace-core**.



4. Copy the JAR package to the following directory:

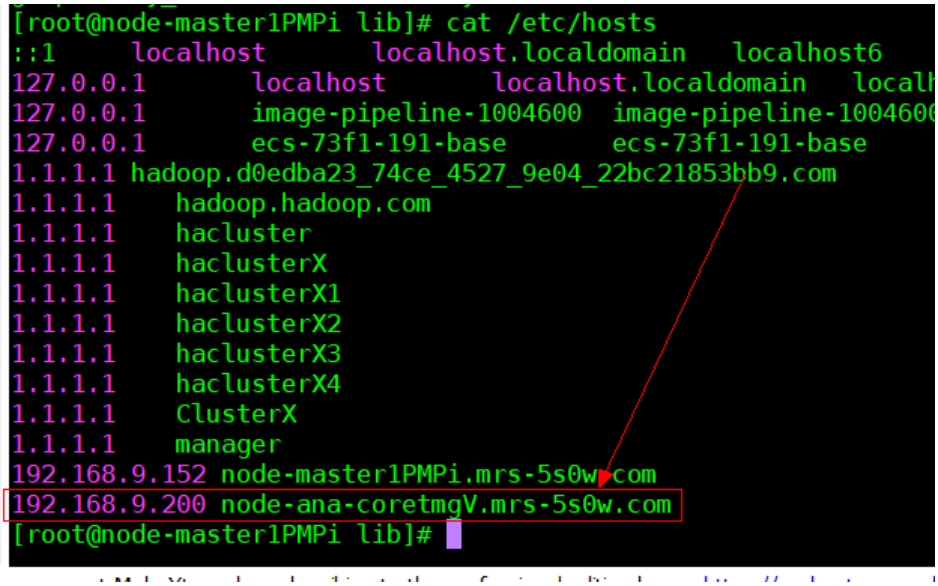
   cp /opt/Bigdata/MRS_1.9.2/install/FusionInsight-Sqoop-1.99.7/FusionInsight-Sqoop-1.99.7/server/lib/htrace-core-3.1.0-incubating.jar /opt/Bigdata/MRS_1.9.2/install/FusionInsight-Hadoop-2.8.3/hadoop/share/hadoop/common/lib/

5. Change permissions.

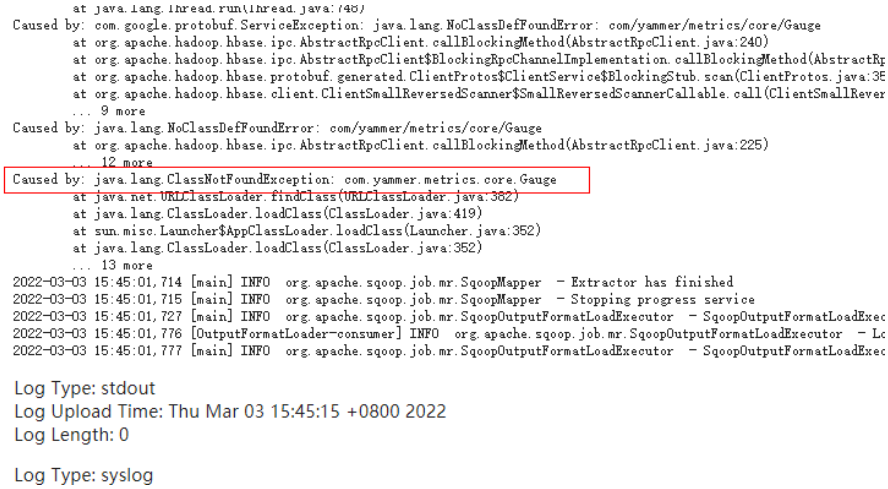
   chmod 777 *htrace-core-3.1.0-incubating.jar* (the copied JAR package)

   chown omm:ficommon *htrace-core-3.1.0-incubating.jar* (the copied JAR package)

6. View the **hosts** file and perform the same operations to copy the JAR package for all other nodes.

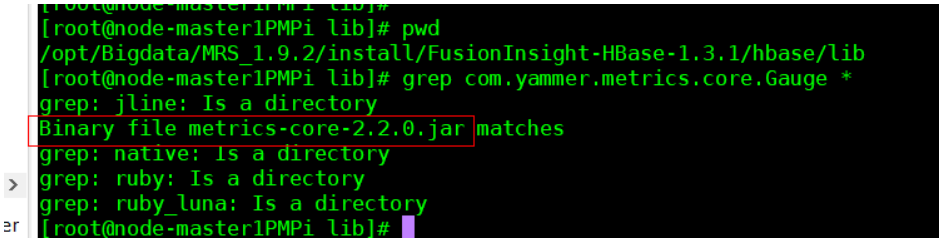


7. Run the Sqoop task again. The following error information is displayed.



Step 2 Use the **grep** command in the **lib** directory of HBase.

1. Go to the **lib** directory of HBase and run the **grep** command.



2. Copy the JAR package.

   cp /opt/Bigdata/MRS_1.9.2/install/FusionInsight-HBase-1.3.1/hbase/lib/metrics-core-2.2.0.jar /opt/Bigdata/MRS_1.9.2/install/FusionInsight-Hadoop-2.8.3/hadoop/share/hadoop/common/lib/

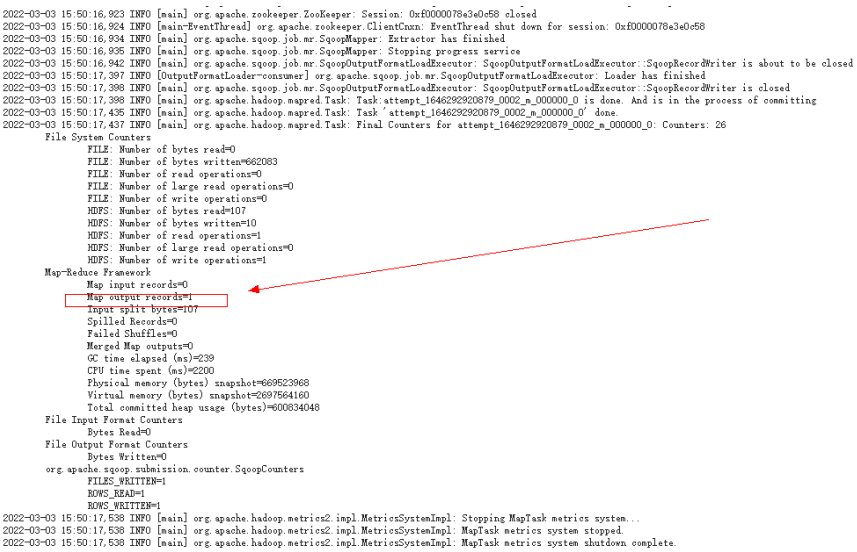
3. Change permissions.

   chmod 777 *metrics-core-2.2.0.jar* (the copied JAR package)

   chown omm:ficommon *metrics-core-2.2.0.jar* (the copied JAR package)

4. View the **hosts** file and perform the same operations to copy the JAR package for all other nodes.

5. Run the Sqoop task.



----End

Conclusion

1. Copy **htrace-core-3.1.0-incubating.jar** in the **lib** directory of Sqoop and **metrics-core-2.2.0.jar** in the **lib** directory of HBase to **/opt/Bigdata/MRS_1.9.2/install/FusionInsight-Hadoop-2.8.3/hadoop/share/hadoop/common/lib/**.
2. Change the permissions for the JAR packages to **777** and **omm:ficommon**, respectively.
3. Perform the preceding operations on all nodes and run the Sqoop task again.

16.17.4 A Format Error Is Reported When Sqoop Is Used to Export Data from Hive to MySQL 8.0

This section applies only to MRS 3.1.0 clusters.

Issue

A format error is reported when a Sqoop task is performed to export data from Hive to MySQL 8.0 in an MRS 3.1.0 cluster.

Symptom

```
2022-03-31 19:56:44,581 ERROR mapreduce.ExportJobBase: Export job failed!
2022-03-31 19:56:44,581 ERROR tool.ExportTool: Error during export:
Export job failed!
        at org.apache.sqoop.mapreduce.ExportJobBase.runExport(ExportJobBase.java:445)
        at org.apache.sqoop.manager.SqlManager.exportTable(SqlManager.java:931)
        at org.apache.sqoop.tool.ExportTool.exportTable(ExportTool.java:80)

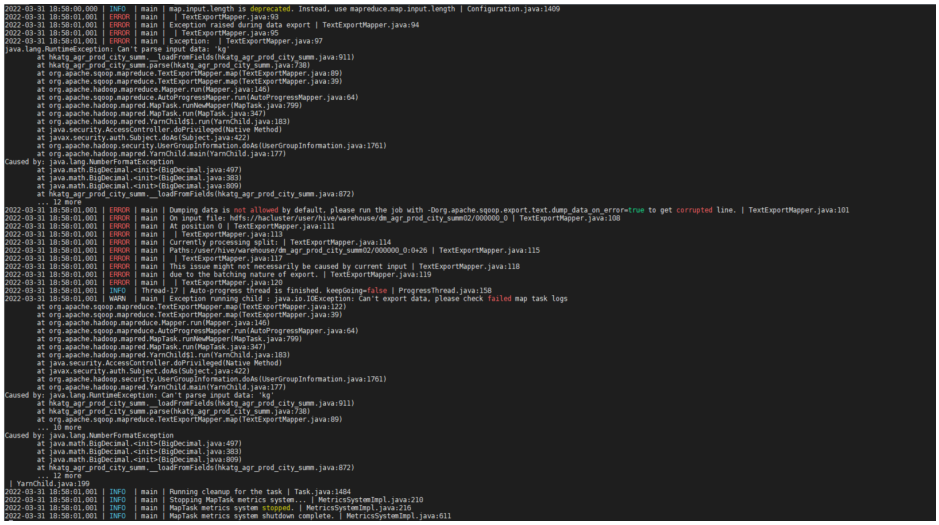
        at org.apache.sqoop.Sqoop.main(Sqoop.java:252)
```



Cause Analysis

The log shows that the format is incorrect.

Procedure

Check that the formats of delimiters and table fields are all correct. Add the **--columns** parameter to the Sqoop statement to make data formats consistent between source and target tables.

sqoop export --connect jdbc:mysql://IP address:Port number/Database name --username ***Username*** **--password** ***Password*** **--table** ***Table name*** **--columns** ***Column fields (multiple columns are separated by commas)*** **-export-dir** ***Export address*** **--fields-terminated-by** ***Delimiter*** **--input-null-string '\\N' --input-null-non-string '\\N' -m 1**

Example:

sqoop export --connect jdbc:mysql://172.16.0.6:3306/lidengpeng --username root --password Mrs@2021 --table hkatg_agr_prod_city_summ --columns year,city_name,city_code,prod_code,prod_name,prod_type,sown_area,area_unit,yield_wegt,yield_unit,total_wegt,total_wegt_unit,data_sorc_code,etl_time -export-dir hdfs://hacluster/user/hive/warehouse/dm_agr_prod_city_summ02 --fields-terminated-by ',' --input-null-string '\\N' --input-null-non-string '\\N' -m 1

16.17.5 An Error Is Reported When sqoop import Is Executed to Import PostgreSQL Data to Hive

Background

The **sqoop import** command is executed to extract data from open-source PostgreSQL to MRS HDFS or Hive.

Issue

The **sqoop** command can be executed to query the PostgreSQL database table, but an error is reported when the **sqoop import** command is executed to import data.

The authentication type 5 is not supported. Check that you have configured the pg_hba.conf file to include the client's IP address or subnet.

Cause Analysis

1. MD5 authentication for connecting to PostgreSQL fails. A whitelist needs to be configured in the **pg_hba.cnf** file.
2. When the **sqoop import** command is executed, a MapReduce job is started. The PostgreSQL driver package **gsjdbc4-*.jar** exists in the MRS Hadoop installation directory **/opt/Bigdata/FusionInsight_HD_*/1_*_DataNode/install/hadoop/share/hadoop/common/lib**, which is incompatible with the open-source PostgreSQL service. As a result, an error is reported.

Procedure

1. Configure a whitelist in the **pg_hba.cnf** file.
2. Delete the **gsjdbc4-*.jar** packages from all core nodes, and add the PostgreSQL JAR package to **sqoop/lib**.

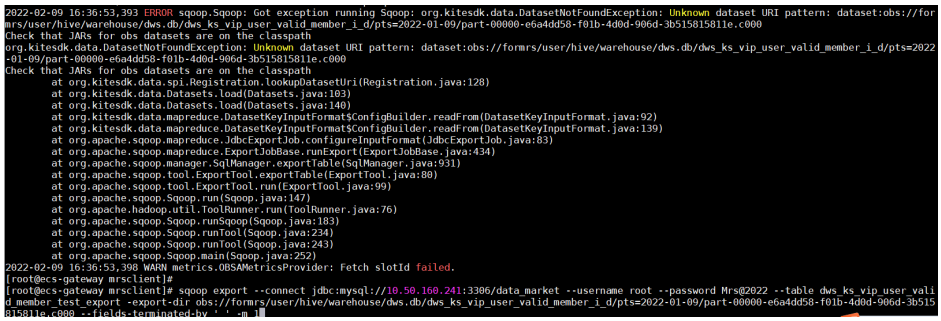
   mv /opt/Bigdata/FusionInsight_HD_*/1_*_DataNode/install/hadoop/share/hadoop/common/lib/gsjdbc4-*.jar /tmp

16.17.6 Sqoop Failed to Read Data from MySQL and Write Parquet Files to OBS

Issue

An error is reported when Sqoop reads MySQL data and writes the data to OBS in Parquet format. However, the data can be successfully written to OBS if the Parquet format is not specified.

Symptom



Cause Analysis

Parquet does not support Hive 3. Data can be written using HCatalog.

Procedure

Use HCatalog to write data: Specify the Hive database and table in parameters and modify the SQL statement in the script.

Details are as follows:

Original script:

sqoop import --connect 'jdbc:mysql://10.160.5.65/xxx_pos_online_00?zeroDateTimeBehavior=convertToNull' --username root --password Mrs@2022

--split-by id

--num-mappers 2

--query 'select * from pos_remark where 1=1 and $CONDITIONS'

--target-dir obs://za-test/dev/xxx_pos_online_00/pos_remark

--delete-target-dir

--null-string '\\N'

--null-non-string '\\N'

--as-parquetfile

Modified script:

sqoop import --connect 'jdbc:mysql://10.160.5.65/xxx_pos_online_00?zeroDateTimeBehavior=convertToNull' --username root --password Mrs@2022

--split-by id

--num-mappers 2

--query 'select id,pos_case_id,pos_transaction_id,remark,update_time,update_user,is_deleted,creator,modifier,gmt_created,gmt_modified,update_user_id,tenant_code from pos_remark where 1=1 and $CONDITIONS'

--hcatalog-database xxx_dev

--hcatalog-table ods_pos_remark

16.18 Using Storm

16.18.1 Invalid Hyperlink of Events on the Storm UI

Issue

The hyperlink of events on the Storm UI is invalid.

Symptom

After submitting a topology, a user cannot view topology data processing logs and the events hyperlink is invalid.

Cause Analysis

The function of viewing topology data processing logs is disabled by default when a topology is submitted in an MRS cluster.

Procedure

Step 1 Log in to the Storm web UI.

- For MRS 2.x and earlier versions: Choose **Storm**. On the **Storm WebUI** page, click any UI link to open the Storm web UI.

  NOTE

  When accessing the Storm web UI for the first time, you must add the address to the trusted site list.

- For MRS 3.x or later: Choose **Storm** > **Overview**. On the **Storm WebUI** in the **Basic Information** area, click any UI link to open the Storm web UI.

Step 2 In the **Topology Summary** area, click the desired topology to view details.

Step 3 In the **Topology actions** area, click **Kill** to delete the submitted Storm topology.

Step 4 Submit the Storm topology again and enable the function of viewing topology data processing logs. Add the **topology.eventlogger.executors** parameter and set it to a positive integer when submitting the Storm topology. Example:

storm jar ***Path of the topology package Class name of the topology Main method Topology name*** **-c topology.eventlogger.executors=X**

Step 5 In the **Topology Summary** area on the Storm UI, click the desired topology to view details.

Step 6 In the **Topology actions** area, click **Debug**, specify the data sampling percentage, and click **OK**.

Step 7 Click the **Spouts** or **Bolts** task name of the topology. In **Component summary**, click **events** to view data processing logs.

NOTE

To enable the function of viewing topology data processing logs of the specified **Spouts** or **Bolts** task, click the **Spouts** or **Bolts** task name of the topology, click **Debug** in the **Topology actions** area, and enter the data sampling percentage.

----End

16.18.2 Failed to Submit a Topology

Symptom

An MRS streaming cluster is installed, and ZooKeeper, Storm, as well as Kafka are installed in the cluster.

A topology fails to be submitted by running commands on the client.

Possible Causes

- The Storm service is abnormal.
- The client user is not authenticated or the authentication has expired.
- The **storm.yaml** file in the submitted topology conflicts with that on the server.

Cause Analysis

A user fails to submit the topology. The possible cause is that the client or Storm is faulty.

1. Check the Storm status.

   MRS Manager:

   Log in to MRS Manager. On the MRS Manager page, choose **Services** > **Storm** to check the status of Storm. The status is **Good**, and the monitoring metrics are correctly displayed.

   FusionInsight Manager:

   For MRS 3.*x* or later: Log in to FusionInsight Manager. Choose **Cluster** > **Services** > **Storm** to check the status of Storm. It is found that the status is **Good** and the monitoring metrics are correctly displayed.

2. Check the submission logs of the client. The logs contain "KeeperExceptionSessionExpireException".

```
org.apache.zookeeper.KeeperException$SessionExpiredException: KeeperErrorCode = Session expired
        at org.apache.zookeeper.KeeperException.create(KeeperException.java:131) ~[zookeeper-3.5.0.jar:3.5.0-V100R002C00B109]

        at org.apache.curator.framework.imps.ExistsBuilderImpl.forPath(ExistsBuilderImpl.java:148)
        at org.apache.curator.framework.imps.ExistsBuilderImpl.forPath(ExistsBuilderImpl.java:36)
        at backtype.storm.nimbus.NimbusLeaderElections.init(NimbusLeaderElections.java:66)
        ... 5 more
```

The preceding error occurs because security authentication is not performed before the topology is submitted or the TGT expires after authentication.

For details about the solution, see **Step 1**.

3. Check the client submission log. It is found that the "ExceptionInIntializerError" exception information is printed, and the message "Found multiple storm.yaml resources" is displayed. The following is an example:

```
Exception in thread "main" java.lang.ExceptionInInitializerError
        at backtype.storm.topology.TopologyBuilder.createTopology(TopologyBuilder.java:106)
        at com.huawei.streaming.storm.example.wordcount.WordCountTopology.cmdSubmit(WordCountTopology.java:117)
        at com.huawei.streaming.storm.example.wordcount.WordCountTopology.submitTopology(WordCountTopology.java:80)
        at com.huawei.streaming.storm.example.wordcount.WordCountTopology.main(WordCountTopology.java:71)
Caused by: java.lang.RuntimeException: Found multiple storm.yaml resources. You're probably bundling the Storm jars with your topology jar.
        at backtype.storm.utils.Utils.findAndReadConfigFile(Utils.java:151)
        at backtype.storm.utils.Utils.readStormConfig(Utils.java:206)
        at backtype.storm.utils.Utils.<clinit>(Utils.java:70)
        ... 4 more
```

This error occurs because the **storm.yaml** file in the service JAR package conflicts with that on the server.

For details about the solution, see **Step 2**.

4. If the fault is not caused by the preceding reasons, see **Topology Submission Fails and the Message "Failed to check principle for keytab" Is Displayed**.

Solution

Step 1 An authentication error occurs.

1. Log in to the node where the client resides and switch to the client directory.
2. Run the following command to submit the task again: (Replace the service JAR package and topology based on the site requirements.)

   source bigdata_env

   kinit *Username*

   storm jar storm-starter-topologies-0.10.0.jar storm.starter.WordCountTopology test

Step 2 The topology package is abnormal.

Check the service JAR package, delete the **storm.yaml** file from the service JAR package, and submit the task again.

----End

16.18.3 Topology Submission Fails and the Message "Failed to check principle for keytab" Is Displayed

Symptom

An MRS streaming cluster in security mode is installed, and ZooKeeper, Storm, and Kafka are installed in the cluster.

When a topology is defined to access components such as HDFS and HBase and the topology fails to be submitted using client commands.

Possible Causes

- The submitted topology does not contain the keytab file of the user.
- The keytab file contained in the submitted topology is inconsistent with the user who submits the topology.
- The **user.keytab** file exists in the **/tmp** directory on the client, and the owner is not the running user.

Cause Analysis

1. Check the logs. Error information "Can not found user.keytab in storm.jar" is found. Details are as follows:

   ```
   [main] INFO  b.s.StormSubmitter - Get principle for stream@HADOOP.COM success
   [main] ERROR b.s.StormSubmitter - Can not found user.keytab in storm.jar.
   Exception in thread "main" java.lang.RuntimeException: Failed to check principle for keytab
   at backtype.storm.StormSubmitter.submitTopologyAs(StormSubmitter.java:219)
   at backtype.storm.StormSubmitter.submitTopology(StormSubmitter.java:292)
   at backtype.storm.StormSubmitter.submitTopology(StormSubmitter.java:176)
   at com.xxx.streaming.storm.example.hbase.SimpleHBaseTopology.main(SimpleHBaseTopology.java:77)
   ```

   Check the JAR file of the submitted topology. It is found that the keytab file is not contained.

2. Check the logs. Error information "The submit user is invalid,the principle is" is found. Details are as follows:

   ```
   [main] INFO  b.s.StormSubmitter - Get principle for stream@HADOOP.COM success
   [main] WARN  b.s.s.a.k.ClientCallbackHandler - Could not login: the client is being asked for a password, but the  client code does not currently support obtaining a password from the user. Make sure that the client is configured to use a ticket cache (using the JAAS configuration setting 'useTicketCache=true)' and restart the client. If you still get this message after that, the TGT in the ticket cache has expired and must be manually refreshed. To do so, first determine if you are using a password or a keytab. If the former, run kinit in a Unix shell in the environment of the user who is running this client using the command 'kinit <princ>' (where <princ> is the name of the client's Kerberos principal). If the latter, do 'kinit -k -t <keytab> <princ>' (where <princ> is the name of the Kerberos principal, and <keytab> is the location of the keytab file). After manually refreshing your cache, restart this client. If you continue to see this message after manually refreshing your cache, ensure that your KDC host's clock is in sync with this host's clock.
   [main] ERROR b.s.StormSubmitter - The submit user is invalid,the principle is : stream@HADOOP.COM
   Exception in thread "main" java.lang.RuntimeException: Failed to check principle for keytab
   at backtype.storm.StormSubmitter.submitTopologyAs(StormSubmitter.java:219)
   at backtype.storm.StormSubmitter.submitTopology(StormSubmitter.java:292)
   at backtype.storm.StormSubmitter.submitTopology(StormSubmitter.java:176)
   at com.xxx.streaming.storm.example.hbase.SimpleHBaseTopology.main(SimpleHBaseTopology.java:77)
   ```

   The authenticated user used to submit the topology is **stream**. However, the system displays a message indicating that the submit user is invalid during topology submission, indicating that the internal verification fails.

3. Check the JAR file of the submitted topology. It is found that the keytab file is contained.

The principal parameter is set to **zmk_kafka** in the **user.keytab** file.

```
[root@8-5-148-6 client]# klist -kt user.keytab
Keytab name: FILE:user.keytab
KVNO Timestamp         Principal
---- ----------------- --------------------------------------------------------
   1 12/19/16 16:28:17 zmk_kafka@HADOOP.COM
   1 12/19/16 16:28:17 zmk_kafka@HADOOP.COM
```

It is found that the authenticated user does not match the principal in the **user.keytab** file.

4. Check the logs and find the error information "Delete the tmp keytab file failed, the keytab file is:/tmp/user.keytab". The detailed information is as follows:

```
[main] WARN b.s.StormSubmitter - Delete the tmp keytab file failed, the keytab file is : /tmp/
user.keytab
[main] ERROR b.s.StormSubmitter - The submit user is invalid,the principle is : hbase1@HADOOP.COM
Exception in thread "main" java.lang.RuntimeException: Failed to check principle for keytab
at backtype.storm.StormSubmitter.submitTopologyAs(StormSubmitter.java:213)
at backtype.storm.StormSubmitter.submitTopology(StormSubmitter.java:286)
at backtype.storm.StormSubmitter.submitTopology(StormSubmitter.java:170)
at com.touchstone.storm.cmcc.CmccDataHbaseTopology.main(CmccDataHbaseTopology.java:183)
```

Check the **/tmp** directory. It is found that the **user.keytab** file exists and the file owner is not the running user.

Solution

- Ensure that the **user.keytab** file is carried when the topology is submitted.
- Ensure that the user for submitting the topology is the same as that of the **user.keytab** file.
- Delete the **user.keytab** file from the **/tmp** directory.

16.18.4 The Worker Log Is Empty After a Topology Is Submitted

Symptom

After a topology is remotely submitted in Eclipse, the detailed information about the topology cannot be viewed on the Storm web UI, and the Worker node where Bolt and Spout of each topology are located keeps changing. The Worker log is empty.

Possible Causes

The Worker process fails to be started, triggering Nimbus to re-allocate tasks and start the Worker process on other Supervisors. The Worker process continues to restart. As a result, the Worker node keeps changing, and the Worker log is empty. The possible causes of the Worker process startup failure are as follows:

- The submitted JAR package contains the **storm.yaml** file.

  Storm specifies that each classpath can contain only one **storm.yaml** file. If there is more than one **storm.yaml** file, an exception occurs. Use the Storm client to submit the topology. The classpath configuration of the client is different from the classpath configuration of Eclipse. The client automatically loads the JAR package of the user to classpath. As a result, two **storm.yaml** files exist in classpath.

- The initialization of the Worker process takes a long time, which exceeds the Worker startup timeout period set in the Storm cluster. As a result, the Worker process is killed and reallocated.

Troubleshooting Process

1. Use the Storm client to submit the topology and check whether the **storm.yaml** file is duplicate.
2. Repack the JAR file and submit the topology again.
3. Modify the Worker startup timeout parameter in the Storm cluster.

Procedure

Step 1 If the Worker log is empty after the topology is remotely submitted using Eclipse, use the Storm client to submit the JAR package corresponding to the topology and view the prompt message.

For example, if the JAR package contains two **storm.yaml** files in different paths, the following information is displayed:

```
Exception in thread "main" java.lang.ExceptionInInitializerError
  at com.xxx.streaming.storm.example.WordCountTopology.createConf(WordCountTopology.java:132)
  at com.xxx.streaming.storm.example.WordCountTopology.remoteSubmit(WordCountTopology.java:120)
  at com.xxx.streaming.storm.example.WordCountTopology.main(WordCountTopology.java:101)
 Caused by: java.lang.RuntimeException: Found multiple storm.yaml resources. You're probably bundling the Storm jars with your topology jar. [jar:file:/opt/xxx/fi_client/Streaming/streaming-0.9.2/bin/stormDemo.jar!/storm.yaml, file:/opt/xxx/fi_client/Streaming/streaming-0.9.2/conf/storm.yaml]
  at backtype.storm.utils.Utils.findAndReadConfigFile(Utils.java:151)
  at backtype.storm.utils.Utils.readStormConfig(Utils.java:206)
  at backtype.storm.utils.Utils.<(Utils.java:70)>
```

Step 2 Compress the JAR package again. Ensure that the package does not contain the **storm.yaml** file and JAR packages related to **log4j** and **slf4j-log4j**.

Step 3 Use IntelliJ IDEA to remotely submit the new JAR package.

Step 4 Check whether the topology details and Worker logs can be viewed on the web UI.

Step 5 On MRS Manager, modify the Worker startup timeout parameter of the Storm cluster (for details about the parameter description, see **Related Information**). Save the modification, and restart the Storm service.

- MRS Manager: Log in to MRS Manager and choose **Services** > **Storm** > **Configuration**.
- FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Storm** > **Configuration**.

Step 6 Submit the JAR package to be run again.

----End

Related Information

1. The **nimbus.task.launch.secs** and **supervisor.worker.start.timeout.secs** parameters indicate the topology startup timeout tolerance of the Nimbus and supervisor, respectively. Generally, the value of **nimbus.task.launch.secs** must be greater than or equal to that of **supervisor.worker.start.timeout.secs**. It is recommended that the value of

nimbus.task.launch.secs be slightly greater or equal to that of **supervisor.worker.start.timeout.secs**. Otherwise, the task reallocation efficiency will be affected.

- **nimbus.task.launch.secs**: If the Nimbus does not receive the heartbeat message sent by the topology task within the period specified by this parameter, the Nimbus re-allocates the topology to another supervisor and updates the task information in ZooKeeper. The supervisor reads the task information in ZooKeeper and compares it with the topology started. If the topology does not belong to the supervisor, the supervisor deletes the metadata of the topology, that is, the **/srv/Bigdata/streaming_data/stormdir/supervisor/stormdist/{worker-id}** directory.
- **supervisor.worker.start.timeout.secs**: After the supervisor starts a worker, if no heartbeat message is received from the worker within the period specified by this parameter, the supervisor stops the worker and waits for worker rescheduling. Generally, the value of this parameter is increased when the service startup takes a long time to ensure that the worker can be started successfully.

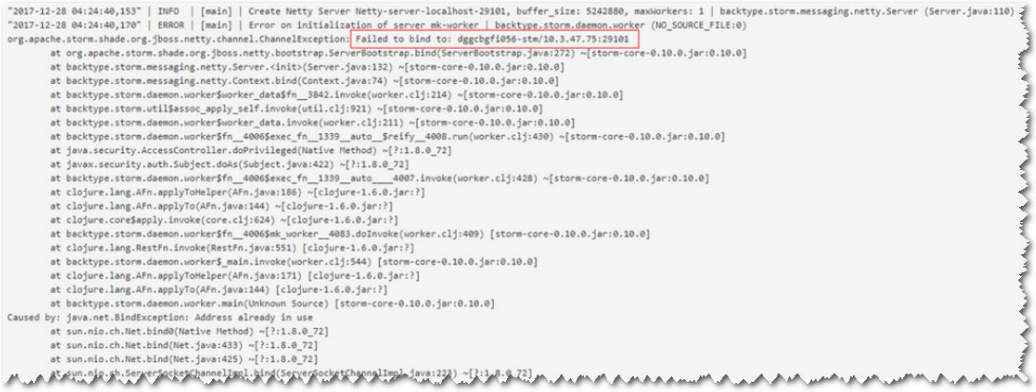
  If the value of **supervisor.worker.start.timeout.secs** is greater than that of **nimbus.task.launch.secs**, the worker is still started before the tolerance time of supervisor ends. However, the Nimbus considers that the service startup times out and allocates the service to another host. The background thread of the supervisor finds that the tasks are inconsistent and deletes the metadata of the topology. As a result, when the worker attempts to read **stormconf.ser** during startup, the file does not exist, and "FileNotFoundException" is thrown.

2. The **nimbus.task.timeout.secs** and **supervisor.worker.timeout.secs** parameters indicate the timeout tolerance time for the Nimbus and supervisor to report heartbeat messages during topology running. Generally, the value of **nimbus.task.timeout.secs** must be slightly greater than or equal to that of **supervisor.worker.timeout.secs**.

16.18.5 Worker Runs Abnormally After a Topology Is Submitted and Error "Failed to bind to:host:ip" Is Displayed

Symptom

After the service topology is submitted, the Worker cannot be started normally. Check the Worker log. The log records "Failed to bind to: host:ip."



Possible Causes

The random port range is incorrectly configured.

Troubleshooting Process

1. Check related information in the Worker log.
2. Check the process information about the bond port.
3. Check the random port range.

Cause Analysis

1. Use SSH to log in to the host where the Worker fails to be started and run the **netstat -anp | grep** <*port*> command to check the ID of the process that occupies the port. In the preceding command, change *port* to the actual port number.
2. Run the **ps -ef | grep** <*pid*> command to view process details. In the command, *pid* indicates the actual process ID.

It is found that the worker process occupies the port. This process is another topology service process. According to the process details, port 29122 is allocated to the process.

3. Run the **lsof -i:**<*port*> command to view connection details. In the preceding command, change *port* to the actual port number.

It is found that port 29101 connects to port 21005 of the peer end, and port 21005 is the Kafka server port.

It indicates that the service layer connects to Kafka to obtain messages as a client. Service ports are allocated based on the random port range of the OS.

4. Run the **cat /proc/sys/net/ipv4/ip_local_port_range** command to check the random port range.

5. It is found that the random port range is too large and conflicts with the service port range of MRS.

NOTE

The MRS service port number ranges from 20000 to 30000.

Procedure

Step 1 Modify the random port range.

```
vi /proc/sys/net/ipv4/ip_local_port_range
32768 61000
```

Step 2 Stop the service process that occupies the service port to release the port. (Stop the service topology.)

----End

16.18.6 "well-known file is not secure" Is Displayed When the jstack Command Is Used to Check the Process Stack

Symptom

Run the **jstack** command to check the process stack information. The error message "well-known file is not secure" is displayed.

```
omm@hadoop02:~> jstack 62517
62517: well-known file is not secure
```

Cause Analysis

1. The user running the **jstack** command is inconsistent with the user submitting the process for viewing the pid information.
2. Storm uses the feature of differentiating users for implementing tasks. When the worker process is started, the process UID and GID are changed to the user submitting the task and ficommon. This way, logviewer can access logs of the worker process and only log file permission 640 is open. After the user is changed, the **jstack** and **jmap** commands fail to be executed for the worker process, because the default GID of the user is not ficommon. You need to run the ldap command to change the user GID to 9998 (ficommon).

Solution

You can use either of the following two methods to resolve the problem:

Method 1: View the process stack on the native Storm page.

Step 1 Log in to the native Storm page.

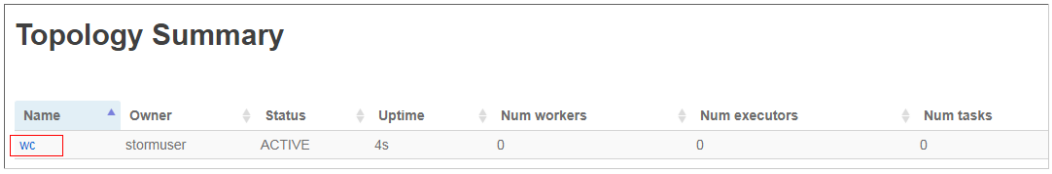
MRS Manager:

1. Access MRS Manager.
2. Choose **Services** > **Storm**. In **Storm WebUI** of **Storm Summary**, click any UI link to access the Storm WebUI.

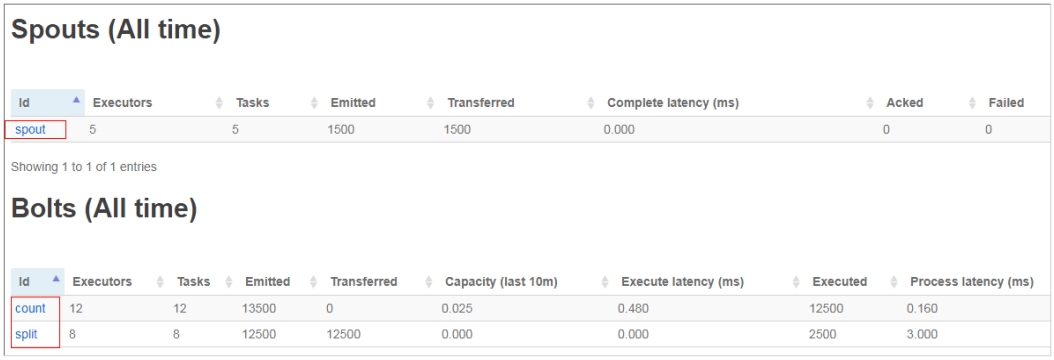
FusionInsight Manager:

1. Log in to FusionInsight Manager.
2. On Manager, choose **Cluster > Service** > **Storm**. On the **Storm WebUI** page of **Overview**, click any UI link to open the Storm WebUI.

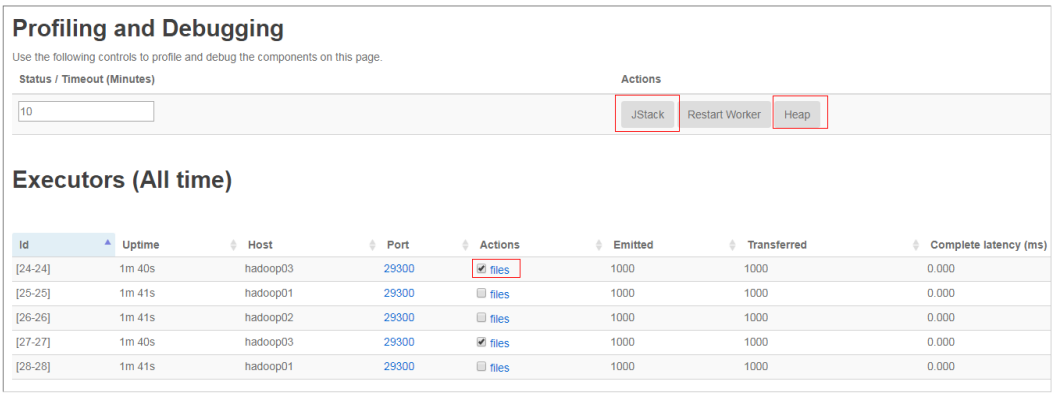
Step 2 Select the topology to be viewed.



Step 3 Select the spout or bolt to be viewed.



Step 4 Select the log file of the node to be viewed, and then click **JStack** or **Heap**. **JStack** corresponds to the stack information, and **Heap** corresponds to the heap information.



----End

Method 2: View the process stack by modifying user-defined parameters.

Step 1 Access the Storm parameter configuration page.

MRS Manager: Log in to MRS Manager, choose **Services** > **Storm** > **Service Configuration**, and select **All** from the **Type** drop-down list.

Operation on FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Yarn** > **Configurations** > **All Configurations**.

Step 2 In the navigation tree on the left, choose **supervisor** > **Customize** and add the variable **supervisor.run.worker.as.user=false**.

Step 3 Click **Save Configuration** and select **Restart the affected services or instances**. Click **OK** to restart the services.

Step 4 Submit the topology again.

Step 5 Switch to the **omm** user on the background node and run the **jps** command to view the PID of the worker process.

```
omm@hadoop02:~> jps | grep worker
22485 worker
111402 worker
```

Step 6 Run the **jstack pid** command to view the jstack information.

```
omm@hadoop02:~> jstack 22485
2018-05-26 08:46:24
Full thread dump Java HotSpot(TM) 64-Bit Server VM (25.144-b01 mixed mode):

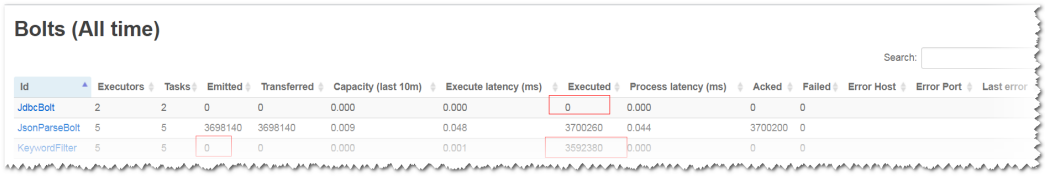
16.18.7 When the Storm-JDBC plug-in is used to develop Oracle write Bolts, data cannot be written into the Bolts.

Symptom

When the Storm-JDBC plug-in is used to develop Oracle write Bolts, the Oracle database can be connected, but data cannot be written to the Oracle database.

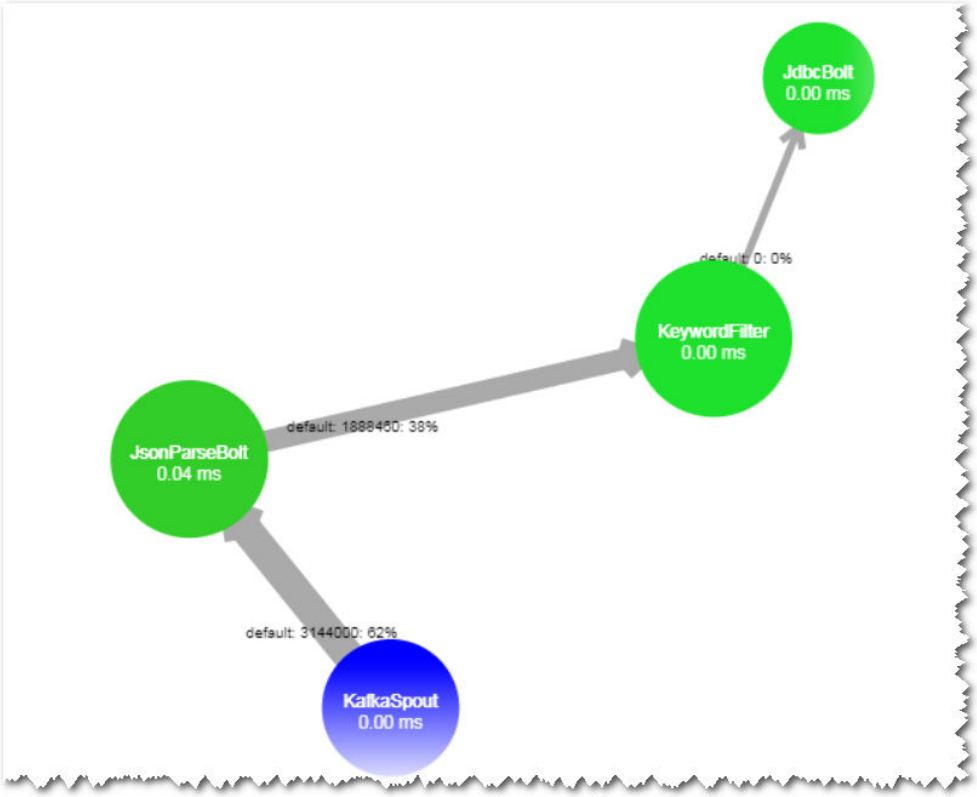


Possible Causes

- The topology definition is incorrect.
- The definition of the database table result is incorrect.

Cause Analysis

1. On the Storm web UI, check the DAG of the topology. The DAG is consistent with the topology definition.

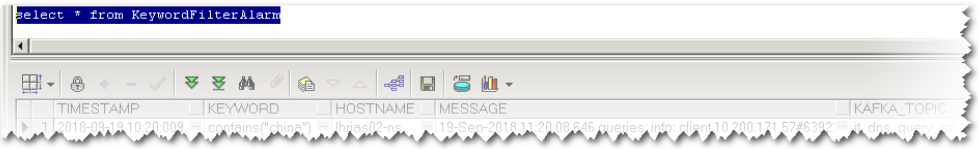


2. The definition of the KeyWordFilter Bolt is consistent with the **expParser** field.

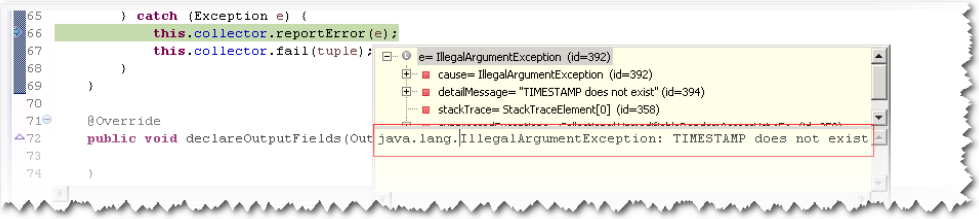
```
@Override
public void declareOutputFields(OutputFieldsDeclarer declarer)
{
    declarer.declare(new Fields("timestamp","keyword","hostname","message","kafka_topic") );
```

```
    if( flag )
    {
        String keyword = expParser.getKeyword();
        System.out.println( message );
        collector.emit(new Values( timestamp, keyword , hostname , message, kafka_topic ));
```

3. View the table definition in the Oracle database. The field name is in uppercase, which is inconsistent with flow definition field name.



4. When the execute method is debugged independently, it is found that the thrown field does not exist.



Procedure

The field name of the stream definition is changed to uppercase letters, which is the same as that defined in the database table.

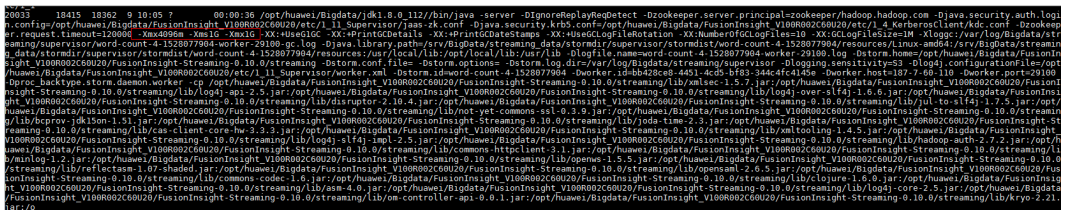
16.18.8 The GC Parameter Configured for the Service Topology Does Not Take Effect

Symptom

The **topology.worker.childopts** parameter in the service topology code does not take effect. The key log is as follows:

```
[main] INFO b.s.StormSubmitter - Uploading topology jar /opt/jar/example.jar to assigned location: /srv/
BigData/streaming/stormdir/nimbus/inbox/stormjar-8d3b778d-69ea-4fbe-ba88-01aa2036d753.jar
Start uploading file '/opt/jar/example.jar' to '/srv/BigData/streaming/stormdir/nimbus/inbox/
stormjar-8d3b778d-69ea-4fbe-ba88-01aa2036d753.jar' (65574612 bytes)
[==================================================] 65574612 / 65574612
File '/opt/jar/example.jar' uploaded to '/srv/BigData/streaming/stormdir/nimbus/inbox/
stormjar-8d3b778d-69ea-4fbe-ba88-01aa2036d753.jar' (65574612 bytes)
[main] INFO b.s.StormSubmitter - Successfully uploaded topology jar to assigned location: /srv/BigData/
streaming/stormdir/nimbus/inbox/stormjar-8d3b778d-69ea-4fbe-ba88-01aa2036d753.jar
[main] INFO b.s.StormSubmitter - Submitting topology word-count in distributed mode with conf
{"topology.worker.childopts":"-
Xmx4096m","storm.zookeeper.topology.auth.scheme":"digest","storm.zookeeper.topology.auth.payload":"-59
15065013522446406:-6421330379815193999","topology.workers":1}
[main] INFO b.s.StormSubmitter - Finished submitting topology: word-count
```

The following worker process information is displayed after the **ps -ef | grep worker** command is executed:



Cause Analysis

1. **topology.worker.gc.childopts**, **topology.worker.childopts**, and **worker.gc.childopts** (server parameters) have priorities: **topology.worker.gc.childopts** > **worker.gc.childopts** > **topology.worker.childopts**.
2. If the client parameter **topology.worker.childopts** is set, this parameter and the server parameter **worker.gc.childopts** are configured together. However, for two same parameters, one of them will be overwritten by the other parameter after it. Take parameter **-Xmx**, as shown in the red box of the preceding figure, as an example, parameter **-Xmx1G** overwrites **-Xmx4096m**.
3. If parameter **topology.worker.gc.childopts** is configured on the client, the parameter **worker.gc.childopts** on the server will be replaced.

Solution

Step 1 If you want to modify the JVM parameter of the topology, you can directly modify the **topology.worker.gc.childopts** parameter in the command or modify the

parameter on the server. When **topology.worker.gc.childopts** is set to **-Xms4096m -Xmx4096m -XX:+UseG1GC -XX:+PrintGCDetails -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M**:

```

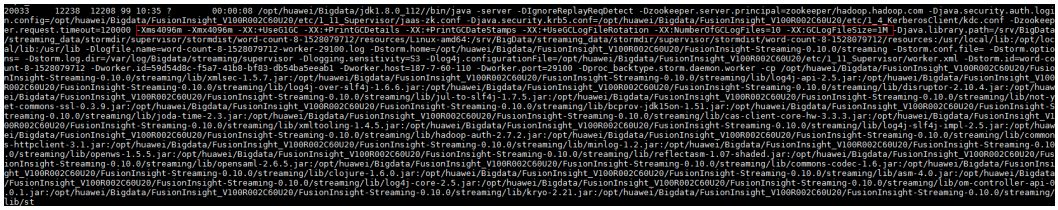
[main] INFO b.s.StormSubmitter - Finished submitting topology: word-count
```

Step 2 Run the **ps -ef | grep worker** command to view the worker process information:



----End

16.18.9 Internal Server Error Is Displayed When the User Queries Information on the UI

Symptom

An MRS cluster is installed, and ZooKeeper and Storm are installed in the cluster.

"Internal Server Error" is displayed when a user accesses information from the **Storm Status** page of MRS Manager.

The detailed information is as follows:

```
Internal Server Error
org.apache.thrift7.transport.TTransportException: Frame size (306030) larger than max length (1048576)!
```

Possible Causes

- Nimbus of Storm is abnormal.
- Storm cluster information exceeds the default Thrift transmission size.

Cause Analysis

1. Check the Storm service status and monitoring metrics:
   - MRS Manager: Log in to MRS Manager and choose **Services** > **Storm**. Check the Storm status. The status is **Good**, and the monitoring metrics are correctly displayed.
   - FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > *Name of the target cluster* > **Service** > **Storm**.

     Check the Storm status. It is found that the status is good and the monitoring metrics are correctly displayed.
2. Click the **Instance** tab and check the status of the Nimbus instance. The status is normal.
3. Check the Thrift configuration of the Storm cluster. It is found that **nimbus.thrift.max_buffer_size** is set to **1048576** (1 MB).
4. The preceding configuration is the same as that in the exception information, indicating that the buffer size of Thrift is less than that required by the cluster information.

Procedure

Adjust the Thrift buffer size of the Storm cluster.

Step 1 Access the Storm parameter configuration page.

- MRS Manager: Log in to MRS Manager, choose **Services** > **Storm** > **Service Configuration**, and select **All** from the **Type** drop-down list.
- Operation on FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Yarn** > **Configurations** > **All Configurations**.

Step 2 Change the value of **nimbus.thrift.max_buffer_size** to **10485760** (10 MB).

Step 3 Click Save Configuration and select **Restart the affected services or instances**. Click **OK** to restart the services.

----End

16.19 Using Ranger

16.19.1 After Ranger Authentication Is Enabled for Hive, Unauthorized Tables and Databases Can Be Viewed on the Hue Page

Issue

Although Ranger authentication is enabled for Hive, unauthorized tables and databases can be still viewed on the Hue page.

Symptom

In a normal cluster with Kerberos authentication disabled, after Ranger authentication is enabled for Hive, unauthorized tables and databases can be viewed on the Hue page.

Cause Analysis

After Ranger authentication is enabled for Hive, the default Hive policies contain two public group policies about databases. All users belong to the public group. By default, the public group is granted the permission to create tables in the default database and create other databases. Therefore, all users have the **show databases** and **show tables** permissions by default. If some users do not need to have these two permissions, you can delete the default public group policies on the Ranger web UI and grant the required user permissions.

Procedure

Step 1 Log in to the Ranger web UI.

Step 2 In the **Service Manager** area, click the Hive component name to access the Hive security access policy page.

Step 3 Click in the rows containing the **all - database** and **default database tables columns** policies.

Step 4 Delete the public group policies.

Figure 16-59 all - database policy

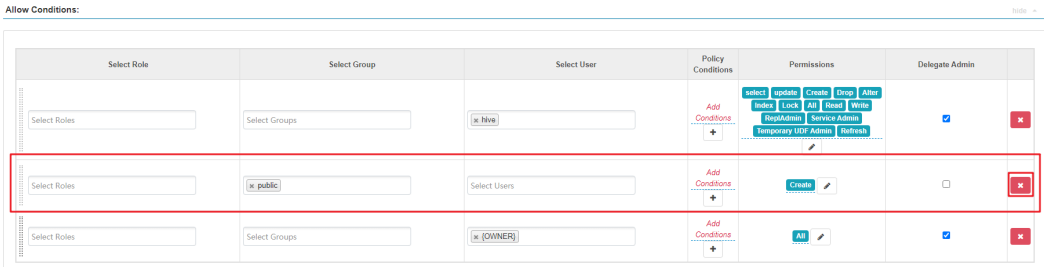


Figure 16-60 default database tables columns policy

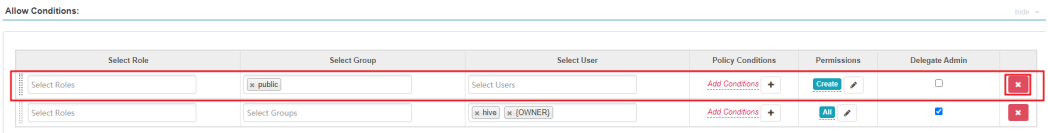


Step 5 On the Hive security access policy page, click **Add New Policy** to add resource access policies for related users or user groups.

----End

16.20 Using Yarn

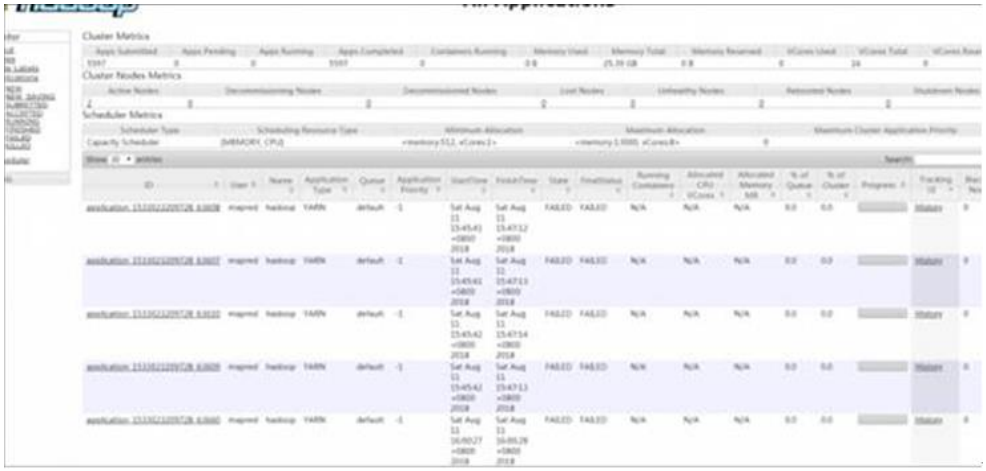
16.20.1 Plenty of Jobs Are Found After Yarn Is Started

Issue

After Yarn starts in an MRS cluster (MRS 2.x or earlier), plenty of jobs occupying resources are found.

Symptom

After the customer creates an MRS cluster and starts Yarn, plenty of jobs occupying resources are found.



Cause Analysis

- It is suspected that there are hacker attacks.
- Set the Any protocol in the inbound direction of the SG to the 0.0.0.0/0.

IPv4	Any	Any	0.0.0.0/0
IPv4	Any	Any	0.0.0.0/0
IPv4	Any	Any	0.0.0.0/0

Procedure

Step 1 Log in to the MRS management console. On the **Active Clusters** page, click the cluster name. The cluster details page is displayed.

Step 2 Click **Manage** next to **Access Manager**. The **Access MRS Manager** page is displayed.

Step 3 Click **Manage Security Group Rule** to check the security group rule configuration.

Step 4 Check whether the source address of the Any protocol in the inbound direction is 0.0.0.0/0.

Step 5 If it is 0.0.0.0/0, change the remote end of the Any protocol in the inbound direction to a specified IP address. If it is not 0.0.0.0/0, there is no need to change the value.

Step 6 After the value is changed successfully, restart the cluster VM.

----End

Summary and Suggestions

Disable the Any protocol in the inbound direction, or specify the remote end of the Any protocol in the inbound direction as the specified IP address.

Related Information

For details, see .

16.20.2 "GC overhead" Is Displayed on the Client When Tasks Are Submitted Using the Hadoop Jar Command

Symptom

When a user submits a task on the client, the client returns a memory overflow error.

```
main path:hdfs://hacluster/user/wangyou

        at org.apache.hadoop.mapreduce.Job.submit(Job.java:1287)
```

Cause Analysis

According to the error stack, the memory overflows when the HDFS files are read during task submission. Generally, the memory is insufficient because the task needs to read a large number of small files.

Solution

Step 1 Check whether multiple HDFS files need to be read for the started MapReduce tasks. If yes, reduce the file quantity by combining the small-sized files in advance or using **combineInputFormat**.

Step 2 Increase the memory when the **hadoop** command is run. The memory is set on the client. Change the value of **-Xmx** in **CLIENT_GC_OPTS** in the *Client installation directory*/**HDFS/component_env** file to a larger value, for example, 512 MB. Run the **source component_env** command for the modification to take effect.

```
export YARN_ROOT_LOGGER=INFO,console

#GC_OPTS for client operation.
CLIENT_GC_OPTS="-Xmx512m -Djava.io.tmpdir=${HADOOP_HOME}"

export HADOOP_CLIENT_OPTS="$CLIENT_GC_OPTS"
```

----End

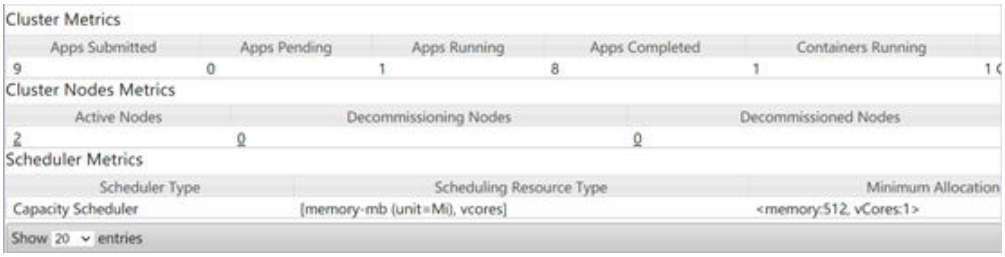
16.20.3 Disk Space Is Used Up Due to Oversized Aggregated Logs of Yarn

Issue

The disk usage of the cluster is high.

Symptom

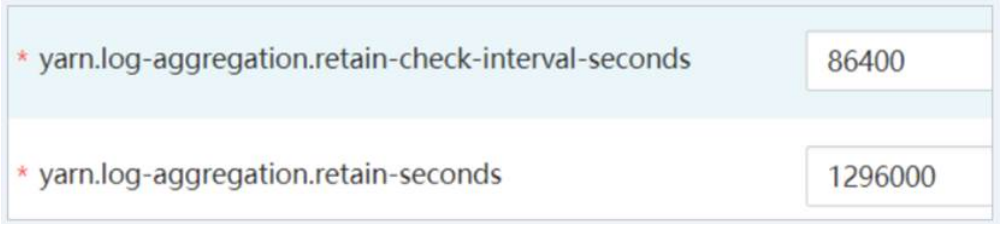
- On the host management page of Manager, the disk usage is too high.
- Only a few tasks are running on the Yarn web UI.



- After the **hdfs dfs -du -h /** command is executed on the master node of the cluster, the command output shows that the following files consume a large amount of disk space.

```
22.5 G   45.0 G   /tmp/logs/root/logs/application_1589278244866_0153
18.4 M   36.8 M   /tmp/logs/root/logs/application_1589278244866_0154
23.4 G   46.8 G   /tmp/logs/root/logs/application_1589278244866_0155
23.5 G   46.9 G   /tmp/logs/root/logs/application_1589278244866_0156
23.7 G   47.4 G   /tmp/logs/root/logs/application_1589278244866_0157
23.7 G   47.4 G   /tmp/logs/root/logs/application_1589278244866_0158
22.5 G   45.0 G   /tmp/logs/root/logs/application_1589278244866_0159
18.5 M   37.0 M   /tmp/logs/root/logs/application_1589278244866_0160
22.5 G   45.0 G   /tmp/logs/root/logs/application_1589278244866_0161
18.8 M   37.6 M   /tmp/logs/root/logs/application_1589278244866_0162
24.0 G   48.0 G   /tmp/logs/root/logs/application_1589278244866_0163
121.3 K  242.7 K  /tmp/logs/root/logs/application_1589278244866_0164
1.1 M    2.1 M    /tmp/logs/root/logs/application_1589278244866_0165
1.1 M    2.1 M    /tmp/logs/root/logs/application_1589278244866_0166
1.1 M    2.1 M    /tmp/logs/root/logs/application_1589278244866_0167
1.1 M    2.1 M    /tmp/logs/root/logs/application_1589278244866_0168
```

- The log aggregation configuration of the Yarn service is as follows.



Cause Analysis

Jobs are submitted too frequently, and the time for deleting aggregated log files is set to 1296000, that is, aggregated logs are retained for 15 days. As a result, aggregated logs cannot be released within a short period of time, exhausting the disk space.

Procedure

Step 1 Log in to Manager and navigate to the all configurations page of the MapReduce service.

- MRS Manager: Log in to MRS Manager, choose **Services** > **MapReduce** > **Service Configuration**, and select **All** from the **Type** drop-down list.
- FusionInsight Manager: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **MapReduce**. On the MapReduce page, choose **Configurations** > **All Configurations**.

Step 2 Search for the **yarn.log-aggregation.retain-seconds** parameter and decrease its value based on site requirements, for example, to **259200**. In this case, the aggregated logs of Yarn are retained for three days, and the disk space is automatically released after the retention period expires.

Step 3 Click **Save Configuration** and deselect **Restart the affected services or instances**.

Step 4 Restart the MapReduce service during off-peak hours. The restart will interrupt upper-layer services and affect cluster management, maintenance, and services.

1. Log in to Manager.
2. Restart the MapReduce service.

----End

16.20.4 Temporary Files Are Not Deleted When an MR Job Is Abnormal

Issue

Temporary files are not deleted when an MR job is abnormal.

Symptom

There are too many files in the HDFS temporary directory, occupying too much memory.

Cause Analysis

When an MR job is submitted, related configuration files, JAR files, and files added by running the **-files** command are stored in the temporary directory on HDFS so that the started container can obtain the files. The configuration item **yarn.app.mapreduce.am.staging-dir** specifies the storage path. The default value is **/tmp/hadoop-yarn/staging**.

After a properly running MR job is complete, temporary files are deleted. However, when a Yarn task corresponding to the job exits abnormally, temporary files are not deleted. As a result, the number of files in the temporary directory increases over time, occupying more and more storage space.

Procedure

Step 1 Log in to a cluster.

1. Log in to any master node as user **root**. The user password is the one defined during cluster creation.
2. If Kerberos authentication is enabled for the cluster, run the following commands to go to the client installation directory and configure environment variables. Then, authenticate the user and enter the password as prompted. Obtain the password from an administrator.

   cd *Client installation directory*

   source bigdata_env

   kinit hdfs
3. If Kerberos authentication is not enabled for the cluster, run the following commands to switch to user **omm** and go to the client installation directory to configure environment variables:

   su - omm

   cd *Client installation directory*

   source bigdata_env

Step 2 Obtain the file list.

hdfs dfs -ls /tmp/hadoop-yarn/staging/*/.staging/ | grep "^drwx" | awk '{print $8}' > job_file_list

The **job_file_list** file contains the folder list of all jobs. The following shows an example of the file content:

```
/tmp/hadoop-yarn/staging/omm/.staging/job__<Timestamp>_<ID>
```

Step 3 Collect statistics on running jobs.

mapred job -list 2>/dev/null | grep job_ | awk '{print $1}' > run_job_list

The **run_job_list** file contains the IDs of running jobs. The content format is as follows:

```
job_<Timestamp>_<ID>
```

Step 4 Delete running jobs from the **job_file_list** file. Ensure that data of running jobs is not deleted by mistake when deleting expired data.

cat run_job_list | while read line; do sed -i "/$line/d" job_file_list; done

Step 5 Delete expired data.

cat job_file_list | while read line; do hdfs dfs -rm -r $line; done

Step 6 Delete temporary files.

rm -rf run_job_list job_file_list

----End

16.20.5 ResourceManager of Yarn (Port 8032) Throws Error "connection refused"

Issue

The ResourceManager of Yarn that requests to submit jobs throws error "connection refused", and the port number configured for Yarn is 8032.

Symptom

One of Yarn's ResourceManager nodes in the MRS cluster cannot be connected, and the port number configured for Yarn is 8032.

Cause Analysis

The service application runs outside the cluster, and the in-use client does not match the latest client configuration provided by the MRS cluster. The Yarn port is 8032, which is different from the actual port of Yarn's ResourceManager of MRS. As a result, the ResourceManager of Yarn that requests to submit jobs reports error "connection refused".

Procedure

Step 1 Update the MRS client.

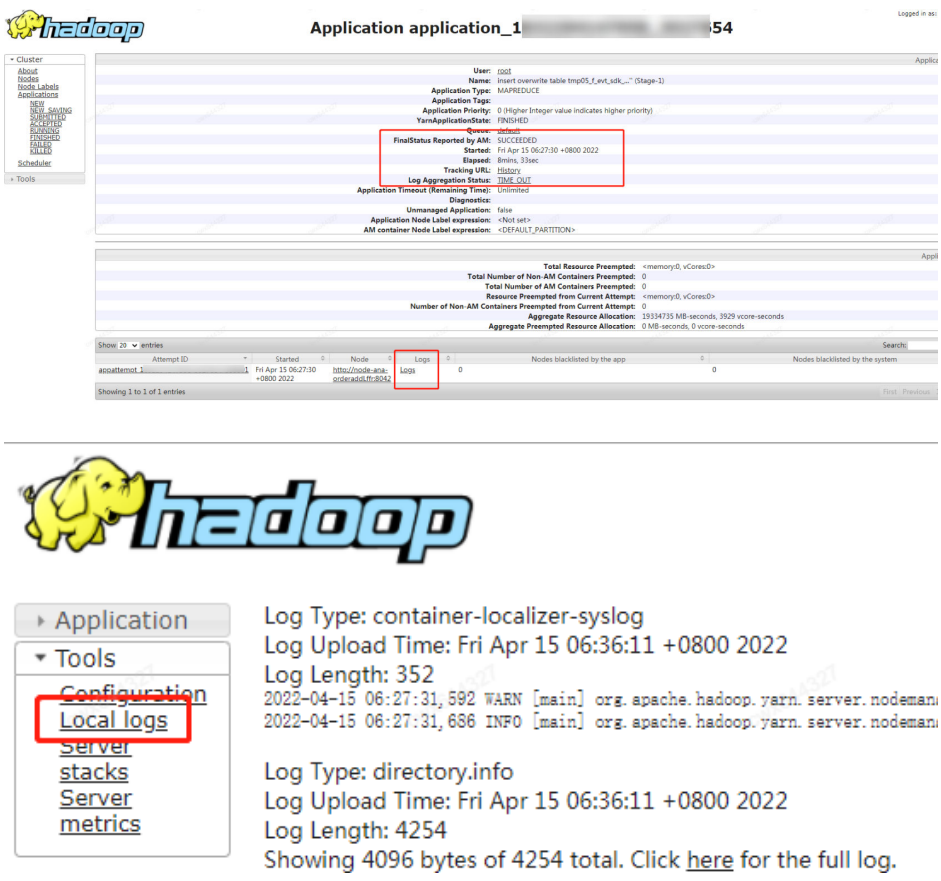
Step 2 Submit the job again.

----End

16.20.6 Failed to View Job Logs on the Yarn Web UI

Symptom

When a user logs in to the Yarn web UI to view job logs and clicks **Local logs**, error message "Could not access logs page!" is displayed.



Cause Analysis

Local logs is used to access service logs. However, for security purposes, this function is inaccessible from the Yarn web UI. You can log in to the active ResourceManager node to view ResourceManager logs.

Procedure

Step 1 Log in to Manager and choose **Cluster** > **Services** > **Yarn**. On the **Yarn** page, click the **Instance** tab and take note of the service IP address of the active ResourceManager instance.

Step 2 Log in to the active ResourceManager node as user **root**.

Step 3 Go to the **/var/log/Bigdata/yarn/rm** directory and view the ResourceManager logs.

cd /var/log/Bigdata/yarn/rm

----End

16.20.7 An Error Is Reported When a Queue Name Is Clicked on the Yarn Page

Symptom

When Yarn uses the Capacity scheduler, error 500 is reported after a user clicks a queue name on the native Yarn web UI.

HTTP ERROR 500 javax.servlet.ServletException: javax.servlet.ServletException: java.lang.IllegalArgumentException: Illegal character in query at index 81: https://[redacted]:20026/Yarn/ResourceManager/21/cluster/scheduler?openQueues=^default$

Cause Analysis

Symbol ^ in the URL cannot be identified. As a result, the page access fails.

Procedure

Step 1 Log in to Manager and choose **Cluster** > **Services** > **Yarn** > **Configurations** > **All Configurations**.

Step 2 Search for **yarn.resourcemanager.webapp.pagination.enable** in the search box.

Step 3 If the value is **true** (default), change it to **false** and save the configuration.

Step 4 On the Yarn page, click **Instance**, select all ResourceManager instances, click **More**, and select **Instance Rolling Restart**. Wait until the instances are started.

----End

16.21 Using ZooKeeper

16.21.1 Accessing ZooKeeper from an MRS Cluster

Issue

An error is reported when a user attempts to access ZooKeeper from an MRS cluster.

Symptom

The customer uses **zkcli.sh** to access ZooKeeper on the MRS Master node, but an error is reported.

Cause Analysis

The command used by the customer is incorrect. As a result, an error is reported.

Procedure

Step 1 Obtain the ZooKeeper IP address.

Step 2 Log in to the Master node as user **root**.

Step 3 Run the following command to initialize environment variables:

source /opt/client/bigdata_env

Step 4 Run the **zkCli.sh -server** *IP address of the node where ZooKeeper is located*:**2181** command to connect to ZooKeeper of the MRS cluster.

The IP address of the node where ZooKeeper is located is the one queried in **Step 1**. Use commas (,) to separate multiple IP addresses.

Step 5 Run common commands such as **ls /** to view ZooKeeper information.

----End

16.22 Accessing OBS

16.22.1 When Using the MRS Multi-user Access to OBS Function, a User Does Not Have the Permission to Access the /tmp Directory

Issue

When the MRS multi-user access to OBS function is used to execute jobs such as Spark, Hive, and Presto jobs, an error message is displayed, indicating that the user does not have the permission to access the **/tmp** directory.

Symptom

When the MRS multi-user access to OBS function is used to execute jobs such as Spark, Hive, and Presto jobs, an error message is displayed, indicating that the user does not have the permission to access the **/tmp** directory.

Cause Analysis

A temporary directory exists during job execution. The user who submits the job does not have permission on the temporary directory.

Procedure

Step 1 On the **Dashboard** tab page of the cluster, query and record the name of the agency bound to the cluster.

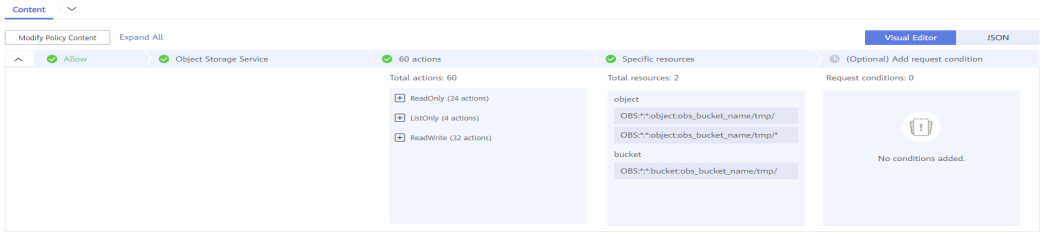
Step 2 Log in to the IAM console.

Step 3 Choose **Permissions**. On the displayed page, click **Create Custom Policy**.

- **Policy Name**: Enter a policy name.
- **Scope**: Select **Global services**.
- **Policy View**: Select **Visual editor**.
- **Policy Content**:
  a. **Allow**: Select **Allow**.
  b. **Select service**: Select **Object Storage Service (OBS)**.
  c. **Select action**: Select **WriteOnly**, **ReadOnly**, and **ListOnly**.
  d. **Specific resources**:
     i. Set **object** to **Specify resource path**, click **Add resource path**, and enter *obs_bucket_name*/**tmp/** and *obs_bucket_name*/**tmp/*** in **Path**. The **/tmp** directory is used as an example. If you need to add permissions for other directories, perform the following steps to add the directories and resource paths of all objects in the directories.
     ii. Set **bucket** to **Specify resource path**, click **Add resource path**, and enter *obs_bucket_name* in **Path**.

     Replace *obs_bucket-name* with the actual OBS bucket name. If the bucket type is Parallel File System, you need to add the *obs_bucket_name*/**tmp/** path. If the bucket type is Object Storage, you do not need to add the path.
  e. (Optional) Request condition, which does not need to be added currently.

Figure 16-61 Custom policy



Step 4 Click **OK**.

Step 5 Select **Agency** and click **Assign Permissions** in the **Operation** column of the agency queried in **Step 1**.

Step 6 Query and select the created policy in **Step 3**.

Step 7 Click **OK**.

----End

16.22.2 When the Hadoop Client Is Used to Delete Data from OBS, It Does Not Have the Permission for the .Trash Directory

Issue

When a user uses the Hadoop client to delete data from OBS, an error message is displayed indicating that the user does not have the permission on the **.Trash** directory.

Symptom

After the **hadoop fs -rm obs://<*obs_path*>** command is executed, the following error information is displayed:

```
exception [java.nio.file.AccessDeniedException: user/root/.Trash/Current/: getFileStatus on user/root/.Trash/Current/: status [403]
```

Cause Analysis

When deleting a file, Hadoop moves the file to the **.Trash** directory. If the user does not have the permission on the directory, error 403 is reported.

Procedure

Solution 1:

Run the **hadoop fs -rm -skipTrash** command to delete the file.

Solution 2:

Add the permission to access the **.Trash** directory to the agency corresponding to the cluster.

Step 1 On the **Dashboard** tab page of the cluster, query and record the name of the agency bound to the cluster.

Step 2 Log in to the IAM console.

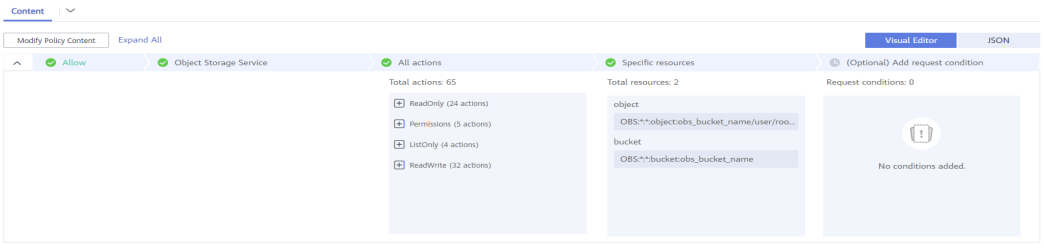
Step 3 Choose **Permissions**. On the displayed page, click **Create Custom Policy**.

- **Policy Name**: Enter a policy name.
- **Scope**: Select **Global services**.
- **Policy View**: Select **Visual editor**.
- **Policy Content**:
  a. **Allow**: Select **Allow**.
  b. **Select service**: Select **Object Storage Service (OBS)**.
  c. Select all operation permissions.
  d. **Specific resources**:
     i. Set **object** to **Specify resource path**, click **Add resource path**, and enter the **.Trash** directory, for example, **obs_bucket_name/user/root/.Trash/*** in **Path**.
     ii. Set **bucket** to **Specify resource path**, click **Add resource path**, and enter *obs_bucket_name* in **Path**.

Replace *obs_bucket-name* with the actual OBS bucket name.

e. (Optional) Request condition, which does not need to be added currently.

Figure 16-62 Custom policy



Step 4 Click **OK**.

Step 5 Select **Agency** and click **Assign Permissions** in the **Operation** column of the agency queried in **Step 1**.

Step 6 Query and select the created policy in **Step 3**.

Step 7 Click **OK**.

Step 8 Run the **hadoop fs -rm obs://<*obs_path*>** command again.

----End

17 Appendix

17.1 Precautions for MRS 3.x

Purpose

Custers of versions earlier than MRS 3.x use MRS Manager to manage and monitor MRS clusters. On the Cluster Management page of the MRS management console, you can view cluster details, manage nodes, components, alarms, patches, files, jobs, tenants, and backup and restoration. In addition, you can configure Bootstrap actions and manage tags.

MRS 3.x uses FusionInsight Manager to manage and monitor clusters. On the Cluster Management page of the MRS management console, you can view cluster details, manage nodes, components, alarms, files, jobs, Bootstrap actions, and tags.

Some maintenance operations of the MRS 3.x cluster are different from those of earlier versions. For details, see **MRS Manager Operation Guide (Applicable to 2.x and Earlier Versions)** and **FusionInsight Manager Operation Guide (Applicable to 3.x)**.

Accessing MRS Manager

- For details about how to access MRS Manager of versions earlier than MRS 3.x, see **Accessing MRS Manager MRS 2.1.0 or Earlier)**.
- For details about how to access FusionInsight Manager of MRS 3.x, see **Accessing FusionInsight Manager (MRS 3.x or Later)**.

Modifying MRS Cluster Service Configuration Parameters

- For versions earlier than MRS 3.x, you can modify service configuration parameters on the cluster management page of the MRS management console.
  a. Log in to the MRS console. In the left navigation pane, choose **Clusters** > **Active Clusters**, and click a cluster name.
  b. Choose **Components** > *Name of the desired service* > **Service Configuration**.

The **Basic Configurations** tab page is displayed by default. To modify more parameters, click the **All Configurations** tab. The navigation tree displays all configuration parameters of the service. The level-1 nodes in the navigation tree are service names or role names. The parameter category is displayed after the level-1 node is expanded.

c. In the navigation tree, select the specified parameter category and change the parameter values on the right.

If you are not sure about the location of a parameter, you can enter the parameter name in search box in the upper right corner. The system searches for the parameter in real time and displays the result.

d. Click **Save Configuration**. In the displayed dialog box, click **OK**.

e. Wait until the message "Operation succeeded" is displayed. Click **Finish**. The configuration is modified.

Check whether there is any service whose configuration has expired in the cluster. If yes, restart the corresponding service or role instance for the configuration to take effect. You can also select **Restart the affected services or instances** when saving the configuration.

- In MRS 3.x, you need to log in to FusionInsight Manager to modify service configuration parameters.

a. Log in to FusionInsight Manager.

b. Choose **Cluster** > **Services**.

c. Click the specified service name on the service management page.

d. Click **Configurations**.

The **Basic Configurations** tab page is displayed by default. To modify more parameters, click the **All Configurations** tab. The navigation tree displays all configuration parameters of the service. The level-1 nodes in the navigation tree are service names or role names. The parameter category is displayed after the level-1 node is expanded.

e. In the navigation tree, select the specified parameter category and change the parameter values on the right.

If you are not sure about the location of a parameter, you can enter the parameter name in search box in the upper right corner. The Manager searches for the parameter in real time and displays the result.

f. Click **Save**. In the confirmation dialog box, click **OK**.

g. Wait until the message "Operation succeeded" is displayed. Click **Finish**. The configuration is modified.

Check whether there is any service whose configuration has expired in the cluster. If yes, restart the corresponding service or role instance for the configuration to take effect.
